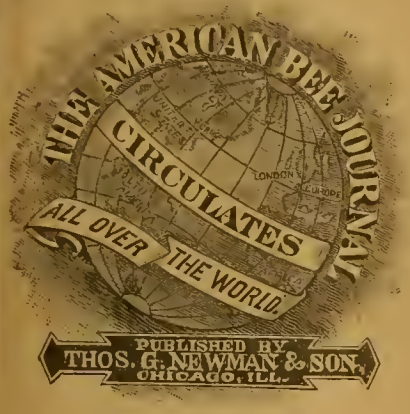
ESTABLISHED IN 1861

THE AMERICAN BEE JOURNAL

OLDEST BEE-PAPER IN AMERICA

VOL. XXV. CHICAGO, ILLS., JANUARY 5, 1889. No. 1.



Issued Weekly at

923 and 925 WEST MADISON - STREET,

At One Dollar a Year.

New Subscriptions can commence at any time.
Single Copies Five Cents each.

George Neighbour & Sons, 149 Regent St., London, England, are our authorized Agents for Europe.

Entered at P.O. as Second-class matter.

Topics Presented in This Number.

To Correspondents.

Our Club Rates are: $1.90 for two copies (to the same or different post-offices); and for THREE or more copies, 90 cents each.

The Bee Journal is sent to subscribers until an explicit order is received by the publishers for its discontinuance, and the payment of all arrearages is made.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one getting up a club, can have Sample Copies sent to those they desire to interview, by sending the names to this office; or we we will send them all to the agent.

Foreign Postage.—To all countries in the Universal Postal Union, 50 cents extra. To all countries NOT in the Universal Postal Union, $1.00 more than the subscription price.

How to Send Money.—Remit by Express, Post-Office Money Order, or Bank Draft on New York or Chicago. If none of these can be had Register your Letter, affixing stamps both for postage and registry, and take a receipt for it. Money sent thus, IS AT OUR RISK; otherwise it is not. Do not send Checks on Local Banks, for they cost us 25 cents each, at the Banks here, to get them cashed.

Make all Money Orders Payable at Chicago, Ills.—Some postmasters in the country insist on making such payable at some sub-station of Chicago, but we want them drawn on the *main office*.

Postage Stamps of any denomination may be sent for any fraction of a dollar; or where Money Orders cannot be obtained, stamps for any amount may be sent.

Subscription Credits.—The receipt for money sent us will be given on the address-label of every paper. If not given within two weeks after sending the money, write to us, for there must be something wrong. Do not wait months or years, and then claim a mistake. The subscription is paid to the END OF THE MONTH indicated on the wrapper-label. This is a continual statement of account.

We will take Canadian paper money for subscription or books; and Canadian postage stamps may be sent for fractions of a dollar.

Do not Write anything for publication on the same sheet of paper with business matters, unless it can be torn apart without interfering with either part of the letter. Both may be sent in one envelope, but must be on separate pieces of paper.

Never Send Silver in letters. It will wear holes in the envelope, or may be stolen.

Emerson Binders, made especially for the AMERICAN BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, postpaid, for 60 cents each. They cannot be sent by mail to Canada.

Lost Numbers.—We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails, we will cheerfully replace them if notified before all the edition is exhausted.

Always Give the Name of the Post-Office to which your paper is addressed. Your name cannot be found on our List, unless this is done.

We will Present a Binder for the BEE JOURNAL, to any one sending three subscriptions to the BEE JOURNAL—with $3.00—direct to us.

Advertisements for the next BEE JOURNAL must reach this office by the Saturday of the previous week.

BEE BOOKS

Sent by mail on receipt of price by

Thomas G. Newman & Son

925 West Madison St.,
CHICAGO, ILLINOIS.

Rates to Dealers.—On 10 or more copies, 25 per cent. discount, including postage; or if the dealer pays the transportation, 40 per cent. discount will be given.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN—220 profusely-illustrated pages, bound in cloth. Price, single copy, **$1.00.** 2 copies, **$1.80.** 3 copies, **$2.55.** 5 copies, **$4.00.** 10 copies, **$7.50.**

Bienen Kultur;—oder Erfolgreiche Behandlung der Bienen, by THOS. G. NEWMAN.—This is a German translation of the principal portion of the book called "Bees and Honey." 100 pages. Price, **40 cts.** Per dozen, **$3.00.**

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, and so arranged that a mere glance will give its complete history. It is strongly bound in full leather. Price, for 50 colonies, **$1.00.** For 100 colonies, **$1.25**; 200 colonies, **$1.50.**

The Bee-Keepers' Convention Hand-Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for Local Bee-Conventions; Constitution and By-Laws for a Local Society; Programme for a Convention, with Subjects for Discussion. Price, cloth binding, **50 cts.** Leather binding, **60 cts.**

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—The edition of 1888 is entirely rewritten, and is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, bound in cloth, **$1.50.**

☞ A few copies of the old edition can be supplied at **$1.25** per copy.

Convention Reports.—A brief history of the North American Bee-Keepers' Society, with a digest of all its previous Conventions, and full Reports of the Proceedings of the Conventions held at Detroit, Mich., in 1885; at Indianapolis, Indiana, in 1886; at Chicago, Ills., in 1887; and at Columbus, Ohio, in 1888. Price, **50 cents.**

☞ Report of either Convention, **25 cts.**

How to Raise Comb Honey, by OLIVER FOSTER.—16 pages. Price, **5 cts.**

Foul Brood, by A. R. KOHNKE.—Origin, development and cure, as taught by the most noted apiarists of Germany. Price, **25 cts.**

Scribner's Lumber and Log Book.—Gives measurements of all kinds of lumber, logs and planks; wages, etc. Price, **35 cts.**

Emerson Binders.—Made especially for the AMERICAN BEE JOURNAL, and lettered in gold. They cannot be mailed to Canada. Price, **60 cts.**

Constitution and By-Laws.—For local associations, with name of the organization printed. Price, **$2.00** per 100.

Ribbon Badges for Bee-Keepers, upon which is printed a large bee in gold. Price, **10 cts.** each. Large and elegant Badges, with rosette, **50 cts.** each.

Photographs of Dzierzon, Langstroth, or Baron of Berlepsh. Price, **25 cts.** each.

Queen-Rearing, by G. M. DOOLITTLE.—Nearest approach to Nature's way. Price, **15c**

Comb Honey—How I produce it. By GEO. E. HILTON. Price, **5 cts.**

Simmins' Modern Bee-Farm, and Its Economic Management—200 pages. Price, **$1.**

Bees and Bee-Keeping, by MR. FRANK CHESHIRE, England. Vol. I, **$2.50.** Vol. II, **$3**

French Edition of "Honey as Food and Medicine," by THOS. G. NEWMAN. Price, **10c.**

Quinby's New Bee-Keeping, by L. C. ROOT.—This is a new edition of Mr. M. Quinby's "Mysteries of Bee-Keeping," entirely re-written by his son-in-law. It is interesting and covers the entire field of bee-keeping and honey-production. Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, bound in cloth, **$1.50.**

A B C of Bee-Culture, by A. I. ROOT.—This is a cyclopædia of everything pertaining to the care of the Honey-bee, and is valuable to the more advanced bee-keeper, as well as to the beginner. It contains facts gleaned from the experience of thousands of bee-keepers, all over America. Price, cloth binding, **$1.25**; paper, **$1.**

Success in Bee-Culture, as practiced and advised by JAMES HEDDON.—It contains 128 pages, well printed on good paper, and illustrated. It covers the whole field of practical apiculture, and is intended for specialists and those who keep bees for the profits of the business. Price, 50 cts.

A Year among the Bees, by DR. C. C. MILLER.—This is a Talk about some of the Implements, plans and practices of a bee-keeper of 25 years' experience, who has for 8 years made the production of honey his exclusive business. Price, in cloth binding, 75 cents.

The Bee-Keeper's Handy-Book, by HENRY ALLEY.—This book contains 270 pages, and is a complete manual of bee-keeping. It gives his methods of Queen-Rearing practiced for 22 years. Price, bound in cloth, **$1.10.**

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, **$2.00**; in paper covers, **$1.50.**

Blessed Bees, by JOHN ALLEN.—This is a romance of bee-keeping, full of practical information and enthusiasm. Price, 75 cents.

The Hive and Honey-Bee, by Rev. L. L. LANGSTROTH.—The work of a master, and will always remain a standard. Price, **$2.00.**

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This book gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50 cents.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—It gives his views on the management of Bees, and details his method for the cure of Foul Brood. Price, 10 cents.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15 cents.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; Recipes for making Honey Cakes, Cookies, Puddings, Foam, Mead, etc. Also Honey as Medicine, with many valuable recipes. This pamphlet is intended for consumers, and it should be liberally scattered, to create a demand for honey.—Price, for either the English or the German edition, 5 cts.; one dozen, 40 cts.; 100 for **$2.50**; 500 for **$10.00**; 1,000 for **$15.00.**

☞ If 100 or more are ordered, we will print the bee-keeper's card (free) on the cover.

Why Eat Honey? (Leaflet No. 1), by THOMAS G. NEWMAN.—This leaflet is intended for distribution in the bee-keeper's own locality, in order to create a Local Market.—Price, 100 copies, 50 cts.; for 500, **$2.00**; for 1,000, **$3.25.**

☞ If 200 or more are ordered at one time, we will print on them the honey-producer's name and address FREE.

Alsike Clover, (Leaflet No. 2). This is intended to scatter among farmers, to induce them to plant Alsike Clover for Pasturage and Hay, and thereby improve the neighborhood for bee-forage. Price, 100 for 50 cts.; 500 for **$2.00**; 1,000 for **$3.25.**

How to Keep Honey, (Leaflet No. 3), by THOMAS G. NEWMAN.—This leaflet is designed to inform producers, dealers and consumers How to Keep Honey, so as to preserve its richness and flavor, and prevent deterioration by being stored in damp and unclean places.—Price, 100 for 50 cts.; 500 for **$2.00**; 1,000 for **$3.25.**

The Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. A chapter from "Bees and Honey."—Price, 10 cts.

Bee-Pasturage a Necessity, by THOS. G. NEWMAN.—Progressive views, suggesting what and how to plant. It is a chapter from "Bees and Honey."—Price, 10 cts.

Swarming, Dividing and Feeding.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey."—Price, 5 cts.

Bees in Winter, by THOS. G. NEWMAN.—Chaff-Packing, Bee Houses and Cellars. This is a chapter from "Bees and Honey."—Price, 5 cts.

The Production of Comb Honey, by W. Z. HUTCHINSON.—It discusses the use of Comb Foundation—when, where and how to use it, etc. Price, 25 cents.

Moore's Universal Assistant, and Complete Mechanic.—This book contains 1,016 pages of over a million industrial facts, calculations, processes, trade secrets, legal forms, items of business, etc., of vast utility to every farmer, mechanic and business man. This is a veritable treasury of useful knowledge, and well "worth its weight in gold" to any mechanic, business man, and farmer. Price, bound in cloth, **$2.50.**

How to Propagate and Grow Fruit, by CHAS. A. GREEN.—It contains over 50 illustrations and two large, colored fruit plates. It tells how to propagate strawberries, raspberries, blackberries, currants, gooseberries, grapes, quinces, peaches, apricots, plums, cherries, pears and apples, with illustrations showing how to bud, graft, and propagate from layers, etc., with full instructions for grafting the grape. Price, 25 cents.

A B C of Carp-Culture, by MILTON P. PIERCE.—It explains the simplest, cheapest and most effective system of carp-culture, and being written by the Secretary of the American Carp-Cultural Association, it cannot fail to be of inestimable value to all interested in the fascinating avocation of carp-culture. 100 pages. Price, 40 cts.

A B C of Potato-Culture, by T. B. TERRY.—It tells how to grow potatoes in the largest quantity, and of the finest quality, with the least expenditure of time and labor. It is not only valuable to potato-growers, but a great part of it applies to the management of almost any crop on the farm, especially to the preparation of the soil, manures, etc. Price, 40 cents.

Kendall's Horse-Book.—No book can be more useful to horse-owners. It has 35 engravings, illustrating positions of sick horses, and it treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, in either English or German, 25 cents.

Western World Guide and Hand-Book.—It contains 288 pages of useful information for home-seekers or tourists, capitalists or laborers. A vast amount of information not to be found elsewhere. Price, 50 cents.

Practical Turkey Rearing, by FANNY FIELD, the most experienced turkey-rearer in America. Written expressly for those who are interested in making the business profitable. All turkey-rearers should get it. Price, 25 cents.

The Hive I Use, by G. M. DOOLITTLE.—It details his management of Bees, and minutely describes his methods for the production and care of comb Honey; management of weak colonies; how to control swarming; how to get the largest yield of honey, etc. Price, 5 cents.

Simmins Non-Swarming System, as applied to hives in present use, by S. SIMMINS, of England.—The author claims that it will inaugurate a new era in modern bee-keeping, and states that it is based upon purely natural principles, and is the only system that can be relied upon, because no other condition exists in the economy of the hive that can be applied to bring about the much-desired result—a total absence of any desire to swarm. 64 pages. Price, 50 cents.

Foul Brood—Its Cause and Cure, by PROF. FRANK R. CHESHIRE, of London, England.—This describes his experiments with the use of Phenol for the cure of diseases of Bees. It is the work of a master mind, and full of very interesting matter. Price, 10 cents.

Dr. Foote's Hand-Book of Health.—It contains hints and information of the utmost importance concerning eating, drinking, dressing, sleeping, bathing, working, etc.

It tells how to cure boils, burns, chilblains, corns, coughs, cholera, diarrhea, dysentery, diphtheria, dyspepsia, ear-ache, felons, headache, hiccough, hoarseness, itching, pimples, piles, rheumatism, ringworm, sore eyes, sore mouth, sore throat, sunstroke, stings and insect bites, toothache, ulcers, whooping cough, worms, etc. Price, 25 cents.

Pocket Dictionary, containing 32,000 words and phrases, illustrated with 670 engravings. 320 pages. Always useful and often indispensable. Price, 50 cents. Mailed free, as a premium for two subscriptions to the AMERICAN BEE JOURNAL with **$2.00.**

Farmer's Account Book.—It contains 166 pages, printed on writing paper, and is ruled and bound. Price, **$3.00.** We will club it and the AMERICAN BEE JOUANAL for a year, for **$2.00.**

☞ If you want it sent by mail, add 20 cents for postage.

Fisher's Grain Tables; For casting up the price of grain, produce, hay; wood measurer, ready reckoner, tables for plowing, etc. Useful to every farmer. Price, 40 cents.

Poulterer's Guide, by C. J. WARD.—It tell how to treat diseases of poultry, etc. Every poultry-producer should have it. Price, 25 cents.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Jan. 5, 1889. No. 1.

EDITORIAL BUZZINGS.

Help a little! Help a little!
Neighbor, lend a helping hand,
To thy heavy-laden brother,
That he may assisted stand.
Pass not by, like priest or Levite,
Heedless of thy fellow man;
But, with heart and arms employed,
Be the Good Samaritan.

1889—the last in the decade of eighties has come to welcome us! We have now entered upon the duties and responsibilities which it presents. Let us each endeavor to do well our part, so that at its close we may not have to look back with regret upon the work we have done!

We are Pleased to notice that Prof. Cook has been again elected President of the "Michigan State Bee-Keepers' Association."

Flowers all the way from New Orleans, La., perfumed our desk, by the kindness of our friend, J. W. Winder, last Saturday. They are sweet-scented, richly colored, and duly appreciated.

Let Every One who believes in defending "our pursuit" against the attacks of the misguided and preverse, join the National Bee-Keepers' Union, by sending a dollar to this office. It only costs a dollar a year, and every bee-keeper should be a member.

Snow around the hives is no detriment. It is porous, and enough air can penetrate it for ventilation in winter. When it forms ice at the entrance, then it must be cleaned away. An examination during and after a thaw is very necessary.

One Day Later.—Heretofore we have closed the forms of the BEE JOURNAL on Saturday, and the printing was commenced on Monday morning. This arrangement often excluded news and announcements of importance which came to hand on Monday, two days later. To prevent this, in the future, we shall keep the forms of type open Monday forenoon; the press will then be started, and the folding, stitching, trimming and mailing will all be completed by Wednesday at 5 p.m., when the JOURNAL will be put into the post-office—*just one day later than usual*. We give this notice to prevent disappointment to those who have been getting their copies on a particular train and day—look for it 24 hours later, and you will not be disappointed. This gives us the advantage of *two days*, while the mailing is delayed only 24 hours.

We Appreciate, even though we cannot give an individual reply to the multitude of kind letters we are daily receiving, which express emphatic approval of the work we are doing in the defense of the pursuit of bee-keeping. This work, especially that devolving upon us in the management of the "National Bee-Keepers' Union," is often difficult and intricate, requiring us to face almost incredible obstacles. It is a consolation, however, to know that so far it has been successfully accomplished, without fee or reward, except in the satisfaction of knowing that we have done our duty faithfully and fearlessly.

The Fifteen Years we have spent in guiding the destinies of the AMERICAN BEE JOURNAL seem but a few short months now that they are past. It is a happy reflection to know that its influence and reputation is *second to none* in the apicultural world. Now its weekly visits are *welcomed* in thousands of homes, and its coming is watched for—aye, "longed for" by aparists in all parts of the world! But who may be its conductor, and who its readers 15 years hence, no one can tell!

The Record and Character of the AMERICAN BEE JOURNAL in the past, is its guaranty for the future. It will "keep abreast of the times," present the apicultural news of the day, and record all improvements and inventions in our ever-advancing pursuit, as soon as they come to light. It is published in the interest of bee-keepers at large, and will lose no opportunity presented to sustain and defend their rights and privileges.

The American Bee Journal for the coming year will be an improvement over all the past years, inasmuch as the experiences of the past will be used to enhance its value, power and usefulness for the future. Sample copies will be sent free to any one who intends to try to get up a club. Now is the time for work.

Dr. W. G. Phelps, of Galena, Md., has "passed to the peaceful harbor on the other shore," after a brief illness. The doctor was well known as a writer for the press—having for years conducted the apicultural departments of the *Practical Farmer* and several other papers, as well as being a correspondent for the AMERICAN BEE JOURNAL. May his eternity be peaceful and happy.

May we not with confidence expect that bee-culturists generally will show us their appreciation by adding to the subscription list of the AMERICAN BEE JOURNAL for 1889, several thousands of new readers? This will secure for us a larger field of usefulness, as well as supply us with the "sinews of war," to accomplish more for the benefit of apiculture and its devotees. Let us work together for this object.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Surprising.—C. H. Dibbern, of Milan, Ills., on Dec. 21, 1888, wrote thus when sending his dues for the Union for 1889:

It is surprising that not more bee-keepers are willing to bear their share of the burden of defending our pursuit.

It is not only surprising, but a lasting disgrace to them.

How Did You Like the full and complete index given last week? The name of the writer was given after each subject, making it doubly valuable to those who keep them for binding. If you have lost any numbers, we will send duplicates if sent for at once, before all the numbers are gone.

Every Day the business letters that come to this office are fully attended to and finally disposed of—none are left until the next day, except those in which the writer has omitted either name or post-office address. We endeavor to be prompt and accurate, and if our subscribers will practice the same virtues, more than half of the little annoyances that happen will be done away with.

We Invite Our Friends to sustain and extend the usefulness of the AMERICAN BEE JOURNAL, which has demonstrated for over a quarter of a Century, its ability to sustain and promote their interests! We make common cause with every bee-keeper, and in turn, every bee-keeper should feel it a *duty* as well as a *privilege* to assist us in every laudable undertaking.

New Year Greetings.

Rejoice, my fellow-soldier ! for another long campaign
Is ended, and its dangers have not been met in vain ;
Some enemies are driven back, some ramparts overthrown ;
Some earnests given that victory at length shall be our own !

Rejoice, my fellow-travelers ! for another year is past !
The heat and burden of the day will not forever last ;
And if some ties are breaking here, of earthly hope and love,
More sweet are the attractions of the better land above.

The light that shone through all the past will still our steps attend,
The Guide who led us hitherto will lead us to the end ;
The distant view is brightening—with fewer clouds between,
The golden streets are gleaming now, the pearly gates are seen.

GLEAMS OF NEWS.

Fire Has Destroyed the first edition of the "Revised Langstroth" book, which was to have been delivered last week. The following from Dadant & Son will explain the matter :

A fire has destroyed the first installment of the "Revised Langstroth," in the bookbindery of Becktold & Co., St. Louis, on the night of the 15th inst. We were called to St. Louis by a telegram, but found, on arrival, that they had already handed the job to another firm. This fire will cause a delay of about three weeks.

There were some 400 publications destroyed by the fire, and the pile of half burnt paper that was thrown out of the windows last Wednesday, filled the street up to the second story.

We regret to hear of this accident and consequent delay—but of course it could not have been foreseen or avoided. It is fortunate that the books were insured, and this shows much thoughtfulness.

The excellent engraving on the next page is from this book, by favor of the publishers. All will recognize it as the familiar face of our friend, Prof. A. J. Cook, of the Michigan State Agricultural College.

Those who have ordered this new book will be obliged to wait until the middle of this month for its arrival. All orders will be filled as soon as possible.

The "Rich" Lawsuit is still pending in Hobart, N. Y., and Mr. Rich expects it to be reached in the general term of the Superior Court. In a letter dated Dec. 25, 1888, he says :

The Union is doing a good work, and why more do not join is a mystery.

It is strange, but the failures of the honey crops for the past three or four years has much to do with it. We hope for a pleasant change next year.

Scientific Legerdemain.— Under the above heading, the *Table Talk* for December prints the following, as a supplement to the Wiley lie, about the making of comb and filling it with glucose. It says :

In these days of adulteration

"When all things are not what they seem,
And everything is something else,"

it is no more miraculous that olive oil should be squeezed out of a peanut, than that Java coffee should be ground out of the chicory root, or that black pepper be only another name for pulverized cocoanut shells. Science is making such rapid strides toward helping us in our gastronomic needs, that Nature herself must get out of the way, or she will be run over.

Even the poor honey-bee was accused, not of laziness, for that would have been too palpable an injustice, but of being too slow, and spending too much time over the clover heads.

"I will remedy all that," said Science.

And she did. Shutting up the bees, she knocked the head out of a barrel of glucose and told them to go to work and help themselves, which they did faithfully. Their long journeys to and from the flowering fields being done away with, they had nothing to interfere with their getting down to actual business. The scheme was a success, for the honey was piled into the combs in treble abundance, and in one-third the usual time.

And yet Science was not satisfied. Greedily she put her wits to work. "What is the use of going to the expense of buying bees ? I can make the comb quicker and quite as well as they ; and as for the honey—well, glucose is honey !"

And so the occupation of the honey-bee being gone, so far as it had any hand in what is known as the "honey of commerce," it now confines itself in a small way to home manufacture, samples of which, if the reader particularly wants, he must particularly search for.

Mr. L. W. Wentworth, of Searsport, Me., sent us the above on Dec. 24, 1888, and remarks as follows concerning it :

I began keeping bees three years ago for pleasure and profit. I have had the pleasure, and lots of it—but the profit I have failed to get. How different it might have been, if I had only known the wonderful way of making honey mentioned in the *Table Talk* which I send you.

What does it matter to the sensational reporters, whether Prof. Wiley has admitted the untruthfulness of the "story" started by him as "a scientific pleasantry" or not ! They neither know nor care anything about it. They are after a sensation, and must have it. They state as if it were truth, that "the occupation of the honey-bee is gone," and that genuine honey is so scarce on the market that it must be searched for ! The fact is that there is not a pound of *manufactured* comb honey to be found. We dare *Table Talk* to produce it ! It ought to be ashamed to publish such falsehoods !

The Farmer's Institute for the Eighteenth Congressional District of Illinois is to be held at Greenville, Bond county, on Jan. 15 and 16, 1889. A lecture is to be given upon "Bee-Culture" during the sessions, as we are informed by the Secretary, W. E. Robinson.

New Bee-Books.—Mrs. L. Harrison thus notices in the *Prairie Farmer* the new edition of "A B C of Bee-Culture," by our friend A. I. Root, in these words :

The wise man said truly : "Of making many books there is no end ;" and had he lived in our day, he might have said that in the making of bee-books there was no end.

The "A B C of Bee-Culture" is just the thing for beginners, grandpa and the children who will climb up on his chair and peer over his shoulder to see the pictures.

The busy bee-keeper, who is all hurry and drive, can quickly find what thousands of bee-keepers say on any subject, for it is gleaned from them all.

In the back part of the book are twenty-one short biographies of noted bee-keepers of this country, with engravings of each, led by the father, L. L. Langstroth, while his friend and co-worker, Moses Quinby, follows in his wake.

The Programme of the Maine Bee-Convention is on our desk, and presents many interesting topics. Here are some of the themes : "Bees and Fruit," by E. P. Churchill ; "Experience in Apiculture," by I. F. Plummer ; "When and how to prepare bees for winter," by F. F. Graves ; "Hints and Suggestions," by Mrs. W. M. Hinkley ; "Retrospective View," by John Reynolds ; "The production of comb honey," by L. F. Abbott, editor of the Lewiston *Journal* ; and "Creating a Home Market," by Mrs. W. A. Crockett. The convention will be held in the Town Hall, Brunswick, Maine, on Jan. 8–10, 1889. All the bee-keepers in Maine should be there.

Mrs. A. E. Manum, of Bristol, Vt., died suddenly in the City Hostipal, Boston, on Dec. 11, 1888, aged 48 years and 11 months. The Bristol *Herald* of last week contains the following notice :

In the sudden and unexpected transition of Mrs. Manum to the higher life, a loving, tender-hearted wife and mother, a kind and sympathizing friend and neighbor is taken from our midst. We mourn her loss, but rejoice that she is free from pain and suffering, and with smiling joy will meet us when we, too, shall lay aside the mortal and cross to the other shore....The remains were followed to their last resting place by a large number of relatives and friends on Friday.

The BEE JOURNAL tenders its condolence to Brother Manum in this hour of bereavement.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. It can be obtained at this office.

When you send us your subscription for 1889, please send the subscriptions of your neighboring bee-keepers, and to pay you for your trouble, we will send you, as a premium, anything you select from our Catalogue to the value of 25 cents on each dollar subscription sent.

BIOGRAPHICAL.

PROF. A. J. COOK.

Albert J. Cook was born on August 30, 1842, at Owosso, Mich. Those who are intimately acquainted with the man will not be surprised to learn that his parents were most thoroughly upright Christians. The daily reading of the Bible, with comments by the father, re-enforced by the constant example of a chaste, honest, and industrious daily life, left its impress for life upon the character of the son.

At the age of 15 years he entered Michigan Agricultural College, where he graduated at the age of 20, having been obliged during his course to suffer the sharp disappointment of suspending study a whole year on account of sickness, his health always having been rather delicate during his earlier years.

Prof. A. J. Cook, of Agricultural College, Michigan.

Upon his graduation he went, on account of his poor health, to California, where for 3 years he labored very successfully as a teacher. He then studied a portion of 2 years at Harvard University and Harvard Medical College, with Agassiz, Hazen, and Dr. Oliver Wendell Holmes, as teachers.

In 1866 he was appointed instructor at Michigan Agricultural College, and in 1868 Professor of Entomology and Zoology in the same college.

He has done, and is doing, a work unique in character, for he instructs the students, not only about insects in general, but about bees in particular. Every student that graduates goes all over the theory of bees, studies the bee structurally from tip of the tongue to tip of the sting, and goes through with all the manipulations of the apiary—that is, if there is any honey to manipulate; handles the bees, clips queens' wings, prepares and puts on sections, extracts, etc. Probably in no other institution in the country, if in the world, is this done.

Prof. Cook is an active and influential member of the North American Bee-Keepers' Association, of which he has been President; was one of the originators of the Michigan State Bee-Keepers' Association, of which he was President for a number of years, and helped start the State Horticultural Society, being a member of its Board for some years. He is widely known as a writer. His "Manual of the Apiary" has reached a sale of 14,000 copies, and "Injurious Insects of Michigan," 3,000 copies. He is also the author of "Maple Sugar and the Sugar-Bush," of which 5,000 copies have been published. He has written much for bee-papers, as also for the general press. He is a clear, practical writer, with a happy style.

In the battle waged against insect-foes, he has rendered valuable service. Remedies which he first advised are now common, and he was probably the first to demonstrate the efficacy and safety of Paris green for codlin moth.

Prof. Cook is of average height and weight, a charming conversationalist, and an intensely interesting lecturer. His very pleasant manner is only a fair index of a genial and loving spirit that, in an unusual degree, strives to put the best construction on the conduct and motives of every one, and throws a mantle of charity over their faults. His spirit of kindness extends to the brute creation; and on his farm, in which he is much interested, he has some fine-blooded stock; and in attempting to engage a hand to work upon the farm, the writer once heard him stipulate as essential that the employee must be kind to animals, and free from the use of liquor, tobacco, and profane language.

Prof. Cook is a great home lover, and proud of his wife and two children. An earnest Christian worker, he has for a number of years done a most important work in conducting a Sabbath-school class containing thirty or forty College students. It is to be regretted that excessive work has told unpleasantly on his health.

[The foregoing biographical sketch is taken from "A B C of Bee-Culture;" and the engraving is from "Langstroth Revised," by favor of the publishers, Ch. Dadant & Son.—ED.]

Who Keeps Bees?—Looking over the large number of letters received in every mail, it is found that an answer to the above question would include: specialists who have no other business; farmers, gardeners, fruit-growers, stock raisers, carpenters, mechanics, manufacturers, poultry raisers, merchants, tailors, railway men, teachers, surveyors, ministers, lawyers, physicians, etc., etc. In fact, it would be far easier to name occupations not represented than those that are. Women, as in all other occupations, are taking a lively and active interest, and making quite a success. —*Western Bee-Keeper.*

A Bee Sting lately caused the death of a promising young lady in England. The Pall Mall *Gazette* thus notices the calamity:

Miss Ella Baker, youngest daughter of Mr. T. Baker, of Kingscote, was stung under the eye by a bee in the garden a few days ago. She treated the matter lightly, and suffered no pain after the customary simple antidote had been applied, saying that she had been stung before; the swelling would run its course and go down again, and she continued to be quite cheerful down to 8:30 on the 14th, when she fell asleep on the sofa. At 9:15 she suddenly woke up in a convulsive fit, and died from syncope within a minute. Miss Baker, who was 29 years of age, was the author of "Bertram de Drumont," and other tales for the young people; also "Stories from Old History," "The Sovereigns of England," "Songs of the Seasons," and other fugitive pieces.

Now is the time to sell the honey.

QUERIES & REPLIES.

Scraping Propolis or Wax from Sections of Honey.

Written for the American Bee Journal

Query 601.—Is it necessary, or desirable, to scrape by hand all sections before putting the honey on the market? that is, if there is propolis or wax on the outside.—E.

Yes.—C. C. MILLER.

It is desirable.—DADANT & SON.

It is at least desirable.—R. L. TAYLOR.

Yes, it is practically necessary.—JAMES HEDDON.

To be sure, highly so.—J. M. HAMBAUGH.

It is desirable— not always necessary.—M. MAHIN.

Certainly it is. Scraping sometimes does not tend to piety, either.—J. M. SHUCK.

It is desirable. Have your goods look as neatly as possible.—MRS. L. HARRISON.

No; excepting, perhaps, a few of the worst ones. It does not pay for the labor necessary in doing it.—WILL M. BARNUM.

Yes, have all sections clean. Cleanliness is next to honesty in selling honey.—A. J. COOK.

I always scrape them if they are in the condition you speak of.—G. M. DOOLITTLE.

It is both necessary and desirable, if you wish your sections to have a "clean face," and your honey to look inviting.—J. P. H. BROWN.

Be *sure* to put honey on the market in the best possible condition, even if the sections should require sand-papering.—A. B. MASON.

There is always a little (more or less) propolis on the edges, and that ought to be scraped before putting them on the market.—P. L. VIALLON.

YES. Do not neglect this important part. Propolis is all right in its place, but it is "matter out of place" on a section.—H. D. CUTTING.

It is very desirable, in my estimation, to have the sections nice and clean when they are offered for sale. We scrape off every particle of glue and wax that may adhere to the sections, as we crate them.—G. W. DEMAREE.

It is certainly advisable to clean all propolis and dirt from sections before putting them on the market. The extra trouble will be well paid for, in the extra price obtained.—J. E. POND.

That is the only way I know of. I would be glad of a remedy if it does not make more work than the scraping. They look so much more neat after being thoroughly cleaned, that I always do it.—EUGENE SECOR.

Yes, by all means; but if your surplus arrangement is "all right," there should never be any propolis on the outside of sections. In this case, prevention is better than cure.—C. H. DIBBERN.

Yes; it is both desirable and necessary, if you wish to have the reputation of doing good work in marketing honey, and obtain the highest prices for the product.—THE EDITOR.

Do Flowers Bloom Profusely and have no Nectar?

Written for the American Bee Journal

Query 602.—1. Do flowers, such as white clover for instance, sometimes bloom profusely, and fail to secrete nectar? 2. If so, does white clover, in a good season, yield sufficient to be plainly visible, when the heads are pulled to pieces? This has been an extraordinary year with us for vegetation, and the ground has been covered for four months with the most abundant white clover bloom, yet my bees only averaged 36 pounds of extracted honey per colony, and swarming was prevented?—British Columbia.

1. Yes. 2. Yes.—P. L. VIALLON.

1. Yes. 2. I never saw it that way.—G. M. DOOLITTLE.

1. Yes. 2. I have seen it yield so as to be visible.—A. B. MASON.

1. Yes. 2. Yes it can be seen, but not as easily as in linden.—A. J. COOK.

1. Yes. 2. Not usually, unless the crop is very abundant.—DADANT & SON.

1. I think that they do. 2. I never saw it; still I never looked much.—C. C. MILLER.

1. Yes. 2. Yes, by pressing on the thumb nail each separate piece.—H. D. CUTTING.

1. Yes, sir. 2. I have frequently seen honey, in good seasons, in white clover when the heads were pulled apart.—J. P. H. BROWN.

1. Yes. 2. Yes; 36 pounds per colony is not a failure, by any means.—J. M. SHUCK.

1. Yes, in some localities. 2. Yes, sometimes. I have known clover to yield pretty well, when one needed a magnifying glass to see any nectar in the blossoms.—JAMES HEDDON.

1. The secretion of nectar varies greatly in different seasons. 2. I have not examined the white clover to ascertain whether the nectar is visible, but I presume it is.—M. MAHIN.

1. Yes. 2. No, not in my experience. The statement made in the question, is a complete answer thereto in your own experience.—J. E. POND.

1. Yes, I have seen the hillsides and pastures white with clover bloom, and the bees in a starving condition. 2. Yes.—J. M. HAMBAUGH.

1. They certainly do. 2. I have never seen the nectar plainly visible in white clover, though I have many times looked for it. It is much more abundant in red clover.—EUGENE SECOR.

1. Yes. 2. Yes, if you split a flowret and hold it so the light strikes it right, with good eyesight you may see the tiny drop at the lower end where the seed forms. You may also taste it with the tip of the tongue.—R. L. TAYLOR.

1. Yes. 2. It does, if a careful examination is made. You can readily tell when white clover is yielding well, by chewing the blossoms. The electric conditions of the atmosphere have much to do with the secretion of nectar in flowers.—MRS. L. HARRISON.

1. Yes, all flowers sometimes fail to yield honey. 2. I have never been able to see honey in white clover blossoms without a microscope. Your yield is about an average for the last season.—C. H. DIBBERN.

1. Yes. Two years ago I sowed, broadcast, about a peck of buckwheat directly in front of the apiary; while directly back of it, and nearly a mile away, was another patch nearly on top of a small mountain. The patch that I sowed bloomed profusely, but yielded no nectar whatever; while honey fairly poured in from the other field. Occurences of this kind are quite common. 2. That would not be a sure "proof." The honey might be there, and still not be visible to us.—WILL M. BARNUM.

1. According to my experience, yes. But white clover is the surest of all nectar-bearing plants. I have never known it to fail entirely when the bloom was abundant, but in one season, in all my experience. But it does not always yield equally well. 2. The nectar is at the bottoms of the tubers, and I have never been able to see much of it by dissecting the blossoms. It is not at all uncommon for flowers, no matter how profuse, to fail to yield nectar when the weather is unpropitious. Such has been my misfortune the past fall.—G. W. DEMAREE.

1. Oh, yes. It has been often demonstrated that sometimes flowers will bloom profusely and yet yield no nectar. 2. Yes; it may be seen by the aid of a glass. If an average of 36 pounds is regarded as anywhere near a failure, your ideas are very high.—THE EDITOR.

CORRESPONDENCE.

MICHIGAN.

Report of the Michigan State Convention.

Written for the American Bee Journal
BY W. Z. HUTCHINSON.

The Michigan State Bee-Keepers' Association held its 23rd annual meeting on Dec. 12 and 13, 1888, at the Business Men's parlors in the city of Jackson, Mich. The attendance was small, and there is, perhaps, more than one cause for it, but the principal one probably is the poor season. The Secretary wrote to about eighty bee-keepers, soliciting their attendance, and the burden of the replies was, "No honey, no money."

The convention was called to order by President Geo. E. Hilton, at 2:30 p.m.; the Secretary read the minutes of the last meeting, which were approved, and Mr. Hilton then delivered the following as the

President's Annual Address:

Again we find ourselves in convention assembled for the purpose of discussing the topics appertaining to our favorite pursuit. Many of us have had experiences the past year that will be of value to us as long as we are engaged in apiculture, and to those that come after us, of less experience.

In some respects, perhaps, there has never been so discouraging a season as the one just past. A few, perhaps, are engaged in bee-keeping for no other purpose than the pleasure they find in it, but a large majority of us have engaged in it because we thought that it paid, and have taken up the pursuit with a view of procuring our bread and butter in this way, with the assurance that we should have honey to spare to spread upon the same.

Lessons of the Past Season.

The past season has taught some of us the lesson, that it is not wise to carry all of our eggs to market in one basket; also, that mixed farming is more safe for the majority than are specialties. I think that for the past two or three years we have heard less of specialists in bee-keeping, and with my past experience in good and poor seasons, I cannot advise the masses to make bee-keeping a specialty.

But in looking over the past year, I see much to encourage us. Those who had any surplus honey at all, have been able to dispose of it at paying prices, yes even at exorbitant prices. Who has heard of honey selling at 30 cents per pound, and the average price for the United States a trifle over 19 cents per pound in the middle of October? Why, the like has never been heard of since Adam Grimm made a fortune by keeping bees; but I prophesy that before March 1, 1889, there will be localities in the United States where a fancy article of comb honey will bring 50 cents per pound, and honey will never be so scarce but that a prime article will bring one-third more than a poor one, even though it be gathered from the same blossoms. This teaches us that the profits depend upon the bee-keeper, for if bees will store just as much honey in a nail-keg (which I doubt very much), it will not bring as much in the market as honey stored in beautiful white sections. But this season even the lower grades are going to be closed out at some price, and before another crop comes, we will be unable to get honey to make cough syrup for our babies.

Blessings of a Poor Season.

Then the past season has established paying prices; it has denuded the markets, and has forever downed that ghost, "manufactured honey." Is not that enough to pay for all our losses (or rather, for what we have not had to lose)? We start in next year with a clean market. There will be a demand everywhere, and it is the duty that every bee-keeper owes to himself, to retain this demand, which is easily accomplished by never sending a pound of honey to the large markets, until you have supplied your home and surrounding markets; these you can control, but as soon as you glut the large markets, you establish a ruinous market at home.

I had no trouble in selling comb honey at 20 cents per pound until several carloads were shipped into Grand Rapids, and sold at 10 cents; then our merchants learned that they could ship honey from Grand Rapids, and retail it at 15 cents, at a better profit than the commission I was paying them; and for the past four years, 15 cents has been our retail price, for in a small place it was very hard to raise the price, unless the market is entirely bare, or will be at the opening of another honey harvest.

The Fall Flow of Honey.

Then in addition to the prospects of good prices for next season, the bees as a rule have gone into winter quarters in excellent condition. The fall rains gave us a nice fall flow of honey, which caused the brood-nests to be well supplied with a good quality of honey, and many of us secured a little surplus. Since the season ended, the rains have continued, and the clover has a beautiful start for next season's crop. We need not lie awake at night fearing that we must contend with free-trade in sugar, because we have not.

I need not tell you that many changes have taken place, all in favor of the bee-keeper; and in all my experience in bee-keeping, I do not know when I have felt so much encouraged. I am sure that the darker hour is passing away, and in the future we can see the dawn of that morning of prosperity in bee-keeping. And now if "'tis not in mortals to command success," by the help of God let us deserve it; let every one go home from this convention with a determination to do better than he ever did before, not only for himself, but for mankind in general.

The Bee-Keepers' Union.

Permit me here to urge every member of this association to become a member of the Bee-Keepers' Union that has done so much for us all, and could do much more good were it properly supported. I am almost ashamed to say that out of 300,000 bee-keepers of North America, less than 400 are members of the Union!

International Bee-Association.

Before this convention closes I hope there will be some action taken in regard to the International Bee-Association. I should like to see the Michigan Bee-Keepers' Association represented at its next annual meeting, in an official manner, and I hope the matter will be thoroughly discussed as to the best manner of being represented.

I have made the assertion, that ours is *the* association of the Continent, and I believe that we are looked upon as at least one of the best bee-keepers' associations in this broad land of ours.

Now as we go to our several homes, at the close of this, the 23rd annual meeting, let each one resolve to do something for the elevation of our brother and sister bee-keepers, and let us be thankful,

"For all that God in mercy sends,
For health and children, home and friends,
For comfort in the time of need,
For every kindly word and deed,
For happy thoughts, and holy talk,
For guidance in our daily walk;
For beauty in this world of ours,
For verdant grass and lovely flowers,
For song of bird, and hum of bees,
For the refreshing summer breeze;
For the sweet sleep that comes with night,
For the returning morning light,
For the bright sun which shines on high,
For the stars glittering in the sky;
For these and everything we have and see,
Oh, Lord, our hearts we lift to thee—
For everyting give thanks."

GEO. E. HILTON.

Following the President's address was an essay by Mr. R. L. Taylor, of Lapeer, entitled,

Apicultural Patents.

Not very long since it was stated in one of our apicultural publications as an assumed fact, that bee-keepers had settled down to the opinion that no one should seek a patent on any invention pertaining to apiculture. I was astonished, and fell to remuinating on the characteristics of bee-keepers. I asked, what are the qualities possessed by them that entitle their business to be singled out and distinguished from all other occupations? for as a general rule, I take it that it is conceded that the patent laws are desirable and beneficial. Whence, then, the distinction? Is it because we are a worse class of men, and are more liable to use patent rights to impose upon others? I think we would resent that idea.

Is it because we are supposed to be more stupid, and therefore easily imposed upon by means of patent-rights? We would also, I think, quickly scout that notion. Is it because we are better men, both morally and intellectually, so that we to a man are not only ready and eager to accord to every one his right, but also have severally sufficient knowledge, acumen, time for investigation, and a judicial cast of mind to enable each one to determine what is the exact right? Then we as good, modest men should be the last to make the claim. I am at a loss for an adequate explanation, but the last supposition as being the more probable, suggested the following reflections:

A good man may, indeed, in some circumstances, properly say that he means right, and will do right as he sees it; but what an amazing amount of conceit must one be endowed with to enable him to proclaim that even when his own interests are involved, he is always able to discern and do the exact right; or, in other words, that he may safely be made to judge in his own case. Yet the whole moral patent idea is without other substantial support than this modest claim.

There is no principle of the common law better established, more salutary or more consistent with reason, than that a man may not be judge in his own case. This is sound, not because men are not upright, intelligent and fair, but because self interest can, as a rule, be relied upon to becloud the moral and intellectual faculties, not alone of other men, but ours—mine. The best men know best how frail they are in such a matter. The above rule was not made obligatory on the judges by king or parliament, they themselves established it.

The moral patent idea to be of use, must be put in force, and to do that, there must be provided some adequate method of arriving at correct decisions. But there can be none, from the very nature of the matter in its court of last resort a man sits as judge in his own case. From a tribunal thus constituted, we cannot do otherwise than expect not a little of corruption and injustice: and how much worse are the features of the matter when we consider that possibly sometime in the future, some one not strictly honest, may steal his way into the fraternity.

The very idea of a moral patent carries with it an admission to the fullest extent of the right of the inventor of an apicultural article, and that there is a debt due him from the one who uses the invention. Why should that one alone be singled out from all classes of creditors to be left to the tender mercies of interested men, for the payment of his claims? If he has an admitted right, what possible objection can there be to giving him legal protection in the enjoyment of it?

Is it not supremely impolitic, by withholding protection, to compel inventors, where the subject matter admits of it, to make a secret of their discoveries?

Again, in the granting of patents, the public stipulates that for the protection given, it shall have, as a recompense, after a term of years, a full right to the invention. What limit is proposed to the moral patent?

Finally, why should we withhold protection and justice on the plea that others contributed towards making the discovery, or that some other one would eventually have made it? All honor to the inventor, and all honor to the patentee, say I, but especially to the latter. It is an honor to be an inventor, but he may let his invention sleep—he may not know its value—may have but a faint conception of its possibilities. But to be a patentee is better; that means not only that a candle has been lighted, but that it has been taken from under the bushel. It implies not only an invention, but that the inventor has discovered its possibilities and value.

Long years before Columbus, the Norsemen found America, but their discovery slept. They rose to no proper conception of the importance of what they had done. We honor Columbus, because before he knew the land, he saw the glory of it.

Brethren, shall we not get our feet out of the miry clay of this moral patent-business, and place them upon substantial ground? Shall we not be willing to give inventors substantial honor, as well as empty glory?

R. L. Taylor.

Mr. Taylor's essay was discussed as follows:

James Heddon—I have advocated moral patents because of the strong feeling in the apicultural ranks against legal patents; but I agree entirely with Mr. T.

President Hilton—My views upon the patent questions have undergone quite a change of late. Heretofore my circulars have said, "Nothing patented." In the future this will be out. I truly believe that the fruits of mental labor should be protected.

Dr. N. L. Higbie—If I see anything that will enable me to secure any advantages, I shall invest in it, even if it is patented. The man who has labored mentally, deserves his reward.

H. D. Cutting—It has always seemed strange to me why bee-keepers should be prohibited, by public sentiment, from getting patents. If a man knows enough to invent something of value, let him patent it.

T. M. Cobb—Whether an article is of value depends, of course, upon its value; but I think that all should have a chance to patent their inventions.

Width of Top-Bars—Honey-Boards.

Dr. Higbie—With wide top-bars less brace-combs are built, and no honey-boards are needed.

Mr. Fellows—My objection to wide top-bars is, that they are in the way when uncapping the combs.

James Heddon—I have used both wide and narrow top-bars. The narrower the top-bars, the more brace-combs will then be under the honey-board, but the less likelihood of any above. I am yet a great admirer of the lateral movement in combs, when we must handle frames instead of hives. A wide top reduces the lateral movement. And now, while we are talking of top-bars and honey-boards, I wish to say that I believe that three rows of holes in a wood-and-zinc honey-board are sufficient. I have tried putting on 3 and 4 honey-boards on one hive, and it made no difference in the results. Just think how the bees, in the days of the box-hive, used to pass up through an inch auger-hole, and fill the caps. When we remember that it has been estimated that in ordinary honey-flows a bee makes only four trips a day, and ten trips in basswood harvest, it will show the folly of regarding in a serious light the time spent in passing through a queen-excluding honey-board. It is something like an election bet. I must wheel you in a barrow from Kalamazoo to this place, and once around this building. Putting on a queen-excluder is like wheeling you from Kalamazoo, and then *twice* around this building.

President Hilton—What Mr. Heddon says about the inch auger-hole is a good point. I have practiced putting sheets of zinc right down on the brood-frames. This closes up many of the openings, and the bees stop up a great many more, but I have never seen that it was objectionable.

A. D. D. Wood—I have tried putting on the honey-boards 5 and 6 high, and could see no difference in the results. I have also tried stopping up all the holes in a honey-board, except the two outside rows, and the results were the same. I was led to experiment in this direction by putting on sections in the night. One hive had an oil-cloth over the brood-frames, and I did not see it. There was a crack at one side, through which the bees had gained access to the case, and filled it just the same as they had the others.

James Heddon—Good. That pays me for coming to Jackson—just to hear that.

The next topic discussed was,

Producing Extracted Honey and Prevention of Swarming.

R. L. Taylor—I would use plenty of combs, so that the bees can have room to spread their honey when ripening it. I would tier up and leave the honey on as long as possible, but I would not allow the different kinds to become mixed. I would use a queen-excluding honey-board. It is a great inconvenience to have brood in the surplus combs.

James Heddon—I used to think that the great advantage in producing comb honey was, that nearly all the work was done in-doors. With my new hive, the same advantage can be enjoyed in producing extracted honey. Just keep tiering up the cases of combs as fast as the honey comes in. Do not wait for the bees to seal it over; as it will ripen just as fast, yes faster, if unsealed. When the honey is ripened it can be taken off just the same as cases of comb honey are removed. Drive the bees down with smoke, jerk off a case, shake out most of the bees, and carry it to the house with the windows arranged for the escape of the bees. All this is done without exposing any combs to robber bees. To extract, simply invert a section of the hive, loosen the screws, slip off the case, and then stand the combs ready to extract. These narrow combs, not quite sealed over, are just the neatest of combs to uncap.

A. D. D. Wood—I prevent swarming when producing extracted honey, by placing the queen and one frame of brood in the lower story, with a queen-excluding honey-board between that and the upper story. The bees build comb in the lower story, and do not swarm.

James Heddon—This is the old Adair idea. I made 30 of these "long idea," or, as some called them, "wrong-idea" hives, years ago. The idea of preventing swarming will work, but it is too much labor.

W. Z. Hutchinson—This is essentially the Simmins' plan.

The convention then adjourned until 7:30 p.m.

(Concluded next week.)

EXPERIMENTS

With Reversing Brood-Combs, Contraction, etc.

Written for the American Bee Journal

BY C. A. BUNCH.

As I have been trying some of the plans as given by some of the leading bee-men, I will give my experience with the same:

Reversing Brood-Combs.

Does it pay to reverse brood-combs in the spring to increase the number of bees? I believe it pays to take the two outside combs, and put them in the centre of the brood-nest about the time that the rest of the brood-combs are full of brood, and not before. I would take these two combs and shave them down to $\frac{7}{8}$ of an inch in thickness before reversing.

Contraction of the Brood-Nest.

Contraction of the brood-nest, or moving the combs close together about $1\frac{3}{8}$ inches from centre to centre to prevent swarming, as advised by some, would not prevent swarming in my apiary, if there were eight combs in the brood-nest, as that is the number of combs that I have to the hive before swarming; though I think that it is a good idea to have the combs spaced $1\frac{3}{8}$ inches from centre to centre, so that the queen will lay in the upper part of the combs, which I believe she will not do if they are much further apart.

Contraction of the brood-nest for the production of comb honey I have tried also; but it seems that bees in Indiana act differently from what they do in Michigan, and I think that it is on account of the season being warmer here.

I hived swarms on 5 Langstroth frames with mostly $\frac{1}{2}$-inch foundation starters, and the balance on empty frames; about the time the frames were built out with comb, the bees began to swarm, and at one time 4 of these swarms came out at once, and settled on a little Siberian crab-apple tree. Oh, what a swarm it was, with a lot of deserted honey-crates behind. The only way to get out of such a dilemma was, to give the bees room for 8 brood-frames, which I did, and after that scarcely a swarm issued.

The Use of Honey-Boards.

As an experiment I used 12 wood-and-zinc queen-excluding honey-boards the past season, for producing comb honey, and the balance of the hives were without honey-boards. It seems that some bee-keepers have no trouble with the queen laying in the sections, while I do. The sections were over an 8-frame hive, for I had the honey-boards over the contracted hives of 5 frames.

I like prolific queens, but I want the eggs down in the brood-nest, where I expect to have them next season—which means that I will use the honey-boards on all hives hereafter.

La Paz, Ind.

How to Employ the Time in Winter Advantageously.

Written for the American Rural Home

BY G. M. DOOLITTLE.

Now that we are in the midst of long winter evenings, it becomes the duty of all to spend these evenings in such a way that they may be gaining in knowledge along the line of the pursuit they have chosen in life. In no business engagement is this more imperative than where the culture of the honey-bee is the chosen occupation, and in no way can this be done to any better advantage than in reading the bee-literature of the day, from which the mind is to be stored with useful knowledge which can be put into practical use as soon as the season of 1889 opens.

When I first commenced bee-keeping I was greatly benefited by the writings of E. Gallup, M. Quinby, A. I. Root, Adam Grimm, and many others of those early writers on this subject; for by their writings I learned my A B C in bee-culture. My first year of experience in bee-keeping by way of putting the things which I had read in practice, resulted in 12 pounds of comb honey and one swarm from the colonies I had purchased to commence with. The next season I obtained 25 pounds of surplus from each colony I had in the spring, on an average. At the end of the fourth season, I chronicled an average of 80 pounds of comb honey, as the average surplus for each colony in the spring.

During these four years I had studied, read and practiced all my wakeful hours, about the bees, having keen enjoyment in doing the same, for I never spent an hour in my life in work per-

taining to bee-culture without its being a real pleasure to me, and this was brought about by those winter evenings when I first began to read up the subject. Many a night have I been awake from one to three hours, planning how to accomplish some result I desired to achieve in regard to the practical part of apiculture, which with the help of what I had read, caused me to accomplish what I had sought after.

I have found that if I would succeed, that as far as possible I should read mainly those articles which came from the pens of practical bee-keepers, for such were the ones who made a success of their calling, and told how they did it. If you wish to learn farming, to whom do you go, the man whose farm grows up to weeds and briars, or to the man who produces good crops each year? To the latter, of course; and so you should do in bee-keeping.

I know that many of our most practical bee-men do not write for publication, and for this reason we can bring in visiting, during the winter, as another help along this line of our qualification. Then we have our bee-conventions, which are held for this special purpose, and while the cost may be considerable, yet if we improve the time as we should, we can learn more than enough to make that cost good, beside the benefit which we derive socially.

All of these things are great helps to us, and should be eagerly sought after, as they will be if we have a natural qualification for the calling which we have chosen. If any persons love tomething else more than they do to study into bee-keeping, and only do this as a sort of duty, let them be assured that they have mistaken their calling, and the sooner they leave it and go to that which at all times gives them pleasure, the better they will be off, and the better it will be for the world.

Upward Ventilation in Hives.

If no upward ventilation is provided for our bees during the winter, the moisture exhaled by them condenses and forms ice on the walls and top of the hive, making their home uncomfortable in cold weather, and as soon as the weather moderates sufficiently, the ice above and at the side melts, causing wet and damp combs, which tends to dilute the honey, thus making it in a condition to cause bee-diarrhea, by the bees being obliged to take so much thin liquid into the stomach. In many cases the water comes in direct contact with the combs occupied by the cluster. When this occurs, if the temperature lowers suddenly, as it often does in mid-winter, the colony is often lost. This shows that upward ventilation is very desirable, still it should be so given as not to cause a direct current of air through the hive.

Borodino, N. Y.

FEEDING BEES.

An Experience in Feeding and Uniting Colonies.

Written for the American Bee Journal

BY MRS. L. C. AXTELL.

For three years our bees have done very poorly, but we did not have to feed them until the fall of 1887, when we fed cut loaf-sugar to a few colonies that seemed short of stores: but very few of the colonies worked upon the sugar, because it was so hard and dry. We thought so last spring, as we had it all to gather off, and melt up and feed in a liquid state; so through the spring and summer we fed 9 barrels of sugar, counting those two.

We ceased feeding about a month in clover time, but had to begin again in July, to keep some colonies alive. We fussed with them a good deal, and equalized their stores to prevent the necessity of feeding, as far as possible, as there is no work about bee-keeping that we dread so much as feeding, and we never feed our bees if they can gather enough from Nature's stores. For one reason or another, it tends to make people suspicious of honey, if they know that bee-keepers feed their bees sugar when they know that bees can get natural stores. But it does not pay to let one's horses, that have done the best they could, die for want of food in winter.

Many bees in this neighborhood died for want of food, but some lived over winter, where there were but few colonies, without any feeding, and this fall they gave a few pounds of surplus honey.

Our bees were in good condition when the fall honey-flow began, and for 3 weeks they brought in honey lively, until the brood-combs became solid "slabs" of honey, which I can assure you delighted our eyes, and gave 800 or 1,000 pounds of surplus. I think that I never saw honey come in faster than it did for a short time, and then is the time one should do all the uniting of weak colonies, as it can then be done so successfully, and with so little loss of bees or robbing.

It does not pay, at that season of the year, to try to build up weak colonies by drawing brood from the strong late in the fall, unless one has young queens that they do not care to kill, and then it is better to remove old or rejected queens, and give their colonies the young queens, getting all colonies in fair wintering condition while honey is coming in.

Roseville, Ills., Dec. 19, 1888.

SEASON OF 1888.

Bee-Keeping in Maine—The Open-Side Sections.

Written for the American Bee Journal

BY J. F. LATHAM.

From May 1, 1888, to the present time, the weather in this section of our broad land, has been inimical to almost every branch of the pursuit of those who derive their sustenance from the bounties of Nature. Cold and wet has been the order of the times. Among the different branches of agriculture, that of apiculture has failed to be remunerative, except in some favored localities. Collectively speaking, there have been but few swarms, and a very small quantity of surplus honey has been stored to reward the efforts of the bee-keeper.

My 59 colonies of bees passed the winter of 1887–88 successfully. During the first stage of brood-rearing in the spring, 2 colonies lost their queens, but by uniting, and supplying them with emerging brood and eggs, until drones commenced flying, my number was reduced but one colony.

During the time for "building up," the weather was so unfavorable that, with few exceptions, my bees failed to respond to my usual treatment for increasing the brood; consequently, when the white honey harvest time arrived, many of the colonies were too weak, numerically, to enter the surplus receptacles in time to meet the first yield. A few of the strongest colonies stored 40 pounds of surplus honey each, the weaker ones from 3 pounds to 20 pounds each. My whole crop of honey in the comb amounted to some over 800 pounds, which, with 10 pounds of wax and an increase of 4 colonies from 9 swarms, represents the income of a working force of 58 colonies for the season.

From the foregoing it is readily perceivable that the pursuit of bee-keeping as a specialty, is somewhat precarious when absolute assurance in a pecuniary sense is considered. I feel prompted to admit that the time spent in caring for my colonies during the time of surplus storing the past two seasons, those of 1887 and 1888, in procuring 2,000 pounds of honey, was more than double that spent in the season of 1886 in procuring the same quantity, plus the time spent in caring

for the colonies during the springs and falls of the former seasons.

If I mistake not, the results of the past two seasons are somewhat averse to the arguments of those who so strenuously advocate *specialty* in bee-keeping, causing them to change the bias of their opinions in regard to its feasibility, as an exclusive occupation. Specialty in bee-keeping, based on the feudal theory of those who advocate the protective-territory system, might meet the demands of specialty in some instances, but the specialist of 50 or 100 colonies will need a prop, at times, if he exercises the requirements of his business in a more enlightened aspect. But, as every evil has its corresponding good, so do poor honey seasons influence good prices, and quick sales for the products of the apiary.

The "Open-Side" Sections.

I think that if Mr. Hambaugh should use sections open at the sides, in a case with the **T** rest as supports, and separators so constructed as to allow the bees a free range, "fore and aft," as well as up and down, he would experience less reason for complaint in regard to "the size" of the one pound sections "appearing contrary to the laws governing the household economy of the bee," as stated on page 795 of the BEE JOURNAL for 1888.

I have used the open-side section in cases (with the tin **T** for supports), constructed so as to allow the sections to be placed *en masse* with separators having openings to match those in the sections. This method allows a free range for the bees, and assures a much better filling of the sides with comb and honey, than when close-side sections are used.

In my experience, when close-side sections are used with close-end separators, the combs in the sections will be rounded off with two or three rows of short, uncapped, and often empty cells on each side of the box, especially when a scanty flow of nectar prompts the bees to curtail their work; leaving the sections lank in appearance, and light in weight—in reality, reducing the honey, however good, to a second grade article, in the estimation of the consumer. A section filled chock-full has a much better appearance, and sells much more readily than one more weighty, if in an unfinished condition.

Cumberland, Me., Dec. 12, 1888.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
Jan. 8, 9.—	Ontario, at Owen Sound, Ont. W. Couse, Sec., Streetsville, Ont.
Jan. 9-11.—	Nebraska State, at Lincoln, Nebr. J. N. Heater, Sec., Columbus, Nebr.
Jan. 15.—	Vermont State, at Middlebury, Vt. Marcia A. Douglas, Sec., Shoreham, Vt.
Jan. 15, 16.—	N. W. Ill. & S. W. Wis., at Rockford, Ills. D. A. Fuller, Sec., Cherry Valley, Ills.
Jan. 16.—	Indiana State, at Indianapolis, Ind. Geo. C. Thompson, Sec., Southport, Ind.
May 4.—	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Report for 1888.—Louis Gerhart, Lyle, Minn., on Dec. 10, 1888, writes:

I had 4 colonies in the spring of 1888, increased them to 8, and took 100 pounds of honey. I worked my bees on the tiering-up system this season, which was generally thought best for a year of this kind.

Stands at the Head.—Mr. G. E. T. Kyber, Green Bay, Wis., on Dec. 21, 1888, says:

The AMERICAN BEE JOURNAL stands at the head of bee-literature, and the information obtained therefrom is far in advance of the remuneration therefor. Compliments of the season.

Uniting Colonies, etc.—Mr. Geo. Eidemiller, McGregor, Iowa, on Dec. 17, 1888, writes:

My increase this year, from 5 colonies, spring count, was 17 by natural swarming. I kept uniting according to time and the strength of the colonies, and by so doing it left me 12 good colonies; from 7 of them I took 650 pounds of comb honey. Extracted honey sells at 10 cents, and comb at 18 cents. I winter my bees in the cellar under the house, and they weigh from 40 to 60 pounds per colony.

Not a Pound of Honey.—Mr. A. C. Balch, Kalamazoo, Mich., on Dec. 24, 1888, wrote thus:

I have had no honey this year, and have had to feed many of my colonies of bees, to keep from starving. I have not taken one pound of honey from them this year.

Bee-Keeping in Alabama.—I. J. Heaton, Pratt Mines, Ala., on Dec. 24, 1888, says:

I began in the spring of 1888 with 41 colonies, some being very weak. I have sold $170 worth of honey, most of it extracted, at 12½ and 15 cents per pound. I now have 53 colonies packed in cotton-seed, with plenty of honey to winter on, I think. There is no clover in my bee-range, and but little basswood. There is plenty of sour-wood, and I have a good market. I contemplate sowing 5 or 6 acres in lucerne clover the coming spring. My greatest pleasure is with my bees. I am well pleased with the AMERICAN BEE JOURNAL, and think it well worth twice its subscription price. I wish its editor and contributors a Happy New Year. I do not feel discouraged so long as I have such noble leaders. Let us all remember the watchword.

Bee-Cellar Ventilators, etc.—C. Theilmann, Theilmanton, Minn., on Dec. 21, 1888, writes:

So far the weather has been very fine. We have no snow as yet. My bees are very quiet at 42°, with the ventilators all open in the bee-cellar. I am sure that my bee-cellar would be too warm for the bees, if I had no ventilators in it. They are very valuable in such weather.

I send my membership fee for the Bee-Keepers' Union. The change of time for paying the fee suits me better than before, as we have more leisure at this time of the year to attend to such matters, than in the height of the honey season.

Good Prospects for 1889.—W. H. Graves, Duncan, Ills., on Dec. 19, 1888, says:

My honey crop this year was next to a failure, and two years in succession makes it somewhat discouraging. I have been used to bees all my life, and expect to keep them as long as I live. They are in good condition for winter. I have just been putting them in the cellar. I have 58 colonies. I never saw white clover so thick everywhere as it is here. I think that we have good prospects for a fine crop for next year.

Prospect for White Clover.—Geo. Shafer, Neoga, Ills., on Dec. 19, 1888, says:

The past season has been very poor, but some better than last year. From 34 colonies the yield was only 1,000 pounds. Bees are in good condition for winter, and the prospect for white clover is good.

Results of the Season.—Wm. C. Wolcott, Eldorado, Wis., on Dec. 17, 1888, writes:

It has been a poor season here for bees. I started last spring with 43 colonies, and many of them spring dwindled down to very small colonies. I increased them to 71 colonies, which are in good condition. I put them into the cellar on Nov. 15. I only had 1,300 pounds of honey, and 1,000 pounds of that was extracted. The comb honey I sold for 15 cents per pound, and the extracted at 10 cents per pound. I intend to take the AMERICAN BEE JOURNAL as long as I live and keep bees.

Fine Weather for Bees.—W. T. Zink, Nicholas, Mo., on Dec. 14, 1888, says:

We are having fine weather. Bees were flying yesterday, and there were no signs of diarrhea. My bees gave me a surplus of about 8 pounds per colony, spring count, with plenty left to winter on. The last two seasons have cooled the ardor of a few bee-keepers here, but I still hope for a rich harvest.

Fine Fall for Bees.—N. W. Afflerbaugh, Cameron, Nebr., on Dec. 17, 1888, writes:

My bees are well supplied with stores sufficient to last them until honey comes

again. I have built a shed, and packed my 53 colonies in it on Dec. 15. We have had a nice fall, and bees were flying almost every day. I had a good yield of honey the past fall, from heart's-ease and golden-rod. I am selling the honey for 20 cents per pound. My honey sells more readily than California honey, and my customers say that it tastes more like honey.

Crossing Races of Bees.—W. H. Andrews, McKinney, Tex., on Dec. 22, 1888, writes:

I wish to say that the whole yield of the apiaries of North Texas for the last six years would not equal one good crop. All of my bees did not gather enough last season to winter half of them this winter. I am a paralytic, having suffered a stroke upon my right side. It came the 15th of last July. I write with my left hand. The man who talks about "crossing" the races of bees with the view of establishing a superior "breed," is clearly lost—off his reckoning. If mongrels are his aim, he need only go to his neighbors' yards, and take the first colony he comes to; 95 per cent. of all the bees in North America are just mongrels, ready made to his hand.

Bees Did Fairly Well.—Mr. John Booth, Barry, Ills., on Dec. 24, 1888, writes:

I have about 20 colonies, mostly hybrids, and on Aug. 26 or 27 there was not a pound of honey in any of my 20 hives; but about Sept. 1 my bees began to gather some honey, and by Sept. 15 they were fairly outstripping anything I had ever seen in the way of gathering honey. But being a plasterer by trade, I was necessarily called away from my bees just when they needed the most attention, to make them the most profitable; but they did fairly well, and our buckwheat cakes will not go dry this winter.

Packing Hives with Sawdust.—Samuel King, Jr., New Paris, O., on Dec. 21, 1888, says:

The forepart of this season was tolerably fair for honey in this locality, but the fall has been the poorest one for 20 years, on account of dry weather. My crop of comb honey was about 750 pounds, from 28 colonies. My 35 colonies of bees at this time are in pretty fair condition, although I had to feed some. I have wintered my bees heretofore altogether on the summer stands, and my method for the past two winters was by using outside casings packed with sawdust, with chaff cushions above the bees, and I think I have wintered them successfully. This year I have put a few colonies into the cellar, to test cellar wintering.

Ups and Downs of Bee-Culture.—A. J. Fisher, East Liverpool, O., on Dec. 22, 1888, writes:

I have kept bees for 25 years, and never have I during that time had as poor results as the two summers of 1887 and 1888. Not one pound of surplus honey did I get, but I had to feed freely for winter stores. If I was a specialist, and depended upon my bees for my bread and butter the last two summers, I would have had to practice Tannerism pretty freely. But if the season of 1889 proves likewise, shall I quit the business in disgust? No, never, as long as a bee lives, and I live. All business has its ups and downs, and these two seasons have been the "downs" in the bee-business with me. Now I am going to prepare for the "ups." Long may live the good old AMERICAN BEE JOURNAL! Hurrah for 1889!

Rearing Brood in December.—Alex. Sherington, Dutton, Mich., on Dec. 24, 1888, writes:

Yesterday one of my colonies of bees was flying very strong, when the weather was at 5° above zero. On examining them, I found that they had five frames partly filled with brood and eggs, and young bees crawling all over the combs. It is a strong colony, and has plenty of honey. My bees are packed on the summer stands, with 14 inches of chaff around them.

[We have been having fair summer weather, and surely the bees thought that, as "December is as pleasant as May," they may as well have a "flying spell."—ED.]

Willing to Try Again.—Nathan M. Woodman, Bushnell, Ills., on Dec. 24, 1888, says:

In this section, we who have tried to do something in handling bees for the past 3 or 4 years, have had such bad luck that we have about become discouraged, and many have ceased keeping bees entirely. I, like the rest, have had my bad luck, but I do not feel like giving up, and I will try once more.

No Snow Yet, etc.—Edwin Bump, Marshfield, Wis., on Dec. 22, 1888, says:

I commenced in the spring of 1888 with 23 colonies of bees. I sold one colony in June, increased my number to 52, and took off 1,500 pounds of white comb honey. I put my bees into the cellar on Nov. 14; that is not bad for a climate where the mercury goes down to 48° below zero. We have no snow yet. My bees are Italians, and I handle them without veil or gloves. A bee-sting does not hurt me as badly as a mosquito bite.

Swarming-Out, etc.—R. A. Rosser, Nelsonville, Ohio, on Dec. 24, 1888, writes:

I commenced the season of 1888 with 32 colonies in the spring, increased them, by natural swarming, to 48, which are now in good condition. I have taken 750 pounds of comb honey. My bees did exceedingly well until the last of June, when we had a very hard rainfall, lasting several days; after the rain it turned cold, and bees did nothing after that. I had to feed in the fall 300 pounds of sugar. Some of my new colonies kept swarming out in October, and when I examined into the cause, I found that they were starving; so I fed them, and had no more swarming. All now have plenty of stores, and if other conditions are right, I have no fears about their wintering.

Experience with Bees, etc.—J. E. Brooks, Howell, Mich., on Dec. 17, writes:

I commenced in April, 1887, with 10 colonies of bees in double-walled hives, and they were increased to 32 colonies by the following fall; but in wintering them in the cellar the combs all molded, and I lost all but 5 colonies, so last spring I began with that number. As no honey was gathered in 1887, I tried to winter my bees by feeding syrup. The season of 1888 has been a failure, as I only had about 100 pounds of surplus honey, and now I have 9 colonies, besides losing some swarms each year by their absconding. I packed my bees on the summer stands this winter. We have had but a few days of cold weather yet, and no snow. I was plowing on Dec. 11, and the ground is not yet frozen. It is raining to-day. Our assessor, last spring, had blanks, and made a record of all the colonies of bees lost last winter, and found that one-half of the bees in this section were lost then. I have tried several honey-plants, and have had no good of them yet. Nearly all of my Alsike clover dried up in July and died. It headed out about July 1, and by July 15 it was gone. I watched, but I never saw my bees at work on it. I sowed some sweet clover and catnip seed. The catnip is the best honey-plant we have here, excepting buckwheat. Most of the honey taken the past season was from buckwheat. It is good enough for me to use on winter pancakes. We had a very dry summer. I expect to keep bees, if I can, so long as I can get what honey we want to eat.

Melissa—How Far Bees Fly.—S. L. Watkins, Placerville, Calif., writes thus:

Last spring I received a small package of melissa seed, and planted a small patch of it about the middle of April. About July 1 it commenced to bloom, and continued until frost came. It grows luxuriantly on our mountain soil, and seems to be a great yielder of honey. Bees work well on the blossoms, and during the height of its flowering, bees swarmed on it. I think that it would pay well to cultivate it for honey.

"How far will bees fly in search of stores?" is often asked. In reading some old numbers of bee-papers recently, I find that there is quite a diversity of opinion, as regards the distance bees go in search of stores. I do not know how far bees will go in a level country, but I can come somewhere near how far they go in this mountainous part of California. In bee-hunting I never tracked black bees more than two miles from their habitation. I have frequently seen Italians and Carniolans three miles from the apiary. I do not believe that bees make much headway when working over three miles from home. Carniolans and Italians are stronger flyers than the common bees, and go further in search of stores.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Cold, bare and brown lie hillside, dale and plain.
They rest from labor now; yet flower, fruit and grain
Shall cover them again. Complain not that they sleep—
Sow worthy seed; a worthy harvest shalt thou reap.

Care in the selection of seed is of prime importance in securing good results. Get worthy seed; seed that is pure and fresh; such seed as James J. H. Gregory, of Marblehead, Mass., raises on his farms, and has sold to the public for thirty years, and worthy harvests shalt thou reap. Send for his 1889 catalogue, free to all.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at 8 cents per pound for Amber and 9 cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. Price 60 cents, postpaid. Subscription for one year and the binder for $1.50.

Money in Potatoes, by Mr. Joseph Greiner. Price, 40 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for $1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for $1.75; or we will present it *free,* by mail, to any one, for a club of three subscribers and $3.00.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, *Sec.*

☞ The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889. W. COUSE, *Sec.*

☞ The annual convention of the Vermont State Bee-Keepers' Association will be held in the Court House at Middlebury, Vt., on Tuesday, Jan. 15, 1889. MARCIA A. DOUGLAS, *Sec.*

☞ The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in the Supervisors Room of the Court House at Rockford, Ills., on Jan. 15 and 16, 1889. D. A. FULLER, *Sec.*

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m. H. M. SEELEY, *Sec.*

☞ The annual meeting of the Indiana State Bee-Keepers' Society will be held in the Agricultural Rooms in the State House at Indianapolis, Ind., beginning at 10 a.m. on Jan. 16, 1889. Reduced railroad rates can be secured by purchasing a through ticket to Indianapolis, taking the agent's receipt for the same, and having it countersigned by the Secretary of the Bee-Keepers' Society. GEO. C. THOMPSON, *Sec.*

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Oct. 13, 1888, wrote as follows concerning their use of the advertising columns of the AMERICAN BEE JOURNAL:

We got more orders from our advertisement in the AMERICAN BEE JOURNAL than from all the other bee-papers put together. We shall advertise in it again next year.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Do Not Forget to send a dollar for a membership fee to the National Bee-Keepers' Union for 1889. It merits your approval, and needs your assistance.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 16@17c.; 2-lbs., 13@14c. Fair white 1-lbs., 14@15c.; 2-lbs., 11 to 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10c. White extracted, 8@9c.; buckwheat, 6@6½c. which is in good demand. Market quiet on comb honey. We expect an increased demand after the holidays. Now is the time to ship honey.

BEESWAX.—22½@24c.

Dec. 22. HILDRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@12½c.—Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

BEESWAX.—22c.

Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c. for best 1-lbs.; very fancy lots have sold at 20c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.

BEESWAX.—22c. R. A. BURNETT,

Nov. 22. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15@16c.; fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.

BEESWAX.—22@23c.

Oct. 25. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 15@17c. 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.

BEESWAX.—23½c.

Sep. 17. THURBER, WHYLAND & CO

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5½@5¾c. For comb honey the demand is light; for extracted it is good, and market firm.

BEESWAX.—Dull at 18@22c.

Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but equal to the demand.

BEESWAX.—22@23c.

Dec. 12. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12½@16c. Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Dec. 17. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs. 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEESWAX.—None in market.

Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½c. California white in 60-lb. cans, 8c.; light amber in same cans, 7¾c.; amber, 7¼c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMEYER & CO., 122 Water St.

BOSTON

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The sales are good, and indications are that all the honey in the country will be sold by Feb. 1.

Dec. 27. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lbs., 16@17c.; fair, 14@15c.; California white 2-lbs., 14@15c.; amber 2-lbs., 12@13c.—Extracted, white California, 7½c.; amber, 7c.

BEESWAX.—None in the market.

Dec. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.

BEESWAX.—21c. for prime.

Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6¼ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lbs., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.

BEESWAX.—20@21c.

Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Jan. 12, 1889. No. 2.

EDITORIAL BUZZINGS.

"Our lives are songs ; God writes the words,
And we set them to music at pleasure,
And the songs grow glad, or sweet, or sad,
As we choose to fashion the measure."

The Bee-Keepers' Advance for December came to our desk on the last day of the year. It could not be much later and keep within the month. Bro. Mason should make more *advance* than that.

The Review for December contains a brief history of its existence, and an excellent engraving of its editor. The *Review* is well edited and printed, and is a credit to the craft. The reading matter has been *topical* during its first year, and has been exceedingly interesting. We club it with the AMERICAN BEE JOURNAL for $1.40.

The Supreme Court of Arkansas is sadly behind its docket, and we are just informed that the appeal in the Arkadelphia case may not be reached for a year. It is a disgrace to America that the Supreme Courts, both State and National, are so far behind as to be detrimental to the interests of our citizens, and the defense of their rights.

The Likeness of Prof. A. J. Cook appears in the *British Bee Journal* for Dec. 13, 1888. By means of that excellent picture the European apiarists may learn to love the face and kind expression of countenance of the Professor, ere they form his personal acquaintance, or know the amiable character of him whom the bee-keepers of America feel *proud* to call their honored son, and representative apiarist.

Gleanings for Jan. 1, 1889, is on our desk, and is as usual very interesting. The Editor's illustrated "Notes of Travel" are continued, and will last for four or five more numbers. He describes in a very instructive manner the persons, places, scenery and experiences of his late trip to California.

This issue also contains a biographical sketch and portrait of the Editor of the AMERICAN BEE JOURNAL ; the former being written by our friend Dr. C. C. Miller. We make our politest bow for the complimentary remarks of both correspondent and editor.

Syracuse, New York, as a market for honey was unfavorably mentioned by Mr. J. W. Tefft, on page 839, who stated that it was the home market of "Doolittle, House, Salisbury," etc. In our comments upon the matter, we solicited some of the honey-producers to write an explanation, and here is what Mr. F. A. Salisbury writes concerning it :

The article by J. W. Tefft, on page 839, in regard to the Syracuse honey market, saying it is the "home market of Doolittle, House, Salisbury, Betsinger, Parks, Ross, Bailey and others," is a mistake. None of the parties mentioned sell much honey there. I have not sold 100 pounds of honey in Syracuse for years. For what I have sold I have received the same as in other markets. The prices quoted in the daily papers here are misleading, as the prices are not changed during the year. Syracuse is not a good place to sell ; so much honey is produced in the vicinity by farmers, who sell for almost any price. They consider whatever they receive as so much clear gain—honey costing them (they think) but very little.

Mr. W. H. Furman, who was well-known in apicultural circles twenty years ago, died on Dec. 29, 1888, at Miller, Dakota. Mr. F. formerly lived at Cedar Rapids, Iowa, but a few years ago he moved to Dakota. He was stricken with paralysis some months ago, and for a time was blind, but recovered, at least partially. His death was caused by a relapse. He was buried at Cedar Rapids on New Year's day. Thus are the pioneers of progressive apiculture passing away.

The Weather is remarkable for this time of the year. Here in Chicago it is almost summer-like—the thermometer ranging in the sixties. We have had no snow worth mentioning, and the ground is soft as in spring. An exchange says that the weather was so spring-like on Christmas Day in the Catskill Mountain region, "that bees and butterflies came out in swarms, lured by the hot sun."

England has also had a liberal share of the mild weather. By telegraph we learn that ten days ago, in a garden near Plymouth, there was no less than thirty spring plants in full bloom.

We hope that summer will not be late in consequence of the mild weather now—but we will not meet trouble half way.

This is the Programme of the ninth annual meeting of the Indiana Bee-Keepers' Association, to be held on Jan. 16, 1889, at the Agricultural Rooms, State House, Indianapolis, Ind., commencing at 1 p.m., and continuing two or more days :

1. President's Address.
2. Making Colonies Strong for the Harvest.—Ora Knowlton, New Brunswick, Ind.
3. Is it Profitable to Use Full Sheets of Foundation in Sections and Brood-Chambers ?—Mr. Abbot, Noblesville, Ind.
4. Does Nature Guard Against the Promiscuous Crossfertilization of Flowers, by Causing Bees to Visit Flowers of One Color or One Genus in Securing One Load ; or do Bees Visit Flowers Adlibitum ?—Prof. A. J. Cook, Agricultural College, Mich.
5. How do You Handle a Swarming Colony to Get the Best Returns from both the Swarm and Parent Colony ?—T. S. Bull, Valparaiso, Ind.
6. To what Extent can We be Theoretical Apiarists ?—Mr. Hubbard, Editor Apiary Column, *Indiana Farmer*, La Grange, Ind.
7. The Anatomy and Physiology of the Honey-Bee. (Illustrated.)—Prof. Webster, Purdue University.
8. The Best Method of Preventing too Much Increase, Especially Second Swarms. —Mr. Mason, Fillmore, Ind.
9. Queen-Rearing.—Frank L. Dougherty, Indianapolis, Ind.
10. The Best Method of Obtaining Straight Combs—Those in the Brood-Chamber Containing 95 per cent. Worker-Cells.—Miss Eva Scholl, Lyon's Station, Ind.
11. The Æsthetics of Bee-Culture.—Mrs. Cassandra Robbins, Indianapolis, Ind.

Mr. A. I. Root, editor of *Gleanings*, has returned from California, and we hope with renewed health and strength. Here is what he says about getting home :

I am once more (Dec. 20) at home again. The past few weeks seem so much like a dream, that every little while I have to shake myself and look around to make sure that I am in wintry Medina instead of away off in California, the land of perpetual flowers and sunshine. I am glad I am here, though, after all.

Catalogues for 1889 are on our desk from—

M. H. Hunt, Bell Branch, Mich.—16 pages —Bee-Keepers' Supplies.

W. D. Soper, Jackson, Mich.—20 pages—Supplies for the Apiary.

J. M. Jenkins, Wetumpka, Ala.—50 pages —Bees and Supplies.

Queries.—We closed the year 1888 with Query 600, and commenced this year with No. 601. This department has been exceedingly interesting, and makes a *feature* not to be despised in the make-up of an apicultural periodical.

Mr. George Knickerbocker was married to Miss Julia C. Collin, at Husteds, N. Y., on Dec. 27, 1888. The BEE JOURNAL extends congratulations, and best wishes for their happiness.

Never Disturb the bees during cold weather. If anything is necessary to be done, wait for a warm day, and then do it about noon.

INTERROGATORIES.

Extracting, Granulation, etc.—Mr. W. S. Harris, of Lime Springs, Iowa, asks:

Please reply to the following questions through the AMERICAN BEE JOURNAL:

1. Which is the best way to strain the honey after extracting? 2. Is it necessary to have the honey capped before extracting? 3. How should I care for it in case it is not capped? 4. Which is the best way to prevent its granulation? 5. Is it advisable during the coming season to replace queens that are four years old, with young ones?

1. Strain it through a cheese-cloth.

2 and 3. If honey is extracted before it is capped, it must be ripened after being extracted, by being exposed to the air in a warm place. Care should be taken to keep insects out of it.

4. Some kinds of honey will granulate more readily than others. If heated, put into cans, fruit jars, etc., and sealed while hot, it will remain a liquid until unsealed. Care should be taken not to let the honey boil, and if the jars or cans are put into hot water, it will be all the better.

5. Yes; queens should be superseded as a general thing after the third season.

Granulation of Honey.—Mr. C. A. Huff, of Clayton, Mich., wrote thus on Dec. 19, 1888, and requests a reply in the BEE JOURNAL:

I was in a store in Clayton, Mich., sometime since, and was quite surprised to here Mr. Arthur Bovee make the statement that pure honey will not candy in less than two months from the time it was extracted. He said that when it did candy in a less time than that, it was sugar. Now as Mr. Bovee is well liked, and a good citizen, as well as a bee-keeper, his word has great weight around here. Is he correct?

While it is true that some *pure* honey will not granulate at all, it is equally true that nearly all the honey gathered in the North will granulate upon the approach of cold weather, or when the temperature is below 70°, Fahr. Mr. Bovee was very indiscreet to make such remarks without qualification or explanation.

Feeding Bees in Winter.—Alfred Robbins, Swartswood, N. J., asks the following question:

I bought a Heddon bee-hive last year, and have bees in one brood-chamber. The hive is packed in leaves, except the entrance. The bees have not enough stores for the winter. In what way can I feed them, and what shall I feed them, as I have no honey? They are native bees.

In reply to the above, at our request, Mr. Heddon says:

I have had very unsatisfactory experience in feeding bees after their period of confinement had begun. I prefer that you would consult back numbers of bee-periodicals and books. I am no advocate of candy feeding. My method is to see that the bees have plenty in the fall, and when I find that they do not have enough, I feed them sugar syrup, usually about a month before they cease to fly. I have had good results, however, in feeding them but a few days before the period of confinement began.

GLEAMS OF NEWS.

MUST THE EXTRACTOR GO?

Under this heading a correspondent of the *New Zealand Bee and Poultry Journal* gives the following as a severe rebuke to some American apiarists, who have suggested the condemnation of the honey-extractor. He says:

Will it be believed that the above query has actually been put forward in an American bee-periodical, and seriously considered by the editor and several leading bee-keepers? The idea of some of them being that the extractor, by enabling bee-keepers to largely increase the production of honey, has been the means of lowering the price of that article to less than one-half what it was some years ago, and this is their reason for seriously considering the question of doing away with it.

Shade of Major von Hruschka! are the bee-keepers of America going mad! The low price of honey seems to have affected their brains.

The editor characterizes the suggestion to discontinue the use of the extractor as "one of the wisest and most important suggestions yet advanced by any one." That man should be helped to a straight-jacket and be confined, before he does any serious mischief; for the person that could back up such an insane suggestion must himself be insane, and is not a fit subject to be at large!

It is but *justice* to American bee-keepers to say that no such proposition has been either entertained or endorsed by them as a body of apiarists!

It is unfair to take the expressions of a few (and a *very few*, at that), and call it the opinion of American apiarists. This is a country of *free speech*, and any man can express his opinion *for himself* without compromising his fellow men, or having his individual opinion charged up to the great body of apiarists, and paraded to prove that they are lunatics!

Our New Zealand cotemporary asks: "Are the bee-keepers of America going mad?" No, sir; the great body of apiarists are quite *sane*, and fully able to cope with all the questions presented concerning our pursuit. They need no "straight-jackets" nor dungeons; neither have they authorized any one to speak for them on any important or unimportant matter!

The AMERICAN BEE JOURNAL has never either published the views which our New Zealand neighbor condemns, nor has it endorsed such ideas. The honey extractor has come to stay, and plays too important a part in honey-production to be dispensed with.

If there be anything to complain of, it was the action of those who first used the honey-extractor, in placing the price of liquid honey at a less amount than was asked for honey in the comb, with wood, glass and wax weighed up to the buyer!

It would be a very difficult matter now to raise the price of the clean, *nct*, liquid article—but at the outset it would have been an easy matter to have obtained a larger price for it than for that in the comb; and had it so been ordained then, no one would ever have thought of such a thing now as saying, "The extractor must go."

Our New Zealand cotemporary concludes with this bit of irony:

"O Science! to what point have you brought us bee-keepers to? To that point where we stand ready to condemn you. You, Major von Hruschka, and you, Father Langstroth, have both been the means of increasing the production of pure honey by your inventions; and notwithstanding that we have hitherto lauded you up to the skies and worshipped you as gods of the bee-keeping world, our eyes have now been opened to the evil you have done under the guise of benefitting us. Away with you and your extractor, and movable comb hives; we will have no more of them, but return to the strained honey age, and our primitive forms of bee-keeping. *O miseras hominum mentes! o pectora caeca!*"

This should teach Americans a lesson. Some excitable persons are always making foolish observations, concocting unwise theories, or advising impracticable methods, giving a wrong impression to those who are watching American apiarists in every part of the world.

Only a short time ago, the *Bee-Keepers' Magazine* published a table prepared by a New Jersey man, to show that nearly all the honey on the market was adulterated, and this was thrown into our faces to prove that apiarists were adulterators, and to clinch the assertion by a clergyman in England, that many "adulterating bee-farms" did exist in America!

Later, the *Bee-Keepers' Review* published an article written by a Detroit man, who claimed to have invented a method for manufacturing honey-comb (which, however, is an imperfect affair, and of no *practical* use in the apiary), and this, too, was used by some to give color to the "Wiley lie," which asserted that "combs were being made of paraffine and filled with glucose by machinery," etc.

These and many other instances go to show that some apiarists are forever "putting their foot into it," by presenting an ax to the enemies of American honey-producers, with which they are invited to chop off the heads of American apiarists generally. If it were used to exterminate these unwise scribblers, it might be excusable—but it is always used to the detriment of the pursuit in general—classing all American bee-keepers together, making them responsible for the mistakes made by a few, and holding up their hands in holy horror, while they ask: "Are the bee-keepers of America going mad?"

Brethren, please take this matter into thoughtful consideration, and let there be no more of such mistakes!

QUERIES & REPLIES.

Tool for Cleaning Propolis from the Sections.

Written for the American Bee Journal

Query 603.—What kind of a tool do you use to clean the propolis from sections?—Iowa.

A dull knife.—DADANT & SON.

A common case-knife.—C.C.MILLER.

An ordinary pocket-knife.—R. L. TAYLOR.

The small blade of a pocket-knife, usually.—J. M. HAMBAUGH.

Any knife at hand.—M. MAHIN.

A strong pocket-knife, or a short table-knife.—A. B. MASON.

The instrument that I use is a sharp three-cornered piece, with a handle to it.—WILL M. BARNUM.

Any knife convenient for the purpose—a pocket-knife is as good as anything.—P. L. VIALLON.

A good, strong knife with a sharp point.—C. H. DIBBERN.

A case-knife; sometimes a wide, dull chisel; that is, a chisel not very sharp.—MRS. L. HARRISON.

I have used an old case-knife, and I find that it works very well.—J.E.POND

A sharp and pointed knife-blade; and sometimes glass and sand-paper.—H. D. CUTTING.

A common case-knife, with a thin, pliable blade.—A. J. COOK.

An old table-knife is about as cheap and as good a tool as you can use.—J. P. H. BROWN.

I use a sharp pocket-knife. There is no propolis on my sections, except on the edges, to be cleaned off.—G. W. DEMAREE.

An old case or table knife having ¾ of the blade taken off, so as to leave the end square, like a putty-knife.—G. M. DOOLITTLE.

A small jack-knife. I use the largest blade, and hold that blade between my thumb and finger in such a manner as to guage its position at all times.—JAMES HEDDON.

I have used a carpenter's paring chisel with good effect. Do not use the cutting edge, but use the sharp corners of the blade with a kind of stroke motion. The best way is to use proper cases, and keep out of "scrapes."—J. M. SHUCK.

One which I have found quite satisfactory is made by breaking a worn-out three-cornered file in two in the middle, and grinding the three sides until the edges are sharp. With this tool in the right hand, and the section in the left, very good and satisfactory work can be done.—EUGENE SECOR.

Any knife, either one carried in the pocket or used at the table, will do. A scraper can easily be made, or you can use the side of a chisel or putty-knife.—THE EDITOR.

Getting Honey from the Red Clover.

Written for the American Bee Journal

Query 604.—1. Can Italian, Cyprian, Carniolan, Holy-Land, Caucasian, Egyptian, Albino or any other kind of bees get honey easily out of red clover? If so, which? 2. If not, which can penetrate the deepest flowers?—A. H.

Yes; bumble-bees.—A. B. MASON.

We have no red clover here, and I cannot say. I do not know, but the Italians are good enough for me.—P. L. VIALLON.

1. Why do you not add "bumble-bees?" then you would have it. 2. The one with the longest tongue.—H. D. CUTTING.

1. No, not generally. I think that any of the breeds may do so sometimes.—C. C. MILLER.

Yes, sometimes. If the flowers are "short," and other forage scarce, all hive-bees store from it.—J. M. SHUCK.

I cannot speak about the "easy" part, but I have frequently seen Italians work upon red clover. From a series of measurements, I have found that the Cyprian and Italian bees can penetrate the deepest.—J.P.H. BROWN.

No, not as a rule. Sometimes Italians and other varieties will work on the second crop of red clover; but it cannot be depended upon with any race of bees.—C. H. DIBBERN.

I have had no experience outside of Italians, blacks and their crosses, and I have never had the pleasure of seeing either of them gathering honey from red clover.—J. M. HAMBAUGH.

I have read of certain strains of bees (Italians, I believe) that were bred up to this, and I think that it is quite possible. We should breed more for "long tongues." It will be *the* principal feature of the "bee of the future."—WILL M. BARNUM.

I have no experience with any bees except blacks, Italian and Holy Land or Syrian. None of them can get honey from red clover "easily," but all of them can get at it sometimes, but with some difficulty. The bees from Palestine and Syria have longer tongues than blacks or Italians.—M. MAHIN.

Italian bees work quite freely on the second crop of red clover, particularly on the smaller heads; and in our apiary some colonies of Italians work much better upon red clover than others. Such colonies we mark "Extra," and breed from them.—MRS. L. HARRISON.

1. Italians, and Italian-hybrids can, at any time when the flowrets are well filled with nectar, and better when a previous drouth has shortened the tubes of the flowers.—R. L. TAYLOR.

We have not tried all, but we think that the Italians come as near to it as any of the others, and it is only at times that they can get honey from red clover—probably when the corollas happen to be shorter, or perhaps fuller.—DADANT & SON.

No. Sometimes all bees can get some honey from red clover. Those with the longest tongues could do the best. Italans and Syrians have the longest tongues of any that I have examined.—A. J. COOK.

In some years all kinds of bees work on red clover, and in other years none of them get any honey worth speaking of from this plant. The Italians will work more on red clover than any variety I know of.—G. M. DOOLITTLE.

Red clover is not such a great honey-yielder as many people suppose. The largest yields of red clover honey I have ever seen gathered, were taken in by crosses between Italians and brown-German bees.—JAMES HEDDON.

1. No, not easily; though it is claimed that the Italians can do so to a considerable extent. 2. From all the evidence I can gather, the Italians can penetrate deeper into the flowers than any other variety.—J. E. POND.

1. I have never seen any hive-bee that could get honey out of red clover at all seasons. I think that it is mostly from the second crop of clover that they get honey, because the blossoms are smaller. If from any cause the first crop is dwarfed, the result would be the same. 2. I have only observed blacks, Italians and Carniolans, the advantage being perhaps with the Italians.—EUGENE SECOR.

1. Acecording to my observations red clover yields nectar very scantily in some seasons, and very profusely in some other seasons. I believe that all the yellow varieties of bees work on red clover, when it yields nectar. The best results that I ever obtained from red clover, was by the use of bees that were a first cross between Italian drones and Cyprian queens. I believe that no bees are equal to this cross as workers on red clover.—G. W. DEMAREE.

Yes; all of the kinds of bees can do so sometimes, but none more "easily" than the Italians. When the nectar is plenty, or the corollas are "stunted" by drouth, it is more easily done than when the tubes are deep. The "long tongues" count in this matter. In this the Italians and Syrians are doubtless at the head.—THE EDITOR.

CORRESPONDENCE.

MICHIGAN.

Report of the Michigan State Convention.

Written for the American Bee Journal
BY W. Z. HUTCHINSON.

FIRST DAY.

EVENING SESSION.

This session was opened by the Secretary, who read an essay from Mr. T. F. Bingham, on

Spring Management of Bees.

When to begin spring management of bees is a point which the subject would seem to fix as at the close of winter. But the best period to begin spring management, is when the bees are gaining stores for their keeper and themselves nine months before that trying period when bees, from causes not well settled, and upon which bee-keepers do not agree, develop apparent weakness, and in some seasons, and not rare instances, fail entirely.

It is not the province of this essay to cover all the well-written field so often trod by bee-keepers, relating to this trying period; but merely to direct attention to the very great value of an abundant supply of honey to last a colony until in any spring, however dreary and cold, the clover or other sure supply of honey shall come.

Some seasons, and in localities from which early and abundant pollen is obtained from forest trees, it is possible for bees to stem this trying period with but a meager previous season's stock of honey. But it is not of common events that we feel the uncommon needs. In springs like the one last passed, no bee-keeper can fail to fully understand that honey, even in excess of usual needs, is of inestimable value in the hives.

Probably no bee-keeper present is without experience in single instances, when from some massive hive, gum (old log) or similar abode, when 75 or 150 pounds of honey not accessible in autumn, the colony has passed smoothly through unpropitious springs, and far out-stripped its scantily supplied neighbors. We all know how oft we have heard that a pint of bees was enough, and 10 pounds of honey ample to winter a colony of bees. We also have many times, to our sorrow, paid the penalty of our broken promises to feed, should unpropitious and fickle April present herself with unwonted winds and storms.

At present there appears to be no absolute method by which spring management can be secured, except by judicious and ample provision, and preparation made the previous season.

T. F. BINGHAM.

After reading the above essay, it was discussed as follows:

James Heddon—I have never lost any bees by spring dwindling, that had wintered perfectly. We may as well take up the subject of wintering, as I can see that that is where we will get to.

The Wintering of Bees.

The convention agreed with Mr. Heddon, and he was invited to lead in the discussion; when he proceeded to give a *resume* of the pollen theory, very clearly showing that the consumption of pollen in confinement was the main cause of bee-diarrhea.

H. D. Cutting—Have you not lost bees in winter when they had only sugar stores?

James Heddon—Yes, but not from diarrhea. They simply perished from cold too long continued; but there was not a sign of diarrhea, no over-loading of the intestines, nor any discharges.

R. L. Taylor—I agree with Mr. Heddon. Many have asserted that they did not believe the pollen theory, simply because bees having pollen in the hive do not always have the diarrhea. It cannot cause disease unless consumed in excess when the bees cannot fly. If honey is of easy access, I think there is less danger of pollen being consumed. There is also a difference in pollen. Some is hard, and seems covered with wax; while some is soft, and seems mixed with the honey.

Dr. Higbie—A compound food is needed. Honey is a compound food, and it is likely that the bees may be wintered upon it.

R. L. Taylor—Does the Doctor mean that a compound food must always be the same? Are its constituents the same?

Dr. Higbie—In winter more carbonaceous food is needed.

R. L. Taylor—That is probably true. In winter we do not move about so much, hence the waste is less, and not so much nitrogenous food is needed. When the bees have relapsed into that semi-torpid condition of successful wintering, but little nitrogenous food is needed. If they need any, they need no more than is contained in sugar syrup.

James Heddon—It does not contain a particle.

R. L. Taylor—I once wintered 200 colonies with no pollen in the combs—nothing but sugar syrup. I never had bees winter better. It is held by many that it is better not to have bees breed late. My experience has been the reverse. I would like to ask whether this is the result of the bees using up the pollen in the fall, or from having young bees.

James Heddon—I think that it is the result of the consumption of the pollen before the bees have ceased flying. Young bees cannot hold their feces as well as old bees can, as all know who have taken off honey.

An expression was taken to see how many believed that the consumption of pollen in confinement was the prime cause of bee-diarrhea. Nearly every one held up his hand.

R. L. Taylor—Well, if pollen causes diarrhea, what are you going to do about it?

James Heddon—If sugar were cheaper, I should feed sugar.

Dr. Higbie—Let me ask, who has left pollen in the combs, and the bees did not have the diarrhea?

James Heddon—I have, and so has every one.

President Hilton—I have for ten years wintered bees successfully, paying no attention to pollen.

James Heddon—You know how you winter your bees, and could tell me, and I could prepare mine for winter in exactly the same way, yet I should suffer losses.

The convention then adjourned to meet at 8 a.m. the next morning, and go in a body to visit the City Fire Department.

SECOND DAY.

MORNING SESSION.

After visiting the Fire Department, the convention again assembled at the Hall, and Mr. W. Z. Hutchinson gave an address upon the advantages and disadvantages of attending conventions, in which he said: "I am free to say that were it not for the social features—meeting and enjoying the company of fellow bee-keepers—bee-conventions would be very slim affairs. The majority of those who attend conventions go for the sake of having a 'good time,' and if it can be afforded, it is all right. Between reading the report of a convention and attending one, there is as much difference as there is between reading a love letter and visiting your lover."

President Hilton said: I have always attended conventions, and went home feeling well paid. The social feature is one of the brightest. This life is not all dollars and cents. It is true that our conventions have of late been poorly attended, but that is attributable to the poor seasons; with the return of better crops of honey, I

think that we may look for the crowds as of yore.

James Heddon—If there were no books nor periodicals, conventions would be grand things, but the interchange of thought by means of the printed page is much cheaper, and fully as efficient.

A. D. D. Wood—I have for several years attended conventions. I do not know as it has paid me in dollars and cents, but I have been paid in the social feature.

The convention here adjourned to visit the State's Prison, having received an invitation from the warden.

AFTERNOON SESSION.

The next meeting is to be held at Lansing, Mich., and the Executive Committee are instructed to choose such a date as to enable members to take advantage of the holiday rates on the railroads—that is, between Christmas and New Year's.

The election of officers resulted as follows: President, Prof. A. J. Cook, of Agricultural College; 1st Vice-President, W. D. Soper, of Jackson; 2nd Vice-President, Geo. E. Hilton, of Fremont; 3rd Vice-President, John Rey, of East Saginaw; Secretary, H. D. Cutting; of Clinton, and Treasurer, W. Z. Hutchinson, of Flint.

The Crosses of Bees.

This was the next topic. Mr. Fellows had tried a cross between the Carniolans and blacks, and was pleased with it.

James Heddon preferred a cross between the blacks and Italians. He secured the right kind of a cross, not by mating queens in confinement, but by filling the air with drones from choice colonies. This was done by removing drone-comb from undesirable colonies, and placing it in the most desirable ones.

R. L. Taylor agreed with Mr. Heddon.

President Hilton had tried the Carniolans, and found them gentle and prolific, but lacking in honey-gathering qualities. He had had just as well-behaved colonies of blacks, as of any other bees.

H. D. Cutting had Carniolans. The hairs are longer and whiter. A cross between the Italians and Syrians will produce the most queen-cells. When a swarm comes out, open the hive, and you will think that you had better go into the "pea-nut" business.

Planting for Honey.

Dr. Higbie mentioned his success with buckwheat and rape. He got no honey from the former, while the latter did quite well.

James Heddon—Millions and millions of pounds of honey go to waste every year, and all of Nature's planting. I will venture to say, that not more than one pound in 10,000 is the result of planting for honey. Planting for honey brings in a crop of bee-keepers. Raising crops that produce honey, or scattering the seed in waste places, of some plant that will care for itself, is all right; but all this should be done as quietly as possible. When a farmer comes to me and says, "I have planted some buckwheat for your bees." I say, "Is that so?" Well, now let me tell you something. The honey from buckwheat is very dark and strong, and pretty poor stuff; in fact, we had a little rather not have it." "Is that so?" he will say, and that is the last we hear from him.

The convention adjourned until 7:30 p.m.

EVENING SESSION.

As usual, the attendance at the evening session of the last day was very small, as so many had gone home. Those that were left gathered around the fire, and indulged in an informal chat until the evening was nearly gone. When the meeting was finally called to order, there was a little discussion as to what should be discussed. The Secretary had mislaid an essay by Dr. Tinker. He had glanced it over, and said, as nearly as he could remember, that it was about the same as his article that appears on the first page of the December *Apiculturist*, which Mr. Heddon was asked to read, and comment as he read, which he did.

Mr. Heddon objected to the use of the word "storifying," as used by Dr. Tinker. The Doctor had borrowed the word from the English, and now applied it to the management of the Heddon hive. The Heddon hive is not a storifying hive. In the old days of storifying, hives were not divided into surplus and brood apartments. The most prominent distinctive feature of the Heddon hive is a *divisible* brood-chamber, *not two* brood-chambers piled one above the other. Mr. Heddon also objected to the Doctor claiming the wood-zinc honey-board as his. Mr. Heddon said that he invented the slatted break-joint honey-board with a bee-space; he had also made it queen-excluding by tacking strips of zinc upon the strips of wood. Dr. Tinker was the first to devise, or at least the first to publish, the plan of placing these strips of zinc in saw-kerfs cut in the edges of the slats.

The Committee on Exhibits reported as follows, after which the convention adjourned to meet in 1889, at the call of the Executive Committee:

Your committee beg leave to report the following articles on exhibition:

W. D. Soper, of Jackson, Mich.—Honey-crate, foundation, one-piece sections, Clark smoker, gloves and veil.

Geo. Hilton, of Fremont, Mich.—Varieties of honey, one feeder, one smoker, honey-knife, and a picture of his home apiary.

Frank A. Eaton, of Bluffton, O.—Section-case filled with sections.

T. F. Bingham, of Abronia, Mich.—Smokers and honey-knife.

Thomas M. Cobb, of Grand Rapids, Mich.—One divisible, interchangable case for sections.

R. L. Taylor, of Lapeer, Mich.—One bottle of honey-vinegar.

H. D. Burrell, of Bangor, Mich.—One shipping-case protector.

N. L. Higbie, T. M. Cobb, W. D. Soper—*Committee.*

LOCATION.

Where to Locate an Apiary—Florida, etc.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

The question is asked by a subscriber where the best place is to locate an apiary by a person who intends to make it his whole business. I am completely at sea in answering this question. My best place for an apiary undoubtedly is in my own door-yard, where I can look out of my kitchen and sitting-room windows during swarming time, and be easy of access at all times. Another thing greatly in my favor is, that I can sell my honey at home, and have not to ship it off to a distant city, to lie in a commission house to granulate, and accumulate dust, and wait weary months before I can hear the jingle of the clean cash.

Many bee-keepers in the North and West were disgusted by losing so many bees during our late, severe winters, and sold their homes and hied themselves off to Florida. One wrote back to the BEE JOURNAL, of the many difficulties he encountered in reaching this land of promise; how he had to wade in the water and push a boat before him containing his bees, but wound up by saying, "I never mind this, for I am in Florida." He was located in the wilderness below Tampa; was determined to get where his bees would not freeze to death. His bees did not die, but his wife died, and, with his little children crying around him, he frantically advertised his bees for sale. Who would want to buy, with no market for honey, provided there was any to sell?

A bee-keeper, formerly of the North, but now located in Florida, said at the late convention at Columbus, O.: "I would rather keep bees in the North than in Florida; but I like the climate, my home is there, and I am going to stay." He is one of those who emigrated because his bees died in winter.

A customer lately said to the writer: "I was down in Florida last April; went up the St. John's and down in the Indian river country. So many flowers, and a shower nearly every day; everything sparkling with drops of water. But I tell you Mrs. Harrison, God never made a better State than Illinois." I fully endorse this sentiment; He may be able to make a better one, but He never has.

There are many views to be taken of this question. If boney only is the object sought, then locate where most of it is to be had. If a good market for honey is desirable, then locate where there is less honey, but a good market for it. I know a bee-keeper who lives about twenty miles from me, who gets a great deal more honey per colony than I do, but I would not pay the price for it that he does if I never had a pound. He lives in the Illinois river bottom, with overflowed lands in close proximity, where the fog is thick enough to cut with a knife, and people have the "shakes." True, his bees have abundant pasture; there are thousands of acres of button-wood, with water up to the chin, and no fear of drouth. The wet, uncultivated lands abound in motherwort, Spanish-needles and golden-rod, *ad infinitum*.

Peoria, Ills.

HONEY-BOARDS.

Their History, Uses and Adaptability Considered.

Written for the American Bee Journal

BY JAMES HEDDON.

Honey-boards are getting to be quite popular, as well as some other things I might mention, over which I have been drawn into considerable controversy while trying to uphold and introduce among my brother bee-keepers. When a bee-keeper invents something that is good, tests it until he knows it to be so, there is an internal enthusiasm, that knows no self-interest and no bounds, which impels him to write about it for the benefit of others, simply because it is a fact. There is some splendid things about the human mind, which grows enthusiastic over truth *vs.* error, and it is good that the world is possessed of that beneficent principle.

It may be of interest to the readers of the AMERICAN BEE JOURNAL to hear something about the history of honey-boards. I will not attempt to exhaust the subject, for I do not know all of the experiments and uses that others have made with honey-boards, but I do know something of my own struggles in inventing and popularizing their use.

Older bee-keepers will remember that Father Langstroth made and introduced with his excellent hive, a rack, frame or board, whichever we may choose to call it, which was placed intermediately between the surplus receptacles and the brood-chamber. This was a $\frac{7}{8}$-inch board with three slots running crosswise, and consequently crosswise of the brood-chamber and frames below. Upon this board, surplus receptacles were placed, having slots which were made to range with the slots of the honey-board, making a passage for bees, keeping the bottoms of the receptacles clean, and facilitating the operation of getting the boxes on and off—a very important aid in the days when we had no smokers and less knowledge of how to handle bees.

From this board I began my operations, which resulted in the break-joint, bee-space honey-board, which has now become so popular the world over. I got my first idea of a bee-space in the honey-board, from a desire to use a honey-board which would maintain perfect bee-spaces, everywhere, and leave a perfect bee-space between the surplus receptacles and the brood-chamber, when it was not in use. Of course no honey-board could do this, unless it contained a bee-space in one of its surfaces. Very soon after constructing and testing, to my great satisfaction, the bee-space principle of the honey-board, I struck upon the plan of having many openings, creating the general surface of the board of slats, and having these slats and the spaces between them so arranged that the slats and spaces exactly break joints with the top-bars (and spaces between them) of the brood-frames below; which, while it gives a perfectly free communication to the hive, making a passage for the bees from below to the surplus receptacles above, at the same time it breaks the *direct* communication, almost wholly preventing the building of brace-combs between the top surface of the honey-board and the bottom of the surplus honey receptacles above.

While it has a tendency to lessen the amount of brace-combs which will be built in the bee-space between the top-bars of the brood-frames below and the lower surface of the honey-board, yet it does not entirely prevent the brace-comb building there; but this does not matter much, as we do not remove the honey-board anywhere near as frequently as we do the surplus receptacles which rest upon the honey-board. So now we can work the tiering-up process with surplus receptacles, without the annoyance of brace-combs.

By the way, I might say, right here, that though I was not the first to practice the tiering of surplus receptacles, yet nearly twenty years ago I did discover its worth as a system, and had many tilts through the bee-periodicals while defending the same. Now it is a popular method, and nearly all the great and successful honey-producers of the day use it.

If I remember correctly, our friend A. I. Root opposed me considerably, greatly fearing that any kind of a honey-board would retard the work of the bees and greatly lessen the surplus honey crop; but I did the best I could in its defense, after I had proven the correctness of my ground, and with the aid of the ever-living principle that,

> "Truth will conquer at the last,
> For round and round we run,
> And ever the right comes uppermost,
> And ever is justice done."

A little study will soon convince the practical hive-maker that no honey-board of any value can be made, that does not contain either one or both, the bee-space and break-joint principles. If a honey-board is made without the bee-space principle, the material in it must be thick; and the thicker the slats which form the general surface of the hive, the more apt are the bees to build brace-combs between their edges, and the heavier, more bungling and expensive is the honey-board. It must be thicker, in order to have any solidity, but where the bee-space is used, the space is formed by the thick outer rim which gives the honey-board its solidity.

Then again, the only way the tiering process can be worked with the surplus receptacles over a honey-board, without a bee-space, is by putting the bee-spaces in the supers, at the bottom, rather than the top, which is very objectionable, for reasons too numerous to mention here. There are few bee-keepers but that have discovered their mistake, if they ever put the bee-space at the bottom.

This break-joint principle also tends to keep the queen below, and I will say that there is so little trouble from queens getting into the surplus receptacles, when these honey-boards are used, and comb-honey is the production, that it is hardly worth while to make them queen-excluding. But for the production of extracted honey, it is well to have them so, and there are many conveniences, even in comb-honey production, in having the boards queen-excluding; consequently for the last four years we have used all of ours, that way.

The best method of making them queen-excluding, is to run a narrow saw-kerf into the edges of the slats,

and as the honey-board is put together, slide in a narrow piece of zinc containing one row of queen-excluding bee-passages. This device can hardly be called an invention, and was thought of by four different bee-keepers all independent of the others. I may mention W. Z. Hutchinson, of Flint, Mich., Chas. E. Boyer, of Anger, O., Dr. G. L. Tinker, of New Philadelphia, O., and myself. This took place some three years ago, and quite a little controversy arose regarding the priority. No one, perhaps, will ever know who was prior, but Dr. G. L. Tinker was the first to publish and give his right in the device to the public (see page 203 of *Gleanings* for 1886).

While Father Langstroth was my honored guest, last spring, I perfected a new invention for queen-excluding honey-boards, which greatly pleased him. It was tested, and proves to make a very excellent arrangement; although, perhaps, it is not much better than the combined wood and zinc board. It consists of an all-metal honey-board containing the same rows of queen-excluding bee-passages, placed on the break-joint principle, the same as the other honey-board. For my eight frame hive, eight rows of openings are made, and in such position that they come directly over the center of the top-bars of the brood-frames below. The whole honey-board is a quarter of an inch shorter and narrower than the wood honey-board. This contraction in the dimensions, prevents all bother from corners of the supers slipping down in. Now this is a complete honey-board, the very best in the world, for the avoidance of the brace-combs, both owing to its composition and thinness of surface, but it has the objection of being liable to bag in the center, or "sag," as some say. To avoid this, two **A** or **V**-shaped pieces of heavy tin are soldered to the under side of the board (when in its normal position); and although they are so large that they come down as much as $\frac{3}{8}$ of an inch, still they will not touch the tops of the brood-frames, because each stiffener (as we will call them) points to the center of a space between the brood-frames, so that the bees pass all around them freely. This makes a complete board.

There is no absolute necessity for these stiffeners, but the bee-keeper needs to learn how to manipulate the all-metal honey-board. He should not pry it loose and then lift directly up on the corners, but after loosening the propolis about the edge, give it a lateral twist and it cuts the brace-combs and twists them in two.

At the recent Michigan Bee-Keepers' convention held at Jackson, the question came up as to whether eight rows of queen-excluding holes were sufficient for the passage of the workers of the strongest colonies of bees. I gave not only my experience from the use of over 500 of these honey-boards for several years, but a Mr. Wood, living near Jackson (who by the way has been a large experimenter), gave additional evidence, which convinced the whole convention that even one-quarter of the passage room so afforded by the eight central rows of queen-excluding holes, would be more than ample for the strongest colonies. Great and expensive mistakes have been made regarding this point.

I think I have been pretty nearly over the ground, and having mentioned the State Convention, I take pleasure in reporting an enjoyable meeting, considering that it was quite poorly attended; but few of the well-known and prominent bee-keepers of the State being present. Prof. Cook was ill, and so we had to do without him, although we much regretted it. R. L. Taylor, of Lapeer, was there, and we were pleased to learn that he recently has been elected to the State Senate, while his brother was elected as Representative in the Lower House. So we see that bee-keepers are not without skill and reputation in other channels of thought.

Dowagiac, Mich.

COLORS AND BEES.

Are Bees Attracted by Colors or Odors?

Written for the American Bee Journal

BY A. C. TYRREL.

Whether or not bees are "attracted by color of flowers," is, no doubt, a matter of supreme indifference to the majority of bee-keepers; and if the question were asked as to the number of a bee's legs, some would say four, others six, or *Ich weis nicht*. All are agreed, however, that bees "get there all the same," whether attracted by scent or color, and that is sufficient for their purpose, when the hives are being rapidly filled with honey.

In a scientific point of view, it may be interesting to glean *all* the facts concerning the habits of the busy little workers, and if it is finally determined by scientific research, that flowers of a particular hue are most attractive, those who "plant for honey alone" will be enabled to select the best varieties. In this connection alone, as I view the subject matter, can the final determination of the question be of the slightest importance to the fraternity.

I agree with Prof. Pammel in this, "That odor is important in attracting insects." I also coincide with the statements based upon experiments made by Sir John Lubbock and Hermann Muller, that "bees possess an acute color-sense, readily distinguishing such colors as blue, green, orange, red, white and yellow."

As the question is chameleon hued, I can argue both sides, for I believe that bees are attracted by "scent," and "color" also.

During the term of bloom of a certain honey-plant that I raise, our bees are constantly hovering over them, attracted, no doubt, by both "scent and color." When I thresh out the seeds in the fall, bees are constantly alighting on the dry stalks in such numbers as to be annoying at times.

My usual threshing-floor is on the roof of a hen-house 8 or 10 feet from the ground. As they cannot expect to extract honey from the old, dry stalks, it seems they are attracted by the odor, which is very pungent and lasting. I am never interviewed when gathering and threshing "turnip seed."

It cannot be said that bees are attracted to *me*, by reason of my elegant (?) form, being nearly six feet one way, lean as a fish-pole, and homely as——.

Madison, Nebr.

MANIPULATION.

A New System for the Management of Bees.

Written for the Michigan Convention

BY DR. G. L. TINKER.

It may be stated as a rule, that a colony of bees dividing up its forces by swarming, will not produce as large a surplus as a colony under the same conditions that does not swarm. In a honey-flow extending over most of the season, the rule may be an exception, but it is a rare thing to occur. In view of these facts, bee-keepers have long sought a means to prevent swarming, or in lieu of that, a non-swarming strain of bees. As it has been the instinct of bees to swarm through all the ages, and since it is the only natural means of increase, it is plain that we may not suppress it; and especially when producing comb honey. We may create artificial conditions, as in the taking away of queens, or of the stores as fast as brought in, and prevent it for a time, but we shall never be able to prevent swarming where natural conditions exist.

The best we can do is to deal with the results of swarming. And I may here say, that we can do this to advantage, and bring about results exceeding anything accomplished in times past.

We are entering upon the way of a more profitable and enjoyable apiculture, as in many things in these days we are marching with giant strides into realms of knowledge more wonderful than the most vivid imagination has even dared to contemplate. A single honey-bee is a helpless thing, but a colony of them has power and utility in proportion to its numbers. Who shall say, then, that it may not be guided to greater results and unheard-of wonders? And this we think, no less than we do, that the most useful and yet abundant, the strongest and yet the lightest metal in all the earth, by the skill of man, is to come forth from the elements and give to the world a new civilization, unthought of possibilities and apparently impossible achievements!

For years I have noted the remarkable impulse with which a young swarm begins its labors, and I have thought that we should take heed and make the most of this impulse to rush matters, and pile up a surplus. But it is clear that the impulse can only be developed through swarming. Hence, it will not be a surprise, if the time is at hand when practical bee-keepers shall cease to look for means to prevent swarming, or a non-swarming strain of bees.

The new system of management that I have devised and perfected, and which I shall claim the honor of introducing to my fellow bee-keepers as a practical procedure, is founded upon the above views, and an experimental trial of three years.

The ordinary management is pursued up to the time of swarming, which consists in getting all the colonies as strong as possible, and ready for the expected honey-flow. A supply of extra brood-chambers are made ready with empty combs or frames half-filled with good foundation, or a part of each. No wiring of frames is done. As soon as a swarm issues, it is hived in one of the prepared brood-chambers on the old stand.

The parent colony is set to one side, and the supers taken off and placed on the prepared hive, and the transfer is usually made while the swarm is in the air. A wood-and-zinc queen-excluding honey-board is placed on the brood-chamber, and the supers over it. And here I will say, that the success of this management is largely dependent upon the perfect working of this honey-board, and its adaptation to large colonies. This matter is so important that it may be wise to indicate certain points in its construction, essential to success, lest any shall test the new system and pronounce it a failure from having made use of an imperfect and unsuitable honey-board:

1. The zinc strips should have two rows of perforations, and be set parallel to, and alternate with, the brood-frames.

2. The wood slats must be plump $\frac{1}{4}$ of an inch wide if the brood-frames are spaced more than $1\frac{3}{8}$ inches from center to center; and the wood should come so close to the perforations that the bees may get a ready foot-hold upon it, and thereby be enabled to pass through the board instantly.

Having hived the bees and transferred the supers, I then shake the bees from the combs of the parent colony, down in front of the new one; but this part of the work may be delayed to any convenient time within 24 hours. Thus all the bees that were in the hive before swarming, are kept together, the brood alone being taken away. A colony so managed acts and works like any young swarm, and as all are large, if plenty of surplus room is given, the product will be correspondingly great.

The brood taken away is placed in another brood-chamber, and put over any colony capable of taking care of it. The added brood is placed over a queen-excluding honey-board, and if supers are on the hive, they are to be carried to the top. With the issue of a swarm, every colony in the apiary is so managed, whether it has one or more added brood-chambers. If all the colonies swarm, the result will be an increase of one or more brood-chambers on every hive.

Extracting may be done from the added brood-chambers as soon as the brood is sealed, or about the ninth day; or the combs may be left in place till all the brood hatches. If extracting is not desired, the combs may be storified on as few colonies as possible, and kept till fall and the making up of the colonies for winter, when as many combs of sealed honey may be used as is necessary to winter the bees.

In preparing for winter, the combs not required should be taken from the bees, or at any time from Oct. 1 to Oct. 15, and placed in the brood-chambers and piled up out-of-doors, and there left all winter. By this means all extra combs can be kept safe from the moth-larvæ from year to year, the only other care being to keep out the mice.

This management requires a different sized brood-chamber than has heretofore been used. I also dispense with the use of "dummies" or other means of contraction. A brood-chamber for brood is all that is required, as we want all, or pretty much all, the storage done in the supers. Such a brood-chamber will contain only 830 square inches of brood-comb, and is large enough for any queen where this management is practiced.

The size of the brood-frame is 7x17 inches, and eight are used in each brood-chamber. It is a plain, suspended Langstroth frame suited to rapid handling; and, it may be added, that no brood-frame ever invented, or likely to be, can be handled as rapidly as a shallow Langstroth frame.

This management results in getting all brood-combs attached to the bottom-bars of the frames. If the combs are old, the lower edge should be shaved off, when, if placed in supers, as here advised, all will be extended to, and attached to, the bottom-bars. Another result is, that in all large colonies built up by this system, the bees build no brace-combs between the brood-chamber and the honey-board, or other parts of the hive, so that it is always easy to take the hives apart.

Management of the Queen-Cells.

It remains to give the management of queen-cells and queens by this system. After shaking the bees from the combs, as stated, if queen-cells are not wanted, they are to be removed. If I wish to hatch them, I proceed as directed, taking care not to injure them. The bees of the colony to which they are given, will complete the cells and care for them. I have yet to find one torn down, whether in swarming time or out. Nor does the presence of the cells incite to swarming, as the queen is unaware of their presence. On the seventh day after, the cells should be cut and hatched in nursery cages.

If I wish to supersede the queen in the lower part of the hive, I leave one of the cells to hatch, and do not disturb the hive (unless they swarm) till about the eleventh day. I then go to the hive, and I will nearly always find the young queen on the honey-board, trying to get below. I place her below, and the work is done, as she will at once destroy the old one.

Usually the young queen destroys all of the cells in the super in three or four days. All goes well while a laying queen is in the lower brood-chamber, until the young queen gets ready to mate, when she is balled and killed by the bees. But if provision is made for her to fly out from the upper part of the hive, it occasionally happens that she is allowed to do so, when the bees will destroy the old queen below. If the queens are kept apart, so that they cannot touch each other, it appears that we may have two or more laying queens in a hive at one and the same time; but I think that the bees attending each queen must have a separate entrance.

As to the drones that hatch from brood placed in the supers, I draw back the cover a little, or raise it up to

let them out. If this is not done, we shall find in a short time only the round shells of their thorax, like so many beads, on the honey-board.

I may say of this system, that I have been able to get more honey in sections by it than by any other plan of management, while the honey stored in the extra brood-chambers has appeared as so much gain over the other plans adopted. I believe the system to be not only perfectly feasible, but more easily executed than any other; the hive must be constructed to storify, so that the section supers (which should be identical with the brood-chambers) can be built up in any way desired.

I shall respectfully ask the bee-keepers to give the new system a trial, believing that no other is capable of affording so large results.

New Philadelphia, O.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Jan. 15.—Vermont State, at Middlebury, Vt. Marcia A. Douglas, Sec., Shoreham, Vt.

Jan. 15, 16.—N. W. Ill. & S. W. Wis., at Rockford, Ills. D. A. Fuller, Sec., Cherry Valley, Ills.

Jan. 16.—Indiana State, at Indianapolis, Ind. Geo. C. Thompson, Sec., Southport, Ind.

Jan. 30, 31.—N.E.O.-N.Pa.& W. N.Y., at Franklin, Pa. C. H. Coon, Sec., New Lyme, Ohio.

May 4.—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Hurford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

To New Yorkers—The Union.—G. H. Ashby, Albion, N. Y., on Dec. 28, 1888, writes:

In looking over the list of members of the Bee-Keepers' Union, I find but few from New York State. The Union has a large suit pending in this State, and more should take an interest in it; for they know not who will want protection next. Now, bee-keepers of New York, please "chip in," and place the "Empire State" in her proper place in the Union, and not allow our industry to be protected at the expense of other States. *State pride*, if nothing more, should place us in the lead in the list of members.

Learning by Experiments.—H. Heidenescher, Jr., Landeck, O., on Dec. 27, 1888, says:

It would be very hard for me to do without the AMERICAN BEE JOURNAL, because I would like to hear from others about the bees. I have 11 colonies of bees in Langstroth hives, and they had a good flight yesterday. I will try to keep on going step by step (slowly but surely) in bee-culture, for it has to be learned mostly by experimenting, and all beginners should do the same.

Healthfulness of Bee-Keeping.—Rev. W. R. Whitney, Altoona, Pa., on Dec. 26, 1888, writes:

I cannot do without the AMERICAN BEE JOURNAL. I like its scientific, moral (I might indeed say, religious) tone. I am a Methodist preacher, and keep a few bees, more for pleasure than profit. For three years I have been in this city—a place not well adapted to bee-keeping—and have been unusually busy in building a new church. Even in the suburbs of a city, I believe the keeping of a limited number of colonies of bees could be made profitable. I wish that professional and business men knew the healthful, pleasurable profit, to both mind and body, to say nothing now of the sweet, health-giving honey that might be had, by keeping a few colonies of bees, and reading the AMERICAN BEE JOURNAL.

Bees Roaring in Cold Weather.—T. A. Anderson, Loutre Island, Mo., asks this question, dated Dec. 31, 1888:

Is Mr. Demaree satisfied as to bees roaring in cold weather? I hope that he tested the matter thoroughly last winter.

Good Prospects for the Next Season.—E. Henkle, Washington, O., on Dec. 26, 1888, writes:

I have been going backwards for the last two years in bee-keeping. I began the winter of 1887-88 with 36 colonies, and last spring I had 30. I had 3 swarms, and not a pound of surplus honey. I had to feed 8 or 10 colonies in October, in order to get them in good condition for winter. My bees died more or less all summer, and I now have 24 colonies in good condition, well protected, cushioned and packed, on the summer stands. We have had no white clover here the last two years, but the prospect is good for a bountiful crop next year.

Mild Winter for Bees.—W. Pearson, La Colle, P. Q., on Dec. 26, 1888, says:

We are having a mild winter here so far. I have 175 colonies of bees in the cellar, that are wintering first-rate so far.

Well Pleased with the Pursuit.—B. F. Fritz, Fulton, Mich., on Dec. 27, 1888, writes:

I have had bees for two years, and I am well pleased with the pursuit. I have sold bees and honey enough to get back all the money I invested, and 10 per cent. interest, besides, while invested; and I also have honey left to meet the wants of two families, besides 11 colonies in good condition. I could sell four times my crop of honey in my home market. Careful marketing is the secret. The demand is so great that my merchant has come to the house to get it. The flora of this locality is good, and I am monarch of all of it.

Loss of Young Queens.—A. V. Kouba, Crete, Nebr., on Dec. 26, 1888, says:

The general complaint of bee-keepers is, that the season just past has been a poor one for honey as well as for increase, and only some individual colonies did well in gathering honey. I have secured 860 pounds of comb honey, and 600 pounds of extracted honey, from 22 colonies, spring count. I have also increased my apiary to 43 good colonies, and 5 nuclei. The spring of 1888, in this locality, was cold and rainy, and I had a heavy loss of young queens on their "wedding flight."

In the early part of May, I made up 21 nuclei, and gave each of them a maturing queen-cell; but before the cells had time to hatch out, there came on a cold spell, and result was the loss of 18 queen-cells. I gave them other cells, but this delay brought on an abnormal condition in the nuclei, and they "balled" every young queen on their return from the mating flight. Only three (and they were supplied with hatching brood) came into good condition. I think that the outlook for wintering is good, and I hope to be able to make a better report next year.

Results of the Season.—Mr. J. A. Richenbacher, Gahauna, O., on Dec. 29, 1888, writes:

The past season has been another poor one for honey, hence there was not much gathered in this locality. Most of my bees were weak when spring came, so I united the weak colonies, reducing the 20 colonies to 11. When spring opened, the prospect was for a good season, and bees did well; but when summer came, the bees did not do so well. White clover, which is our main honey source, did not yield much nectar; linden did scarcely as well; but the fall flowers yielded some honey, but they were cut short by an early frost. I got about 26 pounds of comb honey, and about 125 pounds of extracted honey, and increased my apiary to 13 colonies. I held them back from swarming. It will not pay to keep bees in this locality without planting for them.

Bees in Splendid Condition.—Z. T. Hawk, Audubon, Iowa, on Dec. 29, 1888, says:

There has been no zero weather in western Iowa yet, and, so far as I have heard, bees are in splendid condition. I wish the AMERICAN BEE JOURNAL a happy New Year.

No Upward Ventilation.—Lionel Brokaw, Summer Hill, Ills., on Dec. 25, 1888, writes:

Last spring I began with 10 strong colonies and 5 weak ones, increased them to 20 strong colonies, by natural swarming, and obtained 500 pounds of surplus comb honey. It is worth 15 cents per pound here now. I arranged my hives for winter on the summer stands, well filled with bees and honey, with woolen quilts over the frames, and no upward ventilation. The hives are fronting south, with a wind-break on the northeast and west.

Colonies in Good Condition.—A. Sperling, Dewey, Ills., on Dec. 28, 1888, writes:

My report for this year in bee-keeping is not very encouraging. I wintered 42 colonies, lost 6 during the summer, by swarming out (scarcity of nectar being the cause), and made 4 colonies by division. They gathered very little honey until Aug. 20, previous to that date. Most of my bees had not enough honey in the hive to last them 24 hours, and I had to feed some to keep them from starving. Most of the colonies now are in good condition. I obtained 400 pounds of comb, and 100 pounds of extracted fall honey, and left them enough for winter and spring consumption. About one-half, or more, of all the bees in this locality are dead.

Building Straight Combs.—Mr. Daniel E. Robbins, Payson, Ills., on Dec. 31, 1888, writes:

I think that "B. C.," who asks Query 600, on page 837 of the AMERICAN BEE JOURNAL for 1888, either neglected to level his hives across the frames, or put the foundation in so as to rest on the bottom-bar of the frames. In the first case the combs would not hang in the centre of the frames, but would be attached to one edge of the bottom-bar, or even to the next frame; in the other case they would bulge in a most unsatisfactory manner. I find the Dadant light brood-foundation heavy enough with wired frames. I have also succeeded in getting straight combs built in the frames with only starters, or even without them, by proper spacing of the frames, and leveling the hives. Bees usually, however, build too much drone-comb when foundation is not furnished them; yet I think that it is good policy to let them have one or two empty frames to fill, as otherwise I think that the secreted wax goes to waste. Let us hear from the veterans about this matter of comb building.

Wintering in the Cellar.—C. D. Barber, Stockton, N. Y., on Dec. 24, 1888, says:

It is with pleasure that I enclose $1.00 as my dues to the Union. My bees are in the cellar, where I put them on Nov. 17. They worked very fast here up to Nov. 15, which was the last day that they could work. I put 11 colonies into the cellar for the winter; but one colony will not winter, as it has the diarrhea, and its bees are dying fast.

Beginning in Bee-Keeping.—J. H. Scherer, Lena, Ills., on Dec. 28, 1888, says:

In 1886 I caught 2 swarms of bees, and that is the way I begun bee-keeping. I did not know anything about the business, but I packed them in chaff for the winter. In 1887 I increased them to 8 colonies, and took 200 pounds of honey in 2-pound sections. By the spring of 1888 I had lost all but 4 colonies, and those I have increased to 12, and obtained 300 pounds of honey in 2 pound sections. The last two were bad years for beginners in bee-keeping. I could not get along without the AMERICAN BEE JOURNAL. I like it better every week.

New Bee-House, etc.—C.H. Brader, Sperry, Iowa, on Dec. 25, 1888, writes:

I mentioned the misfortune that I had last March, in the burning of my bee-house (which greatly darkened my home and this vicinity, as published on page 200 of the AMERICAN BEE JOURNAL for 1888); but Providence has again permitted me to view a new bee-house in my apiary. It has both delighted and suprised me and my neighbors to see that I had the courage and spent the labor and time to forward this work again after so much obscurity. My new bee-house is a little frame one, 16x24 feet, and 12 feet high. It exceeds by far the old one in size, value and appearance, with drop-siding placed to the weather, and lined with ship-lap, in order to hold the 4 inches of sawdust placed between the lining and drop-siding. I purchased 13 colonies of black bees in box-hives, and transferred them into eight-frame Langstroth hives about June 1, 1888, and increased the number to 24, which I placed in my bee-cellar on Dec. 20. My yield was about 250 pounds of comb honey, worth about 15 cents a pound, and about 80 pounds of extracted honey, worth 10 cents a pound.

The year of 1888 was one of abundant harvest to the farmers of eastern Iowa. They had very favorable weather, and were nourished with sufficient rains in the growing parts of the year. The value of the past two months cannot be estimated in the way of people preparing themselves for winter quarters. We had warm weather, and hard, dry roads until Christmas eve, when we had a transient shower, and the next morning the mercury was at freezing; toward noon it raised to 40°, and as Christmas night came on it again commenced to rain, and now shows a continuance of rains.

Bee-Hawk.—Dr. Wm. Leers, Sigel, Ills., on Dec. 29, 1888, writes:

On page 839, Mr. W. H. Shaner says that a neighbor told him that "he saw one of the big Italians catch a black bee and fly away with it." That is certainly a big mistake. He doubtless confounded a "bee-hawk" (*Asilus*) with an Italian bee. The former were, in the past season, very troublesome. Every day I caught, immediately in front of the apiary, from 40 to 50 (and sometimes more) with a net of mosquito-gauze.

[Certainly. Mr. Shaner mentioned the matter just to show the ignorance of his neighbor, who also proposed to spread a net and catch a lot of Mr. Shaner's bees, as they crossed the line into his clover field! He did not know the difference between an Italian bee and its dreaded enemy, [the *Asilus Missouriensis*.—ED.]

Prickly Ash as a Honey-Producer.—D. D. Johnson, Summit Mills, Pa., on Dec. 15, 1888, writes:

Are any of the readers of the BEE JOURNAL acquainted with a small tree as a honey-producer, called by some "prickly ash?" I have a few of them, and I have never seen as many bees on so small a tree at one time, at work, as on this tree. It blooms in September, and lasts about one month. The bees work on it from morning until night. It is a great tree to sprout; the buds and twigs of the summer's growth are about ⅛ to ¼ of an inch in diameter. The bunch on which the blossoms are, is about 12 to 15 inches long, and full of smaller branches growing from that one, on which the small flowers are by the hundred. The whole tree is full of sharp thorns. It blooms the third and fourth year after planting, and grows readily. If any bee-keeper is acquainted with the quality of honey that it produces, it might benefit others if he would answer, as my trees are too few yet to test that, but I am planting more. They grow on any rough ground.

[Prickly ash (*Xanthoxylon fraxineum*) has been reported as a good honey-producer in Texas, Kentucky, etc. It blooms in July and August, and as that is between the summer and fall honey harvests, it is of value to the bees. The honey is said to be of good quality.—ED.]

Button-Ball Honey, etc.—S. A. Shuck, Liverpool, Ills., on Dec. 31, 1888, writes:

I have been some 60 miles down the Illinois river, and I find that all along the river bottom bees have done fairly well, where they have received proper attention. The honey is mostly from the button-ball. This honey is very fine. The combs are beautifully white, the nectar clear, and the flavor mild and pleasant. Mr. Wm. Markly, near Marble Town, Ills., obtained 1,800 pounds of comb honey from about 80 colonies of bees. At Snicarte, some thirty miles south of here, a groceryman told me that honey was worth from 6 to 10 cents per pound. This results from bee-keepers not taking and reading the AMERICAN BEE JOURNAL. Mr. Wm. Riley, of Breeds, Ills., obtained 3,000 pounds of honey. Mr. R. is probably the most extensive bee-keeper in this county. His apiaries number 140 colonies, mostly hybrid bees. The weather so far has been exceptionally fine, the Illinois river, a very sluggish stream, having but little ice along its shores. My 135 colonies of bees are tucked away in the cellar. In consequence of the fine weather, the temperature in the bee-cellar is at 50°, with the inside door wide open day and night. I obtained 4,500 pounds of honey, all of it being from the button-ball; of this, 1,600 pounds was taken in the comb.

Wintering Well.—Mr. C. V. Lindsey Attica, N. Y., on Dec. 27, 1888, says:

My 150 colonies of bees had a good flight yesterday, and are wintering well on the summer stands; but I fear that some are short of stores. Our pursuit does not pay, but I must still read up with the times, or fail.

Fears Early Breeding.—C. E. Woodward, Newbury, O., on Dec. 31, 1888, writes:

We have had some very changeable weather this winter—a great fluctuation in the temperature. There has been no snow to speak of yet, and bees have just had a nice flight. In this locality they are wintering nicely, and have consumed from 6 to 8 pounds of their winter stores. I am inclined to think that our bees will begin breeding, if the temperature does not become colder. If they do begin breeding too early, and on too large a scale, the results will be disastrous.

Bee-Keeping in Pennsylvania.—Geo. Spitler, Mosiertown, Pa., on Dec. 26, 1888, writes:

Here in northwestern Pennsylvania, like almost all the rest of our brother bee-keepers the world over, did not meet with much success in securing surplus honey. Bees came through to the spring of 1888 in good condition, though there were a few heavy losses in wintering. The first of the spring was very promising; maple bloomed profusely, and yielded much nectar, especially the hard maple, bees even storing some for future use, which was sorely needed; for not in years was May weather so rough on the bees. The colonies did not seem to be as strong the last of May as they were in the forepart. White clover yielded just honey enough to stimulate brood-rearing, which was done rapidly. Basswood yielded no honey, excepting those trees which stood in very moist ground; which proves that the drouth of the past two, or in fact three, years did the damage. Alsike clover yielded some honey, but there is not enough of it sown, or at least not to do much good. Last spring there was quite a large area sown to Alsike clover. Fall flowers yielded enough, so that almost all colonies stored sufficient on which to winter. Golden-rod yielded more honey the past fall than it had done in years. I got but 400 pounds of honey from 30 colonies, spring count. There were but few swarms.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for $1.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40
Bee-Keepers' Guide	1 50	1 40
Bee-Keepers' Review	1 50	1 40
The Apiculturist	1 75	1 65
Canadian Bee Journal	2 00	1 80
Canadian Honey Producer	1 40	1 30
The 8 above-named papers	5 65	5 00
and Cook's Manual (**old edition**)	2 25	2 00

Convention Hand-Book	1 50	1 30
Weekly Inter-Ocean	2 00	1 75
How to Propagate Fruit	1 50	1 25
History of National Society	1 50	1 25

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2 00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. Price 60 cents, postpaid. Subscription for one year and the binder for $1.50.

Money in Potatoes, by Mr. Joseph Greiner. Price, 40 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for $1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for $1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and $3.00.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

Convention Notices.

☞ The annual convention of the Vermont State Bee-Keepers' Association will be held in the Court House at Middlebury, Vt., on Tuesday, Jan. 15, 1889.
MARCIA A. DOUGLAS, *Sec.*

☞ The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in the Supervisors Room of the Court House at Rockford, Ills., on Jan. 15 and 16, 1889. D. A. FULLER, *Sec.*

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its tenth annual convention in the City Hall at Franklin, Pa., on Wednesday and Thursday, Jan. 30 and 31, 1889. Good hotel accommodations have been secured at one dollar per day.
C. H. COON, *Sec.*

☞ The annual meeting of the Indiana State Bee-Keepers' Society will be held in the Agricultural Rooms in the State House at Indianapolis, Ind., beginning at 10 a.m. on Jan. 16, 1889. Reduced railroad rates can be secured by purchasing a through ticket to Indianapolis, taking the agent's receipt for the same, and having it countersigned by the Secretary of the Bee-Keepers' Society.
GEO. C. THOMPSON, *Sec.*

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Do Not Forget to send a dollar for a membership fee to the National Bee-Keepers' Union for 1889. It merits your approval, and needs your assistance.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. It can be obtained at this office.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 16@17c.; 2-lbs., 13@14c. Fair white 1-lbs., 14@15c.; 2-lbs., 11 to 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10c. White extracted, 8@9c.; buckwheat, 6@6½c. which is in good demand. Market quiet on comb honey. We expect an increased demand after the holidays. Now is the time to ship honey.
BEESWAX.—22½@24c.
HILDRETH BROS. & SEGELKEN,
Dec. 22. 28 & 30 W. Broadway, near Duane St.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@12½c.—Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.
BEESWAX.—22c.
Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c. for best 1-lbs.; very fancy lots have sold at 20c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.
BEESWAX.—22c. R. A. BURNETT,
Nov. 22. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15@16c.; fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.
BEESWAX.—22@23c.
Oct. 25. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5½@5¾c. For comb honey the demand is light; for extracted it is good, and market firm.
BEESWAX.—Dull at 18@22c.
Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but equal to the demand.
BEESWAX.—22@23c.
Dec. 12. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12½@16c. Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Dec. 17. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½. California white in 60-lb. cans, 8c.; light amber in same cans, 7¾c.; amber, 7¼c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 65c. per gallon.
Sep. 26. F. G. STROHMEYER & CO., 122 Water St.

BOSTON

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The sales are good, and indications are that all the honey in the country will be sold by Feb. 1.
Dec. 27. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lbs., 16@17c.; fair, 14@15c.; California white 2-lbs., 14@15c.; amber 2-lbs., 12@13c.—Extracted, white California, 7½c.; amber, 7c.
BEESWAX.—None in the market.
Dec. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEESWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lbs., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.
BEESWAX.—20@21c.
Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

One Day Later.—Heretofore we have closed the forms of the BEE JOURNAL on Saturday, and the printing was commenced on Monday morning. This arrangement often excluded news and announcements of importance which came to hand on Monday, two days later. To prevent this, in the future, we shall keep the forms of type open Monday forenoon; the press will then be started, and the folding, stitching, trimming and mailing will all be completed by Wednesday at 5 p.m., when the JOURNAL will be put into the post-office—*just one day later than usual.* We give this notice to prevent disappointment to those who have been getting their copies on a particular train and day—look for it 24 hours later, and you will not be disappointed. This gives us the advantage of *two days*, while the mailing is delayed only 24 hours.

When you send us your subscription for 1889, please send the subscriptions of your neighboring bee-keepers, and to pay you for your trouble, we will send you, as a premium, anything you select from our Catalogue to the value of 25 cents on each dollar subscription sent.

Let Every One who believes in defending "our pursuit" against the attacks of the misguided and preverse, join the National Bee-Keepers' Union, by sending a dollar to this office. It only costs a dollar a year, and every bee-keeper should be a member.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Jan. 19, 1889. No. 3.

EDITORIAL BUZZINGS.

Dr. C. C. Miller has just returned from Colorada, whither he went to attend the funeral of a brother-in-law. Death seems to have been quite busy in the Doctor's family lately. We are glad to know that he has returned in safety.

Mr. J. Y. Detwiler has returned to New Smyrna, Fla., and on New Year's Day he gathered a bouquet of sweet-scented flowers, and sent them to this office—for which he has our thanks.

Hon. R. L. Taylor, a well-known apiarist of Michigan, has been elected to the State Senate. That body has gained in him another able, conscientious and practical member—one that will be an honor to it and to the State.

The Weather, says Prof. Cook, in a letter, on Jan. 5, is "delightful for winter—regular Spring weather." And so it is in Illinois as well as Michigan. In fact both Europe and America report the same mild winter weather. We do not remember the like as far as our memory can reach. The bees have sported in the sun almost daily.

"Langstroth on the Hive and Honey-Bee, revised, enlarged and completed by Chas. Dadant & Son," is the title of a new book just placed upon our desk by the publishers. It contains 535 pages, 16 full page plates, and 197 illustrations. It is excellently printed on good paper, and substantially bound in cloth.

As the matter for the BEE JOURNAL was all prepared before it came, we must defer a review until our next issue.

The price is $2.00, and it may be obtained at this office.

The Election of officers for the National Bee-Keepers' Union, just held, resulted in the re-election of the old Board, as will be seen by the following, which gives the vote in detail:

FOR PRESIDENT.—James Heddon 95, G. M. Doolittle 6, Dr. C. C. Miller 5, Prof. A. J. Cook 3, A. I. Root 2, Single Votes 6, Blank 8.

FOR VICE PRESIDENTS.—Prof. A. J. Cook 108, A. I. Root, 106, Dr. C. C. Miller, 105, G. W. Demaree, 105, G. M. Doolittle 104, James Heddon 11, Ch. Dadant 9, Eugene Secor 5, Scattering 22, Blank 10.

FOR GENERAL MANAGER, SECRETARY AND TREASURER.—Thomas G. Newman 114, G. M. Doolittle 1, Blank 10.

While the General Manager has no desire to continue in office and would welcome a successor, it is very flattering to notice that he received *every vote but one*, and that ballot recorded a vote for him for President instead, and of necessity required another name for Manager.

Now, will the coming year be simply a repetition of former years? Or, will thousands of bee-keepers flock to the standard and unite with their brothers in defense of the pursuit of apiculture?

Robinson, the one whose abuse of Father Langstroth was noticed in an editorial on page 835 of last year, has raised the ire of our friend Henry Alley, of the *Apiculturist*, who writes us as follows:

I read your remarks and comments regarding the abuse of Mr. Langstroth by C. J. Robinson, in an "Eastern publication." As there are no less than three *Eastern* bee-publications, would it not have been better to have named the particular paper to which your remarks have reference? Why leave your readers to guess which of the Eastern "bee-publications" would stoop so low as speak otherwise than respectfully of one held in such high esteem by all good men as is Mr. Langstroth? Have the courage, Brother Newman, to speak out in meeting. Hurl your remarks (the justice of which we all acknowledge) direct at the editor who admitted to his paper such an article as you mention, concerning a man so honest and pure as our friend Langstroth. The paper to which you allude has not been received at our office. If one comes to hand we shall not hesitate to mention the name of it.

A few years since, this same Robinson tried his luck in getting some goods here on the plea that he would give us a "puff" in some of the bee-papers. Just at that time our goods needed no special "puff," as we had more orders than we could fill. Nevertheless we got the "puff" just the same. But the free advertising given us was not calculated or intended to increase the sale of our goods. But it really did help us, as hundreds of bee-keepers well knew that the author was only venting his spleen at our (supposed) expense.

Oh, yes, Bro. Alley! We omitted the name simply to avoid any feeling, hoping that the editor would apologize for the matter—and not because we had not the courage to particularize. Now that the name is called for, we will say that the article appeared in the *Bee-Keepers' Magazine* for November, 1888, page 325. Such attacks cannot injure the reputation of Father Langstroth—but they are contemptably mean, all the same.

Bees and Grapes.—It has been proven over and over again that bees do not puncture sound grapes in order to obtain the juice. It is true that they have often been seen to suck up the juice from such fruit as they find the skin already broken, and uninformed or unthinking persons then jump to to the conclusion that the bees do injure sound grapes. A correspondent in the *Fruit Growers' Journal* gives the following as the result of investigations made through a microscope, of the bee's tongue:

Dr. James McBride and I have just turned away from the study of the bee's tongue through the microscope, perfectly satisfied that the bee cannot penetrate the outer skin, or even the second skin of the grape. This is also the decision of the leading entomologists, and the scientists of the government have so decided. It would be precisely as if a painter should try to bore a hole through an inch plank with an ordinary paint brush, for the point of a bee's tongue is a microscopic brush, which, if pressed on the outer skin, would spread out like the brush of a painter, and refuse the desired entrance. But when the grapes here and there are pierced by other insects or birds, and most of the juice is left to rot in juxtaposition to the sound and unbroken grapes, the contagious rot would go on from grape to grape until the whole bunch would be ruined, were it not for the useful bee, which immediately plunges its brushy tongue into each orifice and extracts the veasty must from the broken hull, and dries up in a short part of a day all the offending matter, and as a scavenger, saves the fruit from inevitable destruction. The bee is too smart to plunge its sting into a grape, and it is only to save or prolong life that it stings a mortal.

Prohibitory Tax.—The *British Bee Journal* for Dec. 20, quotes the following item from the "St. James' Gazette:"

So extensive has the adulteration of honey with glucose become in America, that, efforts are being made to obtain Federal legislation, after the pattern of the oleomargarine law, to prevent it, by levying a prohibitory tax on spurious honey. No doubt the demand for American honey in foreign countries has been greatly diminished by the sophisticated character of the stuff exported in recent years, which is more like refined molasses than the delicate produce of the bee.

It then adds: "We congratulate our Transatlantic brethren on this step in advance, and sincerely hope that success may attend their efforts.

"Oh, thanks awfully," Brother Cowan, but there is no truth in the item from the *Gazette!* The adulteration of honey with glucose is a thing of the past. The price of liquid honey is so low that it would not pay. We say most emphatically that no steps have been taken "to obtain Federal legislation after the pattern of the oleomargarine law" *or any other pattern*, "to prevent it, by levying prohibitory tax on the spurious article!"

Such a tax would avail nothing—it does not prevent the manufacture or sale of oleomargarine; that is made in greater quantities to-day than ever before.

Our British cotemporary creates a *false* impression, and it would be only just to Americans for it to correct the same, or else copy our most emphatic contradiction of the assertions of the *St. James' Gazette.*

JANUARY.

"Janus am I, oldest of potentates!
Forward I look and backward and below,
I count—as God of avenue and gates
The years that through my portals come and go.
I block the roads and drift the fields with snow,
I chase the wild-fowl from the frozen fen;
My frosts congeal the rivers in their flow,
My fires light up the hearths and hearts of men."
—*Longfellow.*

GLEANS OF NEWS.

Fined for Adulterating Honey.—We notice in the *Bee-Keepers' Magazine* for December, 1888, just received, that under the New Jersey law against adulteration of food, one man has been fined $50 for selling adulterated honey. We are given no particulars, but presume it was the ordinary glass jar of glucose with a little "floating island" of comb honey in the centre. Here is what the *Magazine* says about it:

It is gratifying to note that G. Volner, of Jersey City, agent of Charles Israel, of New York, was tried before the First District Court of Jersey City, and was convicted of selling adulterated honey, and fined $50. This was accomplished through the efforts of Commissioner Newton, of New Jersey. We hope those who have decried his good work, will please take notice.

This is a wholesome lesson, and one likely to be remembered by the parties who have handled the adulterated honey of F. G. Strohmeyer & Co., McCaul & Hildreth, and others named in the list published some months back in the *Magazine*. We think these "honorable gentlemen" (?) will have a smaller sale of glucose and honey in New Jersey after this. Every bee-keeper should uphold Commissioner Newton in his efforts to overthrow, as far as his jurisdiction permits, the adulteration of honey. Let us all join and condemn them as heartily as we do Prof. Wiley.

We are glad to see the law enforced at least in one State against those who adulterate articles of food, and sell them as genuine, for ill-gotten gain.

Cases are *very few* where it is profitable to adulterate honey (for no one will do it at a loss, just for "the fun of the thing"), and if New York merchants have "aided and abbetted" the New Jersey man, they should suffer with him, and be condemned by all honest and conscientious persons. In this we clasp hands with Bro. Aspinwall, and demand honesty and purity in all kinds of business.

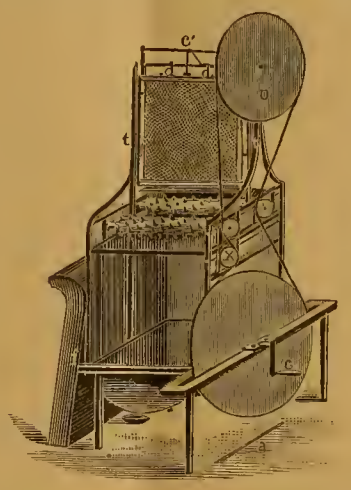
A Cough Remedy.—This is the season when coughs and "colds" are very prevalent, and very disagreeable to have. Many are the remedies recommended, but all are forgotten from one cough or cold to the next time that we may be afflicted. The *Northwestern Agriculturist* suggests the following excellent remedy, which is a simple flax-seed tea, made thus:

Pour over an ounce of whole flax-seed, a pint of boiling water; let the tea stand on the back of the stove for twenty minutes, then strain, and add the juice of three lemons, and honey and loaf-sugar to sweeten.

Muffling the throat is one sure way of courting tenderness and soreness in that region of the body. Honey is highly recommended for all affections of the throat and respiratory organs; and bee keepers should not lack for that simple article of medicine, and recommend it to others.

A New Uncapping Machine.—The *British Bee Journal* has the following concerning this new invention, and thinking that Americans would like to see an engraving as well as description of it, we reproduce the article and illustration:

Since Count Zorzi first introduced an uncapping machine, there have been several others introduced to bee-keepers, but the objection to most of them has been that they were either too expensive, or that they did not work satisfactorily. They have in consequence not come into use, and to become general they must come down in price, like extractors have done. The knife-machines iotended to uncap both sides at one operation, are either noisy, or, unless the knives are kept as sharp as razors, they tear the combs. The first improvement in the right direction was the substitution of a revolving cylinder having projecting points in it something like the cylinder of a barrel-organ. It was introduced by M. Prochask, in 1886, and was illustrated in the *Deutsche Illustrierte Bienenzeitung* of July of that year. The cylinder was vertical, and the comb which was fixed in a frame was pushed past it,much in the same way as the frame is pushed past the knives in Mr. Hooker's patent machine.



M. Peter Wagner, of Kreuzstatten, has just brought out an improvement which, while simplifying the machine, also reduces its cost. It will be seen by referring to the illustration, that the apparatus consists of a square tin can, from which the side *f* is removed to show the interior. The comb to be uncapped is placed into the upright frame, *d d*, which slides up and down the guide-rods, *t t*. The two horizontal cylinders are of wood, and have a number of iron points stuck into them. When revolved at a high speed the cappings of the comb are removed by these points as clean as though they were cut off with a knife. The cylinders can be adjusted for combs of different thicknesses, and the proper speed is obtained by turning the handle c, attached to a disk over which passes a cord. A small wheel, *x*, is placed in the position seen in the illustration, to give the cord a firmer grip of the pulley on the cylinder. The same mechanism that revolves the cylinders is made to lower and raise the frame. The wheel, o, revolves the spindle attached to it, and on this a cord is wound which raises or lowers the frame. The bottom of the can is coned so that the honey can run out and be collected in a vessel placed for its reception. The side, *f*, is movable, and, as will be seen, is turned over at the top in such a way as to cover the cylinders, and prevent splashing of honey.

Preventing Spring Dwindling.—After a mild winter there is generally considerable danger of the bees dwindling in the spring following. The *Bee-Keepers' Guide* for this month gives this caution to the inexperienced:

The mild weather between November and December makes it certain that the winter is to be a short one, and it is helping out the bees which were not in the very best condition. The unfavorable weather during the fall caused an unusual decrease in the brood; and, with a severe, long winter, very serious results might come of it. We should avail ourselves of all the advantage of the weather, and be aware that there are still chances for a change that might be very disastrous to the bees.

If the temperature continues so high during January, the bees are likely to commence brood-rearing, and in this case, if February or March should be cold or favored with a great amount of snow, the greatest care will be necessary to prevent the brood from chilling, and the colonies to finally spring dwindle until all is lost.

If the snow becomes deep around the hives, and there is a prospect for a thaw, shovel it clear away from around the hives. Wet snow chills the brood and bees while dry snow retains the heat of the cluster of bees, and is on this account a benefit.

It will be found profitable to pack colonies with chaff, even in such winters as this, as it keeps the bees quiet, prevents brood-rearing, and holds the snow further away from the hives, so that it will not have so great an effect on the brood-nest when it melts.

If there are any bees still unprotected, we would advise it to be done; do not flatter yourself with the idea that the mildness of the weather makes it unnecessary. The greatest loss of bees we ever knew of, extending over the greatest scope of country, occurred during the March following a mild, open winter; so mild that the bees flew a number of days during February. The low price of honey, and the competition now will not permit of any neglect or any losses by carelessness, if one expects to make any profit out of the business.

Conundrum.—Why is a bee's occupation similar to that of a merchant? Don't they both *sell combs?* Next.

QUERIES AND REPLIES.

Management to Prevent the Building of Drone-Comb.

Written for the American Bee Journal

Query 605.—My bees are in Simplicity hives, with Langstroth frames, being home-made, and do not give entire satisfaction. I intend to get a better quality of frames and transfer the bees. 1. How would it do to place the new hive under the old one, and let the bees build comb naturally? The queen would lay below, and the honey would be placed above. After the brood had all hatched above, and the upper story was filled with honey, I could extract it. 2. Would I get drone-comb built below in this way, or is there a better plan that would disturb the bees less, or cause less loss of time and brood? —Louisiana.

I hardly think that the proposed plan would work well, but a trial of it will tell you.—G. M. DOOLITTLE.

Your plan is an excellent one, though you would have to look out for drone-comb.—WILL M. BARNUM.

1. Your plan would not work in Southern Michigan. 2. I would prefer to crowd, and let them swarm; then you could start with new hives, frames, etc.—H. D. CUTTING.

1. I should not like it. 2. You could count on plenty of drone-comb. It would be better to transfer the good combs, and use foundation for the balance.—C. C. MILLER.

Your plan is one that has many times suggested itself to beginners, but as many times as tried, it has proven a failure. "Modern transferring" is the best plan of all. See bee books and papers.—JAMES HEDDON.

It would do well. Read Mr. Hutchinson's book on how to get comb honey. I should use starters, or full sheets of comb foundation, as I recommend in my book.—A. J. COOK.

Your idea is a good one, only I would modify it so much as to fill the frames of the new hives with foundation. This would be the only sure way to avoid an excess of drone-comb. —J. M. SHUCK.

The Langstroth frame is good enough, if you make it right. Cut the comb out of the "botched" frame, and fasten it in the "well-made" frame with wired sticks, and let the bees keep on at work.—J. P. H. BROWN.

If I tried that plan, I would want to put the queen in the lower hive, and keep her there by a queen-excluder. In that case I think that the bees would build worker-comb; or you can use foundation in the new hive.—EUGENE SECOR.

1. I think that you had better transfer in the early spring; cut out the comb and fasten it in the new frames, and put it directly in the new hives. 2. Probably not; at least only a portion of drone-comb. — MRS. L. HARRISON.

The best way is to cut the combs out of your frames and fit them into the new frames. If the combs are too crooked, or built across the frames so that they cannot be removed separately, I would transfer *a la* Heddon. —P. L. VIALLON.

1. It would probably do; but why not transfer them by the Heddon method? That would certainly be better in every way. 2. You would get plenty of drone-comb below, unless foundation or comb was used.—C. H. DIBBERN.

1. If the colonies are strong, and honey is being gathered in sufficient quantity, and a queen-excluding honey-board is used, your plan might work well. 2. Some drone-comb would be pretty surely built, and it might be mostly drone-comb. By using foundation the building of drone-comb would be prevented.—A. B. MASON.

Your way is too slow. If you do not want to use comb foundation, we would advise you to transfer all the worker-combs that are not too old. Remember that if you give to your queens too much room, the workers will build store, or brood, combs mainly. — DADANT & SON.

1. Use whole sheets of foundation by all means. I have not found the plan stated, to work well with myself. 2. Yes, unless great care and watchfulness is used, and much labor performed in cutting drone-comb out as fast as it is built.—J. E. POND.

I was once in the same fix with 60 colonies. I took them into my honey-room one at a time, removed a comb at a time, and cut the frames, comb and all, to the standard Langstroth dimensions; and having hives at hand properly cut, I transferred them into the new hives, as I made the change in the frames. 1. I think that my plan is preferable to yours. 2. You would get lots of drone-comb.—J. M. HAMBAUGH.

1. It would not do well. 2. Yes, generally. When the colony is strong enough to swarm during the swarming season, drive a swarm from it into the new hive having frames filled with foundation, making sure that the queen is with the swarm. In 21 days shake the bees still in the old hive into another new hive, and you have the old combs clear of bees and brood.— R. L. TAYLOR.

1. The queen would continue to lay above until she had plenty of room below, and until the combs above were full of honey. The plan will not work successfully. 2. You would get too much drone-comb. About swarming time, shake the bees from the combs in the old hives, and let them run into the new, leaving only enough to care for the brood. Have the frames of the new hive filled with foundation, and three weeks after unite the bees in the old with those in the new. Or transfer the combs to the new frames. The latter would be my preference.— M. MAHIN.

1. I do not think that your plan will give satisfaction. I would put a set of frames filled with foundation above the brood-nest, and use them to take a crop of honey with the extractor; and in the fall, after the brood was all out of the combs below, I would exchange the set of combs, putting the new ones in the place of the old ones. 2. Most likely too much of it, besides a waste of time and honey.—G. W. DEMAREE.

Why not let the bees swarm, and then you can give them a new hive filled with comb foundation, and prevent them having too much drone-comb?—THE EDITOR.

Sources from Which Propolis is Gathered.

Written for the American Bee Journal

Query 606.—1. From what flowers do bees gather propolis? 2. Is it packed upon the drum of the legs the same as bee-bread when brought in. Forty years ago, in the wilds of of Wisconsin, when there was nothing but the wild flowers for the bees to work on, the bee-trees that we found were waxed up with it, the same as the hives of to-day. The wild flowers have been gone for years, but the propolis comes in the very same, and looks and tastes just the same as it did in those early days. The bee has nothing to work on now, that it did in those days, but the basswood.—Wisconsin.

1. Many trees furnish propolis. 2. Yes.—H. D. CUTTING.

1. From buds, not flowers. Hickory, horse-chestnut, etc. 2. Yes. There were buds then as now.—A. J. COOK.

1. Here, from a posy called a pine-tree. 2. Yes. Bees gather propolis from resinous weeds, trees, etc.—from many sources.—JAMES HEDDON.

1. Chiefly, I think, from the buds of resinous shrubs and weeds.—EUGENE SECOR.

1. None. They gather it from the leaf-buds of poplar and and other trees. —C. C. MILLER.

Propolis is an exudation from the wood part of the tree or plant, and not from the flower. The pine, balm, gum, various fruit-trees, etc., yield it. —J. P. H. BROWN.

Bees do not gather it from flowers, but from different trees. Propolis is a gum, or an exudation, like rosin.— DADANT & SON.

1. It is gathered from resinous buds, such as the hickory, pine, horse-chestnut, etc. 2. Are you sure that it is

packed upon the legs, the same as bee-bread? If so, this is contrary to the supposition that I have heretofore had. —WILL M. BARNUM.

1. Propolis is not gathered from flowers, but is obtained by the bees from the resinous buds of trees, etc.—P. L. VIALLON.

I am not aware that bees gather propolis from flowers, but I have seen them gathering it from buds.—A. B. MASON.

1. They do not gather it from any kind of flowers, but from the leaf-buds of certain kinds of trees, principally from what is popularly called "cotton-wood." 2. Yes.—M. MAHIN.

From the asters, buds of the hickory, from any plant which secretes a resinous substance, or from a newly-varnished buggy.—MRS. L. HARRISON.

1. I do not know that they get from flowers. 2. I have seen bees gathering it from sumac at the axillæ of the leaf-stalks, and from the buds of the balm-of-Gilead.—R. L. TAYLOR.

1. In this locality, propolis comes largely from the buds of the balm-of-Gilead and poplar. I think that propolis never comes from blossoms. 2. Yes.—G. M. DOOLITTLE.

1. They do not gather it from flowers at all. It is a resinous gum that exudes from various trees. The so-called "balm-of-Gilead" is the great source of propolis in my own locality. —J. E. POND.

This is a subject of which I know but little from personal observation. Father Quinby says: "Propolis is doubtless the gum or resinous coating which protects the buds of many kinds of trees."—J. M. HAMBAUGH.

I do not *think* that bees gather propolis from flowers at all. I believe that propolis is gathered only from the leaves and boughs of resinous trees, and your statement would seem to confirm this view.—C. H. DIBBERN.

1. It is gathered mostly from the swelling buds of trees and plants. I have never seen it taken from flowers. Hickory furnishes much, also cotton-wood, balm-of-Gilead, sweet gum, etc. 2. It is packed much the same as pollen. It was doubtless the propolis that suggested to the ancient bee-folk that bees carried pebbles for ballast.—J. M. SHUCK.

1. I know of no flowers that furnish propolis for the bees. In my locality bees gather propolis from cedar trees, hickory, walnut, and other resinous trees. They also collect paint from decaying wood, and even old pitch from wagon hubs, etc. Pure propolis is a "gum" that oozes from the limbs and trunks of certain varieties of trees, and is collected by bees.—G. W. DEMAREE.

1. The leaf-buds of shrubs and trees yield propolis—it does not come from the flowers. 2. Yes. Fruit and other trees supply it, by the exudation of a gummy substance.—THE EDITOR.

CORRESPONDENCE.

HIVES AND BEES.

Written for the American Bee Journal
BY D. C. BUCK.

A bee-man by the name of Dowell,
Went to the Tri-State Fair,
And with his son he walked around,
To view the wonders there.
That newly patented hive, he said,
Will take the highest prize;
But the Langstroth does just as well,
And better, to my eyes.
I know it s what some bee-men call "slow"—
But I think it is the safest way to go.
Some bee-men might think it strange,
But, really, I shouldn't like to change.

Those Albino bees do look so white,
But don't have near so large a girth,
Nor come up to my Italian bees—
But I know what my bees are worth.
They're good cell-builders, and good to fly,
And stronger workers I never saw—
The Italians are the bees to buy,
And in them none can find a "flaw."
Some bee-men, perhaps, might think it strange,
But, really, I shouldn't want to change.

I heard that Carniolan queen did cost
A good five dollars. Now,
Said Jacob Dowell, my Italian queen
Will beat her laying, anyhow.
I'm sure her progeny are the best,
And they are marked the yellowest.
Some bee-men might think it strange,
But, really, I shouldn't want to change.

As bee-man Dowell and his son
Rode homeward from the Fair,
He said: I wish my hives and bees
Had all of them been there.
And if the judges had been wise,
We might have taken every prize.

Dundee, Mich.

WINTERING.

A Conversation about Wintering Bees in the Cellar.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

Before me is a postal card which reads as follows: "This being my first experience in wintering bees in the cellar, I am not sure whether my bees are doing as well as they should, or not. Will you please tell, through the AMERICAN BEE JOURNAL, how bees should appear, to be wintering well?"

This used to be a point which bothered me considerably, when I first began to winter bees in the cellar, and had it not been for the instructions on this subject, given by Mr. E. Gallup, in the AMERICAN BEE JOURNAL, and elsewhere, I might have made many more mistakes than many beginners now do.

In the first place, when the hives are placed in the cellar, they should be raised at least two inches from the bottom-board, if possible. As the years go by, I am led to believe more and more, that this was the reason that I did not succeed better in my first efforts at wintering bees in the cellar; for at that time I almost invariably left them down on the bottom-board, as in summer, and often with the entrance nearly closed, for it was thought then that something must be done so as to keep the bees in the hive during their sojourn in the cellar. But to the question, "How do I know when the bees are wintering well?"

To best illustrate, I will give a short account of what happened a short time ago: A neighor called to see how the bees were wintering, and to know how I fixed them and the cellar, for wintering those which were put in. I told him that my bees in the cellar were wintering well—in fact, I never had bees appear so nice and quiet as they do this winter in the cellar. After a little more conversation, I asked him if he would like to go into the cellar, to which he answered that he should, very much; but said, "I suppose that you never go into the cellar from the time the bees are put in, till you take them out, as I see it advised in the papers that it is not best to do so." I told him that I went into the bee-cellar whenever I wished so to do, and I did not consider that I did any harm by so doing.

I suppose that I am considered a heretic on this question; but be that as it may, I have every reason to believe that no scientific wintering of bees can be accomplished where no observations are taken.

As we were going into the cellar, a conversation about like this took place, which I will give, as that will help the reader to understand that which they wish to know better than they otherwise could: "What, have you got three doors to go through to get in?" Yes, these three doors enclose two dead-air spaces, so that the cellar is kept at a more even temperature than could possibly be obtained in any other way, and the temperature is the main thing to be looked after in cellar-wintering.

Now, before we open the other door, I wish to say that we must be careful not to strike any of the hives, or breathe on the bees, for we should be as careful not to disturb them as possible.

"What is that low murmuring noise which I hear?" That is the contented hum of the bees in their winter repose, and you can always know that the bees are wintering well, when 50 colonies make no louder noise than you now hear.

"But I supposed from what I had read, that bees 'hibernated' when wintering well, and gave no signs of life." In this you mistake, for bees never hibernate as do ants, wasps, flies, etc., but go into what would more properly be called a "quiescent state," in which you see these to be.

"Hark, there is a bee flying. Do they fly out here in the dark?" Yes; that is only a bee ready to die of old age, and as instinct prompts the old bees to leave the hive when the temperature will permit, it is only obeying nature's law in flying out. See, here are quite a few bees on the floor, but not nearly as many as is the average of most winters. I often come in here in the dark, and listen for these old bees; and many times before, this winter, from two to five would fly out while I was slowly counting 100, but this winter scarcely more than one comes out while I count 500.

"What have you on the floor here? Sawdust?" Yes, every month I bring in a bushel or more of fine, dry basswood sawdust, such as is made while sawing sections, and scatter it on the floor. This sawdust will absorb almost its bulk in moisture, so that I retain it here to keep all dry, sweet and nice. Before I used this, the dead bees on the floor would mold and smell badly, but now all smells sweet and nice, and no mold appears.

"Here is your thermometer. I see that it marks 45°. What are the extremes of temperature in here?" From 43° to 46° above zero, after the first few days when the bees are put in. The disturbing of the bees in putting them in, causes the temperature to rise for a few days, up to from 50° to 55°, but soon lowers to where it now is.

"What, doesn't a warm spell in winter, or a long, cold spell, have any effect on the temperature in here?" No; and a cellar that allows the outside temperature to affect to any extent the inside, I should consider faulty. There are two roofs, and three feet of dry earth between them, over this, which, with the three doors, keeps an even temperature. Now step up and look at these yellow bees as they show underneath the combs at the bottom. And again, look at them as I roll back the quilt at the top. See, they go from the bottom to the top of the hive.

"Why, Doolittle, they are dead." No, I guess not.

"But they don't stir." Let us breathe on them the least bit.

"They are alive; that is a fact. Do they always keep thus quiet?" I have never seen them more uneasy this winter; but the year I used artificial heat, and lost so heavily, I could not lift a quilt without their boiling all over the tops of the frames.

"Where are your ventilators?" Here, at this end, is what used to be the sub-earth ventilator, and in the back end is the upper ventilator; but I have not used either for some years, as I find that all the air which the bees need to keep them in the best condition, comes through the mason work, doors, and earth covering. This is what some would call no ventilation whatever; but you see that the air is pure and good in here.

"Well, I would not have believed that the air would keep so pure, if I had not seen it for myself. But don't the mice trouble you in here?" As you will see, many of the hives have a few fragments of bees on them, so you may know that there have been mice here; but there are no mice in here now, for they have been caught with a trap. The cellar-doors are left open during every fall, till the bees are put in, and hence a few mice are always in at first; but after the doors are shut, no more can get in. We will go now; but first notice that the bees are nearly, if not quite, as quiet now as they were when we first entered, a quarter of an hour ago. If our entering does not disturb them any, why should I not have the privilege of coming in here as often as I please?

Reader, I have tried to make all plain. If I have not done so, tell me wherein, and I will try again.

Borodino, N. Y.

SMOKE.

How to Use Bee-Smokers, and Avoid Stings.

Written for the Farm, Field and Stockman

BY S. E. MILLER.

Experience teaches me that bees are more apt to sting a stranger than the one who is in the habit of working with them. Bees have an aversion to any one who has a bad breath, caused by catarrh or other disease. In fact I am almost certain that bees have a dislike for anything having an unpleasant odor. Aside from the above-mentioned facts, there is no reason why one person should not be as capable of handling bees as another. That is, after becoming acquainted with the little workers, and learning their habits.

To avoid being stung, follow these rules: 1. Never wear black or dark clothing when working among bees. I learned soon after commencing to keep bees, that they were ready to make battle whenever I went into the apiary with black on, while with gray on I was not likely to be bothered. 2. Use the all important bee-smoker. This is the secret of handling bees. With a good smoker in full blast, I think that any one can handle them.

When you wish to work among your bees, get your smoker well fired up, so that you can send a big blast of smoke three or four feet from the nozzle, remove the cover of the hive, and then gently raise the cloth that covers the frames, give the bees a few puffs of the smoke, and if they go below, and are willing to mind their business, you can go on with your work. As a general thing this is all that is necessary with pure Italians. If you have blacks or bad hybrids they will be pretty sure to show fight and fly at you every time you make a move that they do not approve.

I generally pour the smoke upon such bees until they are ready to go below and submit. Whatever you do, keep your smoker in good trim, and always have it within reach. Then if you make an awkward move and excite their anger, you can grasp it in an instant and defend yourself. If several bees dart at your hand, do not jerk it away. If you do, they are almost certain to sting, but if you hold it perfectly still, they will generally alight and appear surprised that the hand remains quiet, and instead of stinging, will proceed to examine it. You can then take the smoker in the other hand and drive them off. It is a good thing to have a boy as assistant, to handle the smoker when you have much work to do among your bees.

3. Never allow bees to think you are afraid of them—on the contrary, have them afraid of you. Bees always detect the least sign of nervousness on your part, and will generally take advantage of it.

4. A beginner should wear a veil. It gives a feeling of safety.

Last, but not least, to avoid being stung, keep pure Italians—no black or hybrid bees.

Bluffton, Mo.

DO BEES HEAR?

The Various Sounds Made by the Bees.

Written for the American Bee Journal

BY C. E. WOODWARD.

This is a question that has been asked of me so many times the past few months, and by some of those who are readers of the AMERICAN BEE JOURNAL, as well as others, that I will try to give some of the experience and observations in my own apiary in 1885.

I would say that bees have different sounds to accomplish different ends. The only natural sound of bees on the

wing, is that produced by the returning laborer, when it comes home at evening laden with that delicious nectar, collected from some flowering field. Who has not been charmed by the sweet, mellow tones, as they died away in the entrance of the hive, like the wind that blows through the boughs of the tall pines of the mighty forest, during a summer sunset in August?

The shrill note of the pugnacious defender of the hive is familiar to every bee-keeper. The sharp sound of bees just beginning to lead out a swarm, heralds its advent to the bee-master, and is very different from the two sounds mentioned before.

The coarse, bass roaring of the swarm is heard only when they are locating their mother, and is kept up by both workers and drones, until the queen is found, and then the bass sound becomes silent.

Next is that sharp, cutting sound, as they begin to cluster in some shady tree, to call the colony together, which is well known to the apiarist, as the signal of congregating. Then comes that shrill, hissing sound of the escort, that led them to the woods; hence the sounds are blended with the roaring of the swarm, making a yet different sound than has been mentioned, and is heard only from absconding swarms.

Again, in that happy hour, when the bees have found or selected a habitation that is suitable for their brood-rearing, and storing the golden nectar, we then hear the happy sound made by hurling the wings in fantastic circles; this sound indicates that all is peace and harmony.

Another sound may yet be located, and that is the sound of distress. This sound is heard only when annoyed and frightened by the black volume after volume of smoke poured in upon them without mercy; and no wail of distress or misery, made by any other insect, can equal it.

There is another sound that I will call attention to, and that is the "ventilating" sound, made at the entrance and all through the hive, which in hot weather may be heard some distance away; hence all the different sounds are instinctively associated with certain purposes, and the movements of the queen are to a great extent generally governed by them. She thus follows certain sounds, as do the whole colony. She never leads the swarm, but the swarm leads her by their sounds. Bees do hear!

In the year 1885, the two queens that missed my attention swarmed from a populous colony at about 10 a.m., owing to their prolificness. They were unable to take wing, hence were obliged to retire to the parent colonies. I expected them to come out again about 3 p.m., but to my surprise, when the sun was near the meridian, out they came, filling the air with those distinguishable sounds, circling high, and each revolution becoming larger and larger, when they took a bee-line west, and away they went over the woods, old and young, queen, workers and drones. Again that shrill, hissing sound was in advance, leading the absconders to a place of abode; but owing to the prolificness of the queen, she was obliged to alight. As she happened to select a small sappling, I brought them back to the apiary, and hived them on drawn combs, and the result of that colony was 195 pounds of beautiful white comb honey.

Newbury, Ohio.

FREAKS OF BEES

Noted the Past Season—Report for 1888.

Written for the American Bee Journal

BY A. E. AULT.

It is my custom to make a record of anything unusual that I may notice in the apiary. I will give a few such items that were new to me, and which I think will be new to the greater part of the readers, as follows:

On June 14, I saw the bees attack and kill several cicadas, or locusts, as they are commonly called, which were very plentiful at that time. The same day I saw a queen return from a flight after she had commenced to lay.

On July 5 I saw a sealed queen-cell that contained a worker-bee, and a young larva. On July 13, I saw a sealed queen-cell that contained a queen in the pupa state and a worker-bee. In both cases the queens and bees were dead. On July 19 I saw a queen-cell with a seemingly well-developed queen, within about two days of hatching. The remarkable feature was, that the queen was in a reversed state, with her head in the bottom of the cell.

If any one else has noticed the same freaks of the bees, I shall be glad to hear of them.

In the fall of 1887 I had 47 colonies of bees, which I wintered without loss, although I united 3 colonies that were queenless, thus leaving 44 colonies. During the past season I increased them to 82 colonies, and obtained 3,500 pounds of honey, of which 300 pounds was in the comb, and the remainder was extracted.

Linden commenced to bloom on July 4, and lasted ten days; in that time my bees stored 2,000 pounds of honey. I also obtained 26 pounds of beeswax.

North Liberty, Iowa.

THE CLOVERS.

Different Clovers Considered as Honey-Producers.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

Every bee-keeper should look ahead for pasture for winged stock; and among the sources of honey supply, the clover family stands first.

Of the forty native varieties, white or Dutch clover is at present most valuable, the amount of honey gathered from this variety being greater than from any other member of the *Trifoliums*, and the quality unexcelled.

Next in value, and one which will likely crowd its half-sister for a place in the front rank in the near future, is Alsike or Swedish clover (*Trifolium hybrida*).

Following this I should place our common red clover, which is so valuable for hay and pasture. The one and only reason why red clover does not occupy the first place is the depth of its honey-cells, which, in the majority of instances, prevents the honey-bees from reaching the nectar.

Some of our fraternity are endeavoring by judicious selection, aided by the law of the "survival of the fittest," to produce a strain of honey-bees with longer tongues, which can reach the rich nectar of the red clover. Any skillful bee-keeper could to-day well afford to pay $10,000 for a healthy and prolific queen, which would produce worker-bees able to work *freely* on the large heads of the first crop of the red.

Next as a honey-producer I would place sweet clover (*Melilotus alba*), and its field proper is not one-tenth occupied, nor its value one-half appreciated. It is a biennial, does not blossom the first year, blooms freely the second, and dies root and branch. It produces honey of fine quality, similar to that of the white clover; fowls pasture on it in the early spring, and sheep much of the season. Its capacity to withstand drouth, and to thrive upon rough, broken and gravelly ground, and its great value as a fertilizer and renewer of worn-out land should recommend it to every farmer who has land, particularly rough land, which needs renewing. Lastly among those which I shall consider in this article is:

Alfalfa (*Medicago sativa*). This was introduced many years ago on our Pacific slope from Chili; it has proven its great value as a hay and forage crop in California and Utah, and is fast coming to the front in Central and Western Kansas and Colorado.

Mr. Wm. Muth-Rasmussen, a reliable bee-keeper of Independence, Calif.,

reports seeuring over 5,000 pounds of comb honey from Alfalfa. It is a very quick grower, and will mature the first crop in about two months from the time that growth commences, the second in about six weeks from cutting, and the third in about five weeks, and yields on an average 5 to 6 tons per acre.

Many flattering reports have come, and are still coming to me, coneerning Alfalfa. It will search for water like a well-digger, and in a sandy soil, go down 10, 12, 16, and even 20 feet. The roots are from 1 to 1½ inches in diameter, and fully ½ of that root decays every year from the outside, at the same time growing larger from the centre.

Let no one who has sown Alfalfa get discouraged if it is small and spindling the first season. You can get no crop from it the first year, the second year a fair crop, and the third it is as good as it will ever be. It is a perennial, of the clover family, but will out-yield red clover for hay, two to one, and unlike it, never falls down, but, like a good soldier, stands up straight.

Peoria, Ills.

CARNIOLANS.

Their Good Qualities and Different Management.

Written for the American Bee Journal
BY F. A. LOCKHART.

I commeneed the season of 1888 with 25 colonies, 20 of which were Carniolans, and 5 Italians, and I increased them to 30 colonies. The season was the poorest one since I have kept bees. I got only one-eighth of a honey crop.

The Carniolans were the only colonies that gave me any surplus. I had them side by side with the Italians, and I gave the one variety as much attention as the other, but the Italian colonies would not enter the surplus receptacles, and I could not get them to do so with any amount of coaxing. They were strong in bees, and filled their brood-chambers full of honey; but that is all they would do. The Carniolans filled their brood-chambers and gave quite a surplus besides. I never saw bees cap their honey so rapidly, and with such snowy whiteness as the Carniolans do.

Some may think that I had a poor strain of Italians. If I had, they were from the progeny of 3 queens from our best queen-breeders. I used to think that there were no bees like the Italians, but I have discovered my mistake, and have discarded them.

I have never seen any strain of bees that had so many good points as the Carniolans possess, all points being considered. They have a little more propensity to swarm, than have the Italians; but why do they have a tendencey to swarm oftener than the Italians? Because they are more prolific than either the blacks or Italians, and for that reason they need to be managed in a different way. Give them plenty of room, and they will make use of it.

My plan for working the Carniolans is as follows: Hive the swarm with the old queen on the stand from whence they came; place the old hive in a new loeation, and give the colony that is left a young laying queen. Cut out all queen-cells before giving the queen, and cage her at least for 24 hours. If you have no young laying queen at hand, cut out all but one queen-cell, and let them rear a queen.

My bees are all in the cellar, and to all appearances they are wintering well.

Remedy for Bee-Stings.

The best cure that I have found for a bee-sting is this:

Take equal parts of soda and vinegar, and rub it on the place stung, while the stuff is fomenting. It will give relief immediately.

Lake George, N. Y., Dec. 24, 1888.

CANADA.

Report of the Brant Bee-Keepers' Convention.

Written for the American Bee Journal
BY R. F. HOLTERMANN.

The annual meeting of the Brant Bee-Keepers' Association was held in the Court House at Brantford, Ont., on Dec. 29, 1888, with President Anguish in the chair. Owing to the expected presence of Mr. S. T. Pettit, of Belmont, an ex-President of the Ontario Bee-Keepers' Association, and a well-known bee-keeper, the attendance was good.

After the necessary business required to close up the year 1888 was transacted, the election of officers took place, which resulted as follows: President, J. R. Howell; Vice-President, T. Birkett; and Secretary-Treasurer, R. F. Holtermann.

The following representatives were elected, as required by the Ontario Bee-Keepers' Association: R. F. Holtermann, D. Anguish, and G. W. Barber, who were delegated to place the views of this Association upon important matters, before the Ontario Bee-Keepers' Association at Owen Sound.

On motion the representatives of the Brant Association were asked to invite the Ontario Bee-Keepers' Association to meet at Brantford for their next annual meeting, in union with the International Bee-Association, which was carried unanimously.

Suppression of Foul Brood.

The question of the desirability of taking means to suppress foul brood was brought up.

S. T. Pettit was asked if the Ontario bee-keepers were not trying to secure legislation in this direction. He replied that such a step had been thought of, and some action in that direction taken, but the matter had been dropped; that there was no doubt that the the disease was spreading. He had lately been at the annual meeting of the Oxford Bee-Keepers' Association, the Secretary of which (Mr. Frith), had, after trying almost everything recommended, destroyed probably over 100 colonies, and it was in that neighborhood. It was reported that prominent queen-rearers and sellers of bees had the disease in their apiaries, off and on, for a number of years, and inspectors should be appointed by the association to inspect any one's bees that they saw fit, who offered them for sale. This would either exonerate any one falsely accused, or prevent bee-keepers from having the disease spread broadcast over the land.

All appeared to see the wisdom and justice of such a course, and, on motion, it was unanimously decided, in view of the fact that foul brood is reported, and known to be spreading in the Dominion, that we respectfully suggest that the Ontario Bee-Keepers' Association appoint inspectors to go through the country and report the condition of any or all apiaries of those selling bees, and also to ask the Ontario Legislature for legislation to prevent the spread of the disease.

Ventilation of Bee-Cellars.

Mr. Phelps introduced the subject of ventilation, by remarking that bee-keepers appeared to have almost concluded that bee-repositories did not require ventilation. He had stopped up his ventilator without any apparent injury; his cellar was, however, not built very tightly.

Mr. Pettit stated that it was the third year he was wintering bees in a cellar; the cellar was built tightly; he had carefully superintended the work, and allowed no slighting in its construction. He thought that it would be almost water-tight, besides it was built in hard clay, and the whole cellar below the level of the clay. He has a sub-earth ventilator, which regulates the temperature. It is 215 feet long,

6 feet below the surface, and part of the distance the one end enters the cellar, the other terminating by a pipe several feet along the surface of the ground. There was a drain below the pipe, to keep the air-pipe from acting as a drain and containing water. The degree of cold outside made some change in the temperature, as it entered the cellar; also the velocity of the wind. The temperature of the cellar ranges from 38° to 40°, generally; at that temperature there appeared to be no breeding, and the bees seemed to come out vigorous. At 45° to 48° more bees died, and they consumed more stores, and would breed.

W. R. Brown—My cellar is very dry, and the temperature ranges from 35° to 37°. I have never lost a colony.

Mr. Pettit—Of course the covering over the frames makes a difference. If much covering is used, the temperature of the hive is higher than if there is not so much covering.

President Anguish said that much depended upon the soil the cellar is in. In reference to outside and inside wintering, bees wintered outside would dwindle less in the spring than those kept inside. He gave his experience in burying bees.

Mr. Pettit said that burying bees would be a thing of the past in Canada. It was important to have ventilation inside or outside regular.

R. F. Holtermann reported that his bees appeared to be doing nicely. There were very few dead bees, and the rest were very quiet.

A vote of thanks was unanimously accorded to Mr. Pettit for his presence, to which he replied in a pleasant manner. R. F. HOLTERMANN, *Sec.*

LAYING WORKERS.

My Experience with Laying Workers, etc.

Written for the American Bee Journal

BY FRED BECHLY.

Last summer I had a colony with laying workers. I divided it into four parts, and gave a young queen to each part. Two of these small colonies had laying workers, and these workers continued to lay, until the queens were mated and laying; after that I could tell nothing more about them.

Now it would seem that the laying workers do not destroy queens, but are, nevertheless, the cause of some trouble. They seem to cause a division in the colony. It looks as if some of the bees consider themselves queenless, while others do not; some build queen-cells, while others destroy them.

I commenced the season of 1888 with 22 colonies, increased them to 33, and obtained 930 pounds of honey—about 60 pounds being comb honey, mostly gathered from fall flowers.

Care of Surplus Combs.

I take the combs from the extractor without allowing the bees to clean them, and store them away in empty hives, or surplus cases. I crowd from 12 to 13 frames into a 10-frame Langstroth hive. I find the moths do not like to lay their eggs in combs wet with honey. Of course the hives must be closed against bees.

Searsboro, Iowa, Jan. 6, 1889.

QUEENS.

Renewing the Vigor of a Colony by Giving a New Queen.

Written for the American Rural Home

BY J. H. ANDRE.

If the majority of bee-keepers that keep black or hybrid bees, knew how easy a matter it is under ordinary circumstances to introduce a queen, bee-keeping would advance with a zeal never known before, within the next five years.

Suppose one has a few colonies in his apiary that are only just holding their own, while others are storing surplus. An examination reveals the fact that it is a weak colony from the cause of a poor queen. If you destroy such a queen, and allow the bees to rear another, you lose from 20 to 30 days' time, according to whether they take eggs just laid, or larvæ, from which to rear one. After all, you may have an inferior queen by this method.

If you wait until it is too late for them to rear a queen from their own resources, and destroy all queen-cells, giving them eggs from another colony, you lose a longer period of time. Therefore, taking the loss of time and change of blood into consideration, it is a better way to send to some reliable dealer for a queen.

The combined "shipping and introducing cage" I do not like, as it is too large, and admits the chance of giving the bees too much shaking in transit; also it is apt to warp or swell, rendering it almost impossible to draw the tin slide. Then when you try to put it in the hive, it will not slip in between the regular space between two frames; and last but not least, one must destroy larvæ and brood in pushing the tins through the combs, and where the cage rests against the face of the combs, brood is frequently destroyed also.

The shipping-cage used by G. M. Doolittle suits me well. It is 2½ inches long by 1⅛ wide, and nearly 1¼ thick, with an inch hole one inch deep close to one end in the narrow side of the cage. A seven-sixteenths hole is bored through the solid end of the block, and near enough to the opposite side of the block from which the larger hole is, so that the small one intercepts the latter below its bottom about one-fourth the width of the smaller hole, thus forming a shoulder so that a stick of candy will stay in place, and not slip into the cage and kill the bees. With such a cage as this, all one has to do in introducing is to cut a hole in a comb the size of the cage, and slip it in so that the side with the screen on is even with the surface of the comb, so as to allow the bees to feed the queen, when they will own her.

In 24 hours remove the netting carefully, slide the frame in place, and the queen is introduced. The cage may be removed at some future time.

The cage could be made so that it could be used 1¼ inches wide, when I should consider it perfect, as 1⅛ inches is almost too wide to go into most frames. I think that a small cross-pin would hold the candy, and this would dispense with the shoulder, and the cage could be used narrower.

SEASON OF 1888.

Report for the Past Season—Marketing Honey.

Written for the American Bee Journal

BY EVAN R. STYER.

On March 28, 1888, I examined 11 colonies that I had in winter quarters. It was a warm day, and having all things ready, I commenced with No. 1, and having transferred it to a new hive, I gave sealed honey, contracting the brood-chamber, and replacing the chaff cushions. Thus I continued until I had the 11 all nicely cleaned and repacked. Nine colonies were in good condition, 2 were rather weak, and during April they dwindled to almost nothing.

Sometime in April I moved them about three miles, to a farm which I now occupy. The move was a successful one, having lost scarcely any bees by the operation.

The spring was backward and cold, and the bees did not build up very fast. I had six swarms in June and July, and one in September. During June 6 colonies gave me 160 pounds of extra fine white clover honey, nicely capped, in sections completely filled. In July I took off 150 pounds more of the same quality.

For August I got nothing. In September I obtained about 100 pounds of

honey of fair quality, making in all about 400 pounds.

During the latter part of the season, while manipulating with the bees, I found them exceedingly cross; so much so that I was almost obliged to give up working with them. The theory of "holding the breath" was of no avail.

In October I lost 3 colonies by robbing. I commenced feeding them sugar syrup, giving to each colony about 18 pounds. Two colonies had natural stores enough. In November I placed them in the bee-house, just in the rear of the bee-yard, raising each hive up about 2 inches, and placing meadow hay around the three sides, leaving the front exposed to the south. So far they seem to be in good condition.

Selling the Honey.

I was determined then to sell the honey for a fair price, and to first-class customers. I represented the goods as being fine, and to be just what I said, or no pay. I called upon a Doctor in one of our large cities, and spoke to him about what I had. He was afraid to invest, but after some persuasion, he consented to take some on trial. He did so, and the result was that we was so well pleased with the flavor and quality, that he ordered quite an amount afterwards, besides selling some for me.

Some I sold to parties living in New York, along the Hudson river. The honey was just what I said it was, and they promised me their custom for next season.

This same gentleman, who is a wealthy merchant in New York city, told me that he had paid as high as $3 per pound for wild honey, which came from Norway. I received 25 cents per pound for all I sold, and have only a little left.

I find plenty of customers in my home market, and I prefer to retail it in this way than to wholesale it. I could dispose of much more, had I the honey to sell. I have a good location for bees, and I intend to increase my apiary to 50 or more colonies.

My neighbors have poor luck—no swarms, no honey, and many often lost all their bees during the winter. They take no bee-paper, and read no books on the subject, but go it blindly. To me it is an exceedingly interesting study. The AMERICAN BEE JOURNAL still grows better.

Morgantown, Pa., Jan. 1, 1889.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Jan. 16-19.—Eastern New York, at Albany, N. Y. Thos. Pierce, Pres., Westbury, N. Y.

Jan. 30, 31.—N.E.O., N.Pa. & W. N.Y., at Franklin, Pa. C. H. Coon, Sec., New Lyme, Ohio.

May 4.—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Feeding Bees in Winter, etc.—Rev. Stephen Roese, Maiden Rock, Wis., on Jan. 7, 1889, writes:

The weather continues very fair for January, with no frost and no snow, and the bees still out on the summer stands. They have a flight almost every few days. I was called upon to take the honey from 3 colonies of bees, for a friend four miles from here, and as I dreaded to kill the industrious insects, I shook them all off from the combs the best I could, and as they were weak colonies, I put them all in one box, and took them home. I placed them in a hive with empty frames, as I had no frames filled, and the weather being so mild, I have been feeding them about 8 or 10 pounds of honey the last three days. They are outside alone; but I do not think much of unsealed honey for bees to winter on. Would you advise placing the "Good" candy over the frames; or furnish them with sugar syrup? Bees in this locality are as yet doing well, and we hope for a good season this year.

[Candy over the frames will probably be best now, but you must not disturb the bees to put it there, except during a warm spell, and in the middle of the day.—ED.]

Mild Weather.—Henry Alley, Wenham, Mass., on Jan. 3, 1889, writes:

We have no more winter weather here now than we have had since Nov. 1. The bees are flying nearly every day.

Burying Bees to Winter.—John Broadhead, Chatsworth, Ills., on Jan. 1, 1889, says:

I have 30 colonies of bees buried in the ground. They are in good condition with plenty of honey. Fifteen colonies are pure Italians. I will try to report in the spring, telling how they winter, and describing my method of burying them.

Bee-Hives and Rheumatism.—T. C. Whiting, Athens, N. Y., on Dec. 26, 1888, writes:

My bees had a Christmas frolic, and were out in full force. The mercury was at 52° in the afternoon. I would like to know the name of the hive I use. The man I got it of has no name for it, only "bee-hive;" and I suppose anything with bees in it would be called a "bee-hive." The hive is 16½ inches long inside, 13 inches wide, and 12 inches deep, and is made of boards 12 inches wide. It has 8 movable frames. I asked a neighbor who keeps about 50 colonies, and I did not find out, although he uses a good many of them. I do not expect to keep bees a great while longer, but it suits me first rate, if I could only see. My eye-sight is too poor, and I am getting too old. I have had bees two years; started with one colony, and I now have 7, which were pretty lively yesterday. I keep bees to cure the rheumatism, and I am freer from it now than I have been for the last two years. I have got so that I do not mind a sting, unless I get too many in one place. They do not swell as they did last year. I have read that bee-stings are good for the rheumatism. I would not like to say that it has helped me, for I do not know for a fact. I have been subject to that complaint for 50 years. Sometimes I was pretty bad with it; you would have thought so if you had seen me when I was drawn into a heap about 2 feet long.

[The hive is evidently a mongrel, taking no regular size of frame. It is a great mistake to make hives not using a regular sized frame. It is undesirable for use, because it often requires frames, sections and supers of irregular sizes to be made especially for it; and is a *nuisance* when bees are bought or sold.—ED.]

Cipher Telegram.—E. Strong, of Kalamazoo, Mich., on Jan. 3, 1889, writes:

Report: Comb honey, 0. Extracted honey, 0. Temperature, 44°. Hopes for another year in the nineties. Fed, 0. Enough to winter on the summer stands.

Honey from Fire-Weed, etc.—H. E. Harrison, Covert, Mich., on Jan. 8, 1889, says:

I wintered 3 colonies last winter, increased them to 5 during the past season, and harvested 450 pounds of fire-weed honey after Sept. 1. The honey was nice and white, and sold as well as basswood or white clover honey, there being no difference except in the taste, which is strong. The drouth of 1887 nearly killed the white clover, and the basswood being scarce here, it did not afford much honey. I did not get any.

Good Honey Crop.—Mr. Adolph Wuerzer, Helvetia, W. Va., on Dec. 31, 1888, writes:

My location is not a bad one for bee-culture. We have hard maples, linden, poplar, black gum, round wood, the clovers and berries; and my honey crop in 1886 was an average of 38 pounds to the colony. In 1887 it was 39 pounds, and in 1888 it was 44 pounds. I read the AMERICAN BEE JOURNAL with much pleasure, and anxiously look for its arrival. I have 45 colonies of bees in good condition, in winter quarters.

Mild Winter—Japanese Buckwheat.—H. L. Rouse, Ionia, Iowa, on Jan. 5, 1889, writes:

If a warm, dry fall and a mild winter are favorable conditions for the successful wintering of bees, then surely bee-keepers in this locality ought to meet with but slight losses this winter. No snow fell until the night after Christmas, when it came down very plentifully, so that it was a foot deep on the level. The ground is not frozen very hard, and as it is well covered with a blanket of snow, what clover survived the drouth will be well protected. Our honey crop for 1889 all hinges upon the coming

spring. If we get plenty of spring rains, I think that the clover will be a fair crop. If not, the old story of 1887 and 1888 will be repeated. I sowed one peck of Japanese buckwheat last spring, from which I received nine bushels of seed. It was sown on about 35 square rods of ground. I had three-fourths of an acre sown with the common variety, from which I harvested only 12 bushels. All who see the Japanese variety, want some for seed. I intend to sow that exclusively another year. I think that it is *the* buckwheat.

Best Prospects in 15 Years.—Messrs. Bray & Seacord, Warthan, Fresno Co., Calif., on Jan. 1, 1889, write:

The prospects are good for a large yield of honey for the season of 1889. Vegetation of all kinds is making a rank growth—in an experience of 15 years, we have never seen such a good prospect as the present. There has been no frost of any consequence, simply a splendid open winter, with an abundance of warm rains for all agricultural purposes; in fact, it is more like late spring and summer weather. When it is not raining, one can do all out-door work minus a coat, or any superfluous clothing. Just imagine the middle of winter, with your April and May climate in California, and you will then understand the situation. We wish the AMERICAN BEE JOURNAL a happy and prosperous year, with a large flow of (milk and) honey.

Fairly Good Honey Crop.—F. M. Merritt, Andrew, Iowa, on Dec. 24, 1888, writes:

The honey crop of 1888 has been fairly good in this part of Iowa. I commenced the season with 8 colonies, and increased them to 21. Three of the 8 colonies were very weak, and required feeding until the latter part of May, when all the colonies built up rapidly on apple-bloom and dandelion, of which there are acres covered with this beautiful yellow-flowered plant. The white clover did fairly well, and I secured about 100 pounds of honey from it, in the extracted form. I got about 900 pounds from the fall flowers, such as golden-rod, wild aster and heart's-ease. I have secured 1,000 pounds of honey, about one-half of it extracted, and the other half in the comb. All the colonies are in winter quarters, and seem to be doing nicely.

Cellar for Wintering Bees.—J. H. Bingham, Lee, Mich., on Dec. 31, 1888, writes:

I had 35 colonies of Italians and hybrids last spring, which I increased to 45, by natural swarming, and took off 35 pounds of comb honey per colony, with the brood-frames still well filled. I have made a bee-cellar this fall. It is 12 feet wide, 20 feet long, and 7 feet high. It is built in a hill-side, with joist over the top, and plank, with 2 feet of sawdust on the plank, and a good roof over the top. I have 45 colonies in the cellar, and the temperature is at 43°. The hill is sandy. There is a ventilator 4 inches square in the top of the cellar, but the cellar is damp, but not enough for water to stand on the hives. Will the bees winter well in this cellar?

[Bees ought to winter well in a cellar made as described above, but they cannot always be depended on for safety. Losses have and will occur sometimes, no matter how wintered. Springing is the most dangerous, and causes more loss, usually, than any kind of winter management.—ED.]

Wintering in a Bee-House.—Samuel Snow, Fayetteville, N. Y., on Jan. 5, 1889, says:

The old year, 1888, has passed on to be remembered as one of the "has beens," and the new year, 1889, has quietly stepped into its place. While the record of 1888 has not been what some of us would wish, yet it is not a bad one, by any means. Let us remember it with gratitude, and with the Almighty's permission, start 1889 with renewed energy, under more favorable auspices, and do more and better work. I commenced the spring of 1888 with 65 colonies, increased them to some over 100, and took over 3,000 pounds of nice comb honey, and 100 pounds of extracted. My bees are in a bee-house (made so that they occupy it during the summer and winter); in which they are now tucked away in forest leaves. They had a nice flight yesterday, and improved the opportunity.

The Past Season's Results.—E. F. Meeker, Duncan, Ills., on Dec. 28, 1888, says:

I commenced the past season with 50 colonies of bees, and I have at present 109 colonies. I took a trifle over 2,000 pounds of honey.

Killed by Accident.—Mr. Fred J. Mudgett, of Meredith, N. H., writes thus concerning the death of his brother:

My dear brother, Raymond L. Mudgett, was shot and killed by the accidental discharge of his gun while hunting on Oct. 3. It is a terrible blow to me; he was my only brother, a promising young man, 18 years of age, and it seems hard to have our loved ones cut down in such a terrible way. How many there are in this broad land of ours that have been called upon to pass through just such sad scenes.

Fed the Bees for Winter.—C. W. Bradish, Houseville, N. Y., on Jan. 1, 1889, says:

The past was the poorest season for bees that I ever saw. I had 75 colonies on June 1, and 90 in the fall, and took about 400 pounds of comb honey. I had to feed two barrels of granulated sugar made into syrup, and 500 pounds of extracted honey, to winter them. Those who have not fed their bees, will lose all this winter.

My Experience with Bees.—W. A. Shafnit, Brighton, Iowa, on Jan. 4, 1889, writes:

I started with 1 colony of bees, which I found when mowing weeds along a hedge fence on July 4, 1883, and put into a box. I then had bees, but I did not have any honey the first two years. I concluded that I did not want them unless we could have honey, so I adopted the 8 frame Langstroth hive, and commenced to read and experiment, and killed some bees, by my ignorance, as some say. The third year I obtained 80 pounds per colony, of comb honey. The fourth year the yield was only about 25 pounds per colony, being a very dry year, and the bees did nothing. They went into winter quarters very light, and I had a heavy loss in the spring, as the season was backward and cold. The fifth year the bees did tolerably well, averaging about 50 pounds per colony, spring count. My greatest trouble is, that they swarm too much. I have been working the past season by the Heddon method of preventing after-swarms, but I did not succeed very well, for swarm they would, and swarm they did. So I concluded that if they would swarm, I would put two and three after-swarms together, which seemed to do very well, and I had strong colonies soon ready for the sections, which gathered the most of my honey. My black bees did not amount to much, but the Italians and hybrids are the bees for this part of the country. I introduced one queen in July, which I am well pleased with. I shall try some more, if everything is favorable. I put 33 colonies into the cellar, and left 2 on the summer stands to experiment with. The winter has been very nice so far, with the temperature at 62° in the shade. The bees on the summer stands had a good flight on Dec. 23. Since Jan. 1, the temperature has been from 38° to 40° above zero.

Poor Season Last Year.—Jacob Copeland, Allendale, Ills., on Jan. 7, 1889, says:

The last year was a poor one for bees and honey in "this neck of woods." From 55 colonies I obtained about 550 pounds of honey, or an average of 10 pounds per colony of nice comb honey in one-pound sections. One young colony and one old one gave me 50 pounds each, and the yield was from that all the way down to less than nothing. I suppressed the increase—which, by the way, was not hard to do—so that I have only about 60 colonies now.

Dark Honey, etc.—I. S. Herron, Marshfield, O., on Dec. 31, 1888, says:

I have my 47 colonies of bees stowed in the cellar, and they appear to be doing well. Last year there was not much of a honey season here. I started in the spring with 27 colonies, increased them to 52, and have lost 5 colonies through queenlessness; being late swarms they did not store sufficient honey to last them even until winter, and I neglected them. I took about 400 pounds of comb honey, mostly in 2-pound sections. All the honey gathered in this county was dark in color, being mostly gathered from poplar, raspberry and blackberry. There was no clover honey.

Very Mild Winter, etc.—Jas. A. Matney, St. Joseph, Mo., on Jan. 7, 1889, writes:

I like to read the experience of bee-keepers from all parts of the country, as printed in the AMERICAN BEE JOURNAL. Bees in this section of Missouri were not profitable the past year. I had 13 colonies last spring, and have only the same number now, and I had very little honey from them the past season. If my bees winter all right, I shall be able to start next spring where I was last spring. We have had a very mild winter so far. Bees were flying last week.

Good Results the Past Season.—S. E. Daggett, Conrad Grove, Iowa, on Dec. 25, 1888, wrote:

On Dec. 1, 1887, I put 6 colonies of Italian bees into the cellar, and took them out the first of last April in good condition. I increased them to 18 colonies, and obtained 500 pounds of very nice comb honey, which I am disposing of at 20 cents per pound. These results were obtained by close attention. My bees are in the cellar, with plenty of stores for winter. I am a beginner, but I have learned to love the bees, and we get along nicely together; thanks to the AMERICAN BEE JOURNAL for its useful instruction.

Moldy Combs, etc.—R. P. Blades, Carmi, Ills., on Jan. 3, 1889, writes:

I had one colony that gave me 156 pounds of comb honey the past season. I had 17 colonies in all, and put them into the cellar on Nov. 25. I put them all on the summer stands to-day to give them a flight, and found, on examination, that the combs were nearly all moldy. The bees appear to be in good condition. I would like to know what to do, or whether moldy combs will hurt the bees. The brood-frames are full of honey. I use the Simplicity hive with 10 frames. I learned in uniting bees after sundown, that they will not sting. It appears that at that time they have no guard out to watch for robbers, and so they let them come in peaceably. However, I give them a puff or two of smoke in the hive. My bees did well the past season.

[The molding will do no harm. Let the bees take care of that.—ED.]

Fall Crop of Honey.—Wm. Hill, of Prophetstown, Ills., on Dec. 31, 1888, says:

On Dec. 12, 1887, I put 41 colonies into the cellar, and left 4 on the summer stands. I took them out of the cellar the last of March, 1888, and lost 4 colonies by spring dwindling. My bees had one good day's work on willow; I had put a good colony on scales, and it put in 8¼ pounds of willow honey. It was cold and rainy through fruit-bloom, and the bees did nothing. White clover and basswood bloomed, and the bees got just enough to keep up breeding. The last of August they commenced to work on heart's-ease and other fall flowers. I secured about 1,700 pounds of the nicest fall honey that I ever had, one-half being extracted, and the rest comb. I put in the cellar on Nov. 27, 45 colonies in good condition, and left 8 on the summer stands. They appear to be doing well.

Beautiful Weather—Quiet Bees—Joshua Bull, Seymour, Wis., on Dec. 31, 1888, writes:

We have had most beautiful weather here all the past fall. "Indian summer" continued clear up to Christmas Day. We did not have any bad storms until Dec. 26, and then Old Winter came howling in, and brought us about 8 or 10 inches of snow. On the morning of Dec. 28, the mercury, for the first time this season, went down to 8° below zero; but it was thawing again on Dec. 30, and it is very mild to-day. My bees are resting very quietly, both those out-of-doors and those in the cellar.

Producing Extracted Honey, etc.—C. W. Dow, Lynn, Mass., on Jan. 8, 1889, writes:

I was very much pleased with the arrangement of the Index for the last volume of the AMERICAN BEE JOURNAL. I have got it bound already, and it makes a very valuable book.

I read somewhere in the AMERICAN BEE JOURNAL, of a correspondent who practiced giving his bees half-depth wide frames to be filled with comb, and then used for extracting. The idea seemed to me to be a good one, and just before the white clover bloomed, I arranged cases for four hives, with seven shallow frames in each, and filled with comb. The result more than pleased me, for I secured the largest and best lot of white clover honey that I have had in the 20 years that I have kept bees. The bees filled the frames solidly full of comb 2 inches thick. I extracted it before the honey was sealed over, and I found that it was heavier, and better ripened than any I ever had before. I also saved the trouble of uncapping. I like the plan so well that I shall try it on all of my hives next season. Why has it always been the custom to produce extracted honey in the same depth of comb that brood is reared in, when the bees always store their surplus honey in combs 2 inches thick, when they have their own way?

Exhibiting Bees, etc.—Mr. Noah Clemmons, Rock Bluffs, Nebr., on Jan. 2, 1889, says:

I have 12 colonies of bees that I got from the woods in November, without any honey or comb, and they are doing well in the basement of my house. I feed them syrup and ground oats, and they eat like chickens. I intend to take my bees and travel from fair to fair next fall.

"What of the Night?"—Eugene Secor, Forest City, Iowa, on Jan. 9, 1889, writes thus:

On Oct. 19 I began taking my bees into the cellar, and finished Nov. 9. If I had foreseen the winter, very likely I should have left them on the summer stands for a month; for the weather has been very mild up to this time. Bees could have flown almost every day till Christmas, and many days since. It has been impossible to keep the temperature of my cellar down to the approved figure. It has ranged from 48° to 52° all the time. Notwithstanding this fact the bees have been remarkably quiet. After a confinement of nearly three months, there are but few dead bees on the cellar floor. I have not examined them closely, but they appear to be all right.

Bees did Well.—A. C. Loomis, of Grand Rapids, Wis., on Jan. 7, 1889, says:

My bees did pretty well last year. I commenced in the spring with 8 colonies, increased them to 14, and obtained 537 pounds of comb honey. They swarmed a great deal, and sometimes I put as many as 3 swarms into one hive. Two large swarms went to the woods.

Good Prospects for Next Season—Joseph L. Flint, Marion, Iowa, on Jan. 7, 1889, writes:

I commenced bee-keeping on June 8, 1888, by purchasing one colony of Italian bees. On June 22 I bought one colony of black bees, and they supplied themselves with an abundance of winter stores, but gave me no increase or surplus. The Italians swarmed on July 4, 14 and 19, and stored 8 pounds of surplus honey. I hive the first swarm on 10 frames full of comb foundation, and it filled the hive, and gave me 22½ pounds of surplus honey in sections. Swarm No. 2 had 9 frames with 2 inch starters, and it filled the hive, but produced no surplus. Swarm No. 3 went to the woods. The honey was mostly basswood, buckwheat and white clover. Bees did not work on red clover or golden-rod. The prospect for an excellent crop of white clover is good for next year.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The Eastern New York Bee-Keepers' Association will hold its next meeting in conjunction with the Farmers' Institute in the Agricultural Hall, at Albany, N. Y., on Jan. 16 to 19, 1889.
THOS. PIERCE, *Pres.*

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its tenth annual convention in the City Hall at Franklin, Pa., on Wednesday and Thursday, Jan. 30 and 31, 1889. Good hotel accommodations have been secured at one dollar per day.
C. H. COON, *Sec.*

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Money in Potatoes, by Mr. Joseph Greiner. Price, 40 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Honey and Beeswax Market.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand slow, with a smaller supply than ever at this season for the past 10 years.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Jan. 9. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16@17c.; fall, 14@15c.; California 1-lbs. 16@17c.; white 2-lbs., 12@15c. Extracted, white California, 7@8c.
BEESWAX.—20c.
Jan. 7. CLEMONS, CLOON & CO., cor 4th & Walnut.

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs, 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
Jan. 8. SCHACHT & LEMCKE, 122-124 Davis St.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@12½c.—Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.
BEESWAX.—22c.
Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c. for best 1-lbs.; very fancy lots have sold at 20c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.
BEESWAX,—22c. R. A. BURNETT,
Nov. 22. 161 South Water St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5¼@5½c. For comb honey the demand is light; for extracted it is good, and market firm.
BEESWAX.—Dull at 18@22c.
Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but equal to the demand.
BEESWAX.—22@23c.
Dec. 12. M. H. HUNT, Bell Branch, Mich.

BOSTON

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The sales are good, and indications are that all the honey in the country will be sold by Feb. 1.
Dec. 27. BLAKE & RIPLEY, 57 Chatham Street.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEESWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40
Bee-Keepers' Guide	1 50	1 40
Bee-Keepers' Review	1 50	1 40
The Apiculturist	1 75	1 65
Canadian Bee Journal	2 00	1 80
Canadian Honey Producer	1 40	1 30
The 8 above-named papers	5 65	5 00
and Cook's Manual (**old edition**)	2 25	2 00
Bees and Honey (Newman)	2 00	1 75
Binder for Am. Bee Journal	1 60	1 50
Dzierzon's Bee-Book (cloth)	3 00	2 00
Root's A B C of Bee-Culture	2 25	2 10
Farmer's Account Book	4 00	2 20
Western World Guide	1 50	1 30
Heddon's book, "Success,"	1 50	1 40
A Year Among the Bees	1 75	1 50
Convention Hand-Book	1 50	1 30
Weekly Inter-Ocean	2 00	1 75
How to Propagate Fruit	1 50	1 25
History of National Society	1 50	1 25

Do not send to us for sample copies of any other papers. Send for such to the publishers of the papers you want.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2 00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for $1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and $3.00.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Jan. 26, 1889. No. 4.

EDITORIAL BUZZINGS.

Rise, for the day is passing,
And you lie dreaming on ;
The others have buckled their armor,
And forth to the fight are gone.
A place in the ranks awaits you ;
Each man has some part to play ;
The past and the future are nothing
In face of the stern to-day.

Our Review of the new book, "Langstroth Revised," is crowded out of this issue. It will appear as soon as we can find room for it.

The Bee Hive for January comes out with a colored heading, minus its cover, and the price lowered to 25 cents a year. It contains 12 pages, is published monthly, and is a spicy little periodical. It will be clubbed with the AMERICAN BEE JOURNAL for $1.20 per annum.

Dr. A. B. Mason is at work for the good of apiculture. He has already delivered two addresses this winter, and is now booked for another at a Farmers' Institute, 60 miles south of Toledo, O. He is also on the programme of the Tri-County Institute for another address at Adrian, Mich. The Doctor is a pleasant speaker, and can interest almost any audience.

Professional Bee-Men.—Judge W. H. Andrews, McKinney, Texas, on Jan. 10, 1889, desires to correct his letter as it appeared on page 12, so as to read thus: "Ninety-five per cent. of all the bees in North America, kept by professionals and their neighbors, are just mongrels." Several words were omitted by the writer, inadvertently.

Not a Late Spring.—According to the following from A. W. Greeley, Chief Signal Officer, the Weather Department apparently does not believe that the present mild weather indicates a late winter and cold spring. He says:

The significance of the unusual weather conditions for the past seven months can be explained only with reference to the abnormal distribution of atmospheric pressure over the northern hemispheres. Under the doctrine of averages we could reasonably look for an open, mild winter, since the late spring and summer was cooler than usual, and to counterbalance the deficiency of temperature in the spring and summer there should be an excess in the winter just now occurring. This, however, cannot be regarded as responsible for future prophecies, since the scientific use of average can only refer to very long periods, and cannot safely be referred to in special short periods, such as six months or a year, in case of temperature and rainfall. My personal opinion is that no one has reasonable grounds for predicting a late spring, on the simple basis of the present winter being so far mild and open.

Well Satisfied.—S. J. Church & Son, Cedar Rapids, Iowa, when sending the dues for the National Bee-Keepers' Union, make the following remarks:

My vote is for the same officers for the National Bee-Keepers' Union who have served so well since the Union has existed. I am perfectly satisfied with the management and the effective work of the Union. I think the General Manager should be paid a liberal salary for services rendered, for the labor and care are too much for the mere honor of the office.

That is natural and right, but the Union is not in a condition to pay a salary, until the expenses of the suits on hand are provided for. The present Manager never expects a salary, but his successor may do so, and it would be right and proper to pay for such services—provided the money necessary to pay it, is forthcoming.

But, alas, with a membership of only hundreds where it should be thousands, there is no chance to do anything like the work which the Union is capable of doing for the pursuit of apiculture. It ought to have 25,000 members, at least.

Did You Ever Think of the magnitude of our Query Department? Up to the end of last year we had published 600 Queries, beginning the year 1880 with No. 601. Ten thousand replies (in round numbers) have been given to the six hundred questions therein propounded. In no other way could the opinions of so many apiarists have been obtained on the topics presented for solution. This Department presents enjoyable reading matter, not only for those who ask the questions, but also for those who reply, as well as the general reader.

Dr. Tinker, of New Philadelphia, O., wrote us on Jan. 18, 1889, as follows: "The weather so far has been remarkably pleasant and mild. The bees, both in the cellar and out-of-doors, are wintering finely."

Mild Winter Weather seems to have prevailed over a large part of the world. The metropolitan daily papers report that the Londoners have bitterly complained of their Christmas—saying that they "gathered to their dinner in a thunderstorm, and walked home through mud and slush."

In many of the bays on the coast of Norway, the water has been found to be frozen at the bottom long before it froze at the top—the weather being so mild.

We are also informed that apple men in the lake counties and other sections of New York State are being subjected to no little worry through the mild weather, which has caused fruit to rot. About half a million barrels of apples, according to persons who claim to know, are stored in the Empire State, and half of these, it is feared, will go to loss.

So it seems that bee-keepers are not the only ones who have cause to complain because of the unseasonableness of the weather. They have suffered two or three years of failure of the honey crop because of bad spring weather. Now it may be their turn to rejoice while others are mourning. Nature gets *even* with us all in a lifetime.

C. O. Perrine, who boasted at the bee-convention at New Orleans, that he was "the boss adulterator of the world," now lives at Riverside, Calif., where he owns an orange-grove. Mr. A. I. Root called there while on his trip to California, and found him as usual in great prosperity.

Much More Food than usual has been consumed by the bees during the mild weather for the past two months. Care must be taken to see that they are well supplied with food, or starvation may be the result.

Mr. A. S. Goodrich, Worthington, O., has lost his wife, and when her lifeless body was lying in its casket, it was expected that he would also pass to the other shore. After five weeks of languishing he is recovering. The BEE JOURNAL extends sympathy and condolence to a bereaved and sick brother.

Abuse is Not Argument.—It does not require much intellect in order to be abusive. No sensible person will throw much mud when rocks are at hand. When an individual stoops to use epithets in a discussion, that is *prima facie* evidence that nothing better is available. "If you have no case, abuse the opposing attorney," is the motto of pettifoggers, the world over.

"What a Beautiful Winter (says Mr. John Haskins, of Empire Prairie, Mo.) we are having. It is warm most of the time, like spring. On Jan. 3, the bees were cleaning the dead bees out of the hives. I hope they will winter finely."

GLEANS OF NEWS.

Honey as a Cure for Diphtheria—As this disease is now very prevalent, and all sorts of cures, including the mopping and caustic process, are offered by well-meaning persons, it may be appropriate to state an instance where honey has been reported to have saved a man's life, when given up by his physician, and not being able to swallow even water for three days. The case is thus stated by a correspondent of the Brooklyn *Eagle:*

Some time ago diphtheria became epidemic in Warrenton, N. C., when I was paying a visit. Of course it was my luck to fall an early victim to that dread disease. I was stopping at Dr. Brownlow's Hotel, and as soon as taken sick I sent for Dr. Howard, who afterward gained a celebrity in Baltimore. He attended to me in the usual way, but I continued to grow worse, until at last he advised me to send for my friends, saying it was unnecessary for him to call again.

It was the custom of Mrs. Brownlow to come to my room every day after the Doctor took his departure and ask what he said. This particular morning when Mrs. Brownlow was told what Dr. Howard had said, she seemed surprised, and remarked:

"You are as good as two dead men yet, and if you will do what a woman advises, I have no doubt but what you will pull through."

Drowning men are apt to catch at straws, and in my serious extremity, I accepted the lady's offer with thanks. She left my room, and in about half an hour returned, holding a quart pitcher in her hands. Mrs. Brownlow approached my bed saying:

"Take a swallow."

I did as requested, and, great heavens, what a feeling I experienced. It seemed to me as if there were four hundred knives in my throat, and every one of them did its share of cutting. My case was not only a bad but a very dangerous one, and while the draught was doing its work, I turned black in the face from choking. At last the matter came up. I drew a long breath and felt relieved.

"You feel better?" said Mrs. Brownlow.

I confessed that I did, and was ugly enough to say that Dr. Howard could not attend to a yellow dog of mine. In course of time I recovered, and when able to get out, called on the Doctor to pay my bill. If my specter had stalked into that office, or if anything else horrible had happened, Dr. Howard could not have been more surprised than he was at seeing me alive, though very weak. He asked what saved me, and I answered, Mrs. Brownlow, who, in my opinion, was a better physician than he.

Mrs. Brownlow's remedy was simple, and one that is in nearly every house. Make a quart of red pepper tea, and after straining, add a tablespoonful of common salt. Then *sweeten with honey* to suit the palate, and gargle as often as possible, always keeping the tea before the fire, so as to have it lukewarm. The pepper and salt are the knives that do the cutting, and the *honey heals the wounds.* In extreme cases one dose of oil will help much at first.

Two Mistakes of the typo occur in Dr. Tinker's essay. On page 26, second column and second paragraph, the word "not" should have been inserted between the words "spaced" and "more." On page 27, and next to the last paragraph, the words "section supers" should have been "extracting supers."

"Can Bees Hear?"—Why have they voice if not for communication? Why does the queen pipe in a peculiar tone as she leaves the hive at swarming time, unless to notify the bees of her departure and locality?

Once wishing to get a bee for microscopic examination, a vial was procured, and a visit made to the cellar where the bees were being wintered. At the appearance of the light, several sleepy-looking individuals came crawling out of the hive; the vial was placed over one of them; no sooner did he find himself a prisoner than he sent forth a shrill cry of distress. Instantly dozens of fellows not at all sleepy rushed out, causing the intruder to make a hasty and undignified retreat.

That bees are indifferent to some noises, and apparently sensitive to others, is evident. It is reasonable to suppose that they hear, but that their hearing is limited to tones in certain keys. The human ear is limited in its capacity; we do not know how much of the finer music of nature is lost to us, as the coarser sounds are to bees. Probably the seeming effectiveness of the tin-pan and dinner-bell in bringing to us a swarm of these domesticated creatures, consists in our presence and evident interest in their movements.—*New York Tribune.*

Fumigating Combs.—The method which Dr. C. C. Miller described in the AMERICAN BEE JOURNAL a few months ago, is as follows:

The powdered sulphur was put in an iron kettle holding about a gallon. A common kettle holding three or four gallons was partly filled with ashes, and in this the smaller kettle containing the sulphur was placed, and over all a tin cover that did not fit closely. I suppose this cover allowed plenty of air to keep up combustion, but made it burn slower than if entirely uncovered. Previous to covering, a lighted match was laid on the sulphur, and that was all the attention it received except the watching, and no doubt it would have burned just the same if I had been a mile away.

The above will answer several questions which have lately come to hand.

Mrs. J. Hilton tells, in *Gleanings*, of her trip to California, and of the Russell Brothers' 7 tons of honey. Orange is three miles from Santa Ana, and why not call on E. Gallup and others while she was so near? Our season here was not considered first-class, yet I will report some of the yields in this vicinity. Mr. Fox had 15 tons; Mr. Miller, 15 tons; Mr. Joplin, 12 tons; Mr. Odlin, 18 tons; and the Hot Springs Apiary, 20 tons. It sold immediately at $100 per ton, or 5 cents per pound wholesale. It is now worth 6½ to 7 cents wholesale. I believe these bee-keepers above named had from 200 to 270 colonies to the apiary. How does that compare with your Eastern apiaries? Of course, we do not use any harness, or have any trouble about our bee-cellars, etc.—E. GALLUP.

The Honey Instinct.—Mrs. L. Harrison makes these observations in last week's *Prairie Farmer* on the above subject. She asks:

How do bees know when there is honey in the flowers? Is it by instinct, or are they first-rate smellers? Do gay colors attract them?

During any warm day, if I melt wax, and have the door or window open, the room will soon be alive with bees, and they will even try to get down the chimney. Dear me! let the wax run over and burn, and there will be a bee-convention in short call; or melt honey, and drop some on the stove. Is this instinct, or do they smell?

I have a plum-tree out there in the garden that never fails to produce a magnificent crop of blossoms, and is fragrant. Sometimes I am tempted to put honey on the blossoms to induce the bees to roam over them, but they know the flowers are no good, and will not produce plums, and there is no work for them to do. They cannot afford to spend their time enjoying the sweet fragrance, and hovering over the delicate white bloom, for pleasure only; they want profit.

If gay colors attract bees, then they ought to hold high carnival over a red clover field, for they could find both bright colors and fragrance. They are not like Oscar Wilde, for they pass great Russian sun-flowers that are over a foot in diameter, and hover over a flower so tiny as to be almost imperceptible. The great bright peonies of our grandmothers' day, and bleeding-hearts of our own time, are passed by for the modest white clover.

Who of our readers do not dislike to take the time in the spring and summer, when every moment is so valuable, to put sections together, paint and repair hives, etc.? All this is work that certainly should be done now, during the cold and stormy weather. Think, too, what a pleasure it will be to feel that all is in readiness for swarms, let them come as early as they will. A golden motto for any bee-keeper is, have everything ready early, and get all in readiness when it can be done with the least outlay of valuable time.—*Indiana Farmer.*

Frank Leslie's Sunday Magazine for February contains several exceedingly interesting and finely illustrated articles which attract attention. In these days of Shakespeare controversy, Mr. Archer's "What is Known About Shakespeare," with its many faithful pictures, will prove especially valuable. There are the usual installments of stories, and several beautiful poems, together with a number of copies of famous paintings, which are always to be found in this magazine.

A Father can give his young son no better present than a year's reading of the *Scientific American.* Its contents will lead the young mind in the path of thought, and if he treads there a while, he will forget frivolities, and be of some account, and if he has an inventive or mechanical turn of mind, this paper will afford him more entertainment, as well as useful information, than he can obtain elsewhere. Price, $3.00 a year, weekly.

The Bloated Bumble-Bee.

Raise the pickens for the chickens,
Raise the baby on your knee,
But never raise a rumpus
With a bloated bumble-bee.

Don't you slight him, don't you fight him,
Even on your own domain;
If you do it you will rue it
When you wrestle with the pain.

Don't you boss him, don't you cross him
When the flowers are in bloom;
If you meet him try to greet him
With respect and lots of room.

QUERIES & REPLIES.

Burning Out Honey-Kegs when They are Made.

Written for the American Bee Journal

Query 607.—Is it necessary to burn out honey-kegs by the cooper, when making them?—Michigan.

No.—MRS. L. HARRISON.

I do not know.—EUGENE SECOR.

I think not.—G. M. DOOLITTLE.

I see no reason why they should be.—WILL M. BARNUM.

No, not to burn them out.—H. D. CUTTING.

I think that it is not necessary, only convenient.—R. L. TAYLOR.

Not being a cooper, I cannot answer.—JAMES HEDDON.

This question can be more correctly answered by the cooper.—J. P. H. BROWN.

I do not know enough about keg-making. That is a question for coopers to answer.—C. C. MILLER.

No. You apt to transmit a coloring to the honey.—J. M. HAMBAUGH.

I find it to be better, especially when soft wood is used.—P. L. VIALLON.

No; and it should not be done unless they are to be waxed or paraffined before being used.—A. B. MASON.

Honey-kegs should never be charred, as the motes of coal will spoil the appearance of the honey.—DADANT & SON.

No; only to make the staves more "pliable," so as to make the kegs perfectly tight.—C. H. DIBBERN.

The cooper heats the staves in order to bend them easily, and without breaking. That much burning is necessary.—M. MAHIN.

I give it up. Ask the cooper. If you mean because of flavoring honey, it would depend some upon the wood. Generally, no.—A. J. COOK.

I think not. It is well and advisable to either give them an inside coating of wax or paraffine.—J. E. POND.

I think not. Cooperage is burned or heated, so that the staves will bend readily to form the "bulge," and close the head of the cask. The hoops may be driven closer, and the joints tighter, if the material be cold.—J. M. SHUCK.

No; but coopers usually put fire in the vessel when forcing the joints, to make tight work of it. Many years ago I made tight cooperage with or without the use of heat. Kegs or barrels charred on the inside are preferred by the manufacturers and dealers in "red liquors," but they are not fit for honey. The charred wood does no harm to the honey, except that it crumbles and mixes with the honey, especially at the sides after granulation.—G. W. DEMAREE.

The cooper heats the staves to make them pliable, and thereby get closer joints. He also "chars" the wood when making them for some kinds of liquors, but such are not fit for honey, which needs neither the color nor the flavor it imparts.—THE EDITOR.

Do Bees Store Water in the Combs?

Written for the American Bee Journal

Query 608.—In the spring water is often found in the combs—do the bees store it there, or is it a condensation?—N.

It is a condensation.—J. M. HAMBAUGH.

It is a condensation.—A. B. MASON.

It is a condensation.—M. MAHIN.

I never saw it here in the South.—P. L. VIALLON.

It is a condensation.—DADANT & SON.

It is a condensation.—JAMES HEDDON.

It is probably a condensation.—C. C. MILLER.

I think that it is found there from both causes.—R. L. TAYLOR.

It is stored by the bees.—WILL M. BARNUM.

I think that it is stored there by the bees from condensation.—H. D. CUTTING.

It may result from condensation, but more frequently from leaky hives.—J. P. H. BROWN.

It may be there from either cause, or from both causes.—J. M. SHUCK.

I think that it condenses there. I have never seen water in the cells.—A. J. COOK.

I have never seen any water in the cells that the bees did not bring.—EUGENE SECOR.

It is the result of condensation, or leaky hive-covers. Bees do not store water, pure and simple, in their combs.—G. W. DEMAREE.

It may be done in both ways. That the bees store and use water is conceded by most bee-keepers.—G. M. DOOLITTLE.

I do not think that bees store water at all; but when found, I think that it is the result of condensation. I shall hold to the above opinion until ab olute proofs to the contrary are given.—J. E. POND.

I do not know. The bees probably store some water while rearing brood, for a "rainy day."—C. H. DIBBERN.

Usually it is a condensation. Sometimes in the early spring, bees carry water on a pleasant day faster than it is used. This may be a wise provision of Nature, or a wise instinct given to the bee, to provide water in the hive for the brood, upon days too cold for storing for the bees to leave the hive.—MRS. L. HARRISON.

Water is necessary for bees when rearing brood, for dilnting the honey, or when liquefying it after being granulated. That found in the combs may have resulted from condensation, the bees may have placed it there for future use, or it may have resulted from leaky hives—at all events when there, it is convenient for use as desired. The bees often visit pump-troughs, and are eager for water, showing that it is a necessity for them, and when found in the combs it is suggestive of being *stored* there by the bees, even though the proof is wanting.—THE EDITOR.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The Northeastern Michigan Bee-Keepers' Association will hold its annual convention on Feb. 6, 1889, at the Dayton Hotel in Flint, Mich., at 10 a.m.
W. Z. HUTCHINSON, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited
G. A. WILSON, *Sec.*

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its tenth annual convention in the City Hall at Franklin, Pa., on Wednesday and Thursday, Jan. 30 and 31, 1889. Good hotel accommodations have been secured at one dollar per day.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

CORRESPONDENCE.

SEASON OF 1888.

The Hard Maples as Honey-Producers—Colors and Bees.

Written for the American Bee Journal

BY G. W. DEMAREE.

It has become a maxim that, it does no good to "cry over spilled milk." Methinks if bee-men have any enemies, as many think they have, they have had their revenge—"sweet revenge"—on account of failure of the bee-business the past year.

On account of the light rainfall during the two preceding years, I was prepared for a light honey crop last spring, and I was not deceived in my calculations. Only the very best Italian colonies gathered a surplus during the early honey harvest. I would not have taken more than enough honey for home consumption, if I had not felt "honor bound" to fill my "standing orders." As it was, I took the lightest crop of honey in all my previous experience.

After the short early flow was over, it seemed that nothing in the shape of bee-forage yielded nectar, and the light supply of stores faded away to an alarming rate. Then came on the great heated spell which lasted nearly four weeks, and my bees dwindled badly on account of the excessive heat, but by the use of shade-boards not a single comb melted down.

The "fall rains," as we bee-men call them, began about two weeks ahead of the usual time, and I felt sure that a fall harvest would be gathered by the bees. During the last week of August a "shower" of thin nectar flowed into the hives, and I visited the fields to find out the source from whence it came, and found the bees working for life and wealth on the big, coarse weed known among farmers as "horse-weed."

The blossoms of this weed are very imperfect to the unaided eye, resembling most of all the common rag-weed. I never before knew bees to get anything but a little pollen from this source. The flow lasted but a few days, and then stopped off short. The thin nectar made a big show, and started brood-rearing rapidly, and never did I see thin nectar disappear so rapidly.

The rainfall was regular and abundant through September and October, and the fall bloom exceeded anything I have seen in this locality for years; but nothing seemed to yield nectar. The weather was good, bad and indifferent, and the bees fussed over an ocean of blossoms, and tried to rob everything in sight, but all failed.

I could not give up the "smart-weed"—it had never failed before. I waited for it to get a little more aged, and waited on and on through October and into November, and hoped that the first frosts might squeeze some nectar out of it, but it was "no good." I sometimes was tempted to lay the blame on the poor bees, until I found that several colonies had actually starved in the midst of a sea of bloom.

A neighbor of mine being a mile away, moved off, and left his bees in my care, to sell them. They were mostly black bees, and I failed to find a buyer for them, and had to move them to my bee-yard. There were 17 colonies of them, and every colony of blacks starved, leaving me but 5 out of the 17 alive, and these were nearly full-blooded Italians; and yet we are told that black bees are superior comb-builders!

I spent considerable money and much valuable time several years ago to free my breeding field of all black blood, and I did not wholly succeed, but now the year 1888 has finished the job for me. There will not be a black drone within five miles of my apiary next spring, and I doubt if the stock will "save seed" in this part of Kentucky.

Hard or Sugar Maple.

Mrs. Chaddock seems to be in doubt as to whether or not this tree produces nectar. In fact she seems to decide that it does not. We must remember that very few honey-producing trees and plants keep up their reputation in all localities, in so great a country as this.

In Kentucky, sugar maple rarely ever fails to yield nectar. It is a profuse bloomer, but opens its flowers so early in the spring, that rains, and otherwise unfavorable weather is likely to be in the way of the bees.

I have often seen a shower of honey come in from this source, and have enjoyed the sight of my bees falling like leaden bullets at the entrances of the hives. The bloom is very short-lived, however, and the flow lasts but a few days, at best.

Flower Colors and Bees.

By the way, I read with much pleasure Mrs. Chaddock's articles. When she does come, she sails in among the cooing doves, and "makes the feathers fly." In fact, I begin to fear for my "reputation" as the "stinging hybrid," since Dr. Mason has "gone through" "Observer" in the *Canadian Bee Journal*, and Mrs. Chaddock has made the fur fly among the professors and scientists, on the discussion of the color of flowers in connection with honey-gathering. I am decidedly with Mrs. Chaddock, and dead against the professors and scientists.

Laying aside all romance, and all guesses, I have found by actual observation, that the richly-colored flowers, as a rule, produce very little nectar. Our best honey-yielding flowers are decidedly *modest* in color and general appearance. I have seen bees searching among grass and weeds for tiny "bits" of flowers that the ordinary observer would pass without notice.

In my opinion, and I have not arrived at it hastily, bees rely upon their instinct and industry to find nectar, more than on any organs of sight or smell that they may possess. I am quite certain that the color of the flowers has little to do with it.

BEGINNING.

A Lady's Experience in Keeping Bees.

Written for the American Bee Journal

BY MRS. B. J. LIVINGSTON.

Five years ago a swarm of bees was placed in our yard under a huge basswood tree. For five years I have groaned over them, and wished I knew what to do to help them furnish us with honey. But all I knew about bees was, that they could *sting*.

But last September I visited a friend's apiary—just a primitive affair, and thought that I caught a ray of light. I borrowed her volume of the AMERICAN BEE JOURNAL for 1887, and have found them more fascinating than a novel.

As soon as I returned home, I sent for an Italian queen, and made my first experiment with the colony, which seemed very weak and helpless. It was in an old hive of the Langstroth style. I smoked the bees down, with cobs in an old kettle, burned my dress, and found that my hands trembled so that I could hardly control them. However, I soon discovered how helpless the little things were in a smoke, and so I became very brave.

I found about four quarts of moth litter in the hive, which I cleaned thoroughly, the bees meanwhile being emptied on a sheet.

The new queen was the first one in the hive; then the stream of bees began to flow in, and I fell in love with them then and there. The renovated hive, with the old frames thoroughly overhauled, was standing on one end of the sheet, and myself on my knees watching intently for the old queen, as

the stream of bees flowed steadily on. I was an hour finding her—have her now in alcohol, as I intend to know the next queen I see!

Providence favored the ignorant, for the new queen was not molested, and in a little over a month, I examined the hive, and found the little, soft, bright-banded bees thick all over the centre combs.

The weather was very fine here during all of September and October, and I kept feeding them honey—not knowing that that was the way to start the queen to laying. I have besides my pet colony, two strong ones in boxes, and after reading a month, I sent for a colony of pure Italians. The dealer did not wedge the frames, and I found the bees badly crushed, as they came some 200 miles by rail.

The weather was so cool that I could not hunt out the queen, to see if she was safe, and I suppose that I cannot tell until spring. If she is all right, I anticipate a pleasant summer with my four fine colonies. They are in the cellar, and seem to be wintering well, as there are not a dozen dead bees to be found yet. I also anticipate great pleasure, as well as profit, from reading the AMERICAN BEE JOURNAL.

Centre Chain, Minn., Jan. 7, 1889.

FLIGHT OF BEES.

An Open Winter—Marketing the Honey Crop.

Written for the American Bee Journal

BY H. J. ROGERS.

The following item is clipped from the *Youth's Companion*, bearing the date of Jan. 3, 1889:

TRAVELLING BEES.—The distances traversed by bees in pursuit of honey are surprising to a person unfamiliar with the habits of these busy workers.

A bee-keeper one morning drenched the backs of his bees with flour, as they were leaving the hives. He did this by a preconcerted arrangement with a friend who had a fine clover field in bloom forty miles away.

The day following the experiment, he received a letter from this friend, stating, "There are plenty of your white-jacket bees here in my clover." It was truly a wonderful instinct that sent the bees so far from home in quest of honey.

We are glad to learn that this question has at last been settled. It has always been a lasting query with me, viz: How far will bees fly? In my younger days I hunted bees considerably, and, at the same time, kept a number of colonies at our home, and I am *certain* that we never caught one of our bees beyond the "two-mile limit."

Truly, this is a progressive age. What will astonish us next? We will soon have bees that will cross the Atlantic.

A Remarkable Winter.

In some respects this has been a very remarkable winter in this locality, the last thirty days being more like April than December. My bees have had several splendid flights—on Dec. 26, and Jan. 3 and 4, more especially. I now feel confident of my bees wintering well. The heavy and almost continuous rains have saturated the soil most completely, and clover will, no doubt, yield lots of nectar next season. I feel much encouraged, especially as the market will undoubtedly be ready for our crop as soon as it is stored, and at good prices.

I am wintering 76 colonies on the summer stands, and one in the cellar, a 3-frame nucleus, which came to me last September, from a neighbor's, one-fourth of a mile away.

I take great comfort in reading the AMERICAN BEE JOURNAL. It is *the best.* As long as I keep bees, and can raise a dollar, I shall continue to take it.

My crop of honey last season was very nearly 2,400 pounds, in one-pound sections. Nearly all is sold at prices ranging from 14 to 17½ cents per pound. I have shipped to Hildreth Bros. & Segelken, and T. G. Strohmeyer & Co., with satisfactory results.

Stannards Cor., N. Y., Jan. 7, 1889.

[The item from the *Youth's Companion* is too ridiculous for anything. The idea of bees going 40 miles to pasturage! That shows what foolishness is "written for the press" by the professional scribblers!—ED.]

READ AND THINK.

The Valuable Apicultural Literature of To-Day.

Written for the Alabama State Convention

BY J. M. JENKINS.

The science of apiculture has received the earnest consideration of philosophers, professors, statesmen and others, men of every station and calling in life, from the most ancient periods of history to the present day; and there have been thousands of volumes of books and periodicals published in the past relating to apiculture. But as the praetical, movable-frame hive is a modern invention (only about forty years old), its manipulation and successful use for honey-production, will be described only in the publications of the present age. For the same reason these books cover the whole ground more completely, their authors having, in addition to previous knowledge of the subject, this grand invention to aid them in their research and experiment. There are several excellent text-books of recent date and moderate price, before the public, and no one attempting to keep bees can afford to blunder along in the dark without one or more of them.

What would you think of a young man, who, no matter how lavishly endowed by nature with brains and reason, should start out without study or preparation, to make a physician of himself on praetice and experience alone? That is precisely what a great many bee-keepers (?) do! If he lives long enough, and the stock of patients, or bees, or of medicine, or money does not become exhausted, he may in time make a passable doctor or bee-keeper. But, my friends, what a long life he will need? No, we cannot afford to start at the bottom and set at naught what has required thousands of earnest, thinking men, and thousands of years to accomplish, whether in medicine, apiculture, or other problems of life.

But some one says, "I don't believe in book-farming." Very likely the same person scorns the idea of himself learning from books about bees. He will probably intimate that what he does not know about bees, "ain't worth knowing, for his pap and grandpap before him all kept bees," (but the worms got amongst 'em a few years ago, and killed 'em all out.) He will also inform you that our winters are not cold enough to kill the worms, and for that reason the South is not a good bee-country. He also relates wonderful stories of his ability to charm bees and handle them as so many flies, but fails usually to disclose his charming secret to your charmed senses.

It is not recommended that one follow the books in every minute detail, but to study the theory and the praetice, and experiments of others, and modify them to suit your own case; considering the season, your climate, the flora of your vicinity, your market, etc., thereby combining theory and practice.

I feel safe in saying that a man may learn more about bees in one year by careful study of the excellent books available, and the intelligent application and practice of his studies, than he would in twenty years without reading, relying upon his own experience and discoveries for information and success.

Life is too short to be wasted in solving mysteries that have already been solved, and in making discoveries that were given to the world through the printing press long ago. Therefore let us make a "short cut" to proficiency in bee-keeping by reading the

best bee-books we can get, and the bee-papers that are published, and at the same time study our bees, visit our neighbor bee-keepers, attend the bee-meetings, talk bees and think.

Wetumpka, Ala.

MANIPULATION

In the Apiary During the Past Season.

Written for the American Bee Journal

BY H. BRAMLET.

My report for 1888 is not very flattering. The first part was very poor, so poor that a number of colonies were in almost a starving condition right in the height of white clover bloom.

Bees built up rather slowly early in the season, but finally they became strong and commeneed swarming, a portion of which I hived on the old stands in contraeted brood-chambers, and thereby sueceeded in getting a few crates of comb honey. At the time of swarming the brood-nests were almost destitute of honey, but a nice start had been made in the boxes, and where the crates were removed from the old stand to the swarm, and none put under them, they were fairly finished; those that were raised, and an empty one put under them, were not so well finished, and but a very little honey was put into the new one, though the foundation was nicely drawn, leaving them in good shape for the fall flow.

The crates left on the hives of the colonies that had swarmed, were cleaned out and left "as dry as a chip," and the honey carried below, where it was badly needed.

The colonies from which the crates were taken, and hives removed to new stand after swarming, suffered severely—lots of brood was carried out.

On occasional evenings all along up to Aug. 10, the contented hum of the busy workers could be heard; but oftener there was the "growl of the opossum" (or the moaning of the drones for mercy).

Although the drones were being killed off all the season, brood-rearing was kept up fairly well until Aug. 15; from then until the last was the most trying time on bees that I ever saw.

September 1 found the colonies reasonably strong in field workers, but destitute of brood or honey. About this time honey began to come in freely, and the result was a nice surplus of combs, honey, and a blocked brood-nest.

The queens seemed slow to lay, or the eggs were destroyed, and after the loss of the old bees the colonies were mere nuclei.

I thought a great deal of uniting, but I could not get the full consent of my mind to do so. I had superseded all the queens that I wished to destroy, with swarm-cell queens.

At present (Jan. 7) I have 48 colonies (or nuclei) packed on the summer stands, with a great plenty of honey.

The fall flow of honey, to the north and west of here, was better and earlier than here—it was some better only 3 miles distant, and considerably so 15 and 20 miles away. On the south and east it was poorer, which I think is not usually the case.

Raleigh, Ills.

WINTERING BEES.

Successful Wintering of Bees in the Cellar and Out-Doors.

Written for the New York Convention

BY R. F. HOLTERMANN.

This subject is one as difficult as it is important—one which should receive careful attention and experimentation by bee-keepers.

As I understand the subject, it means the way to winter our bees so as to consume the least possible amount of stores, and with the least possible loss of vitality. It may not be out of place to briefly enumerate what may effect these desirable ends, and I shall largely leave it to your experience, as to how far they do effect, and how far these conditions are under our control.

1. Stores, quality, quantity, position in the hive, and if sealed or unsealed.

2. Temperature, its variations. Those variations within a given time, and how regulated.

3. Moisture and ventilation—their effects at different seasons.

4. The colony: its numerical strength, age of bees when going into winter quarters, their remaining vitality, and the strain of bees.

5. Pollen, or no pollen, in the hive.

6. The time of putting the bees into the cellars, or putting them in clamps.

7. The time to commence brood-rearing, and the time to take the bees out of winter quarters.

Proper Stores for Winter.

As to stores: In our climate there is perhaps nothing better as a food than syrup made from the best granulated sugar, and yet when we take into consideration the increased quantity of honey thrown upon the market, the unjust suspicion it gives rise to, that bee-keepers are "making honey;" the additional labor to the bee-keeper, the loss in weight between the food given and amount stored in the combs, and the certainty that through the excitement the bees lose in vitality—experience says to us, "Feed sugar syrup no more!"

I cannot say if buckwheat and other grades of honey that we know is inferior, are as good as the lighter grades for winter stores, or not. This I know, they often appear to be as good. This is a point which might be investigated to advantage. Stores should doubtless be sealed; yet in a cellar with a temperature tending to be high, this is probably not essential. The centre of the cluster should, I think, not have combs of honey, but the combs be free for the bees to cluster in, the full combs being towards its outside.

Temperature in Winter.

As to temperature, who will dare to tell us the best temperature at which to keep a cellar, if it should remain stationary all winter, or increase or decrease as the time for taking bees out approaches? Who will tell us if a rise or fall of the temperature within a few hours is injurious? Who will tell us this with certainty?

I know that bees appear to winter well with a temperature ftom 45° to 50°, and with very gradual changes; but is it the best? So many theories have been advanced, so many satisfactory results given under apparently opposite conditions, that we are loth to accept any of them as definite, and the subject must be carefully investigated with the conditions otherwise equal.

Moisture and Ventilation.

Of moisture and ventilation, I know nothing definitely, having seen bees appear to come out equally well with the cellar apparently perfectly dry, and with everything about it saturated with moisture; with sub-earth ventilation and without, with provision for ventilation and without. We must, however, remember that we may be very much deceived in this matter; at 70° there may, to the ordinary observer, be no indication of moisture, yet the atmosphere may be almost saturated so much that at 65° everything will become covered with moisture.

Again, in winter the great difference between the outside and inside temperature is very great at times, and the pressure of the cold air from without is very great upon the warmer atmosphere within, so much so that a greater or less current of atmosphere must be constantly passing in; and I often think that this explains why bees so often become very restless towards spring, when the outside and inside

temperature are more alike, and the ventilation of the cellar is lessened. The remedy, of course is, making provision to allow more fresh air into the cellar.

A Colony's Numerical Strength.

The bees themselves as to numerical strength, disposition and vitality, have doubtless much to do with the question. I believe that a colony properly prepared may winter well, even if it is not what we call an average colony. However, much depends upon the remaining vitality of the bees, if the colony has become queenless early, and they are old bees which have gone through perhaps months of anxiety on account of their queenless condition, and the owner sends off at the eleventh hour for a queen, and adds to the expense sufficient food for winter. I should say that he will probably be able to report the loss of this colony by spring, at least. I destroy such a colony, and until I have more light, I recommend others so to do; the risk is too great.

In a colony long queenless, combs almost filled with pollen are often found. These should be removed in any case. I abhor an abnormal condition of a colony during the latter part of the season, as being liable to unsuccessful wintering.

A colony which has had a vigorous queen, and has not many bees, but all young ones, has good chances for wintering. As to the age of the bees, we do not know. Probably a fully-developed, vigorous bee is sufficient; and here let us remember when comfortable, not working, and with conditions normal, the colony ages very slowly, and to count the strength of a bee by its age, is very misleading. The strain of bees doubtless will make a difference. There is no difficulty in controlling this on the female side, but practically we can, in the honey-bee, only aim at securing certain blood upon the male side.

Putting Bees in for Winter.

I cannot say anything about the pollen theory, only if it is correct, is it practical to remove all pollen from the hive? For me there is too much manipulating about it; and next, if we decide to do this, we must decide that we do not want the bees to start rearing brood until they can fly out and gather pollen, if in clamps; or if in the cellar, until they are taken out. I am by no means prepared to say this.

This brings us to the last heading, and the one upon which we have by no means the most light and definite information. Some now say, put bees into the cellar early in October, and the latest advocate says January. Theory would lead me to say, put them in before the frost can possibly penetrate the hive, and carry them in at a time when the outside temperature is, if anything, a little higher than the inside. Stimulative feeding for brood-rearing I have practiced, but I now condemn it; for spring and fall you may gain a few young bees, but you stimulate the old ones to death. Nature pretty well regulates this matter—when bees through work wear themselves out, they rear brood; when they cease working, and husband their own strength, they do not require to rear brood. As to the time we should put bees out, I do not know. I should say, when I think we have something like settled mild weather.

In conclusion, you will see there is very much which I venture only an opinion upon, and out of it all how many of us can positively say that we know this or that method is the best? And how it should speed us on to investigate, to be open to anything which might give us light, and to be ready to communicate to all others through the press what we are learning.

Brantford, Ont.

GRADING HONEY.

Importance of Grading Honey for the Market, etc.

Written for the American Bee Journal

BY MISS IDA L. SMITH.

The grading of honey for the market is a very important point in aiding to dispose of the product. To arrange it tastefully, so as to attract the eye, and to command the highest price, is the first thought or work.

In selecting over the honey it is very convenient to arrange it in three grades (and some one of the grades will suit somebody's pocket-book)—the first, second and third qualities, and each should be kept by itself.

I cannot give a description of each grade, but each apiarist will best be his own judge in the matter. None but the whitest and best sections should be used, as they aid in selling the honey, and all propolis should be removed before the honey is placed on the market.

In the spring of 1888 I removed from the cellar 13 colonies of bees; 1 was queenless, and I united it with a very weak colony, which, with two other weak ones, just built up nicely during the summer. That left me 9 colonies to work for comb honey. They were not in a very good condition, as the previous year was such a poor one.

From those 9 colonies I obtained 500 pounds of comb honey, and sold it at an average of 15 cents per pound.

Darlington, Wis.

ROBBER FLY.

Value of the Bound Volumes of the Bee Journal.

Written for the American Bee Journal

BY DANA TWINING.

I send an insect that was captured last August. It appears the last of July, and may be seen around on low land. It is not numerous in this vicinity. I once saw one on sweet clover, amid the bees, and it held one a prisoner by its strong embrace. The past season I saw one bearing away a bumble-bee. In Cook's "Manual of the Apiary," I find an engraving of a robber fly, which I suppose is the same as the one I send. Am I right?

My bees averaged 45 pounds of comb honey per colony, spring count. It is mostly fall honey, but of fine quality. I use the Armstrong hive, packed with chaff early in October, and I do not remove the packing until apple-bloom.

Cyclopedia of Bee-Literature.

I have now three volumes of the AMERICAN BEE JOURNAL bound with the "Emerson binder." To a young apiarist, with the complete index, they form an excellent cyclopedia of bee-literature.

The past season was my first experience with a laying worker. Turning to the index of Vol. XXIII, I found that topic discussed on five different pages, by as many different authors.

Then, that colony was without a queen; so I sent to a noted queen-breeder for one, and soon received her. It was my first experience with queen-introduction, so I must "read up." By referring to the same index, I found that the introduction of queens was discussed on nine different pages, and Vol. XXII has as many more.

Green Garden, Ills.

[You are right about the robber fly. The insect sent is the *Asilus Missouriensis*. It captures a bee and then consumes its fluids. When prevalent, it is very destructive.—ED.]

BEE-CELLAR.

Preparing the Bees for Cellar Wintering.

Written for the American Rural Home

BY G. M. DOOLITTLE.

To properly prepare the hives for wintering in the cellar, they should be carefully carried in on some morning when it is a little cooler outside than the temperature which is required for

the bees to fly, and never when the hives are frozen down to the bottom-boards, or to the ground, if this can possibly be helped. When the hives are thus frozen down, the jar and confusion which comes from prying them loose, results in great irritation to the bees, and causes them to consume so much honey that it often leads to unsuccessful wintering afterward.

After getting them to the cellar, the hives should be set on a bench a foot or more off the cellar bottom, and the hives raised by some means at least two inches off the bottom-board or bench. Failing to do this, the hives will not be properly ventilated, and the result will be that the bees may get uneasy from lack of ventilation, which will cause them to consume more stores than is necessary to their existence, thereby needlessly using up the honey, and often leading to disease and death.

If it is not convenient to thus place them, the hives may be turned bottom side up on the bench, and a light, thin fabric of some cotton goods thrown over the hive; still the first is much to be preferred, inasmuch as that in the latter case all the debris from the bees will fall down into the top of the hive, which is now at the bottom, and remain there for the bees to clean out in the spring, if it does not become damp and mold, as it is liable to do, thus souring that part of the honey which it comes in contact with.

I also believe that the cellar should be dark, or that part of it in which the bees are wintered. Some claim that bees will winter as well in a light cellar as a dark one, which may possibly be so, if all of the conditions for successful wintering are present, but as such conditions are usually not all of them present in many, if any cellars, it is always best to be on the safe side, hence the advice to have the cellar dark.

If the cellar is lacking in many of the qualities which go to make a good cellar for wintering bees, then it may be best not to try it at all, in which case we must try the next best plan, wintering on the summer stands packed with chaff, fine hay or straw. While a chaff hive is the preferable thing, yet it is not supposable that any old-fashioned box-hive would be made that way, so we must fix them the best way we can, which is to go to the store and procure a dry-goods box of the suitable size, or otherwise make one, in which the hive can be set, and leave room all around it for the packing.

A space of about four inches is the right amount to leave, for experience has proven that this is better than a larger or smaller amount. The bottom-board should be raised that distance above the bottom of the box, and after having packed under it, it should be secured there, and so as to touch the front side of the box also, as the bees must pass over this to get outside of the box. One-half inch above the bottom-board a thinner board should be secured in some way to both the hive and box, immediately above the entrance to the hive, so as to keep the packing material from obstructing the passage of the bees, for this is now to become the entrance to the hive.

Having this fixed, and the hive thoroughly secured to its place, we now put in the packing, pressing it in tightly, so that as even a temperature as possible can be maintained inside of the hive, packing the material in as nearly alike on all sides as possible. When the top of the hive is reached, the holes which give access to the surplus honey arrangement, should be opened, and two or three thicknesses of cotton cloth spread over these holes so as to keep the packing from rattling down into the hive, and also so that in thus providing for ventilation a direct draft shall not be allowed through the hive.

If the hive is not provided with any holes in the top of it, two or three should be bored through the top so as to give the needed ventilation. Having the holes open, and the cloth on, fill in the packing to the depth of four inches all over the top of the other packing, as well as over the hive, keeping it as evenly distributed as possible, but allowing it to be more loose and open than at the sides. The box should be tall enough so as to come an inch above the packing, so that the cover, which is now to be put on, shall not touch it. This is important, for where the packing touches the cover to the box, it will absorb the moisture which condenses on the cover to such an extent that all will become wet and moldy.

Borodino, N. Y.

STRAIGHT COMBS.

Prevention of Robbing in an Apiary, etc.

Written for the American Bee Journal

BY JOHN S. REESE.

In reading over the answers to Query 600, on page 839 of the AMERICAN BEE JOURNAL for 1888, I do not see that any of them give "B. C." a simple and positive remedy for his trouble with warping and sagging combs. As I understand it, he seems to be in the same "peck of trouble" that I have had, and as my instructor was the very best experience, I will offer it to the inexperienced, and especially the beginner.

We will take it for granted that we all use, or can use, a frame with a comb-guide, and with the comb-guide the top-bar can be made lighter, comparatively stronger, and less liable to sag, which is a serious fault in my apiary. I would suggest the use of flat-bottom comb-foundation, of medium weight, with wire made in it, perpendicular of course. I say "flat-bottom," as I *now* think that it is stronger in proportion to its weight per square foot, than any other; and I say "wire made in the foundation," as it is obvious that "B. C.," nor any one else, could get it imbedded as well as it is done when made in the start.

Now, to fasten the foundation on the comb-guide, make a form that will fit into the frame one-half through, being sure to have it fit snug and firm under the comb-guide. Lay on the foundation, with small strips of wood, say ⅛ by 3-16 of an inch, and drive small wire nails ⅝ of an inch long, slanting through the strip, foundation, comb-guide, and into the top-bar. This will make all more rigid, and hold the foundation beyond all question. These little strips will not take up much space, and I make them very rapidly on a foot-power circular saw.

This nailing foundation in frames may seem a little fussy to the veteran, but I believe that I can rip out the strips and put the foundation in 100 frames in one-half the time that it would take to wire the same number of frames, to say nothing of imbedding the wires in the foundation.

The mere fact of wires being fastened to the bottom-bar of the frame does not prevent sagging, and the only advantage that I have found in having the frames wired is, to hold the comb more securely to the bottom-bar when handling the brood-frames; and the day is fast approaching when brood-frames will be handled very little—not enough to justify the expense and trouble of wiring frames.

Robbing Checked Instantly and Positively.

From the number of inquiries and remedies offered, robbing still seems to be quite a bug-bear to many. My apiary is crowded into a very limited space, and I was much troubled until I discovered the plan of using wire cones at the hive-entrance, arranged with a small hole in the apex, and pointing out from the hive, which would allow the bees and robbers and all to pass out, but would allow none to pass in, until the trap was removed, which should be done at night, when the robbers would be at their respective homes; and the bees that could

not get into their homes during the day, on account of the cones, will then gladly enter, and prepare for a vigorous defense for the next day.

These cones are very easily made, and are from 2 to 3 inches long, and one or more are tacked over one-inch auger-holes, made in a thin strip of wood, as long as the entrance, about 1½ inches wide.

A few of these strips with cones can be kept conveniently near, and will be found useful in other ways, such as preventing swarms from entering some hive that you do not wish them to enter, etc.

Bees Swarming Out.

The first fine days next spring, look out for weak colonies to swarm out, and do not forget that prevention is very simple, by placing a piece of perforated zinc at the entrance of the hives of all the weak colonies.

Last season, a swarm, after being hived in good condition, took a notion to desert, and as I was on hand at the time, with a piece of perforated-zinc, which I got over the hive-entrance before the queen had gotten out, of course the bees returned, and the next day they tried it over again, with the "laugh" still on my side.

Winchester, Ky.

SWEET CLOVER.

Its Honey-Value in the Region of Salt Lake City.

Written for Gleanings in Bee-Culture

BY J. C. SWANER.

Sweet clover grows here along the water-courses, moist waste places, along the roadsides, and in neglected fields. It grows from six inches to as many feet in height, according to the location, and it is covered with an abundance of bloom from top to bottom, yielding in most seasons an abundance of nectar, which, after being gathered and stored, produces honey of the very best quality and color. It does not generally bloom in the first year; but in the second it commences about the first of July, and keeps up a continual bloom until killed by frost, furnishing bees with pasturage, generally from the middle of July until the latter part of August.

Sweet clover is sometimes used for pasturage, and also for making hay, if cut when young, though it is a long way behind alfalfa for that purpose. Though it is sometimes relished by stock, very few would sow it for feeding. If eaten while green, it is in a measure a cause of hoven, or bloat, in cows. If you wish good milk or butter you had better not feed it to milch cows, as it imparts a very disagreeable taste to it. If eaten off by stock it will soon recover, and produce an abundance of bloom for the bees.

It is a very fair fertilizer; and it is also claimed that; if planted on alkali land, it will feed on the alkali and exhaust it, besides bringing to the surface, with its long roots, elements necessary to plant-life.

As sweet clover is biennial, it is not a very hard weed to eradicate, and very seldom troubles cultivated fields, though it will sometimes seed a field; and if such field is planted to grain the following season, it will come up, and is cut off only with the reaper. Next season, if the same field be neglected, it will quite likely be covered with sweet clover, and that, too, sometimes as high as your head. If a field is

Sweet Clover.

cultivated as it should be for two seasons, the clover will entirely disappear. The plant requires a little moisture in the soil the first year; but after that it will grow without. I consider it, for my part, a great deal better to see a roadside lined with it than the sunflowers, etc., that generally grow in such places.

Now, to sum up, sweet clover is our main honey crop in this locality. It is our best honey; and that honey, I may say without boasting, compares favorably with the best grades known.

I do not think it will pay to sow it for honey alone, unless on such land as is considered worthless; but I think it would be a benefit to such land.

As to the amount of nectar it will produce per acre, I am unable to say; but I think it will compare favorably with white clover; in fact, it produces fully two-thirds of our honey crop in this locality, and I should consider this a poor country for honey, if it were destroyed; but as it is, we generally get a crop; that is, the bees generally have some honey to spare.

Salt Lake City, Utah.

Mr. Root adds: "Mr. Swaner has been quite careful and conscientious in giving the objectionable features of sweet clover in the region of Salt Lake City, as well as the good qualities. In that locality there are a very few plants that will stand the fierce drouth of summer; but sweet clover seems to be one of them, and it might be easily grown on thousands of acres that now bear nothing but weeds of no value. Much of this desert land is so light that it is very easily prepared for a seed-bed. After sweet clover has once got a start, it furnishes about as permanent bee-pasturage as anything I have ever found. In fact, I could not find any of the bee-keepers around Salt Lake City or Ogden who say they ever have seasons of no honey at all, such as we have had here several times during the past twenty years. Not only does sweet clover yield honey, but, after testing it in a good many places, I pronounced it equal in appearance and flavor to any honey we have in the world.

"The first time I tasted it at friend Woodmanse's I uttered an exclamation of surprise, and asked him what was the source of the beautiful honey. Even before he spoke, there seemed something familiar in the delicate flavor; and when he said sweet clover, I recognized it as plainly as if it were but a piece of stalk in my mouth. It tastes very much as sweet clover smells when its green leaves are bruised slightly. The flavor is not rank enough to be at all disagreeable. The extracted honey is very thick, and has the same beautiful flavor as the comb honey. It seems to me that these facts give us a wonderful opening for starting a honey-farm where land is cheap, and nothing else will grow on account of the long severe drouths."

[Sweet clover possesses this advantage, that while it comes into bloom late, with the fall flowers, it produces nice, thick honey which is second to none as to quality and flavor. Let all who have waste land sow it for the honey which it so bountifully yields. The seed can be obtained at this office, in any quantity.—ED.]

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Jan. 30, 31.—N.E.O..N.Pa.& W. N.Y., at Franklin, Pa.
C. H. Coon, Sec., New Lyme, Ohio.

Feb. 6.—Northeastern Michigan, at Flint, Mich.
W. Z. Hutchinson, Sec., Flint, Mich.

Feb. 7.—Wisconsin State, at Madison, Wis.
C. A. Hatch, Pres., Ithaca, Wis.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

The Winter in Austria.—Alex. Schroeder, Jr., of Trieste, Austria, on Dec. 27, 1888, writes:

We had splendid weather in December up to the 22d, when rains and fogs set in. My bees were flying busily on the Nespola Japonica and the watering place. I hope that they will go through the winter all right, though I do not like *too* mild winters, with occasional frosts.

Mysterious Carelessness.—Mr. L. Eastwood, Waterville, O., on Jan. 7, 1889, writes:

Years ago bee-keeping was full of mysteries, but one modern mystery remains unsolved, and that is, the carelessness of bee-keepers of their own interests, by remaining out of the Bee Keepers' Union. It is a pleasure to belong to a society where men are equal, and covetousness unknown; there the strong are willing to help the weak without, and where there is no danger of retroactive salary-grabbing. It may be asking too much of our good friends, the officers, but while they are doing so well, I do not want to see any change. It is a bad time to "swap horses while fording a stream," and we are not yet over the dark waters of Prejudice and Ignorance.

White Clover Looks Promising.—Frank Coverdale, Welton, Iowa, on Jan. 10, 1889, says:

My bees are in the cellar, and thus far they are wintering well. They are very quiet, with no signs of disease yet, with the temperature at 42° to 44°. The first snow-storm of any account fell yesterday and day before, to the depth of about 5 inches. I was glad to see the ground covered. It will help to save the clover, which is now in a promising condition. The AMERICAN BEE JOURNAL is superior to all other bee-papers.

Heart's-Ease Honey, etc.—S. G. Palmer, Tobias, Nebr., on Jan. 9, 1889, says:

I am a beginner in bee-keeping, and I have 13 colonies of bees in chaff hives. They are wintering finely, having a flight every few days. I gave each colony 25 pounds of honey for winter. The crop of honey was light here the past season. We have to depend upon heart's-ease for our honey here, which lasted only about twelve days. It gives a good quality of light, thick honey.

Buckwheat and Fall Flowers.—Mrs. O. F. Jackson, Sigourney, Iowa, on Jan. 12, 1889, says:

White clover honey was quite scarce here the past season, and most of our honey was gathered from buckwheat and fall flowers, but it was excellent quality. The bees filled the brood-chambers, and gave some surplus in the sections. We have honey for our buckwheat cakes, and I have sold enough to pay all expenses of the past season. I did not have to feed any of my colonies for winter, as I took frames of honey from strong colonies, and gave them to late swarms. I feel quite hopeful of their safe wintering, when they have an abundance of natural stores.

Hybridizing Bees.—C. Gardiner, Lyn, Ont., on Jan. 8, 1889, asks the following questions:

1. Having 100 colonies of brown Germans, would crossing the queens with selected Italian drones improve them as honey-gatherers? 2. If an improvement, could drones be purchased by the pound from selected stock? 3. Would drones be accepted, or could they be united, and be all right in the hives? 4. What would drones be worth by the pound?

By request, Mr. James Heddon replies to the above as follows:

1. No better bees can be produced than by crossing your brown German queens with just the right kind or strain of Italians.

2. I do not know what to say about the practicability of buying drones. My way always was, and I guess always will be, to buy the Italian queens and keep them at work in drone-comb, getting my drones in that way.

Valuable.—W. M. Rowe, Lawrence, Kans., on Jan. 14, 1889, writes:

I wish to congratulate the Editor on the improvements made in the AMERICAN BEE JOURNAL. It grows better and more interesting with each issue. The number for Jan. 12, 1889, alone, is worth the price of a year's subscription. Success to it.

Bees Did Very Well.—O. P. Miner, Cincinnatus, N. Y., on Jan. 8, 1889, writes:

I had 10 colonies in the spring of 1888, which I increased to 16, and took 370 pounds of comb honey. One colony that did not swarm stored 97 pounds. Considering the poor season, with scarcely any yield from basswood, I think that this is doing very well. My surplus was obtained principally from white and Alsike clover, with some from milk-weed. My bees have done better than the average in this locality. On Dec. 26, and two or three succeeding days, the bees had good flights, and appeared to be in a healthy condition.

Double-Walled Hives, etc.—Mr. Daniel Wyss, New Philadelphia, Ohio, on Jan. 13, 1889, writes:

I have read the AMERICAN BEE JOURNAL with great pleasure since June, 1886. I read quite a number of papers, but no other gives me more pleasure than it does. I have 14 colonies of bees in splendid condition, packed on the summer stands, in hives of my own manufacture. The hives consists of Simplicity frames, lower story and bottom double, with chaff filled between the walls. On this I have four boards 8 inches wide, nailed together like a box without a bottom; this fits on the main hive, and answers as a receptacle for a super, or section-crate in the summer, and for packing material in the winter. On top of the brood-nest I lay one or two thicknesses of burlap, and on top of that I put about a bushel of fine wood shavings; such as is made when sawing out sections. To complete the work, I put a chaff cushion, 4 or 5 inches thick, on the other packing material; and a roof or cover finishes the hive. This hive suits me. My bees had a nice flight yesterday.

Poor Stores for Winter.—S. J. Church, Cedar Rapids, Iowa, on Jan. 12, 1889, says:

My 59 colonies of bees were put into the cellar on Dec. 1, 1888, and so far they are wintering first rate. They stored 200 pounds of comb honey, and 400 pounds of extracted, all being fall honey except 100 pounds from linden. Last winter and spring I lost two-thirds of the bees, leaving 37 weak colonies to commence with on June 1. I think that the cause of loss was poor stores for winter food.

Maine Bee-Keepers.—Mr. L. F. Abbott, editor of the Lewiston *Journal* writes as follows:

In the face of one of the poorest honey seasons for 25 years, the Maine bee-keepers are as hopeful and enthusiastic as ever. It is useless to be discouraged over a failure now and then. It is better far to keep right on in the even tenor of our way, and as far as possible avert the results of poor seasons by good management. How to do this, the AMERICAN BEE JOURNAL is showing most admirably, and I hope that the editor may long continue in the good work, and be well paid for it, too.

Honey-Vinegar—Hoarhound.—J. H. Brown, Prescott, Ariz., on Jan. 1, 1889, writes:

Please answer the following: 1. How long will bees prosper without new stock from a distance? 2. Will vinegar made of honey keep without change, if bottled up air-tight? I secured about a ton of honey this year, and about the same last year, from about 40 colonies, spring count, most of it being dark honey. Of all the plants we have sowed here, nothing will grow but hoarhound, and if anything would grow that cattle would eat, it would do us no good as a honey-plant.

[1. For an unlimited time.

2. As honey-vinegar is made by the combined action of heat and air, it must not be corked up tight—it needs air.—ED.]

Bees had Frequent Flights.—F. H. McDonald, Star, Idaho, on Jan. 2, 1889, writes:

I had 9 colonies of bees last spring, which I increased to 23, by natural swarming. I obtained about 300 pounds of honey, and sold 200 pounds at 20 cents per pound. Bees got plenty of honey for winter stores. They have flown on almost every day until two weeks ago, when the ground froze 4 inches deep, with just snow enough to cover the ground. It is clear and pleasant through the day. This morning it was the coldest—the mercury being at zero.

Good Honey-Flow from Buckwheat.—G. D. Schell, Barron Lake, Mich., on Dec. 8t, 1888, writes:

We hear from every part of the country, that bee-keeping does not pay, but my bees have paid expenses, with a small balance over. I took from the bee-cellar on April 15, 1888, 82 colonies in Langstroth hives in fair condition, but the cold and rainy weather for ten or twelve days, reduced the number to 69 colonies, that I built up during apple-bloom, which was the best we have had for years. The hives were running over with bees, eager for the basswood harvest, which was a total failure, and to my dismay the white clover was mostly winter-killed; so with millions of bees, and nothing to do, the future looked discouraging until the buckwheat bloomed. My, but didn't the bees hustle then? Everything was soon running over with the best of buckwheat honey. I got over 1,000 pounds of it, and increased my apiary to 83 colonies, which were put into the cellar with plenty of stores, but light in bees. They are wintering nicely so far.

Splendid Weather for Bees.—Chas. E. Dow, Lawrence, Mass., on Jan. 8, 1889, says:

We are having splendid weather. There is no snow on the ground, and the river is free from ice. Inside of two weeks there have been six days that my bees have had good flights.

Poor Locality for Bees.—Isaac Darling, Steuben, Ohio, on Jan. 14, 1889, writes:

My bees for the past four years have not paid more than 7 per cent. on the capital invested, to say nothing of the time that I have spent with them. I have come to the conclusion that this locality is a poor one for bees, and unless I can do better this year, I think I will try and dispose of them.

Warm Winter So Far.—Mr. P. J. Bates, White Hall, Ills., on Jan. 16, 1889, says:

So far this winter we have had unusually high temperature—the first ten days of January the mean temperature being 30° above zero. In 1888 the mean temperature was a little over 12°; in 1887, a little over 3°. So far this has been a very favorable winter on the bees in this section of the country, as the most of them went into wioter quarters rather short of stores. They have been quiet, and I am in hopes that they will come through all right.

Cider Stores and Bee-Diarrhea.—Joseph Funk, Beach City, O., on Jan. 11, 1889, writes:

Some of my bees are in bad condition. They got into some boiled-down cider that was almost like molasses. There was nearly a colony of bees in it before I noticed it. I dipped out the bees and spread them on the grass, and they carried so much of the cider into their hive that they now have the diarrhea very badly. What can I do to remedy it? They crawl out of the hive on the floor, and die by the quart daily. My honey crop was so short, and the bees swarmed so late, that 6 colonies did not build combs enough to cluster on, and they starved before cold weather came. I fear they will all dwindle away before they can get new honey in the spring. After July 1, they did not gather enough to live on. The last two seasons were the poorest that I have seen for 50 years. I kept bees for 47 years in succession, using the box-hives until four years ago, when I commenced to use the movable-frame hives. I will have a nice lot of bees for next season, if they do not succumb this winter.

[The bees only need a chance to fly and cleanse themselves. This they can have on any warm day, if they are on the summer stands. If they are in the cellar, they can be taken out and given a flight. Should there be no day suitable for this very soon, you can take the hive into a light, warm room, put a square frame of netting over it, and let the bees fly, permitting the temperature to run down, when the bees will cluster again on the frames, and the hive can be returned to its place. The latter may not pay for the trouble, unless the queens are valuable, or the affected colonies very few and choice.—ED.]

The Union.—James A. Nelson, Muncie, Kans., on Jan. 9, 1889, when sending his dues to the Manager, writes as follows:

I suppose I have lost my vote for officers, but I expect my choice will be elected, viz: all of the old officers. They do as well as could be expected, as well as any one could do, and much better than some would do. I hope nothing may happen to cause the Manager to resign. I trust that the Union may prosper, even if the members are few in proportion to the number of bee-keepers who should belong to it.

[Yes; the old officers were all re-elected. It is surpassing strange that thousands do not flock to the support of the Union. It certainly is their *duty* to sustain an organization created and managed to sustain their rights.—ED.]

Value of Old Combs.—G. H. Ashby, Albion, N. Y., on Jan. 17, 1889, on the relative value of combs and comb foundation, remarks as follows:

For bee-keepers to melt up good combs and use comb foundation, seems to me to be ruinous. Combs for extracting improve with age, for several years, when well cared for, as they grow tougher, and are not as liable to break in handling. If on melting combs you get one-half as many sheets of foundation as you had combs, you would do well. Combs can be kept clean and nice easier than they can be cut out of frames, to say nothing of melting and making foundation. Three cents worth of brimstone, and a very little time, will keep the moth from a thousand frames of comb. All the surplus we obtained in these parts this season was from drawn combs, in sections or extracting combs. It was obtained before June 25, and not a particle of foundation was drawn out in the brood-chamber or surplus case. Where would we have been had we destroyed our combs!

What time of the year should sweet clover seed be scattered in waste places, to obtain the best results?

[It can be sown at any time, and if scattered upon the snow and allowed to sink down into the ground when the thaw comes, it will germinate and prosper. It does not bloom until the second season.—ED.]

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

Do not send to us for sample copies of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

Honey and Beeswax Market.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.
Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but about equal to the demand. Market will be bare of comb honey long before the new crop is ready.
BEESWAX.—22@23c.
Jan. 18. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 14@15c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 18@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 18. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX.—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand slow, with a smaller supply than ever at this season for the past 10 years.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Jan. 9. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16@17c.; fall, 14@15c.; California 1-lbs. 16@17c.; white 2-lbs., 12@15c. Extracted, white California, 7@8c.
BEESWAX.—20c.
Jan. 7. CLEMONS, CLOON & CO., cor 4th & Walnut.

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs, 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs, 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
Jan. 8. SCHACHT & LEMCKE, 122-124 Davis St.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2 00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for $1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and $3.00.

Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Feb. 2, 1889. No. 5.

EDITORIAL BUZZINGS.

Love is the impulse which directs the world,
And all things know it and obey its power.
Man, in the maelstrom of his passions whirled;
The *bee*, that takes the pollen to the flower.

The Bee-Keepers' Advance and Poultryman's Journal for January is on our desk. It is in new form—two columns on a page, and contains 32 pages. It is well printed and edited. We congratulate Bro. Mason on its appearance.

A Correspondent desires us to state the price of the *Australasian Bee Journal*, and the address of the publisher. It is a sixteen-page monthly edited by I. Hopkins, and published by Hopkins, Hayr & Co., Auckland, New Zealand. With postage it will take $2.00 a year to get it.

The Apiary of Mr. H. J. Rogers, of Stannards' Corners, N. Y., is on our desk. It shows about 80 hives, and was taken in summer, when the trees were clothed with leaves, the apiarist was at work in his shirt-sleeves, and his family were out with bare heads watching his movements and enjoying the balmy air. It is placed in our Museum Album.

The Number and Names of the new States shortly to be admitted into the Union, is the subject of every one's thoughts, and Ausburn Towner, on "Our Would-be States," in *Frank Leslie's Popular Monthly* for February, gives us much valuable information about Dakota, Montana, Idaho, Wyoming, Washington, Arizona and New Mexico. The stories of the number are excellent, and the illustrations beautiful.

When D. A. Jones and Frank Benton were looking for the Syrian bees, they told us of some of their very interesting experiences in trying to bring hives of bees from Jerusalem to Joppa, there to take a boat for Europe. They had to hire natives to carry the hives of bees (in clay cylinders) on their shoulders over that rocky and mountainous route, beset with dangers, etc. The donkey and camel drivers had it all their own way then. Now, we see by the news from Europe that "the Sultan has just granted a concession (charter) for the building of a railway from Joppa (or Jaffa) to Jerusalem. This will do away with the most disagreeable portion of the route for western visitors to the city of Jerusalem, and the land of Palestine.

Progress is the order of the day. Mr. W. Z. Hutchinson thus discusses in the *Review* the progress of the present, and compares it with the methods of apiculture in the past:

But it is a pleasure to note that the fixtures and methods of to-day are superior even to those of half a dozen years ago. In this matter of sections and their management, we have most emphatically discarded the plan of putting them on the hives and taking them off one at a time; a few bee-keepers still manipulate them by the wide frame full; but the majority of bee-keepers have adopted some sort of a case or super by means of which 25 or 30 sections can be handled at one time quicker than a wink; and "tiering-up" may be practiced. The old, cumbersome, complicated, laborious, side-storing system is, practically, laid upon the shelf. We feel like taking it for granted that "top-storing" and "tiering-up" with some kind of a case, crate or rack, furnish the best method now known for securing comb honey; that it is the only plan that enables us to handle a "honey shower" with perfect ease, "rattling" the sections on and off the hives in a rapid, business-like way.

The Apiarist who is careful, intelligent and painstaking will succeed, while the negligent and careless bee-keeper will sooner or later fail. Mr. G. M. Doolittle, in the *Rural Home*, makes the following statement, which we would thoroughly endorse and commend to the careful consideration of all:

If any person expects to realize a large income from his bees and never look after their condition (simply hive them and put on the sections), he will find himself greatly mistaken. How many that read this know the exact condition of their bees at all times? If you do not, my friend, you are not caring for them as well as you would for your horse or cow, neither can you expect any more profit from them than you would from a cow or horse if you never looked after them. Bee-keeping only pays when our pets are properly looked after, and if any one cannot spend the amount of time on them which they require, he had better keep out of the business, for sooner or later he will turn away from it in disgust.

The Horticultural Society for Lucas County, Ohio, has elected Dr. A. B. Mason as its President for the coming year. He will fill the office with honor to the society.

Winter Work should now be attended to. It is no time to fold your hands and dream of the future. Concerning the work which should now be given attention, Mr. C. H. Dibbern remarks as follows in the *Western Plowman*:

This is the time to do some heavy thinking and studying. A good deal of work can also be done now in the work-shop, making hives, cases, and other fixtures that will be needed next summer. Sections can be put together, foundation put in them, and placed in cases ready to go on the hives. These are generally found very handy when the busy time comes. It is also a good time to look back over the past season's operations, and determine wherein we can improve in the future.

Increasing an Apiary.—Jacob H. Warner, Middleburg, N. Y., on Jan. 16, 1889, asks for advice on increasing his apiary:

I am a middle-aged man, with declining health. I have owned a few colonies of bees for the last year, and I thought that it paid me fairly, and I would like to own a larger stock. Some have advised me to send to the South, and get a few nuclei. Others think that it is best to buy the native bees. Do you think that it is best to increase my apiary from the colonies I have? Which of the three ways would you advise me to take?

The safest plan will be to increase the colonies you have, and if they are black bees, buy some Italian queens and introduce them. This will give you experience as well as increase.

The British Bee Journal is now publishing articles on queen rearing by Henry Alley, simultaneously with their appearance in the *Apiculturist*. Dr. C. C. Miller, and his methods, are also receiving illustrated attention in that paper. Americans are now "having their day" in our British cotemporary. British honey imports during December, 1888, amounted to 3,033 pounds.

Catalogues for 1889 are on our desk from—

A. D. Cozad, Kremis, Pa.—4 pages—Bee-Keepers' Supplies and Plants.

Cole's Garden, Farm and Flower Seeds, Pella, Iowa—50 pages—Seeds, Garden Tools, etc.

Landreth's Vegetable Garden Seeds—50 pages—Kitchen Garden Calendar, Price List, etc., Philadelphia, Pa.

F. E. Myers & Bro., Ashland, O.—Poster and Calendar—Myers Pumps and Hay Tools.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

BOOK REVIEW.

Langstroth on the Hive and Honey-Bee, revised, enlarged, and completed by Chas. Dadant & Son. This is the title of the new edition of the Langstroth book, just published by Dadant & Son, at Hamilton, Ills.

The first edition of Mr. Langstroth's work was published in 1853. The last revision was made in 1859, and now after 30 years, during which time more has been done to make bee-culture thoroughly practical than in a century previously, another revision has become necessary, and we are glad to know that it has been done so thoroughly by those eminently practical apiarists, Messrs. Charles Dadant & Son. Former editions have sold rapidly, and so will the present one. It is beautifully printed, embellished with 18 full-page plates, and 197 engravings, forming a handsome volume of over 500 pages.

The first chapter is devoted to the "Physiology of the Honey-Bee," and covers the entire subject in a very interesting and instructive manner. On the matter of "color and odor" as a means of attracting bees, it avers that both attract the bees, but contends that "the smell of honey is certainly the main attraction." It asserts that "this attraction is so powerful, that frequently at day-break in the summer, the bees will be found in full flight, gathering the honey which has been secreted in the night, when nothing on the preceding evening could have predicted such a crop; this happens especially when there is a production of honey-dew after a storm."

The antennæ, its nerve structures, hairs, etc., are illustrated, and the same view is taken as in Cheshire's work, viz: that both the organs of hearing and smelling are found in the antennæ—the one being called the "smell-hollows," and the other the "ear-holes." Our author claims that they can smell honey a mile away. To remove the antennæ, therefore, is to deprive bees of their intellect.

Chapter II treats of wax, propolis, etc.; Chapter III of honey, pollen, etc.; and Chapter IV of bee-hives. Here are illustrated and described many of the hives in use from the earthen hives of Africa to the movable-frame hives of America; including the straw hives of Europe, and the observing hives for exhibitions.

Chapter V treats of the popular management of bees, and the aids thereto, such as smokers, veils, etc. The stinging propensities of bees, and the remedies for the poison when injected into the human system, are also described in this chapter.

Swarming and Dividing occupy the sixth and seventh Chapters. Full and explicit directions are given for the complete and economic management of the apiary during the very important period of swarming. The making of nuclei is considered, and this leads us to queen-rearing, to which Chapter VIII is devoted.

On the races of bees, Chapter IX gives the history of their introduction into America; the different varieties are described, and the preference is given to the Italians, in these words:

"The great superiority of this race over any other race known, is now universally acknowledged; for it has victoriously stood the test of practical bee-keepers, side by side with the common bees. The ultimate superseding of the common bee by the Italians, in this country, is but a matter of time."

Chapter X treats of the location of the apiary, the transferring of bees to movable-comb hives; the construction and use of honey-houses, etc., while the "Shipping and Transporting of Bees" is the subject-matter of Chapter XI.

When, What, and How to Feed Bees occupy Chapter XII. Then follow Chapters devoted to Wintering, Robbing, Comb Foundation, Pasturage and Overstocking, Comb and Extracted Honey, Diseases of Bees, Enemies of Bees, etc.

Chapter XX is devoted to the Handling and Marketing of Honey, and its uses for both food and medicine. It is claimed, and very rightly too, that during the past few years the increase of honey-production has been such that the "consumption has barely kept pace with it." The revisers also take this hopeful view of the situation: "But it will soon take its rank among necessities, like butter or syrups, and change from a luxury to a staple."

Happily for honey-producers the day for adulteration is past, and on page 484 we read this characteristic paragraph:

"The present low prices have put an end to adulteration, for a fair grade of....honey can now be bought as cheaply at wholesale as the vile, unhealthy compound, adorned with the names of golden syrup, golden drip, etc."

The authors then poke a little fun at the ridiculous *canards* about "the Wiley lie, concerning the manufacture of comb honey by machinery," and of adulterating liquid honey with glucose, which will cost at wholesale more than the honey sought to be adulterated. They sarcastically say, on page 480, that it is more likely that glucose will be adulterated with honey, than the opposite!

On page 493 a quotation is given from our pamphlet on "Honey as Food and Medicine," concerning the value of honey as a means of building up wasted tissues, and brightening the intellect, and then our authors remark thus: "These words are so true that we have found them translated in European books, by noted apiarists." Then follows a number of useful receipts for honey comestibles and medicines.

"Beeswax and its Uses" being the title of Chapter XXI, directions are given for the production of beeswax, and the many uses for it are enumerated, and receipts given for salves, mixtures, etc.

The last two chapters are devoted to "Bees, Fruits and Flowers," and "Bee-Keepers' Calendar, Mistakes and Axioms." In the former is shown the great value of bees to fruit trees, in fructifying the flowers and increasing the quantity and quality of the fruit.

It also endorses the work of the "National Bee-Keepers' Union," and adds: "Some such association is as necessary to bee-keepers as are Trades-Unions to any group of laborers—"United we stand; divided we fall."

One peculiarity of this excellent book is very rare and well worth metioning. It not only has a copious Index at the end, but a "Table of Contents" at the beginning, referring to the various subjects by bold-face figures (thus **687**) corresponding to similar figures in the body of the work (thus **719**), by means of which one may find any item desired (**687**) in an instant.

By means of these figures the reader is carried from one portion of the book to another, and enabled to "take in" all that is said upon that subject without losing interest therein, or consuming time to find the different matters referred to—making it as *interesting* as a novel; and at the same time as *concise* as historical adventures, and as *complete* and *perfect* as a book of laws.

Take it all in all, this book (Langstroth Revised) is a treasure-house of precious gems—as *vast* as the pursuit, and as *valuable* to apiarists generally as the hoarded wealth of an empire to its patriots and statesmen!

We can furnish this book by return mail for $2.00, the publishers' price. This book and the AMERICAN BEE JOURNAL for one year for $2.75, if sent direct to this office.

We have Received many nice notices of the AMERICAN BEE JOURNAL during the past few weeks, but the following are unique and racy:

Every one in any way interested in bees and the production of honey should have the AMERICAN BEE JOURNAL. It is law and gospel on these subjects, stable as the hills, right up to the times, and only one dollar a year.—*Journal, Lewiston, Maine.*

The AMERICAN BEE JOURNAL is published weekly, and is original. It is oftener quoted, perhaps, than any other authority, and its testimony is reliable. Good bee-keepers should subscribe for it if they want to keep posted on their business.—*Colorado Farmer.*

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The Northeastern Michigan Bee-Keepers' Association will hold its annual convention on Feb. 6, 1889, at the Dayton Hotel in Flint, Mich., at 10 a.m.
W. Z. HUTCHINSON, *Sec.*

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its tenth annual convention in the City Hall at Franklin, Pa., on Wednesday and Thursday, Jan. 30 and 31, 1889. Good hotel accommodations have been secured at one dollar per day.
C. H. COON, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

QUERIES AND REPLIES.

The Highest Temperature Endurable by Bees.

Written for the American Bee Journal

Query 609.—How high a temperature of heat will bees endure, and live?—Michigan.

I do not know.—JAMES HEDDON.

I do not know.—H. D. CUTTING.

I do not know.—EUGENE SECOR.

I do not know.—J. M. HAMBAUGH.

I do not know.—A. B. MASON.

I do not know.—WILL M. BARNUM.

I do not know.—M. MAHIN.

I do not know. Who can tell?—P. L. VIALLON.

There is no practical utility to that question. Next.—MRS. L. HARRISON.

I do not know. I presume that it might differ.—A. J. COOK.

Over 100°, Fahr. Beyond this I have never experimented.—J. P. H. BROWN.

They would succumb at about the point where the wax would melt.—C. H. DIBBERN.

Mine have stood nearly 100°. I do not know how much more they would stand.—C. C. MILLER.

I have known them to stand 115° with no harm, and I suppose that they could live in a higher temperature, but I do not know how high.—G. M. DOOLITTLE.

I do not know. They will stand immersion in syrup nearly boiling hot, and seem happy. You do not want to roast any, do you?—J. M. SHUCK.

I do not know. The temperature should always be kept below the melting point of the combs, else they will break down from the heat, and thus ruin the colony.—J. E. POND.

That depends upon how long they are subjected to the heat, upon their opportunity to get fresh air, and upon how long an existence you would require to call it "living."—R. L. TAYLOR.

The question is too indefinite to be answered directly. A temperature of 180°, in my solar wax-extractor will kill a bee in a twinkle; 160° will kill, but not instantly. I have never tested these matters as an experiment—I only answer as to what I have seen in a practical way. I am satisfied that bees suffer less of vitality when the temperature goes above 100° in the shade. My bees usually "dwindle" during an exceedingly hot spell in the latter part of the summer.—G. W. DEMAREE.

Natural yellow wax melts at from 142° to 145°, Fahr., but it can be molded by pressure at a temperature of about 100°. At the point where combs would melt, the bees become *useless*, and would die in the "general wreck" or ruin of the interior of the hive. They may endure a few more degrees of heat, and still show animation, and if that is the information desired by the querist, then we would say that the bees *may* endure about 150° "and live."—THE EDITOR.

The Best Method of Getting Increase.

Written for the American Bee Journal

Query 610.—1. I have 20 colonies of Italian bees in double-walled chaff hives, all strong and in splendid condition, with all the hives full of honey. I wish to increase them to 40 colonies during the coming season, and in order to get the most surplus honey will it be best to let them swarm, or divide them early in the spring, say about the last of April or the first of May? 2. Will it be to the best advantage to furnish them with queens, or let them rear their own queen-cells?—Illinois.

Let them swarm, and rear their own queens.—A. J. COOK.

1. Let them swarm. 2. Furnish the queens.—H. D. CUTTING.

1. Let them swarm. 2. Let them rear their own.—R. L. TAYLOR.

Rear queens early, and make swarms by dividing.—DADANT & SON.

1. Let them swarm. 2. I should prefer to furnish them with queens.—A. B. MASON.

I should let them swarm once each, letting the parent colony rear its own queen.—G. M. DOOLITTLE.

1. Allow them to swarm naturally, returning all second swarms. 2. Let them rear their own queens—unless you have some particular strain that you want to increase.—WILL M. BARNUM.

1. I would allow them to swarm naturally. If you conclude to divide, do it when the colonies are near the condition of swarming. 2. It will be best to furnish them with queens.—J. P. H. BROWN.

1. Let them swarm; natural swarms are the best, although there are times when it is well to make swarms by division. 2. If your bees are of a good strain, let them rear their own queen-cells.—MRS. L. HARRISON.

1. Knowing nothing of your locality or ability, I cannot answer your first question, but for myself, I should divide colonies. 2. Much depends. I should furnish fecundated queens, in my own apiary.—J. E. POND.

1. To divide early, would be bad policy. I would get them as strong as possible by swarming time, and let them swarm. 2. If divided, the queenless colony should be supplied with a queen or a queen-cell.—M. MAHIN.

First, in this locality, I should let them swarm, in which case they would attend to the matter of queening.—JAMES HEDDON.

Provide laying queens, and divide the colonies not later than May 1, if the weather is good. If further south than this locality, divide earlier; if further north, do it later. They may need feeding to get them to full strength by June 1.—J. M. SHUCK.

1. To divide them has many advantages over the natural-swarming system, and if judiciously managed, no doubt it will give you the best results. 2. Furnish them with queens.—J. M. HAMBAUGH.

If you desire any surplus honey, I should say let the bees swarm *once* naturally, and manage them on the Heddon plan. Should they not swarm, they may be divided later in the season, when the honey crop is about over. Do *not* divide them in the spring. In dividing, it is well to give the queenless part a queen, or queen-cell, from a colony that has swarmed.—C. H. DIBBERN.

1. I think that depends upon whether your principal honey-flow comes early or late in the season. If the latter, dividing might work well, if you can get two strong colonies ready for the harvest in place of one. I should not divide, however, until near the time for natural swarms. 2. You could let some of the colonies rear all the queen-cells that they naturally would, and utilize the best of these to supply others.—EUGENE SECOR.

1. It may not be pertinent to the question, but I think that it is a mistake to attempt to increase your bees to any greater extent than results from natural swarming, allowing no more than one *prime* swarm from any colony. You may make a big show by rapid increase of colonies, but "solid cash" will not materialize. 2. If you must *divide* your colonies, wait until swarming time. It pays best to give the divisions queens at once.—G. W. DEMAREE.

Without knowing anything of your locality, or the amount of your experience or ability to accomplish what you desire to do, it would probably be safer to advise you to let them swarm naturally, and let the old colonies rear their queens.—THE EDITOR.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

CORRESPONDENCE.

CANADA.

Report of the Ontario Bee-Keepers' Convention.

Written for the American Bee Journal

BY R. F. HOLTERMANN.

The annual meeting of the Ontario Bee-Keepers' Association was held at Owen Sound, Ont., in the Council Chamber, commencing at 2 p.m. on Jan. 8, 1889.

The annual meeting has not had a smaller attendance for at least eight years, and probably never. It must, however, not be considered that the association is losing ground—far from it—the membership for 1888 was 231; nor must it be charged that bee-keepers do not desire to attend, but the reasons probably were, the poor season of 1888, the locality, and the bad roads all over the country, making it difficult to get to railway stations.

President Martin Emigh, of Holbrook, occupied the chair. Among those present were, Messrs. Gemmell, R. E. Smith, A. Pickett, R. McKnight, S. Corneil, W. F. Clarke, F. H. Macpherson, J. Miller, Wm. Couse, R. F. Holtermann, D. Anguish and G. Barber.

After the roll call, and reading of the minutes, the reports of the Secretary, Treasurer, and others, were read and approved.

The Secretary, Wm. Couse, stated in his report that about 1,000 invitations had been sent out, and largely responded to by the bee-keepers.

R. McKnight, the Treasurer, reported about $450 on hand, $200 of which had been set aside to secure Langstroth's revised book for the members of 1887.

The auditors, J. Miller and R. F. Holtermann, reported that the books were audited, and found to be correct.

EVENING SESSION.

Mr. Emigh then read the President's annual address.

An essay was then read from Mr. S. T. Pettit, of Belmont, Ont., as follows, on

Priority of Location.

About two years ago, when this thought was presented at the annual meeting of the Ontario Bee-Keepers' Association, the principle seemed to be something of small value, and but little notice was taken of it. Not long after, however, Mr. James Heddon called attention to it, and wrote approvingly, but Mr. Jones thought that it was a case of "the survival of the fittest."

Soon after this, in 1887, a characteristic letter from the pen of Mr. R. McKnight was published, in which we find the following:

"There are some in the fraternity whose generosity would lead them to squeeze out the weak and the small. They would go still further and circumscribe operations in rural districts by a new force known as 'Priority of Locations'—root out big and little from towns and villages, and put the business in the hands of specialists.

"The new doctrine of priority of location is the most presumptuous of all the claims the monopolists amongst bee-keepers have yet hinted at. Such a doctrine is begotten in selfishness, and opposed to justice."

Who in the present age is bold enough to assert that Mr. McKnight is not an original and profound thinker? Listen, while I repeat the strikingly characteristic terms employed—"root out big and little," "the most presumptuous," "the monopolist," "begotten in selfishness and opposed to justice." But just how leaving a man to enjoy his chosen locality without the crowding of bees other than his own, will so operate as to "squeeze out the weak and the small," and "root out big and little from towns and villages," I confess inability to comprehend, and I suppose ordinary mortals will plod on just the same as though that composition had never been written.

"Amateur Expert" writes: "And having done so, proceed to walk into some of the abuses he (James Heddon) so loudly denounces, and then walk into him if he talks of priority of location, etc, and it would be all in good humor." Why, to be sure, "A. E.," that is the proper way to do things. Then "A. E." says, "don't you know that we are free traders and stout upholders of a fair field and no favors? or else how would the priority-of-location doctrine suit our Canadian brethren when they look for a share of our market?"

Replying I will state that I am willing to believe that "A. E." has not given the subject due thought, or else he would see that our purposing to assist in placing within the possible reach of England's millions of hungry and poor, who in all probability never in their lives have enjoyed the pleasure of eating so much as one pound of honey, is a very different thing altogether from squatting down by another already in the business, to the injury or disaster of both; the dissimilarity will be all the more conspicuous when we reflect that we have plenty of inviting unoccupied fields, and that England must look to the outside world for food, or perish. Plainly enough the two cases are not parallel, and not comparable.

Mr. W. F. Clarke says: "Priority of location is another matter which is attracting much attention among bee-keepers. It is proposed by some to pass a law securing to the first comer as a bee-keeper into a neighborhood, the exclusive ownership of the bee-forage within certain limits." Well, I must say that if such legislation has ever been proposed, or even hinted at, it has entirely escaped my notice. I cannot help thinking, however, that Mr. Clarke was drawing upon a much abused imagination when he wrote that statement. But the President, still believing in priority of location, in his annual address of a year ago, again called attention to it. Now permit me to give a few quotations to show that the principle has taken deep root in the better judgments of bee-keepers generally, the fruits of which will be sweet and refreshing to many in the business.

Mr. Allen Pringle says: As to who ought to engage in bee-keeping, and who may engage in it, these are questions which each individual has the natural right to decide for himself, so long as he keeps within both the moral and the civil law. When the latter excludes him from corporations, he has no right to violate it, and when the former excludes him from preoccupied ground, he has no moral right to violate that either.

From a dialogue between Prof. Cook and Dr. C. C. Miller, at a Chicago meeting of the North American Bee-Keepers' Society, I gather that Prof. Cook also believes in the principle.

Mr. D. A. Jones now not only concedes to others priority of location, but advocates it as well. He says: "To me it seems that the question of priority of location bothers some more than it need. There are those who make comparisons of bee-men and store-keepers, etc., but such comparison is not applicable." Then again he says: "With those points in view, no practical man will seek entrance to a section of country already comfortably occupied."

And now we may rejoice in the fact that priority of location, backed up by sound public opinion, "has come to stay" until the time shall come when in the march of progress on all sides, apiculture shall receive that attention from the people, and from Legislators, that its growing importance merits, and it shall be placed upon a legal, and therefore upon a more solid and satisfactory basis; when justice through wise legislation can be done to all the people; and even then the principle of "do unto others as you would that they should do unto you," will be of

service in the new order of things, as an outside guard to watch and ward off the operations of unprincipled parties who may be disposed to appropriate that which belongs to others.

And in conclusion I will say, that because I have enjoyed the privilege of collecting the nectar from my neighbors' fields, orchards and forests, for a dozen years and more, and that although during all these years I have done them good and not evil; that all this does not make me the owner of the nectar of future years—without a doubt in my mind it belongs to the owners of the soil, whose it is, and who have a right as a community, to control the disposal of it in a just and equitable manner, just as surely as they have the right to dispose of any other valuable product of the soil. But in the meantime let us all appreciate and rejoice in the security that the priority-of-location principle affords us. I am strongly impressed with the conviction that any bee-keeper who in the future shall introduce himself upon preoccupied ground, will realize that public opinion justly censures him.

S. T. PETTIT.

Mr. McKnight said that he regretted that Mr. Pettit was not present, and under the circumstances he would but briefly say that what he had written he had no reason to retract.

Mr. Corneil said that the essay, in his estimation, was all right to insert in a bee-paper, but not the kind of an essay that would be expected to be read before a convention.

Mr. Clarke said that he would only take Mr. Pettit's own essay to prove that the writer of it himself advocated legislation.

Mr. Holtermann, who read the essay, pointed out that in reference to Mr. Clarke, Mr. Pettit, in his essay, never said that he did not advocate legislation, only he did not advocate the kind that Mr. Clarke had said was proposed.

A motion was then made that a special general meeting be held of the Ontario Bee-Keepers' Association, at Brantford, during the time the International meets there, and that a delegation be sent to represent the Ontario Bee-Keepers' Association.

Mr. Holtermann asked if this was to be the annual meeting, and was told that it was not. Mr. H. then stated that Messrs. Anguish, Barber and himself were a deputation from Brant, to ask the Ontario Association to have their annual meeting at Brantford, at the same time as the International; that he, as the Secretary, could tell them that the reason the date of the annual meeting had not been fixed by the International, was because they wanted to meet the Ontario in any way possible; he knew the law demanded that the Ontario Association fix the date of their annual meeting at this meeting, but there was no reason why arrangements could not be made for both to meet at the same time.

Messrs. R. McKnight, W. F. Clarke, S. Corneil and F. H. Macpherson opposed having the annual meeting at the same time as the International, claiming that the business of the Ontario Bee-Keepers' Association could not be done properly. Mr. Holtermann claimed that then, as now, the directors could meet before and after the sessions, and they transacted the most of the business.

As he could not make a motion to fix the place of meeting, until the next day, according to the programme, he would move that the question be "tabled" until that time. Whereupon Messrs. McKnight and Clarke withdrew their motion until that time.

Discussions followed upon "Ventilation," the majority being in favor of ventilating hives and repositories.

In discussing the advisability of preventing bees from breeding early indoors when wintering, some were in favor of having them breed early, others not until after being taken out, opinions being pretty well divided. In wintering bees in clamps, some objected to moving the hives together, but advocated separate clamps for each hive.

SECOND DAY.

MORNING SESSION.

The convention was called to order, with President Emigh in the chair. The election of officers was then held, and resulted as follows: Rev. W. F. Clarke, President. Mr. Emigh, the President for 1888, who had refused to serve a second term for President, was elected Vice-President.

The directors of the various agricultural districts were elected as follows:

J. K. Darling, Almonte; M. B. Holmes, Delta; Allen Pringle, Selby; S. Corneil, Lindsay; Wm. Couse, Streetsville; A. Pickett, Nassagawaya; Will Ellis, St. Davids; D. Anguish, Mohawk; R. McKnight, Owen Sound; F. A. Gemmell, Stratford, and R. E. Smith, Tilberry Centre.

It was then decided to fix the place of meeting before electing auditors. After some more discussion, Belleville was selected for the next place of meeting (Brantford receiving 6 votes and Belleville 7), on the second Wednesday and Thursday of January, 1890.

It was decided that a special general meeting be held at Brantford, at the time the International meets there, the President, Vice-President and directors being appointed a delegation to represent this Association.

The election of auditors was then held. Mr. Macpherson stated that the Arts Act did not require the auditors to be members, and nominated Mr. Walbridge. Mr. Holtermann claimed that he must be a member. Mr. McKnight said not, and so did Mr. Corneil; and Mr. Walbridge was elected. Another, not a member, was nominated, when Mr. Holtermann again protested. An eminent lawyer, the Mayor of Owen Sound, who had just welcomed the Association, being present, the decision was left to him, Mr. McKnight jokingly remarking that there must be no "fee." The Mayor declared Mr. Holtermann to be correct. W. P. Taylor, of Fitzroy Harbor, and R. F. Holtermann were then appointed auditors.

Hive-Ventilation in Winter.

Mr. Corneil, in his essay, explained the action of the currents of atmosphere of various temperatures coming in contact. The temperature of the hive was generally about 59° or 60°, whilst the outside temperature in the repository was much lower, and that of the open air as in outside wintering, is even greater. This caused a constant change of air in the hive.

Mr. Corneil had two 2-quart pails—blacked so as to cause greater radiation—suspended in the hive, and by this means secured a higher temperature in the hive than that in the room where the experiments were conducted. A wick, ignited, was then suspended in the hive, filling it with a dense smoke. By this means the direction of the currents of atmosphere could readily be detected.

The experiments conducted by Mr. Corneil showed that the tendency of the currents of air, under the conditions named, is upwards. That if there be but one entrance, as in the ordinary ventilator, and the atmosphere has to enter and make its exit at one opening, the current does not come in at one side and go out at the other, but is divided horizontally, going in at the lower half, and coming out again at the upper. Again, that if the entrance is divided horizontally, by even a piece of paper only, it prevents friction between the two currents, and the circulation may be quite free; whilst if not so divided, the friction between the two currents almost stops the circulation with the ordinary entrance. For this reason an upright ventilator is better than one horizontal, if there be only one ventilator.

Mr. Corneil appeared to favor a rim being placed under the brood-chamber, and between it and the bottom-board. One ventilator, the front one,

should be at the top of the rim, the other in the rear, at the bottom of the rim; this allowed a gentle current of atmosphere to pass through the hive. The entrance, or ventilator, should be regulated by the strength of the colony, an average colony having the ventilator equal to about one square inch in size. If the bottom-boards were tight, the rim could be placed over the brood-chamber. The ventilators should always be placed at the ends of the frames.

Mr. Corneil, at the close of his essay, was plied with numerous questions, which showed the interest that the members took in the question.

Mr. Allen Pringle, of Selby, then read an essay, on

Bees for Pleasure and for Profit.

The number of persons who keep bees merely for the pleasure of the thing, is probably very small, compared with those who keep them for the profit that is in them. A few, however, actuated by the spirit of research, or by curiosity, or a love of natural history, or perhaps in quest of recreation and health, keep bees without the usual dollars-and-cents motive. I think that I will be quite safe in assuming that every member of the Ontario Bee-Keepers' Association, however much pleasure he may get from his bees, has, at the same time, his "weather-eye" open for the profit—be the same more or less.

Wherefore, I may, I think, dismiss this minority class of pleasure apiarists with this brief reference, throwing after them our very best wishes, if not our admiration, and turn attention briefly to bees for profit.

It appears to me that the bees-for-profit-man also gets a great deal of the pleasure, especially when the *profits* are large. There is one advantage he has over the other fellow. It is almost astonishing how pleasant nearly every kind of business (or no business) will become to a man when it "pans out" properly. This is human nature as it *is*—what it *ought* to be we will leave for those who come after us. I shall, therefore, very briefly consider the question of bees for profit.

Bee Keeping with other Business

In the first place, I think that bee-keeping pays best in connection with some other business. I would not care to advise any friend to go into the business of bee-keeping, as an exclusive means of support. The past few seasons have brought to light new and better conclusions on this subject. If, like Manitoba farms, and their wheat, we could raise so much honey that we could afford to go without any the next year, the case would be different. But as the profits of bee-culture, at best, are only say good, or in the fairly living line, the specialist with nothing else to fall back upon, will occasionally find himself coming "out of the little end of the horn," as he comes out of his fiscal year.

As to what kind of business may be profitably supplemented by bee-culture, that depends upon circumstances, and must be decided by each one for himself. The farmer naturally thinks that bee-keeping ought to be in association with farming or some branch of agriculture. So of the school-teacher, mechanic, and others. Although the unavoidable drawbacks to bee-keeping for profit are numerous enough and formidable enough, much, very much, as in everything else, depends upon the man. There are certain conditions of success in every business. Only in rare cases do people stumble upon profitable success. We must work for it, and the work must be well directed.

The bee-keeper who succeeds and makes the business pay, must work well, with his hands, and still better with his head. To come down from the general to the particular, he must have the right kind of bees in a good style of hive, and then must look after them as carefully and intelligently as he would after his stock, or even the children. What might be the best hive for somebody else, might not be the best hive for him, and the same of bees.

For lady bee-keepers and timid men I should recommend the Carniolans or Italians. In hives, the Jones or Langstroth for amateurs is easily handled. So long as the hive is a good movable-frame one, not so much depends upon it as upon the man, and strict attention to business.

The profits of bee-keeping are materially affected by the mechanical part of the business. To economize in this, the bee-keeper ought to make himself handy with tools, and get everything made and ready during the winter months when he has time.

Marketing the Honey.

The profits are also largely affected by the bee-keeper's method of marketing. He may have a good crop and fool it away, as I have seen people do more than once. He gets in a great hurry to sell it as soon as he gets it, and either consigns it to some unknown and irresponsible commission man, or unloads it upon his local market just for what it will bring. In either case the result, as to profit, is generally not profit, but *loss*.

I would say, be patient in marketing, and sell at home. As a rule, leave the commission man alone. When you have a surplus from the home market, send your sample ahead, make your bargain, and then ship according to agreement, C. O. D. When you cannot sell for cash (as also happens with excellent home customers) resort to *barter*—goods for goods—and these can always be used or turned to account some way.

I know of but one way to make bee-keeping pay, and that is to handle the bees and their products as they ought to be handled. As to how, in detail, both ought to be handled, each must learn for himself by observation, reflection, experience, books, bee-papers, etc. ALLEN PRINGLE.

The Hon. Charles Drury, Minister of Agriculture, was elected an honorary member. After some changes in the Constitution and By-Laws, the convention adjourned to meet at Belleville in 1890.

Brantford, Ont.

SWARMING OUT.

Cure for New Colonies Leaving the Hives, etc.

Written for the American Bee Journal
BY WILLIAM CROULEY.

What apiarist has not had trouble from this cause? I think that I am original in discovering a very simple remedy for it; at least I have not seen it in print. It is as follows:

As soon as I hive a swarm, I put a drone or queen trap at the entrance of the hive, and leave it for three days. I had several swarm out through the trap, but they came back faster than they went out, as soon as they discovered that the queen did not come out, and went to work in earnest, and did not try it again. The trap should reach clear across the front of the hive.

Preparing Bees for Cellar Wintering.

My bees are wintering finely. I never had them so quiet in the cellar as they are this winter. I never lost but one colony in the cellar, and that one starved last winter. I think that my plan of preparing them for the cellar is a good one, and as it may be beneficial to some of the fraternity, I will describe it:

My hive bottom-board is the same width as the hive, with a 2-inch rim on the under side, and 4 inches longer than the hive. I use the blank-strip super, the same size as the hive. I put a quilt in the bottom of the super, and fill it with sawdust, dry leaves or chaff, and put it on top of the hive.

There is a bee-space between the super and the top of the brood-frames.

When I put the bees into the cellar, I turn the bottom-board upside down, which leaves a 2-inch space below the frames; and as the bottom-board is longer than the hive, I can see the under surface of the frames, by holding a light in the right position; and looking under once a week, I can detect any unusual mortality.

It is a pleasure to go in the cellar when the temperature is below zero, and see the clusters of bees as large as the top of my head, some of them hanging 2 inches below the frames, and resting on the bottom-board. Very few dead bees have dropped down yet—I think that I could get them all into a quart measure, from 85 colonies.

Redwood Falls, Minn.

MAINE.

Proceedings of the Bee-Keepers' Convention.

Reported for the American Bee Journal
BY L. F. ABBOTT.

The ninth annual session of the Maine State Bee-Keepers' Association was held on Jan. 8, 9 and 10, 1889, at Brunswick. This meeting was designed to unite all the local societies in the State, in one grand convention. The Maine State Society is the oldest organization. Next is the Western State Society, formed some three or four years subsequently, and later the Maine Apicultural Society, organized three years ago, but which has done but little towards discussing the bee-question. Although the past season has been the poorest in the annals of bee-keeping in Maine, a fair representation was present at the opening session.

The opening discussion, set in motion by the President's address, turned mainly upon hives and the wintering problem.

Factors of Success in Bee-Keeping.

Rev. C. M. Herring, of Brunswick, who had success in bee-keeping, made some points in his address which will be of interest to note. He alluded to the unstable character of the enterprises in which men engage. Success and failure are common to all. In bee-culture, the failures are frequent, which should lead to the inquiry, where lies the road of success? He would say, first in the man. One should understand the nature of these insects, and so comprehend their wants. Second, another secret of success lies in the bee, and mainly in the blood. All bees, like all men, are not of equal value. As with horses, cows, sheep and swine, blood will tell. We find in all organic life that interbreeding of the same blood diminishes the vital forces; and also that continued crossing between the different races, improves the stock. It is a mistake to think that all bees are alike. Another factor of success lies in the hive—a hive of the right size and form, and made to protect from cold. The best requisite he would name for the hive is thick walls; next the cubic form, so that the bees can mass in close proximity to the stores. These two ideas he held firmly as a means of success.

The discussion of the points presented in the President's address called out quite diverse opinions. Mr. Greeley, of Clinton, took quite a strong ground against the cubic form of hives. Dr. Morton, of Bethel, seconded Mr. Greeley's views. The discussion revealed the fact that nearly all the bee-keepers were using the oblong frame of the Langstroth pattern. Mr. Reynolds, of Clinton, was of the opinion that chaff hives were superior to wooden walls. Mrs. Hinckley, of Bowdoinham, believed in protecting hives in winter. The practice is quite well established by placing bees in the cellar, as the safest place to winter.

Races of Bees.

Mr John Reynolds, of Clinton, gave his ideas as to races of bees. He thought that each one should decide for himself the value of many things in use in bee-keeping, and in regard to different races of bees. In his opinion, climate creates races of bees; races succumb to climate. Maine's climate creates a dark race of bees; the climate of Italy and the Isle of Cyprus originated a yellow race of bees. Different races are all equally good, perhaps, in their own locality. In his opinion, whoever attempts to keep all races of bees in one locality, will not succeed.

An essay by Mr. I. F. Plummer, of Augusta, contained some points and suggestions.

Local Bee-Associations.

Mrs. W. M. Hinckley, of Bowdoinham, sent an essay, mainly devoted to suggestions concerning the work of the associations. She thought that every town where bees are kept should have a regularly organized society of bee-keepers, holding meetings and comparing notes at least twice a year. There should be one central State society, composed of the Presidents and Secretaries, or of specially elected delegates from each town in the State, regularly incorporated, with power to elect its own officers from members as furnished by the town societies, and to transact business as its necessities demanded.

The State society should select careful, intelligent men in every part of the State to superintend the careful testing of the different races of bees, the different methods of handling, feeding and swarming; the various hives before the public, especially those that have secured such a foothold in the public mind as to allow them to claim standard merit; all the different frames and tools and methods of manipulation in use, and who shall clearly and faithfully report their observations to the Secretary of the State society at the close of each season's work.

The Home Market for Honey.

One of the questions discussed was, "Creating a Home Market." Mrs. Crockett, of Foxcroft, sent an essay which was read by the Secretary, giving her views upon the subject.

Mrs. Crockett spoke of the difficulty of getting the idea established that honey is a staple article of diet, rather than a luxury, and cheaper than berries and canned fruit. One thing that will go far to make a market, is to convince the consumers that the honey we put upon the market is absolutely pure, and hence, a healthy article of diet.

There are confused ideas among customers regarding extracted honey, many believing it to be impure. Hence, we drop the term and call the product comb and "strained" honey, the latter term being a familiar one years ago when bees were kept in box-hives.

The essayist preferred to sell honey direct to consumers rather than sell in the wholesale market.

The profit the trade puts on, above the wholesale cost, brings the product too high, so that the masses cannot afford to purchase it; still if we sell direct to the consumer, and furnish those who prefer comb honey with the best quality at remunerative rates, we shall find plenty to take our second quality for one or two cents less per pound. It pays to have the sections clean and nice, and the clear honey put up in attractive form.

The Feeding of Bees.

How to feed bees in the fall economically and with the best advantage to the colony, was the subject of some discussion. Mr. Greeley gave his plan of late feeding, by turning thick sugar syrup, slightly warmed, directly into the combs. Colonies so fed late in October capped the combs so treated, and he expected them to winter well on the same.

Feeding in the cellar with frames of sealed honey might be accomplished

at any time, by moving the central frames on which the bees were clustered, and placing frames of honey near the bees.

Destroying Moth-Worms.

Moth-worms were frequently found in hives, and in box-hives used to do much damage, but with the frame hive and Italian bees, moth-larvæ were of little account. It is stated that the freezing of eggs or larvæ destroys their vitality.

It was thought best not to extract the combs when working for comb honey.

It is considered an advantage to shave brood-combs to $\frac{7}{8}$ of an inch when putting on surplus cases, thus uncapping the sealed honey at the tops of the frames, and letting the cappings and honey run down between the frames. Then space the frames to a bee-space—$\frac{5}{8}$ inch—and place on the sections.

Our best honey producers used the queen-excluding zinc honey-boards, thereby obviating the trouble often experienced, of brood in the sections.

Well constructed chaff hives were recommended as preferable to single-walled hives, especially for out-door wintering.

Races of bees were a constant theme of discussion among bee-men of the country, but the blacks and the Italians were still the chief races for profit.

The whole machinery of bee-keeping is complicated. It takes years of practice to become conversant with the various ways of manipulating this wonderful little bee.

Dividing Colonies.

Dividing colonies may be profitably and readily practiced after one knows how. It needs practice in handling bees, and familiarity with their ways, to successfully accomplish profitable dividing. It may be done by dividing a strong colony and, finding which section is queenless, give it a laying queen, or else allow the bees to rear a queen.

Another method, involving the same principle, is that of forming nuclei colonies, by putting a frame of brood in a hive, give it a laying queen, then build up from different hives by giving the young colony frames of brood.

Mr. Pike, of Livermore Falls, gave a method of shaking from the frames of a strong colony bees sufficient, into a box made for the purpose, to make a colony—bees from different hives could be mixed in this way, care being used in all cases, not to shake out the queen with the bees.

Keep this mass of bees 24 hours, run a laying queen amongst them, and hive the bees in the ordinary way, and the colony would go to work with the bee's accustomed alacrity.

The officers chosen were: President, Rev. C. M. Herring, of Brunswick; Secretary, Dr. J. A. Morton, of Bethel; Treasurer, W. H. Norton, of Skowhegan; with one Vice-President from each county.

Lewiston, Maine.

WINTER SONG.

Summer's joys are o'er;
Flowerets bloom no more,
Wintry winds are sweeping;
Through the snow-drifts peeping,
Cheerful evergreen
Rarely now is seen.

Now no plumed throng
Charms the woods with song;
Ice-bound trees are glittering;
Merry snow-birds, twittering,
Fondly strive to cheer
Scenes so cold and drear.

Winter, still I see
Many charms in thee—
Love thy chilly greeting,
Snow-storms fiercely beating,
And the dear delights
Of the long, long nights.

HONEY-BOARDS.

The Invention of the Wood-Zinc Honey-Board.

Written for the American Bee Journal

BY DR. G. L. TINKER.

In the report of the late Michigan Convention, on page 23, Mr. Heddon objects to my claiming the wood-zinc honey-board! It has been a surprise to me from the first, that he should, on so slight a pretext, claim this invention as his own, and seek to deprive me of the credit that rightfully belongs to me as the original inventor.

It seems that Mr. Heddon had tacked strips of perforated-zinc on his slatted honey-board, and so used them, but had not conceived the idea of placing the strips in saw-kerfs in the edges of the slats till he saw a wood-zinc honey-board of my construction at the Kalamazoo State Fair, in September, 1885. Yet he now says it will probably never be known who was the prior inventor! Mr. H. has assumed that tacking on the strips was equivalent to placing them in saw-kerfs. If he really thought so, why does he not use the strips now as he did in the first place?

But he was free to state at the Fair (of which I have reliable proof) that my wood-zinc honey-board was a "new thing." Had it not been, he would have stated there and then, that he had used the perforated-zinc in the same way. Instead of that, he said nothing until several months after, when he set up his first claim as its original inventor!

Mr. Heddon admits that I *constructed* the first one (he having simply the idea), and first published it, which should settle the matter for all time. But the "idea" he had, was simply tacking on the strips!

The wood-zinc honey-board is an improvement of the slatted honey-board. The *first* and *original* honey-board had auger-holes or slots to correspond with openings in the honey-boxes that were placed upon it. Father Langstroth was the well-known inventor, and he possessed the genius to create an original idea. Mr. Heddon desires to be thought an original inventor, but he has credit only for a keen perceptive faculty, for all of his "inventions" have been based upon original ideas already advanced by others.

The honey-board being invented, it was natural that many modifications of it should follow, and the slat honey-board was one of them. Thousands of them were in use in this country before Mr. Heddon ever wrote a line on the subject. Even his identical break-joint sink honey-board (see *Gleanings*, Vol. XIII, page 173) had been invented and in use for many years before Mr. Heddon wrote of it. But he was quick to perceive that it could be made a good thing, and he deserves all the credit that attaches to it as a modification of the Langstroth; for he introduced it to the public, and first made known its general value in our modern methods, and takes just pride in having it called "the Heddon honey-board."

Now I have invented the wood-zinc honey-board, giving to the original slat honey-board a distinctly new function. I have since added the essential features of the Heddon honey-board, but Mr. Heddon "objects" to my advertising it as "Dr. Tinker's wood-zinc honey-board," and would deprive me of a right which he is free to take of Father Langstroth, and other predecessors!

Again, Mr. Heddon modified the Moore crate, and called it the "Heddon case," and would be vexed if any one dared to question his right to so call it. Shall I therefore forego a privilege he is free to take and respect his "objection" before the Michigan Convention; because he has an invalid patent on the old slatted honey-board, which, not even in one of its features, was he the original inventor? Certainly not!

I regret that Mr. Heddon should not want to use one of my inventions without laying some sort of claim to it. It is public property, and any one has a right to manufacture and use it, ex-

cept on Mr. Heddon's divisible brood-chamber.

My purpose from the first was, that it should be free to all bee-keepers to make and use. I afterwards sought to control its general manufacture by a patent, and in a pending application of Mr. W. S. Kline and myself, laid claim to it, which was duly allowed. In assigning this claim, the Patent Office decided it a "misjoinder," and it had to be cancelled. It was learned subsequently that a patent, if obtained, would be invalid, owing to certain decisions of United States courts that were unknown to me. Hence, no further action was taken or desired. It is sufficient to know that it was a patentable invention, and that I could yet obtain a valid patent, if I had not made the invention public, as stated by Mr. Heddon. I have suffered no loss in the matter, and now only desire the credit that clearly belongs to me; and I shall insist, that if this honey-board is to be called anything else than a wood-zinc honey-board, it shall be designated as "Dr. Tinker's."

In opposing the use of two-rowed zinc in my honey-board, Mr. Heddon says—"great and expensive mistakes are made regarding this point." But should he make ten times the number of tests with his bees to prove his position, it would not help the matter a particle. The general facts on this point are *exactly as I have stated.* His bees are mainly blacks and hybrids, and it is well-known that these bees will go through small auger-holes, and store honey, when Italians will not, as a rule. So Mr. Heddon's tests in the matter are not worth a fig. While his bees may work fairly well through a few queen-excluding holes in his honey-boards, mine will not; and nine out of ten of all the colonies in this country will not!

Again, two-rowed zincs used in my honey-boards practically opens up the way to a super of open-side sections, or to an extracting super, so perfectly that it is like placing an empty box on the hive, as regards giving room to prevent swarming, and the result is *the same.*

Now I will be kind enough to tell Mr. Heddon that one of my honey-boards used on one division of his hive will almost entirely overcome the tendency to swarm out of such contracted quarters. Some of the bee-keepers using his hive have had to re-hive swarms from five to six times before they would stay; and in a large apiary the annoyance has been a serious matter, requiring the use of a queen-trap before every young swarm. One division of his hive is too small, and the whole brood-chamber is too large for a swarm, but if those who have his hives will use my honey-boards, they will succeed far better.

I am tenacious of the point that the zinc strips should be let into the slats nearly up to the rows of perforations, so that the bees can get a ready foothold on the wood, and get through the zinc without a struggle. While solid sheets of perforated zinc are not a failure, still they are not equal to my wood-zinc honey-board, and can never be made the equal.

Storifying Hives.

As to the use of the English word "storify" instead of the word "tier," I consider it the more elegant and expressive term. I desire no credit for its original use. Our English brethren have long used it synonymously with our use of the word "tier." I have never applied the word to the management of the Heddon hive as alleged. Not even in one instance did I operate the Heddon hives I had, on the plan given in my new management of bees.

I supposed Mr. Heddon knew that my apiary had been run for years for experimental purposes, and that I had many kinds of hives in use. The new management is to be credited to the invention of the wood-zinc honey-board.

New Philadelphia, O.

[We cannot afford space to unimportant disputes where nothing is at stake but personal glory. Messrs. Heddon and Tinker have each presented his side of the controversy, by one article—*now let that suffice.*

This dispute concerning the "priority of invention" may be settled amicably by simply calling it "the wood-zinc honey-board," omitting any personal name.—ED.]

VERMONT.

Report of the Vermont Bee-Keepers' Convention.

Written for the American Bee Journal
BY J. H. LARRABEE.

The annual convention of the Vermont State Bee-Keepers' Association was held in the Town Hall at Middlebury, Vt., on Tuesday, Jan. 15, 1889.

At 10 a.m. the convention was called to order, with President Holmes in the chair. After routine business, the first subject of interest discussed was,

Wintering of Bees in Special Repositories.

The discussion was led by J. E. Crane, who had for many years wintered hundreds of colonies out-of-doors. During the past two or three years he had experimented quite largely with cellar wintering, and at the present time he has about 150 colonies in a special repository under his residence. He had no special means of ventilation in the repository, except a pipe connecting with the chimney. The cellar was very dry. When first put in, the bees were the most quiet at a temperature of from 50° to 55°, and in some cases even at 60°. Towards spring, however, the temperature should be lowered, or early breeding and uneasiness would result.

Mr. C. had placed his bees in the cellar early, and not removed them until natural pollen could be obtained, even six months confinement proving safe, if the bees are quiet. He had been very agreeably surprised in the results obtained, as the bees wintered in-doors had compared favorably in results obtained with the bees of his other apiaries wintered in chaff packing.

The above came as a revelation to the most of those present, as only some five or six wintered their bees in cellars. Much interest was manifested, and many questions asked, in reply to some of which Mr. Crane stated, that he ventilated each hive by raising the cover ⅛ of an inch at one end; that the consumption of honey per colony in the cellar was less than out-doors, but he could not state the saving in honey to the bee-keeper, as much honey was consumed in the spring.

Next followed reports of winter losses for the winter of 1887–88, which showed that the losses were heavier than usual, some of our best bee-men reporting from 10 to 20 per cent., and some (notably Mr. F. H. Walker, of Manchester, who lost 80 colonies out of 167) were somewhat discouraged in consequence of it. Sympathy was not lacking.

AFTERNOON SESSION.

At the opening of the afternoon session, a new Constitution was presented, discussed and adopted. It is hoped that this Constitution will broaden the field of labor of the Society, and promote its usefulness. All members under the old Constitution become members of the "new," by the act of signing it.

The following Board of Officers were then elected:

President, R. H. Holmes, of Shoreham; Vice-Presidents, one from each county represented, viz: Addison county, J. E. Crane, of Middlebury; Bennington, F. H. Walker, Manchester; Chittenden, Geo. Beecher, of Essex; Caledonia, J. D. Goodrich, of East Hardwick; Franklin, B.P.Greene, of St. Albans; Lamoille, J. W. Smith,

of Stowe; Orange, M. F. Cram, of Braintree; Orleans, A. J. Albee, of Derby; Rutland, H. L. Leonard, of Brandon; Washington, D. S. Hall, of Lower Cabot. Secretary and Treasurer, J. H. Larrabee, of Larrabee's Point.

Then followed a very valuable essay by Mr. V. N. Forbes, of West Haven, on

Bee-Pasturage.

Alsike clover was the plant that Mr. Forbes most recommended, and had obtained satisfastory results therefrom. That his assertions were founded upon experience, was proved by the fact that during the past year he had furnished 1,000 pounds of Alsike clover to his neighbors. It had proved profitable both to them and to him. He bought at wholesale, and sold at a slight sacrifice.

The Spraying of Fruit Trees.

In the discussion which followed, Prof. Seeley, of Middlebury College, who was present, was asked his opinion of the results upon bees produced by the spraying of fruit trees with poisons. He thought that no bad effects would ensue in any case, but suggested that the bee-keeper should hint to fruit-men, that the best time to spray fruit was after the blossoms had fallen, and supported the assertion by facts.

Mrs. E. S. Brainerd, of Orwell, next read an essay on,

Marketing of Honey by Small Producers.

She dealt direct with consumers, and furnished only a first-class article. She is entirely independent of commission men.

The President remarked that we should not condemn the commission men too hastily. He had visited the market last fall, and had his eyes opened with regard to the shipping and handling of honey in Boston.

The Bee-Keepers' Union.

Extracts from reports showing the object and uses of the "Bee-Keepers' Union," were read by Miss Douglass, of Shoreham.

Mr. Manum stated that he had been a member since its formation, and he urged its claims very strongly. It is hoped that Vermont bee-keepers will avail themselves of its privileges, especially since an act was introduced in the last Vermont Legislature, prohibiting the keeping of bees within 40 rods of the highway. However, this Bill was promptly killed.

The Chapman Honey-Plant.

Mr. Manum, who was one of the committee appointed some two years ago by the National Bee-Keepers' Society, to report with regard to the "Chapman honey-plant," said with regard to it, that although it furnished honey bountifully, he did not believe that it paid to raise it exclusively for honey. The seed he knew to be good for poultry, and if an oil could be pressed from it, and the residue used in the manufacture of quinine, so as to pay for cultivation, he should esteem it highly for the bees.

A letter was then read by the Secretary, from Mrs. L. Harrison, in behalf of the Illinois bee-keepers, sending words of encouragement and cheer so sadly needed. The Secretary was then instructed to send the thanks and sympathy of the Association to our fellow bee-keepers of Illinois.

EVENING SESSION.

The evening session was very interesting, and it is much to be regretted that many of the members were obliged to return home before evening.

A discussion was opened by President Holmes, on

Prevention of Undesirable Increase of Colonies.

There are, said Mr. Holmes, three classes of bee-keepers who may desire to prevent increase, viz: 1. The specialist, who has bees enough to occupy his whole time. 2. The novice, who keeps a few bees for the honey and pleasure of it, and cannot allow them to interfere with his business. 3. Box-hive bee-keepers.

The best way for the box-hive beeman to prevent increase, does not concern us. The novice, who keeps a few bees may prevent increase by doubling up swarms, as they issue, thus strengthening the weak, and increasing the honey crop.

The best way for the specialist to prevent increase, is a mooted point. However, the speaker had been very successful by removing the queens, keeping all queens young, and by keeping the bees at work. In removing queens he saved the best ones.

Eight or nine days after the first swarm issues, he removes the queen-cells from the parent colony, and introduces a young laying queen, on or after, 13 days from the time the first swarm issued.

From the discussion which ensued, it was plainly evident that upon this subject our bee-keepers were fully abreast of the times.

Ancient and Modern Apiculture.

Then followed an essay by Miss G. M. Wolcott, on "An Amateur's Observations upon Ancient and Modern Apiculture," in which she recounted some of the amusing incidents which attended her first experiences with the bees. By the way, we learn that Miss Wolcott intends soon to take charge of her own apiary of 150 colonies.

J. H. Larrabee read an essay on "English Bee-Keeping."

The session was well ended by an eloquent and interesting address by Mr. Crane, on "The Production of Comb Honey."

The convention then adjourned to meet next year, at the time and place appointed by the Executive Committee.

J. H. LARRABEE, *Sec.*

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Feb. 6.—Northeastern Michigan, at Flint, Mich.
W. Z. Hatchinson, Sec., Flint, Mich.

Feb. 7.—Wisconsin State, at Madison, Wis.
C. A. Hatch, Pres., Ithaca, Wis.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Wintering all Right.—S. A. & M. A. Goodale, Clear Creek, Ind., on Jan. 17, 1889, write as follows:

In the spring of 1888 we had 21 colonies of bees in good condition. All increase was made by natural swarming. We sold 5 colonies, and put 28 colonies into winter quarters in the fall. We secured 900 pounds of extracted honey, mostly from poplar bloom. The golden-rod and asters supplied abundance of stores for wintering, besides a small surplus. The bees "kept themselves" throughout the summer, and gathered their winter supply of food. This is more than most stock can do. Bees had a good flight Jan. 3, and seem to be wintering "all right."

Good Prospects.—A. M. Rhodes, Bethany, Ills., on Jan. 19, 1889, says:

To say that I appreciate the AMERICAN BEE JOURNAL, does not express my feelings. Bees, as a rule, are in good condition. The prospects for bee-keepers are good.

Importance of Reading Bee-Papers.—Henry A. Hyle, Redwood, N. Y., writes as follows:

My neighbor has kept bees for eight years, and takes no bee-paper. He is a well-to do, retired farmer. He had 16 colonies of bees, and lost nearly all through carelessness. He had a strong colony of Italians in a chaff hive, but neglected to put them in condition for winter, until too late—Nov. 29. He came to me, saying that his Italians were dead, and requested me to examine them and ascertain the cause of their death. I found that he had left the poor bees on ten frames, without any cover whatever, only the top or cover of the hive. They had plenty of honey, but had huddled in one corner, and

froze to death. The entrance was left wide open, snow had blown in and melted, leaving water on the bottom-board. A piece of old carpet, covered over them on the frames to retain their heat, would have saved them. Near by was a weak colony in a single-walled hive, in one story; they were found in good condition, covered closely over the frames. By not taking a bee-paper, he lost bees enough in one season to pay for a bee-paper during his lifetime. When he gets into trouble, he comes to me for information. There was no surplus honey here last year.

Results of the Season.—Mr. C. A. Goodell, Mankato, Minn., on Jan. 15, 1889, writes:

I commenced the spring of 1888 with 5 colonies of bees, and increased them to 10 colonies. I cannot complain of my bees, for I took 350 pounds of comb honey, last fall, from 11 colonies. The bees are wintering nicely in the cellar. My neighbor and I found 8 bee trees last fall. We cut one last November, on a warm day, and I saved the bees, by putting them into a hive with plenty of stores, and they are wintering nicely. I like the BEE JOURNAL better every week.

Mild and Dry Winter.—Mr. T. N. Marquis, Wilford, Ills., on Jan. 13, 1889, says:

Bees seem to be all right in my cellar yet. This has been an unusually mild, dry winter here. I am in hopes that I will get a crop of honey in 1889, not having had a crop in four years.

Bees Under the House.—Mr. J. S. Willard, Bedford, Iowa, on Jan. 19, 1889, says:

The weather has been very mild here all winter. I have nearly all of my bees in the cellar under the house. It is warm there for them, I think. It is from 42° to 48° most of the time, and 50° or more at times. We keep the temperature down by opening the inside door. I fear that some of them will fly every once in a while when I am in there. Everything about the hives looks dry and nice. I have 36 colonies in the cellar, and 5 out-doors. Last summer we got half a crop, and the two seasons before we had hardly half a crop altogether.

Good Report for 1888.—Vincent Quinn, Penn Yan, N. Y., on Jan. 19, 1889, writes:

I thought I would send in my report. From my best colony I got 150 pounds of honey; two second best, 90 pounds each; and two more, 28 pounds each. I did not keep account of the whole of them, but my bees beat my father's last season. I have 16 colonies in the cellar, and all are doing well so far. They are all Italians.

Not Much Winter.—E. Drane & Son, Eminence, Ky., on Jan. 22, 1889, write:

We have not had much winter here yet. The mercury was down to 20° above zero one morning Christmas week, and was at 26° this morning, which are the coldest days we have had. The earth is covered with young white clover, and we hope to get some honey when it blooms. We got no surplus the past year, and had to feed 500 pounds of sugar for winter stores. After doubling up weak colonies, we have 104 colonies left.

Shiny Bees.—C. W. Phelps, Binghamton, N. Y., on Jan. 21, 1889, writes:

I had a colony of bees that had a peculiar disease (if it may be called that) last July. Some of the bees would look shiny, and fly around the entrance much the same as robber bees before alighting, when the other bees would kill them after a struggle, or they would get away. At first glance I thought that they were robbers, but as I have kept bees for a good many years, I soon discovered the difference, and I positively know that the bees belong to the hive where they were killed. This killing was kept up all the latter part of the summer, and until winter, after cold, frosty weather sets in; and after the bees were confined in the hive for several days at a time, I would find quite a number of dead ones, or looking at the bottom of the cluster, and on the bottom-board, I would find the bees killing others. After it got cold enough so that they could not fly for several weeks at a time, I found a quart or two of dead ones. Did you ever see or hear of anything of the kind? I think that the bees were *all* killed, but I am not sure. I carried the bees into the cellar, and took the comb and honey away from them, put them into a new hive, and gave them sugar syrup, and the killing stopped after a little while. Of course I do not expect to winter them, but I think that the trouble was in the honey. I have read considerable, but I have never heard or read of a case like this.

[In the fall, shiny bees are often seen in the apiary. They are old bees, and are killed off to save the honey.—ED.]

Carrying in Pollen.—H. S. Gravener, Cypress Mills, Tex., on Jan. 19, says:

We have been busy on the range. Bees carried in pollen on Jan. 15—a little earlier than usual. They did fairly well the past season, a little over 100 pounds of honey per colony.

Expects a Bountiful Harvest.—J. G. Norton, Macomb, Ills., on Jan. 23, 1889, says:

The bee-business has been a poor investment in this part of the State for the last three years; but bees are wintering well, and are in fine condition; so from the present propects, I look for a bountiful honey harvest for 1889.

Wintering Finely.—H. M. Seeley, Harford, Pa., on Jan. 19, 1889, says:

I see by the reports of some that their bees are out nearly every day; here they were out three days at Christmas time, and not again until Jan. 17, when the temperature went up to 60° in the shade, and they had a fine flight. All seem to be wintering as finely as need be.

Bees Wintering Well.—John H Larrabee, Larrabee's Point, Vt., on Jan. 21, 1889, says:

Bees here had a splendid flight on Jan. 18, and showed that they were wintering well. We have no snow, and the mercury has only reached zero twice. We look forward to next year with hope for a better season.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Honey and Beeswax Market.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.
Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but about equal to the demand. Market will be bare of comb honey long before the new crop is ready.
BEESWAX.—22@23c.
Jan. 18. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX,—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand slow, with a smaller supply than ever at this season for the past 10 years.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Jan. 9. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@18c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

EDITOR.

Vol. XXV. Feb. 9, 1889. No. 6.

EDITORIAL BUZZINGS.

Music when soft voices die
Vibrates in the memory!
Odors when sweet violets sicken
Live within the sense they quicken.

Life is Not so Short but that there is always time for courtesy.

The Mild Weather of December and January had its effects on the maples of New England. In Maine and Vermont, and other sections, trees yielded a good flow of sap, and sugar was made in mid-winter, a very unusual occurrence. So says an exchange.

Lizzie Cotton's advertisement has been refused by the Orange Judd *Farmer*. She sent it to the Editor with a small book describing her controllable bee-hive and methods with bees, which she claims will make those who use them rich. She is *modest*, if selling a book worth at most ten cents, and a hive not worth two dollars, for $12.00 can be called modesty!

United Efforts.—Mr. William Stolley, of Grand Island, Nebr., on Jan. 26, 1889, when sending his dues to the National Bee-Keepers' Union, remarks thus:

The bee keepers, as a class, are very much like the farmers; they seem not to comprehend the great advantages of combining for their own good and protection, else the members of the Bee Keepers' Union would have been counted by the thousands long ago. Being absent from home when the officers were elected, I did and could not vote, but I am well pleased with the officers elected.

It is too true, Brother Stolley, but they seem to be asleep—apathy reigns supreme.

NeuerSchweizerBienenfreund is the title of a new monthly Swiss bee-paper, by U. Studer, Niederried, Switzerland, the second number of which is on our desk. This makes the third periodical on bee-keeping now being published in our small sister Republic, where one is "an abundance."

It seems a strange infatuation, that leads to such a multiplication of bee-periodicals. Where one good bee-paper could live and be a real benefit to the pursuit, two or three will spring up and none of them be able to make their influence *felt*, because of their weakness, by reason of the splitting up of the subscription patronage. What would support one would starve three.

This is a *calamity* which is threatened in every bee-keeping country. The power for good and influence for right, which one strong and vigorous publication would maintain, is frittered away by reason of an unhealthy increase of bee-papers. It behooves all to look this matter squarely in the face, and refrain from lending their influence to an increase in this line, which is detrimental to the entire craft.

Until a few years ago England had no bee-paper—now she has three; two too many! A quarter of a century ago in America there was but one (the AMERICAN BEE JOURNAL), now their names are legion, and as a result some of them are sick and dying; others are only half supported, and the *influence* of all, by reason of the multiplication, is much *impaired!*

All this is the result of the suicidal mania for publishing a bee-paper; and if it is not soon stopped, the time will come when many of them will die, and their owners will be poorer but wiser men.

It is quite time to call for *a halt* on such reckless increase—which is just as detrimental in the field of literature as it is in the apiary. In both cases, too much increase will destroy the business, and ruin those who should be benefited by the investment.

Cleaning Propolis from Sections is quite essential, so as to make them attractive when put upon the market. This is usually done by scraping the edges, but a correspondent suggests that a thin shaving be cut off instead of scraping them. He adds:

This is more quickly and easily done with a sharp knife than by scraping, looks better when finished, and there is not so much danger of damaging the capping as is the case in scraping. Bees should never be permitted to get to the outside of sections, but it is impossible to prevent their daubing propolis on the edges, hence the necessity of cleaning. Honey, to bring top prices, must be pleasing to the eye as well as palatable.

Mrs. J. W. Tefft, of Collamer, N. Y., died of pneumonia on Jan. 21, 1889, at Buffalo, N. Y., while visiting friends there. She is mourned by a large circle of friends, as well as her bereaved family.

Mr. William Raitt, of Blairgowrie, Scotland, and one of the editors of the *Bee-Keepers' Record*, published at Liverpool, England, is dead. He died suddenly on Tuesday, Jan. 8, 1889. He was 49 years of age, a widower, and leaves a family of seven children, mostly grown up. From the *British Bee Journal* of Jan. 17, 1889, we gather the following particulars:

On the previous evening he attended what was considered a very successful evangelistic meeting in the Mission Hall, Blairgowrie. On going home from it, he seemed to be in his usual health, and specially happy. About six o'clock next morning, one of his boys, who slept with him, heard him breathing heavily, and called some of the other members of the household, who, on going into the room with a light, saw he was apparently dying, and he expired in a few minutes. The Doctor had been sent for, and shortly arrived. He expressed the opinion that the cause of death had been stoppage of the action of the heart. About three years ago Mr. Raitt had been found almost dead in bed from a similar cause.

Mr. Raitt was a progressive and practical apiarist, and dealer in apiarian supplies. He was the first in England to obtain an American foundation machine, and that was in 1877. He will be sadly missed both in apicultural and social circles.

Personal Discourtesy is entirely unnecessary as well as undesirable when endeavoring to correct an error. We often think some of our best friends err in judgment or in argument, but to correct them will sometimes give offense and break up friendship. A correspondent lately made the following remarks in a private letter:

I have ceased to fight with men as a rule, and now give battle to wrong ideas, as they come out in print. This gives both sides of the question without raising the anger of any one. That this is the better way, I think you will agree. I think it advisable, when battling wrong ideas, to do it so that I can enlighten the public, and not give offense.

We certainly do agree with our correspondent in the above extract, and would gladly have all correspondents copy that noble example.

Statistics are being gathered of the Colorado honey industry. J. M. Clark, of Denver, has reports from about 150 bee-keepers in that State. They report a crop of honey for 1888 of 75,000 pounds. He estimates the crop (including those who have not yet reported) at 100,000 pounds. Concerning this matter, the Colorado *Farmer* remarks as follows:

This is the first attempt ever made to gather statistics of this industry, which will soon be of great importance, as our vast stores of alfalfa give us the advantage over many other States. Our few cloudy days enable them to gather sweets when in more cloudy States they would be hugging the hive.

Alfalfa.—A farmer at Santa Ana, Calif., raised eight crops of alfalfa last year. He was making hay on New Year's Day.

GLEANS OF NEWS.

Prof. A. J. Cook has just returned from New York, where he has been delivering addresses to large audiences in various parts of the State, on "The relation of bees to agriculture." The Professor is an interesting speaker, and his addresses will do much good, by enlightening the agricultural portion of the community upon the true relation of bees to their chosen vocation.

At Albany, N. Y., he delivered a lecture, the outline of which, in the *Country Gentleman*, is as follows:

There is a close relationship between the forces and phenomena of nature. The winds affect the moisture, and the moisture modifies the winds. We cut the forests and let loose the wind and the rain. We crop continuously, starve our soil, and go to the poor-house. Science, which explains this relation, is man's best servant.

This connection of bee-keeping with agriculture well illustrates this relationship, and shows that the farmer needs to know the "whys and wherefores" of all his surroundings. Charles Darwin discovered years ago that cross-fertilization is necessary to full fruitage of many of our plants. Some yield nothing without it. Only insects can do this work for many plants. Early in the season the honey-bee is the only insect common enough to do this work to any large extent. The honey-bee was not a native to America. Thus we know why our early wild flowers are scattering, while the late ones cover the fields and marshes as with a garment. In California, where no winter kills the losect hosts, the early flowers cover the plains.

The honey-bees can reach the nectar of Alsike clover; so the first bloom gives seed. The red clover must wait for bumble-bees, and so the second crop alone is productive. Experiments here and the history of New Zealand prove this. There no seed was produced until the bumble-bee was introduced. Now they raise their own seed. By caging bumble-bees on red clover we can secure seed from the first bloom. Hereafter as we raise our large crops of clover seed, let us think gratefully of the beautiful bumble-bees, rich in their yellow and gold, whose joyous melody in the clover field means for us a bounteous crop and a full pocket-book.

We should especially remember that owing to the cold our insects largely die off, and so for a full fruitage of our plants that bloom early, we must have the honey-bee. This has been proved over and over. Any cultivated plant with sweet or showy flower seeds, must have insects or they cannot bear a full harvest. Our introduced plants mostly bloom in the spring. How important then the bees!

In some cases the wind may be sufficient. Doubtless in all cases insects are great helpers. How often our fruit fails of a full crop, because the cold and rain shut up the bees during the time of bloom. Thus it goes without saying, that the farmer and fruit-grower must either keep bees themselves, or induce their neighbors to do so, or they will fail of the best success. There must be no antagonism between the farmer and orchardist and the bee-keeper. Nature wills that they be friends.

Bees never injure the blossoms of plants; their visits are always and only a benefit. Nor do bees ever destroy sound fruit. The structure and habits of bees, no less than observation, show that this is true. Bees will never attack fruit until a puncture or break in the skin lets free the juice. Then the bee is quick to save the wasting sweets.

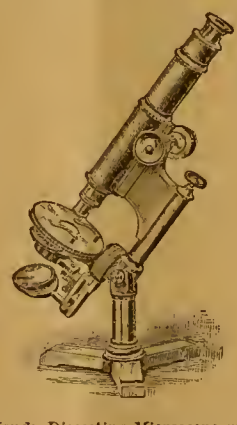
By drawings it was shown that the wasp's jaw was made to tear, but the bee's was not, being gouge-shaped. Bees do, however, visit grapes in swarms, when, for any reason either the puncture of the bird or wasp, or by nature, the juice oozes out. They also crowd about the cider and pomace at the cider-mill, and swarm about raisins exposed to dry out-of-doors. Here the parties interested must unite by screens and other care to mitigate the evil, and then bear and forbear, for all are interested that the bees do not suffer harm. The raisin industry followed the bees, and so bees have the "right of possession." Is it not right then that raisins be dried in enclosures? I am persuaded that when the farmer, gardener and orchardist rightly understand the importance of bees in the natural economy of their own operations, all disputes and unneighborly differences will disappear, and each will rejoice in the others' prosperity, if for no higher motive than mere selfishness.

How Do Bees Breathe?—In an essay by Mr. John Aspinwall, read at the New York State Convention, we find the following very interesting paragraphs:

Bees require a breathing apparatus quite as well as ourselves, and I think it will astonish you when I tell you how complicated it is. In the first place, bees have no lungs like a horse or bird. They do not depend upon one organ to supply the oxygen necessary to enable the several parts to perform their functions.

Before going further, let me explain that the air we breathe is composed of three gases, one of which, oxygen, is the element that sustains *life*, as well as the fire which burns in the grate. Life may be called a burning process.

In ourselves, our blood comes in contact with oxygen within the lungs, and then travels by the most delicate channels to every part of our body. In the bee there is a blood pump like our heart. It is called the "dorsal vessel," and resembles some-



The Handy Dissecting Microscope, made by Bausch & Lomb, Rochester, N. Y.

what an injector, such as is found on every locomotive, but depends upon the opening and shutting of valves, for its successful operation. It leads the blood, received through the several openings in it, to the head, whence it oozes back through the whole body.

Instead of lungs, bees have what is called a "tracheal system"—a trachea is merely an air-tube—and these air-tubes travel in every conceivable direction within the body. They receive the outside air through openings in the body, called spiracles. Adult bees have fourteen of these openings. The spiracles open into large sacs, from which branch out the tubes before spoken of. As I before said, the blood does not receive the oxygen from lungs, and hence these air-tubes must perform this life-giving function. Every part, every member, however small, however delicate, must be reached by these breathing tubes. Bees breathe with a regular motion, but instead of an expanding and contracting of the chest, it is a lengthening and shortening of the abdomen. Watch a tired bee stop at the entrance before going in, and you will see it pant like a tired horse....

Take a good sized pill-box and fill it half full of wax. Catch a worker, and kill it with ether, chloroform or alcohol, and permit the killing fluid to evaporate. With a hair pin, heated over a lamp, make a little bath of melted wax in a convenient spot in the pill-box, and having clipped off the wings and legs of the bee, drop it on its back in the little bath aforesaid. The bee should not be more than half immersed in the wax, which is then allowed to cool. When cold, which will be in about a minute, pour water over the bee until it is covered. In a good light—say sun light—with a needle knife (made by heating the point of a coarse sewing-needle until red hot, hammering it with a tack hammer, on the face of a flat-iron, and after tempering by heating cherry red and plunging in water, sharpened on a hone, and inserted in a match, for a handle), and a fine needle inserted in another match, go to work and cut away the under part of the rings of the abdomen, and carefully lift them off.

If you have good eyesight, or if not, by aid of a cheap lense (magnifying glass) of good construction, you will be astonished at the sight before you. There lie the honey-sac, digesting stomach, bile tubes and intestine. Running in all directions, but starting from the sides, you will note fine white tubes branching out into smaller, and these organs into still smaller, until lost to sight. These are the air-tubes I have been talking about, and you will note that they not only encircle the digesting stomach, but are wound around the other parts in sight. If your lense be strong enough, and you have not ruptured it in your dissection, you may find the nerve system, which lies just under, or when the bee is right side up, just over the wax-producing portion of the abdomen, and which runs the whole length of the bee from tail to brain. You will find it composed of two "cords" almost transparent, with occasional bulgings in which the two "cords" are joined. In and about this very nerve system you will find the fine breathing tubes before spoken of. Up into the compound eye, with its thousands of lenses, run other breathing tubes, every lense being supplied with oxygen in this manner, so that its functions may be performed.

The Ontario Bee-Keepers' Convention was held last month at Owen Sound, the residence of R. McKnight, Esq., Registrar of the County of Grey, who gave the visiting apiarists a right royal welcome. Concerning the next meeting of the International Bee-Association at Brantford, the *Times* remarks thus:

A discussion ensued as to the best course to be adopted in view of this important gathering being had for the second time on Canadian soil. Some were in favor of merging the annual meeting of the Ontario Association with that of the larger body, but it was objected that this could hardly be done in view of the legal status held by the Ontario body. It was felt to be desirable that the American visitors should be received with all cordiality, and to secure this, a special general meeting of the Association was resolved on, and the President and Board of Directors were appointed a delegation to the International body.

The Rev. W. F. Clarke is the President, and Mr. R. F. Holtermann an officer, and we may rest assured that the "cordial reception" will be all that those words imply. We hope for a meeting second to none in the history of the International Society.

QUERIES & REPLIES.

Extending the Brood-Chamber to Secure More Bees.

Written for the American Bee Journal

Query 611.—Is it necessary, or advisable, to again expand the brood-chamber to secure bees enough for the colony to winter well, having been contracted to 5 or 6 Langstroth combs through the white honey season, or from about July 1 to Aug. 10?—New York.

Yes.—H. D. CUTTING.

Yes, sir.—J. M. HAMBAUGH.

I think not.—A. J. COOK.

I am afraid that it is.—C. C. MILLER.

I should say that it is desirable.—A. B. MASON.

It is not necessary, but in my opinion it is desirable.—R. L. TAYLOR.

No; 6 frames are sufficient both for brood and stores.—MRS. L. HARRISON.

Yes. *I* do not practice "contracting" during the honey season. "Keep your colonies strong."—W. M. BARNUM.

I would certainly use more frames in the brood-chamber, if there was a good flow of honey, and the season was favorable.—J. P. H. BROWN.

We never would contract to 5 or 6 Langstroth frames. It is more damaging than useful.—DADANT & SON.

The more bees, the better. I prefer to contract for winter, than during the summer.—P. L. VIALLON.

If I had contracted the hives to 5 or 6 Langstroth frames, I think that I should again expand them to about 8 frames, to make sure of getting plenty of bees for winter.—C. H. DIBBERN.

No, not in this locality; nor do I believe that it is necessary in any similar locality in the United States.—JAMES HEDDON.

Much depends upon locality and season. In some seasons it would be advisable, and in others it would not. I would not contract at all, unless I expected to feed for winter stores.—M. MAHIN.

Not to secure bees, but it is often advisable to so do, that the dark or fall honey may be stored in the brood-comb for food for the bees to winter on.—G. M. DOOLITTLE.

The contracting and expanding question is as yet wholly theoretical, and no rule can be laid down to govern it. The only rule I know of in the matter is, to expand as the colony seems to demand. My bees winter well on from 3 to 8 or 9 Langstroth frames.—J. E. POND.

Do you refer to out-door wintering when, you say, "bees enough for the colony to winter well?" If so, perhaps it would be desirable, still I think that even 5 or 6 frames well filled with brood would make a strong colony—certainly strong enough if wintered in a proper repository. More bees than are necessary to winter well are a positive damage to the bee-keeper after the honey flow.—EUGENE SECOR.

In the first place, I think that it is a mistake to contract at all, if your hives are no larger than an 8 or 10 frame Langstroth hive; but if you must waste your time and injure your bees in that way, it will be necessary to build up your wasted and impoverished colonies if you would have them in good trim for wintering.—G. W. DEMAREE.

I think that the 8-frame Langstroth brood-chamber is just right. This chamber is 12 inches wide, inside. I contract by slipping in an extra brood-frame, making 9; this lessens the spare space, and gives more room for brood, thus crowding the bees into the supers. I consider horizontal, and vertical contraction, and the checking of the queen's disposition to lay, the cheapest kind of "twaddle."—J. M. SHUCK.

Though it is not necessary, it may be desirable to do so under certain circumstances; but as a general rule it is not advisable to do so.—THE EDITOR.

Keeping Bees in a House or Shed.

Written for the American Bee Journal

Query 612.—I have a bee-shed 64 feet long, extending east and west; it is 8 feet wide, and the north side has shutters, so that I can raise them in hot weather, and close them in the time of swarms. On the west end of it I have a house for keeping honey and bee-fixtures. The sun does not shine on the hives at all in hot weather. 1. Is this a good place to keep bees? 2. Is a house a good place to keep bees in, and let them pass through openings in the wall?—Ind.

1. No. 2. I think not.—A. J. COOK.

1. Yes. 2. Not so good as a lawn, in my opinion.—WILL M. BARNUM.

I have never used a "bee-house." I prefer the open ground.—H. D. CUTTING.

1. I would not like it. 2. I would not like a house, either.—C. C. MILLER.

I prefer to have my hives out-of-doors.—J. P. H. BROWN.

1. Yes. 2. The shed is far better than a house.—DADANT & SON.

1. It is, both for winter and summer. 2. I have never used a house, but I would not consider it desirable.—MRS. L. HARRISON.

I prefer to have bees in the open air, and, if possible, partially shaded from the evening sun by trees.—P. L. VIALLON.

1. You ought to be able to answer this question better than I can, for I never tried it (and I never shall). I have never heard of a bee-house (or house apiary) that paid the interest on the investment.—EUGENE SECOR.

1. In this climate I prefer that bees stand out, with only a little shade in the summer. Your shed is all right for winter. 2. I doubt it.—M. MAHIN.

1. Your description is too indefinite. Does the sun shine on the bees in cool weather? Is the shed an open one, or is it closed on all sides? If it is cool in hot weather, and warm in cool weather, it would do. 2. That depends. See answer to 1. It would generally be a very inconvenient place.—R. L. TAYLOR.

1. A shed like you describe has been often used, but I think with poor satisfaction. It requires a great deal more labor to manipulate bees in a penned-up place like a shed. 2. No.—G. W. DEMAREE.

1. The shed has its advantages and disadvantages, all things considered. I would prefer open territory, with large sun shades, and wind-breaks on the north and west. 2. NO!—J. M. HAMBAUGH.

1. I prefer to have the hives where the sun can shine on them in the morning and evening, and be shaded in the hotter part of the day. 2. Having never tried it, I do not know. Some prefer a house.—A. B. MASON.

After keeping bees for many years, in all sorts of places, I prefer at last the full glare of the summer sun. Let the hives have a good shade-board for the hottest weather. I do not think that a house or a shed, or a shady place, is a good place to keep bees.—J. M. SHUCK.

1. I know a bee-keeper who has just such a shed, and his bees do well, and it is a comfortable place for bees and bee-keeper. 2. A house where the bees pass out through the wall is a very good place for bees, but the expense of such a place is out of proportion to all the advantages. A good hive and a little shade is all that is required.—C. H. DIBBERN.

1. With proper care and attention I should say that it would, although I prefer the open air. 2. From my own experience, I should say no. Some claim to have been successful with such houses. They demand too much care and attention to suit my time or convenience.—J. E. POND.

1. It is very good in some respects, and very bad in others. I prefer the entirely out-doors system. 2. I abandoned the house apiary, where the bees flew through the wall. It has both advantages and disadvantages, but more of the latter, I think, considering expense and all.—JAMES HEDDON.

I should prefer to have each hive stand out by itself, on a well-kept lawn; but your arrangement might answer very well, if the hives are not so close as to be unhandy about working among them.—G. M. DOOLITTLE.

Houses and sheds for bees have been "tried and found wanting." No place has been discovered so far which is as generally desirable for an apiary as a well-kept open lawn. Wind-breaks on the north and west are sometimes an advantage, if the apiary is on level ground, and not shielded by friendly woods not far away.—THE EDITOR.

CORRESPONDENCE.

PRICE OF HONEY.

Extracted and Comb Honey at the Same Price.

Written for the American Bee Journal

BY DR. C. C. MILLER.

On page 20 occur the following words: "If there be anything to complain of, it was the action of those who first used the honey-extractor, in placing the price of liquid honey at a less amount than was asked for honey in the comb, with wood, glass and wax weighed up to the buyer! It would be a very difficult matter now to raise the price of the clean, *net*, liquid article—but at the outset it would have been an easy matter to have obtained a larger price for it than for that in the comb."

I produce comb honey nearly altogether, the higher price to be obtained for it being my reason, perhaps coupled with the fact that for years I have made a special study of producing comb honey. But when you come right down to the intrinsic value of honey as an article of food, I think that I must always admit that the same honey is to me better out of the comb than in it. In fact I always prefer for my own eating extracted honey, if it is equal in quality to that in the comb, and I generally produce enough extracted honey so that I can have it on the table three times a day.

If I remember rightly, I have seen the ground taken that chewing the comb gives a piquancy of flavor, or a something that is wanting in the extracted. Take a nice section of honey, cut away half of it and get the free honey from it, either by running it through the extractor, or by pressing it out with a knife. Now you have a half section of honey in the comb, and the clear honey from the other half. If I eat a piece of the comb honey of the size of a hickory-nut, and then with a spoon eat the same quantity of the clear honey, I must say that there is something more satisfactory about the comb honey. What is it? It can hardly be a difference in the honey, for taking the honey out of the comb could not change its quality.

It is claimed that the wax gives the extra flavor. But the wax can give no flavor that it does not possess, and if the wax is chewed alone it has scarcely any flavor, certainly nothing remarkably fine. I cannot think any improved flavor is given by the wax. I think that the difference arises from the fact that in the one case the honey is chewed, and in the other it is not; or, if you please, the comb honey is eaten, and the clear honey is drank. The act of chewing excites the flow of the secretions of the mouth, and this increases the pleasure of the taste.

When I have been extracting honey, I have found that nearly every one who happened to be present, liked to chew the cappings, and a good many of them thought the flavor better than that of honey in any other form. I think that it was simply because there was more chewing.

I think, therefore, we must admit that it is pleasanter to eat the comb honey than to take the same amount of clear honey without chewing. But do we usually use the clear honey without chewing? Of course not, and the question is, not which tastes better eaten alone, but which tastes better eated with bread or some other article of food. In that case one kind gets as much chewing as the other, and I doubt whether the advocates of the wax flavor can tell whether they are eating comb honey or extracted honey on their bread, except as they can *feel* the wax in the mouth. The wax is indigestible, and as ordinarily eaten I know of no advantage in having it present.

So I come back to where I started, that if the quality be the same in each case, I prefer extracted honey to comb honey. But that *if* comes in the case, and "there's the rub." In the majority of cases, the quality of extracted honey is *not* equal to that of comb, and indeed you cannot expect it to be, so long as raw nectar is extracted with the honey, and then no pains taken to ripen or improve it. I suspect that if the quality of extracted honey were always what it might be, and what it should be, that comb honey would be, to a large extent, driven out of the market.

Then why should extracted honey command any lower price than comb? Some succeed in getting the same price for it, and it is the thought of a good many that it never should have been sold for any less price than comb honey. If a wrong has been done, is it too late to right it? Suppose we place the same price on each by raising the price of extracted and lowering that of comb. My friends, the thing wouldn't work. The great law of supply and demand controls the honey market just as it does every other market. You will never again buy a buffalo-robe for as low price as formerly, because the supply has almost ceased. Some kinds of fur that formerly sold for a high price, although in no greater supply than formerly, bring a low price because fashion has forbidden their use, and demand has ceased.

But you say extracted honey as an article of food is of equal value with comb, therefore the price should be equal. I grant your premise, but not your conclusion. If you are correct, then I might say that cotton goods make better overalls than silk, therefore the cotton goods should be higher in price. The fact is, the two kinds of honey are to some extent independent of each other. If people find, in general, that extracted honey is not equal in quality to comb honey, the demand will be less. Then the appearance of comb honey on the table gives it a greater value in the eyes of many.

Now, please do not throw so much blame on those who have sold extracted honey at low prices. It costs more to produce comb honey than the extracted, and so long as that is the case, I think we will always find the price for comb honey higher.

Granulation of Honey.

Referring to Mr. Bovee's opinion about honey granulating (see page 20), I may say that I never knew honey to granulate so early for me as this year. I think that some of it commenced to granulate within two weeks after extracting. The fact that Mr. Bovee never saw honey granulate within two months after extracting, does not warrant him in saying that it never does so. It is possible there might be found persons who had never seen granulated honey, but that does not warrant them in denying its existence.

But please do not be too hard on Mr. Bovee. We have all made mistakes, such as saying that all pure honey would granulate.

Marengo, Ills.

[The foregoing article is right to the point. If extracted honey is equal in quality to the comb, it certainly *is* of more value, because it is *all honey*, and minus the wax and wood. Upon that

"if" hangs the whole argument as to its real value and deliciousness.

As to the pleasure in eating comb honey, there is a certain gratification in chewing it, but the *real* delight in eating it is that of *absorbing* its delicious sweetness; and that is done by the sense of *taste* located in the tip of the tongue. It is "rolled under the tongue as a sweet morsel," says an old sage. David, the psalmist, also avers that wisdom is "sweeter than honey and the honey-comb"—by implication assuming that the comb is even sweeter than the honey it contains!

When eating extracted honey, it is carried by the spoon to the tongue beyond the tip where the sense of taste is located, and much of the pleasure of eating it is lost.

Even though the wax is indigestible, chewing the wax and mashing both together brings out that peculiar sweetness which is so pleasant to the sense of *tasle*, and accounts for the soothing, satisfying, and delightful sensation produced by eating honey in the comb, or of chewing the fresh cappings.

We sent a "proof" of the foregoing article and comments to Dr. Miller, and this is his reply:

Does not the "honey-comb" in the Scriptures always mean honey in the comb? See Luke 24, 42.

If the implication is "that the comb is even sweeter than the honey it contains," then I am wrong, and comb honey has an intrinsic value beyond "extracted." But *supply and demand* is what controls price. My customers have always been told that extracted is intrinsically better than comb, and I kept the price the same as long as I could, but it cannot be held there.

We admit that sometimes the word "honey-comb" in the Bible means "honey in the comb," but *not* always. In the passage quoted from the Psalms such a meaning would make the quotation nonsensical!

That commercial "supply and demand" control prices is true; but public sentiment and education, either in right or wrong channels, are very potent in regulating *values*, and thereby influencing "supply and demand!"

The Doctor correctly told his customers that extracted honey was "intrinsically better than comb," and held "the prices the same" as long as he could, but public sentiment had been educated that it was of *less value* than comb, and "supply and demand," so educated, "regulated" the price at the less amount—and that is the reason he has to admit that "it cannot be held there." The education was erroneous, and the regulation unjust.—ED.]

LOVE AND HONEY.

Love is the centre and circumference,
The cause and aim of all things; 'tis the key
To joy and sorrow, and the recompense
For all the ills that have been or may be.

Love is as bitter as the dregs of sin,
As sweet as *clover-honey* in its cell,
Love is the password whereby souls get in
To heaven—the gateway that leads sometimes to hell.—*Selected.*

EXPERIENCE.

How I Began the Business of Bee-Keeping.

Written for the American Bee Journal

BY F. C. ERKEL.

In the first part of July, 1885, I bought a couple swarms of black bees in box-hives, and moved them home, about two miles, in a spring buggy, before they brought in enough honey to cause any danger of breaking down the new, tender combs. They went right to work, and in spite of

A swarm of bees in July
Is not worth a fly,

as I had been told, they filled up their hives, and were in good condition to go into winter quarters.

I hardly knew the very first thing about bees. I *had* found a swarm on a bush four or five years before, when I was a small boy, and my father had given an old man a dollar for an old box in which he had put the bees when we took them home, and let them stand until they perished the following winter. We had never heard of such a thing as wintering bees in the cellar. I do not think that before I found that cluster, I could have distinguished a honey-bee from a bumble-bee, but when I made up my mind to buy a couple colonies, I also decided to find out all I could about bee-keeping, and handle them in an intelligent manner, or not at all.

I talked with all the old bee-keepers that I met, and got all the information possible; most of them told me that I had better get movable-frame hives, if I had really decided to keep bees; but that I would be sorry I had ever turned my attention toward that industry. One man with whom I talked the most, and who supplied most of the market round about, told me that he had been keeping bees for a number of years, and during all that time he had kept a strict account, and that the bees were in debt to him after all that time. I must confess that that discouraged me some, but I decided that I would not back out until I found out for myself, if there was any profit in them.

In the winter of 1885–86, I put 2 colonies in box-hives in one corner of the cellar, which I had divided off with building paper. I turned the hives upside down, and removed the bottom-board, which left them without a top, but with plenty of air. There I left them until spring, when I took them out of the cellar and placed them on the summer stands; but may be I did not have an interesting time of it, placing back the bottom-boards on those old box-hives with the tops of the combs all covered with bees, which acted in a very hostile manner, I thought, toward one who was trying to work for their own good; but I got them out, just the same, even if the folks did hardly recognize me for the next few days.

The bees went to work with all their little "mights," bringing in pollen, and by May 1, both swarmed, the two large swarms going together, making about three pecks of bees. Then I was in a pretty mess. I had ordered some new hives to put the swarms into, but they had swarmed long before I expected it, and the hives had not yet come. Then, what an idea for them to go together in that way! I had never heard of such a thing.

I nailed together two box-hives, put them on a table which I put under the limb on which the bees clustered; then I shook the bees off the limb in front of the hives, and with a wing I guided about half the bees into each hive, in hopes that there was a queen in each hive, for I wanted to increase my number of colonies, and I thought that it would be a great detriment to have them go together in that way; but it did no good, for although I had them divided quite equally, it was but a short time before they were all in one hive again. I think that was the largest swarm I have ever seen, and they made good use of the time, for in a few days they had the hive full of comb, and swarmed, and they and the old ones kept on swarming, so that in the fall I had 3 colonies in box-hives, and 7 in Simplicity hives. I had increased the 2 colonies to 10, and had taken some comb honey.

During this time I made pretty good use of bee-books, and decided to rear

some queens the next summer, if my bees should again winter nicely in the cellar. They were in good condition when I put them in, and in the spring I took out all the 10 colonies with (as it seemed to me) very little less honey than they had in the fall.

I bought another colony in a box-hive, and one in a Simplicity hive which had a very nice Italian queen, so that in the spring of 1887 I began with 12 colonies, and put 38 colonies into the cellar in the fall, besides about half a dozen that absconded, and one which I sold. I thought that was pretty good for two years, and although I did not get much honey, I had increased my apiary, which I cared more for than honey, and had also given most of my colonies young queens that I reared myself, and brought them up from blacks to hybrids.

I now thought that I had better begin to work for honey, and not quite so much for increase, for although I take the AMERICAN BEE JOURNAL, and, as a general thing, read every word in it, together with other bee-literature, I began to fear that my colonies would increase faster in number if I should let them go on, than I would increase my knowledge of bee-keeping.

Le Sueur, Minn.

BEES OUT-DOORS.

Good Way to Secure the Sowing of Alsike Clover.

Written for the American Bee Journal

BY I. J. GLASS.

I do not know what kind of a bee-keeper I will be called when I say that my bees are still on the summer stands, without any protection whatever. I have previously wintered my bees in the cellar without loss, as I have stated in former communications; but owing to my time being completely occupied in other duties, I have somewhat neglected my bees.

I cultivate a farm of 200 acres, and teach school during the winter, which keeps me pretty well occupied. I have waited all the while for a "cold snap" before carrying them into the cellar, and whenever it did turn a little cold, by the time Saturday came (the day I have outside of school hours), it would always be moderated, and sometimes the bees were on the wing. So I have kept procrastinating until here it is, near the middle of January, giving us regular spring weather. Although there is plenty of time yet to give us a few blizzards, yet I do not look for much severe cold weather.

I supposed all the while that I had 61 colonies, but upon investigating them I find one hive deserted from lack of stores. I thought they were all abundantly supplied with good honey, but that one had been overlooked; the remaining sixty are in splendid condition.

I took 1,000 pounds of surplus from my bees the past season, and retailed the greater part of it at 18 cents per pound in my home market. My bees did not store a particle of surplus honey until after the middle of August, when the boom set in. My hired man let several swarms go to the woods, thinking it useless to secure them so late in the season.

Alsike for Bee-Pasturage.

I induced a neighbor of mine to sow 65 acres of Alsike clover, by paying the difference between it and red clover seed. I got big returns the first season, and another neighbor is going to sow a lot the coming spring, under the same conditions. This, with what I have sown, and what I am going to sow next spring, will give me an abundance of bee-pasturage.

We have had no white clover here for the past two seasons, but the prospect is flattering for a big yield another year, and I trust we who have been having poor yields, will be able surprise even ourselves.

Sharpsburg, Ills., Jan. 14, 1889.

AFTER-SWARMS.

The Various Methods of Preventing them.

Written for the American Rural Home

BY G. M. DOOLITTLE.

There are various methods of doing this, such as removing the old colony to a new stand, as soon as the swarm has left it, setting the hive containing the new swarm on the stand it previously occupied; cutting off all of the queen-cells but one on the fifth or sixth day after swarming, and hiving the after-swarms in a box on top of the old hive till the next morning after they come out, when they are to be shook out of the box in front of the old hive, and allowed to run in, so that the young queens will all but one be destroyed. Now all of the above plans have their various advocates, who think them superior to anything else, but as the correspondent has asked for the *best* plan, I must give him the plan which I consider best from my standpoint.

There are two plans which I have used with good success at all times, and use them in accord with what I wish to do with the old colony of bees. Where I wish to treat swarms the way they are generally treated by hiving them on a new stand, I proceed as follows: As soon as the swarm is hived, I go to the old hive from which it came, and mark on it with a lead pencil, Sw'd, 6-22, which tells me at a glance that a swarm came from that hive on June 22, should that be the date on which the swarm issued, and the one which was marked on the hive. If it should be another day the date is different, but the plan is the same as suited to any day on which the swarm is cast.

On the evening of the eighth day from the date on the hive, I listen a moment at the side of the old hive, and if swarming has been done "according to rule," I hear a young queen piping, when I know that a queen has hatched, and an after-swarm will be the result if it is not stopped. If no piping is heard, I do not listen again till the evening of the thirteenth day, for the next rule is, that the colony swarmed upon an egg or small larva being placed in the queen-cell, which allows the queen to hatch from the 12th to the 16th day after swarming. If no piping is heard by the evening of the 17th day, no swarm need be expected.

When it is heard, which it will be in nineteen cases out of twenty, on the eighth day, I go early the next morning and take every frame out of the hive, shaking the bees off of each (in front of the entrance) as I take them out and return them again, so I shall be sure and not miss a queen-cell, but cut all off, for we know that there is a queen hatched, from the piping which we have heard. Once in a great while the bees will take a notion to go with the queen when she goes out to be fertilized, but such a happening is of rare occurrence, and has nothing to do with what is known as after-swarming. The above is a sure plan of accomplishing what we desire to, under all circumstances which may arise, while those spoken of at first will work at times, and at others not.

The other plan which I use is equally successful with the above, but is used only where the old hive is carried to a new stand while the swarm is in the air, hiving the new swarm on the old stand; in which case I proceed as follows: As soon as the swarm is seen issuing from any hive, I go to the shop where I get a box or hive, which has previously been prepared, having the desired number of frames (I use frames of comb in this case) in it, taking it to the hive from which the swarm came, when the frames of comb are set out of the box near the hive. I now open the hive and take out the frames of brood, putting them in the box. If the combs of brood seem to be well covered with bees, and the

weather is warm, I shake a part of them off in front of the hive, before putting the combs in the box. If few bees, or cool weather, I put all in the box, setting the box in the shade, and a rod or so from the hive, as soon as all of the frames of brood and bees on them are in the box. I now put the frames brought from the shop into the hive, and re-arrange it, by which time the swarm will return if the queen has a clipped wing. If the queen is not so clipped, then the swarm is to be hived in this prepared hive on the old stand, the same as any swarm is hived. I next put the combs of brood and bees which are in the box, in a hive where I wish the colony to stand, and adjust the entrance to suit their wants, when they are left till the next morning. By this time nearly all of the old or field bees have gone back to their old location, so that the young bees which remain are ready to accept of anything in the shape of a queen.

I now go to my queen-nursery and select such a young virgin queen as I wish them to have, place her in a wire-cloth cage, and take her to this hive. Upon opening the hive, I take out one of the central combs, holding the same up before me. As the bees are all young bees, they will at once take to filling themselves with honey, and while they are so doing, I let the queen run on the comb where there are a few cells of honey not occupied with other bees eating out of them, when the queen will commence to fill herself the same as she sees the others doing. The frame is now lowered down into the hive, and the hive closed. In this way the queen and bees appear natural, and I have yet to lose the first queen put in under such circumstances. As the colony now find that they have a queen, they proceed at once to destroy all of the queen-cells, so that no after-swarms ever issue, at least an experience covering a period of six years says that none do. In the above two plans we have something very near perfection, if not quite so.

Borodino, N. Y.

MANAGEMENT.

Hives, Supers, Hiving Swarms, Bee-Cellars, etc.

Written for the American Bee Journal

BY GEO. H. KIRKPATRICK.

I began bee-keeping in 1881. My first hive was a good 10-frame Langstroth, and though I have made a great many experiments with different styles of hives, I have always held to the Langstroth frame, and I expect to do so until I am sure that I have found something better; but I do not expect to ever see a better one.

The hive I have decided to use exclusive of all others, is a plain, simple box, 13¼x20¼ inches, outside dimensions (made of ⅞-inch lumber), cut square on the top and bottom, and receives 8 Langstroth frames. The bottom-board of this hive is made of ½-inch lumber. To make it secure, I tack on a strip ⅞x2 inches, and make a ½-inch groove in it ⅜ of an inch from the top edge; with this strip I make a frame around the bottom, and insert the ends of the bottom-boards into the groove, which makes it solid; and it is also reversible, one side having a ⅜-inch bee-space, which makes it just right to set the brood-chamber on in the summer; while the other side has a 1⅛-inch space—this side I prefer to turn upwards in winter. It gives more space for the dead bees to drop in, and one can, with a wire hook, drag them out at the entrance without touching the bottoms of the frames, and annoying the colony.

The supers are of the same dimensions as the hive, and can be tiered up to any desired height, the only difference being in the thickness of the lumber. The ends are made of ⅞-inch lumber, and the sides of ⅝-inch. This leaves the super just 12 inches wide—the right width to receive 28 sections, 4¼x4¼, and 7-to-the-foot, and can be used with or without separators.

The cover is made of a ⅞-inch board cut 16 inches wide and 24 inches long, and well cleated at each end. I use a wood-zinc break-joint queen-excluding honey-board, and without it the hive would be incomplete.

Spring Management of Bees.

I make a special effort in the spring to get each colony strong, so as to have the hives fairly boiling over with bees at the beginning of the expected honey harvest. It is with these strong colonies that we get the large surplus, and without them our crop of honey would be small, and our pockets empty. It is the strong, populous colonies that fill the sections with nice, white honey, and leave off the propolis. This gives the honey a tasty appearance, and makes it ready for sale at a fair price.

Increase of Colonies.

I prefer to make my increase of colonies by natural swarming. I want large ones, and early. It may be stated, as a rule, that a colony of bees dividing up its forces by swarming, will not produce as large a surplus as a colony under the same condition, that does not swarm. Be this as it may, I prefer the swarm.

Method of Hiving Swarms.

I arrange a number of brood-chambers with about 6 brood-combs, and when a swarm issues, it is hived in one of the prepared brood-chambers on the old stand. The parent colony is then placed on a new stand, and the surplus taken off and placed on the newly-prepared one. A wood-zinc queen-excluding honey-board is placed on the brood-chamber, and the super placed over it. The transfer is usually made while the bees are in the air, or it may be done within 24 hours.

If increase is desired, I work the parent colony for extracted honey the remainder of the season; if increase is not desired, I shake the bees from the combs in the parent colony in front of the newly-hived swarm. I then have all the bees that the old hive contained in the one just right for comb honey. The brood taken away is placed over a colony capable of taking care of it, and is used for starting nuclei, and hatching out the queen-cells that the combs contain. If they are choice stock, valuable queens can be reared in this way, and should be saved.

Cellar for Wintering Bees.

If I were to winter bees on the summer stands, I would by all means use chaff hives, as they are the very best for out-door wintering. But if one keeps as many as 40 colonies, or more, it will pay to build a cellar. The difference in the cost of 40 chaff hives and 40 single-walled ones, will amount to about $60; and that amount will pay for the material to build a cellar, such as I have.

My cellar is 12x18 feet, and built as follows: I first dug a hole 2 feet deep, then built a wall 6 inches high all around the cellar, and on this I placed the sills. I then set up the studding, which was 7 feet in length. I weather-boarded it with pitch-pine lumber, and then cemented it on the outside, and banked the earth up to a height of 6 feet. I used 6-inch joist, and cleated it overhead. I then filled in between the joist with sawdust, and laid on a tight floor.

I then extended the building 7½ feet higher. In the upper story I have a real neat little shop, just the place for nailing up hives and supers, and, in short, just the place to prepare every thing needed in the apiary.

The cellar is ventilated by a chimney built from the cellar, and extended up through the shop. I also have a 6-inch tile running from the cellar out through the bank. This tile I keep filled with flax-tow, except when the cellar gets too warm, then I draw it out, or put it in loosely, so that the air will pass through it.

The cellar is arranged with two doors. I open one of them, and enter the cellar-way; I then close it, and open the second one, which opens into the cellar.

As this cellar cost me only $60, I think that I have a cheap one. When I first began to work in the shop over the bees, I was afraid that the noise would annoy them, but as the hives do not touch the frame of the building, they do not receive any jars. They are placed on scaffolds built from the ground up. The average temperature of the cellar is 44°, and I have no trouble to keep this temperature.

New Paris, O.

CAN BEES HEAR?

The Various Sounds Made by the Bees.

Written for the American Bee Journal

BY A COUNTRY BEE.

The editor of the AMERICAN BEE JOURNAL cannot be expected to be a perfect encyclopedia of bee-literature, with each phrase, and phase, of the various ideas of all the writers labeled and indexed for reference, every time he looks over a manuscript; therefore it is not surprising that the article on page 39, entitled, "Do Bees Hear," by Mr. C. E. Woodward, should have found its way into the BEE JOURNAL.

Permit me to make quotations from an article by Mr. G. B. Peters, Council Bend, Ark., as it appears in the "A B C of Bee-Culture," on the subject of swarming, of which that on page 39 is an exact copy:

"I will remind the reader here that bees have different sounds to accomplish different ends. The only natural sound of bees on the wing is that produced by the returning laborer when she comes, at even, laden with spoils collected from some flowery field. Who has not been charmed by such industrious energy, as those mellow tones died in the entrance of the hive?

"The shrill note of the pugnacious defender of the hive is familiar to every child. The sharp sound of bees just beginning to lead out a swarm, heralds its advent to the apiarist, and is very different from the two former sounds.

"The coarse bass roaring of the swarm before it begins to cluster is heard only when they are in search of the queen, and is kept up by both workers and drones; then follows the sharp cutting sound as they begin to cluster, to call the colony together, which is well known to the bee-keeper as the signal of congregating.

"Then the shrill hissing sound of the escort that leads them to the woods blends with the roar of the rear part of the swarm, making a strange compound heard only from absconding bees. Then, again, in that 'happy hour,' when they have found a house, we hear the happy hum made by a peculiar position of body, and indicating peace and contentment.

"Also a sound of distress, when annoyed by smoke or enemies, rings through the hive, and no wail of misery from any other insect tribe can equal it. Finally we have the ventilating sound at the entrance and all through the hive, which, in hot weather, may be heard quite a distance.

"All these different sounds are instinctively associated with certain purposes, and the movements of the queen are generally governed by them. She thus follows certain sounds as do the whole colony. She never leads the swarm, but is attracted by the roaring mass."

Earlier in the article I find "Queen, workers, drones all take wing, rise high in the air, and abandon old home, kin, and everything forever." Also, "I noticed a revolving lot of bees in each, about five feet through, leading the van with a hissing sound."

[By comparing the article written by Mr. Peters, with that on page 39, it is very evident that Mr. Woodward has copied seven out of his nine paragraphs bodily without credit, and has imposed on us. It is a clear case of inexcusable plagiarism.—ED.]

ODORS AND BEES.

Are Bees Attracted More by Smell than Sight?

Written for the American Bee Journal

BY MRS. M. B. CHADDOCK.

In Prof. Cook's letter about the cardinal flower (on page 926 of *Gleanings*), he says: "All our botanists believe that odor and color in flowers are developed peculiarities .....We see, then, why many showy flowers, like this cardinal bloom, and the Rocky Mountain bee-plant, attract bees and other insects without odor."

But do we *see* it? Is there any flower with nectar in its heart, that is *odorless?* I do not know of any, but I am, of course, unacquainted with the plants named. If the flowers are odorless, the honey must be odorless as well. Did anybody ever smell any odorless honey?

Then I want to ask, does a field of red clover have a stronger smell than a field of white clover? The fragrance of acres of white clover is ethereal, delightful and refined; that of the red clover is stronger and coarser. How does Prof. Cook know that the bees are attracted to the red clover field by color? He admits that the bees are drawn to the white clover by odor, and if the red clover has a stronger odor, what is to hinder them from being influenced by it?

But do the bees generally pass the red clover by? Do they not "roar" over it (at times, when there is no honey in other flowers), alight on the blossoms, and run their tongues into the separate tubes of the blossoms? and will they not keep on doing this until experience teaches them that they can get nothing? They smell the nectar, and are wild to get it, but cannot.

On page 627, of *Gleanings*, Prof. Cook says: "Note the three broad petals. They not only say 'come,' by their bright hues, but by the restful footstool which they offer the weary bees."

Bees care not one whit for "foot stools"—they mean business, pure and simple, and do not hunt around for "footstools." When eagerly reaching for nectar, they hang on the tassel like blossoms of flowers, and roar over the maples and box-elders that offer them no footstool at all. A man clinging with his hands and feet to a sheaf of wheat suspended in mid-air, would have just the same kind of a "footstool" that bees have on the maple blossoms.

That bees are attracted almost wholly by odor seems to me to be too plain a proposition to need proof. Once I put some honey in the cellar-way—a small landing in the darkest corner of the cellar—and the bees went through a crack about half an inch in the thick cellar wall, and carried away the honey. The cellar was full of bees, and they went and came in a regular stream. Did they smell that honey?

In the winter time I keep my empty hives and hives that are partly filled with honey, up-stairs in the "ghost-haunted chamber," or, as we generally speak of it, "the long room." The windows and doors of that room are always to be kept shut. But once the door (opening into another room) was left ajar, and the bees coming in through the bed-room windows, found the honey, and began carrying it away.

Again, when I used to "render out" beeswax, the bees always smelled it, and came swarming around the doors and windows, butting their heads against the screens.

To-day I tried a scientific experiment. (I have just as much right to try scientific experiments as Prof.

Cook has.) I was hanging the clothes on the line, which is out near the bee-hives, and I thought of what Prof. Cook said about the cardinal flowers. I said to myself, "All these red aprons and under-flannels must be as conspicuous as the cardinal flower," and I waited and watched to see if the bees that were flying about would alight on them. I watched for about ten minutes, and only one bee alighted on the clothes, and it did not pretend to use its tongue. Then I came into the house, took a saucer of honey and placed it down among the dead grass, and twisted the tops of the grass over it like an Indian te-pee; and as I went back and forth, I watched to see if the bees would find it soon. In a few minutes I saw half-a-dozen bees flying about it. In half an hour they were "roaring" over it, and had carried the honey away, leaving the comb dry.

In "The Physiology of the Honey-Bee" we read: "17. But the celebrated Darwin was mistaken in saying that the colorless blossoms which he names obscure blossoms, are scarcely visited by insects, while the most highly colored blossoms are very fondly visited by the bees. (Gaston Bonvier, 'Les Nectaries,' Paris, 1879.) 18. For, although color attracts bees, it is only one of the means used by nature to bring them in contact with flowers. The smell of honey is certainly the main attraction, and this attraction is so powerful, that frequently, at day-break in the summer, the bees will be found in full flight, gathering the honey which has been secreted in the night, when nothing on the preceding evening could have predicted such a crop. This happens, especially, when there is a production of honey-dew after a storm. We have even known bees to gather honey from tulip trees (*Liriodendron tulipifera*) on very clear moonlight nights."

If the above quotation proves anything, it proves that *odor* is a much more important factor than *color*.

Again, on page 761 of the AMERICAN BEE JOURNAL for 1888, where the editor of the *British Bee Journal* reviews Prof. Cook's "Manual of the Apiary," he says: "Although their sense of color is very keen, our author (Prof. Cook) believes 'more has been made of this matter of color than truth will warrant.' We think so, too, and believe the experiments of Sir John Lubbock go to prove, not that bees prefer one color to another, but that they can be accustomed to recognize a certain color."

So, then, Prof. Cook says that "more has been made of this matter of color than the truth will warrant"—and to this sentiment I say, "Amen!"

Vermont, Ills.

SEASON OF 1888.

A Large Crop of Fall Honey Secured.

Written for the American Bee Journal

BY JNO. A. THORNTON.

When the spring of 1888 opened, my colonies were in average to good condition, and continued to increase in bees till the time for white clover to bloom, when all were in good condition to gather a large surplus; but there was no nectar in the clover that did bloom. The bees had the swarming fever about this time, which was caused by honey-dew gathered from the oak leaves and some other source. It was of very dark color, and not fit for use except for daily food for the bees. From this source there was 1,200 pounds of surplus taken, about July 15, from the surplus departments, which I am saving for spring feeding.

About Aug. 1, the yield commenced from what is commonly called "smart-weed," and honey continued to be gathered up till Sept. 20, when my crop of honey of the season was all gathered. It amounted to 4,500 pounds in one pound sections, and 3,500 pounds of extracted honey, which I have been able, on account of the absence of any clover honey, to sell at about the same price as I could have sold clover honey. In color it would compare favorably with clover honey.

I began the season with 150 colonies, and increased them to 200 colonies. They were in two apiaries five miles apart. One apiary had only 25 colonies in the spring, and cast nearly 40 swarms through the summer, which caused a great amount of work in uniting and keeping down so much increase. As it was, the apiary was only increased to 49 colonies, and the amount of surplus was 1,500 pounds from this apiary.

The home apiary did not swarm quite so much, though nearly 100 swarms issued from May 8 till Sept. 5.

The method of keeping down increase mostly practiced was, to hive the swarm on the old stand, remove the old stand only to one side for three or four days, when the hatched bees were shaken off in front of the new hive and swarm, and the combs and brood were put on the hives of colonies worked for extracted honey.

The prospects for 1889 could not be better, as all idle ground and pasture land have a good crop of white clover from the seed, as well as a large amount of the common red clover, sown on account of the drouth killing all that was sown in 1887.

Lima, Ills., Jan. 14, 1889.

WINTERING.

The Passage-Ways between the Hives in the Cellar.

Written for the Farmers' Review

BY MRS. L. C. AXTELL.

The 200 colonies that we have in the cellar are arranged in rows three hives high. The rows are all wide enough apart so that we can go between them and sweep out the dead bees once in two or three weeks. It is very unhealthy to so arrange the bees that they cannot be swept out, and lie all winter on the cellar bottom and mold, as ours did for the first few years that we kept bees. Before spring the cellar smelled very badly, and when the hives were carried out in the spring, sometimes there would be bushels of dead bees, when there were 100 to 150 colonies in the cellar. Now the cellar smells pure, and when I take a light down, I can see the round balls of bees cluster clear down upon the bottom-board, as the fronts of all the hives are raised an inch.

It is a pretty sight to see the golden beauties all snugly tucked up in a tight cluster. I feel almost constrained to thrust in my hand and pat them—perhaps I would, if it were not for disturbing them.

The past three years have been hard on bees; those who liked to feed bees had the chance to do so to their heart's content. But few bees have lived that were not fed, even in the midsummer time.

Last summer we found some of our colonies clear out of food. The last of August they began to gather honey, and for about 3 weeks they stored it very fast, filled up their hives nicely for winter, and some of the strongest colonies stored some surplus; but bees late in the fall will not carry their honey above into surplus receptacles, until their brood-combs are heavily laden—first with brood and then with honey—and then, as fast as the brood hatches out, they fill the cells with the honey, until, for want of room, they carry the remaining nectar up above into the surplus receptacles. Our 200 colonies produced about 800 or 1,000 pounds of surplus honey last fall, besides plenty for winter stores.

Roseville, Ills.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Early Brood-Rearing. — Geo. W. Morris, Cornishville, Ky., on Jan. 26, says :

We have had no zero weather here yet. On Jan. 23 I opened two hives—one moderately strong in bees, and one weak—and found eggs, larvæ, and sealed brood in both. Bees have had a dight every tew days up to the present time, and prospects look flattering.

Alfalfa Honey.—Thos. B. Brundage, Sheridan, Wyo. Ter., on Jan. 25, writes :

In the spring of 1888 I purchased 2 colonies of Italian bees (or what were supposed to be Italians, though I do not think they are). They were shipped on May 27, and arrived in Wyoming June 2. I had 2 swarms from one colony on July 14 and 17, and the other colony did not swarm, though it worked diligently. On Sept. 1, I took from the one colony 132 pounds of comb honey, though the rest of them gathered about 45 pounds per colony for winter stores. I have them in a cellar, and so far they have done finely. Honey in this place brings a fair price, and there are only 6 colonies in the county. The bees get their honey from alfalfa and the wild flowers of the valley, which are plentiful, and very rich in nectar. It would be impossible for me to do without the AMERICAN BEE JOURNAL, as it is a true friend to the bee-keeper, and also a guide to success.

Very Mild Winter.—Mr. Abe Hoke, Union City, Ind., on Jan. 27, 1889, writes :

Bees have done nothing for the past two or three years ; but the last year was the worst that I have seen since using frame hives. They gathered honey for a few days in June, then everything was at a standstill. I had two natural swarms, and the entire increase from 21 colonies was 4. I had to feed the bees last fall, and I have no doubt that some of them will starve before May, unless I feed more. We have had an unusually mild winter so far ; the coldest being 6° above zero. At present we have 6 inches of snow, and the mercury was at 30° above zero at 3 o'clock this afternoon.

Bees Doing Well.—F. N. Johnson, Knoxville, Ills., on Jan. 27, 1889, says :

Bees are doing well. We had a poor season last year. I have kept bees for a number of years, and, like all other bee-keepers, I have had some ups and downs. I have used several styles of hives, but I have settled down to a double chaff-packing hive of my own. It takes nearly a square frame. I have not lost a colony of bees in it for six years. I anticipate a big crop of honey this year.

Report for Two Seasons.—Mr. W. Stont, Wilmington, Del., on Jan. 28, writes :

I got no surplus honey in 1887, and hardly enough to winter my bees ; what they did get was gathered too late to cap, and consequently it granulated in the hive. Not being strong colonies, and all old bees, with their vitality all worn out, they were unable to pull through. I lost about half of them. Last spring I commenced with 10 colonies in very poor condition, increased them to 18, and obtained about 300 pounds of comb and extracted, about equally divided. They were put into winter quarters in better condition, both in bees and honey, than I have ever had them, I believe.

Bee-Keepers are Jubilant.—J. M. Young, Rock Bluffs, Nebr., on Jan. 28, 1889, says :

The weather in eastern Nebraska, has been very mild and summer-like so far this winter. The mercury has been to zero but once or twice, and only for a short time. Bee-keepers are feeling jubilant over the fair prospects of wintering their bees with but little loss. My entire apiary is wintering in chaff hives ; every mild day the bees can be noted removing dead bees at the entrance of the hives, thereby insuring that the colony is in a healthy condition, and all is well within. The AMERICAN BEE JOURNAL is a weekly visitor to our fireside, and is fully up to the times.

Small Yield of Honey.—Abner Picket, Nassagaweya, Ont., on Jan. 28, 1889, writes :

I commenced the season of 1888 with 107 colonies of bees, a few colonies being weak, but by the time the honey season commenced nearly all were in good working order. I hoped and expected to receive a large yield of honey, but the bees got barely enough to keep up brood-rearing, until the time of the linden honey-flow. Alsike clover yielded but a bare living for the bees, and I had no surplus in the fall from fall flowers. What I have is 10 pounds per colony, and an increase of 22 colonies, for which I am thankful, as many in this county have not had any surplus or any increase, and had to feed to keep their bees from starving.

Bees Wintering Splendidly.—W. H. Fowler, Jennings, Mich., on Jan. 28, 1889, says :

My bees are wintering splendidly. I bought 2 colonies last spring, I had no increase, and only 50 pounds of surplus honey in sections. I did not get a chance to use the extractor, but I robbed each colony of one frame, just to try it.

Foundation Made on Molds.—J. L. Haworth, Quaker Hill, Ind., on Jan. 24, 1889, writes :

I commenced the season of 1888 with 16 colonies of bees, some of which were weak. I increased them to 24 good colonies, and secured 115 pounds of comb honey, and 820 pounds of extracted. Nearly 700 pounds of it was gathered in the fall. It was very thick, and almost as white as the best white clover honey. I procured one of the "foundation molds" last spring, and made very good heavy foundation with it, but I failed to make any thin enough for the sections. The bees seem to work on it just as well as on Dadant's foundation. My apiary is situated three miles east of Georgetown, Ills. I shall move my bees the coming spring ; they are in the cellar now.

Japanese Buckwheat, etc.—T. R. Canady, Roark, Mo., on Jan. 23, says :

I commenced with 12 colonies in 1888, increased them to 24, and obtained 75 pounds of nice comb honey, and 100 pounds of extracted. Comb honey in one-pound boxes sells for 15 cents per pound ; extracted at 10 cents per pound. I had to feed 175 pounds of granulated sugar to winter my bees on, so I did not get any more honey than I fed sugar. Bees are wintering well so far. The winter is very mild, and bees fly almost every day. They just had a picnic to day in the sunshine. The prospects are good for next season. I sowed 6 pounds of Japanese buckwheat, and harvested 5¼ bushels of the grain. I think that it is the best buckwheat that was ever introduced into this country.

Bees Packed for Winter.—J. E. Turner, Woodington, O., on Jan. 19, says :

I began bee-keeping in the spring of 1888, with 1 colony of bees, which I increased to 4 by natural swarming, and caught 1 swarm, making 5. I put them into winter quarters during the latter part of October, by packing them with chaff, in cases 4 inches larger all around than the hives. I think that they are wintering well. My surplus was about 50 pounds, principally white clover honey. The prospect for next year is very good.

No Danger of Over-Production.—J. M. A. Miller, Galva, Ills., on Jan. 24, 1889, says :

My report for 1888 is 40 pounds of comb honey from 48 colonies, with 7 colonies that had to be fed to keep them alive. This is not very encouraging, but I hope for better days. I keep my bees in the cellar, and they seem to be all right ; with this warm winter, I think that they would do well on the summer stands. If we do not get more honey soon, there will be no danger of an over-production of honey.

Good Results—Sterile Queen.—Jos. E. Stoner, Atlantic, Iowa, on Jan. 24, 1889, writes :

I commenced the spring of 1887 with 5 colonies in old boxes, for which I paid $3 each. I transferred them to Simplicity hives, increased them to 14 colonies, and took 150 pounds of comb honey, worth 15 cents per pound. I commenced in 1888 with 12 colonies, increased them to 16, and took 550 pounds of honey—and now old bee-keepers say that the last two years were the poorest on record.

I put my bees into a cave on Dec. 10. I took off the cap, put on one section-case, put in the slatted honey-board, one thickness of thin cloth, and filled it with fine oats-chaff, leaving the cap off, and I will not put it on again until the bees are ready to be put on the summer stands. This I think is as good a way to ventilate a hive, and at the same time retain the heat of a colony as any I have read of on the ventilation of the bee-hive.

I had one colony with a queen that was sterile. After keeping her four weeks, and finding that she would not deposit any eggs, I destroyed her, and not having any queen to replace her, I gave them eggs from which they reared a queen ; but it was too late in the fall for her to become fertilized, as there were no drones. Will she become fertilized next spring, and go on performing the duty of brood-rearing the same as any queen ?

[No. In order to save that colony, you will have to give it a fertile queen as early as possible in the spring, even if you have to take it from another colony.—ED.]

Caught a Runaway Swarm.—S. E. Wescott, Oxford, N. Y., on Jan. 21, 1889, writes:

I caught a swarm of runaway Italian bees on July 2, 1888, and hived them in a Langstroth hive on strips of foundation. It was a large swarm, and I expected them to get enough honey to winter on, but they did not. On Oct. 4 they had 9 pounds of honey. Up to this time they had been at the place where I was working. I then moved them home, and fed them 13 pounds of sugar made into syrup. When I examined them I found them nearly one-half black bees. Will some one state a good reason for this? The queen is well striped, and so were all that came with here. They seem to be wintering well, and are in good condition.

Laying Workers.—John B. Avery, of Stittville, N. Y., writes:

Last summer I had a colony with laying workers. It being my first experience with them, I was puzzled as to how to get rid of them. I had read that it was a hard matter to get them to accept a queen as long as there were laying workers in the hive. (They had been at work for some time, for the drones were hatching, and they had 6 frames of eggs and brood. A goodly part of the brood was sealed.) Having a laying queen on hand, I thought that I would experiment with them. I did not divide the colony, as Mr. Beckly did (see page 42), but I took away all their brood and eggs, and then shook them all in front of a new hive, filled with empty combs, and placed it on the old stand. It worked well. The queen commenced laying at once, and that was the last of the laying workers.

Bee-Keeping in Nebraska.—Ira N. Lyman, St. Peter, Nebr., on Jan. 14, 1889, writes:

We have some large apiaries in this (Cedar) and adjoining counties. One man in this county, in a good place near the Missouri river, has had bees a great many years, and has hives of almost every pattern, and if any one wants to see the old fashioned bee-gum, or hollow log, used to put bees in, he can see it there now. He built a new bee-house last spring, with a good shingle roof, in an angle like an old-fashioned rail fence. It backs toward the northwest, and is open on the southeast. He has two rows of hives, one above another.

I put my bees into the cellar under a kitchen. It is a good, dry, warm cellar. No vegetables freeze in it. I put the bees into the cellar on Nov. 28, 1888. They were flying on Nov. 27, when it turned colder. I thought that I would put them into the cellar before it got too cold.

I weighed the bee-hives this year, when I put them into the cellar, with the covers on, as they stood on the summer stands. One weighed 68 pounds. One of my new colonies came out on Aug. 29. It was a second swarm. One colony weighed 90 pounds. It was the first swarm out of the same old colony. The old colony that it came out of, weighed 80 pounds; another 62 pounds, and one 86 pounds, with about 20 pounds off for top covers. They are in 10 frame Langstroth hives. Bees carried in pollen as late as Oct. 14—very late for this part of the country. I introduced an Italian queen into a weak, queenless colony on June 24, 1888, and from that colony I received my 2 new swarms. I think that is good for last year. Colonies all entered the cellar last fall in good condition, save one. It took drones in with them. I fear they have no queen. I did not examine them as I should have done.

Bee-Keeping in Arkansas.—J. A. King, Sub Rosa, Ark., on Jan. 14, 1889, writes:

So far the winter in this part of Arkansas has been very mild and favorable for the wintering of bees. We have had no snow, and the temperature has not been lower than about 20°, Fahr. I began last spring with 24 colonies of bees, increased them to 38, and obtained an average of about 60 pounds of extracted honey per colony, which is about a fair average for this locality. The majority of bees in this neighborhood are blacks, managed after the fashion of "good auld times," and have hardly stored enough to keep "the wolf" from their own door. I have the only Italian bees that are kept in the immediate vicinity.

A great many bee-keepers here "know it all," in their own estimation, and would have the "king" to "boss," and the drones to lay the eggs, and prefer the old "gum" to any style of "hive." I am well pleased with the BEE JOURNAL, and wish it a long and prosperous career. Bee-keeping, in its more approved form, is slowly gaining a foothold in this State. Other industries seem to consume all the time, and those engaged in bee-keeping are content to follow on in the tracks their grandfathers left in this art. Although we have never heard the mention of cotton, it seems to be about our most profitable honey-plant.

Wintering in a Bee-House.—Mr. Joseph Hillman, Galesburg, Ills., on Jan. 26, 1889, says:

I have 70 colonies of bees wintering nicely in a house built for the purpose, with double walls, and filled in with sawdust. I could not do without the AMERICAN BEE JOURNAL.

Bee-Keeping in Colorado.—R. C. Aikin, of Holyoke, Colo., on Jan. 19, 1889, writes thus:

I am now a resident of Colorado, but lived the past 15 years at Shambaugh, Iowa. The summer of 1887 was poor, but I made some increase of colonies, and got a few pounds of surplus honey, and by averaging stores, the bees had barely enough to winter on. I put 46 colonies into the cellar in the fall of 1887, and in the spring of 1888 I had 35 to start with. I increased them to 50 colonies, and obtained 2,000 pounds of mostly extracted honey, from heart's ease. The best yield of one colony was 116 pounds; the average yield, spring count, being 57 pounds. The honey was all of fine quality. I sold 1,000 pounds in Iowa, at whole-sale, the extracted at 10 cents, and the comb honey at 12½ cents. I brought 1,000 pounds to Colorado, and I am retailing it at 15 to 25 cents. I am now in a very new county, being only three years since the first settler came into it.

There is not a tree for miles and miles, and not much else but buffalo grass; but I am here to try the bee-business in connection with poultry on a quarter section of government land. I brought with me from Iowa 20 colonies of bees, and I now have them safely housed in a good cave. My best average yield in Iowa was 227 pounds per colony; the poorest, 0—the latter only one year; while my average for the past ten years was close to 100 pounds per colony, spring count. The desire to possess some real estate, and not being able to buy in Iowa, has brought me here. I am the first to embark in the bee business in this part of Colorado; and while I do not expect the yields I had in Iowa, yet, being the only apiary for many miles around, and with good prices, I hope to succeed.

Report for Two Years.—James Jardine, Ashland, Nebr., on Jan. 14, writes:

I have not done very well with my bees for the last two years. In 1887 I had over 100 colonies, and they did not make any more than a living till the basswood came into bloom; that helped them some until the dry weather set in, and then they had a hard time of it to store a very little in the sections. I did not get more than 100 pounds in all. They were put into winter quarters, the most of them with plenty of honey, but I do not think that it was very good honey; at least my bees did not winter well on it, and when I took them out on April 9, I found 15 colonies dead, that had the diarrhea very badly. Some of the other colonies were in very bad condition, and they dwindled down very low, till the warm weather came, then they did better.

I had but a few swarms in 1888, but got about 1,000 pounds of good honey in the comb, fit for market, which I sell at home this year for 25 cents per pound. I put 80 colonies into the bee-cellar on Nov. 20, 1888; all were in pretty good condition for winter, and they seem to be doing nicely so far. The temperature is at 42° to 45°.

I hope that we will have better honey seasons for some time hereafter, for if I had depended upon my bees for a living the last two years, it would have been rather slim living. I was very sorry that I could not attend our State bee-convention. I have had the rheumatism for a month or so, but I am getting better.

Carniolan Bees.—F. H. Harrington, Hartwick, N. Y., asks the following:

1. Are Carniolan and Caucasian bees the same? 2. Can Carniolans fly at a lower temperature than Italians? 3. Are they more willing to enter supers for storing comb honey than Italians? 4. Would a Carniolan queen mated with an Italian drone produce workers superior to pure Italians, for comb honey and wintering on summer stands in a cold climate?

At our request, S. W. Morrison, M. D., answers as follows:

1. Carniolans and Caucasians are certainly very different bees, if I may judge the Caucasians from the only person I can find who has written of them. Carniolans are very gentle, unsurpassed as workers, splendid defenders of their stores against robbers, not disposed to rob, *not made cross by smoke, and do not build more queen cells than Italians.* They are of a dark gray color, *not "orange like,"* not long and slim," not *given to swarming more than Italians.* The reverse of the italicized lines will describe Caucasians.

2. While I had both Italians and Carniolans together in my apiary I could have demonstrated on any morning during the honey season, to any visitor, the fact that Carniolans are always at work in the morning before Italians, and especially is this true and noticeable in cold mornings.

3. When honey is abundant I do not claim that Carniolans will go into boxes more readily than Italians; but during a season like the past one, many persons have written me, who had both races, that they got surplus only from Carniolans. New swarms will begin storing in boxes within three days, invariably, if properly treated.

4. Carniolan queens mated with Italians sometimes produce workers which are very irritable, but not as frequently as do black queens mated with Italian drones. I have seen some very fine workers from the "mixing," but desiring only purely mated queens in my apiary, I did not keep them. No race is superior to Carniolans for wintering.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¾@6c.; dark amber, 4½@5½c.
BEESWAX.—18@22c.
Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.
Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but about equal to the demand. Market will be bare of comb honey long before the new crop is ready.
BEESWAX.—22@23c.
Jan. 18. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 1?@14c; 2-lbs., 11@11½c.—Extracted, 6½@8½c, depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark 8@10c. Extracted, dark, in barrels, 5@5½c; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX.—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c; in barrels and ½ barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand slow, with a smaller supply than ever at this season for the past 10 years.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Jan. 9. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Faocy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs, 9@10c. Extracted white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather we believe
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs, 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Feb. 16, 1889. No. 7.

EDITORIAL BUZZINGS.

To Cure a Cough, roast a lemon very carefully without burning it; when it is thuroughly hot, cut and squeeze into a cup upon one-quarter of a pound of extracted honey. Take a tea-spoonful whenever the cough is troublesome.

A Fine Photograph of the exhibit of J. P. Caldwell, of San Marcos, Texas, is on our desk. It shows his bee and honey exhibit at the International Fair and Exhibition at San Antonio, Texas, from Nov. 13 to 22, 1888. It must have been a great attraction.

A Frame Lifter is received from B. E. Foster, of Utica, N. Y. It is made of the best spring-steel wire forming a semi-circle; the ends of the wires form a kind of tweezers which hold the frame securely near each end, and it is lifted with the wire bow-handle.

Farmers' Institute.—The Newaygo County, Mich., Farmers' and Bee-Keepers' Association will hold their annual institute at Fremont, Michigan, on next Tuesday and Wednesday, Feb. 19 and 20, 1889. In the programme we notice the following: "The adaptability of bee-keeping for the farmer," an essay by A. M. Alton. Mr. Geo. E. Hilton is the Secretary.

The Tenth annual meeting of the Ontario Agricultural and Experimental Union, at the Ontario Agricultural College, was held at Guelph, on the 7th and 8th inst. By the programme we notice that Mr. R. F. Holtermann, an ex-President of the Union, is to deliver an address on "Bee-Keeping as a Branch of Agriculture," in the afternoon session of Thursday.

Another Lie Hunted Down.—Mr. L. W. Baldwin, of Independence, Mo., on Feb. 4, 1889, writes as follows:

A few days ago, while taking orders for comb honey in Kansas City, the proprietor of a store wanted to know if it was pure or manufactured. I told him that all comb honey was pure, as it was impossible to make the comb and fill it and seal it over. He said he *knew* they did it, for he *had seen them doing it.*

I told him that I did not like to dispute a man's word, but I was very sure he was mistaken, and if he would give me the address of the firm, I would prove to him that there was nothing in it. The man that is said to make the comb honey is D. B. Scully, Lake St., Chicago, one of the largest syrup dealers in the city. Now, Mr. Editor, if you will call there and see what there is in it, you will confer a favor on a honey-producer, and a store-keeper who is deceived by the lie of Prof. Wiley.

Of course the hunt turns out as usual. We went to the place indicated, and found a large wholesale and retail syrup and jelly house. Mr. D. B. Scully was not in, but his brother was found. After asking many questions about honey, syrup, jelly, etc., we inquired what honey they dealt in, and ascertained that they obtained their honey from California by the car load—that it was extracted honey, and that they did NOT DEAL IN COMB HONEY AT ALL! They had not a pound of comb honey in stock, and never thought of such a thing as making it themselves!!

Mr. Baldwin can, therefore, inform the Kansas City merchant that he was totally mistaken in this matter—notwithstanding his boast that he *knew* that honey-comb was manufactured, and that he had *seen it done!!*

Press him to name the place or back down; show him Prof. Wiley's retraction as published in the BEE JOURNAL for June 13, 1888, on page 388, where the Professor acknowledged that he "did not believe that it was possible commercially to imitate the comb!!" Tell him that a thousand dollars await *the proof* of the manufacture of comb honey, offered by Bro. A. I. Root!

Every bee-keeper should appoint himself a committee of one to hunt down these *lies* about manufactured honey; and in doing so, will find the hearty approval of all honest men. Apologists for such infamies should hide their heads in shame, for they will certainly be crushed by the triumphant car of truth and justice, as it moves on to victory!

The Mating of Queens.—J. B., of Missouri, asks the following questions:

The queen-bee flies out to mate; is it impossible for her to mate in the hive? Does she not leave the hive by a law of nature, that she may not mate with her own family? If so, if that necessity is obviated, can she not be bred to mate in the hive? I read several bee-papers and books, but I have never seen anything touching on this.

No. It is natural for a queen to mate on on the wing, and not in the hive. It is quite unlikely that fertilization in confinement will ever be successful, even though it may be very desirable on some grounds.

Honey as a Cure for Colds.—In the December number of the *Revue Internationale*, of Nyon, Switzerland, is a recipe for the use of honey as a medicine, which Mr. Charles Dadant has translated for the AMERICAN BEE JOURNAL. At his request it will be added to the next edition of the pamphlet, "Honey as Food and Medicine." Mr. Dadant adds: "I have used this recipe in similar circumstances." Here is the recipe:

A few years ago I got a serious cold; difficulty in breathing, pain about the sides, frequent shivers, etc. Dr. Stroehlin, one of our medical celebrities, prescribed tea of ground ivy as medicine, and milk as beverage, both sweetened with honey instead of sugar. After two days, I was completely cured.

This method, which is very simple, would not please those who spend hundreds of thousands of dollars to advertise their medicines. But, when sick, we take what we know, especially when it is cheap and salutary, with less reluctance than these pharmaceutic preparations, whose unknown manipulations are probably very little appetizing, and which too often act only on our pocket-books.—M. DESQUARTIERS.

Mr. Charles Dadant adds this paragraph to the foregoing:

FRIEND NEWMAN:—You may add that ground ivy, which is a labiate, or of the same family as the sage, is a very small plant, will grow everywhere, and is very good for bees. There is an illustration of it in our book (Langstroth Revised) on page 389. Fig. 138.

Sub-Earth Ventilators.—In regard to these ventilators in bee-cellars, P. H. Elwood says in *Gleanings:*

If properly put down they are beneficial. They keep a more uniform temperature. At one time, when the temperature outside was 17° below zero, the air as it entered the cellar was 37° above. Our sub-earth ventilator is made of glazed sewer-pipe, one foot in diameter for the first hundred feet; for the second hundred feet, 8 inches in diameter. At the end of the 12-inch pipe is an opening, to be used in moderate weather; but in cold weather the whole length of the pipe is used. The joints of the pipe should be securely cemented to keep out the ground air, which is usually loaded with moisture, and heavily charged with carbonic-acid gas. The last is very variable, however. Were I to put down another ventilator I should use 6 inch pipe, as being easier to make tight, and multiply them for capacity; also, if possible, I would have them extend in different directions, as the direction of the wind makes a difference in the draft of the pipe. I would also have one or more of them so laid as to act as drains in case of a freshet. Ours is so put down, and last spring it was used to nearly its full capacity.

A Club Agent down East has taken club subscriptions for papers, gathered in several hundreds of dollars, and then "lit out" with the money. Several subscribers for the AMERICAN BEE JOURNAL sent him their renewals, and lost all the money sent him. This should be a warning to all to send their money direct to this office, unless they personally know the club agent to be responsible. Do not give it to the Postmaster and ask him to send it, but send it yourselves, and save perplexity, annoyance and loss.

GLEANS OF NEWS.

The Evil Effects of Booming.—Mr. Alexander Black, of Sonya, Ont., wrote as follows on Jan. 2, 1889:

I send you an item clipped from the *Farm and Fireside* of Toronto, entitled "Do Bees Pay?" and I would like to know what you think of such a report. I consider such an increase and yield of honey utterly impossible, and I also think that such reports are not calculated to do bee-keepers any good, and may do others much harm, as it will make a great many rush into bee-keeping who know nothing about the business, and make a total failure in it.

Just think of a man making over $120 from every colony he has in the spring, why should not everybody go into the business?

I am in the business, and have studied it for years, and believe that my bees have done as well as the most bees did last season; they increased from 7 colonies in the spring to 17 in the fall, and I got 150 pounds of honey. Of course the increase cost me lots of honey; but it was bees I worked for, and my 17 colonies were put into the cellar in first-class condition, and are wintering well without any signs of disease so far.

I am looking forward to better success next season. We have a fine, mild winter; have had no really cold weather yet. I am pleased with the BEE JOURNAL every week. Long may it flourish.

The item enclosed by Mr. Alexander Black reads as follows:

DO BEES PAY?—The following communication from Byron Iiams, of Worcester, Mo., will be of interest as showing a bee-keeper's actual expense account and profits:

I commenced the season of 1888 with 3 colonies of Italian bees, using Langstroth hives with movable frames. The bees had plenty of honey to stimulate active increase. Plenty of honey came in all through the season for fast breeding, and for building up strong colonies, ready for the grand flow of honey which commenced with Aug. 15, and practically closed Oct. 1. With the use of 200 empty combs, I increased my 3 colonies to 27. I worked 1 colony for queen-rearing, 3 colonies for comb honey, and 21 colones for extracted honey. I sold 2 colonies. The results were:

2,400 lbs. extracted honey at 10c.	$240.00
100 lbs. comb honey at 15c	15.00
Two colonies sold	5.00
25 colonies left, worth	150.00
Total	$410.00
Deduct 3 colonies on hand to begin with, worth	$ 18.00
21 hives at $1.50	31.50
Total expense	$ 49.00
Net profit	$360.50

It is a very fabulous report, to say the least, not only viewed from the standpoint of increase, but also of sale. The 2 colonies sold brought only $2.50 each, only one dollar more than the cost of the hives, but the 25 colonies left are valued at double that price. Extracted honey, at wholesale, bringing 10 cents per pound by the barrel, is not to be despised!

Mr. Iiams was taking the BEE JOURNAL some three years ago, but as he is owing for over a year's subscription, he will be well able to pay it now from his bonanza bees.

Queens and Swarms.—Mr. Albert Vought, Illawara, La., on Jan. 26, writes:

I feel fully repaid for this year's subscription, by Dr. Tinker's article on page 25. I had about decided to manage my bees something after that style, and at the same time accomplish my transferring, but I would ask Dr. Tinker, what becomes of the young queens? or does the old one always leave the hive before the young one hatches? Of course, in my case, where increase is wanted, it is all right. I understand how to manage them before they hatch.

The answer by Dr. G. L. Tinker, of New Philadelphia, O., is as follows:

When a colony of bees casts a swarm, and is managed as advised, it is not usual for the young queens to appear before the eighth day after, and second swarms cannot occur. Upon removing the brood and shaking off the bees, it will be seen if any of the queen-cells are sealed over, when we shall know that if it is placed over a wood-zinc honey-board in the super of another colony, the cells will hatch about the eighth day after.

If now the apiarist is not on hand to attend to the cells, the first queen to hatch will destroy the remaining cells very soon. From this time on until she is ready to mate, or about 4 or 5 days thereafter, she will be found nearly all the time on the honey-board, trying to get below. Upon raising the super, she will be seen at once, and undisturbed by the light, her efforts to get through the zinc are unabated. Hence, she may be readily removed, or the honey-board may be turned over and the young queen be allowed to kill the old one, which, so far in every case with me, she is certain to do. But if the young queen be left in the super until after the eleventh day, or until she is ready to mate, the bees will, for some cause, ball and kill her, and that is the end of all queens hatched in supers *left to themselves* above a wood zinc honey-board, except as stated in next to the last paragraph at the foot of the third column, on page 26.

It is therefore for the apiarist to determine what shall become of the young queens.

Although the young queens will destroy the old ones, as a rule, as stated, still I believe that it is better to remove the old one, if it is desired to supersede her, and then let the young queen have full away, as it seems probable that exceptions will be found to this rule, in which the young queen, after destroying the old one, may herself be balled and killed. At all events, contests between queens should be prevented as far as possible. Transferring by the new system is a decided success, as I transferred a number of colonies in this way last summer.

Wasteful Ignorance.—A correspondent in the Orange Judd *Farmer* of last week thus mentions a case of loss of honey and bees needlessly, through ignorance in the bee-keeper of the simple methods of bee-keeping. He says:

While traveling in central Illinois the past week, I met a bee-keeper living in a locality near a stream, and where heart's-ease was abundant in the fall. He told me that bees there never stored any honey except from clover, and that they wintered very badly—frequently the loss was 30 out of 50 colonies.

I asked him if he ever used an extractor, and he said he did not know what it was.

I then asked him if he ever gave the queen room to lay after the flow from clover was over. He replied that he never disturbed them until cold weather, when he removed the surplus honey.

Now, this man, by not being posted, was losing half or more of his crop, and three-fifths of his bees in winter. He should procure and use an extractor, or take out some of the frames of sealed honey, and replace them with empty worker combs after the flow from clover was over, feeding, if necessary, so the queen may continue breeding, and giving her more room every few days, to insure that there would be lots of young bees in the hive the latter days of August, when the fields of heart's-ease or buckheart begin to bloom. He would thus secure a crop of fall honey, and lots of strong young bees to go through the winter.

An Omission.—Mr. R. McKnight, of Owen Sound, Ont., on Feb. 4, 1889, writes as follows:

In the report of the Ontario Bee-Keepers' Association meeting, as published in the AMERICAN BEE JOURNAL of the 2nd inst., I notice a sentence in Mr. Pettit's essay which was omitted at the meeting at which it was read, but has since been given to the world through the AMERICAN BEE JOURNAL and the *Honey Producer*. This "missing link" is a harmless piece of irony. It reads as follows: "Who in the present age is bold enough to assert that Mr. McKnight is not an original and profound thinker?"

Mr. McKnight himself disclaims any pretentions to either originality or profundity, and does not believe that the world credits him with being either original or profound. Moreover he did not then nor does he now care what Mr. Pettit may say or think of him; but Mr. McKnight does think it rather strange that Mr. Holtermann should cause to be *published* what he was evidently ashamed to *read* before the members of the association. Mr. Pettit's essay was read from a proof-sheet by Mr. Holtermann, and it included the sentence quoted above, but the pen was drawn through it, and it was "skipped" by Mr. Holtermann in the reading.

I was not a little amused when a gentleman present passed the proof-sheet over to me, and drew my attention to the erasure! What I complain of, is the want of candor manifested by Mr. Holtermann in his reports generally. I could give many instances of this, but one will suffice: At our annual meeting a year ago, one of the best essays was contributed by Mr. Allen Pringle; yet this correspondent and editor suppressed it in his report of that meeting as published in the *Honey Producer*. There must be something radically wrong in an editor who, because of personal pique, will deprive his readers of valuable information.

In the "copy" sent to us for publication, the sentence in Mr. Pettit's essay above referred to was not erased—probably by an oversight. Concerning the omission of Mr. Pringle's essay in the report of the convention of 1888, Mr. Holtermann wrote to us (before we received the above letter) that he was not aware of its absence until a few days ago; that it was purely an oversight which he much regretted.

The Hanging Gardens of Babylon were within the precincts of the palace called "The Admiration of Mankind." They consisted of gardens of trees and flowers on the topmost of a series of arches 75 feet high, and built in the form of a square, each side of which measured 400 Greek feet. The city of Babylon, with its famous gardens, was razed to its foundation 600 B. C. Two thousand five hundred and seventy-nine years later we find the celebrated gardens of James Vick, in Rochester, New York. For description, catalogue of seeds, advice how to obtain free a copy of Vick's Foral Guide, and also of the famous new rose, called "Vick's Caprice," address, James Vick, Seedsman, Rochester, N. Y.

QUERIES & REPLIES.

Amount of Stores Used by Bees in the Cellar.

Written for the American Bee Journal

Query 613.—1. If it is a fact, as is generally claimed, that bees consume but about one-half as much honey in a good cellar that they do out-of-doors, is that not so much wasted? 2. If not, are there any other considerations to balance this loss?—Bee-Keeper.

1. Certainly.—A. B. MASON.

Yes, to a certain extent.—H. D. CUTTING.

It is a fact, by weight; that is, in a cold climate.—A. J. COOK.

I have had no experience with cellar wintering of bees here in Louisana.—P. L. VIALLON.

In our climate (Georgia) we have no use of bee-cellars, but winter our bees out-of-doors.—J. P. H.BROWN.

1. No, it is so much saved. 2. None that I know of.—R. L. TAYLOR.

1. No, it is not wasted. 2. Yes. brood-rearing early out-of-doors, especially in winters like the present.—DADANT & SON.

1. No. It is that much saved. 2. The considerations are a balance in favor of the cellar.—J. M. HAMBAUGH.

In an open winter like the present one up to date, bees consume scarcely more stores out-of-doors than in-doors, and winter better, as a rule.—JAMES HEDDON.

As far as I know, cellar-wintering of bees in this part of the country (Indiana) is not much practiced. Among my acquaintances, it has not been a success.—M. MAHIN.

1. Well, yes. 2. The first cost of constructing or preparing the cellar, and then the labor of placing the bees in the cellar and taking them out.—MRS. L. HARRISON.

1. No. 2. Sometimes a cellar is not convenient; and, with a great majority, bees can be properly packed for winter, and as safely upon the summer stands, with *less labor* than they can be carried to the cellar. Your query calls for an article, as there are many points which cannot be touched upon in this limited space.—W. M. BARNUM.

"This is the same old question," and the best we can say is, that "it all depends." As the pursuit has reached that point where bees must be handled by hivefuls and by the can full, there seems no way about it, but for keepers who live in cold latitudes, to store them in a cellar. We look for compensation in the harvest, not in how much they eat during the winter. —J. M. SHUCK.

Yes, I consider it a great waste of honey to winter bees out-of-doors. As a rule, bees wintered in a cellar do better the following season than those wintered out-doors. I know that many good bee-keepers will differ from me, but this is the conclusion that I have come to after wintering bees in both ways for more than 20 years.—C. H. DIBBERN.

I have a heap of ignorance on this subject. If my bees would make a "live" of it out-doors, I think that I would be willing to lose some extra honey. For one thing, they have better ventilation, and I am just old-fogy enough to believe that is very important.—C. C. MILLER.

The extra amount of honey consumed is used as fuel to keep the bees warm. Is the fuel you burn in your stove in keeping the house warm, wasted? If so, had you not better move down cellar with your family, so as to save it?—G. M. DOOLITTLE.

1. As a rule, the more quiet bees are kept, the less honey they will consume. In some years this can be done in cellars, as bees are ordinarily kept; in other years it can be best done out-of-doors. Claims are made for cellar wintering that apply to very cold localities, that would not hold good in warm situations.—J. E. POND.

1. I do not believe that it is a fact. The difference is not so great as one-half. Whatever the difference is, is certainly wasted, if the results are the same. 2. Having never tried but one method, I cannot speak with the confidence of him who has tried both. It is claimed by some that there is less spring dwindling, and better final results by wintering bees on the summer stands. Undoubtedly *climate* has a good deal to do with it. The bee-keeper ought to study the question from the stand-point of locality.—EUGENE SECOR.

1. The more honey my bees have in the brood-nest, the better they winter, and the better work they are able to do when the early honey harvest appears. Perhaps more bees are ruined on account of light stores in winter, than on any other account; therefore, the question of *waste* should not be put in the way of best results. 2. Many apiarists believe that bees are more hardy and long-lived when wintered out-of-doors.—G. W. DEMAREE.

1. Bees consume more honey when wintered on the summer stands, but the consumption would hardly reach to double the quantity, especially in winters like the present one, when cold weather must be of very short duration, if we have any worth mentioning. Honey used to keep the bees in the hive warm, should not be deemed *wasted*; wood or coal used to keep humanity warm in houses is never thought to be wasted—each serves the purpose intended. 2. Against the account for honey used "out-of-doors," place the cost of the cellar or bee-house, the trouble of carting in and out, etc. These would probably balance the account, and leave the choice of methods upon other considerations than value of the honey consumed.—THE EDITOR.

CORRESPONDENCE.

IN-BREEDING.

New Blood in the Apiary an Essential Matter.

Written for the American Bee Journal

BY EUGENE SECOR.

On page 60, in answer to the question, "How long will bees prosper without new stock from a distance?" I notice this reply: "For an unlimited time." Now I doubt the correctness of that doctrine; and, as I am not a queen-breeder, I ought to be allowed an opinion without prejudice.

With such "free commoners" as bees, it is quite a difficult matter to prove to what extent in-breeding is practiced, or with what effect; but if we reason by analogy — from the known to the unknown—it is very conclusive to my mind that nature abhors incestuous alliances.

We know the effect on the human race, of the marriage of near relatives. Any one who has experimented in that direction with our domestic animals, knows its baleful effects. I am aware of the claim in certain quarters, that some of the most valuable characteristics of our domestic animals have been developed by in-breeding, but even admitting that to be true in exceptional cases when done intelligently, every breeder knows it is safe to avoid it as a general rule.

The experiments of Darwin in self and cross fertilization of plants, carried on for many years with a patience and persistence that only a lover of the truth could have shown, proved that the same law governed, too, in the vegetable kingdom. He reasoned that the chief end of bees and other pollen-gathering insects was to fertilize and cross-fertilize the flowers, thereby causing not only greater beauty and perfection of flowers and fruit, but vigor and longevity as well.

Corn grown on one farm for a series of years without the introduction of new seeds, deteriorates. The same is

true of other farm crops. Now if such beneficial results accrue to both the animate and inanimate creations (where experiments have been carried on), who shall say that these highly organized insects, bees, that perform such an important part in developing plant-life by cross-fertilization, are not amenable to the same general law of nature, that seems to govern the reproduction of plant-life itself? Or if both the higher and lower forms of life are benefited by crossing, why not the intermediate?

It may be that this matter has been proved, substantiating the theory expressed; but if it has, I have never heard of it. I can conceive how difficult it would be to fully and satisfactorily verify either theory, in the present state of the art. If fertilization in confinement ever comes to be an established fact, we could proceed upon an intelligent basis to demonstrate the facts. Or, if we could take a single colony and isolate it 15 or 20 miles from all other bees, and limit their increase to 2 or 3 colonies, so that near relatives would be compelled to mate, a few years might throw light on the subject. But, few such places exist, and if they did, bees multiply with such rapidity that only a short time would elapse before the relation would be so distant that the probable harm would be reduced to a minimum. Perhaps that is what was meant by the answer given to the question. If so, our notions may not be so antagonistic as I at first thought.

But I believe in new blood. It seems to me that the history of modern bee-culture proves the desirability of infusing vigor into the apiary, by the introduction of distant and unrelated queens. I would not trust altogether to nature's methods, and compel the queen to fly to a neighboring apiary.

Forest City, Iowa.

IOWA.

Report of the Nashua Bee-Keepers' Convention.

Written for the American Bee Journal

BY H. L. ROUSE.

The third annual meeting of the Nashua Bee-Keepers' Association met in the Council Rooms at Nashua, Iowa, on Jan. 26, 1889, at 1 p.m., with President Tracy in the chair. The minutes of the last meeting were read and approved.

Wintering Bees in Cellars.

In discussing cellar-wintering of bees, Mr. Bird preferred upward ventilation, with the surrounding temperature at 45° to 47°. Others preferred a lower temperature, with scarcely any upward ventilation. A cellar with a living-room above was considered much better for the successful wintering of bees, than one having no fire over the bee-cellar.

"In what way can we best improve our bees?" Answer: It was decided that we should buy a few choice queens, and always exercise much care in breeding from our best bees.

"Would vegetables be detrimental to bees in the cellar?" It was thought not.

Next was the election of officers, which resulted as follows: President, Thos. Tracy; Vice-President, Geo. Stocks; and Secretary, H. L. Rouse.

"Is it desirable to have bees breed in the cellar?" Mr. Tracy would rather that his bees would not breed until after being put out in the spring. Others thought that a few frames of capped brood were a great advantage.

Mr. Stocks advocated facing hives to the north, as the bees would not be enticed out on chilly days. President Tracy puts his bees out of the cellar in the night. If the weather is favorable, he cleans his hives out on the second day after putting them out; and Mr. Potter cleans his hives out on the day he puts them out. Beginners should be very careful about overhauling bees in early spring.

H. L. Rouse then read the following essay on,

Bee-Keeping Alone, or with Other Pursuits.

Shall we make bee-keeping a speciality, or unite it with some other business? I believe that there are a few apiarists at the present day who make bee-keeping their sole business, but their number is small compared with the host that make it a side-issue. Let us consider the feasibility of the "specialty man" first.

Suppose he has invested all his capital in 100 colonies of bees, and fixtures to work them for either comb or extracted honey. If the season is good, and he has no opposition, he will secure a good crop of honey, and thereby make some money. If this continues long, his near neighbors will soon "catch on," and they will keep bees all around him, in which case they will spoil the specialty man's business, and gain nothing thereby themselves.

"But," says one man, "why not enact laws giving the first bee-keeper a certain amount of territory, or let priority of location rule?" I have grave doubts about this being a wise policy to adopt; besides, if the specialists were guarded by such a law, there is another and greater uncertainty to contend with, and that is, the failure of the honey crop from which nobody is secure. All bee-keepers will bear me out in this by their experience of 1887 and 1888.

On the other hand, I agree with Mr. Root, that "it is not best to put all our eggs into one basket." I will not say what other business is best to unite with bee-keeping, as so much depends upon how a man is situated, and also somewhat as to his tastes. To the bee-keeper living in the suburbs of cities, I would say, raise poultry, or he might find the raising of small fruit and garden-truck more profitable. To the bee-keeper on the farm, I have not much to say, as there are various ways open to him, in which he can turn an honest dollar.

In the meantime, do not neglect to give proper care to what bees you have. It would be "penny wise and pound foolish" to allow them to starve, when a few pounds of sugar syrup or honey would bring them through nicely.

I think that bee-keeping has reached "bed-rock." In fact I feel convinced that now is the best time to give bee-keeping our most careful attention. The past two or three failures in the honey crop have driven the slovenly and careless bee-keepers from our ranks. It is the same in our pursuit as it is in other lines of business—the man who is the most careful, prudent and thorough, will succeed the best, while the man who does things by halves will fail, no matter what occupation he follows. If a thing is worth doing at all, it is worth doing well.

The convention then adjourned.

H. L. ROUSE, *Sec.*

TOADS AND BEES.

Will Toads Destroy the Bees?—Experiments.

Written for the American Bee Journal

BY E. STRONG.

That toads will eat bees has often been asserted and never disputed; but the published proof has been wonderfully slim. The same can be said of the indictment against the king-bird. When a boy, I was offered five cents for each bird that I shot, the bee-keeper claiming that they eat the bees. This, father could not allow without proof. We *thought* that we found in the bird's stomach some pieces of the bees, and in some publication an article stated that the king-bird possessed a hard cushion on the top of the bill, placed there purposely to receive the sting of a bee and wasp. So, sentence was passed, to the great delight of the executioner but I never found any

sting in that cushion. Then what becomes of the sting? One powerful thrust of poison in the stomach or mouth of so small a bird would often produce death.

So, in after years, I had learned to doubt some of the things "even read in books," and, as a bee-keeper, "watched out" for Mr. Toad. But he had a bright eye to business, and was never off his guard. He looked pretty full, though, and suspicion was strong against him. Sometimes he was placed on the alighting-board and watched. In this position, he would pick up the flies, and never touch a bee. Yes, he knew better than to get stung. But the bee-papers harped away about toads, and I could not say they were wrong.

A medium-sized toad was placed in a nail-keg and put in the sun without food or water all day. At the cool twilight, he was tenderly placed on trial on the alighting-board. His game eye glittered with tears of joy; but his early education made him proof against temptation, and he was remanded to prison another night and day.

While standing on the alighting-board, a bee sent its sting into the tender membranes of the toad's foot, but the foot never stirred, and did not seem to feel pain, nor did it swell in the days to come.

Each night Mr. Toad was brought out for trial, for four days, with the same results. Hunger and the burning sun had reduced his size and health, but reptile and batrakian that he was, unlike a man, he showed his superiority to the low passions of resentment and hunger, and I let him go. Prof. Cook will easily see that in this respect, development has not improved the human race. Well, the decision of the court was, that toads had some good qualities, and, among the rest, they knew better than to swallow a *live* bee.

A year went by, and all the papers still howled toad! One wet day a toad crawled under a hive when it saw the bee-man approach. It looked guilty, and was promptly placed on the alighting-board. Four minutes went by—but without touching a bee. In the fifth minute it swallowed seven. The officer immediately nabbed that toad, and the ordinary methods of vivisection were applied, with the following result: Five stingers were found firmly imbedded in the coatings of the stomach, which was promptly mailed to our distinguished author on anything pertaining to the bee—Prof. Cook. But I never heard from him, and if the clerks from the Post-office threw it out, they did their duty.

Kalamazoo, Mich.

BASSWOOD.

The Challenge Accepted, and the Proof Furnished.

Written for the American Bee Journal

BY DR. A. B. MASON.

In the AMERICAN BEE JOURNAL for 1888, Mr. R. McKnight, in his inimitably eloquent and facetious way, pays me several compliments, and I enjoyed the article right well, as I do everything he writes. I enjoyed it not so much for what he said, as for the kindly way in which he said it, and were it not for the "challenge" he gave on page 791 of the AMERICAN BEE JOURNAL for 1887, I should be more than pleased to let the matter rest with his pleasant words and kind wishes. But were I to do so, it would be a tacit acknowledgement on my part, that I had made an assertion, to back which I had no proof. To be sure, it is some time since Mr. McKnight made his "challenge," but it is not too late to prove that I was right, and did not "misstate the facts."

On page 791 of the AMERICAN BEE JOURNAL for 1887, he says:

"Dr. Mason misstates the facts when he says that 'Canadians, in a Wiley way,' or any other way, either here or elsewhere, have sought to destroy confidence in the good qualities of American basswood honey, and claim superiority for their own. *I challenge him to name a solitary Canadian* (apart from Mr. Pettit) *who has made such a statement.* (Italics are mine.) 'One swallow does not make a summer,' nor one man a nation, and it is not generous on the Doctor's part to manifest such antipathy against his 'cousins across the border, and their relatives across the pond,' because one of our people holds and expresses opinions peculiar to himself, and in which his fellow countrymen do not sympathize."

To be sure, "one swallow does not make a summer, nor one man a nation," but if *two* did, the "summer" and the "nation" might be made, but there are four with which to make the "summer" and the "nation."

To be sure, three of "the swallows," or men, besides Mr. McKnight, Messrs. Pettit, Jones and Corneil, have not denied making the claim of superiority of Canadian over our linden honey, and Mr. Pettit has the manliness to "stick to his convictions." All honor to the man who does it. I doubt not that Messrs. Jones and Corneil would have done the same, if they had said anything, but what must we think of a man who makes such a claim, and then denies it? Well, I guess we shall have to think his memory was a little treacherous.

I was quite sure that I did *not* "misstate the facts," and to show that I did not, allow me to quote from a circular now lying before me, tens of thousands of which were distributed in Great Britain. The heading is as follows:

"The Bee-King and His Bees. From the *Pall Mall Budget*. A Chat about Canadian Bees." After speaking of "the exhibit of the Ontario Bee-Keepers' Association" at the Colonial Exhibition, it says:

"It has come over in charge of a deputation from the association, who are at present on a visit to this country with a view to open the English market to *the best honey in the world, as they constantly described* (italics are mine) the article which they have on view."

I believe the "deputation" consisted of Messrs. Pettit, Jones, Corneil and McKnight—three besides Mr. Pettit, and they among the most noted Canadian bee-keepers who "constantly describe" the Canadian honey as "the best honey in the world." To be sure, "one man don't make a nation," as Mr. McKnight says, but how is it about four doing it?

How does the above look by the side of Mr. McKnight's "challenge?" Now who is it that "misstates the facts?"

Near the close of the circular before referred to, the "deputation" says:

"We publish a weekly bee-journal, which keeps all our members well informed of the latest appliances for securing the maximum of yield, and the minimum of risk; and we think that all who visit our exhibit at the Colonies, will admit that for *colour, flavour, and specific gravity we throw all other honeys in the shade.*" (Italics are mine.) Don't "claim superiority for their own!" Haven't "sought to destroy confidence in the good qualities of American basswood honey, and claim superiority for their own!" Well, what *does* it mean then, I wonder?

In another place the "Budget," as quoted by the circular, says: "It was with peculiar interest that we bade Mr. Jones welcome as he entered our office with two other representatives (Messrs. Pettit and McKnight) of the Bee-Keepers' Association," etc.; and further says: "We claim to be located in the very heart of the honey-belt of the United States." Since when have the Canadians claimed "to be located" in the United States? Will some Canadian please make me a present of a map of Canada, showing whereabouts Ontario is located in the United States? I have some pretty good maps of the United States, but I do not find "Ontario" on any of them, and it seems a little strange that while claiming superiority for their honey over

that produced in the United States, that they should at the same time "claim to be located in the United States!"

In another place the "Budget" man asks the deputation, "What special advantages have you in Ontario beyond the United States?" "Chiefly in the linden trees. In the honey-belt of the United States of America, there is also less clover than we have, and the lindens are scarcer.....Our forests are full of linden trees, and the yield of honey is enormous. Even if you shake the tree, the honey drops upon you from above."

Is there no effort in this "in a wily way, or any other way....to destroy confidence in the good qualities of American basswood honey?" I wonder if Mr. McKnight wants to throw all the responsibility of claiming superiority for Canadian linden honey on Mr. Pettit.

I was not aware till I got "The Bee-King" circular, that Ontario was larger than the United States, but it must be so, I suppose, for the deputation say, that "in the honey-belt of the United States of America, there is also less clover than we have, and the lindens are scarcer." Whew!! I didn't know that before. I guess that "fisheries commission" had better be empowered to change our northern boundary so that it will run across the continent on the 49th parallel, and so Ontario *will* be in the United States, and then we can get more clover and linden honey, and have some linden trees to shake honey from! What a paradise for lovers of honey; shake it from the trees; Apis Dorsata and Apis Americana are not needed.

Will not some Yankee invent a honey-catcher to be used under Ontario linden trees? If any one *does* invent such a machine, I think I shall be entitled to a half interest in it for the suggestion.

"Less clover honey than we have." *I-s* t-h-a-t s-o? "And the lindens are scarcer." How long have they been scarcer? No effort here "to destroy confidence....and claim superiority?"

In another place the "deputation," or the circular, says that Ontario produces a yearly "crop of honey valued at £100,000." According to the most reliable authorities, that is about one-thirtieth as much as is produced yearly in the United States. If such is the case, and Ontario has more lindens and clover than we have in the United States, the honey ought to drop from our linden and clover **without shaking.**

Less linden and clover than in Ontario, where the honey "drops upon you from above" when "you shake the tree," and still we get thirty times as much honey. Oh my! "it makes me tired" to think of it.

I believe that it would be a good idea to publish the whole circular in the AMERICAN BEE JOURNAL, for aside from a few mistakes about our honey and country, it is good reading, and shows how earnestly the deputation worked for the interest of the Ontario bee-keepers and the Bee-King. It seems a little strange that it was not published in the *Canadian Bee Journal*, with a statement as to about how many copies were distributed. I am sure that it is better and more interesting reading to me than much that was published about the Ontario bee-keepers' exhibit at the "Colonial."

Auburndale, O.

[A portion of the article from the *Pall Mall Budget* was published in the AMERICAN BEE JOURNAL for Nov. 3, 1886, and is illustrated on page 694. We hope this will satisfy all, and that this controversy will end here.—ED.]

QUEEN-REARING.

Method of Rearing Queens for an Apiary.

Written for the American Bee Journal
BY G. W. M'GUIRE.

In the advanced age of this wide, developing pursuit, but few ideas can be advanced that have not already been thought of; but the days of criticism are not over, therefore many are fearful to make public their theories, for fear of the ordeals of the thinking public. Perhaps nothing in the whole bee-industry has received more careful thought than queen-rearing.

First, we want an easy, practicable method, wherewith we can rear handsome, prolific, long-lived queens. In this latitude, about March 1, when bees begin to gather pollen, select the finest colony, that is, the one containing the finest queen; feed this colony about a pint daily, with a closed entrance-feeder. You should, by May 1, have them "boiling over" with bees, with thousands hatching daily, and drones a plenty.

Now put on an upper story with ten frames, filled with brood foundation, with a queen-excluding honey-board between. But before doing this, take out one outside frame, separate the others, and put a new frame of foundation in the centre. The frame taken out can be put in the upper story.

Let the upper story remain about five days. If the weather is favorable, the bees will be largely in the upper story, and have the foundation nicely drawn out. Now remove the lower story to a new stand, and place the upper one on the old stand.

Go to the old hive, take out the frame of foundation that was put in five days previous, and cut it full of oblong slits; it will have larvæ just hatched; exchange this for the old frame, and put it in the centre of the hive. At the end of ten days examine them, and if the bees belong to the yellow race, you may think of going into the "peanut business."

You can now form nuclei from the other colonies, and in 12 hours insert one of the queen-cells, until the number of cells are exhausted. The result will be large, yellow, long-lived queens.

In a week or so the queens will be mated, and laying. By this time the other colonies will begin to swarm; when one swarms, hive the swarm on a new stand, and go to one of the nuclei colonies that has a laying queen, remove her, and cage her in the old hive from which the swarm has just issued. In 24 hours she will be released and laying. You can now place a new queen-cell in the nucleus. By this method the old colonies are not queenless more than 24 hours at any time. If left to "nature's way," they would be at least 15 days without a laying queen; consequently a loss of 30,000 or 40,000 bees, and hence it is wasteful to allow bees their own habits, as far as bees or increase is concerned.

Dark Ridge, N. C.

INDIANA.

Report of the Indiana State Bee-Keepers' Convention.

Written for the Indiana Farmer
BY G. K. HUBBARD.

The ninth annual meeting of the Indiana State Bee-Keepers' Association convened at Indianapolis on Wednesday, Jan. 16, 1889, at 1 p.m., and was called to order by President E. H. Collins. Secretary George C. Thompson being absent, Mr. G. H. Hornbuckle filled the office.

Mr. J. M. Hicks was called to the chair, and Mr. E. H. Collins delivered the following:

President's Annual Address.

While the off years in apiculture are hurrying along with their weary days of labor and disappointment, we have three measurable compensations for our time and effort. The honey market is being cleared, and the number of producers lessened, while the bees remain healthy, and the colonies strong. At the same time our indi-

vidual and collective experience is broadening, as is also our knowledge of apiculture, and improving our methods of manipulation.

Why not prepare a good display at the State and county fairs, and make it a nucleus about which congenial minds may gather? Why not meet more often with our neighbors in their local societies, and even visit them in their homes?

All labor is elevating or degrading in its effects in proportion as it requires thought and skill to guide it. You may force a horse to draw you, or you may drive a pig from place to place; but he can only lead a bee and compel it to build its marvelous combs according to man's convenience, and fill them with the largest stores of the richest sweet, who has studied the law of its instinct, and has mastered the mysteries of the hive.

In bee-keeping, as in everything, "ignorance is the great sin," and research and tact have a most happy reward, while there is no greater pleasure than the study of entomology and the peculiar and fascinating habits of bees.

There is a very active evolution taking place in selecting the more desirable hive and fixtures. Amidst the chaos of inversion, horizontal section, fixed and loose frames and sections, tin, wood and wire-cloth separators, the result so far points to the open-sided one-piece one-pound section—4¼x4¼x1⅝ inches; also to wood for separators, and some form of section-case rather than wide frames. While amid the dust and smoke of hot discussion, we still see the Langstroth hive, or a modification of it, still holding sway.

Items of Interest.

If a hive-cover leaks, or if a hive be often removed or opened to admit light, the bees smoked or the combs disarranged, the queen removed or introduced, or the purpose of the bees repeatedly thwarted, especially during a honey-flow, they may become discouraged and neglect work, or even swarm out. Dr. Tinker, of Ohio, at the North American Bee-Association, gave a method of preventing increase without crossing the purpose or will of the colony.

Some careful experiments are being conducted by Prof. Cook and others on the practicability of planting for honey; on cellar wintering; ventilation; winter stores; queen-mating, etc. Mr. Demaree, of Kentucky, has been experimenting on warming the cellar every few weeks, to a temperature which permits the bees to break cluster for a few hours.

The Bee-Keepers' Union has been doing efficient work in defending the interests of apiculture, and should receive the support of bee-keepers.

At the North American Bee-Keepers' Society, last fall, new instruments of organization were adopted making it a representative body. This society might consider the propriety of appointing delegates.

There is one more subject which should claim the attention of this society, that is the apiarian exhibit at the State fair. Some years a few enterprising individuals have made creditable exhibits. In some States a committee has been appointed by State societies to co-operate with the State Board of Agriculture, and the result has sometimes been that a commodious house was built for the exhibit. We may expect but an inferior display unless some systematic effort is made to prepare for it.

After the President's address, Miss Eva Scholl presented an essay on "The the best method of obtaining straight comb."

Mr. G. K. Hubbard, of La Grange, then read an interesting essay on "Theoretical Apiarists," which will be published hereafter.

Second Swarms.

Mr. W. Mason was assigned this subject, and discussed it as follows:

"This is a mooted question, and I believe that races of bees have a great deal to do with the subject of increase. In preparing for the spring work, one of the main points is, to get ready for the honey harvest. In our spring work, increase is one of the essentials with a successful apiarist as a honey-producer, and to be that, I do not favor a hive with too large a brood-chamber, not larger than 2,000 or 2,400 cubic inches. In this I crowd the combs so as to take an extra comb over the usual manner of spacing, and when I have the brood-chamber full of bees and brood, I at once proceed to put on upper stories, either for comb or extracted honey, as one of the methods to prevent too over-crowded increase; keeping the swarming fever down, either by extracting or adding primed sections, by raising the case of sections directly over the brood-chamber, putting on empty ones in place, and under the first case next to the brood-chamber.

"In case I have a prime swarm, I hive them in another hive. As soon as the queen has her work started, I remove the honey cases from the parent hive to this hive. After the parent colony has reared its queen-cells, I remove all but one, to prevent after-swarms, putting on section-cases as soon as they show signs of being crowded in the brood-chambers. In this manner I am bothered with swarms but little, especially after-swarms, thereby keeping down the swarming fever. As a rule, I never prevent increase of bees, but try to avert the swarming impulse; for if we get a honey crop we must have our hives full of bees; and yet with all of our skill and management, they will swarm, and swarm."

A number of queries were discussed at great length.

The question which agitated the minds of the members the most, was the following memorial, which was ordered to be sent to the State Board of Agriculture:

Whereas, The exhibition of the apiary department at the State fairs has been a hap-hazard affair, we ask as a society that the Board recognize Mr. J. M. Hicks as the superintendent of the apiary exhibit at the fair, and that his recommendation of a person or persons for judge or judges of said exhibit, be appointed."

Furthermore they desire the amount of premiums raised from $99 to $300.

The following new officers were elected: President, E. H. Collins; Vice-Presidents, W. C. Hall, T. S. Bull, G. B. Wilson, J. M. Hicks, Mrs. F. M. Cooper, W. Mason, W. Jordan, L. Snyder, J. T. Coffman; Secretary, G. C. Thompson; and Treasurer, Mrs. C. Robbins.

The bee-keepers desire recognition in the Board of Agriculture, and have instructed J. M. Hicks to represent them at the next meeting of the Board, which occurs on Feb. 19.

The convention then adjourned.

BEE-WISDOM.

Can Bees Reason, and Talk to Each Other?

Written for the American Bee Journal

BY PHILIP WECK.

Those who have watched the sagacity of bees, know that if only one bee discovers where honey is secreted, it will fill itself and return to its hive, and very soon it will bring an army of bees with it to carry home the discovered treasure, as much as fifty pounds a day; and if you assail one in a lonely place, the bee will go home, report the insult, and bring a company with their sharp-pointed weapons, to dart and avenge the insult of the one who was assailed. They are continually on their guard to avenge their enemies, man or beast, who are thousands of times larger than themselves. They have sentinels guarding their hives, which will appear to the reader, from

what I saw; their faculty of reason is very large, which can plainly be seen by the following incident:

One day while examining my hives, I saw a spider lodged in the corner of a hive, spinning its net. One bee flew in front of the hive to fight the spider, but the spider finally succeeded in spinning its web and trapping the bee in it; and while the bee was struggling for liberty, three other bees came to its assistance, and flew all at one time unitedly at the web, at least 20 times, to liberate the entangled bee.

I am sorry that I did not wait for the result, as I liberated the bee from the web myself. I have no doubt but what they would have accomplished their object, broken the web, and freed their imprisoned companion.

Bees are the most wonderful insects that God ever made. Not one lives to be more than one year old, except the queen; yet just look at their industry in laying up treasures for the rising generations, as well as for themselves, coming home doubly loaded when the flowers bloom, from sunrise to sunset, and often by moonlight; what ingenuity is exhibited in sipping honey from flowers, and in manufacturing wax to build their store-house to store their rich treasures; in making cells, which they so wonderfully construct; while in others, the queen will deposit her eggs, and still others are used to store pollen to feed the rising generation; in building queen and drone cells at the proper time; in hindering queens from killing each other, when it is not best; in getting rid of drones when not wanted; and what a grand sight it is to see them swarm!

How wonderfully and skillfully God has made the little bees to gather such luxuries for man.

PASSAGE-WAYS.

Winter Passage-Ways Through the Combs are Unnecessary.

Written for the American Bee Journal

BY G. M. DOOLITTLE.

Not long ago a neighbor bee-keeper called, asking if he might see how I made passage-ways for the bees through the combs, so that the bees might not be caught by each cold snap during the winter, on the outside of the combs, away from the cluster, as the bees were contracted in the cluster so as to keep up the warmth necessary for the colony to pass through each cold spell.

I told him that I never, of late years, made such passage-ways, for I did not think them at all necessary. As it may seem to some that I was just a little "off the track" in so replying, I will give a few of the reasons why I think as I do, as well as some of my observations along this line.

As fall approaches, if we examine a colony of bees, we will find that the activity manifested during spring and summer in the interior of the hive, becomes less and less, so that by the middle of October, in this latitude, all brood-rearing has ceased, and the bees have become partially dormant; still, so far, they have not packed themselves away in a snug cluster, or compact shape for winter.

Every opportunity given by a warm day is improved to void the feces, so that the bees may be prepared for a long cold spell, when such occurs. As the weather grows colder, and the bees contract their cluster, many packing themselves away in the cells until the smallest possible space is occupied by them, and thus the requisite warmth is secured to keep them alive, when the mercury sinks below zero.

All are well aware that in this contraction of the bees (at certain times), many of them are left singly or in little clusters of from five to ten, which do not recede with the main cluster, and thus are chilled where they are, and if the weather becomes cold enough, they are frozen, thus losing to the cluster that number of bees. Some claim that this loss is going on all winter after each warm spell occurred, where large frames are used, and say a reason why bees seemingly wintered so much better in box-hives years ago, was because with box-hives, cross-sticks were used in the center of the hives, which caused holes or passage-ways through the combs in the centre of each, while with a large movable-frame no cross-sticks could be used, as was the case with box-hives, and hence no holes were left as there were in those days; thus compelling the bees to pass over and around the combs of cold honey to keep pace with the receding cluster, instead of passing through the centre of the combs to the next range, which was more nearly filled with bees.

In thus passing around after each warm spell, many bees become stiffened and are caught by the cold, which might have been saved if holes were provided in the centre of the combs for them to pass through. This evidently was the argument used years ago, when the Langstroth frame and others were provided with a shaving bent to form a circle an inch or so in diameter, which was suspended from the top-bar by means of a little strip of tin, supposing that this would effectually secure a passage-way for the bees. However, but a short time elapsed before it became apparent that during a good yield of honey this shaving would be filled with comb and honey, thus making the combs as they were before, as far as passage-ways were concerned, while the combs were much damaged by the plan, to what they would have been had they been built whole.

However, I used to be one who considered these holes necessary, and after failing with the shaving, I next practiced cutting holes through the combs, each fall, which would be filled up the following summer, so that when winter approached, the process had to be repeated.

This taking out all of the combs each fall was quite a job, and when some one suggested that a hole might be bored through one side of the hive, and a square stick made sharp at the end, slowly wormed through the combs to the opposite side, so as to make a hole through each without danger of killing any bees, I was not long in adopting that process.

If holes were to be made through the combs, the above is the best plan I know of; but it soon became apparent to me that the reason assigned as the cause of the death of the bees was not the real trouble, for while making holes one fall, I found little clusters of chilled bees between the combs just outside of the cluster, and also in the sections of a hive, which happened to be left on after the rest had been taken off; these same chilled bees being on the combs right above the entrance to the sections, and only a little way off, and in a direct line with the cluster below.

Later on I found the bees would stay and die within ½ of an inch of the holes which I had made, when it would appear that they could have passed through these passages just as well as not. This opened my eyes, and upon carefully noting the facts which came under my observation, I discovered that when the weather was cool, cloudy and rainy for several weeks before it was severely cold, so that the bees had no chance to fly, this loss was apparently much greater than when a clear, warm day occurred so that the bees had a good flight immediately before a severe cold spell.

By the number of bees that were found on boards and such places, dull and quite stupid after such a fine day, I concluded that these were the very same bees that would have died by not following the cluster, had not a warm day occurred for them to leave the hive to die; hence I say that the loss was apparently greater when no such day occurred, for the bees that were found out around on the boards and grass after a warm day, represented the same bees which gave me so much uneasiness upon finding them dead in

little clusters away from the main cluster, when they were compelled by cold weather to die in the hive; so really there was no difference.

After bees once get thoroughly clustered, I do not see this loss occurring after each warm spell, as some claim that it does, as spoken of above; nor but little after a warm fall like the past has been, when the bees have an opportunity to fly every little while.

After being fully settled for winter, and this loss of bees that are without sufficient vitality to stand the first cold spells, has passed away, a colony will lose but few bees during the rest of the winter, if there is no other disturbing causes, except warm and cold spells alternating, as is attested to by our finding scarcely a handful of dead bees on the bottom-board after a long period of such weather.

From the above I decide that holes through the combs are unnecessary, and that no provision need be made other than exists in all well-regulated movable-frame hives.

Borodino, N. Y.

FACING HIVES.

How to Place the Hives when Taken from Cellars.

Written for the American Bee Journal

BY FRANK COVERDALE.

In which direction should bee-hives front? is a question of great importance. It is also one very little discussed by our ablest apicultural writers, though we have been advised to set out wind-breaks, or build a high fence, and behind all this have the location facing in a southerly direction, thus making a warm, cosy place for the bees in early spring, and a very hot place in the summer. This, in my thinking, is very objectionable, as here is liable to occur great mortality in early spring, and an abundance of swarming right in the midst of the white clover harvest, and before they are really strong enough to swarm; where, if the hives had been fronting northerly, with scattering shade trees (not high trees), so as to shade the hives a part of the time, the trouble might not have occurred.

I would not advise having shade trees very thick. It is from personal experience that I write. I have been experimenting in this direction for about ten years, and I think that I have come to a conclusion that is satisfactory to me. I cannot control my bees in a hot or sultry, close place, for they will hang out on the fronts of the hives, and at a loss of honey, or at my expense. The better the honey-flow, the warmer is the inside of the hive, so it would be well for us, even in this latitude, not to choose too hot a place for the hives. If I should have any slope at all, it would be in any direction except south.

On the other hand, early spring is very trying, and at this time of the year we should do all we can to save the old bees, for if we accomplish this, other things being favorable, we will have plenty of brood, and plenty of bees to gather the clover honey. For hours in the spring of 1888 I watched, with much interest, the little bees fly from the cosy and well-protected apiary, on which the direct rays of the sun rested, causing the bees to take wing in great numbers. Over the willows they flew, with the temperature at 45°, though there were clouds at times, and chilly northern breezes. If my bees had been on the north side of the willows, they would not have been out, taking the chances.

I had one row of hives fronting north, and where the cool breezes could strike the entrance; these bees did not dwindle to any extent, while those in the sun, and facing south, though protected from the wind, dwindled down on the average of one-third of the bees. Thus it may be seen that if the white clover had yielded a surplus, I would have been the loser of hundreds of pounds of honey. In short, I think quite positively, that it is not best to carry bees from any repository, and front their hives to the south, in a sunny and close yard.

Welton, Iowa.

ILLINOIS.

Report of the Northern Illinois Bee-Keepers' Convention.

Written for the American Bee Journal

BY D. A. FULLER.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association was called to order in the county Court Room at Rockford, Ills., on Jan. 15, 1889, by President L. Highbarger. The reports of the members showed 20 bee-keepers present, and their crop of honey for last season was 9,280 pounds of comb honey, and 10,080 pounds of extracted honey. All of the members thought that their bees were wintering well, with plenty of stores, but that the past season had not produced nearly half a crop of surplus honey.

The resolutions laid over from the last meeting to change the name of the Association to "Northern Illinois," and the time for the annual meeting to the third Tuesday in December, were adopted.

A Peculiar Queen.

Mr. R. Gammon asked: Can a queen that produces all three-banded workers be a hybrid? He then stated that he bought a queen, and all of her worker-bees were straight three-banded Italians; but all the queens he reared from her were dark, and their bees were hybrids.

Dr. C. C. Miller thought that there might be a taint of impurity in the old queen; or might it not be that all the seven young queens mismated?

Mr. Gammon thought that it was impossible for all the young queens to have mismated, as all his other queens were purely mated.

The Chapman Honey-Plant.

Is the Chapman honey valuable enough to occupy tillable ground?

Dr. Miller said that for a honey-plant to be worth anything, it must be able to take care of itself; that he had one-eighth of an acre, and the first year he cared for it well, when it grew and did nicely; but the young plants winter-killed badly. There were a great many bees on the blossoms, but did not work as they do on white clover, but would lie on the blossoms and act stupid. While they were gathering from white clover they went from one blossom to another very lively.

President Highbarger said that all of his Chapman honey-plants winter-killed, except a few plants under a snow-drift. These blossomed, and the bees worked on them well, but he also noticed the slow, stupid action of the bees on the blossoms, and also stated that some worm cut the blossoms off badly. He did not think that he could make it pay to raise it especially for honey.

Mr. E. Whittlesey said that his bees worked well on it, but some worm or insect worked in the stalk, killing it badly.

Prevention of Second Swarms.

Mr. Gammon said that his plan of preventing second swarms, was to cut out the queen-cells. It worked successfully with him. He kept about 30 colonies.

Mr. Lee said that was his plan, and it was successful. He had 200 colonies.

Dr. Miller asked how many had tried moving the old colony entirely away, putting the new one in its place. He did that way, and succeeded well.

Mr. Stordock used the Heddon plan, and liked it, as it was a success.

Mr. Herrick had tried moving the old colony away, and lost one. He did not try it again.

How many clip their queens' wings? Seven said that they practiced it. Mrs. Woodard said that by clipping the queens' wings she could hive her own bees, and take care of them herself.

The convention then adjourned until Wednesday morning.

SECOND DAY.

The Wednesday morning session was called to order at 9:45 o'clock, with President Highbarger in the chair.

When should the bees be placed in the cellar for winter? The fact was developed that the members had placed their bees in the cellar from Oct. 25 until Christmas. Some of the members thought that their bees wintered better when placed in the cellar earlier, and disturbed them less.

Unfinished Sections.

How do you prevent having a large number of unfinished sections in the fall?

Dr. Miller takes the unfinished sections from the weaker, and places them on the stronger colonies.

Mr. Whittlesey takes away the completed sections, places the unfinished ones in one row, and fills the empty space of the super with pieces of board cut to fit it.

Dr. Miller also said that he did not think it advisable to tier up too high, as the bees would commence in all of them; but if doubtful as to their needing more room, he would place the last super on top, instead of under the others.

The next order of business was the election of officers for the ensuing year, and resulted as follows: Leroy Highbarger, of Leaf River, President; A. J. Sweezey, of Guilford, Vice-President; O. J. Cummings, of Guilford, Treasurer; and D. A. Fuller, of Cherry Valley, Secretary. The convention returned a vote of thanks to the Supervisor of Winnebago county, for the free use of the Court Room.

It was decided to hold the next meeting on May 21, 1889, at the residence of H. W. Lee, of Pecatonica, Ills.; on Aug. 20, 1889, at the residence of Russel Marsh, of Guilford, Ills.; and the annual at Rockford, Ills., on Dec. 16 and 17, 1889.

On motion, annual dues of the members was made 25 cents per year.

The convention then adjourned.

D. A. FULLER, *Sec.*

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
May 1, 2.	Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.
May 4.	Susquehanna County, at Montrose, Pa. H. M. Secley, Sec., Harford, Pa.
May 21.	Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees Wintering Splendidly.—L. D. Cheasbro, Conway, Iowa, on Feb. 2, 1889, writes:

Bees are wintering the best I ever saw them. Last spring I had 6 colonies, increased them to 24, and obtained 600 pounds of first-class comb honey in one-pound sections. I sold it here at 15 cents per pound. We had no honey-flow until September. White clover and basswood was a failure. My bees are all taking a flight to-day. I examined all of them, and I find more honey in the hives to-day than I ever saw before at this time of the year. It has been so warm this winter that I have not put them into the cave, but left them on the summer stands.

Proper Width of Hives.—G. Kelly, Kalamazoo, Mich., on Feb. 1, 1889, writes:

1. What is the proper width for a hive to contain 8 brood-frames? 2. Is ⅜ of an inch enough space between the bottom of the frames and bottom-boards?

[1. A hive to contain 8 brood-frames should be 12 inches wide, inside. 2. The space at the bottom of the frames should be not less than one-half inch.—ED.]

Producing Comb Honey.—D. W. Dougherty, Springwater, N. Y., on Jan. 21, 1889, says:

I appreciate the efforts of the editor of the BEE JOURNAL for the cause of bee-keeping. We cannot work successfully without the press, one of whose most honorable members is the AMERICAN BEE JOURNAL. The season of 1888 in this part of the country was a poor one, owing mostly to dry weather. I had a small increase, and but little honey from my apiary. I work entirely for comb honey, the tiering-up method being practiced.

Successful Cellar Wintering.—A. J. Duncan, Hartford, Iowa, on Feb. 1, 1889, writes:

The past two years have been the poorest for honey that I have experienced since I have been keeping bees. Last year I took 30 pounds of honey per colony, spring count, some of it being comb honey, but mostly extracted. In 1887 I took 25 pounds per colony, but in 1886 I took 150 pounds per colony, spring count, but I had full combs below and above to hive the swarms on. I never extract from the homestead. I have wintered my bees very successfully for the last several winters in a cellar under the sitting-room of my house, where the fire never goes out in the winter-time. The cellar is 16x24 feet, outside measure, and 7 feet deep in the clear, ventilated by a 7-inch thimble in the stove-flue, which commences on the cellar bottom. The cellar is very dry. A room is partitioned off large enough to hold the bees, and a good thermometer is hung up against the partition which registers as low as 32° for several days at a time, though vegetables do not freeze. My bees are the most quiet at between 32° and 40°. I had my 48 colonies all prepared to put into the cellar last fall, when my wife was taken sick, and so very nervous that we had to walk on tiptoe, and talk in a whisper. She has been sick nearly ten weeks, but is a little better now; consequently the bees are on the summer stands not very well protected, and I fear that some of them have not enough stores for out-door wintering. I label every package of honey, and sell it in the home market.

Bees are Quiet—Mild Winter.—E. W. Councilman, Newark, N. Y., on Jan. 29, 1889, writes:

I have 76 colonies of bees in the cellar, seemingly in good condition, but, like all the rest, last fall my bees did not do well, as I got only 1,000 pounds of surplus honey from the whole business, and not enough increase to make up for previous spring losses. The winter has been very mild, and bees have seemed remarkably quiet in their winter quarters, and thus far but two quarts of dead bees have been swept up from the cellar-bottom, seemingly but a tithing of previous years, up to this date; so by this I think that the prospect is excellent for colonies to come through the winter in a strong condition.

A Delightful Climate.—Mr. John Boerstler, Vashon, Wash. Ter., on Jan. 28, 1889, says:

We have had spring weather all this winter, and not any snow or ice. We have been plowing all along from Christmas up to this time, and are making garden right along. This is the best climate that I ever saw—it is nearly like California. Peaches are already budding, and flowers are in bloom all winter. I am looking for 1,000 emigrants from the East in the spring. I cannot see how they can help coming out West, with the climate we have here. Bees are all right yet. They are flying every few days, and the prospects are good for fruit this year.

Wild Bees.—O. C. Becker, East Saginaw, Mich., on Feb. 4, 1889, writes:

During July and August, I take my summer vacation on the Shore of Lake Huron, where there are wild bees. I have caught them, and put them into a box with honey, when they would fill themselves, leave, and not return. Does any one know of anything that they (the bees) will work on, when there are flowers in bloom? I concluded that nothing could be done in finding bee-trees until after the frosts came.

Bee-Cellars—New System.—R. S. Becktell, Three Oaks, Mich., on Feb. 4, 1889, writes:

The season of 1888 was the poorest that I have seen here in my 17 years' experience with bees. I generally get 20 to 100 pounds of comb honey per colony, but last season I got nothing from 200 colonies. The most of the colonies obtained enough honey for winter, but I will have to feed some in April. I have 175 colonies of bees in the

cellar under my house; it is 12x30 feet. I have kept it at 45° to 50°, except once when it was 52°. The temperature keeps rising when there is but little ventilation to the cellar. Why is this? I think that it is only natural that the bees would gradually raise the temperature, especially after breeding begins, and the thermometer outside indicates only 20° to 45°.

Dr. Tinker's new method of working bees for comb honey, described on page 25, I think will not work. The bees will only average 40 pounds of honey per colony, and his second brood-chamber will hold that amount, which would have to be extracted; and his half-filled brood-frames would be filled too much with brood-comb, etc.

No Surplus Honey for 2 Years.—Rev. John Hunt, Plain City, O., on Jan. 29, 1889, writes as follows:

My account of the bee-business in this region is not encouraging; for the last two years it has been a failure. During that time I have received no surplus honey, and have been obliged to feed with sugar syrup. I had 17 colonies in the fall, but not any of them being strong, I reduced them to 9 by uniting. I am hoping in this way to have a better chance to carry them through the winter. Thus far they appear to be doing well. This winter has been mild and open, and I think that it is favorable for the bees. My neighbor bee-keepers are not doing much better than myself. We hope that the next season will witness a revival of the white clover, which has been killed out by the severity of the weather in time past, or some other cause. I rejoice that there is sufficient enterprise to maintain a weekly bee-paper in the interest of apiculture.

Bees Quiet in the Cellar.—C. G. Ridout, Hutchinson, Minn., on Jan. 24, says:

I began in the spring of 1888 with 5 fair colonies, increased them to 12, and obtained 500 pounds of light comb honey, nearly all clover and linden. The 12 colonies this fall which I put into the cellar, were all strong, and had plenty of stores, more than they needed, I think: but I would rather they would have too much than not enough, which is frequently the case with many.

I would like to ask a question, viz: The winter in this section has been unusually warm, and my bees were put into the cellar early last fall. So long as they remain quiet is it best to leave them undisturbed in the cellar, or should they be given a flight?

[Do not disturb them unless they become restless.—Ed.]

Feeding Bees in Winter.—Geo. W. Ogden, De Kalb, Mo., Jan. 29, writes:

The last year has been a hard one, but we must try again. I shall, at least. I have 20 colonies flying to-day. They are on the summer stands. I tried the cellar last winter, and I cannot say that I prefer it. I think that if bees have plenty of honey or syrup, they will be all right in this State. At least 25 per cent. of the bees in this county will starve. I have fed lots of bees during the last 20 days, for my neighbors. They all have the Langstroth hives. I turn the syrup into the empty combs, from 5 to 10 pounds to the colony, in a few minutes. I have kept bees for 25 years, and have not lost any money by it yet, but 1887 and 1888 were poor seasons with me. I got 150 pounds of honey last year, and 2 swarms, and lost 10 colonies by starvation in August. I put 27 colonies out of the cellar last March. The bee-keepers are going to organize on Feb. 2, at Agency, in this county.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the American Bee Journal for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the Bee Journal.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2 00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Simmins' Non-Swarming System, and the American Bee Journal for one year, for $1.25. The subscription to the Bee Journal may begin anew at any time.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ¼ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Oct. 13, 1888, wrote as follows concerning their use of the advertising columns of the American Bee Journal:

We got more orders from our advertisement in the American Bee Journal than from all the other bee-papers put together.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Catalogues for 1889 are on our desk from—

Wm. W. Cary & Co., Coleraine, Mass.—36 pages—Italian Bees and Apiarian Supplies.

F. A. Snell, Milledgeville, Ills.—16 pages—Apiarian Supplies, Italian Bees, etc.

Frank A. Eaton, Bluffton, O.—16 pages—Italian Bees and Queens, and High Class White Fowls.

Jno. Nebel & Son, High Hill, Mo.—8 pages—Italian Bees, Queens and Bee-Keepers' Supplies.

Dr. J. P. H. Brown, Augusta, Ga.—4 pages—Italian Queens and Bees, and Apiarian Supplies.

Andrews & Lockhart, Patten's Mills, N. Y.—8 pages—Carniolan Bees and Queens.

Jos. E. Shaver, Friedens, Va.—24 pages—Bee-Keepers' Supplies.

Childs & Jones, Utica, N. Y.—52 pages—Cheese Factory, Creamery and Dairy Apparatus and Supplies.

Core's Farm Accountant is a pocket-book of 64 pages published by Arthur S. Core, 170 Front St., New York. It is intended for keeping a correct data of the entire farm, the product of each crop as well as the animals. There are also valuable hints on farm labor, poultry, foods for milk and fat producing, butter, pasturing and soiling, light and heavy soils, apple, peach and berry culture, substances taken from the soil, etc.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¼@6c.; dark amber, 4½@5½c.

BEESWAX.—18@22c.

Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.

Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but about equal to the demand. Market will be bare of comb honey long before the new crop is ready.

BEESWAX.—22@23c.

Jan. 18. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@7½c., depending upon quality and style of package. Market dull and stock sells slowly.

BEESWAX.—22c.

Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.

BEESWAX.—20c. for prime.

Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.

BEESWAX.—22c. R. A. BURNETT,

Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.

BEESWAX.—22@23c.

Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand slow, with a smaller supply than ever at this season for the past 10 years.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Jan. 9. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.

BEESWAX.—20@22c.

Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.

BEESWAX.—None in market.

Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.

BEESWAX.—20c.

Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.

HILDRETH BROS. & SEGELKEN,

Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.

BEESWAX.—19@20c.

SCHACHT, LEMCKE & STEINER,

Jan. 8. 16 & 18 Drumm St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.

H. M. SEELEY, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. Feb. 23, 1889. No. 8.

EDITORIAL BUZZINGS.

Mr. Geo. E. Hilton has been engaged to edit a department on apiculture in the *Michigan Farmer*, and he will make it interesting, too.

Fr. Ledermann, of Fayette, Howard Co., Mo., has passed to "the beyond," leaving his bees to the care of others. We have no further particulars.

If we See Rightly and mean rightly, we shall succeed, though the hand may stagger a little; but if we mean wrongly, or mean nothing, it does not matter how firm the hand is.—*Ruskin.*

Stitching with Wire is now done by machinery upon many periodicals. *Gleanings* has just adopted that method, in accordance with our recommendation. Mr. Root says the machinery gives most excellent satisfaction, and he wonders that he did not adopt it sooner. The cost is only one-fourth of what it took to do it by hand.

A Photograph of Mrs. Mahala B. Chaddock is on our desk, and will be placed in the BEE JOURNAL Album. It is a nice cabinet picture, but Mrs. C. says it flatters her some. It certainly is very attractive, and we expect it is quite natural. A similar photo accompanies the United States exhibit at the Paris Exposition.

By the way, Mrs. Chaddock is getting up quite a reputation as a writer. An article from her pen may be found in the *Popular Science Monthly* for this month. She now writes for several bee-periodicals, and is in correspondence with Sir John Lubbock, an English lord and scientist.

Cleome—Mexican Honey Plant.—Mr. C. H. Sapp, of Ravenna, O., on Feb. 13, 1889, writes as follows:

DEAR EDITOR:—I enclose a description (taken from the seed catalogue of Samuel Wilson, Bucks Co., Pa.) of the "Mexican Honey Plant." I desire to know if you are acquainted with the plant, or know anything of its merits? Could we reasonably expect it to fulfill even one-half what the description claims for it? Would there be danger of its becoming a troublesome weed if introduced? Any other information regarding it will be gladly received through the AMERICAN BEE JOURNAL.

Mr. Wilson has simply given another name to the "Rocky Mountain Bee-Plant," and palmed it off as "the grandest discovery of the modern age." It has been cultivated for bee-pasturage for several years, and is well-known to bee-keepers, and yet Mr. Wilson, in his advertisement, heralds his "new and valuable plant" in these words:

The introduction of this new and valuable plant is destined to be a great blessing to the American people, especially to those who are interested in bees and bee-culture. No other plant, tree or flower now known to the botanical science of the world can equal this beautiful and magnificent specimen in its handsome and attractive appearance and wonderful honey-producing properties.

Nothing can equal the splendor and magnificent beauty of the cleome when in full bloom and alive with bees. Each petal of the lovely flowers contains its miniature drop of honey, which sparkle like diamonds in the morning sun. For those who contemplate keeping bees, either on a large or small scale, nothing could be more useful or easily grown than this magnificent plant.

He then quotes the following from a correspondent:

No other plant known to the civilized world can vie with the cleome integrifolia in producing honey as food for bees. And no other honey is as clear and of as good quality.

He further says: "I have frequently weighed my bee-stands for a number of mornings and evenings, and found many of them to increase as much as nine pounds of honey a day."

Then Mr. Wilson winds up his advertisement with these deceptive words: "As yet the seeds of this valuable plant are very scarce. Our agent, after traversing the mountainous regions of Mexico for nearly two months, only procured about 100 pounds."

Instead of being so scarce, it may be found in ALL THE CATALOGUES of the dealers in bee-keepers' supplies, and quoted at 5 cents a packet, 15 cents an ounce, or $1.25 per lb.—while this Mexican "wonder" is offered in small packets at 25 cents each.

The *plant* is a good one, but is not new; neither is it "the grandest discovery of the modern age!"

The *honey* is also of good quality—but it is not true that "no other honey is as clear, and of as good a quality" as stated in this circular!

The *seed* is valuable, but it is not so scarce as to make it cost several dollars per pound, as Mr. Wilson says!

Its *habitat* is clay, gravel rock and limestone, and it grows in the Rocky Mountains, but it also grows in all the western and southern States, and it was not necessary to traverse the mountainous regions of Mexico for two months to procure one hundred pounds of seed!

It is a pity that Mr. Wilson should have misrepresented this honey-plant, which is none other than *cleome integrifolia*, or the "Rocky Mountain Bee-Plant," re-named by him as the "Mexican Honey Plant."

In reply to our correspondent, we will say that the seed can be sown anywhere—among rocks, on craggy hillsides, along the highways, in fence corners where nothing useful will grow, and where the winds and rains will spread them, and in a few years such waste places will prove attractive to the eye, and yield abundance of sweets for the table. The seed should be sown in the fall, when the plants will bloom the next season.

Mr. John Nau, of Middletown, Iowa, gave us a call last week, and we had a very interesting visit with him. He rightly remarked on the matter of the Bee-Keepers' Union, that downright ignorance was the cause of the senseless opposition to bee-keeping by fruit men. He had been a close observer of the benefit of which bees were to fruit, as he was a fruit-culturist as well as a bee-keeper and stock-raiser.

In the spring of 1881, after a very destructive winter on bees, he was riding over the country considerably, and noticed that the apple trees near an apiary were the only ones that were fruitful. The bees had died by the milions, and were scarce in the spring, and as a result apple-trees were very generally bare of fruit. Whenever he passed apple-trees that showed a good yield, he remarked that bees must be near, and so in a few minutes he came in sight of bee-hives. He made repeated remarks about it, and had several others notice the matter, and he was well satisfied that the bees were of the greatest benefit to fruit of all kinds, especially apples.

He says that if the fruit men would only give attention to this matter, they would keep a few hives of bees, just for their valuable services in fertilizing the fruit blossoms.

Get Ready for the Harvest.—The *Indiana Farmer* makes these very sensible remarks about getting ready now for the coming honey harvest: "Who of our farmer readers do not dislike to take the time in spring and summer, when every moment is so valuable, to put sections together, paint and repair hives, etc.? All this is work that certainly should be done now, during the cold and stormy weather. Think, too, what a pleasure it will be to feel that all is in readiness for swarms, let them come as early as they will. A golden motto for any bee-keeper is, have everything ready early, and get all in readiness when it can be done with the least outlay of valuable time."

GLEANS OF NEWS.

Europe seems to have exchanged weather with America this winter. The latest advices report the wind furious, and the weather bitterly cold. A cablegram of Feb. 9, dated at London, says :

The gale in England and Scotland still continues. Telegraphic communication has been interrupted by the storm, and a number of houses has been blown down. In Scotland a heavy snow-storm prevails, and the railways are blocked. All along the coast there have been numerous wrecks. A bark has been lost off Grimsby, and all hands were drowned.

From Berlin, the capital of Germany, on the same date, comes the following :

No evening train has arrived at Cassel or Frankfort. Traffic on all lines is interrupted by snow.

Insects.—Prof. Lintner, State Entomologist of New York, gives the known number of species of insects in the United States as 25,000, in the world, 325,000, with probably a still larger number not yet known. The number of plant-lice on a single cherry tree has been computed at twelve millions. In one year the entire wheat crop of the State was destroyed, causing a loss of $20,000,000. There are 223 different species of insect enemies to the apple.

White Clover in Poor Condition.—Henry Willson, Clinton, Ills., on Feb. 9, 1889, writes :

It seems that nearly all bee-keepers report the white clover in good condition, but here it is not, and I do not expect the bees to make more than a living from it the coming season ; last season it did not do even that well. My bees averaged 33 pounds per colony last year, spring count (nearly all of it being comb honey, and all from heart's-ease), and enough to winter on. Some of my colonies swarmed without an ounce of honey in the hive. I have 34 colonies in the cellar, but they are not very quiet.

We would like to hear from all apiarists who find that white clover has been damaged this winter. It will be interesting to know this. Will they please report ?

Sowing the Seed of general knowledge about bees is now quite common. Mr. Frank A. Eaton, of Bluffton, O., wrote us on Jan. 31, 1889, as follows upon the matter of scattering knowledge concerning bees in Toledo, Ohio, in addition to that given by Dr. A. B. Mason, mentioned some time since :

Prof. Frank M. Maguire, superintendent of one of the Toledo public schools, recently gave a one hour's lecture on "Bees and Bee-Keeping," to the Century Club of that city, one of the leading literary societies of Toledo. He illustrated the lecture with a living queen, drone, and worker-bee. He also exhibited a queen-cell, section, comb foundation, and drawn-out comb. It was a revelation to the Club, many of them never having before heard or dreamed of the true character of the bee.

Explanatory.—Relative to the "omission" mentioned by Mr. R. McKnight, on page 100, Mr. Holtermann sends the following explanation, which will end that matter in our columns :

You, Mr. Editor, knew that the article was in type, and proof sent to you before my departure for Owen Sound. I there omitted the clause with the kindest intention and best will towards all ; I took a liberty in so doing, and perhaps I should have read it as it was. On Mr. McKnight at least my good intentions were lost.

In reference to the omission of Mr. Pringle's essay, let me say that I did not know that I had omitted it until I hunted the matter up, when my attention was drawn to it last week. The supposition that any "personal pique" existed between Mr. Pringle and myself is erroneous, for at that very meeting I happened to have paid Mr. Pringle's membership fee before the election of officers, so as to make him eligible for directorship for his district. Mr. Pringle and myself have, perhaps, very little in common, yet that does not prove any pique ! I might explain matters a little more fully, and take exception to Mr. McKnight's statement as to the value of the matter excluded, but I do not wish to be the cause of producing any ill-feeling, or intensifying that which apparently exists. I find the school I have been in for some years an excellent one ; it will make me more careful, knowing that I am watched so closely, and caught up so quickly at the slightest slip by some ; and if I could always think that their criticisms were in a kindly spirit, I would find it less difficult to be thankful for them.

New Bee-Association.—Mr. J. G. Graham, of Agency, Mo., writes as follows concerning the formation of a new bee-society :

The bee-keepers of Agency, Mo., and vicinity, met on Feb. 2, and organized "The Agency Bee-Keepers' Association," with 14 members to start with. J. G. Graham was elected President ; Rev. S. H. Murray and E. F. Gordon, Vice-Presidents ; T. S. Smith, Secretary ; and J. E. Wallace, Treasurer.

Bees were reported as wintering well. The subject of hives was discussed ; each preferring his own or the Langstroth. The next meeting will be held on the last Saturday in March. The subjects for discussion are comb and extracted honey, and foundation for brood-chamber and surplus receptacles ; the kind and the extent to which it should be used.

Coins by Mail.—An invention that is being used for sending coin through the mails consists of a piece of pasteboard about the size of an envelope. In it are holes the size of a silver quarter, a half dollar, and a dollar, with red paper seals ready to paste across each slot. A coin can be put in and sealed, inclosed in an envelope, and sent through the mails in safety.

Coins should never be sent through the mails in ordinary envelopes.

Catalogues for 1889 are on our desk from—

H. G. Frame, North Manchester, Ind.—4 pages—Bees and Queens.

George Pinney, Evergreen, Wis.—16 pages—Nursery Stock.

Cleveland Nursery, Lakewood, O.—48 pages—Strawberries, Grapes, Gooseberries, etc.

Planting for Honey.—Mrs. L. C. Axtell, reports her experience with planting for honey thus, when writing to the *Farmers' Review* :

One year ago last summer we purchased one pound of Japanese buckwheat for which we paid 50 cents, sowed it, and it yielded three pecks. Again last summer we sowed the three pecks and got 16 bushels. It is a larger kernel by nearly one-third, and grows more thrifty than the other buckwheat. It hardly had a fair chance to do its best last summer, either, as the ground was weedy, and the weeds got ahead of the young buckwheat.

We had a 10 acre field of Alsike clover that was as handsome as a flower garden, last fall, with all the three kinds of clover in bloom at the same time, the Alsike, the red, and the white clover ; but as bees do not get much honey from clover in the fall, we could not tell how good a honey-plant the Alsike was. It has a most beautiful flower : the top of the clover ball is bright pink, and the lower is white, and many heads on a stem. It is in size about half way between the red and the white.

The Mild Winter has saved millions of dollars in fuel, and allowed builders and others to work nearly all the time—thus proving a blessing to those who need the results of labor.

Clothiers and those merchants who have large stocks of seasonable goods have suffered this time with coal dealers, but on the whole the mild season has been a blessing.

As to winter coming later on, an exchange wisely remarks that "we are now so far advanced in February that there is no reason why much attention should be paid to those croakers who say winter may yet come. Doubtless there will be unpleasant days this month and next, but there will be none of those bitter blasts that threaten the life of man and beast. The winter is far spent ; the days are lengthening out ; the sunshine grows stronger ; the spring is approaching." Let us all be happy and prepare for it.

The Bee and Honey Exhibit for the Paris Exposition, under the superintendence of Mr. N. W. McLain, is now complete, and has been shipped to Paris. It is a part of the exhibit by the United States Government for the International Exposition to be held in Paris during next summer.

Mr. McLain has been in Washington nine weeks preparing the articles collected for transmission, and has a very good assortment of bee-products and bee-keeping implements. He is now at work on the Meat and Dairy Products.

Seed.—The United States Commissioner of Agriculture, Hon. N. J. Colman, has purchased a quantity of the Chapman honey-plant seed for free distribution. Applicants desiring packages of the seed will be supplied while the seed lasts, in the order of their applications. The request for seed should be addressed to the United States Commissioner of Agriculture (Seed Division), Washington, D. C.

BIOGRAPHICAL.

AMOS IVES ROOT.

Among those who have assisted in making the pursuit of bee-keeping thoroughly practical, Mr. Amos I. Root is a prominent figure, and it is but right and proper to here record something of his past life.

The engraving given on this page was made especially for the AMERICAN BEE JOURNAL, from a photograph taken at our request, and this reproduction by the "Ives" process, is, therefore, a faithful representation of Mr. A. I. Root as he now appears, and not as he looked 12 or 15 years ago.

The biography, written by Mr. Ernest R. Root, the eldest son of Mr. A. I. Root, is as follows:

A. I. Root was born on Dec. 9, 1839, in a log-house about two miles north of his present business plant. He was a very frail child, and his father had little hopes of raising him, although the neighbors assured him that his wife would not let him die. As he grew older his taste for mechanics and gardening became apparent.

Among his early hobbies were poultry, windmills, clocks, electricity, chemistry, etc. He did not take kindly to feeding pigs, or, for that matter, general farm work, although he took particular delight in gardening. One of the jobs which he disliked was churning. Accordingly, to appease his mechanical turn of mind, and at the same time relieve himself of an irksome task, he constructed a windmill. This was attached to the churn, and the latter, in obedience to the wind, soon converted the cream into butter.

At the early age of 18, he became so enthusiastic on the subject of chemistry and electricity that he started out on a lecturing-tour, with a fully equipped apparatus of his own construction. Such an undertaking on the part of a mere boy was rather unusual, but he was not one of the kind who followed in the wake of most other boys—indeed, he was even called "peculiar." In spite of difficulties, and in spite of discouragements, he *electrified* his audiences, who sometimes complimented him, and at other times were disposed to make fun when his experiments did not turn out just as he told them they would.

About this time he engaged the services of one Samuel Bates, who acted as an assistant, door-tender, etc. In one of their journeys from one town to another, it became necessary for them, as they thought, to ford a stream. Young Root declared that the water was too deep, and insisted upon not undertaking it; but his companion declared that he would drive through alone, as the horse and buggy was his property. Accordingly the two boys, with the horse, began to ford the stream. They very soon got beyond their depth, and the horse, impeded by the wagon, sank; and Bates, not being able to swim, went down likewise. Amos, who had acquired the art, swam for the shore till he could swim no longer. With presence of mind he sank down and crawled toward the bank until out of the water. Having first emptied the water from his lungs he called for help, and then pushed a rail out to a point where the receding ripple showed his friend had just gone down, never to return alive. This was not the first instance in which Mr. Root saved his life by swimming.

While these tours among the people in the interest of science did not enrich him pecuniarily, it gave him an insight into human nature which doubtless has been of great value to him in his subsequent life. Nor was this the only course in the study of human nature in his early experience. It so happened that there was a country school (one of the pioneer style), which no teacher had been able to teach through a whole term. The big boys had boasted that they could "lick and put out any teacher" the directors might send, and heretofore they were successful in carrying out the fullest intent of their boasts. The last teacher, a college graduate, after being forcibly ejected from the building, cried because the boys would not let him in again.

When a young man of slight figure, in the person of A. I. Root, applied for the school, the directors accepted him. I can assign no reason for such acceptance, in the light of former experience, unless it was the wiry appearance and the determined face of the new applicant. Everything went well for a time in the school; but finally one or more of the big boys contrived to create a disturbance. The result was, the new teacher

MR. A. I. ROOT.

was overpowered by one of the brute forces. The latter called out, "Come on, boys, let's put him out." A. I. Root has a terrible temper when aroused. Now furious, with an almost superhuman effort he flung his burly opponent over, and, before he could recover himself, placed his foot upon him, and demanded of him to lie still or suffer the consequences. Young Root then asked the other boys if they were ready to obey. Order was restored, and the burly fellow afterward became one of his best pupils. Besides this, the teacher received the praise of the directors.

The next hobby of A. I. Root was clock-work and jewelry. Having learned the trade by paying $25.00 for a course of instructions (occupying almost *two whole weeks*), he decided to go into business. Accordingly he went to a friend and asked him if he would loan him a sum of money for a certain length of time. This friend gave him some advice which he has been glad of ever since. It was this: He would loan him the money if he wished, but he urgently advised him to wait a little and *earn* the money by working for wages. Unlike most boys, the embryo business man accepted the latter, and his success in business life proves the wisdom of the advice.

Shortly after setting up in the jewelry business, he was married (in 1861) to Miss Susan Hall. Imbued with a natural love for his work, and endowed with almost ceaseless energy and push, Mr. Root made his business prosper.

Ere long in the providences of time, a new "rootlet" sprang forth, of which I am told the parent branch was exceedingly proud. That was in 1862, and the boy, now a man grown, sometimes signs himself "Ernest."

The business continued to prosper until A. I. Root & Co. were among the largest manufacturers of coin-silver jewelry in the country. From $200 to $500 in coin were weekly made into chains and rings. The firm employed something over a dozen men and girls in the manufacture of gold and silver rings, chains, etc.

In 1865 his daughter Maude, now Mrs. J. T. Calvert, was born into the family. It was about this time that the first swarm of bees passed over his jewelry establishment. As this, together with his other bee-keeping experience, is fully given in the Introduction to the "A B C," I omit it.

About this time he began to write for the AMERICAN BEE JOURNAL, under the very suggestive and appropriate *nom de plume* of "Novice." In these essays, as some of the old veterans will remember, he recounted some of his failures, and some of his successes with bees. The articles seemed to take well, and, in the due course of time, so many inquiries came in, that he resolved to start a quarterly bee-paper, entitled, *Gleanings in Bee-Culture*. No sooner was the first issue put forth, than he determined to make his little paper a monthly.

Very soon after, the manufacture of bee-keepers' supplies was begun in connection with the jewelry business. With the windmill as a motive power, and a buzz-saw, "Novice," with the occasional assistance of the writer, made Simplicity hives. Sometimes the wind would not blow, and orders had to wait. I well remember on several occasions of getting up in the night when a breeze started up, to "help Pa" saw the boards, I holding one end while he managed the other.

As orders began to come, it was thought a foot-power buzz-saw would do what the wind would not. A "Barnes" was ordered, and wind and foot-power were made to answer for a while. To make a long story short, the supply-business continued to grow at such a rate that a little engine was ordered. This likewise was inadequate, and finally it was found necessary to engage a night force, and run night and day. Things continued thus for a couple of seasons, when the jewelry business and the building "up town" was sold (1877), and instead another, larger, was erected near the depot. This is shown on the first page of the "A B C of Bee-Culture." As the subsequent growth of his business is already given fully in the Introduction of the work just mentioned, I omit it here also.

In business matters he is prompt and decisive. An array of complications often arises in business, but his decision is prompt and final. With remarkable celerity he will grasp an idea or the gist of an article. The rapidity with which he will transmit his thoughts on paper is no less remarkable. He will usually dictate four pages of solid printed matter (5,000 words) in little over an hour, and that, too, through interruptions which he permits of clerks plying him with business questions.

While he is attending to his other business the stenographer transcribes his thoughts with a type-writer. Sometimes I think more deliberation in dictating might be to his advantage; but he has not the time nor strength.

His activity is almost ceaseless, and his energy often goes beyond the proper limits of strength. He rises early in the morning, and from that time on till bedtime he is "constantly on the go." I have often desired to see him sit on a hitching-post and

"take it a little easy just for two minutes," but he never has accorded me the pleasure, and it is not at all likely he ever will. He says he would "rather wear out than rust out;" but if the Lord wills, he will do neither just now.

To rest, in the sense of inactivity, is out of the question. That this constant activity, and the wear and worry of a large wholesale and retail business, has necessitated rest, his ill-health plainly shows. Young blood, in the personages of J. T. Calvert, Mr. J. S. Warner, your humble servant, and others, has, within the last three or four years, very materially lightened his labors.

Besides the two older children, are Constance, Caddie, and, last of all, Huber. This sketch would be incomplete were I to omit mention of the many ways that his faithful wife has helped him, in her own quiet, unassuming way, to bear up under his self-imposed tasks; nor should I forget to lay some of the credit to his good old mother, who still survives. It was she who gave him his early Christian instruction, and who prayed for him many years before he gave his heart to God.

Some things concerning the life of Mr. Root I have omitted, because they have been given before. But I must confess, I have not been scrupulously modest in writing up the facts. I have simply told them from the stand-point of another man's son. Without making any apology, I will, therefore, sign myself ERNEST.

It is now nearly 14 years ago that we made our first visit to Medina, O., for the purpose of having an interview with Mr. A. I. Root. He was then in the jewelry business, and had just branched out a little by making a few apiarian supplies, by the aid of the windmill at the top of the building in which the store was located.

We had corresponded some, but had never met. Upon entering the store we inquired for Mr. Root; he came forward, and we gave our name, shook hands, and commenced to chat. Mr. Root took us for Mr. S. F. Newman, of Norwalk, O. Upon being corrected as to our identity, he said, "Now let us shake bands and begin over again." We chatted about the AMERICAN BEE JOURNAL and *Gleanings*, the bees, the pursuit of bee-keeping, etc., and he remarked that he admired the excellent typographical appearance of the BEE JOURNAL, and hoped some future time to be able to have *Gleanings* printed equally well, and then he would be satisfied. Well, Bro. Root has "got there," and *Gleanings* is now printed in a style which is an honor to the craft.

Bro. Root is to be congratulated upon the success of his periodical—*Gleanings in Bee-Culture*. When it was started in 1873, it contained but 8 poorly printed pages, and was published quarterly. Now it contains 32 pages and a cover, and is published twice a month—well edited, beautifully printed, and richly illustrated. Every volume is valuable, and is in our library in substantial binding.

We have had business relations with Mr. Root for 15 years, and during that time we have had a settlement every month (with only one or two exceptions, and then "for good and sufficient reasons") and the balance has always been promptly received or paid, as the account required. We have never had an unpleasant word on finances. Mistakes have been made, but with both parties anxious only to be right, they have been readily adjusted. The monthly balances have often been over a hundred dollars, but the accounts were settled just as promptly as if the balances were only a dollar.

If this were the rule among bee-keepers, how much more pleasant it would be to do business! To get a settlement with some is almost an impossibility; with others it is so lingering as to be disgusting, while others refrain from a settlement until all amicable relations are suspended, and they are literally forced to pay. Let all such copy the example of friend Root, and prosperity, like his, may result to them.

QUERIES & REPLIES.

The Temperature Inside and Outside of a Bee-House.

Written for the American Bee Journal

Query 614.—What should be the outside temperature, as compared with the temperature in a bee-house, when it is necessary to open the doors to cool off the bees? In my experience it should be 10° colder outside than inside; otherwise it is an injury.—Mo.

From 8° to 10° colder.—H. D. CUTTING.

I think that you are about right.—A. J. COOK.

I have had no experience in this matter.—EUGENE SECOR.

I have had no experience with bee-houses, and so I must say that I do not know.—C. H. DIBBERN.

The idea should be to preserve an *even* temperature in the bee-house, regardless of what it is outside.—J. P. H. BROWN.

I think that it could be done with safety when about 50° outside.—P. L. VIALLON.

You may be right. I have no practical experience that would shed any light.—J. M. HAMBAUGH.

My experience is just like yours. The fresh air seems to be of no use, but on the other hand, it excites and arouses the colonies.—JAMES HEDDON.

I do not see what difference it makes about the outside temperature, if it is only colder than the inside.—A. B. MASON.

You have answered your own query a great deal better than I could do it, as I practice out-door wintering, with the best results.—WILL M. BARNUM.

I have had no experience with a bee-house, but I do not see why the difference should be just 10°.—C. C. MILLER.

If your bee-house is properly constructed and properly ventilated, it will never be "necessary to open the doors to cool off the bees."—MRS. L. HARRISON.

I have had no experience with the ventilation of a bee-house. I have tried in-door wintering with a few colonies, but lost every one of them.—M. MAHIN.

It would not be safe to proceed on that theory. If it were 60° inside, and 50° outside, opening doors would be likely to do injury; but if it were 45° inside, and 40° outside, it would not.—R. L. TAYLOR.

This seems to me to be a theoretical question that cannot be answered positively. While bees are quiet, let them alone; when not quiet, cool off the cellar. If there is any certain rule, I should like to know it myself.—J. E. POND.

Build an under-ground special repository, which will need no such fussing to keep the required temperature. Mine varies only from 43° to 46° during the whole winter. When I used a cellar under the house, I kept the temperature down by carrying ice or snow into the cellar.—G.M.DOOLITTLE.

Do not trouble about the *outside*. Hang the thermometer *inside*, on a level with the lower tier of hive, and see that it records about 45° regularly. If it gets warmer than that in the cellar, "cool" it; if it gets colder than that, warm it. Take care of the inside—do not fret about how cold it may be out-doors.—J. M. SHUCK.

I do not think that it is necessary to open the doors of a winter repository to "cool off" the bees. The air should be admitted from an adjoining room, if practicable, and if not, the air should be let in slowly until the temperature is lowered sufficiently to quiet the bees. It is the habit of my bees to sink into repose when the temperature goes down, and to arouse themselves and become active when the temperature goes up. But some bee-keepers are trying to reverse this habit.—G. W. DEMAREE.

If proper methods of ventilation are provided when the bee-house is constructed, the temperature can be controlled without opening outside doors. But if such are opened, it should be some colder outside to be of value. The temperature should be kept at about 45°.—THE EDITOR.

Convention Notices.

☞ There will be a meeting of the Susquehanoa County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

THE RETURN HOME.

I see the hills of home again,
Again the *bees* are humming ;
And slowly down the scented lane,
With measured step in single train,
The cows at eve are coming.

I wander down familiar ways,
I look for old-time faces ;
While memory paints again the days,
And strongly with her touch essays,
To find the old-time places.

I see the house where first I knew,
The summer's golden splendor :
Here first my happy fancies grew,
And dreams that fairyland was true,
And life was sweet and tender.

Strange faces meet me at the door,
And stranger voices telling ;
And so, my dream of home is o'er,
And I shall find it never more,
In stranger countries dwelling.
—*Old Homestead.*

CORRESPONDENCE.

LARVAL FOOD.

What is Used to Feed the Brood of the Bees?

Written for the American Bee Journal
BY L. STACHELHAUSEN.

On page 582 of the AMERICAN BEE JOURNAL for 1888, Query 572 asks for the amount of honey used for brood-rearing. The most of those who reply say, "I do not know." Some guessed, and guessed very high. So this seems a question, which even veterans cannot answer, but we are not quite as helpless.

Von Planta analyzed the larval food. The composition of it for worker larvæ, including the water it contains, is as follows :

Water	71.630
Nitrogenous matter	14.528
Fat	1.941
Glycose	7.844
Other parts	4.057

We see that nitrogenous matter is the most important part of this food, and this comes, without doubt, from the pollen.

Von Planta found in dried pollen of the hazel the following :

Water	4.98
Nitrogenous matter	31.63
Ash	4.01
Cane sugar	14.70
Starch	5.26
Other matter	40.42

We can easily calculate that to 100 parts of larval food for workers, $\frac{1452\,8}{31.63}$ which equals 45.9 parts of dry pollen, is used by the bees to get plenty of the nitrogenous matter. These 45.9 parts of pollen contain $\frac{45.9 \times 14.7}{100}$ which equals 6.75 parts of cane-sugar, and they are changed to F. I glycose in the stomach of the nurse-bee. The starch of the pollen is likewise changed to sugar. So we see that the pollen contains more sugar than is necessary to prepare the larval food.

These analyses make it quite certain that the larval food for workers is prepared from pollen and water only, and no honey at all is used for this purpose.

It may be possible, that after the fourth day the worker larvæ receive a food which contains more sugar, but Von Planta says this is not probable.

We have observed, that in early spring, if no honey can be gathered by the bees, and breeding is going on rapidly, a great amount of honey is consumed by the bees. This seems quite contrary to the above facts. But we know that the bees consume some honey to secure the necessary high temperature. If bees do not breed, the cluster is quite contracted, and it will take less fuel to warm this small cluster ; but if in the spring the cluster is expanded as much as possible, to get room for the brood, the amount of fuel needed is very great. and we can observe this by the rapid decrease of the honey in the hive.

Again in summer, when the outside temperature is nearly as high as necessary for the brood, the bees need no fuel. This explains why a strong colony needs less honey, comparatively, than a weaker one. Surely the bees will consume some honey in summer, too, but now they need it to change it to power, which moves their wings, etc. It seems very probable that pollen is the food for the bees, which builds up the body, while honey is the fuel, which warms and moves it.

If we find that pollen only is used to feed the larvæ, we may ask, what amount of pollen is necessary for this purpose ? I do not know this, but I have some reasons to believe that surely not more than one pound of pollen is used to feed 3,000 larvæ—very probably less.

This matter is of great practical importance. At first we see that a very warm quarter in the spring will save some honey, and even more than in the winter. Second, that by caging the queen in summer, to avoid breeding, the surplus honey cannot be increased, and this idea has to be abandoned—the sooner the better.

It is said, that it is no difference, if pollen is used for the brood, or honey—both have to be gathered by the bees, and if they need no pollen they could gather some honey instead. But this is not true, because the bees fill up the brood-chamber with pollen for future use, if no brood is present—what every bee-keeper surely will have observed.

Some experiments show that more honey is secured, if the queen is caged, or entirely removed for some time. I do not doubt this, but it is easily explained, if we say that the bees used the empty cells for storing honey, which in the other experimental hive were occupied by the brood. Here they had not enough cells for the honey. If we always give to a strong colony empty cells, we will see that nothing is gained by caging the queen. This caging may be done with advantage for the purpose of preventing swarming. I will not discuss this here.

Further, we see how important it is that the bees have plenty of pollen when brood is reared. Some experiments prove that for a short time the bees can rear brood without pollen. They use some surrogates which they find in old combs ; in this condition they may use some honey too, but then the larval food will be of other composition. The larvæ may not die by this diet, but surely we will rear a degenerated colony, and in many cases the bees stop breeding entirely.

Selma, Tex., Jan. 10, 1889.

WINTERING.

Method of Packing the Hives for Winter.

Written for the American Bee Journal
BY WILLIAM STOLLEY.

As usual, I winter my bees in a bee-house, open to the east and southeast. In my former eight years of bee-keeping, I packed them in hay ; put leaning boards over the entrances, and covered all with hay, to the depth of about 2 feet. This year I have somewhat changed my method of wintering, notwithstanding the fact that I have *always* wintered my bees remarkably well.

I have changed all my hives into double-walled, lined in between the walls with heavy building-paper, and ½ inch dead-air space between the walls, all around the brood-chamber. I do believe that this double wall is a more efficient protection against the cold, than hay 2 feet thick.

Ten colonies I have packed and covered with hay as usual ; but 20 colonies I have not packed on the outside, nor covered the hives at all ; but I have darkened the entrances by close-fitting boards leaning against the hives ; should I be correct in my presumption, then I will get rid of the trouble of fussing with hay about the apiary, and the danger of fire is much lessened.

Inside the hive my bees are contracted and packed with the utmost care.

The sides (inside) between the double wall and division-boards are

protected by 3-inch thick chaff cushions. Hill's device is over the brood-chamber, which is covered by a clean sheet of burlap.

Next comes a heavy, double woolen-quilt filled with cotton-batting, and all covered with a chaff-cushion 4 or 5 inches thick. The cover has four 1-inch holes, covered with wire-netting to carry off the rising moisture. Each colony has at least 25 pounds of winter stores.

On Jan. 25 and 29, my bees had, for the first time, excellent cleansing flights, except 2 very strong colonies, which, it seems, preferred to stay inside of their hives. These 2 colonies are wintering on sugar syrup, and one of them is in a New Heddon hive. All the other colonies are wintered on natural stores.

I found all of my bees to be in the very best condition, but few dead bees, dry, and no signs of diarrhea. So far the season has been exceptionally mild, but still too cold for bees to fly except on the two days mentioned. The mercury went but twice, 10° Fahr., below zero, while in the winter of 1887–88, it was several times 30° below, and once even 35°, Fahr., below zero.

I have for two years tried the New Heddon hive, on a small scale, and I like it better the longer I use it. For the production of comb honey it is *the* hive that I shall adopt. The Heddon hives I have packed inside in a box, allowing chaff-packing of 6 inches outside the hive, all around, and in other ways they are arranged like all the rest.

Grand Island, Nebr., Jan. 30, 1889.

WINTER LOSSES.

Preparing the Bees to Prevent Losses in Winter.

Read at the Maine Convention

BY F. F. GRAVES.

I claim no new discovery, nor have I any new theory to advance, but I claim that the winter problem has been long solved. The matter is no longer a problem, but a fact, governed by certain philosophical conditions. Before the advent of the frame hive, when all bees were kept in logs or boxes, whole apiaries were swept away in one winter. Then the cause could not have been so easily known or prevented. With the movable-frame everything is changed; the bees may be at any time examined and put in the proper conditions, consequently they may be safely wintered on the summer stands, or in the cellar.

It is not a certain temperature that is required, as the most successful bee-keepers in cellar-wintering differ almost as many degrees in their treatment, as there is change in a hive out-of-doors. One very successful apiarist, who never lost any bees in the winter, claims that the correct point is about 45° above zero; while others winter as successfully in a fruit cellar, which is kept as near the freezing point as possible—32° to 35°.

More bees die every year from diarrhea than from all other causes combined. Our bees die, and we simply mourn our fate and do nothing to avert a recurrence of the calamity. We attribute the loss to this disease, and go no further, when in reality diarrhea is but a secondary agent—the result of a primary cause, which should be sought out, removed, and guarded against in the future.

Reports are published every year of bees wintering under the most adverse circumstances. The success is attributed to "good luck," and no careful examination is made; so what might be valuable information is lost.

We have worked too much by theory, not using enough common-sense. We have been dodging the main issues, and theorizing on upward or downward ventilation, giving our whole attention to loose or solid packing, writing long articles on the great advantage of a dead-air space, when our bees were starving or contracting diarrhea by eating nauseating and unwholesome food. We have lost sight of some of the most important principles in our great rush after improvements.

The new races of bees for a time absorb our whole attention. Long tongues and three bands have been more sought after than hardy and industrious workers, and as a result, prolificness may have been obtained at the expense of hardihood.

The great question of all advanced apiarists is how to prevent increase. Any race of bees will multiply fast enough. The great object is to have the bees strong in early spring. This can only be done by successful wintering. Some hives may contain bees enough in the spring, but they may be in such a feeble condition as to be of no value whatever. They would be all summer building up, storing no surplus, and requiring a large amount of feed to carry them through the winter. The attention given through the season, and the feed would amount to more than their value. This is no isolated or extreme case. Such cases are too common, and the cause should be ascertained, a remedy applied, and a repetition prevented.

There has been so much written and said about the best hives, best frames, best bees for business, that we have attributed our winter loss and spring dwindling to our particular strain of bees, or hive, or way of wintering; or, what is more common, to the bad weather, when in fact the hive, the weather or place had nothing to do with the disaster.

To winter successfully, the great and all-important requirements is plenty of sealed honey; on this the bees will endure almost any change of temperature or withstand the inconvenience of almost any kind of a hive. Honey gathered in the first part of the season, stored in clean combs, well sealed, with little or no pollen, is almost all that is necessary to successfully winter a colony of bees, and have them come out in good condition to begin the spring work.

The extractor is the greatest invention for the bee-keeper since Father Langstroth introduced the movable frame. Its good qualities have been overrated, but it has been somewhat overworked. We have been too anxious to make a large showing. We have extracted too snug, and left our bees too little honey, retarding their fall breeding, and allowing them to go into winter quarters with too few young bees, and the old ones overworked and enfeebled by braving the cold, windy weather, in vain efforts to replenish their fast failing stores after the frost had withered every blossom.

Feeding Bees for Winter.

The first care of the apiarist should be the perpetual welfare of his bees. With this thought in mind, he should save all frames of capped honey during the season when he finds such in his manipulations, until he has four for every colony. These should be carefully saved, and put in by the side of the cluster, when the bees are prepared for winter.

Late-gathered and unsealed honey is by the bees' breath and change of temperature rendered so thin that it will run out of the cells and down on the combs. This the bees, by their natural desire for cleanliness, will lick up and thereby become so over-loaded as to cause diarrhea.

Honey gathered after the frost has touched the blossoms, being chemically changed thereby, is not fit for the bees to eat when in confinement—another cause of diarrhea.

Syrup made of granulated sugar is far preferable to fall honey, as it contains no pollen and will not readily sour; but it is very difficult to make it of the proper consistency. If it is too thin, it will run out of the cells; if too thick, it will candy, and become so hard that the bees will not eat it. "The best is the cheapest" is the general rule, and it is no exception in this

case, as granulated sugar syrup is but little cheaper than extracted honey, and the time and trouble of feeding, together with the risk of robbing, more than balances the difference in cost between the few pounds needed to last a colony through the winter.

Another great disadvantage in late fall feeding is the liability of stimulating the queen to lay a great many eggs. These, as they begin to develop will induce the bees to bring in pollen, which, at this season of the year, is not suitable for bee-food. Brought in at this time, it is more likely to be put into cells partly filled with honey, and be eaten during the winter, which is another fruitful cause of diarrhea.

Another evil result of late breeding is occasioned by the bees deserting the partially developed larvæ in their efforts to cluster to keep warm during the changeable fall weather. The brood thus abandoned chills and dies, and their decomposing bodies become a source of pestilence that is likely to cause the destruction of the whole colony before spring. All this can be prevented by feeding the bees during the early season, or by giving them frames of sealed honey when they are being prepared for winter.

Waterville, Maine.

ITALIANS.

Characteristics of the Queen, Drone and Worker.

Written for the American Bee Journal
BY DAYTON E. BARKER.

I have received a number of inquiries as to which is the best variety of bees, and especallly about the Italians. Quite a number of different varietes of bees have been imported from various countries during the last twelve years, but as yet none received such universal praise as the Italian bees.

In form, the queen is long and slender, and very symmetrical in all her parts. The whole abdomen of most Italian queens, except the last segment, is of a beautiful golden color. The color of queens vary somewhat, some being darker than others, but all produce fine workers. Her movements among the bees on the combs are well directed and graceful, and on account of her quiet disposition and fine color, she is easly found by the operator, on the combs. I have often seen the queen laying, while holding the frame in my hands.

Italian queens are also more prolific than the common black queen, thus keeping their colonies strong. They also cast larger and earlier swarms than our native bees.

The drones, or male Italian bees, also vary in color, but in general the three first segments or bands are yellow, and somewhat scalloped with black. I have had drones in my apiary, of which nearly the whole abdomen was covered with yellow, and I always prefer to breed from these dark drones; especially those reared from queens that mated with a black drone have a tendency to produce workers that do not show the fine yellow bands so uniformly as they should. My advice is, if possible, not to breed from such drones.

I now come to the point that decides, in the opinion of breeders, the purity of the queen. When the queen is pure, and purely mated, the workers are fine-looking, have three yellow bands around the abdomen, and very symmetrical bodies. They possess agility and strength in a very marked degree, are excellent nurses, always keeping the brood up to the highest possible point. They also have the admirable trait of quietness when the combs are being handled. They do not fly off or crawl over and cluster on one end or side of the combs, but keep their places quietly until driven away by the operator. During the honey season they are very easily handled, but when swarming, they are crosser than our native bees. When robbers are around in the fall, they become fierce, and defend their store well. They also defend their homes in a superior manner against the wax-moth. If properly cared for, a handful of workers with a good queen will soon build up to a powerful colony. As honey-gatherers they are certainly far superior to common bees, working well on mammoth red clover. This grand point, in connection with greater prolificness, beauty and quiet disposition, has made them general favorites.

St. Joseph, Mo.

VENTILATION.

Bee-Cellar Ventilation — Packing Honey for Shipping.

Written for the American Bee Journal
BY C. THIELMANN.

I wish to write of two things which do not agree with my own experiments; the first is, the ventilation of bee-cellars, and the other, crating honey upside down.

Ventilating Bee-Cellars.

Mr. Doolittle tells us that his bees winter, and have wintered, nicely for a number of winters, without any ventilation of his bee-cellar. This we have no reason to doubt, as Mr. D. is held in high esteem by bee-keepers; but we must consider the different circumstances, and the way Mr. Doolittle puts his hives into the cellar; also the make-up of the cellar itself compared with those of most of the other bee-keepers.

In the first place, a great majority use hives with tight bottom-boards, and therefore they cannot remove them when they store the hives in the cellar, and have only the hive-entrance for ventilation, instead of a suspended cluster with circulating air all around it, as with Mr. D's way. This, of course, accounts largely for the differences of cellar ventilation: also for the difference of the best degree of temperature for the bees, in ordinary bee-cellars.

I would estimate that bees suspended in the hives without bottom-boards, would winter better in the same cellar with from 6° to 10° higher temperature, than bees with only an entrance in the hive $\frac{3}{8}$x12 inches; and bees suspended can surely stand it better without ventilation of the cellar, than those in a hive with the bottom-board on, as the former have more free air around the cluster; but the number of colonies plays a big part in the matter.

If Mr. D. had 150 to 200 colonies in his cellar instead of only 50, he would find that the ground on the sides and top of his cellar is not porous enough to supply sufficient pure air for them all; and would be glad that he made ventilators, which he could open the same as I do, this mild winter, and keep the bees healthy.

I am convinced that pure air, with the right temperature in a bee-cellar, has more to do with the safe wintering of bees than anything else, not excepting honey-dew or other unsuitable food, although good sealed honey is the best winter food for bees, no matter what the "sugar man" says.

Crating and Packing the Honey for Shipping.

Mr. Doolittle recommends packing the sections in the crates in the same position as they were built by the bees in the hives, and finds that less honey is broken in transit, than if they are packed upside down. This is contrary to my experiments.

I used to pack my honey the same way as the bees built it in the hives, whereby I had considerable losses by breakage of the combs; but of late years I crate most of the sections upside down, and crate only those sections the other way, which are built solid to the wood on the lower end, and others which have a few cells that are not sealed over, and have also a good support of comb below.

Since I have practiced the above method, I have had but little breakage.

I shipped 5,000 pounds to one man, which was re-loaded twice on the cars, and none was broken. In the last five years I have shipped about 40,000 pounds of comb honey, of my own production, some of it going over 1,600 miles, and only two broken crates were reported; therefore I would advise bee-keepers to pack all the sections upside down, which are not solidly attached to the lower part of the sections. By so doing, the shipper will save money, and also those who buy the honey.

Besides my own experiments, I wish to give a little further information, which I witnessed a few days ago.

Last week I went to St. Paul, Minn., on business; while there I called on a man to whom I have sold most of my last year's crop of honey. He showed me a lot of rather bad-looking comb honey of last year's crop, from all parts of the United States. Some was from California, some from Chicago and other places; some was broken, and some was partly candied. There was 14 crates of it, from almost as many bee-keepers, judging from the appearance of the crates.

This man handles about 30,000 pounds of honey annually. He asked me if that honey could not be brought back to its liquid state. I told him that it could.

"How much would you charge me to do it?" he asked. I told him that it was quite a task to do it, and after it was done, it would not be very nice for table use; the combs would have to be broken in order to liquefy it, without spending too much time with it, and then it would be only bee-food, or honey for pickling meats, etc. After some more talk, he sold me the honey at a low figure.

After the honey arrived at my home, I unpacked it, and found it to be as I expected.

The honey was put up by many different parties, only a small part of it being put upside down. Among it was two crates of California honey, with very tender combs, and only the outside sections were candied; this I found but little broken, but most of what was put up in the same way as the bees had built it on the hives, was badly smashed, and a good deal had leaked out of the crates. This latter class was almost worthless to the trade. My customer could probably sell what was not broken so badly—the upside down part; but he said that he would let that go with the lot, if I would take it all. There was a loss of 75 per cent. on this honey.

By the above, it will be seen that we should be careful not to pack the sections with the weakest part of the comb downward; if they have a good footing, they will withstand a great deal of rough handling.

The weather is nice here, but we have no sleighing.

Thielmanton, Minn., Jan. 30, 1889.

BEE-DIARRHEA.

The Distance Bees Go for Honey, etc.

Written for the American Bee Journal

BY C. F. WEBB.

I have handled bees for 40 years or more, and I do not pretend to know much about them either; but what little I do know, that I think would be of interest to any one, is freely given. I have 200 colonies of bees, of which two-thirds are pure Italians, the rest being crossed with the big German gray bee, and as honey-gatherers I like them best.

I keep my bees during the winter in a cellar under the dwelling-house, and my plan for ventilation is the same as a stove—pure air comes in at the bottom, and impure air escapes at the top. In summer I keep them on the north side of a hill, where the combs will not melt down, and when it is warm enough for the bees to fly there, it will be warm enough for them to fly anywhere; also there will be no danger of them flying away, and getting chilled, and never returning to the hive.

I have found a great many bee-trees in my lifetime, and with one or two exceptions, I have found all on the north, northwest and northeast side of the timber or hill.

Distance Bees Travel.

I never knew bees to go quite 40 miles, for honey, but I have known them to work all of six miles away, and work strongly. I would refer the reader to the Agricultural Report of 1870-71, where it claims that bees worked 8½ miles away.

The Cause of Bee-Diarrhea.

In regard to what is called "bee-diarrhea," I will say that my bees are never troubled with it. I believe if the hive is so arranged as to prevent the bees from sweating, there will be no danger of the diarrhea. That is my experience.

Bees can be given the diarrhea in 20 minutes by sweating them. I have had some 8 or 10 colonies succumb to the disease right in midsummer, by not giving them plenty of air, and thereby causing them to sweat. Upon examination I found them all dead, and an almost unbearable stench arising from them, the same as from cholera.

Where wild bees are in hollow trees with porous or worm-eaten wood above, so that the impurities may pass out, the bees never have the diarrhea; but where the trees are solid above the hollow, I have known them to die from that disease. If any one knows anything to the contrary, I would like to hear it through the BEE JOURNAL.

Union Centre, Wis., Feb. 6, 1889.

COLORADO.

Report of the State Bee-Keepers' Convention.

Condensed from the Colorado Farmer.

The Colorado Bee-Keepers' Association met at Denver on Jan. 16, at 10 a.m., President Milleson in the chair. The minutes of the last meeting were read and approved.

The Secretary and Treasurer presented their reports, which were referred to the executive committee.

A discussion ensued on adulterated honey, and Elwood Easley asked if artificial comb honey were now manufactured. Both the President and Secretary answered that no market had ever been affected by such artificial honey. If such could be made, why did they not produce it this year, when honey was scarce?

"Dr. King," said Mrs. Plumb, of Boulder, "had some honey in a store window; some men were looking—one agreed to show that it was artificial because the 'holes' were of different sizes, and that showed that two different machines were used. He alluded, of course, to the drone and worker cells."

E. B. Hutchinson objected to the idea that if bees were fed something that was not right it was adulterated. It is pure honey if the bees gather it from buckwheat, although it might be poor, just as turnips fed to a cow will injure the taste of the milk, although it will be of poor quality.

The convention then adjourned until 1:30 p.m.

At the afternoon session Mr. Pratt reported, from the Committee on Legislation, in favor of county inspectors to prevent foul brood. Adopted.

Mr. Pratt suggested that each bee-keeper should write a personal letter to the Legislator with whom he is best acquainted, showing the necessity for Legislation to check foul brood.

The Secretary urged members to fill out his statistics blanks. He had reports already showing 129,000 pounds as our honey product. The President said if he made it 200,000, it would not be incorrect, as bee-keepers were too slack in reporting.

President Milleson read his annual address, and presented the Association with a handsome black gavel adorned with the gilt letters, "C. S. B. A.," and decorated with a bee.

Mr. Pratt moved that the gavel be accepted by this Society with thanks, as a memento of Mr. Milleson's public and private devotion to the interests of apiarists.

Bee-Houses.

Mr. De Vinney asked Mr. Knight the advantage of a bee-house.

He replied that one could handle twice the number of bees he could in hives.

Mr. Pratt said, after hearing Mr. Knight's description, before and after seeing his house, he had erected one, and thought it well suited to this climate. His is 8x16 feet, with a matched floor. It stands a foot from the ground, and he will bank it up to keep the wind from blowing under it. The covering is of matched lumber, his boys having shingled it. He lined it with tar paper. It is only 5 feet high—it ought to be six. It has no windows, but a gable which opens; the sides are battened. It holds as much as 44 hives, and is cheap; as an ordinary box will do for a hive.

Mr. Knight spreads a burlap over the frame. Pound sections are placed on the top. He believed they would winter better than when out-of-doors.

Mr. Cushman, of the Delta Association said he noticed his "A B C" book advocated placing hives 7 feet apart, yet these were close together. Is there not danger for a fight where they are so close?

Mr. Knight—The boxes are two feet apart, and the hives above one another; one has 38, another 62 colonies. The alighting-boards are differently colored, and the entrances are different, so there is no trouble.

Mr. Pratt, last summer, had his hives differently colored, yet they were a few inches apart in a row.

Mr. Pratt moved that a standing committee of three be appointed on the disease of bees. Carried.

The President then appointed R. H. Rhodes, H. Knight and Wm. Davis.

Elisha Milleson was re-elected President unanimously; J. M. Clark was re-elected Secretary; and Mrs. R. H. Rhodes, of Arvada, was re-elected Treasurer. For Vice-President-at-large, Mrs. Millie Booth was re-elected. County Vice-Presidents, Alfred Cushman, Montrose; H. Knight, Arapahoe; E. Easley, Jefferson; Mrs. S. J. Plumb, Weld; J. L. Traecy, Boulder; A. C. Alfred, Larimer. Other Vice-Presidents were left for the executive committee to appoint.

S. R. Pratt was elected on the Executive Committee.

California Honey.

Mr. Cornforth said that for 3 to 5 years there had been a shrinkage of about 15 per cent. of California honey. This year the shrinkage had been greater. Last year the sales of California honey amounted to about $45-000, the Eastern honey to about $3,000, the import being a little less than $50,000. Our honey is preferable to California, as Mr. Clark's way of packing 24 pounds makes it more salable than the 50-pound packages of California honey. Moreover, California has not been as careful in selecting, the lower sections being of inferior value. Uniformity should be practiced. In California there are four assortments; about two years ago a firm put it up in blue boxes with a glass front. They have made quicker sales; the average weight of sections is about one pound. He was pleased to see our State growing; the Horticultural Society has grown from nothing; creameries dot our State, and bee-keepers are organizing. These organizations will grow with the State, but other States are growing, so there is no possibility of flooding the market with first-class honey if properly put up. When you are organized and rely upon local trade, you can do nothing. The creameries were unheard of five years ago, now farmers can send their milk to the creamery, and the butter is more uniform than if many tried to work alone. He believed our honey would bring more in European markets than any other honey, as our comb honey is so bright and clear. The amount handled in California is fabulous. He had seen buildings 25x50 filled, and they said that was nothing.

Levi Booth said that the "Pure-Food" bill now before Congress was just what we needed to protect us, and moved that we ask our representative to further its passage. Carried.

Honey-Plants for Bees.

The question-box was opened, and to the question, "Which is the best honey-producing plant?" Mr. Knight said clover was the best, alfalfa gave the most honey.

Mrs. Rhodes preferred sweet clover, as alfalfa did not always produce honey.

Mr. Cushman said that sweet clover was a nuisance in the hay crops; they got more than they wanted in their alfalfa seed from Utah. Alsike clover had been recommended; the Colorado bee-plant was good, and had been sold in California for a high price. In his region there was a barren desert, but water would make the land do well.

President Milleson said sweet clover was the hardest to kill of any of the clover plants, but you could not produce one-tenth as much honey from the same ground on any other plant. If you were to plant ten acres alone for honey-production, it will not pay as much as alfalfa; because you can get hay and honey. Let it stay before cutting; if you lose one cutting you will gain.

Rev. Rhodes said that sweet clover was the only plant that would yield after a frost. If you have hay-seeds in your alfalfa, you cannot sell it well; but keep it for seed, and you can sell it well. He had said we could produce more honey than any other country with our alfalfa, but we cannot use alfalfa for hay and honey both. One year they had no bloom but of the broad-leafed milk-weed honey; it was as nice as any honey he ever ate, so it was hard to say which was the best plant. The main objection to sweet clover was, that it was good for nothing but honey.

President Milleson asked if he had not been obliged to catch his bees and wash off their feet on account of the honey sticking to them.

Levi Booth said you need not fear sweet clover, if you cut the alfalfa, as it was a biennial and died out, but you must cut in the ditches.

Rev. Rhodes said you could kill the milk-weed if you cut it just before it was ready to bloom. It would bleed to death.

The convention then adjourned until Wednesday, March 20, at 10 a.m., to meet at the Chamber of Commerce.

J. M. Clark. *Sec.*

HONEY-PLANTS.

Hints to those Who Want a Good Crop of Honey.

Written for the American Rural Home

BY R. S. RUSSELL.

Who is there who has handled bees and made them his associates, who will doubt for a moment that these industrious little misers will appreciate any improvement in their home and plantation, and doubly repay any judicious outlay toward supplying them any suitable plants from which to extract the honey? I believe that a bee is not happy except when employed gathering the sweets that Nature stores in certain plants.

Now is the time to lay the foundation for an abundant honey harvest. If you have no willows near your apiary, procure a few roots or cuttings, and plant in low land near the apiary. This will bring the earliest pollen, which is the most useful. The bark

will crack late in the fall, and furnish a harvest of honey after frost has killed all the flowers.

Also plant a few soft and hard maples, and tap lightly in two or three places early in the spring. These trees should be near the house, as many bees are chilled and lost in rambling for these early sweets.

Be sure and spare all the basswood on your farm, and plant a few more in old pastures for shade. Plant catnip, the more the better, near the apiary. This is fine for the young bees. Spare all the golden-rod when mowing the fence-corners, also all asters. The bees will tell you what they are when in bloom, if you do not recognize your friends. Sow a patch of buckwheat on July 1 and 20, and also on Aug. 10 and Sept. 1.

Last, but not least, procure at once a supply of Simpson honey-plant seed. It can be sown in hot-beds, and transplanted the same as cabbage, or sown in open ground. It will grow anywhere, in fence corners or waste ground, in shade or in cultivated fields, planted 2½ feet apart. It can be sown in your woods pasture. It is a certain grower, and will "get there" whether cultivated or not. This is beyond doubt by far the best honey-plant of all, giving a steady flow of good honey from the middle of July until killed by frost. The honey accumulates in the cup-shaped flowers, and, if all is removed, it will almost immediately fill up again, thus affording an inexhaustible supply faster than the busy workers can remove and store it.

I have noticed no disease in my apiary since I have raised this honey-plant. I think the secret is, it keeps the bees employed gathering good, healthy honey, instead of trying to extract it from decaying fruits and vegetables in the fall months, which they are sure to do unless they can work on something better. It is a medicinal plant, but is not eaten or disturbed by stock of any kind, and will take care of itself after the first year. It is not a noxious weed that will take possession of your farm, but is easily exterminated.

I can imagine no lovelier stroll than through my woods in August and September. The honey-plants are in full bloom, and the beautiful Italians make the woods musical from daylight till dark. I will not speak of the merits of the different varieties of clover, as of necessity they will be sown, and help to round out a full season for the most industrious creature of God's creation.

Zionsville, Ind.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Fine Winter for Bees.—Mr. D. Y. Kennedy, Batavia, Iowa, on Feb. 9, says:

We have had a fine winter so far for the bees. Last May I had but 15 colonies, and but half of them were strong. I took 800 pounds of comb honey, and left the brood-chambers full of fine honey; I now have 59 colonies in fine condition—44 in the cellar, and 15 in chaff hives out-doors. I had swarms as late as Sept. 11, that are now in good condition, with plenty of honey to last them.

Wintering Well.—Mr. L. D. O'Dell, Protection, N. Y., on Feb. 3, 1889, says:

I commenced the season of 1888 with 15 colonies, increased them to 38, and took 500 pounds of surplus honey in one-pound sections. I put my bees into the cellar on Nov. 18, and, to all appearances, they are wintering well. My first year's experience with bees has been very satisfactory, considering the poor season.

Season of 1888.—Clarkson Pemberton, Lamoille, Iowa, on Feb. 11, 1889, writes:

I commenced the season of 1888 with 19 colonies, and increased them to 30, by natural swarming. My bees looked well in the spring, and I hoped for a big yield of honey, but white clover and linden failed, and all the surplus I got was from wild flowers, which yielded well. I obtained 20 pounds to the colony, of surplus at last, for which I am thankful. My bees were put into the cellar in good condition, and I hope for a better crop in 1889.

Small Hives and System of Management.—B. Taylor, Fillmore Co., Minn., on Feb. 5, 1889, writes as follows:

I have kept bees on a large scale for the last 25 years, and make it a specialty. I am wintering 260 colonies in two apiaries. I have a shop 22x40, with steam power, and perfect machinery for making everything connected with my business. I have practiced the identical system, and used the very same small hives mentioned as new in the BEE JOURNAL by Dr. Tinker, for the last 8 years, and have my bees in such hives now. I think that I have a better hive for that system than anything yet offered. I will send you one with its honey-board and fixtures for your inspection, and if you think my long experience on a large scale with such system and hives would be interesting, I will do my best to describe them. I secured 7 tons of comb honey by it, in the past poor year. I do not work my bees for experimental purposes, but solely for honey, and I have no supplies of any kind for sale. I have used 100 hives with closed-end frames, but I have discarded them for one with all its good qualities, and none of its faults—for serious faults it has.

[Being an extensive and practical honey-producer, we shall be pleased to have Mr. Taylor describe his management for our readers. We want the best there is in every line of practical work.—ED.]

Starting Apiaries.—L. Wayman, Chanute, Kans., on Jan. 30, 1889, writes:

I commenced bee-keeping here in the spring of 1887, with 2 colonies, it being a poor season. One of the colonies starved, and the other one some person stole, leaving me none in the spring of 1888. I bought 7 colonies, and lost 2, thus leaving me 5. I have just finished stocking my apiary of 22 colonies here at home to-day. I am putting in an apiary of 20 colonies in Arkansas, having bought 11 of them. The last two seasons were very poor, but not so poor as in some of the older States, judging from the reports in the BEE JOURNAL. The winter is very mild here.

Bees Flying Half the Time.—Mr. James Kincaid, Clay Centre, Nebr., on Feb. 8, 1889, writes:

I started with 9 colonies last spring, increased them to 25, and secured 600 pounds of honey, mostly comb. Our honey here last season was fine—better than we ever had before. People are taking quite an interest in bees, and some are making it pay well. Bees do well, as a general thing. No bad disease has affected them yet, and the moth has not troubled any. We have a fine class of bees, mostly Italians, some that are not pure, but high grades. We have had a very fine winter, with but little snow, and not much cold weather. I am wintering my bees out-of-doors; some are packed in chaff, and some are not. They are all alive, and seem to be all right so far. They are flying about half of the time.

Chloroform for Bee-Stings.—H. Link, Millard, Nebr., on Feb. 6, 1889, says:

In regard to a remedy for the sting of a bee, often alluded to in the BEE JOURNAL, I have for 12 or 15 years used chloroform, and have always found relief from pain instantaneous upon an application, so have a number of my family, and many friends to whom I imparted the fact. With a small bottle in the outer vest pocket, with a solid cork and well projecting, so as to be readily withdrawn by the teeth when one hand is engaged—the suffering is reduced to a bare knowledge of the fact. By "solid cork," I mean one free of defects that render so many of them readily to break. In 31 years residence in the prairies of Nebraska, I have had many patients that had been bitten by the rattlesnake, and since finding the merit of the remedy for the sting of the bee, I have used it, and it alone, for all the subsequent cases. I give about two (never more than three) applications, full strength, to the parts bitten, and, for a time after, frequent sponging of the part; and beyond in the direction of returning circulation, with a wash of 1 part of chloroform to 6 of water, and at the start 20 to 30 drops well diluted with water, given internally, and repeated every half hour, till my judgment prompted a discontinuance. The relief has been prompt and complete in every instance.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of boney for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Houey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for remeving bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Oct. 13, 1888, wrote as follows concerning their use of the advertising columns of the AMERICAN BEE JOURNAL:

We got more orders from our advertisement in the AMERICAN BEE JOURNAL than from all the other bee-papers put together.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40

History of National Society	1 50	1 25

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¾@6c.; dark amber, 4½@5½c.
BEESWAX.—18@22c.
Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.
Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@17c. Sales slow. Extracted, 9@10c.
BEESWAX.—22@23c.
Feb. 11. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX.—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand from manufacturers is improving.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Africa is a prime subject of interest, and Emma Raymond Pitman's article in *Frank Leslie's Sunday Magazine* for March, on "Slavery and Missions on the East Coast of Africa," will tell much about that part of the dark continent which is foremost in the mind. The Mohammedan women of India are described by S. F. Norris, and P. J. Popoff contributes a valuable article on "Prejevalski's Adventures in Central Asia." There are many short articles and poems, and some beautiful full-page-illustrations.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for $1.00.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Advertisements.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. March 2, 1889. No. 9.

EDITORIAL BUZZINGS.

Ill-grounded passions quickly wear away; What's built upon esteem can ne'er decay.

The Paris Exposition will cost over ten millions of dollars.

Father Langstroth is quite weak and still failing. After a few lines dated Feb. 20, 1889, he writes to us: "I am almost past using my pen." His many friends will be sorry to learn this—though there is some consolation in the fact that he is partially relieved from his old "head trouble."

The California Honey Crop, which was 9,000,000 pounds in 1884, fell to 1,200,000 pounds in 1887, and last year (1888) it was increased to 3,500,000. Fears are already expressed that the crop of 1889 will be a short one.

The Illinois State Fair is to be held at Peoria this year. We hope that Mrs. L. Harrison will see that there is a good display of bees, honey, and apiarian implements. There has never been a creditable exhibit of such since she had the matter in charge some years ago.

Mr. Byron Iiams, of Worcester, Mo., whose report we published on page 100, with the remark that it was "fabulous," now writes us that he "can prove his report to be true, if necessary." That report claimed a *net* profit of $360.50 from 3 colonies in the spring of 1888—an average profit of $120 per colony. If that is so, *he* surely ought to be satisfied! After this, who will dare to say that bee-keeping will not pay—at least in one instance?

The Bee-Keepers' Magazine has not been issued since last December, and we now learn that its subscription list has been sold to the *Bee-Keepers' Advance.* Brother J. B. Mason has been *advancing* on the outposts, and has taken five of them by storm. We are glad to see this, for one good periodical is far more useful and creditable than five *weaklings.*

The *Magazine* has been issued for 16 years, and for most of the time was under the able management of Mr. A. J. King; for the past 3 or 4 years it has been edited and published by Mr. John Aspinwall, at Barrytown, N. Y.

Brother Mason has our congratulations, and we hope the *Advance* will prosper abundantly. We compliment him upon the adoption of the following, which we copy from his last editorial:

We have no quarrels with any one, and do not propose to allow our journal to become a medium for others to quarrel in; and while we solicit articles of interest in our specialties from all, we shall publish nothing of a personal nature which reflects in the least upon any one.

The tendency with some is to be *quarrelsome,* and they appear to be never satisfied if they cannot get something into an article which is an offensive personality. We deplore this, and would much prefer never to receive an article from such writers, rather than to publish unkind personal remarks concerning those from whom they differ, either in theory and practice.

Farmers' Institutes.—Hon. John C. Spooner has offered a Bill in the United States Senate providing for a national system of Farmers' Institutes, to be held throughout the Union under the authority of the new Secretary of Agriculture.

This measure, if it shall become a law, will afford an effective and practical outlet for the work of the various State Experimental Stations; will give a new impetus to improved agricultural and apicultural methods, and also establish such close and friendly relations between the farming masses and the federal government as have hitherto been wholly unknown.

The provisions of the Bill are such that any State may join with the national authority in arranging and managing local institutes, and 5,000 copies of the reports or bulletins will go to each Experimental Station for free distribution, in addition to 1,000 to each member of Congress.

Those who favor this measure should write to their Senators and Representatives, and make their influence felt in its behalf. Bee-keepers are interested in this matter, since bee-culture is very properly beu. discussed at farmers' institutes.

Rural Life, a farm, stock, bee and poultry periodical, which was started a year ago, and "noticed" on page 99 of last year, is consolidated with *Popular Gardening.* This makes *two* less bee-papers, and two "obituaries" of such, this week.

The Wisconsin Bee-Keepers' Association met at Madison, on Feb. 7, 1889, Mr. C. Hatch, President, in the chair. About 60 persons were present. Last season the members produced nearly 40,000 pounds of surplus honey, and 1,910 colonies were placed into winter quarters.

Among the subjects presented for discussion were: "The President's Address," C. A. Hatch, Ithaca; "A Successful Bee-House," E. Pike, Boscobel; "Spring Management," Rev. T. H. Dahl, Stoughton; "Bee-Keeping as a Specialty," F. Minnick, Bessemer; "Points in Bee-Culture," Dr. J. W. Vance, Madison.

Upon motion, beginners were "advised to use the ten-frame Langstroth hive, or the Simplicity;" and "city and town authorities were requested, when selecting trees for shade or ornamental planting, to give the basswood a prominent place among their selections."

The officers elected for the ensuing year were: C. A. Hatch, Ithaca, President; Rev. H. A. Wioters, Madison, Vice-President; F. Jonier, Wyoming, 2nd Vice-President; Dr. J. W. Vance, Madison, Secretary; J. C. Plumb, Milton, Treasurer.

The Nebraska Bee-Keepers held a State convention last January, and we have received the report from the Secretary too late for this issue of the BEE JOURNAL, but it will appear next week. The bee-keepers of Nebraska are justly proud of what they have accomplished during the past few years. They now have a building on the State fair grounds, built for the exclusive exhibit of bees and honey and apiarian supplies. Their premium list for next year will be increased and revised so as to give more and larger premiums, and the State Board of Agriculture have asked for a full report of the proceedings of their last convention, to be published in their annual report. We congratulate our Nebraska brethren upon their work and success.

Foul Brood, so-called, has considerable attention in this issue of the AMERICAN BEE JOURNAL, because of several inquiries concerning the treatment of that dreaded disease.

The Approaching inauguration of President Harrison, and the opening of the new *regime* at Washington, give universal interest to Dr. Ferdinand C. Iglehart's article on "The Nation's New Leadership," which opens the March number of *Frank Leslie's Popular Monthly.* The lives and characters of President-elect Harrison and Vice-President-elect Morton, and of their wives, are sketched in vigorous, picturesque and intimate style; while the accompanying portraits and other illustrations give a permanent, as well as a timely, interest to this contribution. The table of contents of this number of the magazine is as rich and varied as ever, literature and art vying with each other in its attractive pages.

GLEANS OF NEWS.

Seasonable Hints.—There is much apiarian work that *can* and *should* be done in the winter, or before spring opens. Mrs. L. Harrison, in the *Prairie Farmer*, describes her methods of doing some of it, in these words:

MELTING WAX.—I like to do this kind of work when it is too cool for bees to be upon the wing, for, if they are flying, and smell the wax, they will try to gain admittance through the key-hole, or even down the chimney. I re-melt wax over a pot of boiling water, in a pan. This pan should be small enough to fit the inside of the kettle, and be held in place by the rim. When it is melted, I strain it through a coffee-strainer, into pint-basins to cool.

I melt out both ends of a tin fruit-can, to hold the strainer while I pour the wax. The strainer should be hot, and, while not in use, should be set in the oven. I let the wax settle a few moments, but, before it begins to harden, pour it into another pan, leaving the dregs. The pans are all of the same size, so that the cakes will be of uniform size.

Scrape off all bits of comb and propolis, and, however black and dirty it may be, empty it into an all-metal sieve; and, when it is full, set it over a pan half-full of water, and put it into the stove oven.

If the water in the pan boils very hard, it may run over, but if only a moderate fire is kept, there will be no danger. When the wax is all melted and run down into the water, the residue in the sieve can be scraped into the fire. It makes such good kindling that sometimes I scrape it into paper, roll it up and keep it for kindling to build a fire another time.

When the water in the pan is cold, a nice cake of wax will be on top. I put these cakes away until a favorable time, when I re-melt and cool in uniform shape for the market.

ODDS AND ENDS OF HONEY.—Where much honey is handled, there will be more or less that is not in good marketable condition. Pieces that are not capped will be granulated, while others may be only partly filled. The best way I have ever found to utilize such honey is to melt it in a pan over a kettle of boiling water. As soon as it is fairly melted, it should be set off to cool, as heating honey too much injures it. When cold, the wax will be in a liquid cake on top of the honey. This honey, although not as good as extracted honey, can be used for many purposes, and for feeding bees in the spring.

Good pieces of honey can be sold as chunk-honey; the dry, unfilled cells can be scraped off, and that which is filled and capped on one side, and has unfilled cells on the other, can be carefully scraped off, leaving only the base, with its clearly-defined septa of cells. I often fill cheap tin pails with such pieces of honey, and sell pail and contents. Such pieces of honey require very careful handling, and should be lifted with the hands, so that no cells will be broken, as would necessarily be, if a knife were used.

HONEY-HOUSE STOVE.—By the way, I would like to state that there is no stove equal to a cook-stove for a farmer's shop or honey-house. It is so handy to wash and oil harness by, melt glue, or for the boys and their friends to pop corn, crack nuts, make candy, etc., teaching them to love home, and keeping them away from "the corners." When a stove was needed for our honey-house, we took the cooking-stove from the kitchen, where it had done faithful service many years, and had a new one in its place. And all the family have been thankful that we did.

CLEANING HIVES.—This is a favorable time to take all the hives not in use into the shop (which all prosperous farmers have) and give them a thorough overhauling. I know of no better tool to clean out the inside of a hive with than a wide chisel.

When the hives are cleaned out, they should be treated to a coat of paint. I prefer the lower hive to be painted white with lead and oil, and the upper story with red, mineral paint. The roof should receive special attention, especially if it is grooved, being made of two pieces of boards. If the boys and girls want to help, do not push them away, but "let 'em pitch in." There is so much work to be done in the world that it is a pity that all should not help that want to.

Alfalfa Honey.—In *Gleanings* we find the following concerning a sample of alfalfa honey, which will be read with interest:

Dr. C. C. Miller, while in Pueblo, Colo., purchased a sample of alfalfa honey of that region. On his arrival home at Marengo, Ills., he sent us this honey, together with a sample of cucumber honey. The flavor of the alfalfa is fully equal to clover, which it resembles closely. It is seldom that we take more than a good taste of honey sent us as a sample; but after A. I. R. had tasted, E. R. R. and J. T. C. followed suit. With an expression of "That's good," we kept on scooping it up with our knife-blades until—well, there is just a little left for you to try. The fact that this plant yields from three to four crops of hay in a season, that it will grow in most Northern localities, together with the fact it yields a superb honey, are no small recommendations in its favor. The flavor of the cucumber could hardly be called first-class, but on the whole it is better than the majority of the second-rate honeys. The taste reminds one a little of cucumber itself, and this becomes more evident a few moments after tasting.

Bee and Honey Shows at Fairs are very important matters. At the Indiana State Convention there was quite a discussion on the matter, and Mr. G. K. Hubbard, in the *Indiana Farmer*, makes these additional remarks about the desirability of having special buildings for apiarian exhibits:

If the object in having a good apiarian exhibit at the fair is to enlighten the masses, and to induce the careless bee-keepers to keep their bees more intelligently, and to use better implements, we think it would be a mistake to put the display in a building by itself. The money that the building would cost the fair association, would pay greatly increased premiums in our department for several years.

In our judgment it would be better for the association to spend $40 or $50 in the arrangement of a neat booth in the main Agricultural Hall, and put in $50 or $75 worth of good show-cases to contain the smaller articles. In this way, we feel confident, a very tastily arranged exhibit could be made, and that too, in a manner to attract the attention of the masses, and delight the bee-keepers.

Much may be said in favor of a separate building, and we would like to hear from others on the subject. Dr. A. B. Mason and Mr. J. N. Heater, as well as others, are invited to tell our readers what they think about it.

Lizzie Cotton's advertisement may now be seen in many of the religious and literary periodicals, and as many will be deceived by her highly-colored representations, it is timely to give another warning to beginners in apiculture. All the bee-periodicals have repeatedly warned the public not to be deceived, but still she looks for pastures green, by using the columns of the papers who know nothing about her, or her fabulous stories about what can be done with her so-called "new system of bee-keeping." Audrews & Lockhart, of Patten's Mills, N. Y., write as follows concerning her transactions:

Enclosed is an advertisement of Mrs. Lizzie Cotton, which was clipped from the *Household Companion* of New York city. We would say to all beginners in bee-keeping—Let Mrs. Lizzie Cotton's "New System of Bee-Keeping" alone! It is deceptive. We will give here one instance: A party we know bought one of her hives (which was a poor concern) with a swarm of bees in it, for which he paid $20.00. After waiting a long time he got the hive of bees, which was a very small colony, and he is sorry to say that he found out that they had foul brood of the worst kind; and what few colonies he had before, caught the foul brood, and he lost all the bees he had! That was a very unlucky twenty-dollar colony of bees for him. Such is her way of serving people. We are sorry to say that she still seems to flourish and entice people to try her new system of bee-keeping, by her gaudy way of advertising! If she means to do right, why does she not advertise in the bee-periodicals?

This is the first instance that we have heard of her bees being affected with so-called "foul brood." We can hardly think that she would knowingly send out such diseased bees—at least we hope not. The reason she does not advertise in the bee-periodicals is, that none of them would receive her advertisement! She works among novices only.

Bees are Wintering Well, so far, in nearly all parts of America. Mr. N. N. Betsinger, Marcellus, N. Y., writes thus concerning their condition in that State:

Bees in this State are wintering nicely thus far, but all must look out for shortage of honey before blossoms appear again. I have 72 colonies of mine buried in a clamp. This is the second winter I have used the clamp, and I am much pleased with the system, and I shall extend the clamp building next summer, so as to take all my bees. The points of advantage are cheapness, convenience, ease of manipulation, and safe wintering.

Catalogues for 1889 are on our desk from—

George S. Josselyn, Fredonia, N. Y.—20 pages—American Grape Vines.

Christian Weckesser, Marshallville, O.—8 pages—Bees, Seeds, Plants, Potatoes, etc.

Daniel Wyss, New Philadelphia, O.—8 pages—Nursery Stock.

Bush & Son and Meissner, Bushberg, Mo.—4 pages—American Grapevines.

Thos. A. Cox & Co., San Francisco, Calif.—60 pages—Flower, Fruit and Garden Seeds.

Geo. H. Kirkpatrick, New Paris, O.—16 pages—Bees, Honey, and Bee-Keepers' Supplies.

QUERIES & REPLIES.

Getting Worker-Comb Built by a New Colony.

Written for the American Bee Journal

Query 615.—With starters in the brood-frames, five cells deep, what should be the most favorable conditions to assure the building of worker-comb by a newly-hived swarm?—Maine.

A good flow of honey.—H. D. CUTTING.

A good, fertile, prolific queen.—DADANT & SON.

They build every time, with me. I put sections with some comb above.—A. J. COOK.

It should have a young and prolific queen.—M. MAHIN.

Warm, pleasant weather, with plenty of honey in the fields.—MRS. L. HARRISON.

The best is to put in full sheets of comb foundation. It is poor economy to use starters.—P. L. VIALLON.

Most favorable conditions: A big swarm, with a young, vigorous, laying queen, and a plentiful yet moderate flow of honey.—J. P. H. BROWN.

I doubt if I can get my bees to do it. Hutchinson's plan works pretty well with him.—C. C. MILLER.

Plenty of storing-room in full drawn combs above, and a queen excluder between, might accomplish this end.—J. M. HAMBAUGH.

Contract to five frames, giving plenty of section room above, and using a queen-excluding honey-board under the sections.—G. M. DOOLITTLE.

A contracted brood-chamber, a vigorous queen of the current year's rearing, and honey receptacles above containing comb or partly-drawn foundation, from which the queen is excluded.—R. L. TAYLOR.

1. The super on above, with a queen-excluding honey-board between. 2. A queen vigorous enough to keep the cells full of eggs as fast as constructed.—EUGENE SECOR.

"The most favorable conditions should be" just such as will insure the desired result. A warm atmosphere, a good honey-flow, and a young queen are very favorable.—A. B. MASON.

This requires too much of an answer for this department, it seems to me, and I have never seen it answered so fully and completely as in Hutchinson's book, on "The Production of Comb Honey."—JAMES HEDDON.

The conditions most favorable are, that the honey-flow should be light, and that comb will not be built faster than the needs of the queen require. In other words, if built for the queen, it will be worker size; if built for storage, it will be storage or drone comb.—J. M. SHUCK.

A good honey-flow is the prime requisite. The only plan is to watch for the drone-comb, and cut it out when started. If the bees become too persistent, use full sheets of worker foundation.—WILL M. BARNUM.

Just what would be "the most favorable conditions" in any case. As to conditions, it makes no difference whether there are starters or full frames of foundation. A large swarm with a good honey-yield will give good results. The queen should not be over 2 years old, in the case asked about.—J. E. POND.

Some drone-comb will surely be built when starters only are used. The only thing that will discourage drone-comb building is, to put the frames $1\frac{3}{8}$ inches, or less, from centre to centre. Some drone-comb will be built, and if you do not wish to go to the expense of foundation, you can cut out the drone-comb, and fit in pieces of worker-comb instead.—C. H. DIBBERN.

1. A swarm with a strong, young queen, capable of laying all the eggs that she can find room for. 2. Do not give too many frames at a time. But as nearly all swarms are the result of a desire on the part of the worker bees to supersede old or otherwise weak queens, the only safe plan to get good solid worker-combs is, to fill the frames full of foundatton.—G. W. DEMAREE.

Good honey weather, and a profuse supply of nectar are some "conditions" not to be despised. A good queen is always an essential "condition."—THE EDITOR.

Perforated-Zinc vs. Tin or Wood for Separators.

Written for the American Bee Journal

Query 616.—Would perforated-zinc be any better than tin or wood for separators?—T.

No.—WILL M. BARNUM.

I do not know.—J. M. HAMBAUGH.

I prefer the tin.—G. M. DOOLITTLE.

I have never tried it.—A. B. MASON.

I never have tried it.—EUGENE SECOR.

I do not know. Some say yes.—A. J. COOK.

It will do, but it is more costly.—DADANT & SON.

No, I do not think that it would be any advantage whatever, and it costs more.—C. H. DIBBERN.

I prefer the tin separators to all other materials.—P. L. VIALLON.

Yes. Tin rusts, and the perforations in wood are not reliable.—R. L. TAYLOR.

I think not, but I have never tried it.—MRS. L. HARRISON.

I have never tried it for the purpose, but I have grave doubts of its being any better.—J. P. H. BROWN.

No. Wood is the cheapest, and fortunately the very best.—J. M. SHUCK.

It is probably better than tin. For loose separators, hardly enough better than wood, to pay extra cost.—C. C. MILLER.

No; perforated separators have no disadvantages except in theory.—JAMES HEDDON.

There would not be but little difference if the tin and wood were perforated.—H. D. CUTTING.

I do not think that it would. In fact I do not think that perforated separators of any kind are of any value as compared with unperforated. Besides, zinc would be too thick and clumsy.—J. E. POND.

I do not know. I never used separators, and I do not expect to. I can crate my honey without. I put the sections in the crate in the order they were when in the hive, and I have no trouble.—M. MAHIN.

I have never tried it for separators; but I think I can say in advance that it will not do at all. But if it would do even better than tin or wood, its present cost would be in the way of its extensive use. I prefer tin for separators, though I have seen very nice wood separators.—G. W. DEMAREE.

Zinc may be better than tin for separators, but its cost is more; perforations are of no particular advantage, however.—THE EDITOR.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. O. A. WILSON, *Sec.*

CORRESPONDENCE.

FOUL BROOD.

Experience with Curing the Foul Brood.

Written for the American Bee Journal

BY A. A. BALDWIN.

In the fall of 1886 four apiarists (including myself) bought a carload of California honey for feeding our bees, as it was cheaper than sugar, and it would also help the honey market that much. We took the precaution to write to the party that produced it, asking him if there were any foul brood among his bees, and getting an answer that there was no disease among them, we felt safe to use it without boiling.

During the fall and the next spring, we fed it to about 1,000 colonies of bees, and it was sometime in April that we found that we had given them the foul brood. We had had experience in New York with the disease, and knew what to expect. We talked the matter over together, and felt as might be expected—out of patience with ourselves for not being more careful, and on the whole a good deal "blue" about it. We concluded to wait until the close of the honey harvest before making an effort to get rid of it.

The disease progressed much more rapidly in my apiary than in either of the others, showing that the conditions were more favorable for it, or else my strain of bees were not as strong to resist it. Perhaps the water supply had something to do with it, although some of the colonies fed, did not show the disease until late in the season. I had fed 128 colonies out of the 150 before I discovered the disease, leaving 22 colonies all right.

Some two weeks later, I found whole frames full of dead brood, and some 75 colonies that were not hatching enough bees to keep up the strength of the colonies, and if I saved them I would have to be about it. I took the back numbers of the AMERICAN BEE JOURNAL, and looked them over until I found Mr. McLain's remedy, and he was so positive in his statements in regard to the cures that he had wrought with it, that I went to work with no little confidence to treat mine.

I doctored 80 colonies, following his directions to the letter, and watched, as you can imagine, with a good deal of interest, the development of the new brood; but, alas, vain hope! I found that I could as well expect to move into a house from which the occupants had been carried to the grave by small-pox, and remain healthy, as that a healthy bee could be reared in a cell from which a putrid foul-broody mass had been removed. I doubt very much that a remedy will ever be found for the disease, and use the same combs.

I found that combs that had stood empty through the winter, in which I could not detect the disease by the scent or looks, gave the disease to clean, new swarms.

The season (1887) was a very poor one for honey; the healthy colonies gathered barely enough to keep up their strength; but those diseased were fast running down in numbers and in stores, and becoming discouraged, many of them swarming out, leaving their hives in disgust. I had to be on the watch to keep the healthy ones from cleaning out the deserted hives.

Early in July I went to work to make new colonies, by brushing the bees from one, two, or three of the diseased colonies, according to their strength, together into a clean hive, and after two days, giving them six frames full of foundation, and feeding them until they had sufficient stores for winter. These where made strong enough, became strong, healthy colonies. I found later by experimenting, that I could give them foundation at once, without continuing the disease, and thus save time and trouble.

I rendered the combs into wax, and made that into foundation, and used it for brood-combs again. I wintered a few colonies that showed the disease a little, and found some others that developed the disease as they bred up in the spring, some 15 in all, I believe. Some of the worst cases I put on foundation about May 1, feeding them liberally. One of them gave me 90 pounds of comb honey for my trouble. Those colonies that had it light, built up and swarmed, when I brushed out the remaining bees with the swarm, and gave the frames of brood to other sick colonies to hatch out, till I had reduced them to a few colonies; these I made queenless, and as soon as they had a young, laying queen from a healthy cell given them, I brushed them out and treated them as a new swarm.

I steamed most of the hives before using them again. The balance I fumigated with burning sulphur. Both treatments proved effectual. Eighteen of the 22 colonies not fed the honey, remained healthy through it all, in the same yard, and I have no doubt but that the four that took it, got a lick of the honey while feeding the others, or while treating them; for if the disease-germs floated in the atmosphere, or were carried by the bees to the flowers to be taken by other bees to their hives, and thus spread the disease, as some think, none would have escaped it.

During the first stages of the disease it cannot be detected by the odor; but later, as they begin to open the cells to investigate the trouble, thus exposing to the current of air passing through the hive, the putrid contents, it can be readily detected by taking a sniff at the entrance of the hive.

We have conquered the disease, and now have a full stock of as fine bees as we ever had. We may find a few cases during the coming season to deal with, but we are not troubled about it.

We have thus saved by our labor, many of the bees, and a thousand hives worth at least two dollars each; also 1,500 pounds of wax, which, I think, is much better than burning them all, as some recommend.

Our experience agrees with Mr. Quinby's given twenty or more years ago, viz:

1. That the disease is carried in the honey, and in no other way.
2. Thoroughly boiling the honey makes it safe for feed.
3. Boiling, steaming or fumigating with sulphur, renders the hives safe to use again. (I would also add that the wax from diseased combs is safe to use for brood foundation again.) Never feed honey without first boiling it unless you *positively know* it to be healthy.

I hope that this experience may help some brother apiarist who may be in like trouble.

Independence, Mo.

GOOD YIELD.

Keeping Bees in Texas—Peaches Blooming.

Written for the American Bee Journal

BY A. C. ATEN.

During the season of 1888 my bees produced 11,000 pounds of honey, mostly extracted, being an average of 112 pounds per colony, spring count; besides an increase of 40 colonies. They have wintered well, or rather we have had no winter, as there were only three nights that ice formed in the most favorable places.

Roses have been in bloom all winter, and lilies were in bloom in the garden in January. Peaches are beginning to bloom, and bees are busy. There is scarcely ever a spring, however, in this part of Texas, but that we are in danger of losing some colonies by starvation, unless we feed them.

There comes a time after fruit-bloom, that there is scarcely any honey to gather for two or three weeks, and

bees having exhausted their stores in brood-rearing, starve to death unless cared for. The careful apiarist, however, will see that his bees at this critical time are fed, knowing that in a very short time everything will be changed, and his bees will be booming. Just at this starvation-time, bees will eat pollen until they get the diarrhea as badly as they ever get it in the North in winter, and that, too, when they can fly every day; as soon as they are fed, however, they get well. It is almost marvelous how soon they will get well on a proper diet.

While the honey crop fails in some parts of Texas quite often, where my apiaries are situated—13 and 16 miles north of the city of Austin—there has been no failure for many years. It is the rich, black-land prairie, with narrow strips of timber along the streams. The honey is from hoarhound, horsemint, wild marigold, asters, different kinds of fruit, cotton, corn, wild morning-glory, milk-weeds, and various other plant of lesser note. All of our honey is pretty good.

We have had a great deal of rain this winter—more than almost ever known—roads almost impassable, and all business is at a stand-still; but little farming is done yet. The rains appear to be over at present, and the ground dry enough to work.

Round Rock, Tex., Feb. 14, 1889.

SWARMING.

How to Make a Box for Hiving Swarms.

Written for the American Bee Journal

BY J. E. WALKER.

As the time for swarms is drawing near, I will deseribe my swarming-box. I make it of light material, 12 or 14 inches square, and 10 inches deep, with several small auger-holes in the sides. A strong wire bail is put on, and by bending the wire once around in the centre, a ring is formed in the bail.

I have two or three of these boxes in my apiary, and as many straight, light poles of different lengths, made of poplar. I taek a strip of leather to each side of these poles, and over one end, and put on a eommon harness-snap. This I snap into the ring on the bail of the box. I have other poles with a limb left on each, to correspond in length with the one I wish to use.

I push the box up under the swarm or cluster, and punch the limbs, when most of the bees fall into the box. I put the end of the pole on the ground, and lean it away from the limbs of the tree, and soon all the bees that have missed falling into the box, will settle on it. If any come baek to the place where they settled, I keep shaking them off, and they all will soon setttle in and on the box.

Then I lower the box slowly to the ground, take the snap from the bail, and carry the box and bees slowly to the hive. By going slowly, all the bees that are on the wing, will follow the box.

I have the hive ready where it is to remain, leveled with a spirit level. In front of the hive is a loose bottom-board, placed level, and close up to the entranee. I then turn the box upside down slowly, and pour the bees out, when they make a stampede for the hive-entrance. I think that this plan is perfect.

Clarksville, Mo.

ODOR AND COLOR.

Their Influenee upon the Honey Gathering Insects.

Written for the American Bee Journal

BY MAHALA B. CHADDOCK.

On page 838 of the AMERICAN BEE JOURNAL for 1888, Prof. L. H. Pammel, speaks of insects wasting their time when visiting flowers where their services are no longer needed to pollenize the blossoms. The insects know nothing about the needs of the flowers. To prove this, I have only to quote from Prof. Pammel's artiele on pages 634 and 635 of the same volume, viz:

"Muller records the most interesting ease of Salvia Sclarea, in which the tube of the corolla is so long that the honey-bee is not able to get the nectar in a normal way. It made several attempts, but did not perforate the corollas. When, finally, it found several in which the corollas had just loosened, it began immediately to sip the little drops of nectar which still adhered to the base of the corolla."

Now, here was a flower that was too far along to need the services of the bee, but the bee kept on trying to get at the nectar until it found some flowers so ripe that the corollas were loosened and falling off; from these it sucked the little drops of nectar. There is *always* a difference in the eolor of flowers at the different stages of their development, and the *signs* that the insect would need to tell them that their services are no longer needed, ought *surely* to be hung out by the time the corolla is loose enough to fall off!

The fact is, when a flower begins to fade, the coloring-matter seems to collect in the thicker parts of the petals, and makes darker spots or stripes there; but it is only Nature doing her own work, in her own way, and is not a "signal" nor a "sign" of anything. The fact that bees work on flowers when the corolla is so loose that it falls off, proves that bees do not look for "signals" in flowers.

On page 838 (1888) Prof. Pammel says: "Most naturalists agree that color is an important factor, in attracting insects to flowers, and that they have done much to develop the colors in flowers."

Well, in a note in the *Popular Science Monthly*, on page 718, we read: "Dr. Schweinferth has obtained specimens which were originally deposited in the forms of offerings from Egyptian tombs, 4,000 years old, which are as satisfactory for the purpose of scienee as any collected at the present day, and which, consequently, supply means for the closest examination and comparison with their living representatives. The colors of the flowers are still present—even the most evanescent. The chlorophyl remains in the leaves, and the sugar in the pulp of the raisins. Dr. Schweinferth has determined 59 species, some of which are represented by fruits, others by flowers and leaves, and the remainder by branches.

"Mr. Caruthers also referred to the deposits discovered at Cromer, and the remains which exist of pre-glacial flora, and eame to the conelusion that the various physical conditions that necessarily affected those species in their diffusion over such large areas of the earth's surface in the course of say, 250,000 years, should have led to the production of many varieties, but the uniform testimony of this pre-glacial flora, so far as the materials admit of a comparison, is that no appreciable change has taken place."

So, then, we find according to various authors, that color was given to flowers to attract insects to fertilize them, and that insects have done much to develop the colors in flowers. But here, these *eminent* naturalists examine these flowers from Egyptian tombs, and find them true to the flowers that we know; and these deposits at Cromer carry us back 250,000 years, and as far as the materials admit of comparison, there has been no *appreciable change!*

The insect world has done it best for the floral kingdom, for vast periods of time, and still they are about the same! The brightly-colored flowers that Prof. Pammel mentions, contain either nectar or pollen, or both, and the insects are attracted by *the same*; but the hazel, walnut, oak, grasses and sedges are *odorless*, and that is why they are not visited by insects. For if

bees will go through a key-hole into a dark cellar to find honey, they can find honey in any flower that grows, without any coloring-matter about it.

Prof. Pammel wishes me to "explain why the sunflower should have developed the large, conspicuous ray-flowers surrounding the head." That is very easy. They are Nature's works, and grown on natural principles. The sunflower is a vigorous grower, and the numerous seeds demand a suitable support around the edge to keep them from spreading. The coloring is *only accidental*, as it is in all plants.

As to "the vermillion red leaves surrounding the blossom of the poinsetta," they are *entirely unnecessary*, as that little "pocket-book" full of the thickest and sweetest nectar on the *side* of the blossom bud is surely enough to attract all the insects necessary to the fertilization of the flowers. Then there are the stamens full of pollen.

If nectar is placed in flowers to cause them to be visited by insects, why is it not always placed in the centre of the flower? Now, this poinsetta has its little "pocket-book" full of honey on the side, clear away from the pollen, and bees could empty these little pockets, time after time, and never get any pollen on their legs.

Will not some of the bee-keepers in Texas tell us if the poinsetta grows there? It is a native of Mexico, and Texas is pretty close to Mexico, and there are many bee-keepers in Texas. Then tell us if the poinsetta is not a glorious honey-plant; what the honey tastes like; how many tons an acre of poinsetta plants would yield, and if the plant bears many seeds.

Then Prof. Pammel asks if the colors and forms of flowers have been developed merely to gratify our senses. The great end and aim of all vegetable life (of all life, in fact) is to perpetuate itself. The flowers bloom merely that the seeds may ripen—the coloring is only accidental. All nature, the earth, the air, the sky, is full of color, and it is all accidental. It was not made to please anybody, nor to attract anything.

The vast coal-beds of Illinois contain enough coloring matter to color the wearing apparel for the whole world. "One pound of coal affords magenta enough to color 500 yards of flannel; aurine sufficient for 120 yards of flannel 27 inches wide; vermillion scarlet for 2,560 yards of flannel, or alizarin for 255 yards of Turkey-red cloth.

"We are acquainted with about 16 distinct yellow colors, about twelve oranges, more than thirty reds, about 15 blues, seven greens, and nine violets; besides various compounds, giving an almost infinite number of shades and tones of color." And in the face of all this coloring-material which is burned up, we begin to talk and fancify about *why* flowers are colored.

Look at the coloring of the deep-sea fishes. I quote from Sir John Lubbock. I see that all of our Professors are very fond of Sir John Lubbock. He says: "The conditions of life in ocean depths are very peculiar. The light of the sun cannot penetrate beyond about two hundred fathoms; deeper than this, complete darkness prevails. These deep-sea fishes are either silvery, pink, or in many cases black, sometimes relieved with scarlet, and when the liguminous organs flash out, must present a remarkable appearance. The deep-sea fishes are very peculiar. The abysses of the ocean are quite still, and black darkness reigns. (The pressure of the water is very great)." (I had the rest of this copied out of a cyclopedia, but I have lost the paper containing it.)

Now here are these deep-sea fish, down in the dark depths of the ocean, where the sun's rays never go, and they are colored pink, and silver, and black, relieved with scarlet. What were they colored for? and who was to see them? Does not this prove that coloring in Nature is only *accidental*?

Prof. Cook, in his article about "Tiger Beetles," in *Gleanings*, page 49, says: "As the weasel in his winter robes of white, or the Arctic fox is hid by the snow on which he treads." I think Prof. Cook must be a poor hunter, or he would know that dogs trace the weasel, and the Arctic fox by the *odor*, not by the color; and they will follow *scent* for miles without seeing the game; of what use then is the mimicry of color, so far as the weasel and the Arctic fox are concerned? What is color anyway? I say it is pigment!

Sir John Lubbock (Oh, how I love to quote Sir John Lubbock) says:

"Light is the effect produced on us when waves of light strike the eye. When four hundred millions of millions of vibrations of ether strike the retina in a second, they produce red; and as the number increases, they pass into orange, then yellow, green, blue and violet."

The above is a very wise explanation of color, but for ordinary mortals colors are chemical substances, formed in coal, in flowers, in clays, and numerous other substances. They are made by boiling, or stewing, or pressing different substances together, and they are always wholly and entirely accidental! The setting sun, that paints the clouds and hills in crimson and gold, sinks, in a few minutes, out of sight, and the clouds are grey and the hills are green again.

DISEASED BEES.

Eradicating Foul Brood from the Apiary, etc.

Written for the American Bee Journal

BY SAMUEL BARNHART.

In the AMERICAN BEE JOURNAL for March, 1888, I wrote my experience with foul brood, and how I eradicated it from my apiary. Thinking that some at least might wish to know what success I had, I will repeat the treatment.

I put the bees into empty boxes for two days, scalding and cleansing the boxes effectively.

I then put them back on full sheets of foundation, destroying all combs in which there had been any brood, and saving all the nice, white outside combs, some of which were only partly drawn out. I treated all but 2 colonies at the time they appeared to be only slightly affected, but they soon became so bad that it became necessary to treat them she same way.

From the 2 colonies I took eight frames of brood, with a few bees, and put them into an empty box, and they are there to-day, as free from foul brood as bees can be. They were without a queen for at least five weeks, and being weak, consumed all there honey, of which they had a very little. At first I fed them syrup, and afterward gave them two frames of bees and brood from another colony, and in the fall it was as strong as any colony I had. Last spring that was the first colony I divided, and very soon I had two good colonies, both of which stored considerable surplus honey.

After this colony, without any aid whatever, had cleansed their own combs, and was rid of foul brood, I thought, why can I not use the combs I had saved after fumigating frequently, and effectually with sulphur, and spraying with carbolic acid? I then gave the nicest of these combs containing no honey, to several colonies, without any bad results whatever.

Whether there is anything in it or not, I will not pretend to say, but I put a small camphor poke on top of the frames of each colony, and fed a little sulphuric acid through the summer, with an occasional spraying with a weak solution of carbolic acid, the bees at the entrances of the hives. After getting through safely so far, I was foolish enough to risk still further, by giving to a very late, small second swarm, six frames (the last I had), some of which contained some of the old honey; I sprayed them all with carbolic acid, but did not uncap the honey, neither did I use any camphor nor give them any attention whatever. Sometime afterward, when I exam-

ined them, in taking out the second frame, oh, the infernal foul brood! How I regretted using combs with the honey in; being taught when a boy not to "cry over spilt milk," I concluded to do the best I could under the circumstances. I immediately took away the queen, and I suppose for sometime I troubled them with more sulphuric and carbolic acid than was agreeable to them. I afterward gave them a queen, but being late, and the weather cold, they reared no brood. I do not fear but what they will come out all right.

I put them into the cellar the last of November, without one drop of honey in their combs—they are living on sugar candy, and doing first-rate. However they may come out I cannot believe that either the queen or bees ever become affected, but if kept two days in empty boxes, then put into perfectly clean or new boxes, there will be no return of foul brood, unless they get access to foul-broody honey.

The afterpart of the summer here was anything but agreeable or profitable to bee-keepers. There was no buckwheat honey; fall flowers would have produced abundantly, but the weather was so wet and cold, so that the bees could not harvest it. The winter has been open, wet and warm—favorable for out-door wintering. My bees (over 30 colonies in all) are resting very contentedly in the cellar, without giving me any concern whatever. I have them right under the kitchen, where we keep potatoes. Some of the family go in with a light every day, and neither that nor the noise from above annoys them in the least.

Bees Going 40 Miles.

I was telling a dutchman the other day that there was a man somewhere in America, who had bees that went 40 miles to gather honey. "Oh," said he, "dos ist nix. Ouse in Schermany der vos von verry schmart man, vot dinks he likes to go in der pee-pisness. So dot man he pys some bees—great big uns—shust annoder dime so big as yours. So vot you dink him do? Vy, dot man he pe so schmart, so he dinks he makes von air-line railroat, vay up in de air; ond ob, oh, sich berry fine wire midout von ent, so de pees dey haf to go von way unt dey haf to gome von odder way. Den dot man him git oh, so hundrets ob sich wee tiny leedle cars, mit a little loop, so dot dem pees shust fly riet mit dare headts in dos loop, unt avay gos dem cars. Now dos ist so. I dells you, dot man he pe so schmart, him quick git dem pees draned shust so goot all-do-gedder as dem fire gompanies in de citties haf der horses.

Only a Clover Blossom.

Written for the American Bee Journal
BY GEORGE W. YORK.

It was only a clover blossom,
So modest, so pure and sweet,
That grew by the roadside so humbly,
The bee in its flight to greet.

The bee knew the blossom had in it
A drop of liquid so rare,
That 'twere worth an extra exertion,
To search for it far and near.

'Twas a drop of such precious nectar—
Quite fit for the gods to sip—
That the bee gathered up so gently,
Like a kiss that leaves the lip.

'Twas only one drop of sweetness,
Yet joy to the heart it brought,
Of the bee that hovered, so weary—
For long had the drop been sought.

'Twas only a smile that was given,
But it bore a wealth of cheer
To the poor and youthful toiler,
Whose life was so dark and drear.

'Twas only a moment of life yet,
For one who was called to Heaven,
But that was a time quite abundant,
To forgive, and be forgiven.

Thus the *drop* of nectar was ample,
To gladden the weary bee;
The *smile* to make lighter the burden—
The *moment*, a life to free.

Chicago, Ills., Feb. 7, 1889.

WINTERING.

Report for Two Winters—Experiments.

Written for the American Bee Journal
BY DANIEL WHITMER.

On Nov. 20, 1887, I placed in my bee-cellar, under the dining-room, 207 colonies of bees in good condition (with the exception of about six, two or three of which were queenless), and left 36 colonies on the summer stands. I wintered them very well, with the loss of 14 colonies by winter and spring dwindling.

In the spring, by selling some, and uniting others, I started with 150 colonies of Italian bees, but on the account of a very dry season, I secured only 4,500 pounds of honey, mainly amber, and increased my apiary to 204 colonies, 14 of which are hybrids.

On Nov. 19 and 20, 1888, I placed 190 colonies in the cellar very heavy with bees and honey, with but few exceptions, and left 14 colonies on the summer stands. All seem to be wintering well as yet. The temperature in the cellar has been a little higher this winter than desirable, in consequence of the mild weather. It is now where I want it—40° to 42°. They seem to be doing quite well, and I have lost none that I know of yet.

Plenty of Ventilation.

I am experimenting with one colony. Late in the summer, the last prime swarm that issued I put into a 7-frame Langstroth-size hive, made for the purpose without end-boards, the bees being exposed to the weather. They were allowed to build their own comb, and they did well, making no drone-comb, and they filled the hive with brood-comb as straight as a shingle, and gathered enough to winter on.

I placed them in the cellar in that condition, to know how they would winter, and I must say that I never saw bees do better. They are as quiet as it is possible to be, and hardly a dozen dead bees are on the bottom-board—bees and hive being perfectly clean and sweet. This proves that plenty of ventilation in the cellar is a necessity, at least in my locality.

Not a colony in the cellar or on the summer stands shows any signs of diarrhea as yet, and my bees always winter on natural stores. I never expect to fuss with feeding sugar, when the bees can get honey. I have enough trouble in these days of adulteration, to convince some people that honey from the producer is pure and good.

As to the market here, it is not any higher this season than it was last, notwithstanding the scarcity of honey. The market was kept down early in the fall by some injudicious honey-producers selling their honey at less than it would have brought in the market, hence it still remains at from 12½ to 15 cents.

South Bend, Ind., Feb. 15, 1889.

NECTAR.

The Process of Evaporation by the Bees.

Written for the American Rural Home
BY G. M. DOOLITTLE.

Some bee-keepers hold that bees gather honey from the flowers and deposit it in the cells immediately, and if the hive is patented on purpose for evaporating nectar, or the watery parts of it evaporates itself, the bees will, when suitably thickened, seal it up. So they will seal it up, when properly thickened, but the hive has very little if anything to do with it.

When bees gather nectar, maple sap, or any other thin sweet, more than can be contained in the honey-sacs of the bees which stay in the hive, they deposit it in the cells until evening, when they hang in festoons in the hive to evaporate it.

Some claim that the bees which bring the nectar in from the field, deposit it in the cells, but my experiments have led me to believe that all honey brought in by the outside laborers is given to the young bees, they taking it into their sacs directly from the bee which brings it in; and if more is gathered than the sacs of the inside bees can contain, it is deposited by them in the cells till night, and then evaporated down, although this evaporation is going on to some extent during the daytime. At night all hands join, from the outside laborer with jagged wings, down to bees but a day or so old, when the nectar or thin sweet is taken into the honey-sac, thrown out on the proboscis, drawn back in again, and so on, until by the heat of the hive, these small particles of honey are brought to the right consistency, when it is deposited in the cells for sealing up.

In order to do this, the bees hang loosely so that when the proboscis is thrown out it shall not hit another bee, the combs or the hive.

Now by their great roaring, humming, or whatever we call it, the heat is increased in the hive till the nectar is thickened very fast, by this stirring up process, which is being gone through as spoken above.

Take a short straw in your mouth, and blow a drop of water gently through it out to the end, and then draw it in again, and you have an idea of the process, all except the stirring up. The bees do that part better than you can, because they have tools made on purpose for that business.

All bee-keepers of any experience can tell whether the bees have been getting honey of any amount during the day, by the roaring they make at night, as bees only make this roaring while reducing their honey. Let two or three days of rain succeed a plentiful honey harvest, and all roaring ceases with the night of the third day.

Many a night have I watched this reducing of thin nectar to honey, and by the light of a lamp you can see the tiny drops of nectar sparkle, as it is thrown out on the proboscis and drawn in again. When honey is coming in slowly, you will not be likely to see this process, as it goes on so slowly at such times.

All have doubtless observed that when bees are getting honey plentifully it shakes readily from the combs at night, while in the morning before the bees go into the fields, not a particle can be shaken from the combs; this going to show that most of the evaporating of the nectar is done at night.

Borodino, N. Y.

HOUSE-APIARIES.

Experience with Keeping Bees in Houses.

Written for the American Bee Journal

BY W. J. DAVIS, 1st.

From the answers given to Query 612, on page 85, I am inclined to think that some practical experience along the line of the second part of the question would have brought out quite different replies from those given, especially those who condemn without a trial.

I have been experimenting for a few years with house-apiaries, where I have kept bees away from home, and I must say, from three years' experience, that I am *more* than pleased with them.

House No. 1 is 8 miles from my home apiary; easily reached by either of two lines of railroad, which makes it more convenient in doubling the opportunities of going and returning. The house is 12x16 feet, and nicely accommodates 33 colonies, with plenty of chance of tiering-up the section-cases; besides room on the top row for 16 swarms, with room for only one section-case each.

The house is sided with 1-inch grooved siding, and painted two coats. Separate alighting-boards are attached on the outside for each colony, each board being 4 inches wide, and every alternate one painted white, and the next one red, both differing in color from the siding.

The bees do not have access to the inside of the building, but must pass out at the entrance. The advantages of such an arrangement are numerous, viz:

1. Economy. Such a house, and the hives to stock it, will cost less than the same number of hives made for out-of-door exposure. The hives are simple boxes unpainted, made the proper size to hold the number and kind of brood-frames desired, and covered with a light honey-board—I mean *board*, not cloth.

2. There is no cumbersome packing, or carrying to the cellar for winter.

3. If properly constructed, a far more even temperature can be maintained, both in the brood-chamber and section-cases, than with hives standing in the lawn.

4. It makes a superior honey-house, after the surplus has been removed from the hives.

5. The door is shut and locked at night, making everything secure from a class of beings that are not desirable in any community, yet probably all localities have them.

6. It secures a clean and convenient storage for such cases and sections as must be carried over until the next year.

House No. 2 is but 8x10 feet, and was a wintering-house worked over into a house-apiary. It accommodates 20 colonies.

The past three years have been poor honey seasons here, but those in the house-apiaries have done much the best. How they would do in a good honey season, I am not able to say; but I would not have the slightest objection to trying it. I think that the house-apiary would still be ahead. Bee-keepers are not the "bloated bondholders," in this part of the country.

Youngsville, Pa.

BEE-KEEPING

Considered as a Branch of Agriculture.

Read at the Ontario Agricultural Union

BY R. F. HOLTERMANN.

To be in a position to treat the subject before me, I must refer briefly to a few peculiarities in the method of fertilization in the organs of flower vegetation. In doing this, I am indebted to various scientific works.

The stamens and pistils are the essential organs of fertilization in the flower. On the stamens grows the pollen. The pistils are the bodies in which the seeds are formed. The pollen coming in contact with the pistils at a certain time is the important step towards reproductions. Many plants have not the anther and pistils upon the same flower; these must be indebted largely to insect life for fertilization. Again, many which do bear both anther and pistils must also owe their fertilization to insect life, self-fertilization being prevented by either the anther or pistils maturing first. Again, there are others not coming under the head of the two previous, which in order to yield the best seeds, and the largest number, must be fertilized by crossing.

It has been proved by experiment that in such cases pollen placed on the stigma of the flower on which it grew, becomes powerless when pollen is added from the complementary blossom; the prepotency is so arranged as to secure cross fertilization.

Fertilization of Fruit-Blossoms by the Bees.

Now let us take the apple. Each blossom carries five stigmas, and to each stigma belongs a division of the ovary constituting the core fruit. We have here an example of the stigma maturing before the anthers. In the construction of this, as I believe in almost every other flower, the recepta-

cle for the honey is so arranged that the insect cannot reach it without coming in contact with the anther and the pistils. The wisdom of this is manifest. In the case of the apple blossoms, the insect becomes dusted with pollen-grains, and when visiting another flower, deposits it upon the sticky surface of a part of the pistils, causing fertilization.

But one fertilization is not sufficient. To secure a perfect apple, five independent fertilizations have to take place. If none are effected, the calyx which forms the flesh, dries and soon drops. If, as is often the case, only four fertilizations take place, there is an imperfect development of the calyx, the four parts swelling, while the fifth develops imperfectly. The fruit of course is imperfect, and is very liable to drop off during the first storm. Opposite the hollow cheek on the apple you find the pips have not been matured.

Gooseberries, currants, raspberries are largely dependent upon insects for fertilization, and, in the last two, undeveloped parts are often found, due to imperfect fertilization, as in the apple, clover, especially white and Alsike, and not unfrequently the second growth of red (the corolla of which is shorter than in the first growth), is largely visited by bees, and who can estimate the advantages to be gained by the visits of these insects ?

Of course it may be argued that other insects would act as a medium for the fertilization of flowers, and the honey-bee may not be required. Let us see. When we consider the frequent rains during the spring, which, for the time, hinder the visits of insects, and the uncertainty of the temperature, we must at once admit that any agent which gives us a more rapid and perfect fertilization of the blossoms which later develop into useful crops on the farm, is desirable, and that is just what the honey-bee does.

Having now shown the utility of the honey-bee to secure surer and larger crops, and even better specimens of fruit, we at once see the advantage of having bees at work on every farm ?

Who Should Keep Bees ?

The next question will be, Who should keep the bees ? Probably the natural way will be for every man to gather his own crop. Some of our specialists have said, "We can make it pay better because we can with our experience, gather a larger and better crop," and give as an instance, the creamery as compared with farm butter-making. Now whilst the specialist is of greater use in advancing scientific bee-keeping, and is a blessing to the farmers who did not keep bees before he settled in their vicinity, the comparison between the specialist in bee-keeping and the creamery is faulty. Look at all the processes the product from the cow has to undergo before it becomes butter or cheese for the table. Not so with honey ; the product when left by the bee is fit for table use, or in the case of extracted honey, becomes so by a very simple process, as easily learned, or more so, than milking a cow.

To point to the failures the farmer has made in bee-keeping, nothing is said, for in comparison the specialist has made as many ; and there are probably as many failures in every other business. It may be claimed that the farmer has already "too many irons in the fire." That may be true, but the question then would be, Would he better remove some which year by year yield a less return for capital and labor invested, and which would not diminish the profits from other sources ?

Some of our staunchest advocates of specialists are by practical experience feeling that they should combine bee-keeping with some other pursuit ; that it is better not to have "all their eggs in one basket."

Many farmers may not, of course, be in a position to keep bees to advantage—this must be a matter of individual judgment.

Who are Canadian Bee-Men ?

It will certainly be of value in considering this question, to know who are the bee-keepers of Ontario and of Canada. After a careful study of the question, I cannot to-day point out one who is keeping bees alone, and not combining it with something else, and out of these 90 per cent. are farmers, while a small percentage of the balance combine it with gardening.

Again, I doubt if any man could make bee-keeping in Ontario a paying business, unless he or his neighbors cultivated fields ; for the bulk of our honey is secured from land which has been cleared from the primeval forest. Clover and thistle both yield first-class honey—basswood, or more properly linden, is the only surplus honey we take from the forest. This fact, together with what has been shown regarding the fertilization of fruit-blossoms and clover, make it apparent that bee-keeping is a branch of agriculture. But is it so recognized ? The farmer recognizes it as such, and the various agricultural papers have been compelled to so class it. Our "cousins" across the line have given recognition of it as such by having bee-departments at various agricultural colleges, and even by having an experimental station devoted entirely to the advancement of bee-keeping. But how are we situated here ? The absence of a bee-department at this institution, one so long established, offers no pleasing picture to our enterprise. In many instances where the different departments of the farm are referred to, bee-keeping comes under the head of "etc."

Market Quotations of Honey.

Our influential papers give market quotations for every other farm product but honey. What wonder, then, that the exhibit of honey at the Colonial and Indian Exhibition has been a matter of surprise to those visiting it ? This lack of market quotations is an injury to bee-keepers, and is largely the cause of such varying prices ; such quotations would also assist in developing our market. But far more all this lack of recognition is hindering the development of the resources of our country, and in reality impoverishing it. The British market will never open to us until we can give them an unfailing supply of honey. In England, when an article such as Canadian honey drops out of the market for a season, it is uphill work regaining the former position.

In closing I do not ignore the fact that we have amongst us some who see with disfavor every new bee-keeper, and every development of the industry. When a merchant is settled in a prosperous community, he would doubtless often desire to see a law passed to prevent another from starting in the same community ; but in store-keeping, in bee-keeping as well as many other pursuits, it must be "the survival of the fittest," and the best way to look upon this question is not what is best for a few individuals, but for the community, for the country ; and no argument can refute the statement that One wiser, more far-seeing, and One who never wrongs any one, has decreed that bee-keeping is a branch of agriculture.

Brantford, Ont.

BACTERIA.

The Causes of Foul Brood Among Bees.

Written for the American Bee Journal

BY GERD WENDELKEN.

I am extremely interested in the subject of foul brood, and have tried to get all the information about it I could.

Science says that all, or nearly all, diseases are caused by the development of minute vegetable organism, or so-called bacteria. These tiny plants, they say, produce spores, or seeds, which fly in the air, and produce, under certain conditions, foul brood.

Different denominations are applied to the causes of foul brood, such as

fungus, bacteria, bacillus alvei, and leptothrix. It is, I believe, the popular idea that all these are classed to the vegetable kingdom; but in statements about examining foul brood by the use of the microscope, it is said that millions of them are found in diseased colonies, and are also seen rolling and pushing by and over each other, and swimming much as a fish does, by the use of its fins.

Leptothrix belongs to vegetables, but Mr. Cheshire, according to his statement, saw them swimming rapidly either backwards or forwards. I once asked a Professor, "Are bacteria plants, or animals?" The answer was, "Vegetable."

Now, when bacteria move, as stated, then it would seem that plants had changed into living beings. I do not understand this. I think that plants produce plants, and animals produce animals, and nothing more.

Now I desire to understand how bacteria, of minute vegetable origin, can change to living beings, and swim backwards and forwards. I want someone to give me some light on this subject.

Last season my bees had stored much honey-dew; I feared disease, but to-day they had a good flight, and I found them all right.

Marietta, Ohio.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Mar. 30.—Agency, at Agency, Mo.
T. S. Smith, Sec., Agency, Mo.

Apr. 23.—DesMoines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Good Outlook for 1889.—J. A. Delamarter, East Meredith, N.Y., says:

I think that the Union is doing a fine work, and I feel it my duty to pay my fee, not because I need help, for I do not. I have 18 colonies, which were put into winter quarters in good condition. I got but very little honey last year, but I think that the outlook is better for the coming summer—I hope so, at least. The bees had flights until about three weeks ago, and it has been very cold since then.

Early Swarm—Maple Bloom.—J. A. Marsh, Scotia, Mo., on Feb. 15, 1889, writes:

I began the spring of 1888 with one colony of bees—a present from my father-in-law—which I increased to 3 colonies, and took 125 pounds of honey. The bees are in good condition now. The thermometer registered 78°, Fahr., to-day. The bees had a "picnic" on the maple bloom, and about 2 p.m. a swarm issued, or strayed from elsewhere; I hived it—about 1¼ pints of bees. Will it pay to try to save them? The BEE JOURNAL is a regular and highly-prized visitor.

[It would be better to return the small swarm to the parent colony, if that can be ascertained; but if not, to unite them with a weak or queenless colony will be the best disposal of them at this time of the year.—ED.]

Good Prospects for Honey.—T. M. Edwards, Kerrville, Tenn., on Feb. 12, 1889, says:

It is hard to get the old-fogy notions removed from the minds of many bee-keepers in this part of the country; yet a few begin to see the light. My bees are doing finely, being strong and healthy. They have a good time out in the air two or three times every week. I have 150 colonies, and prospects are good for the next crop of honey, which never fails to be pretty good. My crop, last year, was 43 pounds of comb honey per colony. There is no disease among the bees in this country.

Results of the Past Season.—W. H. Miller, Berrien Springs, Mich., on Feb. 14, 1889, says:

Last spring I commenced with 50 colonies in just fair condition, increased them by natural swarming to 86, and took about 700 pounds of comb honey, nearly all being white, in one-pound sections. I have 86 colonies packed in sawdust out-doors. All were in good condition when prepared for winter, and seem to be wintering well, as they keep very quiet.

Wintering Carniolan Bees.—Andrews & Lockhart, Pattens Mills, N. Y., on Feb. 20, 1889, writes as follows:

We never had bees winter so well as our Carniolans are doing this winter. There is not a handful of dead bees on any of the bottom-boards of the hives. The cellar has been kept at a temperature of 45° to 48° all winter, so far. The bees are in that quiet state in which every bee-keeper likes to see them. Bees are hanging below the frames in nearly every hive. Our Carniolans winter remarkably well, and they are more quiet in the cellar than any other strain of bees we ever had.

Our advertisement in the AMERICAN BEE JOURNAL has brought more calls than we have had from all the other bee-periodicals put together. As it is brimful of apicultural news *every week*, we presume others feel as we do—that we would not do without it for five times its cost. It has paid us ten fold the cost of the advertisements. Its large circulation, the world over, gives great advantage to its advertisers.

Report for 1888.—Wm. H. Ford, Marshalltown, Iowa, on Feb. 16, says:

I commenced the season of 1888 with 12 colonies of bees (part hybrids and part Italians), and increased them to 19 colonies. One swarm came to me on Aug. 26, and stored enough to winter on, thus making 20 colonies to begin the winter with. I put all of them into the cellar on Nov. 17, and they are wintering well so far. Last summer I took off about 300 pounds of honey, part extracted and part comb honey. The "old reliable" AMERICAN BEE JOURNAL makes its visits regularly every week, and is welcomed, for I think that no man who keeps bees can do without it for five times the cost.

Odors and Bees—Cleaning the Sections.—Jno. Handel, Savanna, Ill., writes as follows:

Is it not possible that bees are always attracted to the nectar in flowers by the smell, and that they simply use color as a landmark afterwards? I have often noticed that when flowers fail to secrete nectar, they also lack in odor. I think that not only bees, but the bee-keeper himself, with a little practice, can tell when there is a honey-flow, by the odor. Now, then, who can answer these questions: 1. Do the bees drive the odor out of the nectar-distilling cups of the flowers, by fanning it with their wings? Or, does the evaporation of the nectar release the odor, and the bees are attracted by it? Or, is it possible that the flowers attract bees, etc., by their colors, and are tickled by them, until they (the flowers) eject the sweet juice, after the fashion of the ant and plant-louse?

The best tool for scraping propolis from sections and separators that I have ever tried is, one-half of a pair of shears. Sharpen it occasionally.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¼@6c.; dark amber, 4½@5½c.
BEESWAX.—18@22c.
Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The trade is dull.
Jan. 19. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@17c. Sales slow. Extracted, 9@10c.
BEESWAX.—22@23c.
Feb. 11. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX.—22c. R. A. BURNETT,
Jan. 17. 181 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand is only moderate. No overstocking of the market.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 21. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds. 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs, 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. March 9, 1889. No. 10.

EDITORIAL BUZZINGS.

Mr. W. T. Richardson, one of the proprietors of the Monte Blanco apiaries at Santa Barbara, Calif., called at this office last week. The apiaries consist of 1,500 colonies of bees, and was begun in 1880. They are sending honey by the carloads to Boston, New York, and Eastern cities.

Dr. Mason's address at the Tri-County Institute at Adrian, Mich., was very interesting. It took forty minutes, and was listened to with the closest attention. This was a three-day meeting, and the Doctor worked faithfully for the pursuit of bee-keeping. Bee-keepers should improve all such opportunities.

Silo and Silage is the name of a nice 25-cent pamphlet by Prof. A. J. Cook. It is written in the Professor's familiar chatty manner, and is well worth reading and studying, so as to make it of practical use. His preface reads thus :

I write this primer : first, because I have been asked to do so ; secondly, because, from my experience, I deem the silo a tremendous advantage to any farmer, and I wish to influence the farmers to do that which will aid them, in the struggle for success, more than any other one thing. My silo has been a surprising success, and in this little *brochure* I shall tell in a plain, simple way how I grow the corn, build my silo, fill and cover it, and feed the silage. I shall not pretend that this is surely the best method in every respect, but I shall urge that it will all pay, and prove a success ; for I have tried it at an immense profit. There ought to be one thousand silos built in Michigan, and ten thousand in the United States during the next year. I hope and trust that this little effort of mine may aid in bringing this about.

The Professor has proved by experience on the farm his every statement. We can supply it at the publisher's price.

California Honey Crop.—In their fourth annual report of the honey and beeswax crop of California for 1888, just issued, Messrs. Schacht, Lemcke & Steiner, of San Francisco, remark as follows :

A fair crop of honey has been gathered and marketed this season. The quality has also been up to the average, and the price has ruled high enough to be satisfactory to apiarists and dealers. This is as we anticipated in our report last year, and as far as present prospects can be read, the outlook for the next crop is equally good, although fears for a small crop are entertained.

As we have mentioned more than once in our annual reviews, it is very difficult to give a correct estimate of the California honey crop. Our reason for this is found in the fact, that no reliable, or other statistics of the article, are kept in the different counties and localities of the State, as there should be. Consequently we are compelled to rely wholly for this information on reports from our agents and correspondents, which is reliable as far as it goes, and on this authority our estimate of this season's crop is made. From the fifty or sixty thousand colonies in California, for the year 1888, there was marketed of extracted honey, 3,000,000 pounds, and of comb honey, 500,000 pounds, or a total of 3½ million pounds for the season.

This result compared with former seasons is favorable, as the following figures evidence : 1887, 1,200,000 lbs. ; 1886, 5,000,000 lbs. ; 1885, 1,250,000 lbs. ; 1884, 9,000,000 lbs.

A great portion of this season's crop was shipped by steamer or rail, direct from the apiaries to San Francisco, as the following statistics show : extracted, 1,200,000 lbs. ; of comb honey, 300,000 lbs., or a total of 1½ million pounds. This also compares favorably with the receipts of former years, viz : 1887, 1,300,000 lbs. ; 1886, 2,500,000 lbs. ; 1885, 2,000,000 lbs. ; 1884, 3,600,000 lbs. ; 1883, 1,400,000 lbs. ; 1882, 1,000,000 lbs.

Since the first of this year the receipts have been 1,000 cases of extracted and 450 cases of comb, and for the remaining four or five months they will probably be light, as the interior supply is getting limited.

A better demand and higher price of the article, caused much larger shipments of it to be made to Europe this season than were made last year. They amounted by sailing vessel to Europe and other foreign countries 700,000 pounds, and by sail via New York, 175,000 pounds. The principal part of these shipments went direct to England ; the balance to Germany. France did not import any from here during the year, but will probably soon become an importer.

Overland shipments including those for Europe, via New York, amounted to nearly one million pounds, while in 1887 they were 950,000 pounds ; 1886, 2,000,000 pounds ; and in 1885, 1,270,000 pounds.

These heavy and constantly increasing shipments, show that Europe is a large consumer of our honey ; and that it is important to all concerned in the honey-trade, to do everything that can be reasonably done, to increase it, by taking great care in producing a fine article in all respects, and putting it up in good and strong packages. The quality and color should also be looked after by the apiarist, dealer and shipper.

The average price of extracted honey during the last season has been from 5½ to 6½ cents ; for comb honey, 10 to 12½ cents per pound for one-pound sections, while the two-pound sections have been sold for less. Present quotations are 5½ to 6 cents per pound for extracted honey.

It is too early now to say what the crop of the coming year will be. Spring rains are necessary, and if we get them, there will be a good yield. We feel confident though, in saying that the outlook so far is good, that the coming season will probably not be behind the past one, although nothing certain can now be said.

Congress last week passed a resolution favoring unrestricted trade with Canada. Commissioners were appointed to prepare a plan for the assimilation of the import duties and internal revenue taxes of the two countries, and an equitable division of receipts in a commercial union. In its report on foreign affairs, it says :

Our commercial relations with Canada have recently awakened a deeper interest, and received a more thorough discussion than ever before. The tendency of public opinion is plainly toward the enlargement of trade between the two countries.

In Canada the movement has advanced from what a few years ago was an effort for partial reciprocity to a wide expression in favor of unrestricted intercourse and commercial union. The Chambers of Commerce and Boards of Trade of the leading cities of Canada, and more than fifty farmers' institutes and conventions have adopted resolutions declaring in favor of commercial union or unrestricted trade between the two countries.

The answer made by their opponents, and those most closely attached to English trade and English rule has been that the United States has given no indication that it would receive or even consider any proposal, however friendly in spirit, or however favorable to us in its terms it might be. Your committee believes that the power herein conferred upon the President can do no harm, that it will be wisely used, and will lead to beneficent results, promoting the independence, prosperity, and peace of the two great people.

The Bee Hive, in its March number just received, has quoted a part of an item from the AMERICAN BEE JOURNAL of Feb. 16, on page 99, concerning "a club agent down East," who had taken subscriptions for papers and then "lit out with the money." The *Bee Hive* says it would have been much better to have "given the absconder's name or town, than to cast reflections on the honesty of *all* Eastern club-agents." *We intended no wrong.* The dishonesty was recorded because, as we there stated, several of our subscribers had sent him money, and lost it. His name is J. K. Boak, but his address is now unknown to many who would like to know it. Perhaps it would have been better to have given the name before.

Frosted Grain is good for seed. Prof. Green, of the Minnesota State Agricultural College has completed his experiments to ascertain the value of frosted grain for seed. His report made on Feb. 25, shows that from 40 to 90 per cent. of the total amount planted will sprout and grow. He says that the experiments may be relied upon, and hereafter farmers may plant frosted grain with the assurance that it will grow, rather than run in debt for other seed. Oliver Dalrymple, the bonanza farmer of Dakota, and the largest wheat-grower in the Northwest, is inclined to believe that the experimet can safely be relied upon, and will test further on his 40,000-acre farm.

The Third Annual Fair of the Dakota Board of Agriculture will be held at Grand Forks, Dak., Sept. 17 to 21, 1889.

Basswood or Linden Honey.—On page 104 we stated that we hoped the controversy would there end, but as Mr. McKnight thinks he should be heard in reply, we admit one more article from each disputant, and then positively close the discussion in our columns. Mr. McKnight writes thus:

MR. EDITOR:—You have virtually put your foot down on any attempt at further controversy between Dr. Mason and myself, on the alleged superiority of Canadian linden honey over American linden honey. Under ordinary circumstances I should say you are right in doing so; but the Doctor, in his last article, goes entirely outside the question, and treats me so badly, that I ask your indulgence for a little space to reply, promising not to trouble you on the subject again.

I am free to admit that I often say things that would be better unsaid, nevertheless when speaking to the public, through the press or otherwise, I endeavor

> To guard my words with jealous cares,
> Least Bogles catch me unawares.

I have not forgotten to do so when writing on this subject, and have therefore nothing to retract. The "Circular" that furnishes so much delight to the Doctor, supplies him with no proof that I have at any time "misstated facts." Copious as are his extracts from it, he has failed to find one to support his contention. Somebody has addled the Doctor's brain by furnishing him with this (more than two years old) "Bee-King Circular," the existence of which I had almost forgotten, as I have not seen one of them since I left London; nevertheless I acknowledge the fidelity of his quotations from it.

Since he got the Circular, he is wild with delight. He shakes it in my face, exclaiming: "Ha! my man, I have got you now! Did you not challenge me a year ago 'to name a solitary Canadian (apart from Mr. Pettit) who had made the statement that Canadian linden honey is better than the American article?' Here, sir, I have the proof that 'you're another,' and if you are, 'what must we think of the man who makes such a claim and then denies it.'"

Verily, the Doctor is bringing things to an unpleasant crisis; but let him "bide awee," and reflect, when he will find that his "Circular" evidence will not hold in court. I did say that Mr. Pettit made the claim, and I reply to the Doctor's query by assuring him that I do "throw all the responsibility of claiming superiority for Canadian linden honey on Mr. Pettit," and on Mr. Pettit alone—ignoring all responsibility of doing so myself, and I assert that the Doctor has no proof in the circular to the contrary. I made no such claim in England. I made no such claim elsewhere. I have, on the other hand, stood up at one of our own conventions, and defended the high quality of your linden honey when Mr. Pettit claimed superiority for ours.

I could not then, and I cannot now see, why linden trees growing on the south bank of the St. Clair river, should yield an inferior article in honey, than the same kind of trees growing on the north bank yield.

I could not then, and I cannot now see, why the honey from linden trees growing in Michigan, Ohio, Massachusetts, Pennsylvania and New York, should be inferior to honey from linden trees growing in Ontario.

"But how," the Doctor asks, "does this conduct compare with the language you use in your published interview with the editor of the *Pall Mall Gazette?* Did you not say to him, 'We think that all who visit our exhibit at the Colonies will admit that for *color, flavor and specific gravity, we throw all other honeys in the shade?*'" Yes, we did, and I am willing to father the statement and abide its consequences.

The Doctor will please bear in mind that in this we spoke of our exhibit as it stood. We spoke of our collection of honey, and of its quality as a sample of our general product, and not of the merits of linden alone. We took the position that we can beat the world (which, in the Doctor's opinion, means the United States) in the high grade of quality of our honey products; and we are prepared to maintain that position. We frankly admit that the linden and white clover honey of the northern States is as good as ours from the same sources, but there is a much larger occupied pasture field, and a much wider range in the honey-producing flora in the United States than there is in Canada. We get nothing but the best; you get much that is inferior, hence the Canadian honey is higher in its average grade, than the average grade of the American *world*.

The Doctor will hardly take the position that the honey of the Gulf States, and California honey is as good as that produced in Michigan, New York and Ohio. He will not deny that these and similarly situated States take as good honey as the world can produce. The high grade of these States is lowered by admixture with an inferior article from other parts of the Union, thereby lowering the average grade of the country. Our surplus comes almost entirely from the same sources, whence you derive your *best*, viz: white clover, linden and thistle. Our *average* being as good as your *best* samples, and your best being as good as the "world" can produce, it follows that our honey in its average quality is the best in the "world;" hence the honesty, the propriety, and the truth of our claim as set out in the words quoted from the "Bee-King Circular."

The only other world we had in view when this claim was made, was the British. We had seen the products of most of her Colonies on the ground: and they could not "hold a candle" to ours. We had seen and tasted English honey—so highly prized by her people. Its flavor is good, but its color is murky. We had not yet seen the famed Scottish heather honey, but through the kindness of our lamented brother, the late Mr. Raitt, we were afterwards supplied with a sample. In flavor, no other honey is like it, and no other honey can be compared with it. In color it is as dark as molasses.

When the Doctor next tackles me, let him stick to the text. It is upon the relative-merits of *linden* honey the question hinges, and I nail him to that tree.

As to the great yield of our linden, I can only say, that the phenomena of observing honey-drops chasing one another down the cheeks of basswood bloom, is not observable around Owen Sound. It may be seen in the neighborhood of Beeton, for aught I know.

That superior "honey-belt" bothers the Doctor a good deal. I assure him that such there is; and that Ontario lies within it. It is not bounded by parallels of latitude; but isothermal lines, within which the mean temperature is much the same, and within which there grows and flourishes the best honey-producing flowers.

I am pleased to know that the circular has done the Doctor some good. It has added to his geographical knowledge, by furnishing him with the fact that Canada is larger than the United States; though I greatly fear it has disturbed him not a little to learn this. He "smoles" a smile over our alleged claim that Ontario lies within the United States; surely the Doctor knows this is a mistake. If he does not, let me assure him that the delegates, one and all, would rather be situated ontside the "honey belt" than in the Union.

Thank you, Mr. Editor, for your indulgence, while I bow and retire from the field.

R. MCKNIGHT.

Owen Sound, Ont., Feb. 17, 1889.

In order to *close* this controversy in this issue, we here give the reply of Dr. Mason as follows:

MR. EDITOR:—I am glad indeed that you have concluded to let our friend McKnight "kick" once more before he surrenders, for I felt pretty sure he would dodge the issue, and give me a "wild goose chase." I am in the same fix that he is, in regard to saying things that were better unsaid, and I thought after my article on page 103 had been sent to you, that perhaps I was a little too severe on him, but I had either to furnish the proof for my statements, or be willing to admit that Mr. McKnight was right when he said, "Dr. Mason misstates the facts," etc., and I think that it would have been better for him if he had kept in mind the fact that tangible and solid "corporosity" was of more account than "Bogles."

I am not aware of having accused Mr. McKnight of "misstating the facts," but he accused *me* of doing it, and "challenged" me "to name a solitary Canadian (apart from Mr. Pettit)" who has "sought to destroy confidence in the good qualities of American basswood honey, and claim superiority for their own;" and the main object I had in view in writing the article on page 103 of the BEE JOURNAL was, to furnish the evidence that he "challenged" me to produce; and if the "Bee-King Circular" produces such an "addling" effect upon a Yankee, what must have been its effect upon the tens of thousands of English, and others who read it?

But, as what is in the circular seems, according to Mr. McKnight, to have such an "addling" effect on him, perhaps evidence from the "Old Reliable," that never "addles" any one's brain, will convince him that he has "put his foot in it."

On page 694 of the AMERICAN BEE JOURNAL for 1886, in speaking of the Ontario honey exhibit in London, it says: "It has come over in charge of a deputation....who are....on a visit to this country with a view to open the English market to the best honey in the world, as they constantly describe the article which they have on view."

To me, that alone is *conclusive* evidence that somebody besides Mr. Pettit *did* claim that Canadian honey was better than American, and one of the somebodys *was Mr. McKnight*.

Instead of being "wild with delight," as he says, since getting the circular, my heart is saddened at the spectacle he makes of himself in saying, "I made no such claim in England." I could furnish other evidence of the fact that "the deputation" did make the above claim, and will do so further on. When a person's brain gets in such condition that he can deliberately say that he does not care what a person "may say or think of him," as Mr. McKnight does about Mr. Pettit, on page 100, evidence is of no account to him, for as he says, such "evidence will not hold in court."

He credits me with stronger language than I had thought of, but I guess he had it about right when he makes me say, "Ha! my man, I have got you now."

I do not wonder that he "throws all the responsibility" on some one else (Mr. Pettit, for instance), and "ignores all responsibility" himself. Mr. Pettit never denied claiming superiority for Canadian honey, as I know of.

As I read along in Mr. McKnight's article, I am more and more amazed. He first denies all "responsibility of claiming superiority for Canadian linden honey," and then a few lines further on says, "Yes, we did say to the editor of the *Pall Mall Budget* ...'We think that for *color, flavor and specific gravity, we throw all other honeys in the shade*,' and I am willing to father the statement, and abide its consequences." If "color, flavor and specific gravity" does not constitute *quality*, what does?

Now if I ever should make such contradictory statements, I believe I should be willing to admit that whoever exposed me was doing just what Mr. McKnight avers, when he says, "Verily, the Doctor is bringing things to an unpleasant crisis."

So the "responsibility" is not on Mr. Pettit, after all, for Mr. McKnight is its "father" instead of Mr. Pettit, as I had supposed. It was Mr. Pettit and the managing committee I began on, and Mr. McKnight stepped in between, and "takes the consequences."

Yes; I do "bear in mind" that it was the exhibit as a whole, "and not of the merits of linden alone," that was spoken of; but that only makes the matter worse for Mr. McKnight, who further says, "We took the position that we can beat the world....in the high grade of quality of our honey product." Yes, sir; and then denied it! and "that's what's the matter!" The matter of *quality* has already been discussed, and Mr. McKnight has admitted the truthfulness of my statements, so I need say nothing on that score.

Yes, I *did* know that the claim that "Ootario lies within the United States" was a mistake, and I am not sure but that his statement, "that the delegates, one and all, would rather be sitnated outside the 'honey-belt' than in the Union," is also a *mistake*.

Since the appearance of my article that Mr. McKnight "goes for," I have received several letters about it, and one of them from Canada, starts out in this way: "Dr. A. B. Mason, Sir:—If you ever dare to set your foot in Canadian territory, we shall shake the fun out of you, as we do the honey out of the linden trees here," etc.

That looks rather threatening, but just bear in mind that I am not afraid of any, or all the Canadians that breathe, and if I am able, I will be at the International Convention at Brantford, and if I do not have a "glorious good time" with Messrs. McKnight, Pettit, Corneil, Jones, and a few score more of Canada's whole-souled beekeepers, it will not be my fault. Mrs. Mason says she is going with me to keep me straight. She is getting into quite a habit of doing that way, or I do not know what would become of me.

I want to assure Mr. Pettit, and all other Canadians, that I have none but the kindliest feelings towards them, and that for Mr. McKnight "with all his faults, I love him still," and am still in "the field."

Thanks, Mr. Editor, for your kindness in allowing Mr. McKnight and myself this privilege. A. B. MASON.

Auburndale, O., Feb. 21, 1889.

As further controversy would be useless, we close it while both disputants feel so kindly towards each other.

An "Explanation" Explained.

—Mr. Allen Pringle, of Selby, Ont., on Feb. 25, 1889, writes as follows:

"I rise to a point of order," to make a personal explanation in self-defense. The part of Mr. Holtermann's explanation on page 116, which refers to myself, is misleading; and without imputing any intention to misrepresent or mislead, I must set myself right in this matter.

In defending himself against Mr. McKnight's charge of suppressing my essay in his reports to the AMERICAN BEE JOURNAL and his own bee-paper, Mr. H., to show that there was no "personal pique," refers to the fact that he "paid my membership fee before the election of officers, so that I would be eligible for office." It is quite true that Mr. H. kindly *advanced* my fee without my knowledge, in my absence from the meeting; but it is also true that I had never been in the habit of sending my annual membership-fee until *after* the annual meeting; and as soon as I became aware of what Mr. H. had done, I remitted the money to him, that he had, of his own accord, advanced, thanking him for his kindness.

Had I been on the lookout for office, my membership-fee, and very likely myself, would have been on hand; but believing in the principle that the office should seek the man, rather than the man the office, I have not only sought no offices in my life, but have almost invariably refused them when offered to me.

Of course I noticed the omission from Mr. Holtermann's reports to both bee-periodicals, of which Mr. McKnight complains, but thought little, and said nothing about it, knowing that the world would move along as usual, and supposing that Mr. H. knew the reason for such omission, whether anybody else did or not. I must now, however, accept his explanation of that omission. ALLEN PRINGLE.

Selby, Ont., Feb. 25, 1889.

QUERIES & REPLIES.

Getting the Honey Out of the Cappings.

Written for the American Bee Journal

Query 617.—What is the best and the most practical way of getting the honey out of the cappings from extracting-combs?—J. M.

Use a good strainer; then rinse and make vinegar,—A. J. COOK.

I use a large can with a perforated bottom, and allow the honey to drain. —J. P. H. BROWN.

An uncapping-can that will allow the honey to drain off below, is as good as anything that I know of.—EUGENE SECOR.

A gauze-wire receptacle in a warm room, and let them drain for several days.—J. M. HAMBAUGH.

By pressure, properly applied. Put them in a bag; use a clean, flat piece of board as a *lever*.—WILL M. BARNUM.

Drain out what you can handily get, then put the rest in a sun wax-extractor, and that will separate the wax from the honey perfectly.—G. M. DOOLITTLE.

Carefully melt them, let them cool, and then take the wax from the top. You can let the bees do it, if you are not afraid of robbing.—H. D. CUTTING.

Let it drain through a wire-cloth strainer, turning it or stirring it up a time or two.—M. MAHIN.

Heat gently, but enough to melt the wax in a solar wax-extractor or otherwise, and when cool, the wax may be lifted off the honey in a cake.—R. L. TAYLOR.

Drain them through a sieve or capping-can, in a warm place. What little remains may be washed out for vinegar purposes, or for metheglin.—DADANT & SON.

Let it drain on wire-cloth, about ½ mesh to the inch. The little honey left after draining for 3 or 4 days, can be washed off and used for making vinegar.—P. L. VIALLON.

After letting them drain in the uncapping-can, take them out and place them in pans or other shallow vessels, and give the bees access to several of them at one time, at a period when there is little or no honey in the fields. —MRS. L. HARRISON.

Put the cappings in a solar wax-extractor, after allowing them to drain thoroughly. The honey *drained* out is of full quality—that from the wax-extractor is slightly injured in quality by the heat.—J. M. SHUCK.

I know of nothing better than the so-called solar wax-extractor. It brings out the honey in the nicest shape, of anything I know of.—J. E. POND.

Let the cappings drain well, and then wash and use the sweetened water for vinegar; or, after draining, set them where the bees can clean them up. There is no danger of exciting robbing, if placed some distance away from the apiary.—A. B. MASON.

I shave the caps off into a box with a wire-cloth bottom, set over a tin-pan made for the purpose. When all has drained off, or say the next morning, empty the cappings into the sun wax-extractor, and you will soon have a nice cake of wax, with the balance of the honey under it.—C. H. DIBBERN.

Most of it will drain out, with time enough, in any receptacle, with perforated or wire-cloth bottom; then soak and drain out the balance for vinegar or bee-food. It will drain faster, and perhaps without soaking, in a cool cellar.—C. C. MILLER.

When taking honey with the extractor, the cappings are dropped into a box supported by legs of convenient hight. The uncapping-box has its bottom inclining downward toward a common centre, which is a square hole covered with tinned wire-cloth, with about 8 meshes to the inch. A large tin-pan catches the drip. After the cappings have been drained 24 hours or longer, they are put into the solar wax-extractor, which is adjusted nearly level, until all the honey is run out. It would wake up most bee-men to see how much honey I save in this way.—G. W. DEMAREE.

Stir the cappings up loosely, filling a common flat pan a little less than level full of them; put this pan into the oven, leaving the door partly open, so as to bring only a slow heat upon the top. By-and-by both honey and wax will be liquid. Set it away carefully, and let it cool. When the wax has hardened, and the honey is still

warm, tap the wax at the edge of the pan, tipping it up, and the warm honey will drain out clean. Now fill the pan with water, and thoroughly wash the wax from stickiness, and the honey that is obtained is first-class. The reader will see how solar heat can be used at the right time of year to accomplish the same result.—J. HEDDON.

If you should melt the cappings carefully in the stove oven, and let the melted matter cool, then take off the wax from the top, you will save both the honey and the wax.—THE EDITOR.

BIOGRAPHICAL.

MR. EUGENE SECOR.

We have great pleasure in presenting to our readers an engraving, showing the personal appearance, and a short biographical sketch, of America's "poet-laureate of apiculture"—Mr. Eugene Secor.

For the past ten years Mr. Secor has been writing poetry and prose for the AMERICAN BEE JOURNAL and other periodicals, some of the best of the poetic effusions being "Lessons from the Ivy," the "Honey-Moon," the "Bees are Swarming," "Weighing the Baby," and "Gathering the Clan." The latter, descriptive of the Bee-Convention at Chicago in 1887, is so rich that we introduce it here as a sample:

At Chicago they met, a right jolly set,
On a soft, balmy day in November;
Such a "buzz" and "roar" I heard once before—
At an old cider-mill in September.

From the West and the East, to this saccharine feast,
Came the "workers" cheerfully "singing."
And tho' each had a wish to "sip" from the dish,
But few were inclined to be "stinging."

They talked about bees—their *legs* and their *knees*—
Of the God-given nectar in flowers,
Of its value as food, of bare-headed brood,
And the late sad failure in showers.

Our "countryfied ways," the reporter says,
Betrayed the bent of our calling.
At this we're not mad, but exceedingly glad
That our looks far exceeded *his* scrawling.

Such a constant *hum*, without *smoke* or *drum*!
'Twas said each had a "bee in his bonnet;"
But whether that's so, one thing I *do* know,
The "hive" had a *Miller* upon it.

The *Mason* bee took the *Miller* to *Cook*,
Who adjudged from its size and demeanor,
There was no need to tread on nor even put a *Hedd-on*
As it lived on "Sassafras" *Root*—a gleaner.

For three days and nights, surprises, delights,
Made us happy as bees in sweet clover;
'Tis a bright *Green* spot, not soon forgot—
In memories *Hutch*, a rich trover.

'Twould fail me to tell, how the "honey-dew" fell
From many sweet lips, though human;
But I for one, when convention was done,
Went home from Chicago a *New man*.

Mr. Secor wrote the poems used at the Bee-Convention at Columbus, O., last fall, which were set to music by Dr. C. C. Miller for the occasion.

Mr. Secor is not only a poet, but he is also humorous writer. One of the best articles in this line may be found in the BEE JOURNAL for 1883, page 259. It is an amusing sketch, protraying some of the troubles incident upon removing bees from cellars, and is written in the form of a "play"—a jubilee concert. If ever the reader feels blue, just read that and laugh—laugh until you feel "jolly." We laughed over it until we forgot all of our troubles, and all business besides. Try it, and see if it is'nt an excellent antidote for *the blues!*

Then in 1886 he wrote an article of the same character (see page 728),

MR. EUGENE SECOR.

illustrating this maxim: "What's the use of having friends, if you don't use them?" by detailing his experiences with neighbor Smith, who "never buys anything he can borrow!"

The following was published in a local paper, last year, concerning Mr. Secor. That sheet purported to be "Columbia's Letters to Uncle Sam" about Forest City and its principal citizens:

Mr. Eugene Secor is a member of the Real Estate firm of Secor Brothers & Law, Forest City, Iowa, and a man whose history is prominently a part of Winnebago county since 1862. He is a native of Putnam county, N. Y., and was born May 13, 1841.

A boy of 16, he removed with his father to Shrub Oak, Westchester county, where, until the years of manhood were reached, he alternated between work on his father's farm and in pursuing his studies at the district school. His majority attained, he came to Forest City, working during the summer at the mason's trade, and in the winter teaching school.

Ambitious for a classical education, he entered Cornell College, at Mt. Vernon, in 1864, but his brother David going to the war, it became incumbent on him to oversee his brother's official business, he being the Treasurer and Recorder of Winnebago county, consequently the subject of this mention was installed into the duties of Deputy County Treasurer and Recorder, also Deputy Postmaster of Forest City, which position he held for two years.

In 1867 he was Deputy Clerk of the District Court, and in 1868 he was elected District and Circuit Clerk, which office he held to the unbounded satisfaction of the people for three consecutive terms, being elected the last time without opposition. He was elected County Auditor in 1875, and chosen his own successor two years later without opposition.

He was chosen the first Mayor of Forest City, and re-elected three consecutive times. Retiring from the mayoralty, he was elected City Councilman, which position he still holds.

He is a member of the banking house of Secors, Law & Plummer, and the real estate firm of Secor Bros. & Law. In addition to these interests, he conducts a considerable farm, is an enthusiastic fruit-grower, and has the largest apiary in the county.

In 1866 Mr. Secor wedded Miss Millie Spencer, a lady of rare endowments, of Erie county, Ohio. Nine children have been the issue, 3 only surviving—Willard, Alson and Nina.

Mr. Secor takes a laudable interest in school matters. He is a generous supporter and active member of the M. E. church. In short, Mr. Secor is a shining example of western opportunities. He came to this section with good intentions as his only capital, and has by virtuous procedure in all the walks of life, accumulated a comfortable fortune, and firmly established himself in the esteem of his neighbors and fellow-citizens. Mr. Secor also honors the position of Trustee of Cornell College at Mt. Vernon, also Trustee of the State Agricultural College.

He has charge of one of the experiment stations established by the State Horticultural Society to determine the hardiness and desirableness of new fruits, trees and shrubs, before being recommended by the Society.

The various positions of honor that Mr. Secor adorns bespeak the exalted respect in which he is held throughout Iowa. He is Vice-President of the State Horticultural Society; and the President of the Winnebago County Agricultural Society, he being one of the organizers of the latter institution,

and the one to whom is due in largest measure the magnificent success that waited upon its initial Fair last season.

But Mr. Secor is not only a man of keen business perception, but is happily versatile in a literary direction, and by the fluency of his pen in both the spheres of prose and poetry, he has won no little distinction. Mr. Secor is firmly intrenched in Republican principles, and in a word, is a citizen sharing the good-will and esteem of all, and an invaluable member of society.

Mr. Secor is mentioned in the above as an enthusiastic fruit-grower, and as having "the largest apiary in the county." To know something of his apicultural experience then will be interesting to our readers. For their benefit we have gleaned the following:

His bee-keeping experience began in 1870, when he paid $10.00 for a prime swarm of black bees, having paid $3.00 to a carpenter, who was also a bee-keeper, for a frame hive to put them in. He knew nothing of bees, and could not tell a comb filled with sealed brood, from one with sealed honey. He secured a copy of "Quinby's Mysteries of Bee-Keeping Explained," and soon became a subscriber to the AMERICAN BEE JOURNAL and *Gleanings*. All of the books on the subject published in America have been added since, and all the bee-periodicals.

Like all enthusiasts in the business, he tried to improve the frame-hives already in use, by one of his own invention, and various contrivances were experimented with. Owing to the various other duties that take so large a share of his time, he has now given up the idea that the bee-world will all go to smash if he does not put a new hive on the market, nor write a bee-book, nor start a new periodical.

The number of colonies of bees he has kept, has never exceeded 50. His aim has been to keep the number so small that he could manage them without hired help, and at the same time attend to more profitable business. But while bee-keeping has been pursued for the pleasure and education it afforded, he has always made it pay. When he says he has 50 colonies, he does not mean that he has that many hives *with bees in*, but expects every one to yield a profit. He endeavors to keep down increase, and keep up the production of the colonies.

He was a member of the late North American Bee-Keepers' Society, and Vice-President for Iowa for two years. He is a member of the Iowa State Bee-Keepers' Society, and only avoided being its President for the current year by a vigorous protest on his part.

CORRESPONDENCE.

CONVENTIONS.

The New Constitution and By-Laws—Essays.

Written for the American Bee Journal

BY DR. C. C. MILLER.

I am very glad that at this early day there is interest taken in what I hope may be a very profitable meeting at Brantford, Ont. On page 747 of the AMERICAN BEE JOURNAL for 1888, Secretary Holtermann takes up with earnestness some points especially relating to the change in the Constitution, and does it so good-naturedly that it will be an easy matter to talk over any points on which we disagree.

I objected to the name, "The International American Bee-Association," because it seemed to me rather cumbersome, and although "American Bee-Society," as Mr. Newman says, "is short, expressive, and appropriate," still there may be other names equally good. Is the proposed striking out of the word "American," however, from the original name, that which will give us what we want?

"International Bee-Association" is a more comprehensive term than the original name, and is on that account objectionable. To have a society that takes in the United States and Canada sounds pretty big, but when you drop out the "American" and take in the whole world, is it not a misnomer? Mind you, I do not object to getting representatives from across the water—I admire the grit of Bro. Holtermann in thinking that a number of the leading men from other nations can be got to Brantford, and I should *very much* like to meet them there, but it would hardly be an International society unless we could confidentially count on their attending regularly our annual meetings. If we are to use the name "International" with no limiting word before it, the German, English and other societies may with greater reason use the same name, for they have larger meetings, and are, no doubt, just as willing to receive representatives from abroad.

I agree with Mr. H., that life members should equal annual members in privileges.

I do not know enough to say whether it is better to have "time and place" fixed at a previous meeting, or to leave the Executive to decide later. I suspect there are difficulties on both sides. The Executive Committee consists of the President and Secretary, and it is barely possible that there might be a tie vote between the two, or that their decision might not be so generally satisfactory as that of a larger number, or that they might be a little tardy about making their decision. On the other hand, there are often reasons that come up later for a different decision, and it is not always easy to know a year ahead what is best. How would it do to have time and place fixed "at the previous annual meeting," and at the same time give the Executive Committee power to change within a given time, if they saw sufficient reason for doing so?

Article VIII of the By-Laws, Bro. H. says "is optional .....Dr. Miller is wrong; he says *is* to be formed." I have read that article over several times, and I cannot make out anything optional. It says, "A committee of five *shall* be elected, who *shall* have power to organize itself into a 'Honey Company,' etc." It seems to me that means the Honey Company *is* to be formed. If not, then all the articles seems to me optional, for none of them have anything stronger than "shall."

Essays at Conventions.

And now a word upon the remarks of Prof. Cook, on page 740 of the AMERICAN BEE JOURNAL for 1888. He thinks that the Society will do the most good, among other things, by "securing essays for each meeting from representative men from all sections." From this expression, and more especially from expressions I have heard the Professor make publicly, I understand him to think that men who are not present should be represented by essays. It may not be entirely fair to reason from extremes, but there is a good bit of fairness in it, and we might try it. Suppose we have all the representations by essays. Then, as in the great majority of cases, the Professor would get more satisfaction from reading an essay himself, than from hearing it read by an ordinary reader, it would be better for him if all the essays were printed in a pamphlet together, and sent for him to read in the quiet of his pleasant home. In short, a bee-paper filled with good articles would make a good convention.

Commenting upon the Professor's remarks, the editor says: "We agree with the Professor in regard to obtaining essays. The other plan has been 'tried and found wanting.'" "Et tu, Brute!" Do you not recall several meetings we have had in Chicago, friend Newman, chock-full of interest, and those meetings free from essays? I fancy I see the astute editor of the AMERICAN BEE JOURNAL, as he turns his head slightly to one side, looks through his glasses for a

second with a far-away look, then a half-meditative and wholly good-natured look steals over his face as he says, "True, O, King!"

Do not understand that I think essays have no value, but I think, all things considered, a convention is better without them.

Marengo, Ills.

[Now, Doctor, some may think you called the Editor a brute, if we leave it there. You should have explained your Latin exclamation: "And thou also, Brutus," or as we sometimes vulgarly say, "Ditto." Oh, yes, we remember well many conventions without essays which have passed off very nicely, but as a general rule we believe it to be far better to have a subject presented in an essay to which the writer has given some thought, and then have the impromptu discussion follow. We are glad to be able to disagree with Dr. Miller once in awhile just to give variety. Being so generally correct, we cannot often find a chance to do so. We usually have to reply, "True, O, King," and there leave the subject.—ED.]

BEGINNING.

Some Helps to Beginners in Bee-Keeping.

Written for the American Bee Journal

BY MRS. B. J. LIVINGSTON.

Once upon a time, a gentleman was getting up an excursion party to visit various places of interest. Having a friend experienced in such matters, he applied to him for advice. Among other things, his friend said, "Be sure to take one fool along, to ask the questions which the wise ones of your party will be ashamed to ask."

Now I supposed that would be my position when I joined the great excursion party into Bee-Territory; but lo, before I can take my pen to ask the question that is on its tip, some kind guide volunteers to tell me just what I wish to know. So, instead of asking questions, I wish to express my gratitude to those correspondents who describe the details of the business so patiently and persistently.

If I had written a few weeks ago, I should have given a half-dozen names that I thought specially helpful; but as I begin to understand more and more what the experienced are talking about, each article is helpful. I hope that they will not get wearied, but continue to hold out the light towards beginners.

I suppose that I am not the only one who, in bee matters, resembles the bride in pie matters, viz: She wished to surprise her husband with a pie of her own make. She read in her cook-book, "to make a crust, take equal parts of lard or butter, and water, and mix to a stiff paste." The poor thing mixed the lard and water a long time, without favorable results. The directions never mentioned the *flour*. Fellow bee-keepers, that is why I like your articles so well—you do not forget the flour!

In my article on page 54, I spoke of my friend's apiary, using, in my haste, an unfortunate word. When I think of her beautiful home, with the many frame hives clustered cosily here and there among the shrubbery, with all her surroundings, showing such a highly cultivated mind, one word should have been left out. What I really meant was, that I saw no costly honey-houses, bee-cellars, extractors, or the thousand and one things considered as great conveniences to those handling bees.

When her sections run out unexpectedly, I think she uses little boxes from the stores, sawing out places for a piece of glass, and fastening the glass in place with paste and strips of cloth or paper, so that she can see what the pets are doing. She uses a great many newspapers—I must see her again and ask her about that; perhaps it is to shut in the bees, and keep the propolis from the outside of the boxes.

Center Chain, Minn.

MICHIGAN.

Newaygo County Farmers' and Bee-Keepers' Convention.

Written for the American Bee Journal

BY GEO. E. HILTON.

The Newaygo County Farmers' and Bee-Keepers' Association met on Feb. 19, 1889, at Fremont, Mich. The attendance being small in the morning, the meeting was called to order at 1 p.m., by Vice-President T. H. Stuart, and opened with prayer by the Rev. Mr. Hodges. Then followed the Secretary's report of last meeting, which was adopted as read.

An essay on "Profitable Winter Care of Stock," by Wilkes Stuart, was thoroughly practical, and we can point to no better proof of his assertion than his own stock. Rev. Mr. Tower made some able and humane remarks on the above subject, having spent a portion of his life on the farm.

Mr. Macumber did not think it paid to feed stock or raise calves for sale in this latitude, and thought the straw and grain fed would bring more than the stock.

"Creamery," by T. H. Stuart, introduced statistics showing that butter was produced on the improved plans for less than five cents per pound, and that the cost of the plant was but $3,000.

Mr. Olney was very much in favor of a creamery, but would like to know how much he was to receive for his cream.

Wilkes Stuart was in favor of a co-operative creamery, and thought the farming community should establish the plant and reap the benefits.

He had used the Fairlamb can and liked it better because there was more work about it; he was satisfied that all the cream would rise in six hours.

Mr. Walker's experience corroborated with Mr. Stuart's, but he usually let the cream stand 24 hours. Mr. Walker attributed the scarcity of butter at the present time to the fact that previous to the passage of the oleomargarine law compelling the manufacturer to brand and sell it as such instead of butter, the country was flooded with the spurious article to such an extent that butter was forced down to 10 cents per pound, and cows were sold for beef, and had not yet been replaced.

"The Relation of Agriculture and the Agriculturist to the Rest of Mankind," was treated by Thos. J. G. Bolt, who championed the cause of the farmer in words as strong as the English vocabulary contains. A much better understanding of the object of his paper was attained through a very interesting exchange of thought between himself and the Rev. Mr. Hodges, who plainly showed that he knew what farm life was in Canada.

"Little Things in Housekeeping," by Mrs. P. W. Hall, was full of good suggestions, and well received.

SECOND DAY.

MORNING SESSION.

"In the Adaptability of Bee-Keeping for the Farm," by A. M. Alton, he did not advise fruit-raising in connection with bee-keeping, as the busy seasons both came at the same time.

Mr. Gould asked if that did not hold good in general farming.

Mr. Alton concluded that in either case the profits secured through the bees more than balanced the losses.

Mrs. Mallory thought the women could care for the bees.

Mr. Alton recommended farming less land, and keeping some bees.

Mr. Boyd said the profits from 40 colonies of bees doubled the profits on 40 acres of land.

Mr. Horton advised bee-keeping mixed with farming.

"Advice to Young Farmers' Wives," could not have came from a better source than Mrs. M. W. Scott; it was a most excellent essay.

AFTERNOON SESSION.

Upon a vote being taken, it was decided to hold the next annual meeting at Hesperia, Mich.

The election of officers resulted as follows: President, M. W. Scott; 1st Vice-President, T. H. Stuart, 2nd Vice-President, M. Thompson; 3rd Vice-President, Geo. W. Ada; Secretary and Treasurer, Geo. E. Hilton. Committee on Resolutions, M. W. Scott, Wilkes Stuart, and Wm. E. Gould.

"Practical Butter-Making," by Mrs. S. V. Walker, brought out many useful suggestions.

Mr. Walker said he knew butter would attract the odor of vegetables through a brick wall.

The general verdict was that the cold setting of milk was preferable, both as a saving of labor and an increase of profits.

Mr. Wm. E. Gould then read the following essay on,

The Use of the Extractor—Extracted Honey.

Prof. A. J. Cook has well said, "Since Mr. Langstroth gave the movable-frame hive to the world, the apiarist has not been so deeply indebted to any one inventor as to him who gave us the honey-extractor, Herr von Hruschka, of Germany."

The latter half of the Nineteenth Century will be styled by future bee-keepers, "The golden era of apiculture." But a few years ago bee-keeping was in a barbaric state; following the invention of the movable-frame hive by Rev. L. L. Langstroth in 1852, came many inventions of apiarian implements—some poor, but many of great value—which have made bee-keeping what it is to-day.

One of Michigan's leading bee-men has said, that bee-keeping has reached its mamimum greatness, or something to that effect. I differ from him—our chosen pursuit is yet in its infancy—it will not have reached its maximum greatness until on every hill and by every stream is heard the low murmuring of the busy bee, and no flower shall bloom in vain, or "waste its fragrance on the desert air."

Extracted honey should never be called "strained honey." In the good (?) old days of the box-hive, when a colony had died, or had been brimstoned, the comb containing honey and pollen was cut out of the hive, mashed up, and then strained. Honey secured in that way is strained honey, not extracted. Of necessity much pollen remained in the honey, often imparting a flavor not to be desired. Extracted honey is thrown out by a machine called "the extractor," and never contains pollen. Pollen in unripe honey, or, more properly, honey that is extracted before the bees have capped it, will ferment, thus giving the honey a disagreeable taste.

The extractor is simply a large can containing a basket made of coarse wire-cloth. The basket can be revolved, and will contain two or more frames of comb. Before the combs are placed in the extractor, the cappings are shaved off with a knife made especially for the purpose; then the basket is revolved. The centrifugal force thus created causes the honey in the outer side of the combs to fly out against the inside of the can, then, by reversing the combs, the honey may be thrown out of the other side.

Advantages Derived from the Use of the Extractor.

The use of the extractor enables us to secure double the amount of honey, and the combs after being extracted from, may be placed back in the hive to be filled again, thus saving the bees a great deal of work just at the time when every minute counts. Nor is this all. Every bee-keeper knows that large quantities of honey are consumed by the bees when secreting wax for comb-building; now if empty combs are placed in the hive when needed, the honey that would have been used for making wax, is stored along with the surplus honey, thus increasing the product of the colony for the season.

Honey must be coming in in large quantities to insure comb-building, hence in a poor season the bees are very slow to occupy the sections. In such a season a fair crop of extracted honey may be secured when the comb honey crop would be a failure.

When we do not desire any more bees, increase may be prevented much more readily by the use of the extractor than by any other method.

As extracted honey can be produced in larger quantities than comb honey, and can be produced cheaper, hence it finds a more ready sale among the laboring classes generally than comb honey. Extracted honey is rapidly gaining in favor, more than one-half of the honey produced in the United States being extracted.

At the end of the season all unfinished sections may be extracted, and thus what honey is in them is secured in salable shape. The sections, after having been cleaned up by the bees, should be stored away where they will be safe from dust. The next season they will be valuable to entice the bees into the crates of sections.

By using comb-baskets, broken pieces of comb and pieces of drone-comb, that have been cut out of the hive, may be extracted, and the comb used for starters.

By proper arrangements, extracted honey may be secured in the spring and late in the fall, and comb honey in the summer; thus we would secure the best honey in the sections, and the poorer as extracted. By this system more honey is secured, for as I have before said, extracted honey may be secured when the bees will not work in the sections.

The mistake made by amateur bee-keepers is in extracting so closely that the bees starve. When the honey has been taken too closely, the bees should be fed.

Often in the spring the bees fill the brood-combs so full of honey that the queen has not room to lay, thus the value of the colony for the season is impaired; now if the bee-keeper has his eye on affairs, he may throw the honey out of all the combs but the two outer ones, and thus give the queen a chance to lay; but a watchful eye must be kept, for the bees are apt to do the same thing over again. This extracting usually stimulates the bees.

In the fall, all objectionable honey may be taken from the brood-nest, thus giving more surety of safe wintering.

After being thrown out, the honey should be passed through a cloth to free it from little particles of wax—I purposely refrain from the use of the word "strainer." In cold weather it is well to heat the honey, as it flows more readily when warm. In warm weather, if the honey is allowed to stand over night, the wax will rise to the top, when the clear honey may be drawn from the bottom.

Honey should not be extracted until capped; if extracted before, it is thin and watery, and is said to be "green" or "unripe." Green honey is not very palatable, and most of what is thought to be adulterated honey is this very same green honey. With sugar at 8 to 9 cents per pound, and honey at 10 cents, and dealer's commission 20 per cent., what profit could there be in adulterating with sugar?

"But," says one, "how about feeding cheap sugar to bees, and letting them store it in the surplus apartments?" That amount will be used, no matter what the source of the food. Now where is the profit?

The best proof of the purity of honey is its candying. When the temperature goes below 80°, Fahr., honey will candy. Remember that sugar syrup

will not do that, no matter whether the bees or the dealers store it.

To bring candied honey back to a liquid state, slowly heat it; then, if sealed when hot, it will not candy again. When heating, it must not reach the boiling point—a much lower temperature is sufficient.

Extracted honey sells better if put up in small packages. I prefer the pint and quart fruit-cans, as these are of use to the purchaser after being emptied.

People often ask me where honey should be kept, and invariably they think that a cool, damp place is the best. Honey should always be kept in a warm, dry place. It does not matter what kind of honey, for no honey should be kept in a cool, damp room.

WM. E. GOULD.

After the adoption of several resolutions, and the appointment of a creamery committee, the convention adjourned. GEO. E. HILTON, *Sec.*

GOOD HONEY YEAR.

The Prospects for the Season of 1889.

Written for the American Bee Journal

BY HENRY K. STALEY.

The low center of atmosphere which has been moving eastward struck us quite heavily here to-day, and with its round about-to-the-west motion, brought up some warm air from the sunny South, producing effects that could not be said to be far from those of summer.

Consequently to-day, Feb. 16, colonies are having a busy time in carrying out defunct bees, and rendering the bottom-boards of their hives free from the excrementitious ordure that congregated itself their during the winter months. But maugre all this seemingly unpleasant household work, they are having a pleasant time in exercising their wings—but not their stings; at least not on my cutis as in days gone by, and limbs.

It was a pleasant sight for me to stand and watch them in the act of circumvolation, after being confined so many days to winter quarters. As I stood and looked at my bees cutting divers circles, and ellipses, I could not help thinking about the Minor Planets—of which there are some three hundred—how that, in all their deviating ambits, and their great eccentricity of orbits, they neither touch nor collide with one another; when, if it were desired to lift one out with its orbit, all the rest would have to come along, so numerously intersected are their ambits.

Therefore, I say, the apicultural vista that met my gaze seemed to me to resemble the astronomical sight that presents itself to the eye of the astronomer peering through the immense teleseope; and, I can say that it was as pleasant to me as the aforesaid sight of the astronomer is to the man of stars and planets, albeit a modicum of each is visible to the eye at once.

The winter here has been a mild one, and so far all my colonies are alive. Of course we do not know what is coming.

Heaven from all creatures hides the book of fate,
All but the page prescribed, their present state,

and if their is not a killing frost, accompanied with baleful effects to the bees, between this time and spring, I think that we can safely say, this year is going to be a boomer for apiarists in general. Therefore, since we have this hope, let those apiarists who have met disaster after disaster, awake themselves from out their lethargic state of misfortune, and press forward to the goal of success, rendering everything in readiness to catch the "honey showers," and be found not napping when the huge gates of nature, that guard the honey canal, shall drop open, and let in the "little busy bee."

Pleasant Ridge, Ohio.

NEBRASKA.

The Report of the State Bee-Keepers' Convention.

From the Nebraska State Journal.

The tenth annual meeting of the Nebraska State Bee-Keepers' Association began in the Botanical Lecture Room of the University on Jan. 9, at Lincoln, Nebr., at 3:30 p.m., with President M. L. Trester, of Lincoln, in the chair.

Nothing of special importance beyond perfecting the preliminary organization was done in the afternoon meeting, but a little discussion was had on granulated honey.

In the evening the Association listened to a report on glucose, and an essay on wintering bees, by R. V. Muir. A general discussion followed, participated in by nearly all the bee-keepers present, and covering the entire subject.

A vote of thanks was tendered Mr. A. Tower, for his able work in conducting the bee-column in the *Western Resources* during the past year.

An adjournment was taken at 10:40 p.m. until 9 o'clock the next morning.

SECOND DAY.

The convention began with an essay treating on the question, "Does it pay to plant for honey?" by A. C. Tyrrel, of Madison. Mr. Tyrrel advised planting clover for early forage, and melissa for surplus honey in the fall.

Mr. Johnson agreed with the essayist in recommending planting for honey, and advised adding alfalfa to the list of profitable plants.

Mr. Tower suggested that buckwheat ought to be added.

Mr. Muir thought it hardly advisable to plant for honey except in the case of melissa.

Mr. Hardy favored all of the plants mentioned, but thought that none of them would pay to plant for honey alone.

Mr. E. T. Abbott had visited Colorado, and was much pleased with alfalfa. He said that it produces excellent honey, and makes good food for stock.

Mr. Whitcomb recommended alfalfa, if planted where it could be irrigated, or in soil that is not deep to water. Other suggestions were also made by various members, the discussion being very interesting and profitable.

A report of the work of the season was made by Mr. R. R. Ryan, of Bradshaw. He reported that he increased his apiary by division, and complained of imperfect queens. The subject of rearing prolific queens was discussed. a majority favoring rearing queens under the swarming impulse, and dividing the colony when it swarms.

The address of the President, Mr. M. L. Trester, was given in the afternoon. Many valuable suggestions were made, the most important being that pertaining to a better law in regard to foul brood.

An essay was read by Mrs. J. N. Heater, of Columbus, on "How to produce the most honey in marketable shape." As this is the object of all the bee-keepers, the essay was discussed at length. All were of the opinion that it is necessary in this region to keep bees breeding at stated times, in order to have a large number of workers to gather the nectar when the flowers that produce honey are in bloom.

The remainder of the afternoon was taken up with a discussion of the subjects, "How much foundation should be used, if any?" and "How to dispose of honey to the retail trade?"

The evening session was well attended, and the meeting proved to be a very interesting one. The principal feature was an essay by Rev. Emerson T. Abbott, of St. Joseph, Mo., on "*Bees and Horticulture.*"

Mr. Abbott explained that when he prepared the essay he did so with the understanding that the Nebraska State Horticultural Society would meet in Lincoln at the same time and place, and in view of this fact. the subject,

"Bees and Horticulture," had been decided upon.

When the essay was nearly completed, he learned that the Horticultural Society would not meet with the bee-keepers, but, as the subject was a fitting one, he did not change it.

The great mutual benefit to be derived by the bee-keepers and the fruit growers acting in harmony was commented upon.

At the conclusion of the address there was considerable discussion on the subject, after which the meeting adjourned until 9 a.m. the next day.

THIRD DAY.

The morning session was devoted to routine business, and an inspection of the buildings of the University, under the guidance of Prof. Bessey.

Among the principal business done was the report of the committee appointed to consider the recommendations of the President. The request that the Constitution be so amended as to make the tenure of office one year instead of two, was reported upon adversely, and the Association agreed with the committee. In the matter of foul brood, it was decided to appoint a committee of investigation, consisting of Messrs. Johnson, Whitcomb and Burnett.

Mr. E. Whitcomb was recommended to the State Board of Agriculture as a satisfactory man for the place of Superintendent of the bee and honey exhibit at the next State Fair. Messrs. Whitcomb, Burnett and Tower were appointed as a committee to revise the Premium List for the State Fair, and endeavor to get more and larger premiums.

The convention then adjourned to meet in Lincoln, on the second Wednesday in January, 1890.

J. N. HEATER, *Sec.*

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

The Cedar Valley Bee-Keepers' Association will hold its next semi-annual meeting at Waterloo, Iowa, on March 13 and 14, 1889. All interested are invited. J. J. OWENS, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
Mar. 13, 14.—	Cedar Valley, at Waterloo, Iowa. J. J. Owens, Sec., Waterloo, Iowa.
Mar. 30.—	Agency, at Agency, Mo. T. S. Smith, Sec., Agency, Mo.
Apr. 23.—	DesMoines County, at Burlington, Iowa. John Nau, Sec., Middletown, Iowa.
May 1, 2.—	Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.
May 4.—	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
May 21.—	Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Fine Flights Every Week.—R. R. Ryan, Bradshaw, Neb., on Feb. 23, 1889, says:

The bees on the summer stands have had fine flights every week this winter. This is the first cold spell we have had to speak of, two days, and it was 14° below zero last night. We think that the prospects are good for next season. Bees had plenty of honey in the fall, and the winter has been so mild. If the spring does not keep too cold and late, it will be all right.

Separators a Nuisance.—H. C. Gifford, Morris, Ills., on Feb. 26, says:

I have 28 colonies of bees, and work them for comb honey. I do not use any separators. Last year I used the 2-inch sections, and they would average over a pound each. I had 1,750 pounds of honey in one-pound sections, and not more than 40 of them were joined to each other, so I consider separators a nuisance, for the bees will fasten the combs to separators sometimes. I have sold nearly all of my honey at home for 18 cents; but it is a waste to sell 17, 18 or 20 ounces for a pound, so I am thinking of using the narrow sections.

Experience in 1888.—Thos. O. Hines, Anamosa, Iowa, on Feb. 23, 1889, writes:

My experience with bees in the winter and summer of 1888 has a dark and bright side. In the spring I took from their winter quarters 21 colonies, strong in numbers, but short in stores, so I had to feed. The spring being rough and cold, they dwindled away until I had 4 colonies left. I felt very much discouraged, but not enough so as to give up the business, and as my bees were blacks, I thought it a good time to change to Italians. I sent for 4 pounds of bees and 4 tested queens to start with, which I received on May 12, when it was so cold that I had to transfer them in the house. There were but few days that bees could fly until May 20, and everything in the business looked dark; but the honey-flow came, and that with a rush, and found me with my "hat" wrong side-up to catch it—I had no bees! But now comes the bright side: The flow continued without cessation until Oct. 20, when my 4 pounds of bees had increased to 10 colonies, with stores sufficient for winter. I also got 300 pounds of comb honey in sections. My bees, from all appearances, are wintering well, and everything indicates a good time for the honey-producer in this section of country the coming season.

Bees Look Fat and Clean.—Geo. H. Kirkpatrick, New Paris, Ohio, on Feb. 25, 1889, writes:

As to how the bees have wintered in the new cellar deserbed on page 89, I would say, that up to the present date I never saw bees winter better. To-day I examined each colony, and so far as I am able to judge, they are all in fine condition. They look as fat and clean as they do in June during a white clover honey-flow. The temperature I have kept from the time I put them in, from 42° to 44° up to Feb. 1, and since then, from 40° to 42°. At present I have no fears but what I will put each colony out alive in the spring, that I put in on Nov. 25, 1888. So far my neighbors' bees have wintered well, with the exceptions of a few who were so very cruel as to let their bees starve.

Hive-Spaces.—A correspondent at Dutton, Mich., on Feb. 16, 1889, asks the following:

1. Will Dr. Tinker please inform me through the AMERICAN BEE JOURNAL, what is the proper thickness of the wood-zinc honey-board? 2. How much room shall I leave between the brood-frames and the extracting-frames. 3. Is it desirable to make the extracting-frames the same size as the brood-frames? 4. Is it proper to hang the extracting frames crosswise of the brood-frames? X. Y. Z.

Dr. Tinker's answers to the above questions are as follows:

1. The slats I use in my honey-boards are three-sixteenths of an inch thick, and plump ⅞ of an inch wide. The saw-kerf in the edges is made with a No. 24 gauge saw, that is made

heavier at the center than at the rim, to make it run steady. With this thin saw there is so little waste of the wood in the edges of the slats, that if the slats at the sides are let into a rabbet in the side pieces of the frame and nailed, there is no need of a tin strip across the center to stiffen the slats. The frame is a full ½ inch thick.

2. Three-eighths of an inch.

3. Yes; and I prefer to have the extracting super made exactly the same as the brood-chamber, so that they may be used for the one purpose or the other, as may be desired. The bee-space is preferred at the top of the frames, and the entrance of the hive should be made in the bottom-board.

4. Yes; but if the brood-chamber and extracting super are made alike, and the frames are all the same size, it is preferable to storify the supers so that all the frames will be parallel.

Creating a Honey Market.—J. W. Collins, Clarksville, Mo., on Feb. 22, 1889, says:

I now have 58 colonies, 40 of my own and 18 on shares. I want to try and create a honey market at home. My bees are wintering well on the summer stands. They had a flight yesterday, but are housed to-day, as it is cold.

Bees are Very Quiet.—Joseph Beath, Corning, Iowa, on Feb. 20, says:

On March 15, 1888, I took out my bees and gave them a flight, having 40 colonies. I then put them back into the cellar again until April 13, and found 4 dead, 3 of which were killed by mice, and 2 died afterward, leaving me 34 colonies, from which I got 1,730 pounds of extracted honey. I put 34 colonies into the cellar on Dec. 10, 1888, and they have been very still so far.

White Clover all Right.—Mr. Christian Schrier, Peotone, Ills., on Feb. 23, 1889, writes:

The ground has been so dry all winter that the clover has not heaved out yet, but next month can do it. My bees looked well last spring, and I hoped for a big yield of honey, but the white clover failed. I have three acres of alfalfa clover, and I never saw my bees on it. The bees worked on the Alsike clover well, but the Alsike being mixed with the timothy, I cut it for hay while in bloom. I made my increase by dividing, and bought the queens. By Aug. 1, the hives were full of bees, but no honey. I had five acres of buckwheat, and when it began to bloom, the hungry bees worked on it in the morning while wet with dew, and in the evening; so they soon filled their hives with honey, and had some surplus, which I sold at 18 cents a pound, keeping enough for family use. The bees are in the cellar, and are doing well, there being very few dead ones. I raised each hive an inch from its bottom-board.

Wintering in Chaff-Hives.—I. C. Horton, Muskegon, Mich., on Feb. 23, 1889, says:

I have 77 colonies of bees on the summer stands, in the Hilton Improved chaff-hives. They are in splendid condition.

Bait for Bees.—Mr. Jos. Dowell, Hicksville, O., on Feb. 25, 1889, says:

I would say in regard to Mr. Becker's question on page 108, that if he will put one or two drops of the oil of sweet anise in his bee-bait, when he goes to Lake Huron, I think that the bees will come back again.

Good Fall Honey-Flow.—H. S. Bowman, Maquoketa, Iowa, on Feb. 26, 1889, says:

Last season was hard on bees, and bee-keepers in this locality, especially in the spring, and what has always been our harvest; but the fall flowers came to the rescue, and sent the bees into the cellar well supplied with the nicest fall honey I ever saw.

Gathering Honey.—Wm. Richter, San Bernardino, Calif., on Feb. 16, 1889, says:

After having had very dry weather with plenty of wind and sand storms, rain set in to-day, so our prospects for a honey crop are good. Bees gathered a little honey from white thornbush and alfillaree. Dark sage will be in blossom in about three weeks.

Sub-Earth Ventilation, etc.—N. N. Betsinger, Marcellus, N. Y., on Feb. 19, 1889, writes:

If I am not mistaken, two years ago Mr. P. H. Elwood said at the New York convention that his cellar ventilators to admit cold air were entirely closed during the cold weather. If this is so, I would like to know of what use (aside from drainage) that immense sewer pipe is. On page 99 he seems to have changed his views. How can he harmonize this with the denunciation given two years ago on "scientific ventilation?" He then stated that 50 colonies of bees, in repositories, did not require any more air than one person!

Dr. Mason is to be congratulated on his article on basswood honey on page 103. In order to better inform our Canadian cousins, let me say that we have one supply dealer in New York State who cuts enough sections every season to hold more than all the honey produced in the Dominion of Canada. That supply dealer is only one of the many, but he is the largest in our State.

Bees Wintering Nicely.—A. F. Wheeler, Rossville, Iowa, on Feb. 21, 1889, writes:

I commenced the season of 1888 with 13 colonies, increased them to 31, by natural swarming, and 7 or 8 swarms went to the woods. I took 1,000 lbs. of surplus honey in one-pound sections, about half of which was white clover, the balance being light amber. I lost 2 colonies by the worms, or by my neglect of them in the harvest. I put 29 colonies into winter quarters, 25 packed in chaff, and 4 in the cellar. They seem to be wintering nicely, the thermometer registering from 41° to 45° in the cellar. The coldest that it has been out-of-doors is 12° below zero. Ten cents per pound in trade is all that I can get for honey at the grocery store, and I wont take it; 12½ cents is the least that I have sold any for.

Good Results in 1888.—John N. Eubank, Slater, Mo., on Feb. 23, 1889, writes:

I commenced the season of 1888 with 22 colonies, which I increased to 35, by natural swarming. I obtained about 1,900 pounds of honey, principally white clover, and about 400 pounds from red clover. My bees worked on red clover more the past season than they ever did before; but I do not like the honey, as it is dark, and stronger than fall honey. Considering the season, I think that my bees did well. Bees have wintered well in this locality so far. To-day was the coldest of the season—7° below zero. My bees are wintering on the summer stands, have had good flights every few days this winter, and appear to be in a healthy condition. My bees made the best record of any in this locality the past season, as I obtained over 85 pounds of surplus per colony, spring count.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ¼ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¾@6c.; dark amber, 4½@5½c.
BEESWAX.—18@22c.
Jan. 25. O. B. SMITH & CO., 428 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@19c.; best 2-lbs., 16@17c. Sales quite brisk, and market nearly cleaned up of all undesirable honey.
Feb. 28. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@17c. Sales slow. Extracted, 9@10c.
BEESWAX.—22@23c.
Feb. 11. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 18@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX.—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand is only moderate. No overstocking of the market.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 21. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs, 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD.
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. March 16, 1889. No. 11.

EDITORIAL BUZZINGS.

A little bit of patience
Often makes the sunshine come,
And a little bit of love
Makes a very happy home;
A little bit of hope
Makes a rainy day look gay,
And a little bit of charity
Makes glad a weary day.

The Weather in England during February is described as "boisterous," with high winds, fitful storms, rain, hail and snow. The honey season of 1888 was a very disastrous one in England, as well as in America. We are all hoping for a better season during the present year.

Lexington, Ky.—Last week we received an article for the BEE JOURNAL bearing the Lexington, Ky., postmark, but having no name of the writer. If the person who sent it will send us his name, the article will appear in print—otherwise it will have to go into the waste basket.

The Apiculturist for February is just received (our regular copy having been lost in the mail and this is re-sent to fill its place), and our thanks are due to brother Henry Alley for his very kind remarks, "eudorsing" the "note" added to our biographical sketch by Brother Root in *Gleanings* for January. "Kind words can never die." It is a solid pleasure to notice the very friendly feeling now existing among apicultural editors. May it ever continue. Differ we must; to discuss many points of these differences is necessary, but when a kind feeling underlies the discussion, only good will result from it.

More Humbug.—C. M. Burgess, of Council Bluffs, Iowa, on Feb. 23, 1889, wrote us as follows:

MR. EDITOR:—The enclosed was clipped from the Council Bluffs weekly *Nonpareil* of Feb. 14, 1889. Do you think there is anything in it? I think all bee-keepers rely upon you to explain, and also to expose all frauds, and bring the offending parties to justice and repentance. The AMERICAN BEE JOURNAL is a very welcome visitor.

The clipping which Mr. Burgess sent originated with the Davenport, Iowa, *Democrat*, and reads as follows:

A NEW SWINDLE.—A new swindle is said to have been discovered at Oskaloosa, by a woman coming in a drug store and buying a half ounce of "attar of roses"—a butyraceous oil of delicious fragrance, which separates itself from the rose-water during the distillation of dried petals of roses.

A reporter heard this order, and his curiosity became strong as to why she should want so much of this expensive oil—retailing at from $10 to $15 an ounce. After much investigation he found that she used it in the manufacture of "pure" honey.

Syrup made of the proper consistency and color—an easy undertaking—with enough of this oil added to give it flavor, an article in all appearance, smell and taste, so closely representing honey as to fool the most expert; and thus at a cost not to exceed 3 or 4 cents per pound to the manufacturer, this bogus honey is sold in this market as straight, pure strained honey.

Bro. Burgess asks us, "Do you think there is anything in it?" No, there is nothing in it but *falsehood!* It is another of those sensational stories "gotten up for spice" by a reporter for the daily press.

In one particular it is like the Wiley *lie*, written for the *pay* which the daily press gives for sensational stories, and if the writer is cornered, he will claim that he wrote it as a "pleasantry," never expecting that any one would be foolish enough to think there was a word of truth in it!!

This time they want to bring our sisters into the mess, by saying that it was a woman who bought the "attar of roses" to fool the community with. No, sir: no woman did it. She knows more than that, and has more good, sound sense than to try to do anything of the kind! She knows that the addition of "attar of roses" to "syrup" would not "make honey" that will "fool" any one—much less an expert!

The idea of paying $10 to $15 an ounce for "attar of roses" to put into "syrup," and then say that the cost of the conglomeration is only "3 or 4 cents per pound!" Such a thing is ridiculous!

To say that "this bogus honey is sold in this market as straight, pure, strained honey," is an insult to common sense.

We call upon the Davenport *Democrat*, and all who have copied the item to retract it—and save themselves from being the laughing-stock of the age!

A Directory, containing the names and addresses of those interested in apiculture is being gotten up by Mr. Henry Alley, of Wenham, Mass. It will cost $1.25. As soon as it is published we will give a further description of it.

Another Swindler.—A fellow by the name of Lincoln, whose address is given at "89 Aberdeen Street, Chicago" (but who cannot be found at that place), is offering recipes for "artificial honey," which he avers can be made for "8 cents per pound," and can readily be sold at "from 25 to 35 cents per pound," and is "equal to bees' honey," being often "mistaken by the best judges to be genuine!!"

Accidentally we ran across one of the dupes of this man Lincoln, who had honey recipes for sale. We denounced him and his recipes as *frauds*; the fellow was scared and "lit out" as rapidly as possible.

Think of the idea of being able to sell "artificial honey" at from 25 to 35 cents per pound, when the real article of the most delicious kind can be bought from ⅓ to ½ of that price! The fellow, Lincoln, is more of a knave than a fool. He not only tries to swindle the buyers of the "artificial" humbug, but also swindles the agents who buy his recipes by holding up fabulous prices and sales as an inducement for them to engage in the nefarious business!

Echoes is the name of another home-made periodical of 20 pages, published by Will M. Young, of Nevada, O. Both the price and frequency of issue seem to be an enigma at present with the editor. He says:

We would like to issue monthly, but cannot say in this number how often—probably quarterly for 1889—and *one* issue per year may exhaust us completely, and disgust our friends.

The first issue shows considerable tact and some ability in the editor. The quality of the paper is good, but the printing is inferior. Five columns are devoted to bees and their management. The editor has 60 colonies, and had an average of 43 pounds of surplus to the colony, last season. We have read the first issue with considerable interest.

Mr. A. I. Root was so well pleased with his trip to California, that he is still giving very interesting accounts of it in *Gleanings*. More than that, he has planned another trip to the Pacific slope, and intends to stay longer, and see more of that wonderful country, and its wide-awake and jolly bee-keepers. He intends to take Mrs. Root with him next time. We almost envy him the pleasure. When we went to Europe ten years ago, he remained at home hard at work—now the tables are turned, and it is our turn to stay at home and work.

When Systematic and harmonious energies are put forth in defense of any pursuit, such efforts cannot fail to win. When the editors of the bee-periodicals all lay aside every trace of selfishness or party-spirit, and work solidly for the prosperity of the pursuit, it not only shows a pleasing prospect, but it also assures its ultimate success.

GLEAMS OF NEWS.

The Anatomy and Physiology of Bees was the subject of a lecture recently delivered by Mr. John Aspinwall, at the Cooper Institute, New York. The lecture was illustrated by stereopticon views. The New York *Times* gives this amusing account of it:

While in its physical make-up the bee is in many respects the opposite of man in its habits and tricks, yet it very much resembles the lord of creation, and were bees to be transformed into men, some would undoubtedly go into the police force, or in the board of aldermen, while there would not be a few successors to Jake Sharp, and to the inexperienced young toughs who get clubbed by the police, and are then sent up to the penitentiary for dishonesty and general "sass." The occupations of walking delegate and dude mashers are also found in apiarian society.

The little bee, that is, the worker, is a horny-skinned child of toil. It is incased in rings and shields of smooth horn to shield it against attacks of its own species, and it toils as long as there is light. It has not got backbone like a man or a mule, but instead it has a little sting that serves its purpose just as well, and thus manages to maintain its rights. Between its tongue and sting there is a complicated mechanism that is of great use to the farmer and to nature. Aside from the honey that it distils, and which is worth thousands of dollars annually to the farmer and to commerce, its habit of poking its head into flowers and covering it with pollen, which it brushes off into other flowers, renders it a benefactor to nature in fertilizing flowers.

Before the advent of the bee in Australia, it was impossible to get any seeds of red clover there. Of course its process of storing honey might not suit the most fastidious taste, but honey is partially digested cane-sugar, made so by the aid of bee saliva, but as the bee is a perfectly clean little animal that revels in nectar all day long, these little irregularities must be overlooked. Besides, it uses a different mouth for the honey.

The bee is a good flyer, but as its wings are smaller in proportion to its body than are those of the eagle to the king of birds, it has to flap them more frequently, so it flaps away at the rate of 446 flaps to the minute. It has no lungs, but a system of tiny air-tubes extend through all parts of the body, and these it packs with air when it wants to fly. Neither has it a heart, but a dorsal vessel that pumps the blood to the head. The head, as magnified on the screen, is not a beautiful object, and as it is not the center of the nervous system, it would not miss it very much if cut off, if it were not for the eyes, two of which have 4,000 lenses each to see the honey-flowers afar off, and two others to assist in doing the microscopical work in the hive.

The entrances to the hive are very carefully guarded by sentinels, and every bee on arriving at the door is challenged by them with their antennæ. If it can give the countersign it is admitted to the sanctuary, but if it cannot, it is in danger, for bees are very nervous insects, and draw stings on the slightest provocation. The applicant must be a thief, and old thieves are detected by experienced sentinels, but the form of challenging must be gone through first. The old thief-bee is fat, sleek, shining and very suave. If caught by sentinels it will at once try to make a deal and offer the policemen some sugar, and while they are eating, it either slips in and fills up at the cells, or it retreats and tries another hive. If the sentinels are incorruptible, the thief humps itself, then draws its horny shields tight around it so that the stings of the policemen may not penetrate, and runs. A young thief stands up to fight, and gets clubbed. It learns by experience.

The queen-bee has not such a very easy time. She has plenty to eat and eats it, and flies very little; but as she has to lay all the eggs of the colony, and often lays more than her weight of eggs in one day, the bees begrudge her nothing, but let her have her own way everywhere.

The drone is the dude and walking delegate of the hive. He is not very numerous, however. He is fat, and spends his time eating honey, flirting with the girls and the queen, and then takes a quiet nap in the sun. When his charms no longer please he is driven out, and if he cannot get a berth in another hive, he starves. The little worker, however, according to the lecturer, does not fare much better. She lives for about six weeks, when she becomes feeble, her wings get torn and fringed, and she lies down to die in the field, refusing to return to the hive and become a burden to the colony.

Paper has been used for so many things that we are not surprised at any suggestions in that line now. We have bee-hives, railroad car wheels, and a score of such things made of paper, but we draw the line at organ pipes, that is not only humorous but musical. An exchange is responsible for the following item on the subject:

A novel application of paper pulp has recently been discovered, and consists in the production of organ pipes from that material. The origin of the industry is somewhat curious. Crespi Rigtuzzo, the curate of a little Italian village, was desirous of supplying his chapel with an organ, but as the commune was too poor to find the necessary fund, he and an engineer of the name of Colombon hit upon the idea of making the pipes of paper pulp, which gave such satisfactory results that the patent has been sold in Germany for £2,500.

Pruning Fruit Trees.—We occasionally meet with persons who think that trees, in order to bear properly, should be pruned every spring. Similar persons think they cannot start the year aright without a dose of spring physic of some kind. The trees may need pruning, but, at this season or at any other, one rule should be observed. No branches, large or small, should ever be cut away without a reason for it. One should be able to say to himself, why will it be better for the tree to remove a certain branch than to let it remain? If this rule were observed, there would be much less pruning than at present.—*American Agriculturist for March.*

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

Pat Buys a Bee-Smoker, (he has heard somewhere that a smoker is necessary to subdue the bees; he gets one, and is examining it). Shure, and it's an illigant poipe ye'll make entoirely, and wid sich a foine large hole ye have to dhraw wid, and a lovely bit of wood to hould by—but, whisha! where does the terbaccy go? (Turns it over, and at last pulls off the end). Bedad! it's a terbaccy jar ye are wid hould enough for a wake and niver a poipe at all, but I'll thry ye. (Puts in all he has, lights up, and sucks contentedly with the nozzle in his mouth.) Arrah! ye little stinging bastes it's me revenge I'll be taking av yer, for whin ye made me face like a pertatie, and the praste himself didn't know me. (Squeezes the bellows accidentally, and gets a good puff or two internally.) Augh, augh, it's—augh—bad luck to ye for stame injin, ye've clane kilt me entoirely. (Is about to give up in despair when the local expert arrives.)—*Honey-Suckle in the British Bee Journal.*

Good Prospects.—A few weeks ago we asked for reports as soon as it could be determined as to the condition of white clover in the various localities—some having reported that it had been damaged by the freezing and thawing, being uncovered with snow. Mr. C. H. Dibbern, of Milan, Ills., on the 7th inst., makes this report on the subject:

I have carefully examined the white clover in this vicinity, since the ground has thawed out, and find it in excellent condition. I have also taken out 25 colonies of bees from the cellar, and they are all right, too, being exceptionally bright and healthy. I do not think that our winter losses will be over 2 per cent. With improved hives, a better system of management, safe wintering, and an assured honey yield, I consider the prospects very good.

Mind and its Mysteries.—It would be very nice if we could put a mind under a bell-glass as we do a bee-hive, and watch the coming and going of fancies, and the laying up of thoughts—sweet fancies gathered from flowers of fact in memory's cells. —*Rev. James Hamilton, D. D.*

Catalogues for 1889 are on our desk from—

Thos. G. Newman & Son, Chicago, Ills.—36 pages—Bee-Keepers' Supplies.

H. E. & E. L. Pratt, Marlboro, Mass.—16 pages—Bees, Queens, and Apiarian Supplies.

Dr. G. L. Tinker, New Philadelphia, O.—20 pages—Syrio-Albino Queens and Bees and Apiarian Supplies.

H. H. Flick, Lavansville, Pa.—4 pages—Poultry and Turkeys.

Christian Weckesser, Marshallville, O.—8 pages—Seeds, Plants, Potatoes, Bees, etc.

H. P. Langdon, East Constable, N. Y.—4 pages—Bees and Queens.

J. M. Hicks & Co., Indianapolis, Ind.—1 page—Bees and Apiarian Supplies.

Charles A. Green, Rochester, N. Y.—50 pages—Nursery Stock.

QUERIES AND REPLIES.

Amount of Drone-Comb for a Single Colony.

Written for the American Bee Journal

Query 618.—How much drone-comb should there be in each hive to place its colony in a normal and thrifty condition?—S. G.

There need not be any.—A. B. MASON.

Not over 3 square inches.—WILL M. BARNUM.

As little as possible is enough.—R. L. TAYLOR.

Six inches square, in the aggregate.—MRS. L. HARRISON.

Three or four inches square would be plenty.—J. P. H. BROWN.

The bees will take care of that.—H. D. CUTTING.

None, unless you wish drones from that colony; then very little goes a long way.—A. J. COOK.

I would not put any in. The bees will get in a little in spite of you.—C. C. MILLER.

The least you can get built. The bees will look after that, if you try to have none.—EUGENE SECOR.

There will always be sufficient to meet Nature's requirements. How to prevent *too much*, is a wiser consideration.—J. M. HAMBAUGH.

From 2 to 6 square inches, or just enough so that the bees will not cut down worker-comb to build drone-comb.—G. M. DOOLITTLE.

My *design* is to have none, and with this design in plain sight all the time, I have more than I want. A queen-breeder will properly have a different view.—J. M. SHUCK.

None are needed, except for queen impregnation. Two full sheets of drone-comb in a good colony, in an apiary of any size, are sufficient for the entire apiary.—DADANT & SON.

Very little; in fact I do everything possible to prevent them having any at all. It is better policy to select one or two colonies of extra nice bees, and give them a frame of drone-comb for the purpose of supplying drones for the apiary.—C. H. DIBBERN.

I never put in any (except in a few choice colonies for having drones to rear queens), as the bees will always fix some places in the combs for the queen to lay drone eggs.—P. L. VIALLON.

Now here comes a question about which I differ from the "books." My experiments with colonies on *perfect all-worker combs*, has led me to the conclusion that the presence of drones is not essential to normality in a colony of bees, when speaking of colonies as individuals. The whirring noise of the drones' wings in the throng of busy workers is as assuring to the colony that has no drones, as it is to those that have them. Neither does the absence or presence of drones affect the swarming fever, in my judgment. Notwithstanding, I prefer to give all my best colonies some drone-comb.—G. W. DEMAREE.

A long discussion could arise regarding the word "normal." I have had strong, thrifty colonies which gave an immense amount of surplus honey, that had not a drone-cell, nor a drone in the hive, the whole season through.—JAMES HEDDON.

That will depend upon the age of the queen and the conditions of the colony. When I know just what the word "normal" means, I may be able to answer; but different minds give a different meaning to it, so that it is impossible to decide just what the word means, unless more is stated.—J. E. POND.

Normal and thrifty conditions may not go together. A colony may be more thrifty when it is not normal, than when it is. A colony is normal when it has the amount of drone-comb which it would build if left to itself; but it will be more thrifty if it has only a few square inches of it.—M. MAHIN.

Permit just as little drone-comb as possible, and then you will have "an abundance." If you want drones from that special colony, you might permit more drone-comb than usual.—THE EDITOR.

Rearing Drones when Supplied with Worker Foundation.

Written for the American Bee Journal

Query 619.—Will bees rear drones in a hive supplied with full sheets of worker foundation?—G. G.

Yes.—H. D. CUTTING.

Yes.—J. P. H. BROWN.

Occasionally.—WILL M. BARNUM.

Yes, a few.—R. L. TAYLOR.

Yes, but very few.—C. C. MILLER.

Yes, to a limited extent.—J. M. HAMBAUGH.

They will rear all they need.—EUGENE SECOR.

Occasionally very little; usually not at all.—A. J. COOK.

Yes. They will make places for a few.—M. MAHIN.

Yes. Bees will have some drone-comb anyway, according to my experience.—G. M. DOOLITTLE.

If you mean the lower hive, they will rear a few, if you allow them to swarm naturally.—MRS. L. HARRISON.

Yes, they will be almost certain to find some place where they will rear some. If no better place offers, a few drones will be reared by lengthening out worker-cells.—C. H. DIBBERN.

Certainly not, unless, as is sometimes the case, they build a few drone-cells upon worker foundation.—JAMES HEDDON.

Yes. They will enlarge the worker-cells in the lower corners of the comb, sometimes only on one side of it; and they will frequently enlarge cells in different parts of the comb.—A. B. MASON.

Yes; there are always some places where they will, and if there are none, they will make some. Foundation limits the drones, but does not entirely prevent them.—P. L. VIALLON.

There are always a few corners or some places where the foundation stretches a little, where drones will be reared; but the extensive and unprofitable production of drones will be prevented.—DADANT & SON.

Yes, more than are wanted. Foundation does not prevent drone-rearing, but curtails it—keeps it within bounds. There are spaces often in the edges of the combs, also in the bee-space around the frames, where they may be built. I have seen the central space in sectional hives entirely filled with them.—J. M. SHUCK.

Yes, most certainly. You cannot prevent Nature from carrying out her own operations. Not as many drones will be reared, to be sure, but those that are reared in worker-cells, will be dwarfed in size. To prevent excess, I use young queens, and a small amount of drone-comb.—J. E. POND.

If the combs are not perfect, and do not fill the frames perfectly, a few drone-cells will be fashioned by the workers, and a few drones will be reared. But with good sets of all-worker combs drawn from foundation, I work many colonies that are positively without drones at all times.—G. W. DEMAREE.

Yes; the dictates of Nature will be obeyed. The bees will enlarge cells at the corners to accommodate the rearing of a few drones.—THE EDITOR.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

CORRESPONDENCE.

FOUL BROOD.

Spring Care of Bees—How to Distinguish Foul Brood.

Written for the American Bee Journal
BY RANDOLPH GRADEN.

As the winter has been very mild and pleasant for bees, so far they have wintered well; but as the most trying time is yet to come, it is necessary to see that they have plenty of stores, for if the warm weather should continue through February, the bees will start breeding early, and consume considerable honey.

As March and April are very trying months for bees, too much care can hardly be given them, so that the brood does not get chilled. Colonies that are expected to be short of stores, or are weak in appearance, should, when the weather is warm enough to admit of so doing, be examined, and the brood-chamber contracted to suit the size of the colony, and, if short of stores, they should be fed.

Colonies that are not doing as well as they ought, or are not doing as well as those around them, should be examined to see if they have a queen, and if not, a queen should be given them, or a frame of eggs and brood, so they can rear their own queen. They ought also to be examined to see if they are affected with the disease called "foul brood" (or bacillus alvei), as we hear that there is a great deal of that disease in the country.

Appearance of Foul Brood.

In its first stages, the larvæ when attacked begin to move unnaturally, and instead of being curled around on the bottom of the cells, they sometimes turn in such a way as to present their dorsal to the eye of the observer, and it may then be noticed that the color of the larvæ is somewhat yellowish instead of being pearly white. Larvæ thus affected seldom are sealed over, but such grubs as are further advanced in growth before the disease strikes them, are in due time sealed, but as they die, their bodies turn brown and become a putrid mass, the cell sealing sinks, and a small, irregular hole may be seen in the capping. The bees may also be seen very energetically fanning at the entrance of the hive, and in advanced cases an indescribable odor may be observed; and if the cappings of the diseased cells are removed, a very brown, coffee-colored mass will be seen at the bottom of the cell, which is so tenacious that if a head of a pin is inserted into the mass, it may be drawn out, a thread-like and ropy substance. The foregoing are the general indications of the disease.

Propagation of Foul Brood.

Foul brood is a very contagious disease, and if started, and not properly treated, so as to check its progress, it will rapidly spread from cell to cell, and from colony to colony.

As to the propagation of this disease, the conclusions are varied, and as yet not fully understood; but many of our leading apiarists have the idea that the bees, while robbing the depopulated colonies, carry the bacilli or spores on their bodies, or in the honey from apiary to apiary, and from hive to hive. Some go even so far as to think that if a bee visits a flower that has been previously visited by a bee from a diseased colony, the spores of the disease can be picked up in that way, and carried to the hive. I do not think that this is quite correct, and my reasons are these:

About three years ago I noticed a colony that was in advanced stages of the disease, that was being robbed, and upon investigation, I found that the robber bees were located less than half a mile away, and the robbing had been going on for some time, as quite a line of bees were going to and from the hive, and most of the honey from the outside frames had been carried away by the robbers; yet, strange as it may be, no disease has appeared. This shows that the honey contained no spores; also that the bees, by flying less than half a mile, carried no spores to affect the colonies that contained the robber bees. Still, when the disease is once started in an apiary, it spreads very rapidly.

Now if the honey contains no spores, the question would arise, how is the disease propagated? Would it not be reasonable to suppose that it is carried from hive to hive through the air, as an indescribable and nauseating odor is emitted from the hives where the disease is somewhat advanced? What is odor, no more nor less than very minute parcels from the substance from which it arises? and in these progressive times in bee-culture, when bees are sold by the pound, and bees and queens are shipped and sent through the mails from State to State, and from country to country, the disease may also in this way be carried from one country to the other.

It may, after being once started, if not properly treated, become hereditary; as one of our Professors has said, that a queen reared in a foul-broody colony would not live over one year, which I know is not always correct, from the fact that I have seen a queen that was reared in a very foul-broody colony, that lived a part of three years, and lived through two winters; yet if not always treated in the brood-rearing season, her progeny would be affected, and foul brood again appear. This colony was examined in the latter part of August in the third summer of her life, and the brood was all apparently in a healthy condition, yet after leaving them without treatment for 21 days, upon examining the colony, it was again found to be affected with the disease, and upon giving them a heavy dose of the treatment in the forenoon, they swarmed out and left the apiary, going in a southerly direction. This shows that it would be very dangerous to procure a queen that had been reared in a foul-broody colony.

I think that I have shown some very good reasons, as to how bacillus alvei get into a colony. It is also quite certain that very many bees of a colony may be diseased for weeks and even months with this bacillus, and yet foul brood may not be seen, as bees clear out infected grubs so that the infection may not be seen, and yet exist. As to the method of treatment, it is varied, as some use salicylic acid, and others use phenol (carbolic acid); also camphor, powdered coffee, dairy salt, and a preparation of salicylic acid, bi-carbonate of soda, dairy salt, and soft water; also thyme, sulphuric acid, etc., and the "starvation plan." It is evident that the disease yields very readily when properly treated.

SWARMING.

A Woman's Experience in Keeping Bees.

Written for the American Bee Journal
BY MRS. MARTHA ANDERSON.

We have had a mild winter, and my bees, I think, are wintering nicely. Last summer we had a very strange season. My bees commenced swarming on May 16, and kept it up until Aug. 21. They stored no honey the forepart of the season at all, but I suppose they must have gathered enough to stimulate the queen, and to feed the young bees. I do not think I ever saw bees multiply like mine did all through the season. The frames were full of brood in different stages of development, and I kept close watch of my bees, so as not to lose any swarms, until in July, when I thought they had swarmed all they were going to, and as there was no honey for them to get, I found out that they had been swarming all the time, and my neighbors had been getting them. I knew that they

were mine, for I have the only Italian bees in the neighborhood.

After I found that they had taken another "round" of swarming, I began examining them, and took out as many as 12 queen-cells to the hive. From Aug. 15 to the 20th, I examined all of my colonies, wanting to know how many I would have to feed. There was only a few but what had just about a spoonful of honey to the hive, and I thought it would be quite an undertaking to feed 32 colonies that were so strong. I had 10 colonies in the spring of 1888, and they increased to 32 strong colonies.

The fall honey-flow commenced about Aug. 21, and I do not think that I ever saw bees work so hard as mine did. They filled the brood-chamber in a very short time; altogether they stored 650 pounds of nice comb honey in one-pound sections. The flow continued four weeks, or until the frost came. When one swarm issued on Aug. 5, I was entirely out of foundation for them to start on, and I did not get any, because I thought I would not need any more. I took a frame out of another hive, and put it in with a little syrup made of granulated sugar, and in two or three days the queen was laying, and they went to work making comb in which to store honey. That colony filled the brood-chamber and stored 16 pounds of surplus honey besides.

I put the bees into winter quarters in November, and the hives were all that two could lift. I have a long shed for them, open to the east, and packed them in straw. They are all doing nicely. There are not many dead bees to be seen as yet. I think that there will be danger of them dwindling in the spring, on account of the open winter we are having. I like the BEE JOURNAL very much.

Bushnell, Ills., Feb. 23, 1889.

THEORIES.

Theoretical Knowledge in the Art of Bee-Keeping.

Read at the Indiana Convention

BY G. K. HUBBARD.

The proper place for theory to end and practice to begin, before a person's knowledge shall be accepted by others without numerous reservations or exceptions, is a difficult matter to decide in the thousand-and-one questions that are constantly coming up in life; and of course in a pursuit like bee-keeping, where much thought and study are a necessary adjunct, the question comes with more than ordinary force.

As in every other controverted question, there is in this a "golden mean" to strike; and in the judgment of the writer, that person, who has reached the half-way point between the two extremes, is the successful apiarist.

I am inclined to the opinion that bee-keeping need not necessarily be carried on by specialists, with their hundreds of colonies, but that every farmer or tradesman who can take an interest in bees, should keep a few to supply honey for home use.

Among the great mass of bee-keepers, as we find them scattered over the country, there is far too little theoretical knowledge. This is shown by their ignorance of many of the facts concerning the habits and characteristics of bees, that the more intelligent apiarist is as familiar with as he is with the names of his near relatives. With such persons, a thorough study of the theory of bee-keeping will give them more confidence in themselves whenever they wish to vary from some old plan, or when a new difficulty presents itself.

In 1881, when I was quite young in the bee-business, a gentleman asked me to unite 2 colonies of bees for him. I told him I never had done the like, but knew how it was done (you see I had the theory), and a little later, when I had the 2 colonies in one hive, acting as much at home as though they had always been together, I had made a start in the "practical;" but the theory first learned from books, was as valuable as though the same knowledge had been acquired from experiments.

James Heddon has recently said: "I know pretty well who are the practical honey-producers in this country. One who has read and written for papers, and produced honey on a large scale for twenty years knows the difference immediately between a theoretical and practical writer. Such a one, when reading an article, no matter how eloquently and skillfully written, will at once and correctly determine whether the writer has an apiary in his brain, or in his back yard. I look with interest for articles from such men as R. L. Taylor and others I might mention, who ship their honey to market by the carloads."

Here is a good point. We accept information from people whom we know are well posted in apiculture theoretically, with much more certainty, if it is backed by large practice, and especially so if abundant success has crowned their methods of procedure. Let us not forget, however, that it is rarely that a person will succeed in anything by being a mere imitator. You may read a plainly written article on some subject, that takes in more than a brief operation, like the uniting illustration just used (say for example, "The production of comb honey," or "A season's procedure in queen-rearing"), and while we might all be pleased to get the writer's views, not one progressive, intelligent apiarist would do exactly as described.

Your own ideas and methods will creep into all that you do; and thus, unconsciously, you adopt a plan of your own, and with reasons, too, for your method. You see the theory of some one else, and your practice will not always work; but the theory varied to suit your own surroundings, and thus applied to your practices, will be found to harmonize very well. This implies intelligence and a qualification we may call "tact."

I mean by this, good judgment and adaptability; and I consider it perfectly fair to insert this qualification, because I believe that a person who has it not, would be more likely to fail in almost any business. And as bee-keeping is far from being an exception in this respect, it is only fair to assume that a reasonable degree of tact will be employed in reducing to practice the ideas suggested by others.

Keeping in mind the idea which this construction of the word "theoretical" implies, it will be seen that we can very properly be theoretical apiarists to quite an extent. But if you should narrow down the meaning of theoretical, so that it applies only to that species of speculation which never will receive a decisive answer, and from the nature of the case cannot be reduced to practical advantage in the apiary, then of course there can be but one answer to the question.

The bee-keeping fraternity cannot be benefited by people who "dream dreams and see visions." We wish to spend our time on that which will make us more successful from a dollar-and-cents stand-point; that which will enable us to more completely control our colonies as we wish; that which enables us to put a first-class article of honey on the market, with the least expenditure of labor; that which will enable a beginner to expect a reasonable degree of success when he puts in practice the information that he has gained from others. Such theoretical bee-keeping is at once theoretical and practical; and practical theories are of great value, because they carry with them satisfactorily explained reasons, and give the possessor that intelligence and perception that is at the extreme opposite of "luck."

In this busy, pushing world, it is the intelligent, active man who wins—the man who keeps posted, the man who is quick to perceive and apply valuable points in what he reads. A person who is well informed in current bee-

literature, is said to have the theory of the pursuit well learned; and I maintain that, as the pendulum swings between such theory and that other method of procedure—which is nothing more or less than driving ahead in ceaseless, wearisome labor in the apiary, with no thought for new developments, or the plans of others—that between these extremes the successful apiarist will be passed as the pendulum passes the golden mean between them.

WINTERING.

Saving Stores in Wintering Bees in Cellars.

Written for the American Bee Journal

BY JOSEPH BEATH.

In answer to Query 613, on page 101, in regard to wintering bees outdoors, one replies thus: "The extra amount of honey used, is used as fuel to keep the bees warm. Is the fuel you burn in your stove, in keeping the house warm, wasted? If so, had you not better move down cellar with your family, so as to save it?"

Now that is precisely what people have done in Kansas and Nebraska, where both lumber and fuel is scarce, and the soil is generally dry. But who would think of doing it where both fuel and lumber were plenty, and the subsoil full of water?

Again, a part of another answer reads as follows: "Honey used to keep the bees in the hive warm, should not be deemed *wasted*; wood or coal used to keep humanity warm in houses, is never thought to be wasted—each serves the purpose intended."

Exactly so! because a house is the best protection against the elements man has yet been able to devise, and the better that house is built to retain the heat, the less fuel it will take, and the more comfortable the family will be. But, suppose instead of going into the house to make the fire, you should go into the back yard, erect an Indian wigwam, build your fire in it, and take your family there to warm, say with the mercury at zero; would not most of the fuel and the comfort of the family be wasted then? And is not this nearer the condition of a colony of bees in a common hive, left out-of-doors in an average Northern winter?

Of course, the wigwam was all right for the Indian, for it was the best he could do; but surely one-half of the men that keep bees, already have cellars that they could put them into, at least in the Northern States, where it is profitable to do so; and it seems to me, all that might be saved and is not (less the cost of saving), is clear loss.

I leave out of the question the disputed point as to which will come out best in the spring, but I believe, say north of 40°, 41° or 42° north latitude, it has of late years been in favor of the cellar. A large part of the spring dwindling in cellar-wintered bees, can be avoided by letting them alone until warm weather comes, and they can go to work.

The greatest bee-man that used to be in this county, used to winter his bees successfully until about March 1, and then he would put them out, and clean out all the hives, and by May, when they could work, they were half dead; and finally one spring they all died.

Corning, Iowa.

STRONG TEMPTATIONS.

You might as well say to the bee,
As she 'lights on the lip of a flower:
"Its beauty you're welcome to see,
But the honey must stay and get sour."
Do you think she would listen to you long,
With the treasure just under her eyes?
No; she'd find the temptation too strong,
And make a bold dash for the prize.

Or, supposing a bird on a tree,
Where cherries were rosy and sweet,
And you told it to let them all be,
For you thought them too pretty to eat:
Do you think that the bird would obey,
And with feasting its eyes be content?
No. "To let such fruit spoil," it would say,
"Was never Dame Nature's intent."

So do not be cruel and scold,
And ask me a promise to make,
That I'll never partake of the wealth,
That's forbidden to any to take;
For honey was made for man's use—
Though the bee may utter "Nay, nay!"—
Yet 'tis taken away just the same,
And not even a "Thank you" we say.

EVOLUTION.

The Growth and Atrophy of Animal Organs.

Written for the American Bee Journal

BY J. F. LATHAM.

In that pearly atom, the ovum of the queen-bee, are stored the concentrated efforts of nature for limitless epochs, which now develop a perfect insect in sixteen days. The food supplied to the larval bee during the various stages of its growth, bears a strong resemblance to that which is supplied by the co-operating agencies, to nature's spontaneous offspring at a corresponding stage of development. The manner of receiving that food by glandular absorption is very nearly the same in each. At a certain stage the molecular diet is discontinued, and the organs of generation are bared in their growth, illustrating very definitely at what point in the development of cosmic life the same act was consummated by the hidden agencies of nature; thereby establishing the individuality or duality of the sexes as seen at the present time.

From this stand-point, which embraces, so to speak, a view of the sphere of the reproductive agencies in the economy of nature, the evidence is very nearly absolutely conclusive, within the scope of our present sense, that in their primitive stages of development, organisms pertaining to animate life were (and are) androgynous. By discarding conditional conclusions, and assuming this to be a fact, the evidence is as conclusive that the entites of each distinct species would comprise but one gender nominally, but in reality possess the germs of both in a stage of development compatible with the grade of progress to which they had arrived in their evolutionary rounds.

In that occult description of the "creation," delineated in the first chapter of Genesis, we are taught that the waters were commanded to bring forth the moving creature having life, and fowl that may fly in the open firmament. Next we are taught that the earth was commanded (admonished) to bring forth the living creature after his kind, cattle and creeping thing, and beast of the earth after his kind; all in the singular number and masculine gender.

Again, we are assured that the beast of the earth was made after his kind, and the cattle after their kind, and every creeping thing upon the earth after his kind. Lastly, in the order of progressive "creation," man appeared in the image of his Maker—man, by possessing faculties, or attributes, superior to the collective forces of the whole animal "creation" that preceded his advent.

In the second chapter of Genesis, in review of the first chapter, we are taught that man was formed of the dust of the earth, the breath of life was breathed into his nostrils, and man then became a living soul—an intelligent being. As this narrative of the "creation" (purported to have been drawn from Acadian and Turanian sources, more than a thousand years prior to the compilation of the Book of Genesis, as evinced in resurrected Assyrian literature), is but an epitome of the occultism which underlies the development of modern geological research, it requires no stretch of the imagination to grasp the fact that in the first stages of evolution pertaining to the present order of things on this planet, in animate organic life, that which is termed sex, was represented in specific language as a personifica-

tion of the ubiquitous life power so subtly expressed in Oriental physics, as the only one living element of the Universe—the spiritual and material principle, which,although unconscious, and in an indefinite sense "non-existent when separate," develop "consciousness and life when brought together."

Could we go back to the dawn of evolution, when cosmic matter received the first impulse of the spiritual efflux, and imperceptibly responded in the primoidal ripples of life, and accompany it in its cyclic rounds through the countless ages of changing progress until it culminated a comparatively perfect organism, the problem of atrophy in useless members of the body would be readily solved.

As the matter now appears, it seems that the most rational solution of the phenomena would be that, Mother Earth, stimulated by her surrounding correlatives, takes the lead in the changing courses of destiny relative to her offspring, and molds them to the sway of the ruling impulses accompanying the successive periods of growth and disintegration consonant to their situation. If the life element will only admit the existence of monads, Nature is in a condition to nurse them to existence. If the cosmic elements warrant their existence, molecules will make their appearance.

Another degree, and the entites are prompted to life at the starting point of organic beings—beings organically androgynous—thrown from their defferentiating centres in numberless divergencies,supported in their impetus by the agencies which gave them birth; and destined to survive or subside, as the cyclic or cataclysmic changes incident to their progress directed. If, in their passage along the ascending line, the revolutionary changes from water to land rendered them amphibious, and legs and feet were needed to harmonize their existence to the change,the same agencies that prompted the dawn of being was ready to administer to their needs. While in the water, scales were the best protection for their bodies, fins the best means for locomotion, and gills the best organs to convey oxygen to their circulating fluids. When the drift of circumstances decreed the air to be their theater of life, the hidden forces which evolved those circumstances, gave them wings as means of transport from place to place, when searching for sustenance or habitation.

If in a cooling atmosphere, the combustion necessary for their existence required protection, the "Elemental Guardians" supplied them garments of hair, fur or feathers, as their sphere of life required—and, Nature being impartial in the exercise of her functions relative to her multitudinous designs, no discrimination was made, or is made in her dealings with any one species of (animal) life in its journey from the infinitely small to the infinitely great—from inorganic matter to organized intelligence. When, by changing conditions, members once useful to the body become useless, disuse would render them mummetied indices of by-gone functions; thus displaying in the atrophied glands of the queen-bee, that parthenogenesis was, at one period in the existence of her species, a more substantial reality than at its present stage of development; and that one of the functions of our "babboon ancestors" is indicated in the mammary glands of their progeny, leaving an opening for a shadowy conclusion that, with the countenanced authority of ages, as to the merits of a sacred trust, a discrepancy exists in the primeval distribution of the generative attributes.

Cumberland, Maine.

HORTICULTURE.

The Relation of the Honey-Bees to Horticulture.

Read at the Nebraska Convention

BY REV. E. T. ABBOTT.

A very close connection exists between the two subjects, and the relation, one to the other, should be considered in all its bearings. It is evident that flowers are useful to insects, but the question arises, are the insects of any use to the flowers?

First, it is to be seen what benefit the insect is to horticulture, and then what harm, if any, the insects cause to flowers.

An ordinary flower will be taken for an example. Inside of the corrolla is a set of organs called stamens, and on top of them is an organ called anther, containing a powder known as pollen, which carries the male element of the flower, or the sperm-cell. In the center of the flower is another organ, or organs, called a pistil, composed of three parts, the stigma, style and ovary. The ovary is a hollow case or pod, which contains rudimentary seeds, and in which are found at the proper time the embryo sac that contains the germ-cell. To produce fruitage the sperm-cell must be brought into immediate contact with the germ-cell. The question is, how are these two elements to be brought together?

When all of the organs are found in one flower, or in the case of the one described, the process is very simple. A gentle movement of the wind after the anther has ripened will shower the potent grains of pollen down upon the receptive stigma. Soon there is found what is known as the pollen-tube, which, growing downward through the style, enters the cavity of the ovary, and guided by some mysterious yet unerring power, makes its way to the embryo sac. Movement, growth and all formation commences, and thus is formed the fruit and seed, in which lies beautifully folded the embryo plantlet of the future tree, bush, vine, or whatever it may be.

In some flowers the process of pollenation is more complicated. They are so constructed that the pollen cannot reach the stigma, although in the same flower. In some instances the pollen dust is so constituted as to be of no use to the pistil of the same flower, and in many flowers the stamens and pistils are not fully developed at the same time. In these and in other cases some outward agency must be looked to, to bring the two elements together. This brings up another important part of the subject. Not only pollenation is desired, but pollenation in such a way as to secure cross-fertilization, preventing what is known among stockmen as "in-breeding." Here comes in the work of the bees. In visiting the flowers they carry pollen from flower to flower, and thus do for the plant what it cannot do for itself.

It has been shown by experiments that self-fertilized plants, that is, fertilized by their own pollen, are generally much inferior in vigor and strength to those that are cross-fertilized. In many gardens and greenhouses bees are kept for this very purpose.

In this connection, lest some one may ask why this mixing up of pollen of various plants will not create great confusion by the production of hybrids, etc., it may be stated that Aristotle observed, over 2,000 years ago, that bees visit the flowers of the same species as long as they can, and this has been confirmed by later observation. The wind, and other insects than bees are valuable in accomplishing cross-fertilization, but many trees and plants have to depend upon the bee.

The question now comes up, do bees ever injure fruit? The prevailing testimony seems to be that, as a general thing, bees do not perforate flowers. The main ground of complaint has been that the bees injure the fruit itself, especially the grape. Prof. McLain, who is employed by the Government to make experiments in apiculture, has devoted considerable time to this subject. He confined a number of colonies of bees in a house, and endeavored by heat, etc., to bring

about drouth, and they were brought to the stages of hunger, thirst and starvation, the test lasting forty days. Thirteen varieties of grapes were placed before them, and every opportunity afforded the bees to appease their hunger, but in no case were the bees able to pierce the skin of a sound grape, or otherwise harm it. When the skins had been cracked or bursted, the bees lapped and sucked the juice out, but the sound fruit was untouched. My own experience has corroborated these statements. The jaws or mandibles of a worker-bee are not constructed for cutting hard, tough substances.

Permit me to make one remark in conclusion that does not properly relate exactly to the subject, but rightly grows out of it, I think. In religious matters I am inclined to be very liberal, and give the utmost liberty to others; yet it seems to me that no man can study carefully such statements as I have made and kindred facts without being forced to the conclusion that there is a "power not ourselves" behind nature, "which makes for righteousness," whether he agree with me, and call that power God, or not. To me all this is the manifestation of an Infinite Father, and I would it might be to all men.

St. Joseph, Mo.

COMB HONEY.

Some of the Practical Points in its Production.

Read at the Maine Convention

BY L. F. ABBOTT.

There was a time—away back so far that we do not care much about it now—that honey formed the great sweet of the world, and it held its place in the affections of our old-time esteemed relatives up to a little matter of time of about 200 years ago—more or less, a few years either way makes no difference.

The production of cane sugar and syrup by the production of the slaves in the seventeenth century (our remote relatives had not begun to imbibe the great moral lessons taught by the bees), had, in a great measure, displaced honey as an article of food, and while our several-times great grandfathers quite readily "caught on" to the idea of manufacturing sweets themselves from the products of the fields in the sugar-cane, they had the most ridiculously absurd notions concerning the wonderful little bee, that has not changed a whit in its instincts, habits or want of respect for its friends. Hence, while the bee was just as wise then as to-day, and laughed out of both corners of its mouth at the old-time obtuseness of our relatives, in missing the real "business end" of the bee—for which, as now, they often gave emphatic pointers—for this reason slow progress was made in improvements in bee-culture, and instead of increasing the number of colonies, there were annually thousands of them destroyed with the brimstone match, in order to secure their honey. So, on account of this wholesale destruction of bees, and the lack of a proper knowledge of their instincts and their successful management, honey fell into comparative disuse for many years; and this state of things continued, with only slight improvement up to within a quarter of a century ago. Since that period the most wonderful strides have been made, both in the science of bee-keeping and the appliances used in the successful management of bees.

These wonderful improvements, and the close study and painstaking experiments that Yankee bee-keepers have adopted, have been the means of increasing the amount of honey-production immensely, and if this production continues to increase as rapidly during the next ten years, as it has in the last decade, may we not reasonably expect that honey will take its place among the leading products of this country?

Strength of Colonies.

A fundamental principle to be observed in the production of honey in either form—comb or extracted—is strength of colonies; and I would, if possible, make provision for the contingency of weak colonies in the spring, by having all colonies go into winter quarters strong in numbers. There are extremes to be avoided in both ways—too large colonies and too weak ones.

I mean by that, that the abnormally large colonies we often find in the apiary, where a part or all have been run for extracted honey, are not the best to winter, unless special provision is made in order to get them through, and then, my experience has been that it is better to divide such colonies immediately after the summer harvest is over, giving a laying queen to the queenless portion, and build up two colonies for winter in lieu of one. There is a strong liability that the large mass of bees in such a colony, left undivided, will die before spring, while on the other hand, the two medium ones, if properly taken care of, are pretty sure to survive the winter months.

These medium populous colonies in the fall—which may be called strong ones—as a rule, are the ones which will come through the winter, when wintered in a good cellar, nearly as strong as when they are put into winter quarters in November. This may be accounted for on the supposition that early breeding commences, and their number are kept up by the production of young bees.

Now I know there is a point for discussion here; some of our best apiarists believing that it is injurious to the future prospects of the colony to have the queen commence laying before March or April; but it is needless to remark that it is the strong colonies which store the surplus honey in June and July, and take advantage of the white clover harvest. Then the question arises, how shall we attain to this maximum strength of colonies, unless we can start with strong colonies when put upon the summer stands from the cellar?

Now, on the other hand, a weak colony put into winter quarters in November or December, will be weaker in April or May. A little patch of brood will probably be found in such, the last of March. Such colonies cannot be expected to begin work in surplus cases, at least until seven frames of the Langstroth size are pretty well crowded with bees. Ordinarily this cannot be accomplished till the summer honey harvest is well advanced, unless such colonies are helped by stronger ones; and this is hardly a paying method.

All of our considerable apiaries contain more or less colonies of bees which do not come up to the standard of honey-production that others do. I know there are causes, other than the one I have set forth, to which the difficulty may be attributed in part. These are—some of them—want of prolificness in queens, disease in winter depopulating the colony, loss occasioned by age of bees, etc.

Then, if my premises are sound, the first point to be considered in the production of comb honey is the oft-repeated injunction, to have strong colonies in the spring, and to accomplish this, we must adopt a plan at the close of the preceding honey harvest, to insure strong colonies of young bees to place in winter quarters.

Putting Bees Out of Cellars.

Spring now comes with its vicissitudes. The fact is generally admitted (disbelievers can learn by experience) that bees wintered in-doors are more subject to loss by spring dwindling than those wintered out-of-doors. To obviate this as far as possible, it is best to keep the bees in the cellar till May 1, if they can be kept quiet. There are exceptions to such a rule, for sometimes our seasons give us warm weather, and that continuously from

April 15. The past two seasons, early May brought cold weather, which the bees could have passed to better advantage in the cellar, rather than "nosing" around the willows with "overcoats and mittens on."

Stimulative Feeding.

The question of stimulative feeding in the spring is one of importance. There is no question but such feeding has an effect upon the colony in quickening their energies and giving them the impulse of breeding. This impulse is not confined to the queen alone, as some people seem to believe, but the energizing influence pervades the whole colony.

The question of feeding in the early spring to induce breeding is one which needs to be carefully considered, because it is easy to do more harm than good by adopting the practice. I believe it is better to feed in September for spring strength than in the following May, unless it be the very last of the month, as the seasons latterly have come to us.

Keeping the Bees Warm.

But there is one thing that is always in order in early spring, and that is, to take every precaution possible to retain the internal heat of the hive, and prevent ingress of cold from without. The bees have this provident care inherent in their nature, as is shown by their care in sealing up all cracks and crevices in every part of the hive before the advent of cold weather.

The moving of hives in the spring, and manipulating them from the top, as each hive should be when placed upon the summer stands, so far as is necessary to clean out all dead bees and remove moldy combs, and to contract the brood next to proper size for the colony; these manipulations necessarily sunder the carefully glued joints and crevices, leaving numerous ways for the cold to creep in, and warmth to escape from the hive.

This may be quite effectually prevented by the use of cushions, dry chaff and leaves—the latter is always preferable to chaff. Extra pains to tuck the cushions and quilts down, and not be sparing of the amount put on through May, will pay for the trouble.

For the reasons just stated, I would as far as possible winter bees in chaff hives, or change the colonies to such as soon as practicable in May. The chaff hive as now made is superior to the single-walled hive. To Mr. E. P. Churchill, of Hallowell, I believe, belongs the credit of making improvements in the chaff hive, which places it ahead of any single-walled hive I have used for the production of comb honey.

Lewiston, Maine.

HONEY-LABELS.

The Granulation of Extracted Honey—Report for 1888.

Written for the American Bee Journal

BY CHAS. K. BIXLER.

I have before me some labels bearing the following inscription: "This honey will candy as soon as cold weather begins, and is, in fact, the best proof of its purity."

Candying may be a proof in some localities, but is certainly not in this. I have at present honey in glass and earthen jars, both filled at or nearly the same time, of the same kind of honey, and having the same kind of covering. Both jars were kept in the same room, and subject to the same temperature. The honey in the earthen jar was candied long ago, but in the glass jar it is liquid still. Now if the glass jar had been labeled as above, and been sold, what would the purchaser have thought? He would have had some reasons for thinking that it was adulterated. It might leave a wrong impression.

In the winter of 1886 heart's-ease honey did not candy until very nearly spring. I believe that the labels should read so as to leave a possibility for the honey not to candy, something like the following: "This honey may candy," etc.

The Season of 1888.

In November of 1887 I put into a cave 35 colonies of bees. All wintered excepting two, which starved. But very few had honey enough to last until the time of white clover bloom. April was dry, cold and windy, and everything was very late. Box-elder blossomed the last of the month, and bees did very well on it for a few days.

May was cold and wet, and bees did nothing during fruit bloom. They had but little brood for the time of the year. White clover began to bloom the last of May, but yielded little or no nectar. Feeding was the order of the day during the first of June, but in the latter part of the month white clover yielded enough honey to start swarming. I had 6 swarms in an apiary of 33 colonies, mostly Italians. Black bees in this vicinity swarmed from one to four times each.

Basswood failed, and during the last of July some colonies absconded. A good deal of feeding was done. The fall rains began early, and continued through August, which produced an enormous growth of flowers. Beekeepers were hopeful, but just as the principal plants began to bloom, a hailstorm cut down everything in the flower line in this immediate vicinity. The sugar-barrel was the only apparent outlet. The hail was on Aug. 10; on Aug. 17 bees were gathering enough honey to live on, and in a few days they began storing in the surplus receptacles.

On Sept. 12 the flow ended. From 36 colonies I got about 800 pounds of heart's-ease honey—about half comb honey, in one-pound sections. The brood-chambers were solidly filled, and bees have more honey this winter than any winter since 1885. The last was the third poor season in this locality; but white clover is in good condition, and we are hoping for a good flow of honey in 1889.

Honey sold here for 18 to 20 cents per pound for comb, and 10 cents for extracted.

On Dec. 4 I put the bees into a cave. The winter has been very pleasant so far, the temperature in the cave being at or near 42°, Fahr. The bees seem to be wintering finely, and very few dead bees are to be seen.

Hoyt, Iowa, Feb. 4, 1889.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Mar. 13, 14.—Cedar Valley, at Waterloo, Iowa.
J. J. Owens, Sec., Waterloo, Iowa.

Mar. 30.—Agency, at Agency, Mo.
T. S. Smith, Sec., Agency, Mo.

Apr. 23.—DesMoines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees and Toads.—E. E. Smith, Watertown, Wis., on Feb. 26, writes:

On page 102 Mr. E. Strong writes about toads eating bees. As I understand him, he says that toads will not eat bees. The toad that he was watching was either a cunning one, or a different species of toads from what we have here. I had one hive last summer that had a poor cover, and as I did not like the hive, I did not take the trouble to make one, so I put it under a shed. The floor of the shed was about 8 inches from the ground. I leaned a board from the ground to the floor of the shed, so that if any bee happened to fall on its way home, it could come up on the board. One night in the summer I heard a toad coming through the grass, as much as

a rod away. I step back to to see what it would do. It came on and up the board to the front of the hive, and there it stopped. The bees were running around in front of the hive, and one bee came in the direction of the toad, when the toad made a spring, and the bee was gone. The bee was as much as 10 inches away when the toad sprang. I saw it take as many as a dozen bees, and each time the toad took a bee, it stepped back to its place and waited for another. I saw the toad do it again the next night, when I shoved it up to the entrance of the hive, and let the bees punish it; then I took it to the garden, where it belonged. I like to have toads in the garden, as they are very great bug catchers.

Good Season Expected.—Christian Weckesser, Marshallville, O., on March 1, 1889, writes:

Bees seem to be wintering nicely. Much of the winter here was pleasant, but bees have not had much of a flight since November. Of late the weather has been rather severe, but it is moderating, and we hope to soon hear their merry hum again, and hope also to have a better honey season than we have had for several years. I think that the indications are such, and it is well, at this season of the year, to make preparations for it. Many farmers have neglected their bees because they have not been profitable, thus leaving the field almost entirely to those who will be wise enough to have their "dishes right side up" when the flow comes.

Honey Colic.—B. F. Barb, Joetta, Ills., writes thus on Feb. 27, 1889:

Nearly half the people in this locality dare not eat honey on account of its giving them the colic. What is the cause and cure for it? Who will answer?

As Mr. Barb is located in the same county as Chas. Dadant & Son, we referred the matter to them for answer. They say:

We do not know what to answer. Although this is at the other edge of the county, we do not think that the blossoms differ any. We have known of many people that honey made sick, and we find that all such people will easily become accustomed to eating and digesting it by using it regularly, in very small quantities at first. Usually, after the third meal, the stomach is used to it. We find, also, that granulated extracted honey digests best, and that fresh honey is the reverse.

Sickness from eating honey often comes from incautiousness, eating too much of it, or eating it while the stomach is working on food not entirely digested, but in course of digestion. Honey excites the secreting glands of the alimentary ducts to such an extent that it is a good remedy for constipation, and when it is ingested between meals, the course of digestion is sometimes deranged by the influx of too much gastric juice, and pains, colics, etc., are the result. Honey being a laxative, it is best not to eat it in too large quantities when not accustomed to it. We do not know of any unhealthy honey produced in this vicinity.—CHAS. DADANT & SON.

White Clover.—Mrs. L. C. Axtell, Roseville, Ills., on Feb. 23, 1889, says:

On examining the white clover, Mr. Axtell found it injured some by the dry weather of last season, but he thinks if we get suitable rains, we may yet have a fair crop of honey.

Removing Bees from Cellars.—T. Walker, Ashton, Ills., on March 1, 1889, writes:

I would like to learn whether I must place my bees in the same spot when I take them from the cellar, that they were in when I put them into the cellar; or can I place them in a different part of the lawn, without danger of losing any of them?

[If put out of the cellar upon the old stands it may save some *old* bees—to the young ones it will make no difference; therefore it would be preferable, if convenient, to return the hives to the summer stands they occupied when taken into the cellar—though it *may* make but little difference.—ED.]

Uncapping Honey, etc.—Henry Durham, Sylvania, Ind., on Feb. 19, 1889, says:

Bees are wintering finely in this locality. I have 16 colonies mostly in chaff hives. Last night was the coldest of the season—7° below zero. When I was young, I blacksmithed for a living. I heard of a young blacksmith who made a pair of tongs; when he riveted them, he could not work them, so he laid them down and went to an old smith and said that he knew a smith once who made a pair of tongs and could not work them. The old smith said that he ought to have heated the tongs and worked them. So the young man returned and finished them. I know a man that procured an extractor, and had no regular uncapping-knife; so he got a thin case-knife, bent it to suit, sharpened it nicely, tried to uncap a frame of honey, but the comb stuck to the knife like a piece of iron to the hand on a cold morning. Ought he to have warmed the knife? Let us hear about it.

Bees Flying Nicely.—Mr. C. W. McKown, Gilson, Ills., on March 5, 1889, says:

I put into winter quarters last fall, 99 colonies of bees in chaff hives; all are alive to-day, and apparently in fine condition, flying nicely, and seeming to enjoy themselves. As to the prospect of the coming season, I am no prophet.

Cooling the Cellar with Ice.—Wm. Pearson, Oswalt, Iowa, on Feb. 21, 1889, writes:

My bees are wintering nicely in the cellar. I put them in on Nov. 15, with the hives four tiers high. The weather at times here has been very warm, and the temperature went up to 52° in the cellar. At present we are having a cold spell. I will try to keep the bees quiet by putting ice in the cellar, which is not large, and I have 108 colonies packed in it.

Queenless Colonies, etc.—John Kerr, Cedar Falls, Iowa, on March 2, 1889, says:

I commenced the season of 1888 with 4 colonies of bees, being the second winter that I have had my bees out of the cellar. Two were rather weak. The season was very poor for surplus honey last year, and I obtained about 100 pounds of comb honey, had 10 natural swarms, and put 2 back. I have 12 in the cellar, which are doing well, to all appearance. Is it best to examine every colony in the spring to see whether they are queenless? If they are, what is the best course to pursue?

[Yes; it is desirable to examine all colonies in the spring, clean out the hives, and if any are queenless, unite them with a weak colony having a good queen.—ED.]

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin anew at any time.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, $1; ½ pound, $1.75; 1 pound, $3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¾@6c.; dark amber, 4½@5½c.
BEESWAX.—18@22c.
Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 16@18c. Market is very strong and stock of white comb honey is very light.
Mar. 9. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@17c. Sales slow. Extracted, 9@10c.
BEESWAX.—22@23c.
Feb. 11. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Gond dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@12c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.
BEESWAX.—22c.
Jan. 24. S. T. FISH & CO., 189 S. Water St,

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.
BEESWAX.—20c. for prime.
Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.
BEESWAX,—22c. R. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.
BEESWAX.—22@23c.
Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@16c. Demand is only moderate. No overstocking of the market.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 21. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.
BEESWAX.—20@22c.
Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.
BEESWAX.—None in market.
Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.
BEESWAX.—20c.
Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 6@6½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.
HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; amber, 6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c.; amber, 10@11c. Demand is of a jobbing nature, and arrivals are small.
BEESWAX.—19@20c.
SCHACHT, LEMCKE & STEINER,
Jan. 8. 16 & 18 Drumm St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. March 23, 1889. No. 12.

W. M. Barnum, of Angelica, N. Y., on March 11, 1889, says :

My bees appear to be wintering well. This is the general report of the condition of bees this spring, so far.

The Weather is so mild on the coast of North Wales that primroses, violets, snow-drops, chrysanthemums and roses are growing in the open air. The songs of the thrush and black-bird are heard daily.

The Eastern Markets being glutted with oranges, the Southern California growers lately ceased picking for a week. The orange crop in Florida is so great, and prices so low, that much of the fruit is allowed to rot on the ground.

Bee-Candy.—The *British Bee Journal* says : "What is known as Good's candy....should be properly called Scholtz's candy, as this gentleman was its discoverer." Perhaps brother I. R. Good will tell us about that ; or is the above item *news* to him as well as to many others ?

Feeding Rye Flour to bees is a seasonable matter now, and Mr. B. F. Sheets, of Wellington, Ills., made this request on March 9, 1889 :

Please tell me in next week's BEE JOURNAL just how to feed rye flour to my bees. The BEE JOURNAL has given me lots of valuable information about bees. I am only a beginner in the art of bee-keeping.

It should be put where the bees can get at it. Dr. Miller says : "The best way I have tried is to take hive covers 6 or 8 inches deep, put a stone under each near the middle, and put the rye meal on them. As often as the bees work down the feed, turn the cover around so as to leave feed at the upper end." It should be covered so that rains would not make it wet.

Lynch Law.—Much has been heard of Lynch law, and perhaps it would not be amiss to record its origin. Mr. E. C. Jordan, of Jordan's Springs, Va., writes as follows :

Henry Howe's history of Virginia, published in 1845, on page 212, tells when and how "Lynch law" originated. The enclosed paragraphs were published in our local papers at a request. I hope you may think it worthy of a place in your paper :

ORIGIN OF LYNCH LAW.—Lynch law is pretty generally understood as the taking of life, without process of law, of a felon who has been convicted at the bar of public opinion of an offense deserving of death. But it is not so generally known that the name originated in Campbell county, Va., before the Revolutionary war. At that period the country was thinly settled, and was infested with tories and desperadoes—too many of them, apparently, for the local authorities to adequately punish. Col. Charles Lynch, a distinguished officer of the Revolutionary army, undertook to rid his county of the outlaws. He organized a force, arrested the outlaws, and having satisfied himself and comrades of the accused, executed them without reference to the constituted authorities.

While not altogether approving of the desperate remedy for a desperate cause, the beneficial effect of Col. Lynch's action was recognized, and has since been known as "Lynch's law," or "Lynch law."

Lynch's process of meting out speedy justice extended to other parts of the country, and is a well recognized form of redress of grievances to-day, particularly for that class of offenses that are popularly believed not to be adequately punished by the statutes and courts of the State. Col. Lynch's brother gave his name to, and founded Lynchburg, and left a son who was subsequently Governor of Louisiana.

Died at Quincy, Ills., at 1:30 a.m., on Sunday, March 10, 1888, Mr. C. H. Smith. Mr. Allen Lewton writes us as follows concerning the demise :

DEAR EDITOR :—I send you a notice of the death of our friend and brother bee-keeper, Mr. C. H. Smith, who has passed to the summer land, and left his 118 colonies of bees to be manipulated by other hands. He leaves a loving wife and four little children to battle with the cold world. He was one of the foremost and best-posted bee-keepers of this section.

The particulars sent are as follows, gathered from a Quincy daily paper :

Mr. Smith was born in New Orleans, La., in 1852, and next May would have been 37 years of age. In 1874 he came to this city, where he has since resided, marrying a daughter of Mr. Summers, pattern-maker at Thomas White's stove foundry. For years he has been engineer at White's foundry, until recently, when he was taken down with inflammation of the bowels. After suffering for some time he grew better, and his friends looked forward to his recovery, but two weeks ago he took a relapse, from which he never recovered.

How to Build a House.—This is the title of a new book containing plans and specifications for 25 houses of all sizes, from two rooms up ; also, engravings showing the appearance of houses built from the plans given. It also contains much that is valuable to those who intend to build. Price 25 cents. Published by J. S. Ogilvie, 57 Rose Street, New York.

Bees' Visits to Flowers.—Mrs. M. B. Chaddock, in the *Popular Science Monthly* for February, takes exception to an article which appeared in the October number of last year, from the pen of Mr. Grant Allen, concerning the visits of bees to one particular species of a plant at one time when in quest of honey. She remarks as follows in her own vigorous style :

It is not true that bees only visit one species of plants on each trip. Bees will go from the red to the black-cap raspberry and gather honey from both ; and from our sweetest and best grafted apple-trees to the green, bitter, wild crab. Because bees and insects do go helter-skelter among the flowers, we are always budding and grafting, and are never sure of any of our fruits that come from the seed. To prove this, let any one take some flour and stand among the red and black-cap raspberries where they grow close together, when the bees are roaring around them ; put some flour on a bee's back, and then watch it go from blossom to blossom. I think it must convince the most skeptical of two things : First, that bees work on different species ; and, second, the bees know nothing, and care less, about the good of the species. I say it is not true that bees work on the same species while on a trip after honey or pollen. I claim much more than this. They work on the flowers of different families. To prove this, go into a garden of flowers during a dearth of nectar, and watch the bees go from flower to flower. They will fumble around among the petals of any blossom that contains either pollen or nectar, mechanically and indiscriminately.

The January Number of the *Bee-Keepers' Magazine* has just come to hand. It contains an apology for being so tardy, and an announcement of its sale to the *Bee-Keepers' Advance*. Brother Aspinwall bids us all "adieu" in language as follows :

It is not without many sighs of regret, we say good-bye to our many readers, yet we feel it is our best course....The irregularity in appearance each month has worried the editor much, but the honest truth is that he has not had the time to devote to the work required of him as editor, proof-reader, advertising agent, subscription clerk, and many times, mailing clerk.

Shake hands, brother editors, of the agricultural world ; we say good-bye with no feelings of malice towards any of you. Certain it is we have had tilts occasionally, but there was no malice on our side, only a belief in our being in the right ; a simple difference of opinion.

Lastly, to our many readers, we must sorrowfully bid adieu—may God bless you all.

We wish the retiring editor success in his new vocation (at Washington, we believe), and hope it will be more pleasant and profitable than publishing the *Magazine* has been to him.

Catalogues for 1889 are on our desk from—

W. H. Norton, Skowhegan, Maine—1 page—Comb Foundation.

Wm. H. Bright, Mazeppa, Minn.—20 pages—Bee-Keepers' Supplies.

S. H. Colwick, Norse, Texas—4 pages—Bees and Queens.

Lewis Roesch, Fredonia, N. Y.—6 pages—Grapevines, Small Fruit, etc.

GLEANS OF NEWS.

Mr. Robinson, the one whose attack on the Rev. L. L. Langstroth was noticed on page 835 of our last volume, is so completely answered by Mr. Langstroth in the January number of the *Bee-Keepers' Magazine*, that he can offer no excuse even for his vile attacks on that gentleman.

Mr. Langstroth, after copying two articles entire from the AMERICAN BEE JOURNAL for 1881, on the subject, giving details, facts, and figures to disprove Mr. Robinson's bold assertions, quotes his letter to Mr. R., dated Feb. 26, 1881, the last paragraph of which reads as follows:

> Now, friend Robinson, from all I have ever known of you, I must think that you are a man who desires to do what is right. Weigh well what I say, and if convinced that you have fallen into error, I feel confident that you will do what is fair and honorable for all parties in this matter.
>
> Very truly your friend,
> L. L. LANGSTROTH.

Mr. Langstroth then argues the matter as follows:

I received no reply to this letter, and I have seen nothing further from his pen about this matter until I had read his *Magazine* article; from which it appears, that he not only insinuates charges of bad faith against Mr. Parsons, but conveys the impression that he regards me as a joint conspirator with him.

Now, Mr. Editor, the plain English of all this is, that Mr. R. insinuates that Mr. P. stole bees belonging to other parties, and that we then engaged in the business of selling queens, bred from his stolen property! and he further wishes the public to believe that my statements as an eye witness to the facts are unworthy of credit. Can Mr. R. expect to find any credence given by honorable men, to such insinuations?

As, however, he singles me out for a *direct* charge, viz., that while my motto on paper is, "'Give honor to whom honor is due,' I have signally failed to practice what I have preached, and I have tried to rob a dead man of honor justly due him," I must ask a little more space to reply to this accusation. For what Mr. R. quotes and refers to as authority for his insinuations and charges, it would seem that he had access to all needed sources of information, and has therefore no valid excuse for the mistakes he has made.

In the March number of Vol. I, of the AMERICAN BEE JOURNAL, page 69, I am reported as saying to a convention that met in Cleveland, O., on March 15, 1880, "Last fall, Messrs. Wagner, *Mahan*, and myself had imported a few colonies of these bees, *and this was prior to the importations of Mr. Parsons and the Patent Office.*" Does this look as though I wished to suppress the credit which belonged to Mahan and the Government for priority to Mr. Parsons?

Besides, my article in the AMERICAN BEE JOURNAL, from which Mr. R. quotes, declares plainly that Mahan's bees were on board the same steamer (in his own charge), that brought the bees for Wagner & Co. As regards Mr. R's attempt to make me guilty of "an outrage in attempting to wrest from Mahan the credit due to his enterprise," it seems to me hardly to deserve any serious notice.

We both admit that there was a struggle between two parties, as to who should have the honor to put ashore from the same steamer, the first Italian queen-bee. Neither of us pretends to have been an eye witness to the scene. Mr. R. gives his hearsay version of the affair, and I give mine. If the German captain was able to gratify his pride, not only in having the first Italian bee imported into this country, in his own steamer, but to be able to say that he brought the first living queen ashore, it does not detract one iota from the merit due to Mahan, as being the first person to make a special voyage to Europe to procure this valuable bee.

Mr. P. G. Mahan was one of the most skillful manipulators of bees I have ever known, and his name is honorably mentioned a number of times by me in my work on the "Honey-Bee," for new and valuable observations. More than this, in my history of the importation of Italian bees, which Mr. R. criticizes so severely, it plainly appears that while all the queens imported by Colvin & Co., in 1859, died before the next spring—and while only one queen with a handful of bees survived to Mr. Parsons, Mr. Mahan had so distanced all his rivals, in preserving and breeding from his importation, as to be able to supply me with American bred specimens of the Italian variety. L. L. LANGSTROTH.

Dayton, Ohio, Dec. 18, 1888.

Commenting upon the above, the editor of the *Bee-Keepers' Magazine* remarks thus:

Mr. Robinson, in a recent article, was very severe in his criticism of Rev. L. L. Langstroth. He made direct charges of bad faith against the latter, as well as Mr. Parsons, and we are glad that Mr. Langstroth has so carefully cleared up this matter, not in a spiteful manner, but by a statement of facts which can hardly be gainsaid. We believe in getting at the root of everything, and do not believe in hampering what might be the truth, by our personal opinion of an individual.

We are glad that Mr. Aspinwall, before retiring from the field, has done justice to Father Langstroth, by frankly calling his reply "a statement of facts which can hardly be gainsaid," which has "carefully cleared up this matter," etc. It has always been as clear as the noon-day sun to every one who wanted to know the truth.

The Annual Crop Report of the Department of Agriculture, just issued, shows that there is a larger aggregate product of cereals than has ever before been recorded. It will amount to about 3,200,000,000 bushels or, fully fifty bushels per head. This is about three times the average supply per capita of Europe from home production, and receipts from other countries amount to only about one bushel per head. The aggregate potato production is about 200,000,000 bushels. The wool clip of 1888 was slightly reduced in consequence of the reduction of flocks in Texas and elsewhere. The estimated product is 269,000,000 pounds. The meat supply has been very abundant.

The area of maize, as estimated for the crop of 1888, makes an increase of 3,280,043 over the crop of 1887 and 13,304,259 acres over the 1879 census, indicating a gain of 21 per cent. in nine years. The estimate of wheat area makes a reduction of 305,645 acres from the breadth of 1887. The aggregate is 37,336,198, an increase of only 1,905,805 on the area of 1879, or a little more than 5 per cent. The exports will probably be less than those of 1879-80 by at least 100,000,000 bushels, a quantity more than ample for the annual supply of all the increase of population since 1880. There appears to be a further increase of the area of oats, amounting to 1,077,376 acres, or about 41,000,000 bushels increase in the quantity produced. The yield per acre is 26 bushels against 254 bushels in 1887.

The Dog and the Bees.—A dog being annoyed by bees ran, quite accidentally, into an empty barrel lying on the ground, and, looking out at the bung-hole, addressed his tormentors thus:

"Had you been temperate, stinging me only one at a time, you might have got a good deal of fun out of me. As it is, you have driven me into a secure retreat; for I can snap you up as fast as you come in through the bung-hole. Behold the folly of intemperate zeal."

When he had concluded, he awaited a reply. There wasn't any reply, for the bees had never gone near the bung-hole; they went in the same way as he did, and made it very warm for him.

The lesson of this fable is, that one cannot stick to his pure reason while quarrelling with bees.—*Scl.*

Laughing.—Mr. C. Osborn, of Danville, Ind., on March 9, 1889, sends us the following:

> DEAR SIR:—Could you afford to reprint in your valuable BEE JOURNAL Mr. Secor's "Removing Bees from the Cellar," and "What is the Use of having Friends," etc., for the special benefit of the bee-keepers of this vicinity? We have been two years without honey, and are so blue that we never laugh!

Oh! yes, we might reprint it sometime, as soon as we find room. It will help us all to "laugh and grow fat,"—grow more amiable and jolly as the years go around. It will never pay to be *blue* and melancholy! Never.

The April Number of *Frank Leslie's Sunday Magazine* is unusually rich in illustrated articles of present interest. Among them may be mentioned "American Engineers in Angola," by David Kerr; "Duluth and Environs," by William H. Ballou; "Through the Alleghanies on a Locomotive," by H. W. De Long. Easter coming in April, there are some poems referring to that festival, and an article and illustation on "Lily-Culture in Bermuda." Dr. Talmage's sermon is on "Easter Blossoms," and the music page is devoted to an "Easter Carol," by Arthur Henry Brown. The number also contains much interesting miscellany.

QUERIES & REPLIES.

Honey-Extractors—Comb Honey vs. Extracted

Written for the American Bee Journal

Query 620.—1. In making an extractor for the Langstroth frame, should the frame stand on its end, or hang by the top-bar? 2. Which is the most profitable to produce, comb honey at 15 cents per pound, or extracted at 10 cents per pound?—W. S.

1. It should stand on the end. 2. Extracted.—WILL M. BARNUM.

1. Perhaps on the end. 2. I do not know. May be extracted. — C. C. MILLER.

1. Let the frames stand on their ends. 2. Extracted honey, if you have to ship to a market.—P. L. VIALLON.

2. Extracted, if you can dispose of it at that price.—H. D. CUTTING.

1. It should stand on its end. 2. At those prices, the profits would be about equal.—J. P. H. BROWN.

1. On the end, as the size is less, and the extractor is cheaper. 2. For the average man, extracted; for the expert, comb honey.—A. J. COOK.

1. The frame should stand on its end—otherwise the extractor will be too large around. 2. I think that there is not much difference.—E. SECOR.

1. It should stand on the end. 2. If equally easily sold at those prices at wholesale, I should have little choice, and should allow my taste to decide.—R. L. TAYLOR.

1. Let the frame stand on its end. 2. Extracted, by all means; for the labor is less, and the yield much greater.—DADANT & SON.

1. It should stand on the end. 2. It will depend something upon the locality; ordinarily there would be little difference, I think.—MRS. L. HARRISON.

1. It should stand on its end. The honey is more easily thrown out when the frame is put in top downwards. Hanging by the top-bar is the worst position. 2. Extracted at 10 cents per pound.—M. MAHIN.

1. The Langstroth frame should stand on the end in the extractor. 2. Personally I prefer to produce comb honey at the same price as extracted, and as long as I could get 5 cents more per pound for it, I should not lose any sleep figuring on it.—J. M. SHUCK.

1. If you wire the frames, they should stand on the end. 2. Extracted honey at 10 cents per pound, for me. —J. M. HAMBAUGH.

1. It should stand on the end. 2. In some localities, comb honey, and in others, extracted. If one could be sold as readily as the other, extracted would be the most profitable.—A. B. MASON.

1. It should stand on its end. 2. It will depend upon the season and yield, and the experience of the operator, and the demand for honey. With me, I can do better with extracted boney at 10 cents, than comb honey at 15 cents. Others can do better the other way. Try each plan, and see for yourself.—J. E. POND.

1. I do not think that it makes any difference how the frame goes into the extractor—at least I could never see that it did. 2. If each kind sells in about the same length of time in your market, one would be about as profitable as the other.—G. M. DOOLITTLE.

1. I prefer the frame to stand on its end, and to swing towards the bottom-bar of the frame; for the reason that cells incline upwards, and the honey is more easily thrown out. 2. If I could sell extracted honey readily by the keg or barrel, I think that I should say extracted. With me, however, it is very slow sale, and I prefer to produce comb honey, for which there is usually a good demand at 15 cents or more.—C. H. DIBBERN.

1. My extractor takes the frame standing on its end, and I would not have it otherwise. 2. It is most profitable to me to produce both liquid honey and honey in the comb. It would depend upon the readiness of the sale of the one or the other article. If there could be any reason why I should decide to produce all my crop in one or the other form, at the prices you mention, taking one year with another, I would risk the honey-extractor.—G. W. DEMAREE.

1. There are advantages in both ways. If you have plenty of material, ample room in your honey-house, and propose to extract a great deal of honey, then I would advise you to take the combs—well, there are advantages both ways, and I do not know which I would choose. 2. It all depends upon the color of the honey taken from your fields, the strain of bees you keep, what you know about the production of the different kinds of honey, and your market. Usually the proper answer would be, "Extracted honey."—JAMES HEDDON.

1. Usually it stands on the end, and it is just as well. 2. At the prices quoted, the profits would be about equal. —THE EDITOR.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Swarms.—John McKeon, Dryden, N. Y., on March 2, 1889, writes thus:

A favor will be conferred if Messrs. J. E. Pond, R. L. Taylor and G. W. Demaree will please answer the following questions: 1. Is it a violation of the Sunday law of New York State, to hive swarms on Sunday? 2. Has a person a legal right to go on the premises of another to get a swarm off of a tree, or other place, if no damage is done?

By request, those mentioned in the query, have answered as follows:

1. No, it is not.

2. Consent must be obtained to go upon another's land for any purpose. Otherwise trespass is committed.—J. E. POND.

1. Works of "necessity and charity" are expressly excepted from things forbidden to be done on Sunday. To hive a swarm of bees is a necessity, as much as to take out a "beast fallen into a pit," and therefore is not a breach of the law.

2. No. If the swarm is his own, and he has followed it, keeping it in sight, he has the same right to take it that he would have to follow his horse on the land of another, and take it. To do so in either case, would be a trespass, if without license from the owner of the land, express or implied. See Goff *vs.* Kilts, 15 Wend., N. Y., Rep. 550.—R. L. TAYLOR.

2. I believe that the Sunday law of the State of New York is very nearly like that of this State (Kentucky)—all work is forbidden except "works of necessity." From my earliest memory the hiving of swarms of bees has been regarded "work of necessity" by the best men I ever knew. It is therefore not a violation of law to hive swarms of bees on Sunday.

2. According to the "common law," if you keep in sight of a swarm of bees and they "settle" on the lands of a neighbor, you may take the bees without violating the law, if you do not damage the owner of the land. But if your neighbor was at enmity with you, and should forbid you to go on his premises, you then might resort to law in an action for the possession of the bees, by what the law books call "claim and delivery," and you ought to recover them. In accordance with the principles of law, bees may be removed just like other property, if they can be certainly identified.—G. W. DEMAREE.

CORRESPONDENCE.

NATURE'S WAY.

Are we Going Against Nature in Working for Comb Honey?

Written for the American Bee Journal

BY G. M. DOOLITTLE.

When I first began bee-keeping, the sections or honey-boxes were not like those of the present day, as a part of them were made to hold 15 pounds, while the smallest boxes then in use in this locality held fully 6 pounds. Some of these boxes had glass sides, while others had only a small piece of glass over an auger-hole, so that the owner of the bees could see through this glass to tell when the combs were completed, or when the honey was ready to take off; for, when these combs were sealed next to the glass, the whole of it in the box would be so, as a general rule.

In these boxes we frequently found brood and pollen, even when a hive as large as 2,300 cubic inches was used, and many wondered why the queen would go above to lay, when there was apparently plenty of room for her below. The reason for this, as I look at it, is that new comb is being built above, which is generally of the drone size of cells, where the bees have their own way in building it, which, with the desire of the queen to be where the bees are the most active, causes her to go into the surplus arrangement to lay.

Some seem to think that this trouble of brood and pollen in the surplus apartment of the hive is something that comes by our working against Nature in these latter days, caused by the contraction of the brood-chamber, which is done by many of our leading apiarists; but this is a mistaken idea, for I found more brood and pollen in my comb honey years ago, before I ever contracted a hive, than I have since, where no queen-excluding honey-board was used.

As time passed on, the thought originated in some enterprising bee-keepers' head, that honey would sell better if stored in still smaller boxes than those weighing 6 pounds, so we soon had the 3-pound box. This box was used in the same way as its predecessors had been, namely, with glass sides, while it was made long enough to hold only one comb, which comb was about 2¼ inches thick when completed. With this box I had very little success, for the bees seemed very loth to work in it, and when they did so, they would frequently try to put in three combs, which made it in very poor shape for market. For this reason I decided that it was not in accord with the nature of the bees to be cut up in so little clusters, and have their combs as thick as 2¼ inches. Consequently I went back to the 6-pound boxes again, leaving it to others to work the smaller ones as they pleased.

When the 2-pound sections with separators were introduced, I considered them as being still worse than those preceding them, for the bees were divided into still smaller clusters than before; at least this was my first thought. One night, while lying awake thinking on the subject, I believed that I saw a difference between this way of using small boxes and the old way, where glass was used on both sides of the box; for in using separators, the bees were not, properly speaking, divided into little clusters, but virtually had one box of the size given by the number of sections used in one tier, which was generally twice the amount of the 6-pound boxes; for as the tin did not come within ⅜ of an inch of either the bottom or top of the sections, the bees and warm air could pass from one to the other just the same as if no tin was there. But there was so small an entrance that I feared this would be a hindrance to the bees coming up in the sections to work to good advantage, and in order to overcome this, I left the bottom off of all those first used, so that I might not meet with a partial failure, as I had done with the 3-pound sections or "boxes," as all such were termed at that time.

My yield of honey from colonies in these hives was greater that fall than from the other hives, which went far more toward convincing me that this plan would succeed better than anything else could; but I found that in leaving the bottom of the sections off, I had gotten into a job which I did not care to go through with again, and, beside, in using the tin separators so narrow that ⅜ of an inch was left both above and below them, I had a bad job here also, for the bees built through here so that the combs were mashed in putting on the glass afterward.

Although still fearful that I might lessen the yield of honey by putting on the bottoms of the sections and widening the tin, yet I resolved to try, so the next season found me putting sections on a few hives, the same as I use them now, while the rest of the apiary was worked with the 6-pound boxes as heretofore.

At the end of that season I found that the colonies having the sections with separators, gave me the largest yield, and the combs in these sections were simply perfect; while many of those in the larger sections were far from being so. These sections had a comb about 1⅜ inches thick, which thickness the bees seem to prefer for storing honey, although they can be made to use either of those thicker or thinner. The entrance to the sections also seemed ample, and by a little figuring, I soon saw that the ¼-inch space between each section was greater as a whole than the entrance given to the larger box.

When the next season came, I worked about half of my bees with sections, and the other half with the large boxes, thus using caution when starting out on something new, as I always think it advisable to do. The result of that season proved the same as that of the seasons before, so that I then adopted sections entirely, and firmly believe that such an arrangement does not inconvenience the bees in the least, over what they would be in a box of the same capacity without separators.

When the queen-excluding honey-boards came before the public, I tried them slowly, as I did the sections, using more and more with each year, till to-day I am fully prepared to say that none of these things are of any inconvenience to the bees. Only in this way can any one fully say what is good, and what is not; for the condemnation of a thing without using it, amounts to nothing. The old injunction of "prove all things, and hold fast to that which is good," is as valuable to-day as it ever was.

Borodino, N. Y.

MANAGEMENT.

Putting Bees Out of Cellars—Spring Methods.

Written for the American Bee Journal

BY MISS IDA L. SMITH.

The best time to take a retrospect of any line of action is after we have passed through it, and by our failures in the past we are able in a degree to avoid the rock upon which so many are wrecked. In apiculture, as in many other pursuits, to avoid failures many of our plans have to be laid, reaching far ahead. It is not in the management that prepares the strong colonies for the honey harvest, that an apiarist shows his skill, but in getting the weak colonies strong, and ready to go into the sections.

Apiculture is a continuous chain the year around, each part of a season depending upon the preceding, so that entering upon spring management of bees we will presume that everything has been done in the proper way, and at the right time; we will especially assume that the bees have been win-

tered in a cellar, and everything surrounding them, and the care, was such that there has been no loss of vitality other than would result from age.

In this latitude the time to carry the bees out of the cellar is usually from April 20 to May 1. In removing bees from the cellar, a time should be selected that has the appearance of several warm days together. A little ingenuity can be used in devising plans for carrying them out, that would be the least fatiguing. The work should begin as soon as the sun is sufficiently warm in the morning, for the bees to commence their cleansing flight almost as soon as they are placed on the summer stands.

The following arrangement I like: Height of the hives from the ground, not less than 4 inches; first row 6 feet apart, facing the east; the second row facing the south, and about 2 inches from the rear of the first row; the third row is 6 feet from the second, and opposite the spaces in the first and second rows (so that the morning sun will shine in the entrance), and so on.

In this climate as late as May 20 we often have cold weather sufficient to chill the brood, and entirely stop brood-rearing, for which reason spring protection of some kind ought to be used. The lumber in boot and shoe boxes answers every purpose, to make rims for the hives 18 inches deep, and 2 by 3 feet; the covers should be water-tight, and they will also answer for shade-boards in the summer if needed.

For the packing to fill in between hives and the rims, sawdust, fine hay, or chaff is very good, using small blocks to keep the entrances free.

Before packing, and after the bees have had their flight, see that they have plenty of stores to stimulate brood-rearing; those that have not, mark it in a record-book, to be fed, and if any are found queenless, unite them with a colony having a queen. It is well to leave the packing on until the time to put the cases on.

Now is the time to get the hives ready for the summer. The cases, sections, foundation, separators, smoker, and the swarming-box, should all be in readiness when the honey harvest begins; and last, but not least, the bee-veil should have attention.

Every apiarist should rear queens to have them ready for the swarming season, as no apiarist can afford to have a colony queenless during the honey-flow.

See that your bees have water, if you are not near a river or small stream.

My tools consist of a long screw-driver, a large knife, and a scraper.

Darlington, Wis.

COMB HONEY.

Some Practical Thoughts on Its Production.

Read at the Maine Convention

BY L. F. ABBOTT.

Given a certain number of strong colonies of bees in the spring, how shall they be worked to produce the largest amount of comb honey? This question is not so easily answered as it might at first seem to be; but ordinarily I believe it profitable — the honey-flow of course being good—to let one swarm issue, allowing the parent colony to rear a queen, destroying all but one of the queen-cells about the fifth day after the swarm issues. Previous to swarming, however, when seven or eight frames are well filled with brood, and the bees seem disposed to build bits of comb in all available spaces, the time has come to put on surplus cases.

Now we will say that five colonies are each in seven frames, and ready to receive sections for the storing of surplus honey. The season is now advanced, and weather warm, so the brood we have to take from the hives to reduce the brood-nest will not suffer from exposure. Each hive is opened and reduced to six frames, leaving the best filled with brood and eggs. Those frames taken out may be placed in a hive with a portion of young bees adhering to the combs, and form a new colony. At the expiration of a couple of days, a laying queen may be given this colony—ordinarily she might be introduced at once—which will be ready in three or four weeks, or so, for a section-case, and will send off, probably, a young swarm, which should be made to stay at home, or equivalent to that, of which I will have more to say about subsequently.

Shaving the Combs.

The old hives now have six frames which should be carefully shaved, over the portion containing honey, to $\frac{7}{8}$ of an inch, and spaced in the hives to bee-space—$\frac{3}{8}$ of an inch. If the frames are fixed with reversible attachments—as I would have them—reverse the frames and use a dummy on each side so the surplus case will fit without leaving any open space.

Twenty-four or twenty-eight one-pound sections supplied with thin foundation are enough, and perhaps if half the number could be so arranged to place on at first, it would be better than the larger number. After these sections are all filled with comb, and two-thirds of the upper portion capped over, this case may be raised, and another case of the same size placed upon the brood-frames. A wide frame containing eight sections might be placed each side of the brood-frames,—after removing the dummies—but I should expect that they would be immediately filled with eggs by the queen.

If the honey-flow is copious, our five colonies will each send out a swarm by June 10. Hive them upon empty combs or sheets of foundation, and, if preferred, the new colony formed by frames of brood taken in reducing the old colonies to six frames when putting on the section-cases, may be drawn upon to the extent of a frame for each new swarm, replacing the frame so taken by an empty comb or foundation, which the laying queen will quickly occupy.

Restrict each colony to sending off one new swarm, and these new ones not to be allowed to swarm at all. Such first swarms will probably swarm in about four weeks. Let the swarm issue, hive in the ordinary way, place on a new stand a little distance from the former stand, and put the frames from the parent colony, bees and all, into the new hive, in the new location; place on the surplus case, and things will be likely to go on through the season without more trouble by swarming. If they do swarm out again, after a couple of weeks, put them over again, and keep them to work in surplus room.

The old colony, having all queen-cells but one removed, five to eight days after sending off, the swarm will very likely swarm again, in three or four weeks, when they, too, should be changed over as described for the others.

Objections may be raised to this plan, on the ground that if one has a large number of colonies, it is undesirable to increase as fast as this method contemplates.

In rebuttal it may be urged that, as a rule, the old colony and one new swarm issuing from it—all things being favorable—will store more honey than the old colony alone, prevented from swarming. Again, the method I have given somewhat in detail, contemplates putting only strong colonies into winter quarters. Reduce the number of colonies by doubling up at the end of the honey harvest; make sales of colonies according to value, reserving the best for yourself, as you would select your sheep and lambs, keeping the best yourself, and turning the inferior ones to the butcher at what they will bring.

But this course of allowing the old colonies to cast a swarm need not be followed, if one is satisfied with the product of that. By running over the

combs and changing to new locations two or three times, the increase probably would be largely checked, if not entirely prevented.

Increase of Colonies.

If one has but a small number of colonies, and wishes to increase as fast as possible, and yet get as large amount of surplus comb honey as possible, I know of no better plan than the following:

We will say the apiarist has four colonies; by the methods I have given, encourage breeding in the spring, and when the time arrives for putting on surplus cases, contract the brood-apartment to five or six frames, shaking off nearly all the bees from the frames removed, and place them in a hive with a laying queen. Shave all brood-combs to ¼-inch, and space them to ⅜ of an inch. When the old colonies send off new swarms, capture the old queen and return them to their respective hives, supplying their places in the new colony with young, laying queens, which can be introduced at this time without much danger. Remove all queen-cells from the old colony, to prevent after-swarms, and let brood-rearing proceed. By this method, in a good honey-flow, colonies may be increased very fast, and a good amount of surplus honey be obtained.

The plan of shaving the combs to ⅛-inch thickness, and spacing the frames to a bee-space, I believe to be of considerable importance. The idea was not original with me, but as far as I know, to Mr. E. P. Churchill belongs the honor of first giving this method to the bee-keeping world.

Using the Extractor.

Can the extractor be used to advantage in running an apiary for comb honey, by extracting from the brood-frames when putting on the surplus cases? This is a question I am not fully prepared to answer either way, and certainly not in the negative. I have used the extractor in that way, and thereby secured a good amount of honey, but it is generally a mixture of fruit-bloom and clover honey, neither one nor the other.

On the whole, I am not sure but as good results will be obtained by letting the honey remain in the combs, when manipulating the hives for the surplus cases. The theory is, that in shaving and spacing the combs and reversing them, the bees will carry the honey from the brood-frames and deposit it in the sections. I am inclined to think that this is generally true. Then if one cares for sameness in quality of his comb honey, it is better to extract the mixed honey, and secure the virgin article from the clover bloom.

Lewiston, Maine.

BEE-CELLAR.

Wintering Bees in the Cellar—Experience.

Written for the American Bee Journal

BY A. D. LORD.

I am located two miles from any timber land, having commenced in the spring of 1887 with 3 colonies, and increased them to 7, which I wintered in the cellar under the house. There was plenty of bees in the spring, but some of the colonies dwindled to a mere handful, and I only saved them by buying a few by the pound and giving some to each colony. They were slow in building up, but increased again in 1888 to 18 colonies, and I took 250 pounds of comb honey.

I put in the bees on Nov. 8, and each colony was weighed, so that I might know just the amount of honey that it takes to winter them. They have lost in weight up to the present time (Feb. 26) from 2½ to 4 pounds each.

I will endeavor to give a description of my bee-cellar:

I commenced by digging 5 feet into the ground, then setting up studding 7 feet high, and ceiling it all around as tight as lumber could make it. It has two doors to pass in and out, and it is 8x12 feet, with a ventilator at each end.

Before putting the bees in, I took a section of the hive, and putting a piece of cotton cloth over the bottom and filling it about 3 inches deep with oats, to absorb the moisture, which, I think, has done well, for the bees are perfectly dry all the time. The temperature has been from 34° to 40°, and they seem to be perfectly quiet all the time.

I have carefully scraped up all the dead bees, and they weigh 1½ pounds at the present time.

Amiret, Minn.

FEEDING BEES.

What and How to Feed During a Mild Winter.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

Bees during a mild winter, like the present, consume more honey than in a cold one. When they are often upon the wing exercising, they require more food than during a cold winter when they are in a semi-dormant state. Bees store their pollen or bee-bread in the base of the cells, and fill up with honey. When they have consumed the honey, they will rear brood in the center of the cluster, the nurse-bees eating the bread so as to give milk to the young, or, in other words, feeding it to the young half-digested, as the pigeons feed their young. These little patches of brood in the center of the cluster are a wise provision of nature against the loss of the queen, for as long as they have eggs or larvæ not over three days old, they can rear another queen or mother bee.

As the drain upon the bees' stores has been excessive, owing to the mild weather and consequent activity of the bees, the owners of colonies, whether few or many, should not let them starve. If he does, he loses not only the bees, but all the honey they had in the fall. Bees consume their stores very rapidly in the spring while rearing their young, for scientists tell us that insects during their larval state consume more food than during the remainder of their lives.

Honey as Food for Bees.

Honey is their natural food, and nothing else is to be resorted to when it is to be had. Large apiaries usually have in store dark honey that is not salable, and broken or partly-filled comb, which can be utilized in this way. I have a few two-pound sections, in which the queen laid and drones were reared, discoloring them, rendering them unfit for food, and these I shall use as feed for bees, turning them down over the cluster.

I do not advise feeding bees in early spring, except to prevent starvation, for it arouses them to activity, and they will try to rear more brood than they can cover; and let the weather turn suddenly cold, contracting the cluster, much of it will perish. More young queens will be reared by feeding, but it will be at the risk of the lives of the old bees, for it is a severe draught on their vitality, preparing their food; they also fly out for water on chilly days and perish. When a bee loads up with cold water it gets numb, and cannot return home. If the old bees die off faster than the young ones are able to take their places, the colony must ultimately perish.

Making the "Good" Candy.

This candy was the invention of a prominent bee-keeper, whose name it bears, and is made as follows:

Heat liquid honey until hot, but not up to the boiling-point, and stir in confectioners' sugar until it will absorb no more, when it can be made into cakes with the hands. This candy will not be sticky, yet keeps soft and moist, so that bees can feed from it.

A cake of this candy could be slipped down into the cluster and save a colony from starvation, and yet not arouse them to undue activity, as the feeding of liquid honey or syrup would do.

The Feeding of Syrup to Bees.

This should be used only as a forlorn hope, when the bees' natural food is not to be had, for a laborer is worthy of his hire, whether a bee or a human being. It is not particular what kind of sugar is used for making syrup in the spring, when the bees can fly every few days; but, in the fall, nothing but the very choicest will answer.

I generally pour boiling water upon the sugar in a pitcher, and stir it up with a spoon, making a thin syrup, which I feed warm. The undissolved sugar will settle in the bottom, and it should be allowed to settle, for it will harden in the feeders, and become bothersome.

Feeders and Robbing.

I have many different kinds, and use them according to time, place and condition. If I desire to feed liquid honey or syrup when it is cool weather, and am desirous of keeping all the warmth possible in the cluster, a one-pint Mason jar, with a perforated cover, answers the purpose admirably, as it can be turned over a small hole, and the bees take it through the perforations. I have tried the quart jars in the same way, but the result was not satisfactory in my hands, for the syrup came down faster than the bees could take it, and it would run from the hive and be wasted. It needs to be set perfectly level, and then it will not run out.

Wooden vessels answer the purpose much better for feeders than those having a smooth surface, like tin, glass or earthen-ware. If a tin or glass vessel should be filled with liquid honey or syrup, and be accessible to bees, in a very short time they would be a writhing, struggling, drowning mass; while, if the same quantity were in a wooden vessel, every bee would get out.

Bees appear to be able to take a grip on wood, which they cannot do on other surfaces. Small wooden-bowls, or butter-dishes, if they do not leak, make good feeders. I once showed to a bee-keeper a feeder that was cut out of wood, by a wabbling saw. He said that it would get full of drowning bees. He was mistaken, however, for I filled it immediately with syrup, put it over a strong colony, and in a very short time it was clean and dry without a dead bee. Any sort of a vessel can be used, if it is filled with chopped straw or shavings.

In all feeding operations, care must be exercised lest robbing be induced. When food is placed in the upper story of a hive, if bees from the outside can gain admittance, the colony will soon be taken by storm, and stores stolen.

DIVIDING

Colonies to Secure Increase Explained.

Written for the American Bee Journal

BY J. M. HICKS.

In compliance with a promise made to the members of our Indiana State Bee-Keepers' Society, I will give my favorite method of dividing colonies for judicious increase and profit. This, of course, depends much upon the condition of the colony, which should be full of brood and worker bees, as if they were to be left to swarm in the old or natural way. This condition can readily be known in several ways, viz:

First, we usually find them quite well supplied with drones, which come out to play late in the afternoon.

Second, we can also know, by opening a hive that is full of bees and brood, with a good, prolific queen, actively laying eggs in the brood-frames; also quite a number of drone-cells may be found sealed over in the combs, all of which are requisite for the welfare of the future of the new colony.

We can now examine the frames of brood, and when we find the sheet or frame on which the queen is busy laying eggs, lift it carefully out, and hang it in a new hive of the same size and pattern, replacing the vacant space in the full colony with a new frame, and if filled with good empty comb, so much the better.

Now close up both hives, and move the old colony to a new location; then place the new hive with the one frame of brood and queen where the old hive stood, and you will have the satisfaction of seeing the working-force return to the new hive, and with their queen, where all will be peace and harmony, and in less than 48 hours a fine, strong colony of bees can be seen working with a will.

From the old colony made queenless (in order to make the "artificial" swarm, as above mentioned), at the end of 8 or 9 days we can with safety cut out several queen-cells and insert one or more in any other colony or colonies that may be queenless; or, if desirable, other new colonies can then be made by taking a frame or two from strong colonies, and thus re-queen all new or "artificial" swarms, saving much valuable time. Always leave one or two queen-cells in the old colony, that they may hatch and rear a queen for themselves.

I would further add, that it will be better by far to save all of the best empty or old combs in order to refill empty or new frames for the bees, thus saving much precious time for the bees, as well as many pounds of the best honey, which is always gathered in the forepart of the season. Look well to the bees!

Indianapolis, Ind.

BEE-CULTURE

Considered as a Branch of Agriculture.

Read at the Illinois Farmers' Institute

BY G. A. GROSS.

There is probably no branch of farming so generally neglected and so little understood as that of bee-keeping. If it cannot be said of every farmer, that he can keep bees successfully, still there are many that with a little intelligent care could cause their bees to make a welcome addition to their income.

It is not an occupation that is restricted to men only—many a farmer's wife or daughter would find it a fascinating pursuit, as well as an easy way of being independent of "father's pocket-book;" for the work is not hard, nor does it demand one's whole time. One daily visit to the hives, taking only a few minutes, a little extra watching at swarming time, the putting on and taking off of sections—this certainly is not work that will overtax a woman's strength. All over our land are found women who rank among the most successful apiarists.

I have frequently heard the remark, that this is not a good country for bees, and until six years ago I would have heartily endorsed that opinion, for I had kept bees for 18 years, and never had much success with them. Finally I lost my last colony, and came very nearly giving up the pursuit. But at that time I read an article about the modern improvements in bee-keeping, became interested again, sent for a book describing the new way of handling bees, bought one hive, and started anew, trying to take the best care of the bees. As a result, at the end of four years I had 70 colonies, had sold considerable honey, and two years' more work with the bees, has confirmed me in the opinion that our county is as good a place to keep bees as any in the United States, with the exception of California.

With our variety of flowers, coming as they do at intervals during the summer, we possess a great advantage over the northern part of our country which is celebrated for its large yields of honey.

In this county (Bond), up to Aug. 10, 1888, the season had been the poorest on record—no swarms and no

honey, was the general complaint. I do not think that my 57 hives contained more than 25 pounds of honey, and I had the prospect of feeding all my bees, but heart's-ease came to the rescue, giving us the best honey-flow I ever saw. In the five weeks that it lasted, my bees gathered over 3,000 pounds of honey. See what a loss it would have been, but for the bees. I have no doubt that for the lack of bees to gather the honey, our county suffers a loss that annually counts up in the thousands of dollars.

But there is still another reason for keeping bees, that should have a great weight with farmers—I mean the very important part which bees bear in the economy of nature in fertilizing flowers, and thus increasing the crop of fruits of every kind.

Having seen a few of the reasons why farmers should keep bees, let us consider what the bee-keeper needs to enable him to reach the best results.

First, he must understand something of the nature of bees, how they live, how they work, what variety is best to use, etc. A colony in its normal state consists of one queen, or mother-bee, several thousand workers, varying from 6,000 to 40,000, and a few hundred drones, or male bees; these last being present only at certain times of the year.

The queen is the only perfect female bee in the hive. She can easily be recognized by her size, for she is about twice as long as a worker-bee. Upon her depends the prosperity of the colony, for she is the only one that lays the eggs. Take the queen away, and the colony is doomed, unless the bees have eggs from which to rear another one.

A good queen will lay from 2,000 to 4,000 eggs a day, being more or less prolific, according to the flow of honey. The life of a queen is much longer than that of the workers, for while she lives from two to four years, a worker-bee will not, on an average, live longer than six or seven weeks; though in winter their life is prolonged from five to six months.

The drones are known by their short, thick bodies, and loud buzzing when on the wing. Their life is of very uncertain duration, lasting from a few days to a few weeks at the longest.

Italian and Black Bees.

We need only consider two varieties of bees, the common black bee, and the Italian; of these two races the latter are generally preferred. They are of more pacific disposition, and besides their good moral character, they are more industrious, working earlier in the morning, later in the evening, and on days when the black bees would find it too cold to leave their hive.

The tongues of the Italian bees are also longer, enabling them to get honey from flowers that the common bee has to pass by; and finally, their queens are more prolific.

Of the different kinds of hives used by progressive bee-keepers, all without exception have the one feature of a double story. These two stories—the brood-frames below, the cases with sections above, with the honey-board between the two, are the main features necessary for the successful production of comb honey.

How to Avoid Stings.

The handling of bees is easy to any one who is not afraid of stings; but these can be avoided, to a great extent, by the use of a veil and smoker, and by observing the following precautions:

Never go between the hives in a hurry, nor walk in front of the entrances so as to disturb the bees in their passing in and out; avoid all quick motions, all jars of the hive, and when you have any work that will neeessitate the opening of a hive, always choose a time when the bees are out at work, smoking first the guards at the entrance, then, after taking off the cover, sending a few puffs of smoke among the frames, after which you can go to work with impunity. Finally, if a bee should come buzzing about you, keep perfectly still, close your eyes, avoid breathing on it, and it will soon leave.

In writing the foregoing, it has been my aim to call the attention of the farmers to a field that has been too much neglected. In this pursuit, as in all others, to him who would succeed, four conditions are necessary, viz: He must understand it; he must love it; he must believe in it, and, last but not least, he must stick to it.

Greenville, Ills.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
Mar. 30.—	Agency, at Agency, Mo. T. S. Smith, Sec., Agency, Mo.
Apr. 23.—	DesMoines County, at Burlington, Iowa. John Nau, Sec., Middletown, Iowa.
May 1, 2.—	Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.
May 4.—	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
May 21.—	Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees in Fine Condition.—T. F. Bingham, Abronia, Mich., on March 6, 1889, says:

Bees have had a series of fine sports on the wing within the past week, and are in first-class condition. Those in the cellar are in excellent condition, and as quiet as if asleep.

Good Prospects for Clovers.—Wm. G. Cory, Cason, Ind., on March 6, 1889, says:

Bees in this locality are doing well, only a few colonies having died from want of stores. I use the Armstrong Crown hive, packed with dry forest leaves, and my bees winter well on the summer stands. The prospect is good for all kinds of clover. The AMERICAN BEE JOURNAL is a welcome visitor.

Foul Brood.—A. L. Leach, Livingston Co., Ills., on March 1, writes:

My bees are in unusually good condition at the present time. I have no loss to report for this winter. The reports of individuals and conventions indicate that foul brood prevailed to an alarming extent during 1888, and three associations passed resolutions invoking Legislative aid. To me this is very absurd. I would as soon think of legislating to control the weather, which, no doubt, causes it to come and go. I have had two years' experience with foul brood, and lost 15 colonies in the early part of the winter of 1887. Last spring I purchased 10 healthy colonies, and used the diseased combs, increasing the 10 to 22. My other colonies were affected with foul brood from the previous year, and of course they all became affected. I devoted three months with various experiments in which the popular impressions of the disease had but little show; prob-

ably very many will doubt it when I say, that I can cure it with little labor and small loss, and it is not right to burn or destroy affected colonies, as it is only moderately contagious, and not liable to be carried from one place to another.

Yes; we doubt it, but are quite ready to learn the *modus operandi*, and have it thoroughly tested. But here is something later from Mr. Leach:

LATER.—Since making the above statement in regard to foul brood, I have read Mr. Baldwin's article on page 134, a part of which corroborates my experience, which has been thorough and conclusive, and which I can demonstrate to a certainty. I would have written very differently, if I had read Mr. Baldwin's article first. It was my intention to publish a full course of treatment after getting comments on my statement. My experience with bees and queens that are affected, also with old combs, is thorough and comprehensive.

Bees Wintering Well.—R. A. Rummel, Butler, Ind., on March 9, 1889, writes:

My bees are wintering well, except late swarms that did not gather enough honey to winter on. There was not much surplus honey gathered here last year, but the brood-chambers were well filled with golden-rod honey. The forepart of this week was warm, and the bees were out thick, visiting sugar orchards, but it is cold again now.

Reading Bee-Papers, etc.—D. R. Rosebrough, Casey, Ills., writes:

The white clover in this vicinity looked well last fall, and I still hope that it will not be killed; yet the weather is very hard on it at present, as we have had our coldest this month (February). What do we learn from the AMERICAN BEE JOURNAL besides bee-culture? 1. It keeps us informed as to the weather, not only in Illinois, but throughout the United States, all Europe, and Canada. 2. It tells us of the condition of the crops of the country, and the state of the health of the people. It acquaints us with hundreds of persons whom we would never know. It is a common occurrence for a man to call at my office, and speak to me as though he was a brother, and tell me it was in the BEE JOURNAL that he first saw my name. 3. It tells us the price of honey all over the country, and which of the two races of bees is the strongest—the blacks or yellow bees. The country and woods were full of bees when the yellow race was imported, and in my neighborhood, 12 years ago, when an Italian queen was first brought to this (Clark) county, her grand daughters would be black bees every time; but now that is not the case, as every bee-yard in this neighborhood has the yellow bees. Persons living five miles from Casey, who never saw a queen, have at least half yellow bees. I think that the black bees are fast disappearing, and that within another 12 years black bees cannot be found here. My bees are wintering nicely. The last summer thinned bees out in this county—the old farmers say that the moths killed them.

Warm Winter Weather, etc.—J. L. Gray, St. Cloud, Minn., on March 9, 1889, says:

My crop last year from 50 colonies in the spring, was 3,080 pounds, 2,000 pounds of comb honey, and one-fourth increase of colonies. I have 75 colonies in the cellar, but the exceedingly warm weather from Feb. 27 to March 7, taxed my ability to keep them quiet, but I succeeded very well with ice, and open doors at night.

Good Season Expected.—W. A. Hodge, Victory, Wis., on March 10, 1889, writes:

I commenced the spring of 1888 with 24 colonies of bees, mostly Italians, and I have now in the cellar 43 strong colonies, after selling 8 colonies last fall, besides in swarming time 3 swarms went to the woods. My honey crop for the past season was about as follows: One thousand one-pound sections of honey, 250 1½-pound sections, and about 200 pounds of comb honey in the old-fashioned boxes. I sold it at an average of 11 cents per pound, and I am well satisfied with the result; but I expect much better results the coming year.

Apple Bloom—White Clover.—Wm. Malone, Newbern, Iowa, writes as follows:

The winter of 1880–81 killed nearly all the bees in this county, and the winter of 1884–85 left none in box-hives and "log gums." Four neighbors living from 2 to 6 miles west of here, had large orchards, and each had from 10 to 25 colonies of bees in box-hives. The winter of 1884–85 destroyed all their bees, and the next season they had no apples. I wintered 5 colonies out of 38 that winter on the summer stands. A Mr. Crane, 1½ miles east of here, wintered 20 colonies in the cellar, and my western neighbors went to Mr. Crane for apples the following fall, as Mr. C. and his immediate neighbors had plenty of apples. When bees can work on apple-bloom, there will be plenty of fruit.

I cannot tell the exact condition of the white clover yet, but I think that it is winter-killed badly. The ground is frozen hard about 2 feet deep, is bare, and has been so nearly all winter. Bees are wintering tolerably well. I have 52 colonies in the cellar or cave, and 12 on the summer stands; the latter have consumed but little honey yet, and have had a flight about every week all winter.

Bees had a Grand Flight.—Mr. Jacob Oswalt, Maximo, O., on March 4, 1889, writes:

For the past two years the honey yield in eastern Ohio has not been more than one-fourth of a crop, and the quality of the honey was none of the best. I am wintering my bees on the summer stands in the Falcon chaff hive; they are all going to "pull through" the winter nicely. They had a grand flight to-day—I suppose they wanted to take part in the grand Inauguration Ball going on at Washington, D. C. Bee-keepers in eastern Ohio, at this writing, are not very well supplied with bee-fixtures, and if the coming summer should prove to be a good one for bees and honey, many of our bee-keepers will be caught napping.

Bee-Keeping for Pleasure.—George Hodges, Belmont, N. Y., on Feb. 25, 1889, writes:

I have noticed in the BEE JOURNAL that some one mentioned the "blood of bees" as we would speak of cattle. I have never seen any blood in bees. I have only 4 colonies, but I never keep them for profit, as I have never obtained anything except plenty of honey for my own use. I did not get a swarm last year. I think 2 swarms came out one day, and both went together, and not being at home at the time, they went to the woods, so I did not get any swarms. I often think that I will try something different with my bees, as I see so much in the BEE JOURNAL of profit in bees, but I do not get it myself. There are a great many bees kept in Belmont, but their keepers do not read bee-literature.

Experience as a Teacher.—Mr. Christian Weckesser, Marshallville, O., on March 1, 1889, writes thus about publishing new papers :

I noticed in a recent issue of the AMERICAN BEE JOURNAL an "obituary" of *Rural Life*, a paper which I published a year. It may be proper to say that, to many persons it may seem desirable to publish a periodical, while the disadvantages and undesirable features of such an enterprise are not apparent until the papers are "on their way," when, becoming manifest, they are not properly conducted, the matter they contain may become of little utility, and finally become filled with matter that is considerably worse than useless, or misleading in some direction ; and not being profitable, great offers and inducements are given to secure subscribers, with which a paper that is carefully edited may not be able to compete, and be profitable to the publisher. Again, an amateur printer may think that the necessary expense a trifling matter. After making trial of this, I confess I am wiser, and though I have little of a pecuniary compensation for a year's hard labor, I feel well paid with experience. The transaction was honorable ; the paper was not poorly conducted—and it would probably be a credit for more publishers to have their papers consolidated, rather than to "eke out a miserable existence."

Commend Us to the Arab.

A couple of Americans meet, grab each other's hands, and you wonder how much water they have contracted to pump in five minutes. An Englishman nears a friend and they pound each other on the shoulder, while you look on nervously, wondering who will draw first blood. Frenchmen meet, and they fall to kissing each other, while you go off in a corner and feel sick. Italians fall into convulsions, while you are hunting for the doctor. The Portuguese hook their chins over each other's shoulders, as if they wanted to find which pocket holds the handkerchief, while Spaniards hug each other with tears streaming down their faces, leaving you in doubt as to who has died, but the Arab, when he meets his friend, advances toward him, they join hands in firm pressure for just a moment, and then, without a grimace or movement of the lips, raise their own hand and touch it to their lips, saying afterward: "Welcome sight." The whole thing is done with dignity that is thoroughly manly, and yet with a hint of tenderness that is nothing less than beautiful.—*Boston Transcript.*

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Don't Fail to Read A. J. King's advertisement on page 190.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents ; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—We quote : Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good ; for comb, limited. Prospects are not as good for honey as in 1888.

BEESWAX.—Scarce, at 18@22c.

SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

SAN FRANCISCO.

HONEY.—White comb, 10@11½c.; dark, 6½@8c. White extracted, 6½c.; light amber, 5¾@6c.; dark amber, 4½@5½c.

BEESWAX.—18@22c.

Jan. 25. O. B. SMITH & CO., 423 Front St.

BOSTON

HONEY.—We quote : Best white clover 1-pounds, 18@20c.; best 2-lbs., 18@18c. Market is very strong and stock of white comb honey is very light.

Mar. 9. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 16@17c. Sales slow. Extracted, 9@10c.

BEESWAX.—22@23c.

Feb. 11. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote : White clover 1-lbs., 16@17c.; 2-lbs., 14@15c. Good dark 1-lbs., 13@14c.; 2-lbs., 12@13c. Buckwheat 1-lbs., 13@14c.; 2-lbs., 11@11½c.—Extracted, 6½@8½c., depending upon quality and style of package. Market dull and stock sells slowly.

BEESWAX.—22c.

Jan. 24. S. T. FISH & CO., 189 S. Water St.

ST. LOUIS.

HONEY.—Choice white clover comb, 13@15c.; fair 11@12c.; dark, 8@10c. Extracted, dark, in barrels, 5@5½c.; choice, 5½@6c.; in cans, 6@7½c. Market is quiet but steady.

BEESWAX.—20c. for prime.

Jan. 17. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Best 1-lbs., 17@18c. Extracted, 7@9c. for best quality, according to body, flavor and style of package. Trade is limited to local consumption. Off grades of comb honey are slow at lower figures than given above. But few will buy dark comb.

BEESWAX.—22c. K. A. BURNETT,
Jan. 17. 161 South Water St.

MILWAUKEE.

HONEY.—We quote : Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9½@10c.; in barrels and ½-barrels, dark, 5½@6c. Market dull. The very best sells slowly, and inferior qualities are neglected very much. Damaged, broken and leaky comb honey not wanted.

BEESWAX.—22@23c.

Jan. 10. A. V. BISHOP, 142 W. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is better for dark extracted, which is scarce.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Mar. 11. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—White 1-lbs., 16c.; fall, 14c.; California 1-lbs. 16c.; white 2-lbs., 14c.; extra 2-lbs., 13c. Extracted, white California, 8c.; amber, 7c. Market dull.

BEESWAX.—20@22c.

Jan. 22. CLEMONS, CLOON & CO., cor 4th & Walnut

KANSAS CITY.

HONEY.—Choice 1-pounds, 15@16c.; dark 1-lbs. 12c.; 2-lbs., 14c.; dark, 11c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock large.

BEESWAX.—None in market.

Jan. 4. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—White, in 1-lb. sections, 15@16c. Extracted, 9@10c.

BEESWAX.—20c.

Jan. 1. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote : Fancy white 1-lbs., 14@15c.; 2-lbs., 12c Fair white 1-lbs., 14@15c.; 2-lbs., 10 to 11c. Buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. Extracted, white, 7½@8c.; dark buckwheat, 8@8½c. which is in good demand. Market dull, except for extracted buckwheat; for all other kinds it is quiet, owing to unseasonable weather, we believe.

HILDRETH BROS. & SEGELKEN,
Jan. 10. 28 & 30 W. Broadway, near Duane St.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Good Enough.—Audrews & Lockhart, of Patteu's Mills, N. Y., on Feb. 20, 1889, wrote as follows concerning their use of the advertising columns of the AMERICAN BEE JOURNAL:

We got more orders from our advertisement in the AMERICAN BEE JOURNAL than from all the oth er bee-papers put together.

Advertisements.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. March 30, 1889. No. 13.

EDITORIAL BUZZINGS.

This Week we present our readers with a choice Song, set to music by Mr. A. W. Wilson, entitled, "Maggie, the Cows are in the Clover." Music will enliven any household, and this song is easy for the performer on the organ or piano, and has a sweet air. Bee-keepers can change the chorus to read thus, if desired:

The bees are swarming over,
They've tried it now since morn;
Go and hive them, Maggie, out behind the barn.

Hon. Edwin Willits, President of the Michigan Agricultural College, and the honored friend of apiculture, has recently been appointed First Assistant Secretary of Agriculture, by President Harrison.

Mr. Wm. H. Shane, one of the most successful honey producers of Medina County, O., died on the 7th inst. He was not only a good bee-keeper, but also a good Christian.

Ivar S. Young, of Christiania, Norway, writes us that he intended no wrong in the articles he wrote for his paper about his visit to America a year ago, but he fails to explain many things he said derogatory to Americans. We must accept his assertions, however, even though we can see no consistency in them.

In Minnesota this is the latest report of the weather. It is from C. G. Ridout, of Hutchinson, Minn., and dated March 21, 1889. He says:

The weather is fine, 60° above zero, and the sun shining, but no snow, and very little ice. It is the earliest spring known for many years.

That Picture.—Dr. A. B. Mason, of Auburndale, O., writes thus concerning the engraving on page 150, showing the face of our esteemed friend, Mr. Eugene Secor:

It looks just exactly like him (only a little better), and if any one should tell me that it was not a good likeness, I should take a second look at him to see if he was not demeuted.

He then remarks thus about the present condition of his bees which were wintered in the cellar:

We had some warm days last week, so bees could fly, but ours are still in the cellar and in good condition. On Thursday I put out the colony that was the lightest in stores when put in winter quarters last fall, and it had brood in all stages, and stores enough to last till May. I also put out one to which I introduced an imported queen on Nov. 17, and found it in good condition, with plenty of honey, a goodly number of young bees, and brood in all stages.

The Minnesota State Bee-Association was organized at Minneapolis last January, and the officers elected for the first year were: President, L. H. Wilcox, of Hastings; Vice-President, Wm. Danforth, Red Wing; Secretary, Wm. Urie, Minneapolis; Treasurer, J. Bass, St. Paul. Executive Committee, B. Taylor, Wm. Dwire, and J. Bass. The Secretary writes:

This association is organized for the purpose of bringing all the bee-keepers and others who are interested in apiculture together, for their mutual instruction and improvement regarding methods of managing bees, and other things that may be to their advantage, and to those about to engage in the business. The first meeting will be held at the Experimental Farm the same day the Horticulture Society meets, of which due notice will be given.

Fight Between Insects.—An exchange gives this interesting bit of insect news:

A traveler in South Africa reports seeing a caterpillar crawling at a rapid pace, followed by hundreds of ants. Being quicker in their movements the ants would catch up with the caterpillar, and one would mount his back and bite him. The caterpillar would turn his head and bite the ant and kill his tormenter. After slaughtering a dozen or more of his persecutors the caterpillar showed signs of fatigue. Betaking himself to a stalk of grass the caterpillar climed up tail first, followed by the ants. As one approached he seized it in his jaws and threw it off the stalk. The ants, seeing that the caterpillar had too strong a position for them, resorted to strategy. They began sawing through the grass stalk. In a few moments the stalk fell, and hundreds of ants pounced upon the caterpillar. He was killed at once.

Prof. Cook, in a private letter, just received, says:

Bees here seem to have wintered very nicely, though I had to warm the cellar repeatedly by the use of a kerosene stove.

The general opinion is that bees have wintered well, though some of those in cellars are reported as having the diarrhea slightly. They will soon get over that after having a good chance to fly.

Detecting Adulterated Honey.—Mr. E. G. Haven, Belleville, Kans., on March 16, 1889, asks this question:

Can you inform us through the AMERICAN BEE JOURNAL how to detect adulterated from pure extracted honey?

That is sometimes rather difficult, but here is a method which will generally prove successful. It is from a Canadian writer in the *Dominion Grocer*. He says:

Genuine boney can be readily distinguished from "manufactured honey" by a microscope. The former has few or no sugar crystals, and abounds with pollen grains, while the imitations have little else than these crystals, with rarely a trace of pollen grains. The honeyed taste of the manufactured article may come from honey comb or beeswax being mashed up with the article used in the manufacture. Each class of plants has its own specific form of pollen grain, and any one conversant with this branch of botany could tell from what part of the world the honey came, by studying the pollen grains that it might contain.

Hiving Bees on Sunday is commented upon by one of our correspondents in a private letter, and as the subject was brought up on page 182 of our last issue, it may be interesting to read the following opinion from a legal as well as apiarian stand-point:

The Sunday law in all States where civilization pure and unadulterated rules, allows of work of necessity and charity being done on the Sabbath. Hiving bees must be considered a work of necessity, consequently legal.

Unless a party obtains consent he has no right to go on to another's land to take bees away. It would be a trespass so to do, but if no injury was done, the damage recovered in a suit at law would be nominal only, say one cent or one dollar.

Catalogues for 1889 are on our desk from—

Dr. G. L. Tinker, New Philadelphia, O.—20 pages—Bees, Queens, and Apiarian Supplies.

G. D. Howe, North Hadley, Mass.—78 pages—Potato Manual.

James A. Nelson, Muncie, Kansas—12 pages—Queens, Comb Foundation, etc.

Dr. A. B. Mason, Auburndale, O.—4 pages—Egg Preservative.

S. L. Watkins, Placerville, Calif.—1 page—Bees and Honey.

Oliver Foster, Mt. Vernon, Iowa—16 pages—Bees, Queens, Honey and Supplies.

Thomas S. Wallace, Clayton, Ills.—4 pages—Bees and Queens.

An Admirable historical and anecdotal article, with illustrations, on Washington's Inauguration, leads off the April number of *Frank Leslie's Popular Monthly*. It cannot fail to be in general demand at this centennial period, when President Harrison is preparing to join the commemorative celebration by traveling to New York over the same route taken by our first President one hundred years ago. Another seasonable article is Ensign Wilkinson's account of "Samoa, and the Troubles There." The serial and short stories, literary essays, poems, biographical and natural history sketches, humorous verse and, above all, the art illustrations are profuse and varied, more than sustaining the great reputation of the *Popular Monthly*.

MAGGIE, THE COWS ARE IN THE CLOVER.

SONG.

QUERIES AND REPLIES.

Share to be Given when Keeping Bees for Others.

Written for the American Bee Journal

Query 621.—Suppose that in the spring I take on shares 40 colonies of bees in box-hives, and am told to do with them as I please; but I am to give the owner a share of the increase of bees, in 8-frame Langstroth hives, in the fall, with a slatted honey-board and one Heddon surplus-case on each hive. What share should I give him? Remember that I get nothing but the bees in the spring, and he gets no honey.—Iowa.

Your trade is too obscure; I cannot say.—J. M. HAMBAUGH.

If you are to get all the honey, you should give at least half of the increase.—J. P. H. BROWN.

I should say that if you give him 50 colonies, you would do very generously.—A. J. COOK.

Make the best bargain you can, and stick to it.—MRS. L. HARRISON.

Make the best arrangements together, so as to satisfy both.—P. L. VIALLON.

If you get all the bees in the spring, and all the honey, you should be willing to give him all the increase, if you are allowed to manage the bees, and do it reasonably well.—R. L. TAYLOR.

About one-third. I should not advise you to enter into any such arrangement.—WILL M. BARNUM.

You had better let them alone, unless you can buy them outright.—H. D. CUTTING.

There are so many circumstances which would widely alter just conditions, that I would not try to answer. —JAMES HEDDON.

No mortal can tell. During the past two seasons, 1887 and 1888, it would have been working "for the fun of it," and paying pretty roundly for the privilege, in most localities. No "Hawkeye" should get caught in such a "take."—A. B. MASON.

All depends on the season. If as good as it was here in 1877, you could afford to give him 40 colonies. If as poor as it was in most parts of the United States last year, it would pay you well to let them entirely alone.—G. M. DOOLITTLE.

If the 40 old colonies are to remain the property of the original owner, and only the increase is to be divided, then I should not give him over one-third—that is, you to furnish all the supplies and do all the work.—C. H. DIBBERN.

Find the value of the bees in the box-hives, and the value of bees in the new hives, and give him bees enough in the latter to pay the value of the bees in the former.—M. MAHIN.

I do not know. Whatever the arrangement agreed upon may be, it should be free from conditions, anything vague, liable to be misunderstood, or liable to be understood more ways than one. It should be reduced to a writing in duplicate, that each party may have a copy.—J. M. SHUCK.

If I understand the question, you want to know how many colonies of bees in Langstroth hives in the fall you shall pay for 40 colonies in box-hives in the spring. Figure the actual value of each, and act accordingly. If the risk of wintering is much, you might give him 40 colonies.—C. C. MILLER.

When bees were more valuable than they are now, some years ago, I thought it a good thing on my part to take them one-half for the other. But now I think it would depend upon the locality, and what one was able to do with the bees.—G. W. DEMAREE.

If you return the old hives in the fall, and 20 in the new hives, I should think that both might do well—if the season is propitious, and you know how to *manage* them. But if you did not have that many swarms, and no honey, it would be a losing game for you. I believe, however, that both of you will feel better in the fall if a definite number is agreed upon.—EUGENE SECOR.

I do not know. If the case were mine, and here, I should make a contract that I thought would pay, but to take bees in box-hives to care for and pay back in filled Langstroth hives, I should feel as though I had a hard job before me. It will depend, too, upon the season and yield. The better way, I think, would be to arrange the trade upon a basis such that you will give him a certain amount in value in Langstroth hives, the proportion to depend upon the success of the undertaking.—J. E. POND.

There are too many contingencies to be able to tell what would be exact justice to both parties. Taking into account the uncertainties of the season, if you give the owner a good share of the increase, while you take the honey, it would be as fair an arrangement as you can now make.—THE EDITOR.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

CORRESPONDENCE.

PARTHENOGENESIS.

Some Remarks on Mr. Latham's Article on Evolution.

Written for the American Bee Journal
BY DR. C. C. MILLER.

On page 168, Mr. J. F. Latham gives some instruction about queen-bees. I am not scholar enough to understand the whole of what he says—in fact there is a good deal of it that I do not understand at all, and I wish that some one who does, would, for the benefit of us common bee-keepers, give us the gist of it in plain English.

What are the points in it that we are to know to enable us to rear better queens? If I get the right bearing of the writer, I am to understand from "the atrophied glands of the queen-bee, that parthenogenesis was, at one period in the existence of her species, a more substantial reality than at its present stage of development." Now are we to understand that Dzierzon is all wrong, and that parthenogenesis "at its present stage of development" is not a very "substantial reality?" Is it not a very "substantial reality" that a virgin queen may lay eggs that hatch?

Another part of the article I think I can understand, but possibly I do not get at the author's real meaning. He speaks of the first and second chapters of Genesis, and then says: "As this narrative of the creation (purported to have been drawn from Acadian and Turanian sources, more than a thousand years prior to the compilation of the books of Genesis, as evinced in resurrected Assyrian literature) is." etc. Now I have read the Bible a good deal—I have read every word of it from beginning to end, and I have no recollection of a single passage in it where it "purported to have been drawn from Acadian and Turanian sources." On the contrary, there are passages in it that show very plainly that it purports to be a direct revelation from God himself. Thus, in II Timothy, 3. 16: "All Scripture is given by inspiration of God." That there are men who do not believe in the Bible as a Divine revelation, I have long known, but this is the first time I have ever known that any one believed or taught that the Bible itself "purported to have been drawn from Acadian and Turanian sources."

If I might be allowed, I should like to ask, if the narrative was "drawn from Acadian and Turanian sources more than a thousand years prior to

the compilation of the book of Genesis," what was done with it during those thousand years after it was "drawn," and before it was used?

Now, mind you, in what I have said, I do not pretend to discuss the question as to whether the Bible is genuine—I have only talked about what it "purports" to be. If Mr. Latham has some other than the common meaning for the word "purported," and simply means to say that there is something not entirely genuine about the Bible as the revealed will of God, then I have a word to say.

I do not consider the pages of the AMERICAN BEE JOURNAL the proper place for religious discussions. We meet here as bee-keepers to discuss matters relating to bee-keeping. Among my friends are some whom I highly esteem, who do not believe as I do in the Bible. Mr. Latham has the right to disagree with me, but surely he must know that in the ranks of bee-keepers there are not a few who reverently study the Bible as in very truth God's word, and when he goes out of his way to lug into a parenthesis a fling at that which we hold so sacred, I feel pretty sure that a careful reconsideration of the matter will make him feel that it would have been better to have treated with a little more courtesy that large number who, although in his opinion they are mistaken in their belief, are at least sincere therein.

Marengo, Ills.

[In-so-far as the matter referred to has a bearing upon parthenogenesis in bees, it is admissible; but a discussion of the subject from a religious standpoint, would be inappropriate to our columns.—ED.]

SEASON OF 1888.

Honey as Digested Nectar, and Sowing Alsike Clover.

Written for the American Bee Journal

BY SAMUEL RAU.

The spring and early summer of 1888 opened with many auspicious omens, calculated to inspire new zeal and rekindle hope in the minds of a multitude of discouraged bee-keepers in this part of the honey-producing world, who emerged with dampened ardor from the conflicts of the preceding unpropitious season.

There was ample nectar in the early bloom to promote brood-rearing, and bees never bred up better, in my recollection. Everything looked bright and encouraging. Colonies were populous and in good condition for business at the proper time; but alas! in spite of all the rosy promises, the harvest time came and went, and we were left with very little surplus to gladden our hearts, and what little we did manage to squeeze out, was not of the best quality.

The natural outcome of a season like the one just passed, is too much swarming and too little surplus. Bees seemed to get just honey enough to keep up brood-rearing. My berry business demanded much of my time about then, so that my bees were allowed to do too much swarming; the result was, 30 swarms and 400 pounds of surplus comb honey from 40 colonies, spring count.

A few of the swarms were a little late, and quit housekeeping before buckwheat bloom was fairly over; others I doubled up, fed 250 pounds of sugar and honey, and finally, with many misgivings, I put 59 colonies into winter quarters, many of them not overburdened with winter stores, and a few rather short for the winter campaign. Forty-two colonies having the least stores, I placed in a bee-cellar improvised for the occasion, but the temperature runs too low, and a few colonies have already gone the way of all the earth; but more about this when we "get out of the wilderness."

Digested Nectar.

While Prof. Cook is undoubtedly correct in a scientific point of view, in defining honey as "digested nectar," yet it impresses me as being about as inelegant as it is scientific. It would be equally correct to say that mutton was digested grass, yet a good many of us would hardly fancy that way of expressing it, because, for want of taste and symmetry in the expression, it might lead to reflections that would be more productive of ill than good effects.

Planting for Honey.

While general, or extensive, planting especially for honey may be neither profitable nor desirable, it is quite clear to my mind that we can still do something in the line of planting, that will ultimately prove profitable. Several years' experience with Alsike clover has demonstrated clearly to me, that it pays the apiarist to cultivate it. With me it is a surer source of honey than white clover, and aside from that, it makes an abundance of most excellent hay, for which purpose I prefer it to red clover.

I never saw bees work on white clover like they did on Alsike last season; the only trouble was, there was not enough of it.

I also plant raspberries for commercial purposes, as well as for the early nectar that they furnish my bees, and I find them very profitable in this way. They help early brood-rearing wonderfully, and have never failed me in all my past experience.

The planting of basswood (linden) can be made a source of profit, as well as a world of pleasure, whether planted in waste places, fence-corners, or as timber belts. It is easy to transplant, grows rapidly, makes valuable timber, and in time yields honey abundantly, besides exerting a beneficial climatic influence.

Columbiana, O.

WINTERING.

The Fall, Winter and Spring Management of Bees.

Written for the American Bee Journal

BY C. A. BUNCH.

When I take off the last surplus honey in the fall, I see that each colony has a good queen, and plenty of young bees, and if they do not have one or both, I shake the bees off the combs, close up the hive tightly, and use the combs in the spring, unless I need them to give to some colony that I find short of stores. All colonies that do not have 25 or 30 pounds of honey I will feed—honey if I have it in brood-combs, if not, I feed a syrup made of granulated sugar, as I never allow a colony to suffer for food, if I know it.

I next prepare the bees for wintering. I have five double-walled hives, three filled with chaff or cut straw, and two with dead air spaces, all with bees in them, and 20 colonies in single-walled hives, all of which I am wintering on the summer stands.

To prevent mold and damp chaff and quilts, I stop all upward ventilation with a board or plank with chaff above the board. I use plenty of chaff, and it is pressed down tightly. I like these boards the best when they are made so that the bees can pass over the frames. Such an arrangement will keep the bees from freezing; and I have found out by experience that the entrance must be left open the full width, all through the winter; if not, the bees will get too warm, and sweat so much that a small entrance will soon close up with ice—at least here in northern Indiana I find the hives to be that way. My hive entrances are open $\frac{3}{8}$x18$\frac{3}{8}$ inches through the winter, until in April.

Managing Bees in the Spring.

In April, when a colony is reduced by the old bees dying off, I close the entrances to about $\frac{3}{8}$ by 4 or 6 inches, and this will cause the bees to build up

fast, and will keep the brood from chilling while we have so much changable weather. I am not in a hurry about unpacking the bees until about time to put on the sections.

Last spring, and a year ago last spring, the most of the hives were full of bees, and swarming commeneed from May 16 to the 20th. One swarm that I hived a year ago last spring, on May 16, built five Langstroth frames full of comb, with only foundation starters in the brood-nest, and stored some over 100 pounds of comb honey, besides enough to winter on. The season of 1888 was a poor one for honey in this part of the country. I think there was too much drouth.

La Paz, Ind.

BEES STARVING.

Season of 1888—Fruit-Growing and Bee-Keeping.

Written for the American Bee Journal

BY J. M. CLARK.

The past was an "off year" with me in bee-keeping. I wintered 37 colonies, and lost 2 from starvation during the backward spring of 1888, so I commenced the season with 35 colonies in good condition. I moved them about half a mile the last of May, and lost only about a pint of bees, by their returning to their old stands.

By supplying them with extracting combs, I succeeded in increasing them to 40 colonies, by natural swarming, and secured 200 pounds of extracted honey, over and above enough to carry them through the winter.

After doubling them back to the original number (35 colonies), I put them into my new bee-cellar, in which the temperature has ranged from 35° to 46°. They have been very quiet until within a few days (March 8) 3 or 4 colonies have become quite uneasy, and spotted their hives some.

I am combining bee-keeping with small fruit-growing, and last year I got two crops from my raspberries—one crop of honey (about one-half of my honey crop), and one crop of berries—in fact about the only plants that yielded honey last summer were raspberries and buckwheat.

We hear of a good many in this locality who are losing their bees this winter by starvation. One of our leading bee-keepers killed all his bees—about 60 colonies—last fall, thinking that he could purchase in the spring cheaper than he could buy feed to carry them through the winter. I think that he will "get left."

I am not discouraged by the past failure, and propose to keep my "dish right side up," so that when a good season comes I may then catch my share. With such a honey crop as I had in 1886, and the number and condition of my bees in 1888, my crop would have been tons, instead of hundreds of pounds.

Hillsdale, Mich.

The Boy and the Bee.

Written for the American Bee Journal

BY GEORGE W. YORK.

A little boy just ten years old
(Who lived upon a farm),
Went out to watch his brothers plow—
In this there was no harm.

So quietly he walked along—
This happy, barefoot boy,
So free from care, or anything
That sometimes does annoy.

A clover field was being plowed;
The air with sweetness filled;
And many bees did hover round
The nests they once did build.

One bumble-bee was out of sorts,
Indeed he was quite mad,
And seemed delighted when he saw
The careless, joyful lad.

"Now I'll just whisper in his ear,"
Thought angry Mr. Bee,
"And tell him all about my home,
His brothers spoiled—you see?"

So thinking, Mr. Bee flew on,
To greet the little boy;
And when they met, the bee began
In words devoid of joy;

But as the bee revealed his tale (or tail),
Oh, how that lad did yell,
"Mother! Mother!" in fearful sound,
And rushed for home pell-mell.

Across the mellow ground they flew,
That bee and boy—my brother;
The bee still with his tale (and tail) engaged,
The boy still howling "Mother!"

Which won the race I scarce can tell—
I know the speed was high;
The lad went like the swallows famed,
That once did "homeward fly."

Chicago, Ills., March 18, 1889.

BEES IN CITIES.

How Bee-Keeping Can be Made to Pay, etc.

Read at the New York Convention

BY M. C. HAND.

For many years I have been a careful and diligent student of this most interesting branch of natural history. This industry is confined almost entirely to the country, for there is where milk and honey flow, probably for the reason that "God made the country, and man made the town." It may be interesting to know the circumstances that led me to become interested in the honey-bee, which are as follows:

When this city (Syracuse) was a mere hamlet of a few buildings, I removed the stumps of the forest trees for a place to build a home, on a lot that is now fast becoming the centre of the city. I spent the best energies of my life in building up the town; by industry and economy I acquired a competency for my few and simple wants the remainder of my life, and retired to a sizable lot in a less densely populated part of the town.

I soon found that God never designed us for lives of idleness, and, to keep my health, I must still be active. So I went to work in my garden of one-sixth of an acre, with the determination to solve the problem of how much a few feet of surface could be made to produce. I was ignorant in this business of how to take the first step, and I resorted to publications on the subject, as I did later to bee-papers, and I found the conflicting of opinions in both cases were misleading. When I find old bee-keepers squarely opposed to each other, on vital points connected with their pursuit, I must believe that they have yet much to learn on the subject of bee-keeping. There is no disagreement that two and two make four, for the reason that that problem is solved.

I have now arrived at that point where I invite the most careful attention as to how I mastered the most difficult problems in both pursuits, and achieved a great success. I believe I have found the "key" that will unlock the secrets to success, in nearly all the pursuits of life. I did not find this key to success in works of horticulture, or in bee-papers, but in the Bible. It abounds in the choicest lessons for our instruction.

There is no evidence that Paul knew anything about horticulture or apiculture, yet I am indebted to him for this key to both. He says, "The invisible things of God are made known to us in the things that are made." If this be true, and I believe it is, the thing for us to do is to study "the things that are made." If you would be successful with the bees, you must study the bee itself, and find out all those invisible things essential to its life and requirements, and then furnish those to the bee. Until you do this, success will not follow you. As proof that I am correct, I will tell you what I have done.

Studying Things that are Made.

By studying the tomato, it grows for me a vine 10 or 11 feet high, loaded to the top, some specimens being 17 inches in circumference. By studying the strawberry, a little spot half the size covered by my house, yielded me 7 bushels; some of the fruit measuring 10 inches in circumference. By studying the bees, I have learned to bring

them through the cold winters without losing a colony for years, unless they were queenless in the fall.

As further proof that I am right, I have photographs here to show, of a plot of ground 30 feet square, that paid me $283 a year.

I found that under the shade of my fruit-trees nothing would grow, as all plants are sun-worshipers, and would not thrive without its life-giving rays; this led me to make the acquaintance of the honey-bee. I accordingly built attractive little homes under my trees, so that every inch of space should produce.

I soon discovered that the bees had laid out highways to and from their flowery fields miles away; then I found that while near them, their highways were so low, that when returning with a heavy load of honey, they would sometimes bump their heads against my hat, and in that case they would deposit their honey, and return in a minute, to chastise me for obstructing their right of way.

To obviate this difficulty, I constructed all around my bee-yard, a wire trellis 10 feet high, and covered it with grape-vines, which gave a great amount of grapes, and completely obviated the bees flying so low as to come in contact with any one in the garden; and it was a sight to stand in their little yard, and see them fall down like drops of rain when they came directly over their hives; and though my neighbors and their children were frequently within a few feet of the bee-yard, I never heard of one case of bee-stings in ten years. So quiet and unseen were they, that I believe if I had closely applied dividing colonies, I could have kept bees in the city for years, without a dozen persons knowing it.

But my mistake was in inviting all my neighbors and friends in to see my little workers. I will relate what difficulty this lead me into.

Bees and Fruit.

One evening I was in the house of a distant neighbor, and while in conversation with him, his good wife came in and held up a partly-eaten pear in her hand, and said, "See! Mr. Hand, how your bees are eating up our pears!"

The neighbor then said: "Yes; your bees have injured my pears for several years, and this year they drop off worse than ever."

Had this been some ignoramus who had not yet found out that bees had no teeth, and could not eat pears, nor anything but what was in nearly a liquid state, I would not have been so surprised; but he was no less a personage than an editor, and must have printed or read a thousand times about the little moth that deposits its egg in the blossom of the pear, and before the fruit is perfected, causes it to drop off. To charge this to the sting of the honey-bee is simply ridiculous.

This same editor had published in his paper, a short time previous to this occurrence, a very interesting account of the United States Government Bee-Experimental Station at Aurora, Ills. From the store of information I will only quote the following:

"Do bees injure fruit? is a question which interests every one in the country who owns fruit-trees or grape-vines. A part of the experiments has been to establish the truth in regard to the matter, and the agent declares that the little creatures are innocent of all the destructiveness popularly laid at their door."

I felt that I must convince him that my bees were innocent of this charge, or that I must remove them. I accordingly called on him, armed with the highest authority coming from the Government, and published in his own paper, thinking that it would be sufficient to convince him.

When I called at his house, and sent in my name, that I would like to see him, he rushed out to meet me like a lion from his den, in a great rage, exclaiming in the most angry manner:

"Mr. Hand, have you come here to talk bees? I have no time for that purpose;" and pointed me the way out.

This is the first time in my life that any inhabitant of this globe has ever "fired" me off from his premises. We had been acquainted for a third of a century, and he knew if I was a bee-man, I never was known to "sting" any one.

I have no ill-will against this editor; neither do I wish to make money by Tom Moore's suggestion, who says:

"The best speculation I know of for a man of pelf,
Is to buy such an Editor for what he is worth,
And then sell him for the price he sets on himself."

Perhaps I should say as further proof, that I still entertain the kindest feeling toward this editor; that I removed my bees, which necessitated the purchasing of land two miles away, and erecting a bee-house, the whole at an outlay of more than $1,000.

The only object I have in referring to this matter is to urge upon those engaged in this industry, the necessity of convincing the public of the impossibility of bees to injure fruit. I speak of this man as an editor, to show you that, notwithstanding his intelligence, he was, or seemed to be so much in need of knowledge, that I think it is the duty of all the bee-societies to sow broadcast over the country, and avoid, as far as possible, these unpleasant occurrences among neighbors.

Syracuse, N. Y.

EXPERIMENTS.

Having but Few Uncapped Sections in the Fall.

Written for the American Rural Home
BY G. M. DOOLITTLE.

How to manage our bees so as to secure the greatest yield of comb honey, is a question of great importance to all those who are engaged in producing such honey for market, hence we often have articles on this topic giving us instructions regarding it. But comb honey is of little value unless thoroughly sealed or capped over, so that "How to manage our bees so as to have few uncapped sections in the fall," is a question of nearly as much importance to us as the first.

For years I was troubled by having from one-fourth to one-half of the combs in the sections not fully sealed at the close of the honey harvest, which were only salable at a reduced price; but of late I have a few of such, even in a poor season.

After experimenting for a year or two regarding the matter, I became convinced that the cause of the trouble was in giving the bees too many sections, and especially conducive to this was the plan of tiering up sections late in the season. How often have I, years ago, spoiled a promise of an abundant yield of comb honey by tiering up four or five days before the honey harvest closed. To tier up sections profitably requires considerable tact, and especially do we want a thorough knowledge of the honey-resources of the field which we occupy.

I think that there is too much injudicious talk in some papers regarding not allowing the bees under any circumstances to cluster on the outside of the hive, the idea being generally conveyed that when bees thus cluster out they need more room. Now, it depends when this clustering-out occurs, whether more room is needed or not; and hence I say "injudicious talk." If the clustering-out occurs at the commencement, or in the height of the honey harvest, then more room should be given, while if at the latter part of the honey harvest, or in a time of honey-dearth, no more is needed; for more room at this time results in the one case in many unfinished sections, and in the other an absolute waste of time used in enlarging the hive.

To illustrate: During some seasons we have but a very few days of honey secretion, and that often after the flowers which produce the yield are rather past their prime. At such times we often do not have on the hive one-half of the capacity which we would

use in a good season, and for this reason the bees begin to be crowded out. Hoping that the weather may be good during the rest of the time that the flowers are in bloom, we give double the room to our colonies, only to have it turn bad weather again, thus giving us only partly filled sections in the fall, while had we left them as they were, all would have been finished.

Well do I remember one such season when in time of basswood bloom we had bad weather up to the middle of the bloom. At this time I had on each hive a surplus capacity of about twenty pounds, when all at once the yield of honey became abundant, and the bees began to be crowded out. Hoping that the weather might be good for some time, I spread the sections on a few hives, by placing some empty ones between those nearly full, giving at most only about 35 pounds capacity, while when all is favorable, I use 60 pounds capacity. The result was that the bees immediately took possession of the empty sections, while the weather turned unfavorable again, and when the season was over I got no more than 5 to 10 pounds of capped honey from these colonies, while those not touched gave 20 pounds of nice capped honey. In this case the bad weather was the cause, for the spreading was not carried far enough to be unseasonable, but in former years I have been the cause of the trouble by spreading or tiering-up but a few days before the honey harvest closed.

Again, after the basswood bloom had failed, there came on a very hot spell when not a bit of honey was to be obtained, and the result was that the fronts of my hives were black with bees. According to the advice above alluded to, I should have given more room, and if the bees then persisted in clustering out, I must take my smoker and smoke each colony until they all went in and staid there. Any one can see at a glance that this would be of no use, for at such times the bees are doing just as much for the benefit of the apiarist, hanging on the outside of the hive, as anywhere.

But to return. My plan of operation to secure all capped sections is as follows: When the bees show, by building little bits of comb here and there about the hive, that they are ready for the sections, I put on sections to the amount of about 20 pounds, and leave them thus until the bees are well at work in them, when I add about 10 pounds more room, placing it at the sides of the first given them. When this room is fully occupied, I give more room at the sides to about the same amount given before, and were I using the tiering-up plan, I should have my surplus arrangement so arranged that at this time I could raise up about one-half of the sections already on, putting empty sections underneath them, instead of raising up the whole 30 pounds, thus giving them more room, a little at a time, as the bees have need.

By the time the bees fully occupy the room last given at the sides, the first 20 pounds given them is ready to come off; and when this is taken off the partly filled sections on either side are drawn together over the centre of the brood-nest, and empty sections given at the sides again to the amount which I think they will need. Thus I keep taking off and putting on sections, taking the full ones from the middle, and putting the empty sections at the sides until the season begins to draw towards its close, when as fast as full ones are taken from the center, the others are drawn up till the space is contracted to the original 20 pound capacity, or even less, if I think it is necessary. In this way the bees are given all the space they really need, while the chance for many uncapped sections in the fall is quite small.

By a little study the tiering-up plan can be made to conform to the above, and worked on the same principle. I think that any plan which requires the tiering up of from 30 to 40 pounds capacity, or the spreading out of the same number of pounds at one time, is a wrong policy to adopt, while the giving of a small amount of surplus room as needed, seems to me to be a wise course to pursue.

THE PROSPECTS.

The Deep Snow Protecting the Clover—Basswood.

Written for the American Bee Journal

BY IRA BARBER.

So far bees are in good condition in this locality, and our prospects for clover is good. There is a great depth of snow all over the fields, which has protected the grass and clover from all harm so far; and as there is from 2 to 3 feet all over our fields now, we are in hopes that it will remain until freezing weather is over.

We got no honey the past season, and where large numbers of colonies of bees were kept together, all had to be fed to keep them alive. I commenced the season with 130 colonies, and it took 3,300 pounds of granulated sugar to keep them alive since June 1, 1888, and I expect to have to feed 1,000 pounds of sugar this spring, before they can get a living. It has cost me more to keep my bees the past season, than it has in all the time since I became a bee-keeper, 37 years ago.

Our prospects for honey from basswood are not very good, on account of an ice storm that we had here in January, that did a great amount of damage to all kinds of timber, and especially to basswood. The ice loaded on the trees to such an extent as to strip every limb from any quantity of the trees, and all are more or less damaged.

If it were not for the bright prospects for clover the coming season, our hopes for a good crop of honey in this locality would be pretty slim.

De Kalb Junc., N. Y., Mar. 14, 1889.

SPRING.

Management for Pleasure as well as Profit.

Read at the Wisconsin Convention

BY REV. T. H. DAHL.

How to manage our bees in spring so we can have a powerful force to gather the nectar when the honey season comes on, is a question of no little importance for a wide-awake bee-keeper. Many bee-keepers have weak colonies at the beginning of the honey-flow, but crowded hives—of bees, not of honey—when it is past. Strong colonies when the bees are consumers, and weak colonies when they are producers, is very poor philosophy. Applied to agriculture it would make every farmer in our country bankrupt.

The secret of success in apiculture is to have strong colonies in the right time, ready for the honey-flow. There can be no doubt about the correctness of this, but the question is, how shall we get them strong in the right time? Now, certainly, this must be our aim in all our management, both fall and winter, but more especially so in spring. The earlier the honey-flow is, the more difficult the management, but also the more important.

The first question will be, when to take the bees out, if they are wintered in the cellar or any other repository. Here is difference of opinions. Some believe in giving them their liberty as early as possible. Others—and I among them—consider it wise to take them out as late as possible. One of our prominent bee-keepers has said very significantly, that he is in favor of putting them out two weeks after the right time. I will give a few reasons why it it well to take them out late in the spring.

As soon as the bees get out on the summer stands they will generally commence breeding. If they get out early, they will breed early. But is not this

just our desideratum, if we would have them ready for an early flow? Certainly, if the good, warm weather could be relied upon to be steady through the whole spring, but we all know this is not the case. We are generally blessed with a good many "squaw winters." Cold nights set in and kill the brood, the bees become discouraged, and so we have "spring dwindling."

Another reason: The bees, when taken out of the cellar, will fly at every possible chance. The winds in early spring are often cold, and thousands of the poor, diligent workers will never return to their home, and the consequence is, chilled brood, weak colonies, and in many instances empty hives.

When, then, shall they be taken out? Not before they can gather pollen from maples and willows. I am every year wintering some of my colonies on their summer stands, and they will tell me when the work has begun. I now take the bees out of the cellar and put each on the same stand they occupied the previous season.

In taking them out I follow this method: I use a leather strap with hooks in each end—*a la* Doolittle. This strap I put over my shoulders, fasten the hooks in the hive, and off we go. I prefer to carry them out in the evening, as they will not rush out so much *en masse* the next morning after they have been out in the open air the night previous.

As soon as the weather permits, I examine them to see how much space they need, and if they have plenty of food. If any are deficient they are marked, and afterwards are supplied with combs of honey left over from last season, or are fed. A splendid rule is to have all our colonies well supplied with stores throughout the whole winter and spring. Colonies occupying too much room are confined to as many combs as they can cover. This is done by means of division-boards or dummies.

Why do I contract the hive? To accumulate the heat and thereby encourage breeding. If the colony is very strong, and the hive is an eight-frame Langstroth, I do not contract, because such a colony is able to fill that space with sufficient animal heat for brood-rearing; if let alone it generally gets everything booming for the harvest.

The other colonies I give more room as often as needed. It is my custom to put a comb in the centre of the brood-nest to force brood-rearing. If the colony needs feeding, that comb is full of honey, if not, it is empty. If more than one comb is required each week, I give the necessary comb at the outside of the brood-nest.

This judicious "spreading of the brood-nest" I have never found to be detrimental to the bees, but always beneficial. I have to depend on white clover as the only resource for surplus honey, and I must have a good force of bees ready when it commences to bloom, or the entire season is lost. Some bee-keepers practice packing in the spring. I tried it one year, but found it too expensive.

I would emphasize the following points: 1. Do not take the bees out of the cellar until late in the spring—not before there is something for them to do. 2. Let them be well supplied with stores. 3. Confine them to a space in proportion to their strength. 4. Give the queen plenty of room for breeding, and see to it that it is kept up till the hives are crowded with workers ready for the harvest.

Stoughton, Wis.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Mar. 30.—Agency, at Agency, Mo.
T. S. Smith, Sec., Agency, Mo.

Apr. 23.—DesMoines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Packing Bees—The Weather.

—A. Holding, Langley, B. C., on Mar. 5, 1889, writes:

I had 12 colonies of bees last season, and they averaged about 40 pounds of extracted honey per colony. I protected 14 colonies last fall on the summer stands, under a shed, with a double-walled case (with about 3 inches of space between each wall) slipped on over the hives. The cases are about 6 inches deeper than the hives, and these spaces over the frames are filled, some with clean old sacks, and some with wool. I think that they are all alive, as bees are flying from all the hives. They would have wintered well, however, this winter, so far as cold was concerned, in the unprotected hives. We are having fine, warm and clear weather with frosty nights. I should judge that the temperature in the sun to-day was not less than 80°. I observed the bees for the first time carrying pollen on March 3.

Results of the Past Season.

—B. F. Carter, Patterson, Iowa, on Mar. 11, 1889, writes:

I packed 35 colonies of bees last fall out-doors, with a good bed of straw under them and between the hives, leaving the fronts open. They have had several nice days to fly every month this winter, and from all appearances they are in good condition, except one colony that came out and went into another hive. There are but few dead bees as yet. My yield of honey was 400 pounds from 20 strong colonies and 8 weak ones. I increased my apiary to 45 colonies. I sold 10 colonies for $30 last fall, and $26 worth of comb honey in one pound sections, at 15 cents per pound. It was the poorest yield I ever had, but I am not discouraged. My bees are hybrids and pure blacks. The best yield I ever had from one colony was 140 one-pound sections of honey in one season, three years ago.

Wintering in Chaff-Hives.

—H. L. Sisson, Freeport, Mich., on March 11, 1889, says:

I have 7 colonies in chaff-hives on the summer stands, all wintering finely. The winter has been very mild here, and the bees have had several flights during the time. They are in far better condition than one year ago at this time.

Early Pollen Gathering, etc.

—Geo. E. Hilton, Fremont, Mich., on March 16, 1889, says:

The first pollen was brought in yesterday, and to-day it is coming it quite lively. The snow is nearly all gone, and it is the first time I ever saw pollen brought in in March, in this latitude. I have lost only one colony so far, out of 250, and that was queenless.

Honey Colic—Stormy Weather

—C. G. Ridout, Hutchinson, Minn., on March 14, 1889, writes:

On page 172 I notice the following question, which is answered by Chas. Dadant & Son: "What is the cause and cure for honey giving people who eat it, the colic?" I do not wish to contradict Messrs. Dadant & Son, for they evidently speak from experience, and intended to aid the many honey-colic sufferers; but their experience and my own, and that of several of my friends, is certainly contradicting; for I have invariably found it to be the case that, where honey was inclined to make persons sick, a small amount

was almost always sure to give them the colic, when, if they would eat a good *lot* of it, with bread and lots of *butter*, they never feel any unpleasant effects therefrom.

Last week the weather was fine, and continued so until last Wednesday, when it commenced snowing, and continued until the snow was two inches deep; this morning it commenced raining, and is still at it, and from the appearance of the sky, it may rain the remainder of the week, in which case the danger from high water will be the first of the season.

My 12 colonies of bees that are in the cellar are in good condition, from all outward indications, for I have not examined them yet, but I think that they will all come out strong and healthy. Honey keeps at a steady price, 20 cents per pound for comb, and 12½ cents for extracted, regardless of color.

Moving Bees, etc.—Mr. David Crumrine, Fayette, O., on March 18, 1889, writes:

I finished moving my 70 colonies of bees 20 miles on March 4, with no combs broken, and no colonies smothered. We had fine weather and good roads, and the bees are in fine condition. I cannot do without the AMERICAN BEE JOURNAL, as it contains so much instruction, and that is what every bee-keeper is in need of, that has a desire to keep up with the times.

Gathering Pollen from Maples.—K. A. Dyke, Effingham, Ills., on March 16, 1889, says:

We are having very fine weather the whole of this week; bees have been very busy bringing in pollen from maple every day. White clover is coming up finely, and appears all right here, and very thick; but we rarely have much honey from it in this locality. Our bees have wintered without loss, on the summer stands again, and are very strong for the time of year. They have consumed quite a large amount of stores, though.

Very Favorable Prospects.—John Nebel & Son, High Hill, Mo., on March 15, 1889, write:

We are having April showers to-day, with the temperature at 70°, and bees are gathering pollen. This is surely spring weather, and it is two to three weeks earlier than usual. Our bees are in good condition for commencing this season's work, as they have wintered excellently, each colony still having plenty of stores and plenty of bees. Now, if only white clover will continue to do its part, we may expect plenty of honey. The clover has stood the thawing and freezing weather the past winter, without any material injury; but the clover has looked as favorable many times before, and entirely failed to secrete nectar, with fields white with millions of blossoms, and we have failed to secure any surplus honey. We cannot predict for the honey crop the coming season, though the prospects are good at present. Neither can we count on honey until it is gathered.

Clover in Excellent Condition.—Thos. B. Reynolds, Dayton, O., on March 15, 1889, says:

We have had remarkable weather the past week—70° in the shade—while a year ago this time it registered zero. The bees are flying like they do in June weather, and gathering pollen fast. There is every prospect for a fine season, the white clover being in excellent condition.

Best Season in Ten Years.—R. M. Tate, Elihu, Ky., on Mar. 18, says:

Bees in this part of the State are in fine condition, as we have had but little cold weather this winter. The past year, in this county (Pulaski), was a good one for honey—the best in ten years. I have only 14 colonies, in Langstroth hives, and all have come through the winter safely.

Bees Wintering Splendidly.—J. L. Way, South Newbury, O., on March 11, 1889, says:

Bees have wintered splendidly so far, and have a good lot of honey on hand yet. My 25 colonies, in the Falcon chaff-hives, are all right, and as clean and sweet as they were last fall. They are packed on the sides with clover chaff, and on top with leaves.

Bees and White Clover all Right.—Thomas S. Wallace, Clayton, Ills., on March 16, 1889, writes:

On Nov. 27, 1888, I put 100 colonies of Italian bees into the cellar, which has stone walls, and the floor cemented, which keeps dry and dusty. The bees are all in movable-comb hives. I put them out on March 5, and 99 were alive, one having starved to death; 3 other weak colonies had lost their queens, and the rest were in the best condition that I have ever seen bees at this time of the year. I have examined them, cleaned the hives out, and found the queens all laying; most of the hives had sealed brood and bees hatching out. Our prospects for honey this year are good. I have 9 acres of Alsike clover, that was sowed last spring, and it looks well. The white clover is all right now; it came from the seed last year. The past two seasons killed out almost all of the old white clover, and if we can have seasonable weather this year, we will have a large crop of honey.

White Clover and the Bees.—Geo. L. Transue, Easton, Pa., on Mar. 15, 1889, says:

I examined my bees on March 13, and found them in splendid condition, very strong and considerable brood; in fact I do not think that they could be any better. Prospects for white clover are first-class in this section of the country.

Bees in Good Condition.—A. W. Fisher, Ganges, Mich., on March 16, 1889, says:

I commenced the season of 1888 with 43 colonies, increased them to 54, and took 3,400 pounds of comb honey in one-pound sections, and 120 pounds of extracted honey. I am wintering my bees on the summer stands, packed in chaff; all seem to be in good condition now. I have wintered my bees on the summer stands for the past 15 years, and I have never met with a serious loss.

A Flower.—R. H. Campbell, Madison, Ga., on Feb. 27, 1889, writes as follows:

I send you a species of flower that at this date is covering the earth almost everywhere, and though nearly every day is cool, the Italians are fairly roaring on it. I never saw it before here, and frost has no effect upon it. It has rained nearly all winter, and the earth is full of water. Vegetation ought to be very rank this spring. We had no winter until January and February, but those months have been genuine winter. My bees wintered well, and have an abundance of honey.

Uncapping Honey.—H. E. Hill, Titusville, Pa., on March, 16, writes:

In reply to Mr. Henry Durham's question on page 172, I would say, having a pail of *cold* water handy, and occasionally dipping the uncapping knife into it, will be found to obviate

the difficulty referred to, and greatly assist in making a clear, smooth cut, if the knife is very sharp, as it should be for uncapping. A good uncapping-knife is indispensable in the apiary. I believe there is but *one* good knife, made for that purpose; I have used a number of different kinds, but I find it "false economy" to butcher combs with a cheap knife. The Bingham & Hetherington uncapping-knife is worth just its price more than any other I have ever used.

Bee-Keeping as a Business.—James A. Scott, Harrison, O., on Mar. 13, 1889, writes:

In this locality there are many bee-keepers owning from 3 to 20 colonies. Many have had the "bee-fever," but did not avail themselves of the many excellent bee books and papers, and consequently failed for want of knowledge. The general opinion here is, that keeping bees as a business is unprofitable. We have had three poor years in succession. Foul brood prevails extensively—several apiaries of from 12 to 20 colonies being entirely dead. I must admit that no one has followed bee-keeping intelligently and persistently, long enough to know how profitable it may be. I greatly prize the back volumes of the AMERICAN BEE JOURNAL, as books of reference.

Costly Neglect.—It is a very great mistake for a farmer to pay big prices for machinery to till his soil, and then leave them out to take the weather. Yet, strange to say, a man can hardly travel fifty miles through our settlements without counting a dozen or more ploughs, hay-racks, reaping machines, etc., standing in the field where the farmer unhitched from them when the season's work was done. Some even have tool-houses, but have neglected to store their implements. This is a burning shame, for next year the farmer will be patching up and trying to work with old, weather beaten, sun-warped, rusty implements, and one year hence he will be in the market buying new ones. Thus he will be at a great loss of time this year in making his much-abused implements answer, and at the great expense next year of buying new machinery, which if served in a like manner will soon wear out also. Now, the first object of every farmer should be to house his tools when through work with them, as they will last double as long by this treatment. Nothing is truer than the statement that sun, wind, rain and snow wear machinery more than judicious use.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin now.

Honey and Beeswax Market.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.

BEESWAX.—Scarce, at 18@22c.

SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.

Sales are good, but market is short of fancy white comb honey.

BEESWAX.—24c.

Mar. 22. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.

BEESWAX.—22@23c.

Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.

Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Money in Potatoes, by Mr. Joseph Greiner. Price, 25 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Feb. 20, 1889, wrote as follows concerning their use of the advertising columns of the AMERICAN BEE JOURNAL:

We got more orders from our advertisement in the AMERICAN BEE JOURNAL than from all the other bee-papers put together.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Advertisements.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. April 6, 1889. No. 14.

EDITORIAL BUZZINGS.

Oh, where shall rest be found ?
The weary wand'rer cries ;
And echo answers, "Where
They do not advertise."
—*Washington Critic.*

March went out with a cold wave. The last few days here in Illinois were cold, with frosty mornings, and on the last day there was a cold rain. The latter was very much needed, and will do lots of good. The bees are reported generally in excellent condition, and so far wintered without loss. Every indication now points to a good honey season—though the spring may not be as *early* as some have expected, it will be on hand in good time.

Restoring Oil-Cloth.—An old and reliable English cook-book give this recipe as an oil-cloth restorer :

Melt one-half of an ounce of beeswax in a saucer of turpentine. Rub the surface of the oil-cloth all over with the mixture, and then rub it with a dry cloth.

Two Articles in this issue are devoted to the new Constitution and By-Laws of the International Society. A presentation of the points made by Dr. A. B. Mason and R. F. Holtermann, will be very beneficial, and aid intelligent action at the next meeting. We favor some of the changes suggested, and hope to be at the meeting and "take a hand" at the discussion of all the points that may come up. Meanwhile let others make suggestions.

Our Readers will do well to examine our advertisements closely. Those who advertise in our columns mean business, and those whose advertisements we insert are generally worthy of consideration.

Some have Asked what the "Honey Producers' Exchange" amounts to, and what are its objects, methods, etc. The following statement is sent to us by its President, Mr. P. H. Elwood, and will give all the needed information. He says :

The "United States Honey Producers' Exchange" was organized under the auspices of the New York State Bee-Keepers' Association, in convention at Utica, N. Y., Jan. 17, 18 and 19, 1888.

Its object is to furnish to its members, prompt and reliable information as to the honey crop throughout the United States. Six or more reporters are appointed in every honey-producing State, who forward their reports to the Secretary on the first day of May, June, July, August and September. The Secretary compiles these reports from each State (separately), and on the 10th of the month forwards to each member of the "Exchange" the reports from the whole United States.

These statistics embrace the increased or diminished number of colonies going into winter quarters, loss in winter and spring, condition of bees at the beginning of the season, proportion of full crop of honey gathered both white and dark, comb and extracted, the quantity of honey in the different markets remaining unsold, with price, etc.

The advantages of this information is too apparent to require any elaboration. We would only say that if you know the honey crop, the market is yours, and you can secure prices in keeping with the amount of honey which you know is on the market.

The "Exchange" has met with great favor among bee-keepers, several members present at Syracuse (Dec. 11–13), and others from abroad, among whom are many of the largest honey producers of the United States, stated that the information furnished by the reports during the past season had been worth many dollars to them in the disposal of their honey, while other prominent bee-keepers pronounced it the best thing that ever came from the association of bee-men.

Feeling assured that all wish to reap a share of the benefits of these statistics, a cordial invitation is extended to all to join the "Exchange," by forwarding your membership fee to the Secretary, G. H. Knickerbocker, Pine Plains, N. Y., which will entitle you to the reports for one year, and also if you can attend its meetings, to all the advantages of membership in the New York State Bee-Keepers' Association, without further expense. The fee is one dollar per year, but it is hoped that enough bee-keepers' will join so that the dollar will cover the cost of two years' reports, in which case you will receive the same for that length of time. Three or four hundred new members are yet needed to bring this about. The "Exchange" has the support and endorsement of such well-known men as Dr. Miller, Messrs. Dadant, Grimm, Manum, Crane, Cushman, Vandervort, Dr. Mason, Dr. Tinker, Pond, Cary, Root, Capt. Hetherington, Martin, Barber, Isham, Doolittle, Clark, Aspinwall, Van Deusen, Heddon, Taylor, Cook, Hilton, Cutting, Valentine, Demaree, Shuck, Foster, Secor, Wilkins, Rasmussen and many others.

Each member will also receive with the report sent out May 10, a list giving the names and address of all the members and reporters. These statistics will not be furnished to the bee-papers for publication, but will be sent only to members. We could not meet our expenses were we to make public our reports.

The "Honey Producers' Exchange" is a valuable aid to the wide-awake honey-producers, and should receive their full confidence and support. Its officers are P. H. Elwood, President ; I. L. Scofield, Vice-President ; G. H. Knickerbocker, Secretary; C. G. Dickinson, Treasurer. These names are a guaranty of its standing and honor.

The Advance published by J. B. Mason & Sons, Mechanic Falls, Me., after copying our remarks on page 131, appends the following :

We wish to tender our thanks to friend Newman for the above very kind notice of us, and we are so glad that such kind feelings exist between the editors of our bee-periodicals instead of a spirit of rivalry. We appreciate any kind words from friend Newman, first because he is one of the ablest, if not the ablest editor we have in our fraternity. In his career he has shown himself bold and fearless, ever ready to stand for right and condemn wrong. We met him at the New Orleans bee-meeting, and found him to be a kind-hearted, generous, good-natured fellow. He ably edits the oldest bee-journal in America, and the only weekly published in the United States.

We would like every one of our readers to see a copy of the good old AMERICAN BEE JOURNAL, that has stood the test for over 25 years, and has been a welcome visitor to the editor of the *Advance* for over 20 years.

If there is one thing more than another that we dislike it is unkind personal remarks between those who should be friends. Any point may be freely discussed without making an unkind personal allusion. We believe in the *fullest discussion* in the kindest manner possible. To agree with our brother editors is our chief aim, and when we must differ in our views on any question, we desire to do it with candor and in kindness. Thanks, Bro. Mason, for the kind words and compliments.

Mrs. Lizzie Cotton has just received the following free notice in the last number of the New York *Voice :*

The AMERICAN BEE JOURNAL warns all against Mrs. Lizzie Cotton's "New System of Bee-Keeping." None of the bee-periodicals, it says, will accept her advertisements.

The above paragraph doubtless was brought out by the warning remarks found on page 132 of the BEE JOURNAL, in regard to Mrs. Cotton's deceptions. But the *Voice* failed to state that it had also been one of her dupes, in that it also published her advertisement of her alleged "New System of Bee-Keeping."

At this Centennial period nothing could be more appropriate than the opening article in the ILLUSTRATED HOME JOURNAL for April, entitled "One Hundred Years a Nation." It is intensely interesting throughout, giving scenes, anecdotes, and historical incidents in such an instructive manner that one can hardly find a place to stop, until all is read. The number has 43 illustrations, and contains two continued stories, of more than average merit, besides ten illustrated articles, music, essays, historical sketches, and considerable miscellaneous matter. It is a large quarto, and each issue contains 36 beautifully printed pages. It is published monthly by Thomas G. Newman & Son, 923 and 925 West Madison Street, Chicago, Ill., at $1.50 a year.

For clubbing rates with the BEE JOURNAL see page 221 of this issue.

BIOGRAPHICAL.

REV. STEPHEN ROESE.

On this page we reproduce an engraving showing the features and appearance of Mr. S. Roese, of Maiden Rock, Wisconsin, who is one of the many successful bee-keepers of that progressive State. At our request Mr. Roese has written out a short autobiography for the AMERICAN BEE JOURNAL, and we present it to our readers. He was left an orphan when only 13 years old, but has fought "the battle of life," and is now 60 years of age, having spent much of his life in missionary work among his German countrymen in England and America, endeavoring to do them good, and help them to

REV. STEPHEN ROESE.

a better life. But we will let him tell his story in his own language. He says :

I was born on July 3, 1829, in the town of Wolira, Electoral Hesse-Cassel. My parents were at one time well-to-do farmers ; my father having served in the great war against Napoleon Bonaparte, from 1806 to 1815, in both the decisive battles of Leibzig and Waterloo. He was given to strong drink, which brought the family to want and loss of home. My good mother died when I was 10 years of age, and my father was accidentally killed (while intoxicated) by a wagon being upset in a dug-out road, leaving me an orphan at the age of 13. While standing at my father's grave, and seeing my last earthly hope lowered into its bosom, I gave myself into the keeping of Him, who has promised to be "a father to the fatherless," and vowed sacredly to God, by His help, that as whisky had killed my father, it should never kill me. This promise laid the foundation for my life of total abstinence.

At the age of 20 I was drafted into the military service, in 1849, at the time of the general revolution in Europe, and my five years of military service was a constant equipment, and moving to and fro during the Crimean war. On petition I was grauted a furlough to go on a visit to Holland. At Rotterdam I took passage for London, England, where I was in a strange land with a straoge language, making my home near White Chapel, London. I met with a German missionary there, whom I assisted in his ardent labors, and helped in the Sunday-school.

After three months in that noted city, I longed to cross the Atlantic, the land of the free, where my sister in Rockland county, N. Y., was waiting for me. On my arrival at New York, Oct. 30, 1855, by recommendation of the German London Missionary Society, I was employed as colporter among the Germans by the American Tract Society. During that four years, I studied and fitted myself for a better work. By experience and change of views, I became connected with the Baptist Mission, and entered the services of the American Baptist Publishing Society as missionary among the Germans in the Upper Mississippi Valley, from which service I was compelled, by sickness, to retire two years ago. I am now doing Bible work for the same Society, as my health and strength permits.

For many years I had a longing desire to study the nature of honey-bees, but I feared their stings. At last I became owner of a colony of bees, which I moved in mid-winter, and I wonder now how they lived through, for I nearly worried them to death, carrying them up and down stairs, until, in the spring, hardly a handful of bees were left. They swarmed, but the next winter they all died.

My desire to keep bees was so strong that I bought another colony the next spring. On taking them home, a distance of 13 miles, the roads being miry and bad, I ventured to drive on the ice of Lake Pepin. After getting on the ice (I did not know it was springy near the shore), I soon found myself with the horse, buggy and bees immersed in water. By the help of some skaters near by, I saved the horse, but my bees could not endure so much water, and I had to purchase another colony ; this, however, lived and did well until the following winter, when they all perished. After that I obtained a colony of hybrids, and having heard and read of the Langstroth movable-frame hives, and many other improvements, I was not slow to avail myself of these advantages, and I feel grateful for them, in which all modern bee-keepers are partakers, and which the venerable Father Langstroth was instrumental in giving to the world.

The instructive reading of bee-periodicals, the exchange of thought and experience of bee-keepers, queries and answers, etc., all has a tendency to make bee-keeping one of the most fascinating industries in the world. Show me a successful bee-keeper, and I will show you an intelligent person.

Intelligence being the moving power in this great onward work, they are a combined brotherhood, ready to sacrifice and stand by each other in time of need. Comparing the tenor of the bee-periodicals at the present date with those of years gone by, it can be truly said that knowledge is increasing.

Catalogues for 1889 are on our desk from—

Gaiani, Bonaghi & Co., Porta, St. Felice, Bologna, Italy—3 pages—Queen Bees.

Reynolds Brothers, Williamsburg, Ind.—4 pages—Hatcher for Fowls.

Wakeman & Crocker, Lockport, N. Y.—6 pages—Machines for Constructing Honey-Boxes.

W. T. Falconer Manufacturing Company, Jamestown, N. Y.—20 pages—Apiarian Supplies.

Empire Washer Company, Jamestown, N. Y.—16 pages—Washers, Wringers, Clothes Racks, etc.

S. L. Allen & Co., 127 Catharine St., Philadelphia, Pa.—32 pages—Tools for Farm and Garden.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. "Sister Gracious," in *Vick's Magazine*, speaks thus concerning their use by boys and girls :

They are invaluable in the conservatory, or even with a few plants. For boys and girls they make delightful studies, and arouses in them an enthusiasm for investigation. Our active, mischief-loving boy was a whole hour studying a scale insect on an ivy leaf. He said, "I thought they were the homeliest and most stupid of bugs, but with my glass I really see something to admire in them. They don't have legs, but 'they get there all the same,' for the mouths all down each side of their bodies suck the sap out of the leaves, and this makes ugly brown spots." And the work of going carefully over each leaf and sponging off the insects was more cheerfully accomplished because he had been so inter-

ested in studying the creatures' strange ways. Take the magnifier into the garden on a summer afternoon, and the children will be more interested in the wonders it reveals than in fairy stories or old legends.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Subscribers who do not receive this paper promptly, will please notify us at once.

The first bank in the United States was the Bank of North America, chartered by congress at the instance of Robert Morris in 1780, and by the state of Pennsylvania in 1781, with a capital of $400.000. It is still in existence in Philadelphia.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at Tarbell House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

QUERIES & REPLIES.

Blankets or Quilts over Frames —Hive-Covers.

Written for the American Bee Journal

Query 622.—1. Do you consider a blanket or quilt over the frames essential? If so, what do you use? 2. Do you use flat or raised hive-covers?—Minnesota.

1. No; it is a nuisance. 2. A flat cover.—R. L. TAYLOR.

1. Yes, every time. I use Indian-head muslin. 2. Flat.—MAHALA B. CHADDOCK.

1. I do not. 2. I use flat hive-covers. —J. M. SHUCK.

1. I use either a quilt or a honey-board. 2. I have both in my apiary; but I prefer the flat cover.—J. P. H. BROWN.

1. Yes, for winter; and oil-cloth sections for summer. 2. Flat covers only.—C. H. DIBBERN.

1. I have used enamel-cloth, but oftener heavy sheeting. 2. Flat.—C. C. MILLER.

1. Yes; I use burlap. I think that it is best, all points considered. 2. Flat.—J. M. HAMBAUGH.

1. We use oil-cloth quilts and straw-mats, and would not do without them. 2. We use half-story covers with a roof over them.—DADANT & SON.

1. Out-doors, yes; in the cellar, no. Cheap factory cloth or burlap covered with a chaff bag of the same. 2. I use flat covers, and winter my bees in the cellar.—A. J. COOK.

1. No, it is not essential, but I use them because they are good and convenient. 2. Raised, but flat.—A. B. MASON.

1. I prefer to use an enameled-cloth over the frames next to the cover. 2. Both kinds, but I prefer the flat ones, if well made.—H. D. CUTTING.

1. I prefer to use one at all times when the sections are not on. 2. I use what is termed a "cap" or "hood," 8 inches deep.—G. M. DOOLITTLE.

1. Something to retain the heat is desirable. I have used dry sawdust contained in burlap, with very good results. 2. I use raised or comb-roofed hive-covers.—M. MAHIN.

1. No; I do not like it. 2. A flat cover made of one board is just as good as anything.—EUGENE SECOR.

1. Yes; something both warm and porous. 2. I use and greatly prefer raised covers.—WILL M. BARNUM.

1. I can handle bees more rapidly where quilts are used to cover the frames; therefore I consider quilts the best of all to cover over the frames. Of course, quilts are not "essential," because boards can be used in their place, for I have used them; but they require too much fussing to get them off and on. 2. I prefer a flat cover with a shade-board over it.—G. W. DEMAREE.

1. Well, perhaps it is not absolutely essential, but quite desirable. I use quilts for some hives, and chaff cushions for others. 2. Flat, and usually made of two boards matched together. —MRS. L. HARRISON.

1. I use a blanket that will allow moisture to pass through. The composition makes no difference, either a piece of old carpet or any other substance, that will confine the bees. 2. I use "Hill's device," giving about one inch over the frames. —J. E. POND.

1. It may not be essential, but it is always a good thing. In a winter case for a hive for out-door wintering, I use a plain board over the frames, but a blanket or quilt is just as good, and no better, with suitable packing. 2. I use a flat cover lined with roofing-tin.—G. L. TINKER.

1. While not "essential," perhaps, it seems to retain the heat, which is very desirable; burlap will do this, and yet absorb the moisture. 2. Flat covers answer every purpose.—THE EDITOR.

Glass in the Surplus Apartment —Kind of Hive.

Written for the American Bee Journal

Query 623.—1. Would not a glass in the surplus chamber be an advantage to see when the bees need room? 2. What kind of a hive do you use?—M.

1. None whatever. 2. A modified Langstroth.—J. P. H. BROWN.

1. No. 2. I use the Heddon-Langstroth, and the Heddon and Langstroth chaff-hives.—A. J. COOK.

1. I use glass in some hives, and it is a great help. 2. The plainest, cheapest, well made Langstroth hive that I can make.—H. D. CUTTING.

1. I never use such now, but I used to. It would be no advantage to me. 2. The Gallup hive with some modifications.—G. M. DOOLITTLE.

1. I do not think that a glass is of any advantage. 2. I use the Langstroth hive, that will take four 4¼x4¼ sections.—J. E. POND.

1. No; you can see much better from the top of open sections. I use the New Dibbern Invertible hive, and want nothing better.—C. H. DIBBERN.

1. I consider glass in or about a bee-hive unnecessary. 2. I use the "Invertible" hive.—J. M. SHUCK.

1. If you use surplus boxes, yes; if you use a case for one-pound sections, like the Heddon-case, a glass is not necessary. 2. The eight-frame Langstroth.—MRS. L. HARRISON.

1. No. It is a very simple thing to raise the cover, or one end of a case, to see what is needed. 2. The New Heddon hive, principally. —R. L. TAYLOR.

1. No. If you use the right kind of a case, it is entirely unnecessary. 2. The Langstroth, principally.—EUGENE SECOR.

1. Yes. 2. My frames are nearly the size and form of those that are called Gallup frames.—M. MAHIN.

1. No. It will not pay for the extra expense. 2. The Quinby, *a la* Dadant, and 10-frame Simplicity.—J. M. HAMBAUGH.

1. If you will tell me *where* you would place the glass in the "surplus chamber," I will tell you that I do not think it would pay. 2. The Langstroth-Simplicity. No better hive was ever made.—WILL M. BARNUM.

1. No apiarist who means business, wants to bother with looking through glass. He wants to open the hive and know for sure. 2. The Simplicity and Gallup.—MAHALA B. CHADDOCK.

1. I have no use for any. 2. It is known here as the "eight-frame Everett-Langstroth," taking the Langstroth frame.—A. B. MASON.

1. Oh, no. You can see plainer without any glass in the way. 2. The Langstroth, with a trifling variation that is no improvement.—C. C. MILLER.

1. It would be with close-fitting tight crates, and close-top sections; but not with open sections or frames, when the raising of a corner of the quilt can show the condition of things. 2. We use a large Langstroth-Quinby hanging-frame hive.—DADANT & SON.

1. Nothing satisfactory can be seen through glass in supers. 2. The movable-frame Langstroth in principle, which time and experience will continue to demonstrate the most practical hive, to the practical bee-keeper.—G. L. TINKER.

1. The way my surplus cases are made, glass is of no use. I cover the surplus cases with bee-quilts made of enameled-cloth, and by taking off the hive-cover, and turning back the quilt, I can see what progress has been made, at a glance. 2. I use a modernized Langstroth hive—the best hive in the world.—G. W. DEMAREE.

1. Looking down between the open-top sections will be more satisfactory than glass, when you want to ascertain when the bees need room. 2. We have never used any but the Langstroth hive, except when testing some new feature, by request.—THE EDITOR.

CORRESPONDENCE.

CONSTITUTION.

Some Suggestions on the New Constitution and By-Laws.

Written for the American Bee Journal
BY DR. A. B. MASON.

When at the meeting of the North American Bee-Keepers' Society at Chicago, in November, 1887, I listened to the reading of the report of the committe on a New Constitution, etc., for the Society. I was very favorably impressed with its completeness; and I must confess that to see the editor of the AMERICAN BEE JOURNAL standing there, but the shadow of himself, and scarcely able to stand, or talk, through weakness, the result of a recent severe illness, it elicited my sympathy for the production.

When he stated, before making the report, that most of the work had been done on a sick bed, when *rest* would have been a boon to the fevered, tired brain, I realized that but few would have made any report; but, with characteristic energy and *vim*, Mr. Newman was "on deck," ready to report.

When the committee, to which the report was referred for consideration, simply recommended that the matter be laid over until the next meeting, I felt indignant, and had I not felt that the members of the committee were incapable of such ungentlemanly conduct, I should have taken their action as a direct insult to Mr. Newman, and I fully agree with Dr. Miller's statement when he says, that "Mr. Newman is entitled to a hearty vote of thanks, and the committee appointed to report upon the matter..... deserve a no less hearty vote of—censure, for their neglect to consider and report;" and I then and there decided that if the opportunity were presented, somebody about my size would see what could be done about it.

The subject came up on the morning of the second day's session at Columbus, O., last October, and but little was said about it, and my being in the chair, and not just in the "spirit" to stir matters up, the subject was dropped. During the evening session, Mr. Newman will remember that I called him to the chair, and I "took the floor" for the constitution, and he knows the result. Secretary Holtermann says, "President Mason brought the matter up so (to me) unexpectedly, that it took my breath away." That it is "perfection itself," no one has claimed, and I think that suggestions "are in order;" and for one, I hope that the suggestions will be made, but *do not* "suggest" that certain portions are not right, unless suggesting what is thought to be better.

I also think that Dr. Miller's suggestion on the change of name from "International American Bee-Association" to "American Bee-Society" a very good one; but I should prefer to have it "North American Bee-Society." I would erase the words, "its officers," from Sec. 1, Art. III, and I would insert the words, "and life" in the same article, Sec. 4, between the words "annual members." This section allows no one but members to participate in discussions, which, I think, is right.

In order to do away with the possibility of a tie vote in the executive committee, would it not be desirable to so change the last clause of Sec. 1, Art. IV, so as to read, "the President, Secretary and Treasurer shall constitute the executive committee?"

It seems to me that the last clause of Art. V should be so changed as to make the dues from affiliated societies payable on or before the first day of the annual meeting. My reason for this change is, that a goodly number of bee-keepers' societies do not meet until after the first of January, and some have meetings in the summer, and some in the fall or early winter just before the meeting of the International.

In the first clause of Art. VI, leave out the words "time and;" and change the last word of the article to "time." Leave out Art. VII entirely, and change the numbering of Art. VIII and IX to VII and VIII.

I am decidedly in favor of so changing the last clause of Art. II, of the By-Laws, as to not have it operative in regard to the present President, or that the address be delivered at such time during the sessions of the convention, as Dr. Miller may be absent, or "caught napping," or if such change is not made, and the Doctor cannot be caught off duty, he had better make ample preparation for the President's defense. (See page 711, near the bottom of the middle column, of the AMERICAN BEE JOURNAL for 1888.) It seems a little unfair for the Doctor to so emphatically, metaphorically, sit down on the rising ambition of the present and future Presidents, after he has "passed the chair," and had an opportunity to show off his ability.

In Art. IV, after the word "treasurer," leave out the word "after."

As regards Art. VIII, it may be possible that the committee of five that may be elected (Dr. Miller is wrong in saying, on page 151, "A committee of five *shall* be elected") will inaugurate the proper plans for a "Honey Company"—at least it can be tried.

For the present would it not be advisable to repeal Sub-Sec. 2 of Sec. 2, in Art. IX, and also Art. XI?

Section 2 of Art. XII *seems* to rather "tie the hands" of the executive committee, and confines its selections of essayists and speakers to members of of the Association. A majority of those considered by the executive committee as desirable essayists for the next convention are not members of the Association.

The committee may also think best not to carry out Sec. 1 of the same Article, till after the next meeting of the Association.

It seems to me desirable to add to the first clause of Sec. 3, Art. III, "except persons already members, who may retain their membership by the payment of one dollar, unless objection be made by a member, when the membership shall not continue unless the applicant receives a majority of all the votes cast, as in the case of new members."

I wonder why no apicultural society has yet elected a delegate to the next meeting at Brantford. Does the $5.00 affiliation fee stand in the way? I understand that was the reason why the Michigan State Society refused to affiliate at its last meeting.

If our State (Ohio) Society meets before the meeting at Brantford, I feel confident that there will be at least one State Society affiliated with the International.

Auburndale, O.

[For editorial remarks, see page 211. —ED.]

DESTROYING ANTS.

Report for 1888—Coffee-Bean Honey.

Written for the American Bee Journal
BY WALTER B. DOWNING.

My bees are in good condition, except some are short of stores. I have been feeding a little already. I commenced the season of 1888 with 39 colonies, more than half of which were hybrids. The pure Italians did very well, the best colony storing 80 pounds of honey in the one-pound sections, while some of the hybrids hardly made a living.

There was too much rain and cold for the bees to work on the locust. I got some of them started in the sections a little before the locust quit blooming; then came the raspberries, coffee-beans and white clover. I took about 1,200 pounds of white honey,

nearly half of which was in one-pound sections; the rest was extracted honey.

The rains and cool weather cut off the fall honey-flow before the bees secured enough for winter stores, and I had to feed 200 pounds of sugar. I expect to feed a barrel more this spring. I have 45 colonies now.

I have never seen coffee-bean mentioned anywhere as being good for honey. The bees work on it while the white clover is in bloom. I think that it must yield considerable honey.

The ants bothered a great deal about the honey-house last season. They were those very small black-ants, and increased very rapidly. I declared war on them, but I hardly knew what to try first, as there have been so many things recommended by different ones. I tried scalding their nests, which were in the ground close around the edge of the house; but scalding did not kill them out. I had just been doing some painting and while I had the turpentine there, I thought that perhaps the turpentine would scare them off; so I poured a little on several nests; they did not seem to mind it much at first, but when I went back awhile afterward, I found that the turpentine had soaked down and killed all the ants in the nests. The ground was dry; it might not do so well if it was wet.

Lexington, Ky.

BEE NOTES.

Seasonable Hints for this Time of the Year.

Written for the American Rural Home

BY J. H. ANDRE.

In this, as in all other business, it is far easier to supply a demand than create one.

I have never seen a bee-hive yet that I could not find a good point about, nor one that I could not find a bad one also.

During the summer a queenless colony will hardly ever have any trouble in uniting with a colony that has been hived but a day or two; but if it tries to do so with a colony having plenty of stores during the busy season, they are shown no mercy, but are killed at once.

If increase is wanted, by driving swarms, it is better to leave the old colony, and remove the swarm. As it will be a small one, if done in this way, build it up with the brood from the parent colony, or what is better, from some other one, and make three from two.

When you have hard work to get the bees out of the sections, it is probable that the case has been left on too long, or at any rate, the bees were not doing much in the surplus department, and it was being used as a stow-away for young bees that had never been out of the hive, or at most, only a few feet from it.

Doolittle's method of removing the sections as soon as they are filled, although it may be more work, has the merits of obtaining more white honey, and always gives the bees plenty of business; also one never loses any young bees, as is frequently the case where the whole of the sections are removed at once.

As I had heard much guessing on the weight of a swarm of bees, and wishing to ascertain the facts, I weighed the hiving stall, and after getting a swarm clustered on it which was a medium-sized one, I found its weight to be 10¼ pounds. Probably a very large one would weigh from 12 to 13 pounds.

It is always best if you find that a colony has nearly finished a case of sections, and then have done but very little for two or three days, to remove it at once and give them a case of empty sections, as they might not finish it in several days. If a new one is given them, they usually go to work at once. The unfinished sections may be placed in the next case, or even given away, rather than let a colony lose so much time.

It is no use to disguise the fact that small sections sell the best. The two-pound sections must go. The small sizes will contain only about half a pound in a few years. The most of mine at present will average about ¾ of a pound, and it is very much less trouble to dispose of them. If I should make any new cases this season, they would be arranged for half-pound sections, perhaps two stories of sections in one case.

By planting the red raspberry, bee-keepers would have the best bee-pasturage known, and a crop of fruit also. Raspberry has never failed to furnish honey here. Last season we had an abundance of white clover, but not a drop of early honey from it. But for the raspberry, my crop would have been slim. Indeed, I count it the richest and best honey in the world, and red clover is second best.

With a natural swarm of bees it works well to remove the old colony to a new stand and hive the new one on the old, as the parent colony usually contains much sealed brood that will hatch in a few days. But suppose a swarm is driven, and the old colony removed without making an examination. It might be that the colony contained but very little sealed brood, and much in the larval stage. The consequence would be, that nearly all of the bees would return to the new swarm, not leaving enough for housekeeping, and the colony would be ruined, or at all events worthless for the season, unless built up from other colonies. It is an easy matter to see how this might happen through loss of a queen, and after the young one commenced laying there would be nothing but larvæ and eggs in the hive.

Lockwood, N. Y.

STARVED BROOD.

An Experience with Starved or Diseased Brood, etc.

Written for the American Bee Journal

BY J. P. WYLIE.

In the spring of 1887 I had 45 very strong colonies of bees, but the season being so dry, the bees did not store any more honey than would keep them from starvation, although I believe that they must have starved the brood, as 17 colonies had more or less dead larvæ scattered over the combs, and when the hives were opened, they emitted quite a strong smell. I began to think that my apiary had the foul brood, so I began to get rid of it.

I killed the colonies that had the rotten brood, and burned the combs and bees, and saved the hives, putting them away so that the other bees could not get at them.

I put into winter quarters, in the fall, 28 colonies, packing them in chaff, as I always do, and out of the 28 colonies only 22 lived through the winter (the greatest loss in number of colonies since I have kept bees); those that were left did well enough until about swarming time, when I discovered about 4 more colonies with dead larvæ. I just burned hives, bees and all, and thought that I had cleared my apiary of the trouble; but it was not long before I found it in another colony, so I concluded to let it go, and see whether it would get better of its own accord or not. It got better, and I obtained two crates of honey from the 18 colonies, and saved 8 swarms, thus making 26 colonies to pack in chaff for wintering.

From the 18 colonies I got, on an average, 28 pounds of comb honey, and this was gathered from the smart-weed in the fall.

This is not a good locality for bees, as we have to rely upon the white clover and smart-weed, and the white clover was nearly killed out by the last two dry seasons; but last year there was a little alive yet, and I think that there will be some honey from it this year.

Prairie Center, Ills., March 12, 1889.

CONTRACTION.

Experience with Contracting Hives—Toads and Bees.

Written for the American Bee Journal
BY S. H. HOVIS.

Two years ago I purchased my first movable-frame hives ; at that time the subject of contraction of the brood-chamber was being discussed, and I thought surely this is just what I want, when so many bee-keepers are advocating it in the bee-papers ; so I adopted the contraction theory, having 10 colonies in box-hives. I transferred about half of them, giving them about 5 or 6 frames, and leaving the largest and best looking boxes, to see which would come out the best.

During the summer the bees in box-hives swarmed, and I put the swarms on 6 frames, and these with the others on movable-frames. I gave the best of care ; and in return for my care and trouble, I expected the supers filled with nice honey in one-pound sections; but, alas, I was disappointed—not one gave me a pound of surplus, while, on the other hand, those in box-hives had the pleasure of taking care of themselves, which they did nobly, besides giving me some surplus, and were strong colonies when put into winter quarters.

With the above results I was not satisfied, but I placed the hives all in a row facing the southeast, with a shed over them, boarded up on the north side and at the ends, and packed all around with straw. I hoped that the reverse might be true in the spring.

All the colonies wintered, apple-bloom came, etc., and those in box-hives were strong and vigorous, and three of them stored some surplus in fruit-bloom ; but the others were weak, and did not increase in strength like the former. After fruit-bloom the contracted colonies were so weak that a neighbor's bees robbed 4 colonies of them—they were too weak to defend themselves, so I gave them a thorough examination ; one had a handful of bees and a queen, while others had increased to be fair colonies. I looked at the box-hives, and they were full of bees.

With these results, I took in the situation, and I said to the contraction theory, "Get thee hence ; thou art an offense unto me ;" and I cast the "demon" out, by tearing out division-boards, uniting colonies, and giving to each colony 8 or 9 frames ; the result of this was that last fall, when buckwheat and fall flowers came, I had strong colonies, which gave me from 16 to 50 pounds of surplus each, with the brood-chamber full of winter stores.

I wish to add that the 2 colonies which gave the largest yield, were in box-hives, the honey being taken in one-pound sections. I use the Simplicity or Langstroth frame, and I am now making the hives with the brood-chamber just 12 inches inside, which is just right for 8 Langstroth frames, and I think that it will admit of 9 frames for brood-rearing.

The weather the last week has been very pleasant, and the bees have flown nicely for four or five days, although the snow is not all off yet along the fences and roadsides where it drifted ; notwithstanding this, to-day (March 18) my bees were not only busy at work cleaning house, but they were busy carrying in pollen, which was beautiful, light yellow, and they came in well loaded with it. This surprised me, for I did not expect to see it for a month yet. It is certainly early for this latitude—the northwest corner of Pennsylvania.

Experience with Toads.

On a warm, moonlight night last August, about 10 o'clock, I walked around my hives to see if all was right. I lean a board from the ground to the edge of the stand of all my hives, so that heavily loaded and old bees can crawl up when they drop down before they reach the entrance. One hive was lower than the rest—about four inches from the ground, with a board in front ; I noticed that a large toad had stationed itself on the board just in front of the entrance, and about four inches from it. My presence did not annoy it in the least, so I stooped down close to see what was going on. The bees were frightened, running up and down the front of the hive ; the toad did not move, but every little while I could hear a kind of a smack, as is made with a person's lips.

The hive being shaded a little, and the toad one of those independent creatures that had things its own way, I went to the house and got a lantern ; I turned the light on it when I was some distance off, then approached quietly until I was in close proximity, and watched closely.

The bees were running and buzzing around, and I could hear that smack very often, and see the toad's mouth open a little, and the bee directly in front of the toad would disappear, but so quickly that I could not account for it. All at once a bee came running out past the toad, and halted by its side ; this was my opportunity to see where the bee went. The toad turned half around, bowed his head (I heard the same sound as before), its mouth opened a little, and the bee went somewhere, but I was *still* in doubt, unless the toad has a long tongue that it can use with lightning speed.

I cannot say where the bees went, for the toad did not spring at them, as the toad did that Mr. Smith mentioned on page 171 ; neither did it take the bees off the board with its mouth. Will some one please tell why toads act so differently ? or was I deceived in my observations ?

Pearl, Pa.

INTERNATIONAL.

The New Constitution, and the Meeting at Brantford.

Written for the American Bee Journal
BY R. F. HOLTERMANN.

I was almost afraid that the discussion on the new Constitution and By-Laws of the International Bee-Association was about to drop, for the time being. I believe that by a proper interest being taken now in the matter, we can meet at Brantford ready with all necessary changes, not occupy time which can be more profitably spent, and come to conclusions likely to be such as to require no further revision.

Dr. Miller objects to simply "International," yet thinks that "American" will screen him from anything beyond Canada and the United States. What about South America ? I have no great objection to International, but if a departure from North American Bee-Association is advisable (and after reconsideration I doubt it), I think that International Bee-Association will do, and the next International will have to call theirs No. II. We have the field.

I like Dr. Miller's suggestion about fixing the time and place at the annual meeting, and giving "the executive power to change within a given time, if they saw sufficient reason for doing so."

But let me say right here, that Art. VII of the Constitution says that the President, Secretary and Treasurer shall constitute the executive committee ; so the Doctor need not think that he is going to get out of his duties in that way.

Art VIII of the By-Laws, says : "A committee of five may be elected who shall have power, etc." I wonder where Dr. Miller is quoting from. I have the bound report as published by Mr. Newman, and doubtless this is correct.

Essays at Conventions.

I believe in them, to a certain extent. I should not like to see a meeting taken up by essays, and crowding out discussions. Essays can be boiled down—take about 8 to 10 minutes each—and lead up to a discussion,

lengthy and animated, concentrating our thoughts upon a certain line, and prevent rambling discussions. I must favor the right kind of essays.

About trying to get representatives from other nations to Brantford, I may say that I have had considerable correspondence upon the matter, and it has received attention in some of the leading European papers; but I have come to the conclusion that our Association is not in a condition to undertake such a matter this year. When we do undertake it, it must be done well, and in a way that the Association can feel proud of. Our meeting must then be occupied as little as possible with business, and we will require funds.

During the present year we must arouse greater interest in our Association; as far as I know, not one who was not at the last meeting at Columbus, has become a member of the Association. This should not be; and before the next meeting, an invitation will be sent directly to many who ought to be with us, and who ought to be members. Of course the list will be very incomplete, yet any who do not receive this notice, will, it is to be hoped, favor us with their presence, and all become members.

The surplus fund shall, I trust, remain in the treasury, and before many more annual meetings have been held, it is to be hoped, and I believe sincerely, that we will have a grand International meeting—one which for some time will give bee-keepers on more than one continent fresh food for reflection, and advance bee-keeping.

I have written to the Secretary of every district association in Canada, so far as I know, before they met in convention, urging them to send representative to Brantford at our next meeting, and I may say that already there is no doubt, if we have even only a medium season, we shall have a grand meeting. What is required now is, the addresses of all the secretaries of associations in the United States, so that they may be urged to do the same; for this I must depend upon the kindness of others.

We want representatives from at least every State association, and deputations to invite the associations to the next place of meeting. It will be seen that the hearty co-operation of many are required, and at once. Let us only make up our minds that success shall crown our efforts this year, and, with a fair honey season, we shall have a very large number of bee-keepers assembled.

Brantford, Ont.

[For editorial remarks, see page 211. —Ed.]

KA-CHING! IT'S SPRING.

Ka-ching! The balmy spring has come,
The sun shines warm on all below:
I thought the streams would surely run,
It seemed so warm within, Ka-choo!

Why, who had thought the wind so sharp!
It chills me, truly, through and through,
I wonder if the month of March
Is really spring? Oh, dear! Ka-choo!

I saw a bird this morning flit
Amid the boughs of yonder pine;
And so I thought I'd wait a bit
And sun myself. Ka-choo! Ka-ching!

Well, really, I'll not wander far—
Ka-choo! It seems so out of place
To sneeze so when the birds, so gay,
Are searching for a resting place.

—*Vick's Magazine.*

BEE-CANDY.

The Sholz or Good Candy—Honey and Pollen.

Written for the American Bee Journal

BY PROF. A. J. COOK.

There seems to be some doubt about the "Good" candy having been described previous to the discovery made by Mr. Good. There is no doubt but that Mr. Good re-discovered and re-described this, with no knowledge that it had already been successfully used.

If the reader will refer to Mr. Langstroth's excellent work, "The Hive and Honey-Bee," 3d edition, page 274, he will find the following:

"The Rev. Mr. Sholz, of Silesia, recommends the following, as a substitute for sugar candy in feeding bees:

"'Take one pint of honey, and four pounds of pounded lump sugar; heat the honey, without adding water, and mix it with the sugar, working it together to a stiff, doughy mass. When thus thoroughly incorporated, cut it into slices, or form it into cakes or lumps, and wrap them in a piece of coarse linen, and place them in the frames. Thin slices enclosed in linen may be pushed down between the combs. The plasticity of the mass enables the apiarist to apply the food in any manner he may desire. The bees have less difficulty in appropriating this kind of food, than where candy is used; and there is no waste.'"

As I have said, there is no doubt but that Mr. Good re-discovered this excellent method of preparing candy; and made it applicable to shipping; thus doing away with the bottle of water. So we still may keep his name. Can we afford to call it the "Good-Sholz candy?"

Gathering Honey and Pollen.

I should like to hear from others on Mrs. Chaddock's criticism on the way bees gather honey and pollen. I have observed quite carefully, and I believe that it is quite exceptional for bees to gather two kinds—either of honey or pollen—on the same trip.

Mrs. Chaddock says, "Go into the garden or orchard, and observe." That is just what I have done, and I have concluded from these observations that, though bees do very rarely gather from different flowers on a single trip from the hive, yet such action is exceptional, and only proves the rule that they do not do so.

I should like to hear from Messrs. Doolittle, Dadant, etc., on this point.

Agricultural College, Mich.

PRIORITY

Of Location Not a Simple Question.

Written for the American Bee Journal

BY S. T. PETTIT.

On page 234 of the *Canadian Honey Producer* is an interesting letter from the pen of Mr. J. E. Pond, in which he says: "The question of priority of location is one of the most simple yet brought to the attention of bee-keepers; yet some are attempting to make quite a bugbear of it. Considered in its simplest forms, it amounts to just this, and no more: Can any one who chooses, keep bees upon his own lands? This is all there is in the question, and discussion, no matter how long drawn out, can make nothing more, nothing less, of it."

I was a good deal surprised on perusing the strange position taken by our usually clear-headed friend; and now if Mr. Pond will kindly, at his leisure, on some fine warm, sunny, spring-like morning, call on me, I will accompany him across several sugar-bushes, or drive by the road, as he may choose, about three miles, and visit a friend who is now in the interesting transition state from the farmer to the bee-keeper. He has kept bees in a crude way for many years; has four sons, enough to do the farm work; hence his ambition to devote his time to improve upon his old ways, and make a little out of his bees.

Just last summer another man (a good man, for aught I know) purchased a small lot of land, built a house, and is planting an apiary near by the other man. Now it is quite clear, that this procedure means injury or disaster to both, for profits on bee-keeping now-a-days come only to those most favorably situated.

Now when I tell Mr. Pond, that Ontario has hundreds of unoccupied fields for honey-producing purposes just as desirable as this one, I think that he will agree with me that this

friend should have located in some field not preoccupied by another.

This one example is enough; many more could be given. It does seem to me, that there is a fitness and fairness of things backed up by the best interests of the intruding party, that should influence bee-keepers to observe the priority-right principle. So it will be seen that I cannot agree with Mr. Pond, that the simple question, "Can any one who chooses keep bees upon his own land?" covers the whole ground of the priority-right prineiple; evidently that conclusion has been rather hastily reached.

Very true, the doctrine of the survival of the fittest will usually *kill off* all but one in most localities; but, oh! the loss, the cruelty, the heart-burnings, and the unseemliness of the whole unbrotherly, inhuman process; enough has come under my own personal observations to fill a volume, and sadden the hearts of a nation of bee-keepers.

When in a discussion I hear any one hurl at his opponent "selfishness," and the like, I generally smile, and soliloquize thus: "Abuse is not arguments—*they* are exhausted.

Belmont, Ont.

BEE-CELLARS.

Even Temperature of Under-Ground Cellars, etc.

Written for the American Bee Journal

BY REV. STEPHEN ROESE.

The weather here is very soft and open, and the bees in my above-ground bee-house are getting very uneasy, so that the floor is quite covered with dead bees. Had I known that the winter would have been so open, I would surely have left them on the summer stands; but as it is, I will have to make the best of it, and do the next best thing. I fear that if settled weather of some kind does not soon come, some colonies will get very weak, and heavy spring dwindling will be the result.

It is my candid opinion that underground bee-cellars furnish the most even temperature for bees to winter in successfully, and, if life is spared, I shall prepare one for next winter. It is hoped that the pleasing key-note—the joyful hum of the busy bee—will soon greet the apiarist's ear, and banish all fear of spring dwindling—a disaster so much dreaded in the northern latitude.

The BEE JOURNAL is a welcome guest, and deserves credit for punctuality and candor in bringing that which is wholesome and good; and its contributors and aids must surely be a class who do more than eat, drink, and sleep; for late improvements and modern devices speak louder than words. If legislation and law-making require brains, most surely successful bee-keeping requires intellect and mental exercise to study the ways and nature of the industrious bees, for the benefit of mankind.

Maiden Rock, Wis., Mar. 17, 1889.

SECTION-PRESS.

Press for Folding Sections and Fastening Foundation.

Written for the American Bee Journal

BY C. THEILMANN.

I find the following on page 171 of the AMERICAN BEE JOURNAL for 1888, written by Ed. S. Eden:

"It is somewhat interesting to me to read the different replies to my letter on fastening foundation in sections, as published on page 790 of the BEE JOURNAL for 1887; each one claims that his method, or machine, is just what is wanted; but I fail to see as yet (even after reading Mr. Alpaugh's letter on page 125) that the point of satisfaction is reached. One of the faults with the majority of machines is, that they cannot be adjusted to different sized sections; some machines (and Mr. Alpaugh's is one of them) can only fasten foundation into 4-piece sections, and that before the sections are put together. Each machine must be made for a certain size of section," etc.

I feel it my duty to say something about the Alpaugh foundation fastener and section-press, as I put all the foundation into my sections to perfection, and folded the sections perfectly at the same time last season, with this splendid combined machine. I know of no machine that fastens foundation more perfectly and more speedily than this machine does it, and at the same time fold the sections perfectly square.

My sections are all one-piece, and when folded by the machine, the foundation is sealed in by a steel blade, which is heated by a small lamp made out of a small tin cup. I have used about one pint of Signal Service oil (costs 15 cents) to fasten about 12,000 full sized pieces of foundation into sections.

I have put out my bees 20 days earlier than last year. I put out 217 colonies yesterday, and all are in fine condition. To-day (March 21) they brought in pollen from the soft maples, which are in bloom. Last year it was April 10 when the first pollen came in. The weather is fine, and farmers have commenced seeding.

Wabasha Co., Minn.

ONTARIO.

Proceedings of the Haldimand Convention.

BY E. C. CAMPBELL.

The annual meeting of the Haldiman Bee-Keepers' Association was held at the Town Hall in Cayuga, on March 1, 1889.

Those present were Jas. Armstrong, President, in the chair; Messrs. W. Kindree, D. Anguish, Israel Overholt, M. Schisler, F. Rose, Isaac G. Wismer, O. Fathers, Robt. Coverdale, James Jack, and the Secretary.

The minutes of the last meeting were read and confirmed.

The election of officers was the first business, when the following were elected: President, James Armstrong; Vice-President, F. Rose; Secretary-Treasurer, E. C. Campbell. Directors, Isaac Overholt, Wm. Kindree, W. Atkinson, and F. Mehlenbacher.

The President read extracts from the By-Laws of the Ontario Bee-Keepers' Association, when it was moved by Mr. Campbell, seconded by Mr. Overholt, that the Secretary be authorized to send $5 to the Ontario Bee-Keepers' Association for affiliation with that Society for 1889. Carried.

It was moved by Mr. Rose, seconded by Mr. Overholt, that the President correspond with the Secretary of the Ontario Bee-Keepers' Association with reference to securing a lecture from some prominent bee-keeper at our next meeting.

Pasturage for Bees.

Mr. David Anguish, President of the Brant Bee-Keepers' Association, read the following short essay on bee-pasturage:

I know by experience that there is more importance in pasturage for bees than there is in the management of the apiarists. The last season's crop of honey will explain what I mean better than I can. You are all aware that I got a very fair yield of honey when you all failed here in Haldimand. I do not pretend to say that I am a better apiarist than there is in Haldimand county.

Brant county gave a very fair yield of honey, with the exception of a few localities in and around the city of Brantford. There was one bee-keeper in the county of Brant, who, from one colony in the spring, increased to four, all very strong, with plenty of honey to carry them through, and he got 125 pounds of surplus comb honey in one-pound sections; it was all gathered from Canadian thistle and buckwheat.

I think it would be advisable for every bee-keeper to try some of the

Chapman honey plant. I know it would do well on heavy land, and it comes in bloom when there is nothing else for the bees to work on; and it would be advisable to sow buckwheat, if for nothing else than for the bees.

Some may object to this, but I am pretty sure if you would get some of the Japanese buckwheat and try it you would never be sorry that you did so. Buckwheat is like all other honey plants, if the weather is favorable the bees will gather honey very fast. I had one colony gather 11 pounds in one day, from that plant alone.

DAVID ANGUISH.

The President agreed with Mr. Anguish on the necessity of having good pasturage for bees; and no matter how good an apiarist one may be, if there is no pasture for the bees the result will be a failure.

Mr. Rose moved 32 of his colonies to the county of Norfolk, where there was a large quantity of Japanese buckwheat, and they gathered sufficient honey to winter 64 colonies. In answer to Mr. Overholt, Mr. Armstrong said that bees gathered honey from the second crop of red clover, when other clover is scarce.

It was moved by Mr. Anguish, seconded by Mr. Rose, that the next meeting be held at Cayuga, if a lecturer is secured; if not, at Nelles Corners, on the last Tuesday in May.

E. C. CAMPBELL, *Sec.*

GRAHAM FLOUR.

Feeding Rye Meal and Graham Flour to Bees.

Written for the American Bee Journal

BY ALLEN LATHAM.

On page 179 is a request concerning rye meal. I am not going to tell how to feed rye meal, but I will describe the manner in which I feed Graham flour.

Now, why feed Graham flour instead of rye meal? Last spring I placed some Graham flour beside the meal which I had always used before, and I noted the result. Before two hours had passed, there were but few bees on the meal, and on the other hand, the flour was crowded with them—indeed they took to it as they would take to pollen. "No more rye meal for me!" I said, and I fed flour as long as the bees needed it.

As to the way of giving it to the bees: Dr. Miller's is a good one—I have practiced it myself until this season; but this spring I am not at home more than once in two or three weeks, and there is no one in my family who will touch "the bees."

When I was at home a fortnight ago, I took a large box 5x4x4 feet, and leaving one side open to the south, I made the top water-proof, nailed some cleats on the bottom (so that the meal cannot collect in one spot), and left about five pounds of Graham flour there. It is early now, and I thought that five pounds would be sufficient. I can get my brother to replenish it on some dark night.

The best way to start the bees on the flour is, to toss a small amount right in front of the entrance, where the bees will have to go over it.

Cambridge, Mass.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Apr. 23.—DesMoines County, at Burlington, Iowa. John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bright Prospects for 1889.—J. V. Caldwell, Cambridge, Ills., on Mar. 22, 1889, says:

My bees have been taken out of the cellar in good condition. I lost only 2 colonies out of 120. The prospect for a good season is bright, in my opinion. The past two seasons have sorely tried the pluck of bee-men in this locality, but we hope for better things in the future.

Working on Maple Sap, etc.—H. M. Seeley, Harford, Pa., on March 22, 1889, writes:

There has been a change made in the place of holding the next meeting of the Susquehanna County Bee-Keepers' Association. It will be held at the Tarbell House, instead of the Court House.

My bees are working to-day on the sap of the hard maple, as busily as they ever work in the summer. I have not lost a colony, although I am having trouble enough in other ways. My father and mother were both taken sick one week ago, and now father is dead, and mother is but a very little improved; still we hope for the best.

Looking for a Successful Year.—Geo. F. Robbins, Mechanicsburg, Ills., on March 21, 1889, writes:

The clover is injured very little, if any, here. We had no prolonged drouth last summer to kill it out. The winter has been mostly mild and dry, so that freezing and thawing, and tramping by stock has not affected it much. My bees have wintered well. I put 44 colonies away for winter in poorer condition than ever before; none have died, one is queenless, and the most of them are good, strong colonies. The season so far is opening beautifully. If the weather does not turn out to be too dry, I will look for a successful year.

Bees Doing Well, etc.—S. Burton, Eureka, Ills., on March 25, 1889, says:

My bees seem to be doing well. They have been gathering pollen for past few days, and seem to be strong and active. My loss is 4 colonies out of 32. The four were late swarms. I think that the prospect for a honey crop is very good now.

Early Pollen-Gathering, etc.—J. Blackhall, Hobart, Ind., on Mar. 25, 1889, says:

My 58 colonies of bees are all very strong, and carried in natural pollen on March 22—the earliest of any year in my experience.

Alsike and White Clover, etc.—Samuel King, Jr., New Paris, O., on March 17, 1889, writes:

The past winter has been a mild one, the temperature being 3° below zero only once. Although the winter has been mild, the bees have flown only a few times during the time. The past 7 days have been beautiful—the temperature ranging from 65° to 72° in the shade. My bees have wintered unusually well. I took 6 colonies out of the cellar on March 14 in fine condition. They gathered pollen from soft maple on March 16 very freely. There is a large number of maple trees ranging from ¾ to 1¼ miles from my location, and it is quite a treat for the bees so early in the season. I have 6 acres of Alsike clover, and I mowed a part of it last year; I am very much pleased with it as a honey-producer, and also for hay. There is a fair prospect for white clover in this locality.

I commenced keeping bees in 1867, receiving primary instructions in bee-culture from a neighbor bee-keeper,

who was thoroughly acquainted with the business at that time. I read A. J. King's and Rev. L. L. Langstroth's books, and last of all I got the "A B C of Bee-Culture." I am now reading the AMERICAN BEE JOURNAL, and do not see how I could do without it. I have not kept more than from 35 to 40 colonies at one time, but I have produced a good deal of comb honey since keeping bees, and received a fair price for it. I have never been able to supply the home demand. I produce comb honey altogether.

Mild Weather—Bees all Right.—Leslie Stewart, Jefferson, N. Y., on March 20, 1889, writes:

The weather is very mild here now, though we have had some severe weather at times; but take it the winter through, I think that it has been the most open one that I have ever known. The bees appear to be wintering much better than usual, but of course the next month will tell the story. Last year it was April 25 before I removed my bees from the cellar, but I think that the weather will be warm enough to safely remove them this season by April 1. Those bee-keepers who are wintering their bees out-of-doors, report the bees in good condition.

Bees Wintered Nicely.—John Scherer, Lena, Ills., on March 18,1889, says:

All of my bees wintered nicely excepting 2 colonies. I have examined them as closely as I could, and they had lots of honey and pollen. They were all in one bunch, with lots of honey around them. I would like to know what caused their death. The other bees were flying nicely on March 15. I have them packed in chaff yet, and I will keep them there for a while yet.

Manzanitas—Now Extracting Honey.—S. L. Watkins, Placerville, Calif., on March 16, 1889, writes:

All indications at present point to a prosperous honey season in this part of California this year. All colonies are carrying in pollen and honey at a wonderful rate. The willows and alders along the margins of streams are in bloom, and furnish an abundance of pollen, while the manzanitas that clothe the mountainside keep the bees roaring over their fragrant bell-shaped flowers from morning until night. The manzanitas are very rich in nectar. The honey, when first gathered, is very thin, and will run from the combs with the slightest jar. It generally candies about six weeks after gathering. All the colonies are breeding up rapidly; hive-entrances are crowded with young bees out suning themselves; and others are on the wing in front of the hive, marking their home preparatory to starting after their first load of pollen, or honey, as the case may be. Several colonies of Carniolan bees filled their hives so full of honey last fall, that I had to take away several full frames, and insert empty combs in their places to give breeding-room. I shall begin extracting in a few days.

Wintering in Good Condition.—N. M. Hollister, Fayetteville, Ark., on March 22, 1889, says:

Bees here are coming through the winter in good condition so far. A few of my hybrid colonies are the strongest I ever saw, for the time of year. I like the weekly visits of the AMERICAN BEE JOURNAL very much.

De-Queening Colonies.—Friedemann Greiner, Naples, N. Y., on Mar. 23, 1889, writes:

Forty-two years ago, Rev. Dr. Dzierzon first spoke of the practice of "de-queening a colony of bees to increase the honey crop." Baron von Berlepsch afterwards experimented in this direction, and after some experimenting, gave up the practice as an unsafe one, in 1856. Of late, we find nothing of the kind mentioned in the German bee-literature, which fact leads to the conclusion that the practice is not a popular one at present.

Rye Flour for the Bees, etc.—Mrs. L. C. Axtell, Roseville, Ills., on March 26, 1889, says:

In our apiary we have entirely discarded the feeding of meal or flour to bees, as it is considerable bother and some expense; and we think that our bees are better off without it, as they had better stay in the hive until they can get natural pollen, in this vicinity. I would like to know who of our extensive bee-keepers still practice it. We are much more successful in producing and selling comb honey than extracted honey.

I opened the hives of 4 colonies this forenoon, that were wintered out-of-doors; one had 4 combs with brand-new sheets of capped brood; two hives had 3 sheets; one had two sheets of capped brood; and all had some capped drone-brood and plenty of honey. The bees apparently have not consumed as much honey as is usual in the winter, so we consider the prospect for a large yield of honey very favorable, so far as the bees are concerned; but we are having very dry weather now, and our honey crop will depend upon whether we get sufficient rains or not. All our bees that were wintered in the cellar, came out strong, with no loss.

Small Loss in Wintering.—J. Van Deusen & Sons, Sprout Brook, N. Y., on March 26, 1889, write:

The winter has been very mild, and there are prospects for an early spring. The loss of bees in wintering has been very light.

Carrying in Pollen.—F. Hentrick, Wall Lake, Iowa, on March 26, 1889, says:

I have taken my bees out of the cellar. They did not do very well. I saved one colony out of six, and one on the summer stands, making two. They are doing well now. They carried in pollen on March 23 and 24, which is early for this latitude. I like the AMERICAN BEE JOURNAL, and would not do without it. Some of my neighbors' bees are doing well, on account of reading the BEE JOURNAL. I hope that I can handle bees better in the future.

Honey from Cappings.—Mark Coffin, Milton, Ky., on March 23, 1889, writes:

Query 617, on page 149, asks about the best way to get the honey out of cappings, and I read carefully the answers from the veterans, expecting that some, or at least one, of them would give my answer. I thought it strange that some of them had not tried it; then I thought that perhaps they had, and found it worthless; but then, "wise men do not always think alike." As I have been working for comb honey, I have had no experience in extracting, and have had no cappings to "squeeze." My way of doing it would be, to take a frame (of course I would want two) and tack on No. 16 wire-cloth on one side, fill it with cappings, tack on a thin board on the other side, or wire-cloth on both sides (so that it could be turned, as in extracting a comb), put it into the extractor, and sling out the honey. If the veterans have tried this, and find it will not work, let some of them say so, and save me and others the trouble of trying it.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Honey and Beeswax Market.

HONEY.—White 1-lbs., 16c.; fall, 14c.; 2-pounds, white, 14c. Extracted, scarce at 8@8½c.
BEESWAX.—26@22c.
Mar. 28. CLEMONS, CLOON & CO., cor 4th & Walnut.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1 lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX.—22c. R. A. BURNETT.
Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.
BEESWAX.—21c. for prime.
Mar. 25. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.
BEESWAX.—Scarce, at 18@22c.
SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales are good, but market is short of fancy white comb honey.
BEESWAX.—24c.
Mar. 22. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.
BEESWAX.—22@23c.
Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.
Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

The Illustrated HOME JOURNAL

Published Monthly at $1.50 a Year,

will be clubbed with the American Bee Journal and both mailed to any address in the United States and Canada, one year, for **$2.00.** This low rate will be extended to all those who have already paid for the Bee Journal for 1889. To such the Illustrated Home Journal will be sent one year for $1.00 extra. Following are the

CONTENTS OF THE APRIL NUMBER.

EDITORIAL BUZZINGS.

Birds sing to the heart—to yours and mine—
In spite of chilly weather,
They sing of hopes—human, divine—
Twain spirits share together.

They sing of love heart-warm and true,
All thro' the balmy weather,
They sing till high in heaven's blue
The soul floats like white feather.
FRANCES ADAIR, in Inter-Ocean.

We Regret to learn that Mr. Isaac Hopkins, editor of the *Australasian Bee Journal*, is indisposed, and has had to cease all business for a time. Mr. O. Poole is installed as temporary editor, and manages it quite well. The AMERICAN BEE JOURNAL extends its sympathies to Bro. Hopkins, and hopes for a speedy restoration to health.

Beeswax.—Mr. W. R. Henwood, of Morven, Ont., asks how to separate beeswax from tallow and rosin. Tallow renders the wax soft, and emits an unpleasant odor when being melted; and rosin makes the fracture smooth and shining instead of granular, and may be dissolved in cold alcohol, while the wax remains untouched. We know of no way to separate beeswax from tallow. Such wax is fit only for candles or grafting-wax.

Queen-Excluding Point.—H. L. Hughes, of Lime Springs, Iowa, on April 4, 1889, asks this question:

MR. EDITOR:—Will you please answer this question through the AMERICAN BEE JOURNAL: What is the space that will prevent the queen from passing through, but will allow the workers to pass?

It is quite difficult to decide the *exact* size to exclude a small queen and yet admit a loaded worker—but it is generally agreed that nine-fiftieths of an inch is about right; that is a trifle smaller than five-thirty-seconds of an inch.

Mustard and Rape.—A correspondent in New York asks these questions:

How are rape and mustard as honey-plants, with regard to both quality and quantity of honey? Are they good for anything else besides honey? When should the seed be sown? Of the different species of mustard, which is the best? Have hollyhocks honey in them?

We reply: Chinese or black mustard yields considerable nice honey. Sow early in the spring, broadcast 25 pounds to the acre, or drill it in, 8 or 10 pounds to the acre; cultivate to keep the weeds down at first, later it will kill out the weeds.

Rape yields good honey; sow it about four weeks before you want it to bloom.

Holly yields excellent honey.

Exhibits of Honey-Plants.—Mr. Julius Moesch, Indianapolis, Ind., asks us to state in the AMERICAN BEE JOURNAL how to arrange a collection of honey and pollen plants for fairs. He says: "As some of them bloom in the spring, shall I press a leaf and blossom of each plant?"

In brief reply we remark: Consult Cook's Manual concerning the time of bloom. Collect the leaves and blossoms when the plants are as dry as possible, and spread them out between newspapers, or better, between thick felt carpet-paper. Place a weight on top. When dry (in from 10 to 15 days), mount them on heavy book-paper, by fastening them bodily to the sheet by thick mucilage. To preserve them from insects, apply a solution of corrosive sublimate, using a camel's-hair brush to all parts of the specimen.

Friend Gravenhorst, whose biographical sketch and portrait appeared in the BEE JOURNAL for Nov. 14, 1888, writes thus in a private letter:

You have honored and delighted me by publishing that biography, for German bee-keepers are very jealous of English and American methods, and apicultural inventions, which I and a few others delight to defend.

We spent several days in company with friend Gravenhorst ten years ago this summer, and found him among the foremost of the progressive bee-keepers of the present century.

The Many Friends of Mr. N. W. McLain, late special agent of the United States Department of Agriculture, in charge of the Apicultural Station at Hinsdale, Ills., has been chosen by the Board of Regents of the Minnesota State University, Director of the State Agricultural Experiment Station, and Professor of Agriculture, in charge of the Station and State Experimental Farm, at St. Anthony Park, Minn., four miles from Minneapolis, and six miles from St. Paul. He has already taken charge of the Station, and his address will hereafter be "St. Anthony, Minn." We congratulate Prof. McLain upon his appointment to such a responsible position.

A Compliment.—The biographical sketch and portrait of Mr. Eugene Secor has called forth considerable comment. Among others we will enumerate two from his own State. The Winnebago *Summit*, for March 14, 1889, has this to say:

The last number of the Chicago AMERICAN BEE JOURNAL, publishes a portrait and biographical sketch of our townsman, Mr. Eugene Secor. The portrait is life-like, and the sketch is well written. Mr. Secor is a well-known authority on the subject of bee-keeping, and has shown by actual results his knowledge on this important industry. He has been a correspondent of the JOURNAL for ten years past, and has written many good things, both in prose and rhyme. In the sketch is incorporated a rythmical description of the Bee-Convention in Chicago in 1886, which is exceedingly well written. Mr. Secor looks well in print, and ought to feel complimented at being termed the "Poet Laureate of Apiculture."

The Iowa *State Register* for March 22, 1889, gives this notice:

A WORTHY COMPLIMENT.—The last AMERICAN BEE JOURNAL of Chicago has a good picture of a worthy citizen of Iowa, Eugene Secor, Esq., of Forest City. It also has a lengthy biographical sketch of Mr. Secor's public services, as well as his eminent success as a bee-keeper. Mr. Secor is well known all over Iowa, and is highly appreciated. He has faithfully discharged the duties of nearly every office in Winnebago county, and has had various stations of honor and responsibility in numerous societies and organizations. His literary talents are of a high order, and his poetic genius flashes out brightly on frequent occasions. And yet he is eminently a practical man, and usually makes a grand success in whatever he puts his hands to. He is one of Iowa's good practical men, who can be loved and trusted in every department of industry.

We are glad to learn that our friend Secor is so favorably known at home, and that the notice we gave him is appreciated by his many friends.

Down East the prospect for spring is thus described by J. H. Larrabee, Secretary of the Vermont Bee-Keepers' Association, on the 2d inst.

We are having a very favorable spring for the bees. Soft maples will be open in a day or two. With the bees in good condition, clover plenty, and the blooming year for basswood, you may hear from Vermont in 1889. My 99 colonies have come through with the loss of only one, by queenlessness; indeed bees all through the State are in good condition.

In the West the weather has been colder during the past week than it was in February—and the early spring theory has had a set-back.

Mayor Heddon is the new title won by our friend, James Heddon, at Dowagiac, Mich. He was elected by a small majority over one of the most popular men in the city. Mr. A. M. Moon was also elected Justice of the Peace in that city at the same time. Mr. M. is son of Mr. A. F. Moon, the "father" of the "North American Bee-Keepers' Society," and at the time of his death the late editor of Moon's *Bee World*, published at Rome, Ga. Bee-men are popular in Dowagiac. The AMERICAN BEE JOURNAL offers congratulations.

GLEANS OF NEWS.

Spring Work.—A correspondent in the Ohio *Farmer* gives these hints about seasonable spring work in the apiary :

There are many fine days from the first of March until spring fairly opens when we can handle bees in perfect safety. I have found to my entire satisfaction that there is no time during the year that my attention is more demanded than during March and April. These two months are the key to large honey crops, and I must have my bees in such shape at this time that I can attend to their wants.

I endeavor to put my bees in the best possible coodition for safe wintering during the fall months, but at my regular time of making examination during the following March I have never failed to find that attention was needed, and often many colonies are saved just at the nick of time.

I may have been very particular to give each colony in the fall the necessary amount of provisions, but from some cause I am not able to explain, many will consume almost their entire stores by the following March, while others have abundance in reserve. Hence such colonies must be provided with provisions, or they will starve long before spring sets in.

While it is a fact that food cannot he provided in winter weather in some forms, it can be in perfect safety in others, and not only in perfect safety, but it is very beneficial to healthy colonies, and very healing to those affected with diarrhea. This most dreaded disease generally shows itself in March, and fine days, together with careful manipulating, will bring such colonies through.

All colonies badly affected thus should be placed upon clean combs and provided with candy made from pure granulated sugar. This candy is the only safe winter food we can give bees.

Liquid food of any kind fed to bees during winter is very damaging to them. It tends to produce diarrhea, while this candy referred to will tend to heal it.

After the weather has become broken,and the bees can get a good flight once or twice a week, we can safely feed liquid food, and we should commence as soon as possible by feeding a little to every colony once a day.

From this time forth all depends entirely upon our management as to the force of bees we have on haud ready for the work when the harvest comes. By judicious feeding to stimulate brood-rearing, we can easily have our force double what it would otherwise have been if allowed to take their chances. Large crops of honey wholly depend upon the strength of the colonies, not upon the numbers in the hive.

Catalogues for 1889 are on our desk from—

J. W. Bittenbender, Knoxville, Iowa—4 pages—Bee-Keepers' Supplies.

S. W. Morrison, M. D., Oxford, Pa.—4 pages—Carniolan Queens.

Hulbert Fence & Wire Co., 904 Olive St., St. Louis, Mo.—24 pages—Fencing Wire-Work, for Residences, Cemetery, or Public Grounds.

W. E. Clark, Oriskany, N. Y.—26 pages—Apiarian Supplies.

Martin & Macy, North Manchester, Ind.—12 pages—Bees, Apiariau Supplies, Poultry, Plants, etc.

Rumsey & Co., Seneca Falls, N. Y.—16 pages—Spraying Pumps.

Morehouse & Annis, Rochester, N. Y.—8 pages—Garden, Field and Flower Seeds.

W. E. Clark, Oriskany, N. Y.—28 pages—Bee-Keepers' Supplies.

The Bees are Swarming Over.—On page 196 was published a pretty melody, which, no doubt, delighted many a bee-keeper's family ; but to make the words more appropriate for the apiarian home, they have been parodied by Geo. W. York as follows, and now all bee-keepers can join heartily in the song :

I love to wander by the brook,
That winds among the trees,
And watch the birds flit to and fro—
But hate the hum of bees ;
'Tis my delight from morn till night,
To ramble on the shore,
But often there my mother's voice
Comes from the kitchen door—

Chorus—Maggie, Maggie,
The hives are running over,
The bees begin to swarm ;
Go and hive them, Maggie,
Before they leave the farm.

I'm not allowed to have a beau,
Except upon the sly ;
So yesterday he came and took
Me far from mother's eye ;
We strolled along so lovingly—
From bees far out of reach—
When just from out that kitchen door,
Came that unearthly screech—
Maggie, Maggie, etc.

He took me to a country fair—
Went up in a balloon ;
Says he to me, "We'll go and see
The man up in the moon ;"
We drifted over towards our farm,
And never thought of bees ;
But suddenly I heard a voice
Come far up through the trees—
Maggie, Maggie, etc.

That music on page 196 was "a treat" to our subscribers, unannounced and unexpected, and we find that it struck the popular chord. Many have written to thank us for the surprise, aud asking us to insert more music occasionally. The following from friend C. P. Dadant is only a fair sample of many others :

Please send us another copy of No. 13 of the AMERICAN BEE JOURNAL for my daughters. They find that tune very nice, and wish you would occasionally put in another such a treat.

Molasses for Feeding Bees in the Spring.—Mr. W. S. Peck, of Stafford, N. Y., asks the following questions to be answered in the AMERICAN BEE JOURNAL :

Is New Orleans or any other cane molasses fit to feed bees in the spring ? What is the cheapest good feed for bees ?

We answer : When the bees are flying freely in the spring, anything that the bees will take will not be very objectionable ; so that you can feed them molasses *then* without much danger. On general principles its use cannot be recommended. Sell the molasses and buy sugar, if you have no honey to feed the bees.

Chapman Honey-Plant Seed.—The United States Commissioner of Agriculture has a quantity of the Chapman honey-plant seed for free distribution. Applicants desiring packages of the seed will be supplied while the seed lasts, in the order of their applications. The request for seed should be addressed to the United States Commissioner of Agriculture (Seed Division), Washington, D. C.

What Apiarists Say about the April number of the ILLUSTRATED HOME JOURNAL, which they have just received, may be ascertained by the following which are samples of the multitude :

J. E. Pond, of North Attleboro, Mass., has this to say of it: "The ILLUSTRATED HOME JOURNAL is received. The work is simply superb, as a specimen of typographical execution. As a journal for the home it is first-class, clean, interesting, and instructive, not only an ornament to the library or drawing room table, but a means of giving to many homes a much-needed source of amusement, as well as instruction, both moral and secular. To those who know you, the JOURNAL seems just like you. For the purpose it is intended, I know of none that are quite up to it."

Dr. C. C. Miller, of Marengo, Ills., writes thus: "Well, well; the editor and publisher of the good old AMERICAN BEE JOURNAL is now publisher of a literary magazine. Well, you were born a publisher; so I am not surprised to see it gotten up in such beautiful style, on paper that is a pleasure to handle. I wish it great success."

Dr. G. L. Tinker, of New Philadelphia, Ohio, writes : "The April number of the ILLUSTRATED HOME JOURNAL is received. It is beautifully printed and illustrated, and is full of choice and instructive reading-matter for the family. It is deserving of a wide circulation, for it stands secoud to none of the popular monthlies."

Mrs. Mahala B. Chaddock, of Vermont, Ills., expresses her opinion thus: "I have read the April number of the ILLUSTRATED HOME JOURNAL through, and pronounce the workmanship excellent, and the matter good, cheerful and useful—fully up with the times—and I wish you success in publishing it. I send you a short story and some poetry for the next number."

Charles Dadant & Son, of Hamilton, Ills., write thus: "The ILLUSTRATED HOME JOURNAL is indeed very nice, and after having seeu it, we want it regularly. We compliment you on its appearance."

N. W. McLain, Director of the Minnesota State Agricultural Experiment Station, St. Anthony Park, Minn., writes: "I like your new magazine, the ILLUSTRATED HOME JOURNAL, and I hope you will find it very profitable. I shall have pleasure in contributing an article for its pages, as soon as I can find the time to do so."

George E. Hilton, of Fremont, Mich., writes: "The April number of the ILLUSTRATED HOME JOURNAL is at hand. The typography, quality of paper, and general finish of the mechanical work, as well as the entertainment and instruction it contains, like everything else that comes from your hands and office, is simply A No. 1. My wife is also delighted with the HOME JOURNAL. May it receive the reward it so richly deserves."

S. W. Morrison, M. D., of Oxford, Pa., writes: "Your beautiful HOME JOURNAL is received. I take great pleasure in welcoming such a clean, healthy and instructive journal (as it is) into my home."

G. M. Doolittle, of Borodino, N. Y., writes thus : "The April copy of the ILLUSTRATED HOME JOURNAL came last night. It is simply PERFECTION in all its parts."

J. M. Hambaugh, of Spring, Ills., has this to say : "The ILLUSTRATED HOME JOURNAL is at hand, and is certainly a credit to its editor and publishers. May its success be all that you desire."

Never did the advent of a magazine for the family touch such a responsive chord, or receive such a hearty welcome.

Trial subscriptions will be taken 3 months for 40 cents each; or it will be clubbed with the BEE JOURNAL for a year at $2.00 for both. Agents, who are working for premiums, may take "trial subscriptions," and count 4 as one yearly subscriber. One sample copy sent free to subscribers of the BEE JOURNAL, upon application. That will tell you all about the "Premiums" offered for getting up clubs, and "Cash Prizes" for the largest clubs sent in before Sept. 30, 1889. "Good pay for good work" is our motto. See page 238.

BIOGRAPHICAL.

W. Z. HUTCHINSON.

This week we present to our readers the likeness of Mr. W. Z. Hutchinson, who is well and favorably known to our readers as a correspondent for years, and at present the editor of the *Bee-Keepers' Review*, which is now in its second year. Dr. C. C. Miller gave this biographical sketch of Mr. H. in *Gleanings* for Dec. 15, 1888:

W. Z. Hutchinson is one of the many, who, although born in the East, have spent in the West all of life that can be remembered. Born in Orleans Co., N. Y., Feb. 17, 1851, he was taken, four years later, with his father's family, to the dense forests of Genesee Co., Mich., where his father literally hewed out a farm. W. Z. had the full benefit of pioneer backwoods life; and although hunting, trapping, etc., had a full share of his time, his natural bent was toward machinery. This passion for machinery was, as he advanced in his "teens," put to practical use by building a turning-lathe, and beginning the manufacture of spinning-wheels and reels. These he continued to make for several years, peddling them out in the surrounding country.

At 18 years of age he began teaching school winters. While thus "boarding around," a copy of King's "Text-Book" fell in his way. It was to him a revelation. He learned that the owner had about 50 colonies of bees down cellar, which he was not long in asking to see, and for the first time he looked upon a movable-comb hive—the American.

The next season, in swarming time, he visited this friend, and the charms of bee-keeping appeared greater than those of any other business. Although not really owning a bee till the lapse of many months, he became then and there in spirit a bee-keeper, reading all he could find on the subject, and visiting bee-keepers. The introduction of woolen-factories compelled him to abandon the spinning-wheel trade; and one afternoon in June, while peddling out his last lot, he made a sale to a farmer about 16 miles from home; and although it was only about four o'clock, he begged to be allowed to stay all night, urged thereto by the sight of a long row of brightly painted hives. This bee-keeper had an only daughter, and the reader can weave his own romance, upon being told that the father, Mr. Clark Simpson, became the father-in-law of Mr. Hutchinson.

In 1877 he began bee-keeping with 4 colonies, and an excellent theoretical knowledge of the business. Mr. H. has never kept a very large number of colonies, but has made a comfortable living by the sale of comb honey. In 1887 he removed from Rogersville to Flint, Mich., where he established the *Bee-Keepers' Review*, which fills a place not previously occupied, and is edited with the ability that might be expected from one who has been so favorably known through his many articles published in the bee-periodicals and other papers.

In appearance, Mr. H. might more readily be taken for a professional

W. Z. HUTCHINSON.

man than for a farmer or bee-keeper. Tall, straight as an arrow, with side whiskers, and rather dark complexion, he presents a conspicuous figure at the gathering of bee-keepers, where he is always in office, whether the gathering be local or national.

In the last *Review*, Bro. Hutchinson copies our article from page 83 on the unhealthy increase of bee-papers, and adds:

The last 25 years have witnessed wonderful progress in the arts and industries. Bee-keeping has not lagged behind. With this progress came an increase in journalism, and in the publication of books, but the production of apicultural literature has not been multiplied to any greater extent than has that devoted to other rural industries. It is true that many bee-papers have been born only to struggle and die; but the same is true of many a venture in *all* the fields of journalism.

It is true that competition is one factor in the combination of causes that has brought failure to so many journalistic efforts, but there is more than one *kind* of competition. Brother Newman has mentioned *one* kind, the competition of numbers, but that of *quality* is passed unnoticed. We believe that, in the field of apicultural journalism, more failures have come from the superior qualities of competitors than from their numbers.

This competition among bee-papers is really a *benefit* to bee-keepers. It acts as a spur to the editors; and, in their efforts at vieing with one another, better journals are produced. Too many bee-papers have been started with no intention of competing in the race for *quality;* the primary object being simply that of furnishing an auxiliary to a supply trade—a sort of side-issue. Others have been started with no conception of the obstacles to be met and overcome. Many a journal has gone to the wall because the editorial work has been done in a listless, dreary, half-hearted way that actually courted failure.

"'Tis not wealth, nor rank, nor state,
But its 'git up and git' that makes men great."

To succeed in apicultural journalism, there must be a thorough, practical, working knowledge of bee-keeping; a personal acquaintance with apiarists and with the hobby of each; and the journal must stand *first* in the affections of its editor. In the highest and truest sense, it must be his "baby." For it he must be willing to rise early and work late; to wear plain clothes, yes, *patched* clothes, if necessary; to live on simple fare; and there must be no hesitation as to whether he can afford this or that for his journal; he must simply pull out his pocket-book and *lay it on the altar.*

Neither will it answer for him to sit in his office week after week and month after month; he must work with the bees, get out among bee-keepers, visit conventions and apiaries, and know what is going on; in short, he must leave no stone unturned in his efforts to bring his journal up to the highest standard. This is only a *part* of the price that must be paid for success in apicultural journalism, and he who cannot pay it willingly, cheerfully, yea, *proudly*, would better adopt some other style of wooing the fickle goddess.

As to the hard work, expense and "grit" necessary to succeed in the publication of a bee-periodical, the above are some graphic remarks from one who has "been there," and knows all about it. The *Review* is a home-made periodical. Bro. Hutchinson is

its editor and type-setter, and the work is all done at his home by the assistance of Mrs. H. and their children. It is well gotten up, beautifully printed, ably edited, and deserves a liberal support.

QUERIES & REPLIES.

Best Kind of Fuel to Use in Bee-Smokers.

Written for the American Bee Journal

Query 624.—What kind of fuel do you consider the best to use in a bee-smoker?—Bee-Man.

Half decayed hard maple.—J. M. SHUCK.

Elmwood slightly decayed, and *thoroughly* dry.—R. L. TAYLOR.

Any dry wood, and sometimes a little green wood.—DADANT & SON.

Partly decayed maple, beech or elm.—G. M. DOOLITTLE.

Rotten or dozy wood.—C. H. DIBBERN.

I use coarse cotton rags, corn-cobs, or anything that I can get to burn.—J. P. H. BROWN.

I use elmwood. It is the best I have used.—H. D. CUTTING.

Dry hickory or sugar-tree wood; corn-cobs do very well.—M. MAHIN.

Rotten wood, or "punk" *thoroughly* dried; cotton rags, properly tied in a roll.—MRS. L. HARRISON.

On the whole, I prefer decayed wood—a sort of dry-rot. This makes much smoke, with little heat, and burns long.—A. J. COOK.

Dry rotten elm, should your work be limited; but for an all-day's job, hard-wood chips of almost any kind.—J. M. HAMBAUGH.

Dry rotten wood. I keep some chopped up, ready for use, in a box behind the cook-stove, where it is always dry.—MAHALA B. CHADDOCK.

I prefer the fine ribbon-like shavings obtained in sawing sections. It makes a great amount of smoke, and is always at hand.—G. L. TINKER.

Rotten pine, soaked in salt-petre, with a little "excelsior" (fine shavings) to start up with.—W. M. BARNUM.

I use decayed apple-tree stumps; but any fuel that will burn, and give "lots of smoke," is good enough.—J. E. POND.

Really, I do not know. It is largely a matter of convenience. One of my apiaries is in an evergreen grove, and there we like pine cones best, because we can pick them off the ground. Elsewhere, planer shavings are mostly used. Rotten wood, sound wood, rags, corn-cobs, peat, etc., are good.—C. C. MILLER.

Pine shavings have given me just as good satisfaction as anything. They should be well packed.—E. SECOR.

The best I ever had was the rotten wood of the willow; but for several years I have been using rotten elm.—A. B. MASON.

The best fuel I have ever tried (and I have used nearly everything) is decayed elmwood. Some other woods are nearly as good, but the elm gives more smoke, with less heat, than anything I have tried.—G. W. DEMAREE.

Dry hickory, half-decayed hard maple, punk, planer shavings, corn-cobs, peat or rags are all well suited, besides other things, for fuel for bee-smokers.—THE EDITOR.

Distance Between Apiaries of Different Races.

Written for the American Bee Journal

Query 625.—About what is the nearest that two apiaries could be approached to each other, one containing Italian, and the other black bees, and keep the Italians pure?—J. L.

About ten miles.—H. D. CUTTING.

Probably one-half mile.—MRS. L. HARRISON.

We cannot *assert*, but we would say about five miles.—DADANT & SON.

Eight or ten miles, I think would be required to make it sure.—R. L. TAYLOR.

My experience says from four to five miles.—G. M. DOOLITTLE.

Italian and black bees will cross where distant four miles.—J. P. H. BROWN.

It would be perfectly safe at six miles. A shorter distance may do, but I am not certain.—C. H. DIBBERN.

I do not think that any one knows. I should prefer to have the apiaries at least five miles apart.—A. J. COOK.

I suppose that six miles would be considered a safe distance.—MAHALA B. CHADDOCK.

I cannot say positively, but I would hate to risk them any nearer than five miles.—J. M. HAMBAUGH.

I think that three miles is a safe distance. Others will put it further, but I think that they are mistaken.—G. W. DEMAREE.

That puts me in mind of a question once asked as to how far apart Lombardy poplar trees should be set. The reply was 50 miles. That about answers this query. Not that bees will fly 25 miles, but with runaway swarms flying 8 to 10 miles, as I have known them to do, any one can readily see how liable to mix they may be, when we think that they are at a safe distance.—EUGENE SECOR.

I do not know. Consult the back volumes of the AMERICAN BEE JOURNAL, and the standard works on bee-culture.—A. B. MASON.

To make the matter certain, I would not want them nearer than five miles. I have reason to believe that they will sometimes cross at that distance.—M. MAHIN.

From four to five miles; though I am inclined to think that *three* miles would practically insure no inter-crossing.—WILL M. BARNUM.

Some think half a mile, and more think two miles or more. Possibly the shorter distance may be nearer right.—C. C. MILLER.

I do not know. Cross-mating may occur if the two apiaries are a hundred miles apart. The woods are full of bees, and the wild bees cannot be controlled. Satisfactory results have been obtained were the apiaries were five or six miles apart.—J. M. SHUCK.

About seven miles. The queen, in my opinion, never flies far from the hive, but the drones make long flights on warm days, when the air is still. If the the apiarist does not mind an occasional hybrid, it will do to locate the apiaries three miles apart.—G. L. TINKER.

At least three miles; at 2½ miles I have had them mix. Four miles in a direct or "bee-line" would be preferable to myself.—J. E. POND.

We should not feel safe if they were nearer than five miles—though in some localities they may be nearer and not deteriorate.—THE EDITOR.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at Tarbell House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

CORRESPONDENCE.

VENTILATION.

Wintering Bees in Cellars that are Ventilated.

Written for the American Bee Journal
BY DR. C. C. MILLER.

As much because I think the matter exceedingly important, and would like to learn the truth, as because I think I know a little about it, I want to say something about ventilation of cellars.

There are a great many things unsettled in the domain of bee-keeping, and I consider the whole matter of wintering bees as one of them—at least it is unsettled with me. But there are some things pretty definitely settled, and among them I count this, that bees, to winter in the best manner, *must have plenty of ventilation.* You need not tell me that Mr. Doolittle winters his bees without ventilation—he does nothing of the kind. Even if he shuts up his bees in a cave, and leaves them untouched all winter (and it makes me green with envy when I think of it), closing his ventilators tight, still those bees get ventilation through the walls and soil the roof, possibly about all they need. I suspect, however, that if there could be a freer exchange of air without lowering the temperature, his bees might be the better for it.

Now do not let us get into a quarel on account of a misunderstanding of terms. By plenty of ventilation, I mean a sufficient change of air in the cellar so that the bees shall have all the oxygen they need, and not be obliged to breath poisonous gases. How much it takes to make plenty, I do not know. If enough air for their needs comes through the cracks of a cellar-wall, then they have plenty of ventilation. But whatever it be, whether a 12-inch tile or an invisible crack, that much or that little they must have, or they will suffer.

In the last 30 years I think there has never been a time when there were not some who insisted that, bees wintered out-doors, were healther, stronger, and built up faster in the spring than those wintered in the cellar; and why shouldn't there be something in it? Take two men alike in all other respects, only that one lives mostly in the open air, and the other in a close room, and we know that there will be a marked difference in their physical condition. One is weaker and paler than the other, and the general rule for all animals is, that for the best physical development plenty of pure air is essential.

Now the sole object, I think, of wintering bees in cellars, is to keep them in a higher temperature than they would have out-doors. Aside from temperature, the nearer the cellar can be kept like out-doors, the better. Even some of those who insist that bees use so little air that no attention need be paid to the ventilation of a cellar, insist just as strongly that the ventilation of the hive is very important, even to having the whole space under the hive entirely open. What is the use of ventilating the hive? Why, to get better air in it, to be sure.

But suppose the cellar be hermetically sealed, every time the bad air of the hive is changed the air of the cellar becomes vitiated so that it is only a question of time when the ventilation of the hive becomes practically impossible, for the simple reason that there is no pure air in the cellar. A single colony in a cellar might get along comfortably well, even if not a thimbleful of fresh air could get into the cellar, if the cellar were large enough, and a hundred colonies might do equally well, *if the cellar were large enough.*

But a cellar which would winter finely 10 colonies, depending upon the fresh air that would force its way through the walls, might prove a failure with 100 colonies. It must be remembered that if ten times as many colonies are put into a cellar, each colony will *not* have one-tenth as much air.

For the sake of illustration, suppose that each hive with its contents displaces one cubic foot of air; and suppose the cellar contains 510 cubic feet. If 10 colonies are placed in it there will be left for them 500 cubic feet of air, or 50 cubic feet for each colony. Now if 100 colonies are put in, displacing 100 cubic feet of air, there will be left for them 410 feet of air, or 4.1 feet for each colony—about one-twelfth as much as when one-tenth as many hives were there.

If I am not mistaken, the matter of ventilation is not troublesome in the South, where the temperature also takes care of itself; but in the colder portions of this country, there is always more or less of a struggle going on with both, and a perfect ventilation cannot be obtained without a sacrifice of heat, nor the best temperature without some sacrifice of ventilation. Just what is the best compromise in each case is not easy to determine, and I suspect that it is quite possible that some of our notions about wintering bees may undergo considerable change.

For one, I am far from satisfied with my own practice. If I could winter my bees in a cave, like Mr. Doolittle does, with no care whatever, I should be willing to have my colonies come out a little weaker if necessary in the spring; or if I could let them stay out-doors without care in winter, I should be willing to have my winter losses considerably heavier, provided those colonies which did live through should have healthier and more vigorous bees.

AND WHAT?

Deacon Smith on Bee-Keeping with other Pursuits.

Written for the American Bee Journal
BY EUGENE SECOR.

Deacon Smith has the happy faculty of hitting the nail squarely on the head. He does not know a rule in grammar from the subtlest philosophy ever dreamed of, but his contact with the world has given him a common-sense view of the common affairs of life falling under his notice, and although sometimes told in a blunt and homely way, his conclusions are often forceful as well as amusing.

He likes to administer his criticisms in the way the hunter aimed his rifle—to *kill*, if it was a bear, and to *miss* if it happened to be a man. At least that's what I thought a few evenings since, when the Deacon "hooked onto Mirandy," and brought her over to our house "to see the good woman," while *we*, as usual, entertained each other—*he* doing the talking, and I listening eloquently.

Its a treat to hear him talk; and to get him started, all I have to do is to wind him up like a Waterbury watch (but it doesn't take so long to set him going as it does to wind the aforesaid Waterbury).

Knowing the Deacon to be a sensible man, devoid of all impracticable ideas, and knowing also that the question at the head of this article has been discussed by many of the best writers and thinkers in apiculture, I was anxious to learn the views of a practical bee-keeper who does some thinking on the subject without the writing; so in answer to the question, he began:

"What do I think would go along well with bee-keepin'? Well, I'll tell you. The *best* occupation *I* know of is bankin'. You may talk about your chicken business, and your small-fruit business, and your farmers' and dairy business, and all the etceteras, but they don't compare with bankin'.

"Wasn't you tellin' me once of the two Irishmen leanin' on their spades, and Mike says to Pat, now Pat, hoat would you rayther do for a livin' if ye

had your choice ; and Pat says, leanin' heavy on his spade, 'Well, Moike, for a *nice, clane, aisy* job, I'd loike to be a Bishop ?' Now that's my ticket exactly, only I'd like to be a Banker.

"I tell you there's nothin' so soothin' to the feelin's of the honest and hard-workin' bee-keeper, when the clover blossoms don't give down, and he goes about weepin' and mournin'—like Rachel of old—for the basswood bloom because it is not, as to know that his bank account is in a healthy condition, and will stand the wear and tear of a year's hard times, without patchin'.

"If a fellow carries on the chicken business, he has got to get up in the mornin' when the old rooster calls him, or his Plymouth Rocks won't catch the early worm we hear so much about. If he is farmin', the calves will want their breakfast before 8 o'clock, and the dew on the corn leaves has got to be knocked off or he won't get a boomin' crop. If he raises berries for a livin', he'll have to be astir before sun-up, or he'll get left ; but with the bankin' business, he don't have to open shop before eight in the mornin', and he can shut up at five, count his cash, and go home and see if the woman and boys have tended the bees all right.

"If a drouth kills the clover crop, all he has to do to make both ends meet, is to loan a little more money at a little bigger rate of interest. If an early frost nips his buckwheat before the bees get their hives full, he can call it a *stringency in the money market*, and tax his customers a little more for an *accommodation*.

"You say 'everybody can't be bankers ?' Of course not. If they was, there would be no one to furnish business for them ; neither can everybody be bee-keepers, because if they was, there would be nobody to buy our honey ; and I reckon about as many folks can be bankers as can be a success at bee-keepin'.

"The next best thing to bankin' is keepin' supplies to sell to other bee-keepers. In fact I don't know but this is the best thing after all, for they call these men *specialists*. That's a big name now-a-days. If a man is only a 'specialist,' he must be awful smart ; and if he produces honey, and sells queens, and makes bee-hives and other fixin's, and prints a circular every year to coax every other fellow into the business, he'll get his name in the paper (and may be he prints one himself), and most always gets his picture in, too. Of course that don't advertise his business any, but it makes him feel awful good to be called the "King-bee." Its better to be a big toad in a little puddle, than to be a tadpole in a mill-pond ; and the big toads are the fellows that make bee-keepin' a specialty, in order to get their names in print, while at the sametime they run a carpenter shop, or buy and sell a hundred things a bee-keeper don't need, only to be in fashion.

"I hain't made nothin' keepin' bees for two years, and if I could make somethin' sellin' contraptions to my neighbors, it would go a long way toward helpin' the clover crop out. These newfangled things for the apiary take first-rate before people get their eye-teeth cut. They are bound to have 'em you know, and if I sell 'em to 'em, I'll be a *specialist*, and get my name in the papers as the 'great king-bee of Puckertown.'

"It would tickle Mirandy awfully to have folks writin' to me askin' me questions, and callin' on me every day but Sunday, to carry home some of them beautiful hives and fixin's, that'll git honey whether there's any in the flowers or not.

And then I'd invent some great bee-savin' fodder that would link my name to posterity as the only original Smith genius the world ever produced, and all the tribes of Smith will rise up and call me blessed.

"You may, if you like, follow bee-keepin', and break your back over the strawberry patch, but I'll be a specialist and sell goods to the rest of the world."

Forest City, Iowa.

APRIL TEARS.

Oh ! April, bonny April, why shed such show'rs of tears
When the green, green grass is springing over all the waking earth,
And many a fragrant flower the wood and meadow cheers,
And many a bird from budding trees sings songs of love and mirth,
Oh ! April, bonny April, why shed such show'rs of tears ?

"My tears are not of sorrow. They are happy, happy tears,
The golden sunshine makes of each a sparkling rainbowed gem ;
I am so glad as each sweet flower and joyous bird appears,
To think that back to our dear land my voice has summoned them.
My tears are not of sorrow. Thay are happy, happy tears !"

—*Vick's Magazine for April.*

LINDEN HONEY.

Moving Bees to Secure Honey from Basswood.

Written for the American Rural Home
BY G. M. DOOLITTLE.

A correspondent wishes me to answer the following questions :

"1. I am thinking of moving my bees, the coming summer, a few miles to where there is an abundance of basswood, hoping to secure a greater yield of honey than I at present receive, as I have no basswood near me. What do you think of the idea ?

"2. Are not the blossom-buds formed on the basswood-trees a few weeks previous to the time of their opening, so that I can know by this whether there is a prospect of honey from that source, in time to make preparations for moving ?

"3. Are there any seasons when basswood blooms in profusion, when there is no honey-yield from it ?"

In answering the first question, I would say that the plan is a good one, and I can see nothing against it, except the expense. I believe basswood to be the greatest honey-producer in the world. In fact no report has ever been given (if I am correct) of an average yield of 20 pounds per day from a single colony for 30 days in succession, except from basswood. Mr. Gallup had a colony do this. I had one which stored that for about 10 days, the best yield being 66 pounds in 3 days.

Now, if the questioner can move his bees to the basswood, and return them at an expense of $1 per colony, it will be seen that 10 pounds of honey from each colony will pay the cost, counting honey at a very low figure, if he should get that much surplus ; and if the cost should even come up to $2 each, 20 pounds would make it good.

By going back over my account with my bees for the past 16 years, I find that from basswood alone, my yield of honey has not been far from 60 pounds, on an average, from each colony, each year ; the lightest yield being about 35 pounds, and the heaviest 120 pounds. This is the average yield of the yard, not the yield of an individual colony.

Now, if you call 60 pounds what we can expect one year with another from basswood, and that it will cost 20 pounds of that honey for moving the bees to the basswood, we shall have 40 pounds left for profit ; or, if honey sells at 15 cents per pound, as it does at present, that when sold will give us $6 per colony as clear money on each colony, over what we should have had if we had not moved them. So if 100 colonies are moved, we have $600 over all the expense for our undertaking.

In answering the second question, I will say that the fruit-buds and leaflets of all trees with which I am familiar, are formed in June and July of the preceding year, so that the results of the next season's honey-yield, as far as buds and flowers are concerned, are already formed in embryo, on the apparently bare and lifeless branches of the basswood trees. They wait only for the warmth of spring, to bring this dormant life into growth.

As soon as these buds unfold (the latter part of May) then we can see and know whether to make prepara-

tions for moving the bees or not. By examining closely we can find the bunch of buds at the base of each leaf, curled up, looking like the half of a very small pea, or perhaps a little fuzzy caterpillar would explain it better. With each week this bunch of buds grows till at the end of about seven weeks from the time the trees put on their green in the spring, they open their flowers, filled with nectar to invite the bees to a sumptuous feast.

Of course, a cool season will retard the time of their blossoming a little, and a hot season advance it; but the above is the rule. Thus the practical eye can tell nearly two months in advance, as to the promise of a yield of basswood honey.

In replying to the third question, I will say that I never knew a season when the basswoood did not furnish *some* honey. The shortest yield which I ever knew gave a three days' yield, in which honey was so plentiful that the bees could not prepare room fast enough to store it, with a gradual tapering off of two days more, making five days in all. The longest gave a yield of 25 days, with three of them so cold that the bees could only work a little in the middle of the day.

The state of the atmosphere has much to do with the secretion of honey in the basswood flowers. The most unfavorable weather is a cold, rainy, cloudy spell, with the wind in the northwest. If basswood bloomed at a time of year when we were liable to have much of such weather, there might be such a thing as an entire failure of honey from it. But as a rule, we have very little such weather at this time of year.

The condition most favorable to a large yield is, when the weather is very warm, and the air filled with electricity. At times when showers pass all around with sharp lightning and heavy thunder, the honey will almost drop from the blossoms, providing no rain chances to come within a mile or two of it. At such times as this, I have seen honey in the blossoms after they had fallen off on the ground, so that it sparkled in the morning sunshine. Then, this nectar is honey and not sweetened water, which makes basswood doubly valuable over most of the other honey-secreting plants and trees.

One bee-load of nectar from the basswood, in a dry, warm time, is equal to three from the white clover, or five from some other of our flowers. In a rainy time there is not so marked a difference. At times when basswood was yielding its best, I have seen more than a bee-load of honey in a single flower. I have taken one stem of blossoms, when the yield was great, and jarred it over my hand, when I would have several drops of nice honey in it. At such times as this, 1,000 colonies of bees could find all the honey which they could carry, if all were left in one place; at all other times, I think from 100 to 200 colonies would be ample for any locality.

Borodino, N. Y.

FAIR EXHIBITS.

Separate Buildings for Apiarian Displays.

Written for the American Bee Journal

BY DR. A. B. MASON.

On page 132 I am asked, among others, to tell what I think about separate buildings for bee and honey shows at fairs, and the request is prefaced by these words: "Much may be said in favor of a separate building."

Yes "much may be said in favor of" such a building, but I think that much more may be said in favor of *usually* making apiarian exhibits in buildings in which other exhibits are made.

It is "just splendid" for bee-keepers to have a building all to themselves. The Michigan bee-keepers have had such a building for six years at their State fair, and it is nice for *them;* I think that it was in 1883 that they had their first separate building at Detroit, and very nice displays were made by M. H. Hunt, W. Z. Hutchinson and H. D. Cutting. There were also some smaller exhibits, but the building being off to one side, it was not visited by the crowd.

The next two years the fair was at Kalamazoo. The building was larger and better located, and was visited by all who desired to see the exhibit. For the last three years the fair has been held at Jackson. It is not well located, visitors having to go at least 60 feet, I should think, away from the regular thoroughfare, to see the exhibit; and when the ground is muddy, as fair-grounds generally are during fair time, people are not going far out of their way to see what they are not especially interested in.

At the Ohio Centennial last fall, our honey-building was located fully 75 feet from the main thoroughfare, and there were many days when mud was supreme, that our building was pretty well neglected, and we felt "kinder lonesome."

At our Tri-State Fair, here at Toledo, the managers have several times offered to put up a separate building for us, but I have so far preferred our present location, which is in one end of what is known as the Main Hall—the largest building on the grounds—in which is the Art Gallery, dry goods, notions, clothing, everything made by the ladies, sewing machines, musical instruments, flowers, fruits, vegetables, grains, seeds, the products of the kitchen and dairy, etc., and no one can see these without seeing the bees and honey.

Exhibits at the Tri-State Fair.

Our first exhibit was made in 1882, and "ye editor" being present as judge, said this in the AMERICAN BEE JOURNAL for Sept. 20 of that year, in regard to that exhibit:

"Bee and Honey Show at Toledo, O.—Such a grand success was this new feature of the Tri-State Fair, that the managers have already promised the bee-keepers all the space they may desire at the fair for next year.

"The small corner set apart for the bee and honey show was so crowded all the time, that it was with great difficulty that any one could get through the crowd, and utterly impossible for one-quarter of those who desired to examine the exhibits, to even get within a stone's throw of them."

Every year since, the honey exhibit has been an attractive feature, and we much prefer to remain in the main building, to having a building by ourselves. Last year one of the directors spoke of leaving out the honey-department, so as to save so much money ($81), but he was "alone in his glory." They have found it difficult to fill the space we occupy with anything else.

We make a specialty of exhibiting honey, and display it to the best possible advantage. The number of exhibitors is generally so small in most localities, that a building of respectable proportions could not be so filled as to do credit to our specialty.

I believe that the premium list is of vastly more importance than the building. No one is going to make an exhibit in any department unless it *pays*. That is what we are all after, the *pay*. Many exhibits are made without any premiums being offered, the sales and the advertising being sufficient remuneration.

In this locality the sales and advertising in the honey department are not enough to pay, although the sales increase every year. Last year there was an unusual demand for honey.

If a separate building is used, it must be filled, or the fair managers will be disgusted, and wish they had saved the money invested in the building for some other purpose. If the exhibits are made in connection with other displays, and the show of honey, for any reason, is small, other exhibits will take its place.

Last season being such a poor honey season, there was but one entry made here besides ours, and we had to "spread ourselves" to occupy the alloted space; and living only about a

mile from the fair, it took us but a few hours to "get there," and the space was occupied so that visitors said it looked better than ever—and it paid us better than ever.

I believe that in nine cases out of ten, a separate building is not needed, and would be a positive damage. Even where there is a large display, it is by a few exhibitors, and "lots" of other bee-keepers will say, "I could beat that," but they never try.

The premiums should be so arranged as to bring out those things that are most attractive to the general public, and give to each exhibitor, so far as possible, enough premiums to pay all expenses; and I am sure that the social part, and the pleasure had in the endeavor to add to the general display and general good, will pay well for the time spent. But whether the exhibit is made in a separate building or otherwise, an effort should be made to aid the managers in making the fair a success, and not have them feel that our department is a burden.

At the Michigan State Fair, the bee-men are a positive help to the managers, and cause them no anxiety. Here at our Tri-State Fair, they pay no attention to our way of doing things, for as they say, "Everything will be all right in your department, anyhow;" and at the Ohio Centennial, at its close the Society told me that our department was the only one that run smoothly, and from which no complaints were made; and when any of us wanted anything, the officers were glad of an opportunity to do us a favor.

A good way to help make it pay is, to take a goodly supply of "provender" in the lunch-box; bedding enough to make a comfortable bed on straw, and live on the grounds. A small oil-stove, that can be had for a dollar, will readily warm up cold "vittles," and make the tea or coffee; and so far as my experience goes, there is plenty of milk to be had, fresh from the fountain, for "little or nothing," or honey, and there is lots of comfort in being at home.

That is the way I lived at the Centennial for eight weeks, and nearly all the time I had from one to three besides myself at my table, and others were living in the same way in our building. A small oil-stove, as above referred to, boiled our "taters," and cooked our meat, etc.

Such a way of living is a regular "picnic," and beats a hotel or boarding house "all to pieces." No cooks, or waiters, or boarders to growl. Good square meals, and good square appetites; good honey always on the table, good company, and a good time generally.

Auburndale, O.

BEGINNING.

An Amateur's Experience in Keeping Bees.

Written for the American Bee Journal

BY A STUDENT.

In the spring of 1886 I got one colony of pure Italian bees, in an 8-frame Langstroth hive, for which I paid $8. I moved them eight miles in a lumber-wagon, and put them in the shade of a large crab-apple tree. Although the frames were in no way fastened, there were no dead bees or broken combs.

The surplus arrangements for comb honey were put on at once, and the bees went to work in them immediately, and in a short time they stored about 12 pounds (which was all the surplus honey I got that year), when they swarmed. As the queen's wings were clipped, she was easily caught upon leaving the hive, when the old hive was removed to a new location.

The bees clustering in a tree as soon as they missed their queen, gave plenty of time to put an empty hive on the old stand, and the bees shortly after returning in search of their missing mother, entered the new hive, the old queen being allowed to run in with them.

They immediately went to work, and when I looked at them about eight days afterwards, they had the hive full of comb, and the four middle combs were full of worker brood, while the other four were nearly all drone-comb, and had some eggs and larvæ in them, and some honey. Had I done as I should, and taken the surplus arrangements from the parent hive, and placed them on the new swarm when they were first hived, eight days before, I have found from later experience that there would have been but very little drone-comb built by the new colony, and the swarming impulse would, as a general thing, have been done away with for the season, and the new colony would have stored nearly 50 pounds of surplus honey.

But ignorance is expensive, as I learned to my sorrow before the next spring. The old colony cast 4 after-swarms, the first two of which were of good size, but the last two were very small, and as they were all hived on eight empty frames, it may justly be imagined that they did not "wax rich in stores;" and when fall came, with the frosty nights, the busy little workers were obliged to suspend work, and they were, as I have since learned, in a poor condition to withstand the long and cold winter.

The first swarm cast by the old colony, swarmed about the middle of July. Both of these swarms were, however, in good condition for winter, having plenty of honey and bees.

About the first of November these 7 colonies, all from natural swarming, were placed in the cellar under the house, and directly under the living room, the noise of which seemed in no way to disturb them, as some seem to think. I did not examine the bees until the next spring, after they were placed on the summer stands; then I found the last 2 after-swarms dead, and the 2 others were so very weak that I united them, thus leaving me 4 colonies to begin the season of 1887 with.

The cause of the death and weakness of the 3 colonies was starvation, caused by too much room, consequently scattered stores. Bees, to winter well, should have *just* the amount of combs, well filled with sealed honey, that they can compactly cover, and these frames of comb, if less than a hiveful, should be placed in the middle of the hive, with a dry basswood division-board on each side (made the same size as the brood-frames), and the spaces at the sides filled in with dry fall leaves—soft maple leaves are the best.

The honey-board inverted with a piece of gunny cloth tacked on the top side should be placed over the frames, leaving a ¾-inch space between the top of the brood-frames and the slats of the honey-board, thereby giving the bees plenty of room to pass over the tops of the brood-frames, from one to the other, which is essential to successful wintering.

I have always, since the first winter, placed an empty **T**-super on the top of the honey-board (arranged as just described), and filled that with leaves, and then placed the cover on that, giving the hive the same appearance it has in the honey season with one 24-pound super of sections on; only in this case the honey-board is inverted, and has a piece of gunny-cloth tacked on the upper side of it, to prevent the leaves from falling through on the brood-frames, and the super is filled with leaves, instead of one-pound sections.

During the summer of 1887 I increased the 4 colonies to 9, and took 300 pounds of comb honey in one-pound sections. I use sections 2 inches wide, preferring them to those more narrow, for the reason that they always hold one pound, and for that reason they can be much more readily sold by the single comb than the others.

In the fall, before putting the bees into the cellar, I united so that I had but 6 colonies, and one of these, I am now satisfied, was queenless, the queen having been killed while transferring them from a hollow limb, into which they knew no more than to go and

make lots of trouble getting them down and into a respectable hive.

Getting a Swarm from a Tree.

It was a swarm that left in spite of cow-bells, tin-pans, dust, sand and water; and after giving me a chase of nearly three miles, in the middle of an August day, with the thermometer at 98° in the shade, it finally got away by crossing a small lake; however, they were seen by one of my neighbor's to enter a hollow oak-limb, about 60 feet from the ground.

So one evening, about a week afterwards, father, myself, and a German by the name of Joe, who was working for us, went down to the lake, in the woods of which the bees had made their home. Joe enclosed his head in a bee-veil, and with a bee-smoker well lighted, and a saw and rope fastened around his waist, started up the tree with "fire" in his eye. He had "fire" in both eyes when he came down shortly afterward. He also had a piece of wire screen to fasten over the hole in the limb.

Joe had, of his own free will, agreed to lower the swarm safely to the ground for $1.00, saying, "Dat vas nodings." I think, however, that he changed his mind before he got down again from the tree. The smoker had worked loose, and fallen to the ground, and when he got to the bees, contrary to what he expected, the bees were crawling all around the entrance on the ontside. However, he succeeded in getting the screen over the entrance, but was obliged to leave a few dozen of the guards outside, and they, true to their reputation, kept Joe busy.

He succeeded in tying one end of the rope around the limb, preparatory to lowering it when he had it sawed off. Everything would have been lovely, had it not been that in sawing off the limb, he sawed into the hollow, and when the limb fell, it seemed to wake up an immense lot of bees, which came out of the end of that hollow log with bayonets fixed, and intent to kill.

Joe had neglected to unwind the rope from around his waist, and with the bees swinging just under his feet, he slid for nearly 20 feet down the tree, without once stopping. When he first started down the tree, his veil loosened, and the bees struck for unexplored regions, which seemed to increase the speed with which Joe descended the tree. He, however, got to the bottom in a very short time after starting, and so did the bees—the one exceedingly hot and increasing in size, the other mad and vicious.

But by the use of the smoker, which was relighted, we succeeded in tying a coat over the end of the log, and in that way carried it home, and there it was left in the wagon until morning, when we split the log open, and drove the bees into a hive. We got nearly two panfuls of nice clover honey from the log.

The bees, however, were not satisfied, and came out several times that day, and clustered every time on the same rose bush. Finally, to make them behave, I had to give them a frame of eggs and brood from another colony. From these I thought that they would rear a queen, if theirs was lost, but this they did not do, and I know not why.

Joe grew fat over his experience, but seemed to have enough, judging from the way he spoke about "those confounded little bugs."

Last spring, when I examined the bees after putting them on the summer stands, I found 5 of the colonies with bright combs, nearly full of brood and eggs, and a good lot of bees in each. The sixth colony had moldy combs full of dead bees, and the hive was badly spotted. They evidently died of diarrhea, caused, no doubt, by having late and thin honey to winter on.

The 5 colonies increased, by natural swarming, to 12, and gave 500 pounds of surplus honey, in one-pound sections.

I use the tiering-up system, and so far it has been satisfactory, especially when honey is coming in very rapidly; but where honey is coming in very slowly, I think that I should prefer to take the sections out as fast as filled and capped, and after removing the unfinished ones to the sides, place the empty ones in the middle. I say empty, but they are not, for I use full sheets of foundation in them. By placing the new sections in the middle of the super, it stimulates the bees to commence work in them at once.

Fastening Foundation in the Sections.

I have read considerable in the AMERICAN BEE JOURNAL lately, and in the past few months, about fastening foundation in sections. The trouble seems to be the fact that the bees draw out much faster the side of the section that the wax is spread out on, in fastening in the foundation, thereby bulging one comb into another. As yet I have had no trouble of that kind, and I think that none will, if they place the sections in the supers as I have done.

I use a "Parker foundation-fastener." My supers hold 24 one-pound sections, 4¼x4¼ inches, six in each row across the hive. Now the first section that is put in each of the four rows, is turned so that the side that has the wax drawn out on the top of it from the foundation, is next to the side-board of the super; the next one to it is turned the opposite way from the first, and the third the opposite from the second, and so on, until the super is full. In that way the side of each section that is liable to be bulged, is brought opposite to the corresponding side of the other, and the sides that the wax is not drawn out on, are also brought together, thereby causing the foundation of each section opposite, to be drawn out with equal rapidity, and preventing one comb from bulging into the other.

Hutchinson, Minn.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Apr. 23.—DesMoines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex.
G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of futura meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Not a Colony Lost.—O.M.Morris, Hebron, Ind., on March 26, 1889, says:

I have been in the bee-keeping business for several years, and I always wintered them on the summer stands. Some winters I have lost quite a number of colonies, but this winter beats them all, for I had 167 colonies last fall, and all have wintered nicely, without the loss of a single colony.

Sub-Earth Ventilation, etc.—P. H. Elwood, Starkville, N. Y., on March 15, 1889, writes:

I notice what Mr. Betsinger says on page 156. He prefaces his remarks by the words, "If I am not mistaken"—but as is often the case, he is mistaken. I said at the New York State Convention that, the exit ventilators of my cellars (those carrying out warm air) were closed in the coldest weather. I said further, in explanation, that this did not cut off all ventilation, as the sub-earth ventilator was always open, and bringing in a large volume of fresh air. This could not happen if the natural ventilation was not sufficient to carry out this large amount together with that coming in through crevices and porous material. I stated in convention that from 100 to 200 colonies (the number varying inversely in proportion to their activity)

in winter quarters require as much air as one person.

In proof that I have not changed my views on ventilation for several years, I will refer Mr. Betsinger to an article on page 233 of the AMERICAN BEE JOURNAL for 1878, and to one in the *Bee-Keepers' Magazine* for 1888, page 114. I have not headed any of my articles "Scientific Ventilation." There is a great amount of nonsense palmed off as science, and I have had no desire to add to the quantity. So long as I am in accord with such authorities as Cheshire and Corneil, there will be no need of bolstering up any of my articles with a scientific title.

Lost One-Third in Wintering.—Wm. Robson, Rolla, Mo., on March 28, 1889, writes:

For the past two seasons the busy little honey-bees have not paid; indeed they have not stored honey enough to winter upon. I have lost one-third, fall count, and several have lost all they had. The first pollen gathered was on March 13; since that time there has been considerable activity among the bees, but, for a change, we are this morning treated to a blanket of snow, about 2 inches deep. From present appearances, we will have considerable white clover for the bees to revel in, the coming summer.

Bees Wintered Perfectly.—Frank Waring, Philipsburg, Pa., on March 28, 1889, says:

The winter being very mild, the bees wintered perfectly on the summer stands. On March 23 I saw them carry in natural pollen (they had been carrying rye flour for some days previous to this), and they have been at it every day since. That is not bad for the Alleghany Mountains—over 2,000 feet above the sea level. The weather seems about a month ahead of the Almanac.

Good Prospects for the White Clover.—R. P. Blades, Carmi, Ills., on March 30, 1889, writes:

The prospect for white clover is better this year than it has been for three or four years. It seems that every vacant spot is covered with white clover; but as for the honey that it produces, I cannot say, as it has been nearly a failure since I have been interested in bees. The honey that is gathered here is from black-gum and poplar. Maple is our spring honey source, but I do not think that it gives much nectar, but it is good for pollen, and is very welcome, as it is the first to bloom. The flow of fall honey is from smart-weed and Spanish-needle; also other little blooms that have no names, or at least I have never heard any names for them. I have sown 4 acres of Alsike clover this spring; if the Italian bees like that, I will sow more next year. I have 11 colonies of bees in Simplicity hives, some of which I transferred three years ago. The combs in the brood-frames are rough and getting old, and have too much drone-comb also. Would it do to take out the side frames, remove the old comb, and refill the frames with comb foundation?

[Yes; that will not only get rid of the excess of drone-comb, but give the bees something to do, and incite them to labor.—ED.]

My Experience with Bees.—Robert Schultz, Alma, Wis., on March 30, 1889, says:

I commenced in the spring of 1888 with one colony of Italian bees, for which I paid $6.00. I had one swarm from them. I then bought 3 colonies of black bees, and put 2 of them into box-hives, and the other in a Langstroth hive; the 2 in box-hives are dead. I put my bees into the cellar, and put them out on March 12. They are strong yet. I found 4 clonies last fall in hollow trees, 2 being Italians, and 2 blacks. I took the honey from the blacks, and the Italians I put into the cellar, but they have all died.

Favorable Winter for Bees.—S. B. Brillhart, Kendallville, Ind., on April 2, 1889, writes:

I have kept from 25 to 50 colonies of bees for the past 18 years, but the past season was the poorest of all, to get surplus comb honey in the sections; yet my bees seemed to do well, and gathered enough to go into winter quarters in good condition, but nothing to spare for their keeping. I commenced the season with 38 colonies; in the fall I packed 42 colonies in leaves on the summer stands, 40 of which are now in good condition. I also have 23 colonies 6 miles in the country, which were left standing out without any protection, 18 of which are reported in good condition. The past winter was very favorable for wintering bees, so all that was necessary here was, plenty of good stores; but unfortunately, many bees that had no care will lack this essential, and will have to be mentioned with the dead before May 1, 1889.

Bees Flying Every Day.—Mr. Nathan Mercer, Neosho, Wis., on Mar. 25, 1889, writes:

Last year my bees dwindled down to 30 colonies from 100 in the fall of 1887, so I worked for increase instead of honey last year, and had 48 colonies last fall, all in chaff hives. They stored hardly enough for winter, so I fed them in the fall about 300 pounds of sugar and honey mixed together; to-day they are all alive and in splendid condition, whith plenty of honey, lots of brood hatched in every hive (except 3 queenless ones), and with bees enough to cover from 7 to 10 combs in each hive. They have flown out every day for the last two weeks, and yesterday they gathered pollen. They are the strongest colonies that I ever saw for this time of the year.

Bees are Booming.—Arthur H. Weston, Gallatin, Mo., on March 3, 1889, writes:

My bees are booming. All the 29 colonies on the summer stands, have wintered well. I have finally adopted the standard Langstroth hive. I have taken the AMERICAN BEE JOURNAL for several years, and I find it worth a wagon-load of the common kind.

Cellar-Wintered Bees.—S. J. Youngman, Lakeview, Mich., on April 1, 1889, writes:

Bees have wintered well in this part of Michigan, both in cellars and in chaff packing; but cellar-wintered bees will undoubtedly suffer now, as at this date there is 4 inches of snow on the ground, and bees have been out at least ten days, as the weather when they were put out, was unusually fine. My bees gathered pollen at that date. I fear great mortality in bees under such adverse conditions in thin, shallow hives, without even wind-breaks. I prefer my bees snugly packed in clover chaff until at least the middle of May.

None Lost in Wintering.—Mr. Lionel Brokaw, Summer Hill, Ills., on April 1, 1889, writes:

It is with great pleasure that I can report my bees this spring without the loss of a single colony, and it is the first winter that I ever wintered all of them. They are on the summer stands, in single-walled Simplicity hives, as described on page 27. I kept them covered with snow during the winter, when there was snow on the ground, but this being the warmest winter that

I ever saw, I do not care to risk them out another winter. I now think that I will try the cellar next winter. I also purchased, at neighboring sales, 5 more colonies, mostly Italians; thus with my former 20, it makes me a neat little apiary of 25 colonies this spring, and they have an abundance of honey for breeding purposes, too. The bees carried in pollen during the whole month of March, when it was fair, from the apple and elms. I am selling comb honey for 12½ cents this spring. There is a good deal of broken and soiled comb honey in the market here, which makes it drag. I like the AMERICAN BEE JOURNAL very much.

Wintered on Sugar Stores.—Lemuel Stout, Philadelphia, Pa., on March 31, 1889, says:

All of my bees (4 colonies) came through the winter nicely on 60 pounds of sugar and 30 pints of water, fed in November, 1888, without any tartaric-acid nonsense. I started with Hill's device, with cotton over it, six years ago, and with that kind of feed, and have never lost a colony. I opened the hives on March 24, and they were carrying in pollen. When I put them away I do not believe that the colonies had 4 pounds of honey in all.

Short-Winged Bees, etc.—E. B. Cohoon, Lakeview, Ont., on April 1, 1889, writes:

I imported an Italian queen from the United States last fall, and on examining her progeny this spring, I find fine, full-developed bees, well bred, but with wings only half the proper length. Can any one explain the cause of this? The bees are in fine condition.

I have 10 colonies of bees wintering in the cellar under the house, and they are coming out finely so far. The weather was fine here for sometime, but has changed for cold now. Yesterday it snowed nearly all day. I think very much of the AMERICAN BEE JOURNAL, which visits me regularly every week, and I could not do without it while I am inclined to work with bees.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at 8 cents per pound for Amber and 9 cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,
PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:

This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck; 20 cents per lb.—by express or freight.

Honey and Beeswax Market.

HONEY.—White 1-lbs., 16c.; fall, 14c.; 2-pounds, white, 14c. Extracted, scarce at 8@8½c.
BEESWAX.—20@22c.
Mar. 28. CLEMONS, CLOON & CO., cor 4th & Walnut.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX.—22c.
Mar. 25. R. A. BURNETT, 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
Mar. 25. HILDRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.
BEESWAX.—21c. for prime.
Mar. 25. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.
BEESWAX.—Scarce, at 18@22c.
SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales are good, but market is short of fancy white comb honey.
BEESWAX.—24c.
Mar. 22. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.
BEESWAX.—22@23c.
Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.
Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD.
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. April 20, 1889. No. 16.

EDITORIAL BUZZINGS.

Sweet April! many a thought
Is wedded unto thee, as hearts are wed;
Nor shall they fail, till, to its autumn brought,
Life's golden fruit is shed.
—LONGFELLOW.

A Golden Thought for us all is thus shaped by Mr. Johnson: "History can be formed from permanent monuments and records; but lives can only be written from personal knowledge, which is growing every day less, and in a short time is lost forever."

The Bee; its Life and Labors—was the topic upon which Mr. G. B. Jones gave a lecture on March 22, before the students of McMaster College, Toronto, Ont. The subject was amply illustrated by charts, and the *Globe* says that "the lecturer showed his enthusiasm in, and careful study of, the subject discussed."

Scientific Queen-Rearing, as practically applied; being a method by which the best of queen-bees are reared in perfect accord with Nature's ways. This is the title of a new book of nearly 200 pages written by G. M. Doolittle, of Borodino, N. Y., and is now being printed at this office. It will be published and ready for delivery by May 10, 1889, and will be sent postpaid for one dollar. It will be printed in the highest style of the art, and is nicely illustrated.

In this book Mr. Doolittle details the results of his experiments in rearing queen-bees for the past four or five years, and is the first to present his discoveries to the world. It will be out in good time for every progressive bee-keeper to test the various discoveries which it details, during the present season. Send all orders for the book to this office. The usual discount to dealers in lots of 10 or more copies.

Bees and Vegetables.—The following vegetables are valuable to apiarists, says an exchange:

Of the pea and bean family the Lima bean is about the only one that attracts bees, though it is claimed by some that the various sorts of cow-peas (Dolichos) are honey-yielding.

The blossoms of the cucurbita tribe are very rich in honey and pollen; in other words, cantaloupes, water-melons, cucumbers, squashes, and even pumpkins are useful in more ways than one. The two former may be cut in slices and exposed to the bees during the dry month of August; being destitute of acids—unlike most fruits—they furnish a most valuable substitute for the nectar that is so scarce in the fields and woods at that time of the year.

Turnips allowed to run to seed are of the highest value to the bee-keeper; the variety called "seven-top" is said to excel all others in that respect. The same is true of mustard. Seed onions are very much relished by bees, and colonies become quite heavy from that source alone. The tassels of Indian corn also furnish a large quantity of pollen.

Extracted Honey is coming into use largely. It is most salable if it is put up in glass jars and tin pails, the former being preferable for small quantities, which may hold from one up to ten pounds. These should be carefully labeled and tightly closed, says the Lewiston *Journal*, and then adds the following:

The proper marketing of honey is of the utmost importance to the producer, and if good quality, and put up in such packages as are most popular, will command the highest price, and be in constant demand. Its consumption is rapidly on the increase at home, while abroad an extensive market is being opened up, of which California producers are taking advantage by direct shipment. Highest in quality and in price is the white comb honey, which this year commands a good price at wholesale, put up in one-pound sections. These are just the size an individual wishes to purchase to carry home for his family as he returns from his business occupation, and not only is of delicious flavor, but it is pleasing and attractive to the eye. The larger, old-fashioned boxes, containing many combs, are rapidly going out of demand, and soon will be difficult to dispose of at any fair price.

Paste for labels on tin pails may be made thus:

Make a thin solution of white glue, then thicken it with wheat flour until it is about the consistency of paste. This is to be made the same as any other paste. Cover one side of the label with the paste, then put on the honey can or pail, and I think you will not have any trouble about labels coming off.

Paste made in this way will hold the labels to the tin so well that they will not come off. Just try it, if you want to make your honey to be attractive, and to sell readily. A nice label on a can of honey helps wonderfully.

This Sensible Talk comes from a farmer, and was published in the *Pacific Rural Press*, advising the date-palm cultivators to encourage the presence of honey-bees to fertilize the "date" bloom, and thus cause it to bear fruit more abundantly. Under the heading of "Bees and Fruit," he writes thus:

EDITORS OF THE RURAL PRESS:—In a recent issue in an article on the date-palm of Mr. Wolfskill's propagation, I note what is said of the difficulty of fertilizing the fruit blossom. Allow me to suggest an idea to this venerable horticulturist, and others interested in the cultivation of this valuable food. I am of the opinion if a few colonies of bees were located in near proximity, say a quarter or a half mile, there would be no failure on the part of the fruit to perfect 90 per cent. of the berries. The busy little bee going from the male to the female plants with its basket of pollen, and rubbing about in the flora of each, completes the work which Nature for some reason has left to be performed by an outside agency. The "date" must be, I am quite sure, a honey-producing plant.

Note the economy of the method I propose. While it eclipses in its completeness the bungling manipulation of the human species, it also harvests the nectar which would otherwise be "wasted upon desert air." The prejudice of fruitmen is so strong and deeply rooted that I fear my suggestions will go unheeded. Often a bigoted people in the present stage of progress and radical change, lay a charge at the door of innocence, and persecute even unto death.

If the sins which are charged to the busy bee were laid at the doors of the guilty, our friend might escape; but the fact that it is found in bad company, condemns its case without further investigation. Remove all birds and other pests that prey upon your fruits, and convert your orchards into an apiary, and I will wager that you suffer no loss. Our best authorities claim, and I think correctly, that the bee never punctures the fruit, but follows rapidly any other agency which has commenced the work of destruction, repairing the damage so far as its manipulations are concerned, by collecting the nectar and sealing it in the tiny jars for the future use of his persecutors, who, in their blindness and ignorance, heap indignities upon its defenseless head for these good offices.

As the Scotch poet says, "Man's inhumanity to man, makes countless thousands mourn," so his inhuman treatment of his benefactors in the brute and insect life, is the cause of untold mourning.

From "Insect Life," sent out by the Division of Entomology, Washington, D. C., we learn this: "At a meeting of the Entomological Society of France, lately, Mr. H. Lucas exhibited two specimens of the common honey-bee, which were collected near Bordeaux, and which were remarkable from the fact that in one the left eye is small, while the right eye, on the contrary, is strongly developed, and even extends beyond the medium part of the front. With the other specimen the exact contrary occurs, and it is the left eye which is more developed than that of the right side, which is plainly smaller. On account of this extremely remarkable anomaly, it could be said that these bees, from this character, belong upon the one side to the male sex, and upon the other to the neuter."

EASTER-TIDE.

Written for the American Bee Journal

Now joyous spring-time cometh,
An' birds begin to sing—
An' ilka wild-bee hummeth
On busy wanderin' wing.

Now up o'er braes an' meadows,
Wee flowers peep frae the ground—
An' cushats 'mang the shadows
Their mournfu' love-notes sound;

Now ilka burnie's dimplin'
An' rinnin' ower wi' glee—
An' free frae winter, wimplin'
It's glad course to the sea.

Frae numbin' sleep up-springeth
Auld Nature's soul, an' straug,
An' sweet, an' clear out-ringeth,
Her resurrection-sang.

FRANCES M'CONOUGHEY.

Hilliard, Mich.

GLEAMS OF NEWS.

Death of an Eccentric Woman.—The following facts are gleaned from the Winchester, Va., *Times*, of March 27, 1889, under the heading of "Died with her boots on." It was sent us by Mr. E. C. Jordan, and reads as follows:

Miss Rosana McCormick, the remarkable anchoress, who was welt known in this city and in the northern portion of this county, was found dead in her bed (near Jordan's Springs) on Sunday morning. She was about 67 years old. The story of her life has quite a tinge of romance. She gave the best years of her existence to the support and care of her mother, upon whom she lavished all her affection. After the death of her mother, Miss Rosana determined to go it alone, and for a quarter of a century she has fought the battle of life with no companion save her faithful dog.

The close of the war found her a friendless and almost a penniless woman, but by industry and frugality she soon began to accumulate, and at her death she owned two farms, and a large number of cattle.

She was apparently a frail woman, but possessed indomitable energy. Often the neighbors would hear her driving her cattle to pasture at the hour of midnight, and in the spring time she would spend whole nights in the shed among her sheep and lambs.

She always wore men's boots, and in the years after the war, it is said she never failed to carry a loaded revolver in one of them. It appears that she rarely ever disrobed; her boots were on, and her body was lying on a fertilized sack, on the floor, with a rude pillow under her head, when her spirit took its flight to the land of shadow. Her lonely life terminated in a lonely death, no one was near when the dread summons came.

She believed with Shakespeare, "Throw physic to the dogs, I'll none of it," and persistently refused the advice of her neighbors to call in a physician. The coroner's inquest developed the fact that death had been caused by pneumonia.

Miss Rosana presented quite a picturesque appearance when she came to our city, arrayed in a tattered costume, and carrying a large staff in her hand, and always accompanied by her dog, whom she rightly called Faithful. Though she wore the rudest of garments, and usually slept on the floor, several dress patterns of silk and other costly material were found in her bureau, and several elegant feather beds were in the house.

Miss McCormick was the pioneer bee-keeper in that part of Virginia. Mr. Jordan writes concerning her thus:

About 40 years ago she found a swarm of bees on a bush by the roadside. She put them into a nail-keg, and from this colony she raised a fine old-fashioned apiary, and for a great many years she produced large quantities of honey. I think she deserves to be kindly remembered by the bee-fraternity.

This very eccentric woman had a good education, and was a well-posted and brilliant conversationalist. The most intelligent guests at the popular Jordan's White Sulphur Springs (near by) enjoyed her company. The was buried on the Monday following, a large attendance being present, at the grave-yard near by. She had a sister, niece and nephew in Ohio, but had not heard from them since the war. They will inherit her property.

Why Advertise in the AMERICAN BEE JOURNAL? Here are some good reasons:

1. Because it has a large and influential circulation in every State and Territory, Canada, and other foreign countries:
2. Because it is well-printed, and an advertisement in it appears neat and attractive, and invites a reading.
3. Because it reaches just the class of persons desired—professional men, lawyers, doctors, and the best of the rural population.
4. The rates are low as possible, and the returns from advertisements are satistactory.

Catalogues for 1889 are on our desk from—

George E. Hilton, Fremont, Mich.—12 pages—Apiarian Supplies.

A. O. Crawford, South Weymouth, Mass.—20 pages—Folding Paper-Boxes.

J. I. Parent, Birchton, N. Y.—1 page—Comb Foundation and Supplies.

A farmer near Talbotton, Ga., who lives on an estate formerly owned by his father, says there are good chestnut rails now in use on the farm that were split by the Indians when they owned the country.

The temperature of Siberia was once much milder than at present. This change of climate is said to account for the conversion of what were once sedentary birds there, into birds that migrate to South Africa and elsewhere.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at Tarbell House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The DesMoines County, Iowa, Bee-Keepers' Association will hold its annual convention in the Court House at Burlington, on April 23, 1889, at 10 a. m. All bee-keepers are invited. JOHN NAU, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

What Apiarists Say about the April number of the ILLUSTRATED HOME JOURNAL, which they have just received, may be ascertained by the following which are samples of the multitude:

Dr. A. B. Mason, Auburndale, O., April 6, 1889, writes: "The ILLUSTRATED HOME JOURNAL is, as the 'girl of the period' would say, 'awful nice.' It 'is a thing of beauty.' The paper, typography, illustrations and matter are first-class in every respect. It will be a welcome visitor at our house. Mrs. M. and the baby have had a good time with it already. The first article, 'One Hundred Years a Nation,' is very good indeed, being like that on page 16, on 'Four More States,' full of boiled-down information. Well, it is all good, 'so there.'"

S. A. Shuck, of Liverpool, Ills., writes as follows: "The ILLUSTRATED HOME JOURNAL came to hand in due time, and it is brimful of such fascinating pen-pictures of historical and other incidents that one finds no stopping-place. The illustrations, I think, are FINE INDEED. I wish you success."

H. D. Cutting, of Clinton, Mich., thus expresses his views of it: "The ILLUSTRATED HOME JOURNAL is like everything else from your office—clean, bright and tasty, filled with good reading from cover to cover. I wish you great success."

E. H. Cook, of Andover, Conn., editor of the "Bee-Hive," writes: "The April number of the ILLUSTRATED HOME JOURNAL is at hand. It is a very neat and tasty publication. I shall mention it in the next issue of the 'Bee-Hive.'"

J. B. Mason, of Mechanic Falls, Maine, acknowledges the receipt of the ILLUSTRATED HOME JOURNAL for April, and says, "I shall be much pleased to receive it regularly, and I shall offer it in clubs with the 'Bee-Keepers' Advance' in the next issue."

Elvin S. Armstrong, of Jerseyville, Ills., thus writes: "On behalf of 'the ladies of the household,' I would say that your ILLUSTRATED HOME JOURNAL for April came duly to hand. You should be proud of it—we are. I wish it the greatest success."

F. A. Snell, of Milledgeville, Ills., writes: "The ILLUSTRATED HOME JOURNAL is received and read. It is very nicely gotten up, and we are well pleased with its contents."

Henry A. Cook, editor of the Denison, Iowa, "Bulletin" remarks thus: "The ILLUSTRATED HOME JOURNAL looks well, and so far as its appearance and contents are concerned, certainly starts out well. I hope you will find it both pleasant and profitable to continue it."

Mrs. W. H. Bright, of Mazeppa, Minn., acknowledges the receipt of the April number of the ILLUSTRATED HOME JOURNAL, and adds: "We are much pleased with it."

Mrs. T. F. Bingham, Abronia, Mich., writes: "We have been much interested in perusing the April number of the ILLUSTRATED HOME JOURNAL, and wish it much success."

Never did the advent of a magazine for the family touch such a responsive chord, or receive such a hearty welcome.

Trial subscriptions will be taken 3 months for 40 cents each; or it will be clubbed with the BEE JOURNAL for a year at $2.00 for both. Agents, who are working for premiums, may take "trial subscriptions," and count 4 as one yearly subscriber. One sample copy sent free to subscribers of the BEE JOURNAL, upon application. That will tell you all about the "Premiums" offered for getting up clubs, and "Cash Prizes" for the largest clubs sent in before Sept. 30, 1889. "Good pay for good work" is our motto. See page 238.

QUERIES AND REPLIES.

Dividing and Contracting to Prevent Drone-Comb.

Written for the American Bee Journal

Query 626.—If I divide my bees by taking the queen and frame of brood, and place it on the old stand, shake most of the bees off in front of the hive on the old stand, remove the old hive to a distance, and give the new swarm, say five empty frames with starters, fill the empty space with dummies, and place the sections from the old hive on the new, will they be more liable to build drone-comb than if allowed to swarm naturally, and contract to the same number of frames?—Iowa.

No.—MAHALA B. CHADDOCK.

No.—DADANT & SON.

They will.—J. P. H. BROWN.

I think not.—EUGENE SECOR.

I should think so.—J. M. HAMBAUGH.

No, I do not think that they will.—H. D. CUTTING.

I think not; but I cannot say for certain.—MRS. L. HARRISON.

I doubt if you will find much difference. Try it and report.—C. C. MILLER.

I think not unless there is a "swarming fever," which is not allayed by the division.—R. L. TAYLOR.

I do not think so. I see no reason why they should. Possibly, however, a desire to swarm might be retained, then there would be more danger.—A. J. COOK.

Yes, they would be very liable to build drone-comb. It is a poor way to increase your bees.—C. H. DIBBERN.

I should say no. A queen-excluder should be used, to prevent the rearing of brood in the sections.—J. M. SHUCK.

Probably there would be little difference. That frame of brood will be apt to cause some drone-comb in either case.—G. M. DOOLITTLE.

Your plan would be an excellent one, were it not for the liability of bees to build drone-comb when not wanted. I should expect more to be built with your plan.—W. M. BARNUM.

I think that they would be more likely to build drone-comb, but much would depend upon the number of bees, the age and prolificness of the queen, and the honey-flow.—M. MAHIN.

I do not know, but I should think not, if there was plenty of room in the sections for storing surplus, and the queen was excluded from them, and the dividing done before the swarming impulse.—A. B. MASON.

It will depend upon the age of the queen. But little store or drone-comb will be built in the brood-nest, if the queen is young and prolific; otherwise there will be too much drone-comb. But as a rule, there will be drone-comb built by proceeding in the way you mention. I have tried your plan often, but I now prefer to let the bees swarm.—G. W. DEMAREE.

This question opens up too big a subject for the space allowable, as the whole matter of division, in connection with natural increase, is at issue. A plain answer cannot be given, so I "pass."—J. E. POND.

No; but the procedure named will usualy result in getting a lot of bee-bread in the sections; for, until comb is built in the brood-chamber, there will be no other place to put the pollen. One of the five frames should contain empty comb, or the sections should not be put on till comb is built.—G. L. TINKER.

Probably you would discover but very little difference. There are too many uncertainties about the matter to give a direct answer.—THE EDITOR.

Uniting Colonies Without Destroying the Queens.

Written for the American Bee Journal

Query 627.—1. In uniting two ordinary colonies of bees without destroying one of the queens, is there not great danger that both will be killed? 2. If not, is there not danger that the surviving queen may be seriously injured?—Bee-Keeper.

Yes.—G. L. TINKER.

No, to both queries.—A. B. MASON.

1. There is some danger. 2. There might be.—J. M. HAMBAUGH.

It is best to destroy one queen before uniting.—H. D. CUTTING.

1. There is danger. 2. There is. Always cage the best queen and destroy the other.—J. P. H. BROWN.

1 and 2. Unless the uniting is so done that there is no fighting among the workers, I should fear injury to both queens.—R. L. TAYLOR.

1. It would seem so, and yet I have had no experience to confirm the fear.—EUGENE SECOR.

I think not; though I usually destroy the queen that I think is the least valuable. This is certainly wise, if there is any choice in the queens.—A. J. COOK

1. If rightly done at the right time, I do not think that there is much danger. 2. Not much, I think.—C. C. MILLER

There is some danger of it, indeed. It is much better to kill one queen, especially as one of them is almost sure to be more valuable than the other.—DADANT & SON.

No, not in swarming time, as we have frequently united two, and many times three swarms, in one hive, and left them to adjust the queen question to suit themselves, and usually with good results. Still, if we always had time to examine and find the queen, we should prefer to give only one, and that of course the one which we considered best. At any other than the swarming period, we should never think of allowing more than one queen.—MRS. L. HARRISON.

1. No; both queens are never killed. This is my experience. 2. The surviving queen is all right.—MAHALA B. CHADDOCK.

1, The bee-keeper should choose between the two, and do the killing himself. If he does this, No. 2 needs no answer.—J. M. SHUCK.

1. I think not; still I prefer to remove the reigning queen before introducing the new one. 2. If proper precautions are taken, any queen may be safely introduced. See various articles written on the subject.—J. E. POND.

1. No. I never knew such a thing to happen. 2. No. A queen not worth looking after in uniting, will generally come out all right. If I had 2 choice queens, I should prefer not to treat them that way, as each would be worth saving. No improvement of stock can be made by the above plan.—G. M. DOOLITTLE.

This method is quite commonly practiced, and, usually, with good results. Of course, there is danger of the surviving queen being disabled; if so, the bees will attend to that matter. This "method" is based upon the supposition that there is plenty of brood in the hive. I would never introduce a really valuable queen upon this plan.—WILL M. BARNUM.

No. My experience is that only one will be killed. The queen is balled by the bees, and finally killed. I do not think that one mature queen ever destroys another; neither is it likely that the surviving queen will be injured.—C. H. DIBBERN.

1. I have never *known* both queens to be killed, but I think that there is danger of it. 2. In a case of that kind, I had both wings of the surviving queen gnawed to the stubs, and the stubs to shreds. She was not otherwise injured.—M. MAHIN.

1. It is a dangerous proceeding, but they sometimes come out all right. Sometimes both queens are "balled," and both may sometimes be killed. To say the least, it is a sloven, careless way to unite bees. 2. Yes; where a queen has once been balled, as she is most likely to be under such treatment, she is rarely ever worth much.—G. W. DEMAREE.

Seldom, if ever, are both queens killed, and it is not always the best queen that survives—it is therefore better to select the best queen if you can, and kill the other yourself, for there is some danger of the surviving queen being injured.—THE EDITOR.

CORRESPONDENCE.

POLLEN.

Getting the Pollen Out of the Combs.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

A correspondent writes: "Please tell us in the AMERICAN BEE JOURNAL, how I can get the pollen out of some combs which I have. I fear that it will hurt them, as there is so much of it that the bees may not remove it."

In some localities bees store so much pollen in their combs, that it seems to those not as familiar with the inside workings of the hive as they might be, that some device for removing this pollen would be of great benefit to them; hence I have heard of offers as great as $25 from a single person, for some plan to remove pollen from the comb.

Some advise making into wax the combs containing much pollen, and then work the wax into comb foundation to put into the hive for the bees to draw out into the comb again; but all such advice seems to me to be a damage, rather than a help.

In this locality, we get large quantities of pollen—probably as much as is gathered in any place in the United States—yet I have never melted up a comb on that account; neither did I ever have any thrown out by the bees, as others claim that they have, unless the pollen had become mouldy.

With me, there are two different periods that the bees store much more pollen than is worked by the nurse-bees into chyme for the young brood; one is, during the bloom of hard maple, and the other during the white clover bloom. I have had combs of pollen gathered during the yield from hard-maple which weighed as high as 4 pounds; at such times as this I work as follows:

Whenever the bees gather so much as to crowd the queen, I take it away for the time being, and place empty combs in its stead. If there comes a few rainy or windy days at this time, I find that the pollen is all exhausted, so that the cells are once more empty or filled with eggs, as it takes large quantities of food for the numerous brood at this season of the year. After apple-bloom there is but little for the bees to work on, and the surplus pollen is soon used up and more needed, when I put back that which was removed, and thus brood-rearing is kept up more effectually than by feeding syrup, honey, or any of the many plans of stimulative feeding.

I consider plenty of pollen in the combs during the period of scarcity between apple and clover bloom, to be of great advantage. Of course this season of scarcity may not come just at this time with all, but, in my opinion, there is a period of scarcity of pollen at times during heavy brood-rearing in all localities; wherever such is the case, this pollen is of far more value than is generally conceded, and when all bee-keepers realize its true value, there will be none left to ask how they must work to get it out of the combs by any process, save having it converted into brood.

The pollen gathered during the white clover bloom is treated differently from that gathered early, which rarely ever has honey placed at the top of it, while that from clover is placed in the cells till they are nearly three-quarters full, when the cell is filled with honey and sealed over, so as to preserve it against a time of need the next spring. This pollen is what some fear so much, if left in the hive during the winter months, believing that it is the cause of bee-diarrhea; but I find that where bees winter perfectly, no brood is reared of any consequence till into March, and where no brood is reared, there is no pollen of any amount eaten.

Bees will starve with plenty of pollen in the hive, when they are not rearing any brood, as I have proven several times to my detriment in trying experiments; and it is only as brood-rearing commences that we can depend upon pollen to keep our bees from starving, in any sense of the word.

During the summer I find much pollen in this preserved state, especially in hives that are for a little while queenless, and when such are found, they are hung away in the room for storing combs, and sulphured, as occasion may require, to kill the larvæ of the wax-moth, which are sure to injure such combs very much, if not thus treated.

Combs containing pollen under honey are readily distinguished from those without, by holding them up before a strong light, and looking through them, especially so if the combs are new.

When spring opens, I again take the opportunity of placing all the combs that I have on hand containing pollen, near the brood, and I find that this answers a better purpose to stimulate brood-rearing at this time of the year, than the feeding of rye or oat meal, as is so often recommended. It is better, inasmuch as it does not lure the bees out of the hive in all sorts of unreasonable weather, to die from cold and the wearing of themselves out, so that they die of old age much sooner than they otherwise would, say nothing of the cost of the meal. In this way the pollen is used to a far better advantage than by inventing a machine to throw it from the comb.

If the correspondent who asked the above question, will try this plan, I think that he will find that his fears are groundless, regarding the bees leaving the pollen without removing it. If he should not, and still desires to get it out, it can be done by soaking the combs containing the pollen, in tepid water, for a week or so, till the pollen becomes soft, when it can be thrown out with the honey-extractor, the combs dried, and afterward given to the bees again.

Borodino, N. Y.

QUEEN-REARING.

Method of Rearing Queens for my Own Apiary.

Written for the American Bee Journal
BY J. F. M'INTYRE.

We have had a good rain this month—10 inches in four days, making 22½ inches up to date. The prospects are medium to good. Swarming has just commenced. I am preparing to start nuclei, as I make my increase in that way, from the best colonies that swarm first. I have tried nearly very way of hatching queens and starting nuclei, that I have seen in print. As I have never seen published the way I practice most, and like best, I will describe it. It is as follows:

I select the strongest and best colonies in the yard, that I wish to breed from; if I want early queens to be laying when the rest of the apiary is swarming, I give them hatching brood from other colonies to make them swarm early. When they swarm, I catch the queen, and allow the swarm to go back, disposing of the old queen as may be thought best.

If the colonies swarmed according to rule, in about ten days I listen at the top of the hive every evening, till I hear the young queens piping; the next morning, about 8 o'clock, I take a number of queen-cages, open the hive, cut out the queen-cells, and put one of them into each cage.

I can easily find the queen that is hatched, by her piping, when I cage her, too. I have had 10 queens hatch in ten minutes after the cells were caged.

My hives are 10-frame Langstroth, and I usually make 10 nuclei out of each colony, by taking one frame of brood and bees for each nuclei, and putting it between two other combs with some honey in.

If you have enough hatched queens to go around, let one out in each nuclei; if not, give them a cell, and shut them up until evening.

When the swarm is hived on a new stand, the queen-cells not capped in the old hive are often neglected; by returning the swarm, they are more uniformly good, and the bees are less likely to give up swarming and tear down the cells.

A strong colony like this is the best kind of a "lamp-nursery," because you only need to visit it about once in two days, catch the queen that has hatched, and cut out all cells that have a little opening where the queens stick their tongues out to be fed, and put them in cages; for the queens will bite open the cells, and come out very quickly when the bees are driven away.

I have used one colony for a long time in this way, giving fresh queen-cells, and cutting out those ready to hatch, every two days.

Fillmore, Calif., March 25, 1889.

LINDEN.

Report of Two Season's Work in the Apiary.

Written for the American Bee Journal

BY F. J. KRUMM.

Bee-keeping has been rather an up-hill business in this locality the last two seasons. I commenced the season of 1887 with 21 colonies in chaff hives, all hybrids except one Italian colony; during swarming time 54 swarms issued, but by uniting swarms and doubling-up the old colonies, I increased my apiary to 44, and obtained 600 pounds of comb honey, and 200 pounds of extracted honey.

The season of 1888 I commenced with 36 colonies; 61 swarms issued, and I increased my apiary to 58 colonies; 27 of the first swarms were accompanied by virgin queens, the old queens remaining with the parent colonies. Eight queens were lost on their mating tours. I reared 14 queens, of which only 5 became fertilized.

The honey harvest commenced very encouragingly. During fruit-bloom, and wild-ivy bloom, the bees stored honey in the brood-chamber. White and Alsike clover began to yield nectar about June 5, and bees commenced storing honey in the sections. On June 28 basswood opened, and yielded fairly well until Tuesday noon, July 3, when an east wind set in, and no more honey was gathered (with basswood in full bloom) until July 7, when the wind changed to the south, and at 4 o'clock it seemed as if every bee tried to be the first to get to the woods. Now, the question is, how did the bees know that just at that time basswood began to yield nectar again? But it only continued a few days, and that was the last of our spring honey crop.

The fall honey crop was almost a total failure, but I obtained 400 pounds of comb honey in one-pound sections, and 300 pounds of extracted honey from unfinished sections. So far I have lost 6 colonies in wintering—3 starved, and 3 were queenless.

Pleasant Bend, O., April 2, 1889.

Pat Going into Baze.

Written for the American Bee Journal

BY W. S. N.

Och, Meester Printer, yees a nioity foin man,
Yees maik iverything so illigent wid your pen;
It maiks meself as mad as any wit hen,
To see such unholy blathering about yer haze—
Better be more saveing of yes q's and pays.

Its meself, sure, and me own wife Kithreen
That bought a foin swarm, and an illigent queen,
With workers and droons with honey probossoms,
To ate oop the honey-dew, and throost in the blossoms.

But bad luck to me, I was just as big a foel,
As Eugene Secor's awate kicking muel;
If yer raders are ignorant, and don't get my maneing,
Send for the bay-paper, ye'l see them in "Glaning";
They are crazy as bid-bugs, kicking for their lives—
Muel Doctors say its "breaking out of the hives."

Now what I'm 'bout tellin', yees, consarning my baze,
Vees may put in yer paper, Mr. Printer, if ye plaze;
And bejabers, sor, its a sad thing for to tell,
What to me and my Kithreen lately befell.

Its just two years now since we two were wed—
Believe me, Meester Printer, our dare Jemie, he is dead;
And his sowl lays slapeing in the meadow of aze.
His poor mither went and got down on her knaze
Crying and wapeing and told it to the baze—
And this is what she solemnly and riverently said:
"Baze! Baze!! Dear Baze; our Jemie is dead!"

But thin, sure, came the rub, as Shakespeare says,
Somewhere ye'l rade it in his wonderful plays:
"It'a more noble to suffer the arrows and *stings*"
Than to stand oop with shalala to battle in the rings—
And give them fits—but, ah! a wild hellemelleu,
The varmints ivery last one buzzed and flew,
And stabbed my Kithreen while knaleing on the ground,
And knocked her out twice the very first round.

I drew my shalala, born in old Tyrone,
I busted three quanes and killed three droons;
Kithreen was so fraid she knaled down and prayed
To the Virgin, crossed, and counted ivery last bade.
Looking up to heaven, she prayerfully said:
"As now I lay me down to slape,
I pray the Lord my sowl to kape;
If I should die before I wake,
I pray the Lord the baze to kape."

Now if iver yes be blathering so very foin,
Count on no baze, Meester Printer, in moin.
If I should bust and die, my last word would ba,
The best way to kape baze, is to keep um away.

It's me picture I'll send yees all beautifully stung—
I'd rather live in Erin and be shot or be hung,
And spind in pace and harmony the rist of my days,
Than indure the "arrows and stings" of the baze.

America! the Divel take yes land of the fray,
Of toads and snakes, and cussed old bay;
Give me ould Ireland, the land of foin praters,
And yees may go to blazes wid yees vile, stinging crathers.

Please read me epitaf, whin I am dead:
"Beneath this stone lies Pat of Tyrone,
That was kilt by a bay, and chased by a droon;
And died by the swellin' of the head;
No, not ded, sor, but just slapeing.
I'd rather be in Purgatory dead,
Than to spind me life in bay-kaping—
Me and Kithreen in one grave slapeing."

Mason City, Iowa.

DIVIDING.

Advantages of Dividing Colonies Over Natural Swarming.

Written for the American Bee Journal

BY WM. G. HEWES.

I was much surprised to see on page 69, the number of bee-keepers who advised the propounder of Query 610, to "let his bees swarm." Prof. Cook, in advising that way, did especially fill me with wonder, as in his "Bee-Keepers' Guide," (at least the old edition—I have not the new one) he distinctly states his preference for dividing.

Eight years ago, in Louisiana, I got that book, and practiced dividing, as laid down therein, on my colonies. The result was that I doubled my apiary, and obtained over 200 pounds of extracted honey per colony, which sold in St. Louis for some $900.

A hundred yards or so from my apiary, a brother had 80 colonies which he let swarm naturally. His increased to only about 100 colonies, and the 80 did not gather one-half so much honey as my 50. His were blacks, with a trace of Italian blood; mine were mostly pure Italians.

I estimated then, and I still think so (after some years of bee-keeping on a large scale, during which time I have had much experience with both swarming and dividing), that Prof. Cook's "Guide," from having guided me into the path of dividing, was worth, to me, $200 that season, or $4.00 for each spring colony, besides the extra increase which I obtained.

Three years ago I commenced bee-keeping in California, with 115 colonies (85 of them on shares.) There were other apiaries located around me, from 2 to 5 miles. The first season was a good one, the second I got nothing, and last year was almost a failure. In the three seasons, two of them poor ones, by dividing I increased the 115 colonies to 357.

Some of my neighbors, who let their bees swarm, have a little more, and some of them a few less colonies than three years ago. Their locations were all as good, and most of them better, than my own, as mine is contiguous (or was—I have moved since) to large grain-fields and oak forests, neither of which supplied any honey.

In my apiary the past season were 20 colonies in hives with a frame 2 inches shorter than the rest of my apiary, but in all other respects—strain, strength and stores—alike. As I could not divide these colonies by my favorite method, without supplying hives of a like pattern, I decided to let these 20 swarm.

The apiary consisted of 234 colonies —214 to be divided, and 20 to divide themselves. The 214 increased my apiary to 356 ; the 20 added one colony to the number. The 214, with the increase from them, averaged about 50 pounds of honey to the colony, and built (I was too poor to buy foundation) some 2,000 combs in Langstroth frames ; the 20 did not average 15 pounds per colony, and of combs built not one, as their hives were full.

In a comparison of the two systems, I find the following advantages in favor of dividing colonies :

By dividing, the queens, and even the drones, are reared from selected stock ; by swarming, the bad strains with the good are equally propagated. By dividing, our bees sally forth to sip the nectar from *two* strong colonies, where in the early spring was found but one ; by swarming, our strong colonies of the early spring, become weak ones just when we most need them strong. By dividing, ye bee-man walketh with solid footing on ye *terra firma*, where evolution intended him ; by swarming, ye bee-man must needs ofttimes, as ye little bird, roost high in ye tree, and when he falleth therefrom, he findeth he is not made as ye little bird. Aye, verily.

ALSIKE CLOVER.

The Origin and Value of this Excellent Honey-Plant.

Written for the American Bee Journal

BY S. J. YOUNGMAN.

As the season is now at hand to sow both for forage and bee-pasture, perhaps a few hints from those having had experience in that direction would be both seasonable and profitable to those having stock to feed and graze, and bees ; of which there is no doubt but what the sowing of certain plants may help the yields of honey in localities where drouth is more or less prevalent.

Much has been said in favor of Alsike clover, and my experience with it, both as a forage and nectar-producing plant, will warrant all the praise given in its favor ; but, at the same time, all contemplating its propagation, should endeavor to do so intelligently, as its success and large growth depends largely upon the manner sown, and soil planted on. Many mistakes and consequent disappointments have been made by not knowing the characteristic traits of this plant.

I would advise, first, never to sow Alsike clover alone except for seed, but sow with red clover and timothy for all purposes. Second, never sow on dry, sandy land ; but on clay loam, bottom land, and reclaimed swamp and marsh land it may be expected to flourish luxuriantly.

As so little is known of this valuable plant, and its origin, I will, for the benefit of the readers of the AMERICAN BEE JOURNAL, give the report of the Department of Agriculture for the year 1887, which may be found on page 304 of the Report, with a beautiful illustration of the plant :

"Alsike Clover (*Trifolium hybridum*). —This differs from the common red clover in being later, taller, more slender, and succulent ; the flower-heads are upon long pedicels, and are intermediate in size and color between those of white and red clover. Its

ALSIKE CLOVER IN BLOOM.

botanical name was so given from its being supposed by Linnæus to be a hybrid between those clovers ; but it is now known to be a distinct species. It is found native over a large part of Europe, and was first cultivated in Sweden, deriving its common name from the village of Syke, in that country. In 1834 it was taken to England, and in 1854 to Germany, where it is largely grown, not only for its excellent forage, but also for its seed, which commands a high price. In France it is little grown as yet, and is frequently confounded with the less productive *Trifolium elegens.*"

The following is condensed from *Les Prairies Artificelles*, by Ed. Vianne, of Paris :

"Alsike does not attain its full development under two or three years, and should, therefore, be mixed with some other plant for permanent meadows. It is best adapted to cool, damp, calcareous soils, and gives good results upon reclaimed marshes. It is adapted neither to very dry soils, nor to those where there is stagnant water. Being of slender growth, rye-grass, rye or oats are often sown with it, when it is to be mowed. In fertile ground, weeds are apt to diminish the yield after a few years, so that it requires to be broken up. It is generally sown in May, at the rate of 6 to 7 pounds of clean seed to the acre ; sometimes it is sown in pods, at the rate of 50 to 100 pounds to the acre, either in spring or autumn, after the cereals are harvested.

"Alsike sprouts but little after cutting, and therefore produces but one pasturage. The yield of seed is usually 170 to 180 pounds per acre. The seed separates more easily from the pods than that of ordinary clover, and as the heads easily break off when dry, care is required in harvesting.

"It does not endure drouth as well as the common red clover, but will grow on more damp and heavy soils, and it is said that it can be grown on land which, through long cultivation of the common clover, is clover-sick."

FARMERS.

The Adaptability of Bee-Keeping to the Farmer.

Read at the Fremont Farmer's Institute

BY A. M. ALTON.

This is a subject which is receiving considerable attention at the present time. One question is, will it properly develop the intellectual and moral nature, so that the worker will develop all his faculties while striving to earn a comfortable subsistence ?

"It is not all of life to live, nor all of death to die."

As to bee-keeping, there can hardly be a question as to its moral and intellectual tendency ; for proof I have only to cite you to shining examples (both living and dead), who are, or have been, engaged in the pursuit. Who ever heard of a bee-master being guilty of a crime ? Then it will be congenial to those fitted by nature to follow it, just as a natural mechanic feels as home with the tools with which he cheerfully earns his living.

There is no use in saying that every man will make a successful bee-keeper, any more than to say that every man is by nature an artist, or every woman a musician. Unless a person possesses certain qualifications, either natural or acquired, he would very likely make a failure of bee-keeping. Among the necessary qualifications are perseverance, industry, the love of home more than riches, a talent for looking after details, promptness, and last, but not least, reasonably good health.

As a rule, I believe that bees should form a part of the surroundings of every ideal rural home; not only because it adds to the beauty of the landscape, but because in the economy of nature, bees are necessary to the perfect fertilization of the vegetable kingdom. And then, you can take your enjoyment as you go—mixed, it is true, with pain and toil, but still a life of enjoyment.

You have one important advantage over the merchant: Your out-door life gives you a physical vigor which he cannot enjoy; you have better food than he, even if he eats from the same dish, for he has not the same hunger to spice it. The man who eats his food with a thorough relish is the better man for it physically and mentally, and perhaps morally and spiritually.

Let not one suppose that bee-keeping connected with farming is a pleasant pastime which lazy and incompetent people can take up with success; for the lazy and incompetent, there is no success; for the lazy and incompetent, there is no place anywhere. It would be well for them to die at once, if they were fit to die. But any man or woman who will learn the business and begin wisely, can find in bee-keeping with farming, a healthful pursuit.

If farming were conducted in a better way than it usually is, and a few colonies of bees kept in connection with it, the two pursuits would be found to harmonize. As a rule, farmers attempt to work too much land, and the consequence is a low grade of farming, poor crops, their crops of both grain and fruit are inferior, and if there is a bee-keeper near, they are apt to try to make themselves believe that the bees are the cause of the poor crops. If instead of trying to farm 200 acres, they would put the same amount of labor on 80, and keep about 50 colonies of bees, sowing Alsike clover, buckwheat, etc., the investment would be much less, and I think that the results would be more satisfactory; and then, at times, if the farmer was not well balanced, he would almost go crazy with so much to see to.

Perhaps this question might be asked: What branch of farming would be best to unite with beekeeping? I would advise stock and poultry raising. Whatever branch the farmer may take up, he must expect to forsake all for that branch.

"When the loud clear notes of the dinner-horn
Are heard by the farmer while plowing the corn,
With the day just begun on a fine summer morn,
To him it was warning
That the bees are swarming,
And the interest is equal to a new baby born.
Old Doll is left standing alone in the row,
In the spot where the dinner-horn prompted the 'whoa,'
And off to the house, in a sweat he must go,
For when bees go a-frollicking
Like bobolinks rollicking,
No time must be lost in delays, you know."

BASSWOOD

Honey as a Medicine—Planting Linden Trees.

Written for the American Bee Journal

BY H. O. KRUSCHKE.

I have recently been examining my apiary, and the bees have wintered splendidly.

Sore Eyes and Erysipelas.

About two years ago my neighbor, Wm. Megow, had the misfortune to have one of his eyes put out. He received remedies from our best doctors, but they gave him no relief. Having heard that honey was good for sore eyes, he sent his son to me after some. I sent him extracted honey, which gave him immediate relief. He diluted it with water and dropped it into the eye.

Mrs. Esther Worden, of Necedah, Wis., was suffering with erysipelas; she was advised to bathe the affected or broken-out places with diluted honey. She did so, and was cured in a very short time.

Planting Basswood Trees.

I attended our State Bee-Keepers' Society meeting at Madison, in February. It was as good as any meeting that I have ever read reports of—that is not saying much, however. Very little was done of practical value to bee-keepers, aside from becoming acquainted with some members of the "sweet" fraternity. The only thing having real benefit to bee-keepers in view, was a resolution, requesting city and town authorities to include the basswood in their shade-tree selections.

I would like to see something better inaugurated regarding basswood. It is planted so sparingly as compared with elms or soft maples. It is certainly as beautiful as these, and by far more useful, and no tree is hardier or more easily grown.

What I am thinking of is this: The State should grow linden trees for gratuitous distribution. Bee-keepers could then take them, and plant them along the streets, roads, and in parks; and the authorities should look after such trees when planted. Bee-keepers would not be asking too much, for fish are hatched for our sportsmen, and also game wardens are kept. Money is distributed to hortieultural and agricultural societies, stock-breeders' and wool-growers' societies, and to State and County fairs, etc. We would only be very modest in our request, and I am sure that we would meet with little difficulty in obtaining it.

The nicest lane I have seen for a long time, is the one leading from our State University (at Madison) grounds to the Experimental Farm. It is nearly half a mile long, and is lined with linden trees on either side the whole length. Bee-keepers, wake up! Favors are granted to those who ask for them. I would like to hear from others regarding my ideas of planting linden trees.

Duester, Wis.

BEE-SUPPLIES.

Some Good Suggestions to those Who Use Bee-Supplies.

Read at the New York Convention

BY C. W. COSTELLOW.

In these days of sharp competition, any business, to be successful, must be conducted with great economy, even to (and I think that I ought to say especially in) the smallest details. Bee-culture, in all its branches, is no exception to this rule. To the older bee-keepers, I hardly think that I can give any new advice, but to those comparatively young in the business, I may be able to offer some points which will be profitable for them to consider.

First, I find that we can reduce our expenses in two ways—by a saving on the first cost of the supplies, and by getting the most value, or use, out of those supplies.

Nearly all of the dealers in bee-keepers' supplies offer discounts for goods purchased during the winter months, and one of the easiest ways to save, is to take advantage of these discounts. Dealers like to do this, for several reasons, viz: Without these discounts there would be comparatively nothing done in the supply trade in the winter; and then, they like to have these early orders, to relieve the crowd and rush of business during the honey season. It also keeps the business moving, and furnishes the cash with which to run it through the dull season.

The bee-keeper should include in one order, all that he will be likely to need throughout the season; by this means, he has the advantage of wholesale-rates. Here we also get another advantage, namely, on transportation.

Expressage on transportation of heavy goods is always expensive. If the goods are shipped by freight, the greater the weight, the lower is the freight, up to 100 pounds. For illustration, the rate on supplies from where I live in Maine, to Boston, Mass., is, for a package weighing 5 pounds, 25 cents; on a package, or several, weighing 100 pounds, it is 25 cents; and on a package, or several, weighing 200 pounds, it is only 30 cents. So you see that a great deal can be saved by ordering the supplies all at once.

To show the importance of this matter of saving on transportation, allow me to give the following case, which actually occurred:

In 1887, a supply dealer sent two bee-hives to a new customer; the next July he received an order for supplies amounting to 75 cents, to be sent by express, which cost 60 cents; on July 14, the same customer ordered $1.00 worth of goods by express, which also was 60 cents; and again on Oct. 6 another order of $1.71, by express, as before, with the same charge for transportation. Here we have $3.46 worth of supplies, on which the customer paid $1.80 express charges; *all of which* might have been *saved*, as all these supplies might have been sent with the hives, by freight, for the *same amount* that the hives were sent for. That customer has learned something by experience. I learned that he will know better another year what he wants, and will order all of his goods (as nearly as possible) at one time.

There is another way in which we can save on the first cost, and that is, by buying of that dealer who offers goods at the lowest rate; but this is not always the best way to do—it is often a "penny wise and pound foolish" transaction.

This brings us to consider the second way in which we can save expense, and that is, by getting the most value for our money. It is true, that a supply dealer may, for a short time, and for some special reason, offer goods at less than cost, but a business cannot be conducted for any considerable time in this way; and if a dealer offers goods considerably lower than others in the same business, we may be reasonably sure of one or two things—either the dealer is manufacturing cheaper than his competitors, or he is furnishing a cheaper grade of goods. My advice in this line is, buy the best goods that can be found; and get them as cheap as you can.

The *best* goods are the most profitable, for several reasons, viz: In the matter of hives and supplies which we use year after year, the stock out of which they are made must be good, so that they may last a long time; sections, and like goods, should be of good quality, to be attractive, and draw custom in the market. All supplies should be accurately and nicely made, so that the several parts may be put together without waste of time; and if everything is accurately made, the bee-keeper will save much time in all the manipulations of the apiary, for "Time is money."

Much money is wasted in the purchase of supplies, by changing often from one style to another. It is true, that if our pursuit is to advance, some one must experiment with new and different arrangements; but as experimenting is an expensive business, if we are trying to save all we can on supplies, we should leave the experimenting to others.

Use the Standard Sizes in Bee-Supplies.

The last thought to which I shall call your attention is, to use standard sizes in all your bee-supplies; by which I mean, sizes which are kept in stock by dealers generally; for by this means you will be better able to take advantage of business competition; you will be able to get the supplies at any season of the year, without loss of time; and, as a general thing, you will be able to buy proportionately cheaper than you could odd-sized goods, which must be made to order.

There are probably many other ways to save on the expense of supplies for the apiary, and if we gather and profit by the various thoughts advanced by experienced bee-men, it will be quite a source of profit in our business.

HIVES.

The Size of Hives Best Suited to the Apiarist.

Written for the American Bee Journal

BY J. E. POND.

The question of "how small a hive *should* be," is now being agitated, but I judge that the advocates of small hives would be looked upon with more favor, if the fact that some reading between the lines could be done. One thing is certain, the hive that is "just the thing" for the expert producer of honey, will not give good results in the hands of the noviee, or even the general bee-keeper, as a larger hive.

Tests, as ordinarily made, are of little value. Figures wont lie, if footed rightly, but they may be so placed as to prove almost anything in a statistical way; so with hive-tests—they may be made for the purpose of proving a theory, and apparently prove it; but when tested in another way, prove something else.

As yet but little real advance has been made in hives since the "Langstroth" was first made public; and as yet no better general results have been made than with the ordinary Langstroth hive. Mr. B. F. Carroll secured his big yield with this hive, and I doubt if he could have obtained it with a smaller one.

There may be times and places where a smaller hive would work well, but the extra cost of a ten-frame hive over an eight-frame one is so small, that the loss to a single colony, when the larger hive is needed, would more than out-weigh the extra cost of a dozen hives.

In the answers to queries, I find that the great majority favor a ten-frame hive. This agrees with my own experience, and I believe that experience generally will coincide therewith.

An ordinary ten-frame Langstroth hive, 14¼ inches wide, is none too large for a fair colony, especially when the colony is expected to store its own winter supplies. Only experts can succeed in cleaning out the brood-chamber of honey, and filling up for winter by feeding, and they fail as often as they succeed.

Now the ordinary bee-keeper is on a different footing, and it is he for whom I am writing; and I advise, as the result of my own experience, backed up by the experience of bee-keepers generally, that better results will be obtained from a ten-frame Langstroth hive, or its equivalent, than from any smaller one, no matter how many horizontal splits it may be cut into.

North Attleboro, Mass.

WINTERING.

Experience with Toads—Priority of Location.

Written for the American Bee Journal

BY CHARLES WALKER.

I am putting the bees out of the cellar, and I find that I have lost 7 or 8 colonies so far, from 105 wintered in the cellar. The trouble was that I could not keep the temperature low enough, the mercury frequently going up to 55° or 60°. April, so far, has been full of "squaw" winters; to-day, however, has been pleasant, with south wind, and house-cleaning has been the order generally with the bees. Many are taking the first flight.

Toads in the Apiary.

Regarding toads, I have noticed that since I have kept bees, the increase of toads has been nearly as rapid as that of the apiary. Soon after sundown I have seen them come out from under the honey-house, and make a bee-line for the water-trough, that is always kept full for the bees. I have counted 30 or 40 of those toads, and have been suspicious of them, as they are named as enemies of bees. I have been on the watch for their depredations, but as yet I have never caught them. I have treated them as a sort of pets, and watched them play on that old trough; but what they did after I retired, is a question that I shall try this

season to solve; and if I find them eating live bees, I will fix their toadships.

Priority in Bee-Keeping.

I think that priority of location is the simple side of that question. If one State should pass such a law, it would not be constitutional, and would not stand a test. It would be like one farmer having a fine peach-orchard, and the neighbor over the line (who has none, but wishes to set out some) saying, "You must not set your trees so close to mine, as they will destroy mine, and not do well."

This is a world of competition, and we must sometimes compete with our neighbors, and the survivor will be the fittest, with the bee-keeper, as with all other pursuits.

In 1880 I had here only one colony, while our neighbor a mile or two away, owned 145. My apiary gradually gained in numbers, and at the end of 8 years, from that single colony, and the purchase of one queen, I had the largest apiary, and to-day I have a fine apiary, while that neighbor has not a single colony left; but there are legitimate causes for these changes, and it depends considerably whether a man dabbles in every new hive that is announced.

Bravo, Mich., April 6, 1889.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Apr. 23.—DesMoines County, at Burlington, Iowa. John Nau, Sec., Middletown, Iowa.

May 1, 2.—Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.

May 4.—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.

May 21.—Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees Dying in Texas.—Jennie A. Young, Ft. Worth, Texas, on April 5, 1889, writes:

Bees in this part of the country are dying from some unknown cause. They seem to be building comb and storing honey, but it seems that the young bees come out of the hive, and are unable to fly, crawl around for a while, and then die. If any one can enlighten us on the subject, through the columns of the excellent AMERICAN BEE JOURNAL, and suggest a remedy, he will confer a lasting favor upon benighted apiarists in this, our sunny Southland.

Getting Rid of Ants, etc.—W. H. Graves, New Carlisle, Ind., on April 3, 1889, writes:

My bees wintered nicely on the summer stands, only losing one colony. My report for 1887 was a little "off;" I reported 25 or 30 per cent. loss, but my real loss was 47 colonies out of 110. I have 82 colonies now in good condition. In 1887 my expenses were something near $100, and I got about $100 worth of honey; in 1888 I had over $200 worth of honey, and my cash expenses were 10 crates at 11 cents per crate. My bees carried in their first pollen on March 26, and on the 25th I saw the first dandelion in bloom.

Those whose apiaries are troubled with ants, should try bruising green catnip on the hives where they are infested with ants. That has been my remedy for the last 12 or 15 years, and it drives them away when almost everything else fails. I have never heard of any one else using it. It seems to quiet the bees also when they are cross.

Good Prospects for White Clover.—Jas. E. Brown, Milwaukee, Wis., on April 3, 1889, says:

I never had bees in better condition on April 1, than they are this year. The prospects for white clover are good. I have 75 colonies in the cellar yet. I take my bees out of the cellar about April 15.

Weighing the Bees, etc.—Ira N. Lyman, St. Peter, Nebr., on April 4, 1889, writes:

We had the nicest winter here that I ever saw. I was brought up in Iowa and Nebraska, and have been acquainted with bees ever since I was about two or three years old. My father used to keep his bees in hollow logs and the box-hives; the windstorms would blow them over, and we set them up again. We left them on the summer stands all winter, but it was in the woods, in Johnson county, Iowa. When we got any honey it was in a little square box put on top of the hive, with a few auger-holes to make the connection; or sometimes we took off the top-board, and dug out some honey. When the movable-frames came into use, it did away with the "king-bee" and digging down from the top of the hive for honey. Then the Italian bees came at $10 per queen, the first I saw. With the Langstroth hive and the Italians, bee-keeping changed with me. I think that it is a pleasure and a profit in any common season.

My bees came out in splendid condition this spring, save one colony that had some drones when put into winter quarters; it died as I expected it would. It had about 30 pounds of honey left in in the hive. I weighed all of my bees when I took them out of the cellar on March 5, and weighed them after they had been pretty well cleaned out, and flying several days. Two colonies lost 5½ pounds, one 17½, and one 8 pounds—a little over 9 pounds per colony during the winter in the cellar. One colony that lost 17½ pounds, was very uneasy, and anxious to get out of the hive. I had them fastened in with wire-cloth in front of the hive-portico. I think that the bees winter best in a dry cellar, in a prairie country. Bees gathered pollen from willows on April 1. My bees used lots of rye flour, and are still working at it. The prairies are getting green, and everything is nice, only we get no rain, and had no snow all winter. We are wishing for rain. Small grain is nearly all sowed.

Season of 1888.—Mrs. W. T. Henley, Black Jack, Mo., on March 31, 1889, says:

I started last spring with 4 colonies in good condition, and increased them to 12, by natural swarming. I obtained a good supply of honey, but nothing like a full crop, some of it being the loveliest that I ever saw. There are not many bee-keepers around here. Honey is in fair demand, and brings good prices. I hope for a good honey year for 1889.

Section-Case.—M. Tailor, of Benton County, Iowa, writes thus:

Seeing the great good the Bee-Keepers' Union is doing, and likely to do, my conscience gives me no rest until I send you my dollar for membership, and especially as my crop last year was exceptionally good, being about $90 worth from 4 colonies, spring count. I am only an amateur, and keep a few colonies of bees on a town lot, for recreation and pleasure, and I got both, and profit too.

I will here describe a section-case, contrived by me last year. I will not call it an "invention," although I have seen nothing like it. It is very simple, and above all, cheap and efficient. If it is of any value, the bee-fraternity are welcome to it.

It consists of 4 pieces of board, and 8 common wood-screws, nothing more unless separators are wanted, then two ⅛-inch tin strips are put in crosswise between the end rows of sections, and

the separators rest on them. The case holds 28 1¾-inch sections. I use say ⅞-inch lumber, cut all pieces the exact width of the sections used, usually 4¼ inches; the length of the sides are the length of 4 sections—17 inches; add one thickness of the boards used, ⅞ inch, and from this I deduct say ⅛ inch, so as to make a close fit over the sections. The end-pieces will be 13⅛ inches long. The joints all lap one way.

In using the case, two alternate corners can be screwed together permanently, but this is optional. Place the sections together upon a level board, slip the case over them, and screw up the other two alternate corners until the sections are held firmly in place. This makes a surplus case that can be reversed, storified, or handled in any way. Of course it is necessary to use a honey-board, but a queen-excluding honey-board ought to be used with all kinds of surplus cases for comb honey.

In taking off the sections, all that is required is to unscrew the two alternate corners (or all four, if desired), and the sections will all come out in a bunch. This will save many mutilated sections, and broken cappings, especially by the novice.

I have been reading the AMERICAN BEE JOURNAL for one year, and I consider it indispensable for any one wanting to keep posted.

Wintered in Straw Hives.—Abe Hoke, Union City, Ind., on April 8, 1889, writes:

My winter report for 1888–89 is much better than I expected last fall. I put 26 colonies into winter quarters, and lost only 3, by starvation, two of which were no good last summer. One colony was one of the best that I had, but it did not have as much stores as I thought it had. It was in a round straw hive, with the frames running to the centre. I think that with plenty of stores, a colony would winter safely in it, in any climate. It is double-walled, and cost me six days' work to make it. It has 23 frames; one runs across the centre of the hive, and supports the ends of the others.

Early-Reared Queens, etc.—James Kincade, Clay Centre, Nebr., on April 5, 1889, writes:

As a general thing the bees have wintered finely. A few bee-men have lost some colonies. I have 24 colonies, all in fine condition. I examined them lately, and found all with queens, and laying. The greater part of them have not used half of their honey; but one colony needs feeding, that swarmed on Sept. 2, and would have had plenty, but was robbed. The rest of the apiary do not need anything except warm weather to bring out the bloom. They are getting pollen from ground feed, wherever they they can find it. The weather is fine most of the time. We have had a few windy days this month. My neighbor has 2 colonies, one of which he found without a queen this spring; the other had brood and eggs, and was all right until lately, when he saw what he thought to be queen-cells, so he took one frame and gave it to the colony that had no queen; now he has two young queens. The question now is, will those queens remain until there are drones to mate with? or will they have to be destroyed, and others reared, as this is rather early for drones? I have seen 2 drones flying from one of my colonies for the last week.

[You give no dates, and all we can say is, that if the queens were not fertilized within 15 or 20 days, they will be drone-layers only.—ED.]

Shipping Honey, etc.—Rev. S. Roese, Maiden Rock, Wis., writes:

We are living in an age of wonders, and this great American nation seems to take the lead in science and art, and the invention of machinery of all descriptions, with steam and electricity subjected to serve at will. The bee-keeping family all over the land has reason to feel grateful for modern improvements in bee-keeping, and the friendly ties of associations and bonds of union which have been formed to promote industry, love, harmony and good-will for each other. It is rejoicing to see what the Bee-Keepers' Union has accomplished in defending bee-keepers in their industrial rights.

I have now 80 colonies of bees, mostly Italians, and 4 colonies belonging to another man, which I keep on shares, but the weather last winter was so mild, that I had to open the bee-house door at night, to admit cool air. My bees are mostly in good condition, with the exception of 6 or 7 colonies which need some feeding. I shall make some of the "Good" candy, and place it over the frames. All weather indications seem to point to a good honey crop the coming season.

I shipped some of my comb honey to St. Paul by express, and found it all broken, so that I had to sell it at anything that I could get for it. I shipped the next lot by freight, which arrived all right. I would advise bee-keepers never to ship comb honey by express, for I see that they handle boxes and packages very roughly, without any care whatever.

Ground Corn and Oats for Pollen.—O. B. Barrows, Marshalltown, Iowa, on April 6, 1889, writes:

Before I put my bees out of the cellar in the spring, for 80 colonies I procure one-fourth of a ton of meal, by grinding corn and oats together. I turn about one dozen hive-covers bottom upward, one end higher than the other, and put two or three quarts of the meal into the upper end; when it is worked to the lower end, I reverse the end, as recommended by Dr. Miller, but always so changed as to be most exposed to the sun. When it is pretty well worked over, I add new meal.

After reading Allen Latham's article on feeding Graham flour, on page 219, I bought a sack of Graham flour, and put some in each box at one side; but my bees showed a decided preference for the corn-and-oats meal. Bees were at one time nearly done working on the meal, but since the freeze, they work on it immensely. The losses in wintering in this vicinity will not average 2 per cent.; but unless we have rain to make the clover grow, it will probably be a misfortune that they did not all die in wintering; still we are in hopes of yet seeing the silver lining to the cloud.

Experience with Bees, etc.—Geo. H. Auringer, Bonniwell's Mills, Minn., on April 6, 1889, writes:

Two years ago I bought 3 colonies of bees, one was strong, and the other two were weak. The strong colony I was afraid to touch, but the others paid no attention to me at first. I got no swarms from the weak ones, but the other swarmed three times, and the first swarm swarmed, so I secured 4 new colonies from one. I sold 2, and put 5 colonies in the cellar. I obtained about 300 pounds of honey the first season. Last spring I put the 5 colonies out on April 20, seemingly as strong as they were the fall previous, and they all went to work the same day carrying in pollen. They were in three different kinds of hives which I did not like, so I bought 14 hives that were all alike. I let the bees swarm all they would, and had from 2 to 3 swarms from each colony, and some of the first swarms swarmed again. I now have 19 strong colonies. I secured 600 pounds of honey in 1 and 2 pounds sections. I have one colony out of the cellar that is carrying pollen in now. I will put the rest out in a few days. I am well pleased with the AMERICAN BEE JOURNAL, and can heartily recommend it to all who keep bees.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

Chapman Honey-Plant Seed.—The United States Commissioner of Agriculture has a quantity of the Chapman honey-plant seed for free distribution. Applicants desiring packages of the seed will be supplied while the seed lasts, in the order of their applications. The request for seed should be addressed to the United States Commissioner of Agriculture (Seed Division), Washington, D. C.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Subscribers who do not receive this paper promptly, will please notify us at once.

DORÉ ART PORTFOLIO,

PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Honey and Beeswax Market.

HONEY.—White 1-lbs., 15@16c.; fall or dark, 12@14c. Extracted, 8c. for white. Supply large and demand light.
BEESWAX.—None in market.
Apr. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX.—22c.
Mar. 25. R. A. BURNETT, 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.
BEESWAX.—21c. for prime.
Mar. 25. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.
BEESWAX.—Scarce, at 18@22c.
SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Quantity of honey in the market is sure to be entirely closed out before new crop comes.
Apr. 8. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.
BEESWAX.—22@23c.
Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.
Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:

This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Advertisements.

WANTED—You to send for my illustrated price-list of Apiarian Supplies for 1889; also **five cents** for my pamphlet, **"How I Produce Comb Honey."**
GEO. E. HILTON,
16A8t FREMONT, MICH.
Mention the American Bee Journal.

ITALIAN BEES, QUEENS, and EGGS from Light Brahma and Wyandotte Poultry One Untested Queen, $1; three for $2. Eggs, $2 for 13. Price-List Free.
Address, H. G. FRAME,
10E13t NORTH MANCHESTER, IND.
Mention the American Bee Journal.

SECTIONS, first-class, $3.00 per 1,000, and **Foundation** cheaper than ever. Dealers will do well to get our Prices. **Alsike Clover, Japanese Buckwheat,** &c. Free Price-List and Samples. M. H. HUNT,
2E13t BELL BRANCH (near Detroit,) MICH.

HUMPHREYS' HOMEOPATHIC SPECIFIC No. 28
In use 30 years. The only successful remedy for
Nervous Debility, Vital Weakness,
and Prostration, from over-work or other causes. $1 per vial, or 5 vials and large vial powder, for $5.
SOLD BY DRUGGISTS, or sent postpaid on receipt of price.—Humphreys' Medicine Co., 109 Fulton St., N. Y.
4A13t

HANDSOME SECTIONS.

WE have a limited quantity of One-Pound Sections, 4¼x4¼, a trifle less than two inches wide, with narrow tops, in packages of 1,000 each. They are manufactured from extra white lumber, are very uniform, making them the finest and most attractive honey-section in the world. Price, $3.50 per package.
THOS. G. NEWMAN & SON,
923 & 925 West Madison-Street, - CHICAGO, ILLS

FROM ITALY.

I ALWAYS keep in stock the **ITALIAN QUEENS** that come direct from Italy. These are called "Imported." I rear them just as fine. Send for Price-List of 1889.
Address, R. H. CAMPBELL,
10Etf MADISON, Morgan Co., GEORGIA.
Mention the American Bee Journal.

British Bee Journal

AND BEE-KEEPERS' ADVISER,

IS published every week, at **10s. 10d.** per annum. It contains the very best practical information for the apiarist. It is edited by Thomas Wm. Cowan, F.G.S., F.R.M.S., etc., and published by John Huckle, King's Langley Herts, England.
Mention the American Bee Journal.

Voice of Masonry and Family Magazine.

Three years a Paper and twenty-five a Magazine. Now unexcelled. Contains fine **Portraits and Illustrations**, and a great variety of articles, stories and poems for Freemasons and their families; also **Eastern Star, Masonic Gleanings and Editorial Departments.** Price per year, $3.00.
JOHN W. BROWN, Editor and Publisher,
182 & 184 S. Clark Street, Chicago, Illinois.
Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. April 27, 1889. No. 17.

EDITORIAL BUZZINGS.

Morn's rosy light gleams everywhere
To all the air,
To perfume Lent;
And every flower in beauty dressed,
Wears jeweled crest,
From heaven sent.

The milk-white bloom of cherry-trees
Hath charmed the bees
From Winter's cell;
And one can hear soft whisperings,
And whirr of wings,
And songs as well.

—*Seed Time and Harvest.*

The Rev. Dr. M. Mahin has been appointed to the pastorate of Grace Methodist Episcopal Church in Richmond, Ind., and his address will hereafter be at Richmond, Wayne county, Ind.

The British Bee Journal for April 4 contains a good likeness of Mr. Charles Nash Abbott, its former editor, together with a biographical sketch of his life and work in the apicultural line.

A Poultry Department is to be added to the *Canadian Bee Journal* next week; the form will be changed, pages enlarged, and cover omitted. This will be the second bee-paper in America having added the poultry feature. We wish it success.

We Deeply Sympathize with Capt. and Mrs. J. E. Hetherington, of Cherry Valley, N. Y., in their affliction—having lost their youngest son, John Edwin, on the 3d inst. He was 4¼ years of age, and was a bright and intelligent boy, giving promise of becoming an energetic and useful man. It is a sad blow to both mother and father, for Johnny was the "sunshine" of that home. The AMERICAN BEE JOURNAL now offers its condolence to both.

Transferring Bees, etc.—I. E. Myers, Mahtomedi, Minn., on March 27, 1889, writes:

I am beginning bee-culture with one colony, that I found in the woods last fall. I have them in their "log-cabin" yet, but I want to change them into a Langstroth hive. When I was a boy, yet at home, my father would transfer the old colony into a new hive once in about 4 years. We used water to drive them from one to the other; but my "log cabin" is so long that the expense of building a tub around it to hold the water would cost more than the colony is worth, although the bees are numerous and apparently doing finely.

I have made a feeder for them, so that I can feed them and not compel them to come out after the food. It is fastened to the log with screw-nails, and a hole bored through the feeder and the log to give them access to the honey. By the sliding of a slat of wood between the two I can close the passage while I clean out the feeder-trough. The feeder works like a charm. It is amusing to see the bees take in the rye-flour.

I send you some of my bees, to learn what kind they are. Some call them Italians, and others hybrids; but I do not see any difference from those that my father had 40 years ago.

The bees did not come to hand—they were probably lost in the mails. Mr. Myers asks how to transfer the bees to frame hives. As several have asked to have Mr. Heddon's plan of transferring bees reproduced, we give it here. He says:

About swarming time I take one of my Langstroth hives containing 8 frames of foundation, and with smoker in hand, I approach the colony to be transferred. First, I drive the old queen and a majority of the bees into my hiving-box. I then remove the old hive a few feet backward, reversing the entrance, placing the new one in its place, and run in the forced swarm. In two days I find eight new straight combs with every cell worker, and containing a good start of brood. Twenty-one days after the transfer, I drive the old hive *clean* of all its bees, uniting them with the former drive, and put on the boxes, if they are not already on. If there is any nectar in the flowers, the colony will show you comb honey. About the queens: I usually kill the forced queen as the bees run in.

I run them together as I would one colony in two parts. Now to the old beeless hive; of course there is no brood left, unless a little drone-brood, and we have before us some combs for wax, for more foundation, and some first-class kindling wood.

If you have no method by which you can use a full hive of frames, of full sheets of foundation, running a full swarm into them at once, by all means procure it without delay.

We hope this will be sufficiently "detailed" to oblige our correspondent. It should be remembered that every beginner ought to have a good "book" for convenient reference at all times.

Catalogues for 1889 are on our desk from—

S. W. Morrison, M. D., Oxford, Pa.—4 pages—Carniolan Queens.

G. K. Hubbard, Fort Wayne, Ind—16 pages—Hives and Bee-Keepers' Supplies.

C. Mathews, Imlay City, Mich.—4 pages—Bee-Keepers' Supplies.

J. B. Mason & Sons, Mechanic Falls, Me.—20 pages—Bee-Keepers' Supplies.

E. L. Goold & Co., Brantford, Ont.—20 pages—Bee-Keepers' Supplies, etc.

Mineral Wax.—A. E. Maley, Auburn, Neb., sends us the following item from the New York *Mail and Express*, and wants to know if it is true:

A car-load of a peculiar mineral arrived in this city a few days ago. It was ozocerite, or mineral wax, and it came from Utah. Until recently this substance has not been known to exist in any quantity except in Moldavia and in Galicia, Austria. Three years ago, however, a deposit of the queer substance was discovered on the line of the Denver & Rio Grande railroad, about 114 miles east of Salt Lake City. The mine is known to cover at least 150 acres, and over 1,000 tons per year can now be produced.

Ozocerite resembles crude beeswax in appearance, and can be used for nearly all purposes for which wax is employed. It is now largely used in the manufacture of waxed paper. It enters into the composition of several brands of shoe polish. Mixed with paraffine, it produces an excellent grade of candles. One of the largest fields for the new material is the insulation of electric wires. It is claimed that ozocerite is preferable to any substance previously employed for this purpose. As the mineral wax comes out of the ground in condition to be used without refining, unless it is required for some special purpose, it is much cheaper than the product of the honey bee, and it is evidently destined to be extensively used in the future.

We have heard much about the mineral wax product, in general, but have nothing to offer about the "Extensive deposit of ozocerite recently found in Utah." Perhaps some of the wide-awake bee-keepers of that region can tell our readers something about it.

Several Copies of a circular sent from Chicago, signed by F. Andrews, have been received at this office. It offers a book on the "Secrets of Bee-Keeping" for 15 cents, and a model of a hive for $3.00. We have made four trips to the address given, to buy a book, but can find no one there. A woman from another room in the same building was found, who said that Andrews was there only a few minutes each day, and that he was going to California in May. It is useless for us to caution any one, for our readers do not send "a nickel and a dime" for any "secrets" of bee-keeping. They know better. It is the "novices" he is after. The circulars seem to have been sent to post-masters, and by them distributed into the "boxes," to catch the unwary, and obtain many $3.00, and "nickles and dimes," for Mr. Andrews to go on "a trip around the world."

The May number of *Frank Leslie's Popular Monthly*, crowded as usual with attractive pictures and good reading, opens with a well illustrated article by George C. Hurlbut, on "The Paris Exposition and its Significance," which is of special interest and timeliness, closely preceding, as it does, the opening of the great French Universal Exposition in commemoration of the one hundredth anniversary of the fall of the Bastille. Its many attractions, in the form of stories, sketches, essays, poems, scientific articles, art illustrations, make up a model number of this popular magazine.

MR. DOOLITTLE'S NEW BOOK.

—:o:—

"Scientific Queen-Rearing, as Practically Applied" is its title, and it contains 176 pages. It is nicely printed on good paper, and contains 20 illustrations besides a portrait of the author. The latter is very good, and we reproduce it here for the benefit of our readers.

Yours Truly
G. M. Doolittle

The first Chapter is devoted to the author's first interest in bee-keeping. The second Chapter dwells upon the importance of good Queens. Chapter III and VI describe Nature's way of rearing Queens. The fifth Chapter details the old methods, pointing out their imperfections. Chapter VI enumerates later methods, as steps to the "new way," which fill the next 20 pages with very interesting details.

"Getting the Bees off the Cells," is the subject matter of Chapter VIII; followed by chapters devoted to "What to do with Queen-Cells"—"The Queen-Cell Protectors"—"How to Form Nuclei"—"How to Multiply Nuclei"—and the methods used by the author to have "Queens Fertilized in the Same Hive where there is a Laying Queen."

This is followed by a chapter on Bee-Feeders and Bee-Feeding, and then the author deals with the all-important matters of "Securing Good Drones," and the "Introduction of Queens," in the following language:

SECURING GOOD DRONES.

It is my belief that we, as apiarists of the Nineteenth Century, do not look to the high qualities of our drones as much as we ought, or as much as we do to these qualities in our Queens. To me, it seems that the matter of good drones is of greater value, if possible, than is that of good Queens; for I believe that the father has as much, or more, to do with the impress left on the offspring, than does the mother. We select our Queens with great care, but leave them to mate with drones of a promiscuous rearing from all of the colonies in our bee-yard, as well as with the "scrubs" reared by our neighbors, or from such swarms as may be in the woods near us. Now this ought not so to be; for if we would have the best of bees, our Queens must mate with the best of drones.

To this end, it seemed to me that one of the most desirable things possible about Queen-Rearing, would be the fertilizing of Queens in confinement. For this reason I have tried every plan given to the public, for the accomplishment of this object," but, as I said in a previous chapter, I have so far nothing to record but failures. I would willingly give $500 for a plan by which I could mate the Queens that I rear, to selected drones as I wish, and do this with the same ease and assurance that our other work about the apiary is carried on.

As we cannot as yet, do this, I find that the next best thing that I can do, is to set apart two or three of my very best Queens for drone-rearing, causing them, as far as may be, to rear all of the drones in the apiary. I do this by giving these colonies a large amount of drone-comb, and keeping up their strength, if need be, by giving them worker-brood from other colonies.

The other colonies are largely kept from rearing drones, by allowing only worker-combs in their hives, and by giving them a comb of drone-brood occasionally from one of the colonies rearing drones, just when they want drones the most; for if this is not done, they will have drones anyway, even if they have to tear down worker-comb to build such as is needed to rear them in. As soon as the major part of the drones from this comb have hatched, it is taken away, before the inferior drone-brood (if any is placed in the comb) has time to mature. In this way I get all the drones reared from my best Queens, and only fail in not being able to sort out the weak and feeble ones, or, in not being able to select the most robust drones for the Queens.

To be sure, we can use the drone-traps now before the public, to keep the drones of the poorer colonies from flying; but to me, this causes more work and more disturbance with the bees, than the plan outlined.

Again, the rearing of drones, causes a great consumption of honey, and it seems foolish to be wasting honey in rearing drones, only for the sake of killing them afterward.

Beside knowing how to rear mostly good drones, we want to know how to get them early in the spring. This is something not often spoken of, but it is one of the things which must be done by the Queen-Rearer who would please his customers. To do this, I place drone-comb in the center of the hives having my drone-rearing Queens, doing this in the fall, so that whenever the bees have any desire for drones, such comb will be handy for the Queen.

If these colonies are not very strong in the spring, I make them so, by giving hatching brood from other colonies, till they are running over with bees, while in addition to this, I often insert a drone-comb full of honey, right in the center of the brood-nest; for in the removing of a part of all this honey, the bees coax the Queen to lay in this drone-comb, to a degree that otherwise could not be attained. In this way I usually succeed in getting drones from one to three weeks earlier than I otherwise would.

To keep drones late in the fall, I make a strong colony queenless, at the close of the honey-harvest, and in this colony I put all of the drone-brood that I can find in my drone-rearing colonies at this time. As much of this brood is in the egg and larval form, when given to the queenless colony, I have them hatching after all the other drones are killed off, for queenless colonies which are strong, are very choice of drone-brood. In this way I generally have a hive full of nice drones, as late as I desire to rear Queens, keeping them frequently into October.

As soon as I am through with such drones, I introduce a Queen to the colony, when the bees will destroy them at once, if feeding is withheld. I always feed a colony keeping drones when honey is not coming in, for they need much food to make them fly freely, and that is what we want them to do, on every warm day at that season of the year.

One other item that I wish to notice at some length, before closing this chapter on drones, is this: From the fact that worker bees can lay eggs that will hatch drones, and that Virgin Queens can also lay eggs which will also produce drones, the theory has obtained very largely among bee-keepers, that the drones from a fertile Queen must of necessity be of the same blood, as they would have been had this Queen produced drones before she was fertilized. In nearly every book written on bees, that I have read, where this subject is touched upon, we find words to the effect that, "a pure Queen, however mated, must produce a pure drone of her own variety." Mr. Alley's "Queen-Rearing" is an exception to this, I am happy to note.

Now I am not prepared to say how, nor wherein, the drones are changed by the mating of the Queen; but this I do know, that drones *are* contaminated, to a certain extent, by the mating of a Queen of one blood, with a drone of another blood. Any one can prove this, for in four generations, by mating the Queen each time to these pure (?) drones, a bee can be produced which no man can tell from a hybrid. That this contamination does not show in the first cross, is the reason, I believe, that the theory has been accepted, by nearly all, as the truth.

To illustrate: Take a pure black Queen, and after she has mated with a fine, yellow Italian drone, let her rear all of the drones produced in an apiary containing only black bees. Of course, the drones from this Queen will all be black to look at, the same as they would have been had she mated with a drone of the same blood as herself. Now rear Queens in this apiary, from any of the pure black mothers in it, and these young Queens will mate with the drones from this mismated Queen. These young Queens will apparently produce all black workers and drones, the same as they would have done had these drones come from a pure black mother, mated with a pure black drone; but when we rear Queens from these young mothers, now and then one will show a little yellow, which would not have been seen, had not the drones from this mismated Queen been the least bit contaminated, To detect any slight contamination of blood in our bees, we must always look to the Queen progeny, for the Queen is the typical bee of the hive; hence they will show an impurity where the workers and drones would not.

Now, take one of these young Virgin Queens showing a little yellow, and have her mated with a pure yellow Italian drone—the same as was done with the first Queen. From this one rear all of your drones again, while you rear Queens from her mother, which young Queens would be sisters to the one now producing drones. Having one of these last young Queens fertilized by the desired drones, next rear Queens from her, and you will find that some of these Queens will show quite a little yellow on them; yet so far the drones and workers show little if any difference.

Take one of the yellowest Queens from this last lot, and have her mated with a yellow drone again, going over the same process of mating as before, and you will get Queens in this third generation, which will (many of them) be quite yellow; while the workers and drones will show "yellow blood" about them, by occasional "splotches" of that color.

Now follow out the same line of breeding once more, and you will get both workers and drones, which any Queen-breeder in the land will call hybrids—calling them rightly so, too. These hybrids could not possibly come about by this way of breeding, only as drones from a mismated Queen are contaminated; for so far as we have used no drones except those which were pure black, according to the parthenogenesis theory, yet we have a hybrid bee as the result.

Worker bees and drones do not show a little variation of purity, as much as does the Queen, hence if we would know of the stock which we have, we must rear Queens from them. Failing to do this, we often decide that we have pure drones for breeding purposes, because these same drones look all right.

If I have made this matter plain, and I think that I have, it will be seen how much value it would be to the scientific breeder of Queens, if he could select just the drone he wanted, and then have a valuable Virgin Queen mated with that drone. In this way we could accomplish as much in securing the "coming bee," in two years, as we now accomplish in a life-time.

Let no one be longer deceived about *pure drones* from a mismated Queen; for if such drones are allowed to fly in your yard, you cannot expect any satisfactory degree of purity from Queens reared therein. I have been forced to this conclusion by many carefully-conducted experiments as already described.

THE INTRODUCTION OF QUEENS.

Perhaps there is no one subject connected with bee-keeping that has received so much notice in our bee-papers and elsewhere, as has the introduction of Queens; yet all who have read the methods and discussions given, must have plainly seen that success does not always attend the efforts in this direction. On the contrary, many losses have been reported, and these losses are not confined to the inexperienced altogether, for we often hear of our most practical apiarists occasionally losing a Queen.

The reason for so many losses, it seems to me, arises from the fact that bee-keepers in general do not understand that a discrimination should be made between Queens taken from one hive and placed in another, and those which have come long distances by mail or express. In introducing Queens, it should always be borne in mind that a Queen taken from one hive in the apiary, and introducing into another, does not require one-half the care that must be given to a Queen coming from a distance. The reason for this seems to be, that a Queen taken from a hive in the same yard, is still heavy with eggs, and will not run around, provoking the bees to chase her, as will a Queen after having had a long journey.

In introducing all ordinary Queens coming from my own apiary, I generally adopt one of the two following plans: The first is, to go to a nucleus or other hive from which I wish to get a Queen, and when she is found, I take the frame of brood she is on, bees and all, together with another frame from the same hive, carrying them to the hive from which I am to take the superannuated Queen, when they are left with the Queen between the two combs, while I secure the poor Queen and dispose of her; then I take out two frames from this hive, and place the two frames, brought from the nucleus, in their places, and close the hive. I now shake off the bees from the two frames in front of their own hive, carrying the combs to the nucleus; or if the nucleus will be too weak, I carry bees and all to it.

The object in taking the two frames with the Queen, is so that while waiting outside of the hive, she and the most of the bees may cluster between them, thus becoming quiet. When placed in the hive, both are put in together, thus leaving the Queen quiet among her own bees. In this way I do not lose one Queen out of fifty, and as the operation is so simple, and the Queen so quickly installed, the advantages more than over-balance so small a loss.

The second plan, is to go to any nucleus and get the young Queen in a round wire-cloth cage (such as all bee-keepers have in their apiaries) before looking for the Queen to be superseded. After she is in the cage, I place her in my pocket, and close the hive that I took her from, and

look for the Queen that I wish to remove; having found her, she is killed or otherwise taken care of, and this hive is also closed. I next blow in at the entrance enough smoke to alarm the whole colony, pounding with my fist on top of the hive until I hear a loud roaring inside, which shows that the bees are filling themselves with honey. I now let the Queen that I have in the cage, run in at the entrance, smoking her as she goes in, while I still keep pounding on the hive. In doing this, nothing but wood-smoke should be used, for if tobacco-smoke were used, many of the bees would be suffocated.

If this is done when there is danger of robbing, I wait till just at night, about the operation. If more convenient, the Queen can be taken out of the hive at any time during the day, and the operation of putting in the new Queen done just at night. Some seem to think that the operation will be more successful if done in this way, but so far I fail to see any difference as to results. The idea is to cause the bees to fill themselves with honey, at the same time smoking them so that the Queen and bees smell alike. This plan is as free from loss as the other, still it is not quite so simple as the first—I only adopt it where it is not handy to use the former.

Where any colony has been queenless from three to five days, a Queen can generally be successfully introduced by dropping her in honey, and rolling her over in the same, till she is thoroughly daubed with it, when the cover to the hive is lifted, and the Queen dropped from a spoon right down among the bees. This is equally successful with the others, but I do not like the plan, on account of having to keep the colony queenless so long. Even a Queen from a distance, can generally be safely introduced by this plan.

To introduce a Queen that has come to me from abroad, or one which I consider of more than ordinary value from my own apiary, I proceed as follows: First, I take the cage containg the Queen and her escort of bees, to the little room where I handle queen-cells, and open the cage before the window, so that if the Queen takes wing, she will not be lost. I then catch the Queen and clip her wings (as given in the chapter on that subject), when she is placed in a round, wire-cloth cage; but I allow none of her escort to go with her, as I consider such bees when left with a Queen one of the prime causes of the many losses which occur to the purchaser of Queens.

Having the Queen's wings clipped, and in the cage, I next take a piece of wire-cloth, containing 14 or 16 meshes to the inch, and cut it four-and-one-half by eight-and-one-half inches in size. Now cut a piece three-fourths of any inch square out of each corner, and bend the four sides at right angles, so as to make a box, as it were, three inches wide by seven inches long, and three-fourths of an inch deep. Next, unravel the edges down one-half way, so that the points can be pressed into the combs, and if the corners do not stay together as they should, they can be sowed together with one of the wires which were unraveled [Fig.5, page 50].

Having the cage ready, and the Queen to be introduced, in your pocket, proceed to look for the Queen to be replaced, and after removing her, examine the combs until you find one from which the bees are just hatching, or where you can see them gnawing at the cappings of the cells, which comb should also have some honey along the top-bar of the frame above the hatching brood.

Now shake and brush every bee off this comb, and place the Queen that you have in your pocket on it, by putting the open end of the cage near the comb over some cells of unsealed honey, when she will go to the comb, and as soon as she comes to the honey, she will begin eating. While she is doing this, put the large cage over her and the hatching brood, as you wish, taking all of the time that is needed, for as long as she continues eating, she will not go away, nor be disturbed by any of your motions.

Having honey in the cage is necessary, for the bees outside of the cage cannot be depended upon to feed a Queen when she is being introduced. Some claim that if the cage is made of wire-cloth having large meshes, the bees will feed them; but after losing many Queens by depending upon the bees to care for them, I say always provision your introducing-cage in some way, so that the Queen is not dependent upon the bees for her food while in the cage.

Even when keeping Queens in the queen-nursery, where placed in queenless colonies, I find that the bees often refuse to feed them; so I now provision all cages of all kinds, notwithstanding the claim put forth by some of our best bee-keepers, that several caged fertile Queens will be fed by a colony having a laying Queen, if they are put between the combs in a hive having such, for safe keeping. Finding a whole queen-nursery full of dead Queens, after trusting them to the care of a colony of bees having a laying Queen, is generally more convincing than many words given in support of an untruthful theory.

But to return: Fit the cage so that it comes over three or four square inches of honey, and as much of the hatching brood as possible; for these hatching bees have much to do with the speedy introduction of the Queen. Having all fixed, leaved the hive from 12 to 48 hours, according as your other work will allow you, when the hive is to be opened, and the cage examined.

If all has worked as it usually does, the bees will be found spread out evenly over the cage, the same as they are on any of the rest of the combs. When such is the case, the cage is to be carefully lifted from over the Queen, letting her and the young bees that have hatched during her confinement, go where they please, keeping watch all the while to see that the bees treat her kindly; if they do this (as they will, nineteen times out of twenty), the comb is to be placed in the hive; if not, she is caged again. In from one-half to one hour after liberating her, look at the Queen again, and if she is now treated as their old Queen was before her removal, the hive is closed, and she is considered safely introduced.

If, on the contrary, the bees are found clustered thickly on the cage, biting the wire-cloth and showing signs of anger, the frame is to be placed back in the hive and left till the next day, when, if they still show the same symptoms, you must wait until they are scattered over the cage, as spoken of at first, before letting her out.

I often release a Queen in 12 hours, and find that she is all right; and I rarely have to wait to let her out, more than 24 hours. Still, in extreme cases, I have been obliged to keep them caged nearly or quite ten days.

Do not be afraid of the Queen dying in the cage; for if she is placed over honey, as I have advised, she will live a month, and there is no need of losing any Queen if there is not too much haste used, in letting her out. Even then, there should be no danger, if the apiarist is on hand to release the Queen from the bees which cluster (or ball) her, as they always do a Queen for sometime before they kill her. Such clustered Queens can easily be relcased, by smoking the bees till they free her.

In liberating a Queen from a "ball" of infuriated bees, she is liable to take wing and fly away, thus losing her in that way. To guard against this, I either clip her wings before trying to introduce her, or take the "ball" of bees into a room while smoking them apart. Again, there is some danger that after the Queen is free, a bee from the cluster will sting her, if this bee gets to the Queen singly; and for this reason, I always secure the Queen in a wire-cloth cage as soon as the last bee has let go of her.

If the bees of any hive have once clustered a Queen, I find that it is very hard work to get them to accept the same one afterward; for this reason, I generally take a Queen that has been clustered, to some other hive and introduce

her there, giving the infuriated colony another Queen or a queen-cell.

However, not one Queen in one hundred is treated in this way when using the above plan, for, as a rule, I find that the young bees that have hatched in the cage with her, have accepted this Queen as their mother; thus the news is conveyed from them to the rest of the bees in the hive, so that she is fed by "all hands," which causes her to keep the cells enclosed by the cage, from which the young bees have hatched, well supplied with eggs.

* * * * * * *

The advantage that this plan has over any other where the Queen is to be caged in the hive, is in the young bees hatching out in the cage with the Queen; and as they have known no other mother, they accept her at once, thus forming an escort which the older bees, sooner or later, are obliged to accept, as being a part and pareel of the colony.

By any of the above plans, there is very little danger of losing a Queen, yet none of them are absolutely safe; nor would I use them were I to receive a very valuable Queen, say one worth $10, for with such Queens we do not wish to take a particle of risk.

After studying on the method of forming nuclei by the "caged bees" plan, as I gave in the chapter on that subject, I saw that by using that process, I had an absolutely safe plan of introducing a laying Queen, even were she worth $100. I have used this plan with all the valuable Queens for several years, and have not lost a single Queen, nor do I believe that I ever shall lose one by it, unless she should happen to fly away in putting her in the box with the bees; nor will she do this, as long as I clip all of my Queens' wings.

My usual method of using this plan, is to get bees enough from the upper stories of different hives to form a good, strong colony, doing it just the same as I gave in the chapter on forming nuclei, only I take the bees out of four or five different hives, and off from 10 to 15 combs, according to the strength that I want the colony. After having the bees in the box, they are treated just the same as there described, giving them the valuable Queen, in the same way that the Virgin Queen was given.

In hiving them, give as many empty combs, or combs of honey, as you choose, but do not give any more brood at this time than you did to the nucleus; for if more brood is given, the bees sometimes will swarm out with the Queen in a few days, where made so strong, the same as a natural swarm. If you desire to give brood, do it by giving a frame or two at one time every few days, after waiting four or five days from the time of hiving, before giving the first frames.

If you do not have bees in upper stories having a queen-excluder under them, then go to two or three colonies in ordinary hives, look for the Queens, and as fast as they are found, put the frames that they are on, outside of the hives. Now smoke and jar the bees on two or three frames from each hive, till they fill themselves with honey, when you are to shake as many bees down through the funnel into the box, as you want in your colony, and proceed as before.

If you desire to introduce the Queen to a certain colony, (the same as we have been doing by the other plans given), kill or take away the old Queen, and cause the bees to fill themselves with honey, the same as in the last instance; when all the bees that you can get, are to be shaken off the combs through the funnel into the box.

Having all of the bees in the box that you can possibly obtain, treat them the same as before, until you are ready to hive them. After they are placed in the cellar or other cool place, take all of the combs having brood in them, and give them to the other colonies, leaving one or two frames of honey in the hive, to hold till night, the bees which you did not succeed in getting into the box, and those returning from the fields. These combs should be put in the centre of the hive, so that when night comes the bees will be mostly clustered on them, instead of about the side of the hive, as would be the case if they were left next to one side of the hive. When you hive the bees having the new Queen with them, take these two combs with the bees out of the hive, putting in other combs as before, using only one having a little brood in it, and that taken from another hive, so that they are not given their own brood.

Having all prepared, proceed to hive the bees as was done with the nucleus; or, if preferred, the bees can be shaken down at the entrance, for, as this is their old home, they can go nowhere else, even should they try to do so. After the larger part of the bees are in the hive, shake the bees off from the two combs, and let them run in with the others. In five days, commence to give the brood back again, and keep on doing so occasionally until all is back in the hive, as it was before.

The above I believe to be an infallible plan for introducing Queens, and well pays for the time and trouble, when we have a very valuable Queen coming from a distance, which we would not lose on any account; yet it will hardly pay to spend so much time on ordinary Queens, except by way of experiment, or when desiring to make new colonies in addition to introducing Queens. Where a Queen comes to me very unexpectedly, I always use this plan, taking the bees from an upper story or two, thus forming a small colony with the Queen, which colony is built up later on, by giving frames of hatching brood. Using it in this way, it always gives me the assurance of success, in any case of emergency.

He then gives directions for introducing "Virgin Queens"—and shows how to "Keep a Record of the Cells, Queens," etc. The last four chapters are devoted to "Clipping the Queen's Wings"—"Shipping, Queen-Cages, Bee-Candy," etc.—"The Injury done to Queens in Shipping"—"Quality of Bees and Color of Queens"—and advising the rearing of Queens for the pleasure as well as profit it gives. The book is intensely interesting, and ends with these paragraphs:

Another point right here (and one which I consider worth much more to any one, than the price of this book; even though he may keep only two colonies of bees), and that is: If you desire to supersede any Queen in your yard, on account of her being too old to be of farther use; or if she is of another race of bees from what you desire; all you have to do is to put on an upper story, with a queen-excluding honey-board under it, place a frame of brood with a queen-cell upon it, in this upper story, and after the young Queen has hatched, withdraw the queen-excluder, and your old Queen is superseded without your even having to find her, or having the least bit of time wasted to the colony.

In fact, the possibilities which this perforated-metal may bring, have only just begun to loom up before us, so that what the future may bring forth in this matter can hardly be conceived by any. Truly, our pursuit is one of the most fascinating of any of those that are engaged in by man; and I am thankful to Him who ruleth all things, that I have a part and a lot in this matter.

That all who read this book may try to carry out the thoughts herein advanced, to still greater perfection, and strive in the future to rear only Queens of superior value, so that we may soon be able to say,

"THE COMING BEE IS HERE,"

is the best wish of the author.

The book is now ready, and will be mailed to any address for $1.00. All orders should be sent direct to this office.

CORRESPONDENCE.

NECTAR.

The Gathering of Honey and Pollen by Bees.

Written for the American Bee Journal
BY CHAS. DADANT.

In answer to the wishes of Prof. Cook, expressed in his article on page 217, I give here some remarks on the above subject.

Bees are attracted to the nectar by its odor, mainly. Then, after having unloaded their honey-sacs in the hives, they use their eyes to find more quickly and more surely their way back to the spot where they had completed their last load, and continue, on the same kind of flowers, as long as they find something in them to take.

I have noticed the bees of a colony gathering a kind of honey, while the bees of another colony, placed near by, gathered at the same time, honey different in color and savor.

I have seen Italian bees, exclusively, working on red clover; while black bees, exclusively so, worked on buckwheat.

Some of our colonies had dark honey-dew in their hives, while others had only white-clover honey; some had fruit-juice, while others had dark honey from the fall blossoms.

As the same kinds of some flowers vary a little, bees are soon accustomed to visit their diversely-tinted varieties. For instance, a bee will go from a purely-white head of clover to another which is rose-colored; for there are hardly two plants of white clover whose flowers have exactly the same tint.

Having watched bees working on a patch of differently-colored blue-bottles, I saw one bee stick to the white variety and pass by the other colors without paying any attention to them; while another bee visited, one after another, the white, the blue, the purple, etc. I noticed the same when watching bees on the asters, the knot-weeds, etc.

There is, consequently, no wonder to see bees visiting several kinds of apple-trees during the same trip. This reminds me of something unusual that I noticed in France long ago. There was an apple-tree loaded with apples, very similar to the kind known here as "Bellflower." Some of the apples, instead of being entirely white, had ribs, like muskmelons, colored in gray. Not far from it was another tree of a variety known in France as "Gray Reinette." No doubt the bees of an apiary placed in the same orchard had brought the pollen of the gray apple to the flowers of the white, and the fecundation had not remained confined to the seed alone, but had extended through the pulp to the part of the skin corresponding to the heterogeneously-fecundated kernel.

When the crop of honey is scarce, bees visit all kinds of nectar-yielding flowers, passing from one to another, without seeming to mind the difference. But we do not think that they act the same when they are in quest of pollen, if we notice the regular color of the lumps that they bring to the hives.

How the Toads Eat.

In reply to Mr. Hovis in regard to toads eating bees, on page 216, I would say that, although the toad eats small insects, its mouth is very large. To get its prey it does not act like the ant-eaters, whose heads are elongated, and which thrust their tongues—that are coated with a viscid saliva—among the ants, and retract them in their narrow mouths.

As soon as an insect is within the reach of the toad, its tongue is thrown out by a kind of springing motion, the back part of it forward, and returned as quick as lightning; as the tongue is coated with a viscid substance, the lightest contact suffices. This motion is so quick that it is about impossible to notice it, except by the swift opening of the mouth, and the smack which is heard when the tongue jumps back and the mouth shuts up.

Hamilton, Ills.

IN COUNCIL.

Report of the N. E. Ohio, N. Pa. and S. W. N. Y. Convention.

The Northeastern Ohio, Northern Pennsylvania, and Southwestern New York Beekeeper's Association met at Franklin, Pa., on January 30, 1889, at 2 p.m., with President D. H. Lefever in the chair.

Secretary C. H. Coon, of New Lyme, O., called the roll, and the treasurer, George Spitler, of Mosiertown, Pa., read his report after the secretary's report was read.

The President's address, in a humorous and semi-serious vein, came next. H. M. Erwin, editor of the Franklin *News*, made the address of welcome in behalf of the executive committee and the citizens of Franklin. The address was impromptu, and those who listened to it were highly pleased. The response was by M. E. Mason, of Andover, O.

Some time was given for the enrollment of names and paying of annual dues, after which the first question on the programme was discussed as follows, viz.:

"The Best Method of Disposing of First Swarms, when Increase is not Desired."

Mr. Mason said that as his whole aim was to get the most honey possible, he had tried to find some method by which increase could be prevented as much as possible; for bees will swarm. By his method, bees are allowed to swarm naturally, yet with little increase of colonies. They first swarm in an empty hive, and he hives them in the usual manner on from six to eight frames filled with comb, or foundation, using division-boards to contract the brood-chamber. Then put the next swarm into the hive from which the first swarm issued. The third swarm is put into the hive from which the second swarm issued, and so on. By this method he had large colonies—a thing so desirable and necessary to secure comb honey, and yet the bees' propensity to swarm is satisfied.

Mr. Reynolds hived his swarms in hives from which swarms issued the previous day, or in hives whose colonies are queenless; puts sections for surplus honey in the hive in about 12 hours, if he has lots of comb in the brood-nest; if not, he waits a day or two. He said that he had no trouble from bees swarming out, unless a swarm had issued from a hive three or four days; in such cases he would destroy the queen-cells previous to putting in the swarms.

Mr. Pettis, of Lake, Pa., related the experience of a neighbor who made it pay to have increase of swarms; he sold his swarms at from $3 to $7 each. If he had too many he sometimes made a sale, and generally secured good prices.

D. W. Burnett, New Vernon, Pa., has had no reason to prevent increase of swarms, for he has ready sale for his bees at $6 a colony, in a simple body of the hive, which he thinks pays him for all trouble.

Consumption of Winter Stores.

A member said that he could see but little difference in out-door or cellar-wintering in the consumption of stores.

Mr. Sutton thought that out-door wintering was best, because the bees have opportunity for cleansing flights—a thing very desirable. They will also breed sooner.

Mr. Reynolds had at one time 12 colonies—six of them he put into a cellar (a dry one), and six were packed in straw on the summer stands. Those out-doors came through all right, and built up rapidly in the spring; those in the cellar came through the winter, but he lost all of them in the spring by dwindling.

C. H. Coon packs part of his bees out-doors, and part in the cellar. Those out-doors are quiet, while those in the cellar seemed to be very uneasy the past winter; there are many of them coming out of the hives; the hives are damp, though the cellar is dry. He has oil-cloth on top of the frames. His cellar was well ventilated. He loses his bees after putting them out in the spring. Last spring he kept the bees in the cellar very late, and they did well.

Mr. Mason said that the average cellar was not the right place to winter bees. The temperature ought to be kept at 40° to 45°. He does not believe it advisable to carry bees out of the cellar to give them a cleansing flight. He has always been more successful by out-door wintering.

Mr. Lefever thinks that the want of proper stores is the cause of more failures than any other method of wintering. He has had much trouble from stores gathered at cider-mills by the bees. He related how a friend put outside combs to the inside or center of the hives, and the center combs to the outside of the hives, with good results. Another neighbor had cut a bee-tree, and, the combs being badly smashed,

the honey was fed to the bees, and all died. The See brothers, of Geneva, he said, had good results in wintering bees on fire-weed honey.

Mr. Coon spoke of disastrous results from too much extracting, and would not extract any honey from the brood-nest—in fact he did not use the extractor at all, only in extracting for others, except to extract from unfilled sections. He extracted for a neighbor who laid his loss of bees to cellar-wintering; but he believed it to be caused from taking all the good honey from the bees. He would advise saving the good combs for wintering.

Mr. McLean and Mr. Sutton found buckwheat honey very good for wintering bees.

An expression was taken as to which was best for wintering, an extra large colony, or a medium one; the vote was unanimous in favor of the medium colony for good results in wintering.

Mr. Sutton said that feeding broken combs to bees would start brood-rearing, which, if late in the fall, would be apt to bring on disaster, because the young bees were too weak for wintering.

"How would you dispose of second swarms?"

Mr. Sutton—Place a bush tied to a pole near the cluster; they will settle on it, and you can lean it up against something; then take the queen-cells all out of the hive and put the swarm back where it came from, unless more colonies are wanted; if so, hive it in a new hive.

Mr. Lefever said that if it was a choice colony, crowd it by stimulation so that it will swarm early. Old colonies could be divided and queen-cells inserted.

"How late did you ever have a swarm issue and live?"

Mr. Green had one come on August 17, and it did well.

Mr. Mason had one come on September 17, and it gathered honey enough to live on until spring.

The general opinion was that late and second swarms were not desirable, because the clusters would be too small to winter successfully. The convention then adjourned until evening.

WEDNESDAY EVENING.

The first question for the evening was: "Is the catching of swarms in traps, at the entrance of hives, as they issue, a success?"

M. E. Mason said that it was a success with him. The box is made of thin stuff and is 24 inches long, 14 inches wide, and 10 inches deep. The top of the box is made of wire-cloth. A connection made of tin extends from the lower edge of the box, as wide as the hive-entrance; the box is placed at the hive just as the swarm commences to come out. The swarm must be allowed to remain in the box a short time,—long enough to become quiet, or the bees will take wing again when let out of the box. The bees are emptied out by a three-inch door, the length of the box.

A few present had used the Alley queen and drone trap successfully.

"Is it advisable to have hives stand in the shade?" was next discussed.

J. H. Haggerty, of Polk, Pa., likes the shade from 9 o'clock to 3 p.m. He will have grape-vines for shade in the near future.

Mr. Coon was troubled several times by bees swarming out. Sometimes several swarms were in the air at the same time. He shaded them with a shade-board, and raised up the hives about one-half inch, and had no more trouble. He now ventilates the hives by raising the cover a little.

Mr. McLean would have temporary shade. He had his bees in an orchard, and noticed that those in the dense shade did not do so well as those in the sun. The bees need much sun when working on white clover.

"What is the best method of preparing bees for winter?"

Mr. Haggerty first wintered his bees on ten Langstroth frames, but he now uses from six to seven, and has one on but three frames. His bees are packed tightly, with only a hole in the bottom-board covered with wire-cloth, for ventilation; he uses a few frames because he used too many at first,—and there was too much honey. He has chaff on top, too, and closes the entrances of his hives, but opens them on warm days to give the bees a flight. Too many bees are lost in the snow, if the entrances are left open.

Mr. Sutton said if success is desired in wintering bees, they must be prepared early in the fall. If they need feeding, feed early. He prefers the jelly-glass feeder—an atmospheric feeder, and makes a syrup of 25 pounds of sugar and 10 pounds of water. Last fall the buckwheat was cut off early, so he had to feed; he prefers feeding sugar to feeding good comb honey, because it is cheaper; but best of all, have frames filled with honey.

Mr. Wilson had sugar to crystallize for him; but crystallization can be prevented by using a little glycerine in the syrup.

Mr. Mason said that he had more trouble in "springing" than in wintering bees. The first good day in spring he takes out all the frames that the bees cannot cover, closes up the frames with division-boards on each side, and covers with oil-cloth so as to economize heat, which assists in brood-rearing.

Mr. Sutton also uses oil-cloth over his bees in summer.

What must a person do, whose bees need feeding in winter? If bees are in the cellar they might be fed the "Good" candy. If out-doors, let them alone, or feed over the cluster.

Is it advisable to raise the hives from the bottom-boards? If so, how high? Quite a number prefer a slight ventilation at the top of the hive.

Does it do any harm to have the entrance of the hive covered with snow? No; not with upward ventilation.

The convention adjourned until 9:30, Thursday morning.

SECOND DAY.

MORNING SESSION.

The convention was called to order at 9:30 a.m., by President Lefever.

The first question: "Is it profitable to use sections with full sheets of foundation, that were in the hive the previous season, but not drawn out?"

Mr. Sutton did not use full sheets of foundation in the sections,—only starters. He thought that he got a thinner septum by using starters only.

Mr. Mason said that it all depended upon the appearance of the sections; if very badly spotted and covered with propolis, he would not use them; if the sections are clean, and if the foundation is badly eaten at the corners, as it often is, he would cut out the old foundation and put it on the wax-pile, as it is impossible to get honey in nice shape with foundation thus eaten. He would advise all to use full sheets of foundation in the sections, because then you have all worker-comb. If only starters are used in the sections, bees are apt to build drone-comb at the bottom of the starter, which, at swarming-time or before, is very apt to tempt the queen to go into the sections, especially if there is none, or but very little, drone-comb in the brood-nest.

Mr. Lefever referred to bee-keepers who had lost bees in wintering, which he attributed to excessive contraction of the brood-nest at the time of the white-honey harvest. He would not have less than eight frames, so that the bees would have good honey to winter on.

After a lively discussion it was found that the majority rather favored not too large a hive, yet more opposed too much contraction at the time of the honey harvest. The election of officers for the ensuing year was the next business in order, and resulted as follows:

W. A. McLean, of Osborn, Pa., President; H. S Sutton, of Franklin, Pa., first Vice President; George Spitler, of Mosiertown, Pa., Secretary, and R. D. Reynolds, of Cooperstown, Pa., Treasurer. Executive Committee, M. E. Mason, D. H. Lefever, and C. H. Coon.

Cleveland, O., was chosen for the next meeting, at the same date as the meeting of the Ohio State Beekeepers' Association.

"What is the best method of extracting wax from old combs?" was asked.

Mr. Sutton puts broken-up combs into burlap sacks, which are then put into a wash-boiler, or large kettle; when melted, he presses it out as best he can by using sticks to press it with.

Some use the Swiss wax-extractor. Different methods were given, but none seemed to be perfectly satisfactory with old combs. There was no trouble with new combs. Be cautious, and do not boil the wax.

The convention then adjourned until 1 p.m.

AFTERNOON SESSION.

The first question was: "What other business is best suited to go with bee-keeping?"

Mr. McLean thought that fish-culture would go well with bee-keeping if a person was rightly situated.

Mr. Lake has fish, bees and chickens, but they all need attending to at the right time, if success is desired.

Mr. Lefever said that poultry will help, and he believes that winter dairying will pay the best of anything in connection with bee-keeping, if a person has

good, succulent food, such as ensilage, roots, etc.

Mr. Green follows milk-dairying, and delivers milk to customers in Greenville. He makes the two go well together.

Mr. Coon keeps sheep, and made it pay well by raising early spring lambs for market.

"How do you remove propolis?"

Mr. Sutton uses fine sand, and also Seneca or lamp oil. Alcohol is good.

"How would you build up colonies in the spring, in time for the honey-flow?" Work for honey, but not for swarms, and do not divide the colonies.

"How soon after the swarm issues, ought the sections to be put on?" Put them on in about twelve hours, if you have the hives full of combs, or frames filled with foundation.

"How soon in the spring should upward ventilation be stopped, to promote brood-rearing?" The weight of opinion was in favor of a very slight upward ventilation by absorbents, such as chaff, leaves, saw-dust, etc. On the first nice day in the spring, put on oil-cloth, and cover again with absorbents.

After unanimously passing appropriate resolutions, the convention adjourned.

FEEDING.

The First Pollen Gathered for the Season.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

Bees gathered their first pollen on March 15, amid general rejoicing. It is meet that they should rejoice, with the first new bread of the season, after living on canned goods so long. This new, fresh diet will impart new life to the denizens of the hive, and they will awake from their drowsy slumbers, and no more "folding of their hands to sleep." Spring-time has come, and "the voice of the turtle is heard in the land;" the elms are flowering, and yielding pale-yellow pollen, and catkins are appearing on the willows, which will soon yield honey and bread. All Nature rejoices, and the "Old Man of the Woods" arouses from his slumbers and shakes the snow from his mantle.

The queen, being fed so generously by her subjects, will commence her arduous labors of rearing a large family. It is to be hoped that she will not be too ambitious, and lay more eggs than the bees can hover. To-day (March 18) is quite cool and chilly, and the bees will contract the cluster, to keep warm, and if in doing so the larvæ are unprotected, they must perish. I remonstrated against our bees being removed from the cellar during the warm days—although they were loud in their demands for a flight—fearing that the weather might change to cold, and that the cellar bees might be attacked with a spell of "spring dwindling;" while those that had passed the winter upon the summer stands would not be affected by it, being more hardy from exposure. Therefore fresh air was admitted more freely into the cellar, and their loud demonstrations ceased, and only their quiet, happy hum was to be heard.

Spring Feeding of Bees.

I will take back all I ever said about stimulative feeding in early spring. Localities may differ in this respect, as in many other things, but I am convinced, by repeated trials, that it is a decided injury here. It excites bees to activity, and they will fly out in inclement weather, in search of water and mineral salts, and perish, and their death prove a serious loss to the colony, at a time when their services were most needed. More young bees may be reared, but at a time when their services are not worth so much to the commonwealth as the old ones are.

Feeding rye-meal, ground-oats, pea-flour, or unbolted wheat-flour in early spring, as a substitute for pollen, is advocated by many, the food being placed in shallow boxes, in sunny nooks protected from winds. This may be well in some localities, but here the pollen appears almost as soon as it is safe for bees to fly, as the overflow from the river draws out the frost from the roots of trees before it is out on the highlands.

Some bee-keepers report bushels of food appropriated by bees, but, where there are so many mills and flour-stores, they prefer to fly from home in quest of it. I have seen those white bees entering hives in early spring, but, as soon as pollen appears, there will be no more dusty millers seen.

Peoria, Ills.

PRIORITY.

The Legality of Priority of Location.

Written for the American Bee Journal

BY J. E. POND.

I should give no further time to discussing the above question, did I not think that in justice to myself a brief reply to Mr. S. T. Pettit's article, on page 217, should be made.

In stating my position as I have since the discussion first began, I have taken none but a legal view of the matter; sentiment has been entirely ignored, as it has nothing to do with a question of legal rights. I may feel that any competitor, no matter what the business, might have let me remain untroubled in my chosen locality; but what am I to do about it, if he keeps within the law?

I have asked time and time again, for those who view the question as does Mr. Pettit, to give some plan or method by which the evil, as he deems it, may be remedied; as yet, none is offered, but instead thereof, I am asked how I would like it myself to have my own field occupied? Well, now, to what more is the bee-keeper legally entitled, as a matter of legal rights, than "the butcher, the baker, the candle-stick-maker," etc., whether the same be sentimental or practical? Till this question is answered differently from what Mr. Pettit will answer it himself, or until he or some other will devise some plan by which human rights can be legally ignored, I must assert, and try to maintain whenever called upon to do so, that the sole question is just that simple that Mr. Pettit criticises, viz.: Can any one who chooses, keep bees upon his own land?

One reason for making the question thus simple is, that if I am met with the idea that the keeping of bees may constitute a nuisance, my answer at once is, what is a nuisance in myself in keeping bees must also be a nuisance on the part of my neighbor; and does not, therefore, form any factor in the original problem.

I have no doubt that Mr. Pettit feels as he writes, and I can only ask him the question (which his article confessedly admits has but one answer), viz.: If another man does plant an apiary on his own land, in such a way that it may interfere with your rights, what are you going to do about it? or how can you legally prevent it? And again, what legal remedy can you advise in the matter? Again, doesn't Mr. Pettit rather beg the question, not only in the whole article, but when he says that he thinks that I will agree with him that the man ought to have located elsewhere?

I have not written the above with a desire to cause a discussion, but to endeavor to show that I have not "hastily reached a decision;" and to ask any who think that I have, to show wherein I am in error.

Gathering Honey and Pollen.

My observation generally has shown me that Nature, as a rule, makes no mistakes; that "like produces like," and that in cross-fertilization, the rule follows as elsewhere. Mrs. Chaddock may have seen bees traveling to different flowers on the same trip, but that does not prove anything, even argumentatively; 'cause why? Because (a woman's reason, I know), that if when she saw bees going to the different flowers, I think that she would have found, on examination, that there was no pollen in them, and as a consequence, no chance of mis-fertilizing.

As for myself, I have experimented in this very matter quite largely, and I have never seen one instance of a bee working on different varieties of flowers on the same trip at any time; and I do not believe that anyone has seen them do so at a time when cross-fertilization was possible. If Mrs. C. has seen this, let her say so, and I will believe her; but simply saying what she has on the subject, does not affect the question at all; for the reason, that the rule is not broken, unless the conditions are not right for breaking.

I do not advocate at all the wonderful second sight that some claim for bees, but I am an advocate of the doctrine that "Nature makes no mistakes;" and the mere fact that bees have been seen to visit different varieties of flowers on the same trip, is not necessarily even the exception that proves the rule.

North Attleboro, Mass.

Month of April.

Written for Vick's Magazine

BY MRS. M. J. SMITH.

Patter, patter, patter,
Hear her feet on yonder hill;
Coming, coming, coming,
How the little branches thrill,
Singing, singing, singing,
Wakening every tiny rill;
Listen, sister, listen,
Cease your shriekiog, March, be still.

Almost swelled to bursting,
Holding scents to woo the bee,
With a gladsome knowledge
Of the bloom we cannot see,
Little buds are peeping
Upward, outward, just to be
First to let this maiden
Kiss, and set the petals free.

Poets call her fickle,
In the far-off days of yore;
Poets call her changeful,
And they sit beside our door;
But I call her constant,
Ever bearing plenteous store,
At the time appointed
Entering the humblest door.

Were our friends as changeless,
Were our lovers just as true,
If the thoughts we scatter
Fell like April's morning dew,
Clear as crystal, giving
To some cold heart impulse new,
Morrow's dawn would open
The millenium to view.

CANADA.

Report of the Brant Bee-Keepers' Convention.

Written for the American Bee Journal

BY R. F. HOLTERMANN.

The Brant Bee-Keepers' Association met at Brantford, Ont., on March 30, 1889, at 2 p.m., with President Howell in the chair.

The steps necessary to retain affiliation with the Ontario Bee-Keepers' Association were taken, the members for the Ontario being as follows: G. H. Morris, S. A. Dickie, R. J. Howell, Thos. Murray, Thos. Birkett, and G. W. Barber, with Representatives D. Anguish and R. F. Holtermann. An invitation was received to meet at Harley, Ont., at the next quarterly meeting, which was accepted.

It was decided that if the Grant would allow, to give toward the prize-list at Brantford and Harley, for honey and bee-keepers' supplies. The prize-list was then made up, which will amount to over $60.00 for Brantford. A list of names for judges was made out, and the Secretary instructed to correspond with those selected.

Results of Wintering, Etc.

President Howell reported that he had lost 4 colonies out of 32; two of them had starved outright, and several he knew were too light in the fall.

Mr. Ramey stated that he had packed chaff around his hives, about 6 inches thick, and the colonies were all alive and doing well.

This question was asked: If a colony is divided, will the one left without a queen build its own queen-cell? Answer: Yes; if brood three days from the laying of the eggs is given them, or eggs. It was, however, suggested by one, that it would not be advisable to divide colonies.

Mr. Birkett said that he generally put all second-swarms back, and had but little trouble.

D. Anguish reported that his bees were all alive, yet he put 4 colonies out ten days ago; 3 of these had consumed 10 pounds of stores each. The temperature was about 48° above zero.

T. Birkett keeps his bees in the cellar, and 3 colonies died (starved) out of 56. The cellar was dry, and too warm to keep potatoes in. The bees were very quiet.

Mr. Barber put 103 colonies away—35 outside and the balance in the cellar. One colony was starved, and the balance he thought were alive. The present temperature of his cellar was 45°; but generally it was 42° to 43°.

Mr. Murray winters his bees outdoors, in a shed facing the south. The hives are chaff-packed all around except at the front, so as to expose them to the sun. He uses a shade-board at times, and leaves the entrance open 2 inches wide. One colony has perished out of 18, caused by an undeveloped queen. There were drones late in the fall.

C. Edmonson put 4 colonies away in the fall, in saw-dust packed hives; 1 colony has starved.

W. R. Brown put away 12 colonies; 1 perished and the balance are dry and nice.

W. Morris wintered his bees outside, in clamps. He put in 12 colonies, and all are doing nicely.

J. McIntyre wintered 4 colonies, and they appear to be doing nicely.

Stimulative Feeding.

"Does it pay to stimulate brood-rearing by feeding in the spring?" was asked. T. Birkett said: Give bees plenty of food all at once, then let them alone. All present appeared to agree with Mr. Birkett.

Brantford, Ont.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at Tarbell House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The Darke County Union Bee-Keepers' Society will hold their spring meeting in the court-house at Greenville, O., on Friday, April 26, 1889.
J. A. ROE, *Sec.*

☞ The 11th annual session of the Texas State Bee-Keepers' Association will be held in the apiary of W. R. Graham, of Greenville, Hunt Co., Tex., on May 1 and 2, 1889. All bee-keepers are invited. The last meeting was held here last May, and was the best ever held. So we look forward to a good time next May. A cordial welcome and hospitality will be tendered to all who come. G. A. WILSON, *Sec.*

☞ The semi-annual meeting and basket picnic of the Progressive Bee-Keepers' Association will be held at "Welcome Apiary"—the residence of Mr. J. B. Hains—in Bedford, O., on Thursday, May 2, 1889. All interested are invited to come early and bring their friends. A special invitation is extended to the ladies to be present. Manufacturers of bee-keepers' supplies are requested to bring with them, or send, samples for exhibition. Let all come prepared to do their part towards making it an interesting, as well as a profitable, meeting.
MISS DEMA BENNETT, *Sec.*

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
April 26.—	Darke County and Union, at Greenville, O. J. A. Roe, Sec., Union City, Ind.
May 1, 2.—	Texas State, at Greenville, Tex. G. A. Wilson, Sec., McKinney, Tex.
May 2.—	Progressive, at Bedford, O. Miss Dema Bennett, Sec., Bedford, O.
May 4.—	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
May 15.—	York and Cumberland, at Waterboro, Me. C. W. Costellow, Sec., Waterboro, Me.
May 21.—	Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.
Dec. 4, 6.—	International, at Brantford, Ont., Canada. R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Oranges in Florida.—W. S. Hart, Hawk's Park, Fla., on April 15, 1889, writes:

It looks pretty bad for Florida orange-growers, according to "The Eastern Markets" item on page 179, doesn't it? Let me say that our oranges dropped badly the past season, have been delayed on the way to the north, and many have arrived in bad condition; but the prices have averaged well, and still continue to do so. Nearly all of my crop went to Boston, and $3.50 per box was the lowest price obtained, with $4.50 for "fancies." There are fortunes in such prices, or half as much. It was the dropped oranges that rotted here.

Ventilation of Bee-Repositories.—H. B. Sisson, Ottumwa, Iowa, on April 15, writes:

As a constant reader of the principal bee-papers of the country, and as the ventilation of the winter quarters of bees has been my hobby for the last 25 years, I can also state that I too know a little about the subject, as I have wintered from 150 to 200 colonies year after year with only a loss of from 3 to 5 per cent. Dr. Miller states in his article, on page 231, that he knows a little about ventilation, yet he gives the reader no information in regard to his method. Oxygen is necessary to the life of the bee, and to remove the poisonous gases is the question that I have settled, and have given my methods to the public heretofore.

Signs of a Good Honey Crop.—Rev. Stephen Roese, Maiden Rock, Wis., on April 19, 1889, writes:

Of the 84 colonies that I put into the bee-house last fall, I took out, on March 19, 82 alive; but 4 were queenless, judging from there being no brood in the hives, and they united at their first flight with a colony having a laying queen, and 3 more have, since the cold spell, dwindled away, which I united with other weak colonies. The weather is fine but cool, and the bees do not feel like venturing far home; consequently close watch must be kept, so that robber-bees will not get into some weak colonies. The maple and elm buds have opened, and pollen is coming in during the midday hours very fast. With the exception of 3 or 4 colonies, my bees are all in good condition, and I consider them a month ahead, judging from last season at this time. We have all the signs of a good honey crop this season.

Good Honey Season Expected.—J. K. Rich, Cato, N. Y., on April 16, writes:

I took my bees from the cellar to-day, and found them in good condition. I wintered 28 colonies in the cellar, and 12 on the summer stands; I lost one of the latter for want of stores. I have 12 colonies of Italians, and 4 of Carniolans, and the balance are blacks. I am very much pleased with the Carniolans. The prospects are that we will have a good honey season here. The white clover looks well, and we had no ice-storms the past winter to injure the baswood; I shall look for a large yield of the latter.

Three Poor Seasons.—Lewis Schnerr, Turnpike, Pa., on April 6, 1889, says:

I am a boy 12 years old. My father has 50 colonies of bees, and we have to feed them now. For the last three years it has not paid to put the sections on and off, as there has been no honey.

Toad-Stools for Smoker Fuel.—H. M. Seeley, Harford, Pa., writes:

I notice on page 230 that none who answer queries use the same bee-smoker fuel that I use. I have tried many kinds, and the best for me is the toad-stools growing on old maple and birch stumps and logs. They will not go out until they burn out, and they give all the smoke necessary—for me, at least.

Early Drones—Good Prospects.—John E. Turner, Woodington, O., on April 9, 1889, writes:

The weather is very mild here this week, and the bees are just "boiling over." Mine began to gather pollen from sawdust on March 14, but on the 15th they began to work on the maples. They are all very strong, and are breeding very rapidly. I have a colony of black bees that has a lot of drone-brood capped over. It is quite early for drones to be hatching now! The white and Alsike clovers are in good condition here, and the prospects for a good season are flattering.

Alsike and White Clovers.—Chas. K. Bixler, Hoyt, Iowa, on April 12, 1889, writes:

Bees in this vicinity have wintered exceedingly well. My 36 colonies wintered without loss. The first pollen was gathered about March 15, from soft maples. Now cottonwood and elm are yeilding an abundance of pollen. In the last week we have had plenty of rain. White and Alsike clovers are in splendid condition, so the prospects are good for a splendid honey-year; but we will have to wait, for the hopes of to-day may be soon blasted.

White Clover Looks Promising—Chester G. Ridout, Hutchinson, Minn., on April 13, 1889, writes:

The weather here is exceedingly fine for this time of the year. We have had no rain to mention this spring, and the grasses and clovers are greatly in need of a heavy shower. I took my 12 colonies of bees from the cellar and placed them on the stands last Friday (April 5), and found all strong and healthy; with but one exception they had plenty of sealed brood and eggs. The one having no eggs or brood was short of stores, and I was obliged to give it 4 frames of sealed honey. With a little feeding, however, I think it will build up for white clover, which at present looks very promising. I find that if a little tobacco is mixed with the fuel when put in the bee-smoker, the crossest bees can be handled with comparative safety.

Wintered in Fine Condition.—S. M. Kelley, Kirby, Wis., on April 10, 1889, says:

I took 22 colonies of bees from the cellar on April 6, in fine condition. To-day they are very active, bringing in pollen from the skunk-cabbage and pussy-willow, which is abundant in this vicinity.

Bees Wintered Well.—J. B. Dunlap, Rochester, Ind., on April 10, 1889, says:

My bees have wintered quite well, and, have been very busy for nearly a month. I wintered some colonies in the cellar, and had 3 on the summer stands. I had 4 colonies on the summer stand, but I lost one of them.

Early Pollen-Gathering, etc.—M. R. Cullison, M. D., Adel, Iowa, on April 15, 1889, says:

Last fall I prepared 44 colonies of bees for an extra hard winter, and as a consequence they got too warm, bubbled over, and 12 colonies are left to tell the tale! Should the weather prophets be extinguished? or only the few, that continue to take just a little stock in their predictions?

Wintered Extremely Well.—C. A. Goodell, Mankato, Minn., on April 8, 1889, writes:

I put 17 colonies of bees into the cellar and I put 17 out this spring, all very strong excepting 1, and that is all right now. The first pollen was gathered by the bees here on March 19—earliest I ever saw it gathered in Minnesota. The weather has been very bad for the last 10 or 12 days for the bees; it is raining some while I am writing—the first rain this spring. The bees have wintered extremely well in this locality.

Populous Enough to Swarm.—S. D. Haskin, of Waterville, Minn., on April 12, 1889, says:

I never have had bees booming so in the spring. They worked almost every day since March 1. Some are populous enough to swarm, and keep up their happy hum all night, though it often freezes quite hard. A Mr. Kenny, here, makes sorghum molasses so pure that the bees will take it quite freely.

Cellar-Wintering Theory.—W. A. Hodge, Victory, Wis., on April 12, 1889, writes:

I have been watching the cellar-wintering plan for a number of years, and I am fully satisfied that the cellar is *the* place to winter bees, provided that it is a good dry one, and so arranged as to be ventilated when necessary. Now for some of the proof: I put into my cellar, last fall, 43 heavy colonies of bees, and this spring I have taken out 43 colonies nearly as heavy as when I put them in. My neighbor, only a short way from me, has a good, dry cellar, into which he put about 50 colonies, and he has taken out every one of them in good condition.

Bees in Good Condition.—Geo. Spitler, Mosiertown, Pa., on April 9, 1889, writes:

I overhauled the bees, yesterday, that I have packed out-doors, and I found them all in good condition. I have lost but one good colony out of 23. The bees carried in pollen at a lively rate; none are queenless, and there is lots of brood. I have some colonies in the cellar that are all quiet, except one. I will carry them out after the next rain, which is coming soon. White clover is in good condition. I have heard of but few losses of colonies.

Neglected Bees May Starve.—Christian Weckesser, Marshallville, Ohio, on April 15, 1889, writes:

We have just had quite a spell of cool weather, and the bees have not been able to do much, but generally they are in good condition, though care must be exercised to keep them supplied with stores till clover comes, which promises to be good. No doubt bees that are neglected will starve before then, if they do not get more, accordingly, than they have thus far. This will not be very harmful, however, driving, as it does, the careless out of the "field."

Swarms Expected Soon.—John Boerstler, Vashon, Wash. Ter., on April 13, 1889, writes:

Bees are doing well, and will swarm soon—the drones are flying already. I think that we will have a good honey harvest this year. My hybrids are doing the best, I think. I believe they will be ahead of my Italians. They are the largest hybrids that I ever saw. I have just received some Chapman honey-plant seed from the department of agriculture, at Washington, D. C. I will give it a good trial this year. We have had summer weather all along. Fruit looks well.

Loss of Weight in Winter.—O. B. Barrows, Marshalltown, Iowa, on April 15, 1889, writes:

On page 220, Mrs. L. C. Axtell says: "The bees apparently have not consumed as much honey as is usual in winter." Of 35 colonies, carefully weighed on putting them into the cellar, and weighed again after taking them out, the smallest loss was 5¼ pounds, and the greatest loss was 22 pounds, the average being 12½ pounds. There was no perceptible difference in loss between those put in on November 8, and those put in on November 19; but perhaps there was not difference enough in time to be any test of Dr. Mason's new departure.

Prospects of a Good Season.—E. F. Quigley, Unionville, Mo., on April 13, 1889, writes:

The following is the report of the condition of bees in this (Putnam) county, so far as heard from: 98 per cent. have wintered well, and 5 per cent. were queenless. Nearly all the bees in this county are in box-hives. The first pollen gathered was on March 15. The weather is a little colder now. Bees wintered in my apiary as follows: Carniolans, 1st best; pure Italians, 2d; hybrids, 3d, and blacks 4th best. No amount of warm weather would induce the Carniolans to come out. They used less honey than any others, and are the strongest of any now. White clover is in fine condition, and the prospects are good for a large honey yield for 1889. My 1888 honey crop was 40 pounds per colony of comb honey.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00...	
and Gleanings in Bee-Culture	2 00....	1 75
Bee-Keepers' Guide	1 50....	1 40
Bee-Keepers' Review	1 50....	1 40
The Apiculturist	1 75....	1 65
Bee-Keepers' Advance	1 50....	1 40
Canadian Bee Journal	2 00....	1 80
Canadian Honey Producer	1 40....	1 30
The 8 above-named papers..	5 65....	5 00
and Langstroth Revised (Dadant)	3 00....	2 75
Cook's Manual (**old edition**)	2 25....	2 00

Root's A B C of Bee-Culture	2 25....	2 10
Farmer's Account Book	4 00....	2 20
Western World Guide	1 50....	1 30
Heddon's book, "Success,"	1 50..	1 40
A Year Among the Bees	1 75....	1 50
Convention Hand-Book	1 50....	1 30
Weekly Inter-Ocean	2 00....	1 75
How to Propagate Fruit	1 50....	1 25
History of National Society	1 50....	1 25

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

What Apiarists Say about the April number of the ILLUSTRATED HOME JOURNAL, which they have just received, may be ascertained by the following which are samples of the multitude:

Prof. A. J. Cook, Agricultural College, Michigan, writes thus: "The Illustrated Home Journal, is at the very head in style, typography, and everything that pertains to the printer's art, and no wonder, for T. G. Newman is its publisher. The initial number surely promises a genuine success, if success is possible in this day of severe competition. We wish the enterprise a full measure of prosperity."

P. H. Elwood, Starkville, N. Y.: "The April number of the Illustrated Home Journal came a few days ago, and it seems to be a general favorite in the family circle. I have no doubt it will be a grand success."

J. W. Vance, M. D., Madison, Wis., writes thus: "We are very much pleased with the Illustrated Home Journal, and wish it abundant success."

Frank A. Eaton, Bluffton, O., writes thus: "I am delighted with the Illustrated Home Journal; its contents are choice literature, and it is filled with fine instruction, which makes it true to name. Its typography and quality of paper are the best. I shall carefully preserve Volume IV, commencing with the April number, and have it bound."

Mrs. L. C. Axtell, Roseville, Ill., writes thus: "The Illustrated Home Journal is received, and I have read the greater portion of it through, and find it a magazine of much better tone than the most of our home and fireside reading; in fact I am well pleased with it, and wish you success."

The Rev. M. L. Williston, Chicago, Ills., writes: "The Illustrated Home Journal has come, and I admire this Centennial number greatly. You have made a rich issue of it."

G. W. Demaree, Christiansburg, Ky., says: "As a magazine for the family, the Illustrated Home Journal cannot help being a pleasing visitor in the families, wherever it goes. I have seen nothing of the kind in our family that is so pleasing as your Illustrated Home Journal."

H. H. Brown, Light Street, Pa., writes thus: "I received the Illustrated Home Journal for April a few days ago. It is a magazine that should be found in the homes of all who desire a paper that gives instruction, and its articles are of such a nature that they cannot help but please all who read its pages."

C. H. Dibbern, Milan, Ill., thus writes: "The first number of the Illustrated Home Journal was duly received. I have now had time to look it over, and form some opinion of the character of the work. Coming all unannounced, it is certainly a very agreeable surprise to us all. The style of printing, and the character of its contents, are first-class. The Illustrated Home Journal will no doubt take its place speedily among the leading journals of the day, and do what it can to make the world better and happier."

G. K. Hubbard, Fort Wayne, Ind., writes as follows: The Illustrated Home Journal was duly received, and shows that it has been through the hands of skilled workmen, from its general make-up. The editor evidently has a correct idea of the PURE and ENTERTAINING class of reading which should be placed in our homes. I wish you abundant success.

Never did the advent of a magazine for the family touch such a responsive chord, or receive such a hearty welcome.

Trial subscriptions will be taken 3 months for 40 cents each; or it will be clubbed with the BEE JOURNAL for a year at $2.00 for both. Agents, who are working for premiums, may take "trial subscriptions," and count 4 as one yearly subscriber. One sample copy sent free to subscribers of the BEE JOURNAL, upon application. That will tell you all about the "Premiums" offered for getting up clubs, and "Cash Prizes" for the largest clubs sent in before Sept. 30, 1889. "Good pay for good work" is our motto. See page 238.

Honey and Beeswax Market.

HONEY.—White 1-lbs., 15@16c.; fall or dark, 12@14c. Extracted, 8c. for white. Supply large and demand light.
BEESWAX.—None in market.
Apr. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX,—22c. R. A. BURNETT,
Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.
BEESWAX.—21c. for prime.
Mar. 25. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.
BEESWAX.—Scarce, at 18@22c.
SCHACHT, LEMCKE & STEINER,
Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Quantity of honey in the market is sure to be entirely closed out before new crop comes.
Apr. 8. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.
BEESWAX.—22@23c.
Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.
Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Damand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

Convention Notices.

☞ The second meeting of the York and Cumberland Bee-Keepers' Association will be held in the Good Templar Hall, at South Waterboro, Maine, on May 15, 1889, at 9:30 a.m. A cordial invitation is extended to all. Matters of interest will be discussed. Bring your hive or some useful implement for exhibition. Hotel accommodations may be had in the village at reasonable rates. C. W. COSTELLOW, *Sec.*

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

EDITOR.

Vol. XXV. May 4, 1889. No. 18.

EDITORIAL BUZZINGS.

Shadows.—John Andrews, of Patten's Mills, N. Y., sends the following poetic gem :

When darkness spreads its shade around,
And Hope is shadowed by a fear,
And Fear sits trembling with a tear
Upon its cheek, is wan, and sear,
An anxious wish, or thought, or prayer,
Is breathed in silence everywhere.

The British Bee Journal is to be reduced to one dollar a year, after July 1. It will be mailed to America for $1.50 a year.

We are Sorry to learn that Mrs. Cowan, wife of the editor of the *British Bee Journal*, is again very ill, at Lausanne, Switzerland.

In Smith & Smith's advertisement in Nos. 14 and 16, the offer of smoothing irons was incorrectly stated. Please read the advertisement as corrected on page 285 of this issue.

In Kentucky, Mr. J. T. Wilson writes us that bees are doing finely. He says : "My nursery is in operation. The ground is covered with white clover. The locusts will bloom heavily. The weather is warm and dry."

Winter Packing should be removed and not allowed to remain around the hives in the summer. This is in answer to a question coming from one of our subscribers in Indiana. There are many reasons why it should not "remain all summer." It will keep the hives too cool, and retard brood-rearing. It causes dampness, and is generally disagreeable both to the bees and to the apiarist.

A Good Honey Season is universally expected as well as desired. As *hope* is made up of both expectation and desire—we may correctly announce it as **"the hope"** of all bee-keepers, at the present time.

In the *Western Plowman* for May, just at hand, Mr. C. H. Dibbern expresses himself thus :

As predicted last fall, bees have generally wintered well. The honey gathered during the autumn was excellent for winter stores, and the mild winter has dealt very gently with the bees. I wintered all my colonies (about 175) in the cellar, and I do not think the loss will be over 2 per cent. They are still well provided with honey, which will last till they can get plenty in the fields. The clover has also wintered exceptionally well, so that we may confidently count on a good honey season.

Further on he gives the following as his opinion about the crop :

The season seems to be much earlier than last year, and although it is now but the middle of March, spring seems to be here to stay. Our bees are now all out of the cellar, fully a month earlier than last year. All of them have come out alive, something that has not happened for many years. They are also in exceptionally good condition. From what we can learn from the bee-papers, bees, both in and out doors, have wintered well.

The conditions are all very favorable toward a good honey crop, and bee-keepers should leave no stone unturned to secure their share when it comes. We cannot secure a share of the crop if we are not ready or the bees are not ready. We want the best bees, best hives, and best systems of management known to the most advanced bee-keepers. Then we need not worry about competition. What if some box-hive man produces a few pounds of honey and sells it cheap, that will not put a low price on our white sections filled with still whiter honey.

I commenced bee-keeping 23 years ago by buying one colony in a Langstroth hive, and have had bees ever since. Most of my bees are descendants of that original colony. I do not think that a year has passed that I did not learn something valuable about bees. I still find that there is a great deal to learn.

Mr. J. M. Hambaugh, of Spring, Ills., thus wrote us on April 22, 1889 :

I never saw brighter prospects for a honey harvest, both as regards the clover crop and condition of the bees numerically. I will be putting on surplus arrangements in a few days, for the hives, large Quinby (*a la* Dadant) and ten-frame Simplicity, are *boiling over.*

The Invention of what is known as the "Good" candy was referred to on page 179. The *British Bee Journal* stated that it was the invention of Mr. Scholtz. We requested Mr. I. R. Good to "tell us about" it. He has not done so. Now Bro. T. W. Cowan writes us from Switzerland about it, and gives us the positive proof that it was the invention of Mr. Scholtz. In his "Guide Book," Mr. Cowan mentions it as Scholtz' candy, and in Dadant's Revised Langstroth, on page 321, it is distinctly stated that both are one and the same thing. So there is another laurel for our German brethren. We are glad to make public these facts.

David Ross, of Esbon, Kans., wants to know if we were aware that "Lizzie Cotton" was a man. He sends us the *American Stockman* where the statement is made. Oh, yes, we have published that statement several times, and probably that is where the *Stockman* got its intelligence from. The gender would be no detriment, if the actions were square and right. Of course we do not approve of sailing under false colors. Open, true, honest, square and honorable work will pay every time.

Mr. Ross adds this about his bees : "My bees are doing nicely this spring. There is capped drone-brood in many of the hives."

Judge Richie's Address before the Farmers' Institute at Bluffton, O., was a very fine effort. We give an extract from it in this issue of the BEE JOURNAL. He is an eminent lawyer, and has just taken his seat on the Common Pleas Bench of that District. He is also a practical bee-keeper, having 30 or 40 colonies, which, however, are more for pleasure than profit. His Italian bees are very fine. The Judge will assist the pursuit whenever it is in his power to do so—and help to defend it against ignorance and prejudice.

Young Queens are important to every colony of bees. In ordering Doolittle's new book, Mr. J. D. Goodrich, of East Hardwick, Vt., thus expresses himself on this subject : "Please send me one of the books just as early as possible, for I wish to try the method this season. I believe in young and good queens every time. In looking over my bees, in the spring, I almost invariably find that the best colonies have young queens, and are the ones to winter the best."

Swarming is Nature's provision for the perpetuation of the race of bees. W. S. Withey, of Milford, N. H., asks : "What is the best way to keep bees from swarming ?" They cannot be kept from swarming as long as they feel crowded, and have a desire to seek more room by emigrating from the old hive. It can often be retarded, however, by giving them more room—or the colony can be divided, and thus accomplish the same thing in another way, as if they had swarmed.

Catalogues for 1889 are on our desk from—

A. G. Hill, Kendallville, Ind.—32 pages—Bee-Keepers' Supplies and Bees.

J. L. Flint, Marion, Iowa—1 page—Fowls.

H. H. Brown, Light Street, Pa.—20 pages—Bees and Bee-Keepers' Supplies.

Arbor Days.—April 26 is Arbor day for Minnesota ; April 24 is Arbor day for North, and May 2 for South Dakota. These days should be generally observed ; a day cannot be devoted to a better service. Villages, schools, neighborhoods and families should unite in making Arbor days memorable.—*Exchange.*

GLEANS OF NEWS.

That a Bee Dies soon after losing its sting, has been very confidently and repeatedly asserted. In fact, it has been considered a "settled fact," and so it has been reiterated without question. Now it appears that Mr. Doolittle has been making an investigation in that line as well as in queen-rearing. The results of experiments are thus stated by him in the *Rural Home* for last week:

A correspondent wishes to know whether a bee can live and do work after it has stung a person, leaving its sting; or if it dies, as is generally believed by many persons who keep bees. Up to within the past ten years nearly all believed that a bee which had stung any one must surely die, for in leaving the sting, as the honey-bee nearly always does in stinging an animal, a part of the intestines was supposed to be left with the sting, poison-sac, etc., from which it was argued that the bee could not live.

This seemed so reasonable that I formerly believed that the idea which prevailed was true, till one day after a bee had stung me, leaving its sting, it came to attack me again and again, with all the fury and vengeance possible for a bee to work itself up to, getting in my hair and singing away as only an angry bee can sing, which will make the cold chills run up and down the back of the most hardened individual. As this bee apparently had no thought of dying, it was caught and caged with two or three others, and kept a week or so to see what would become of the matter. At the end of the week it was apparently just as lively and healthy as any of the rest, when all the bees were set at liberty.

At another time, when putting up queens to send away—in catching the escort-bees which were to go with the queen, one of them stung me on the end of my finger, leaving its sting, when it immediately ran into the cage. As I did not wish to remove all of the bees and queen, to get it out, I let it go, soon after which the thought came to me that here would be a chance to test the theory of the death of the bee from losing its sting, as the queen was going to Texas, which journey would require from eight to ten days time. Accordingly I wrote to the party to whom they were sent, telling him all about the matter, and asking him to take notice particularly when the queen arrived to see if there were any dead bees in the cage.

In due time he replied that the queen arrived in splendid condition, and that there was not a dead bee in the cage.

Several times since then I have tried similar ways to see if such bees as had lost their stings were in any way inconvenienced thereby, and as far as I can tell, by means of confining them, so as to know that I have the same bee, I can see no difference between such bees and those which have their stings, as to length of life.

Whether they gather honey or not, or whether they are allowed to live in the hive without their weapon of defense is something which would be next, if not quite, impossible to tell, for in this case we have no means of keeping track of an individual bee.

As bees are not tolerated in the hive, which are in any way imperfect, it might not be unreasonable to suppose that the perfect ones might drive off such an one which had lost its sting, as being incapable of defense, were the hive attacked.

That it was not the design of nature for the bee to always lose its sting when defending its hive, is manifest where bees repel robbers to the extent of hundreds and thousands of slaughtered ones, when in such cases not one bee in one thousand loses its sting, but keeps it so that it can slaughter bee after bee till the attacking party is repelled, or they lose their lives in the combat. At times they do lose their stings in other bees, but not often.

Mistakes are made by everybody at sometime in their lives—for there are none "perfect." Mr. C. D. Duvall, of Maryland, writes of many mistakes made by bee-keepers, in the Maryland *Farmer*, in this language:

As Josh Billings says, "Eggsperience is a good skule, but the tuition is purty hi," but if we are careful and observing, we need not pay so dear for all our experience, but profit by the experience of others. This is not only true in bee-keeping, but in any other business.

One of the first, and a very common mistake beginners are liable to make, is in commencing with the wrong hive. I made this mistake and paid pretty dearly for it, too.

The first hive I bought was a "patent hive," that was no more fit to keep bees in than a nail-keg.

The second style of hive I bought was a decided improvement over the first, but with many faults and imperfections, but being inexperienced, I did not find this out until after I had made up a large supply.

The third style of hive I bought was the Simplicity-Langstroth hive, and it was the first practical hive I ever used, and it is the hive I am now using. Never make the mistake of buying or using hives except those that take some of "the standard frames."

I made a mistake in thinking I could make more money by rearing queens for sale, instead of honey-production.

I made a mistake in thinking that I could depend entirely on my bees for support, exclusive of any other business, by having several apiaries located at different places, but after buying out several bee-keepers' entire stock and fixtures, and running three apiaries for one year, I found it a very costly experiment, as I now have about twice the number of hives that I use, that I am getting no profit from.

It is a great mistake to keep too many bees; in this section of country one person should not keep over 75 colonies, and a small number will give a much better profit, and if properly cared for will prove as profitable as anything on the farm; but right here is where a great mistake is liable to occur, by wanting to increase too rapidly. In some sections of the country a large number of bees can be kept profitably, but not in Maryland, as the honey crop is too uncertain.

It is a great mistake to be too eager to increase the number of colonies, for the novice is almost sure to make a corresponding mistake by being disappointed, and becoming discouraged, and giving up the business before he has given it a fair trial. Better commence in a small way and let the colonies increase with your experience.

Japanese Buckwheat.—A Kern county (California) farmer who has been experimenting with Japanese buckwheat, reports that in all respects it is far superior to the American buckwheat. It produces twice the number of pounds to the acre, makes remarkably fine cakes, can be sown at any time, and he thinks will prove far more profitable than wheat to the farmers of California, if they can be induced to make a trial of it. It is also a good honey-producer.

Apiary of Walter Harmer.

The illustration on this page presents a view of the apiary of Mr. Walter Harmer, of Manistee, Mich., together with his small-fruit garden and poultry-yard, of which he has sent us a description, reading as follows :

Seven years ago my brother and I bought two acres of land in the suburbs of the city, and which was not fenced or cultivated, but covered with stumps and logs. The view looks south, away from the city, and the enclosure shows about two-thirds of one of the two acres mentioned above. All the buildings in sight (but two) have been built lately. The picture was taken by my brother last August, from the top of the fence on Eighth street, which runs east and west—west to Lake Michigan about 1¼ miles.

My apiary is on the left, as will be seen. Mr. A. I. Root, when on a visit here in the winter of 1887-88, pronounced my 38 colonies of bees in excellent condition. I believe that his words were, "I never saw bees in nicer condition in a cellar." They wintered well, but the following August (the time this picture was taken) found my apiary dwindled down to 18 colonies. I had sold only one that spring, but the season was the coldest and latest that I ever knew. In the fall I doubled 2 colonies back, making 16, which are in good condition to-day —April 3. I can sympathize with those bee-keepers who secured no increase and very little honey last season.

It will be seen that there are 40 8-frame Heddon-Langstroth hives out, for I had empty hives placed for the increase (that did not come), and are all sloping toward, and facing the east, but set with a spirit level, crosswise. They are painted red, white and blue, and were put out as follows : One red, one white, one blue ; one white, one red, one white, etc., one-half of them being white.

When I was putting the hives out in the spring, I thought, "What a nice name, 'Red, White and Blue' would be for an apiary ;" and in a day or two afterwards I was handed a card with the name, "The Red, White and Blue Apiary ;" and also on it the name of Geo. E. Hilton. Of course I gave up the idea of using that name, but I like it just as much, and I know that Mr. Hilton is capable of doing justice to any thing, or name, that he adopts.

I keep a brick on each hive, which helps to insure the bees against damage by wind.

Next will be seen a strawberry-patch, which I intend planting to raspberries, for I find that they pay me better in connection with poultry and bees, than do the strawberries.

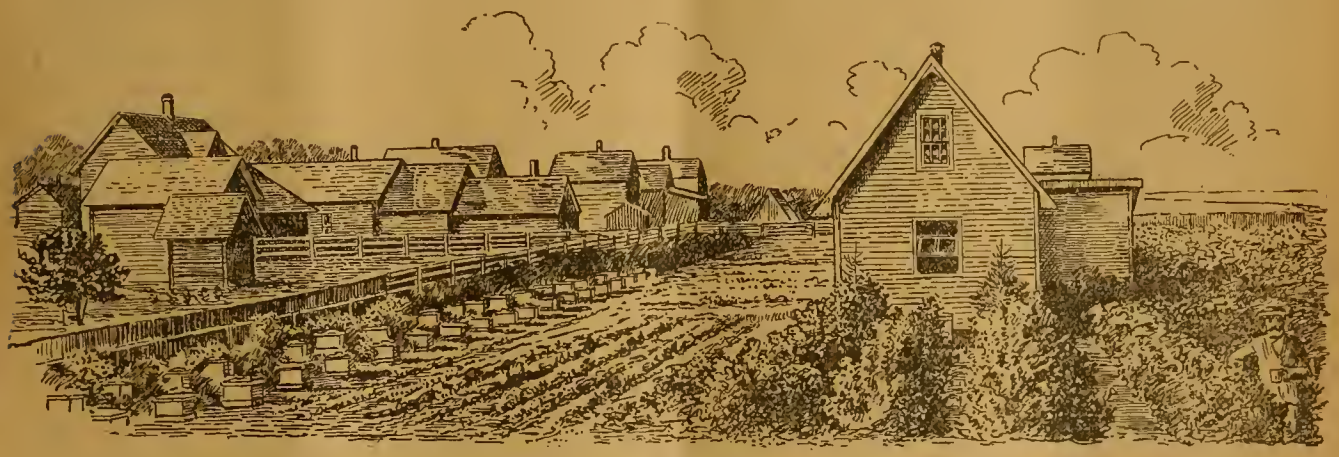
The three rows of bushes directly in front of the house are currants, the rows being about 90 feet long, and yielded 252 quarts of fruit last season. If what experience I have had is worth anything, I can strongly recommend the growing of currants, as well as raspberries, in connection with the keeping of bees and poultry. Every season's work seems to throw light in the direction of showing the numerous advantages in connecting these three branches of industry.

The bee-house, as I call it, is 12x24 feet, and the cellar will hold 100 colonies. The first floor consists of two rooms, one 8x12 feet, for a honey-room, or for anything to be kept from dust ; the rest is a work-shop, store-house, etc. The upstairs part gives a great deal of room for storing everything not in use at certain times of the year ; there is plenty of room to walk upright in it, the roof being steep ; and the rafters and roof-boards are dressed smooth, so it will be seen that this part of the building is exceedingly useful.

The windows work on a pivot in the centre, which makes them very convenient for letting out bees. There is a Root chaff-hive standing under the window, between the two balsam-trees. There was a great deal of ripe fruit on the bushes when the view was taken, and the writer is supposed to be busy gathering it, but in reality he is having his picture taken.

The little building at the rear of the bee-house is in size 13x20 feet, and will accommodate about 30 head of poultry; the main building is 23x50 feet, (not shown in the picture, being on the right hand side) and will accommodate 150 head more, which I think is enough to have on one acre. I have about one-fifth of the ground in grass, where the poultry must be contented for a week or two, while the fruit is being gathered.

I am rather discouraged in this locality for bee-keeping—my chosen pursuit. I can always get a good crop of fruit and eggs, as I have a sprinkler in connection with the City Water Works ; but for the production of honey we want a more genial climate, where a cold wind is not likely to blow from the large Northern Lakes (like Lake Michigan) for nine months in the year.



Apiary of Mr. Walter Harmer.

The Rev. Robert Collyer has given to Cornell University the factory bell which called him to work at 6 a. m. and sped him home at 8 p.m., when between 1831 and 1838, he was a factory operative in Fewston, Yorkshire, England. In his letter to President Adams, he says : "It will be pleasant to think of it as born again, converted and regenerate, now while the ages of Cornell endure, calling people to nobler occupations, and so much more welcome —a sweet bell, I hope ; not jangled out of tune and harsh."

QUERIES & REPLIES.

Amount of Stores Bees Consume in Winter.

Written for the American Bee Journal

Query 628.—During mild winters, will bees consume more stores than in cold winters?—New York.

Not so much.—J. M. HAMBAUGH.

Yes, sir!—WILL M. BARNUM.

Not in this State.—G. M. DOOLITTLE.

No; less, other things being equal.—R. L. TAYLOR.

It depends upon circumstances.—C. C. MILLER.

Usually, no; occasionally, yes.—J. M. SHUCK.

They will, in this climate (Georgia).—J. P. H. BROWN.

I can tell better in April, after weighing.—H. D. CUTTING.

Yes, if they fly every few days. Not in cellars.—C. H. DIBBERN.

Not unless they breed extraordinarily. Bees, without brood, consume most in cold weather.—DADANT & SON.

No, No! No!! Now some one will arise and dispute this; but still I say, No.—MRS. L. HARRISON.

Yes, if wintered on the summer stands. No, if in the cellar, when the temperature is kept right.—MAHALA B. CHADDOCK.

No, it is the excessive consumption of stores and long confinement that has caused the great mortality during the cold winters.—G. L. TINKER.

That will depend upon how mild, and how cold. The warmer it is, if not so warm as to disturb their "quiescent" condition, the less stores they will consume.—A. B. MASON.

Sometimes they will, and sometimes not. There are so many other factors to consider, that this question cannot be answered, yes or no.—J. E. POND.

If out-of-doors, I believe they would. If in-doors, in a proper temperature, I do not see why it should make any difference.—EUGENE SECOR.

No. The colder the winter, the more food is required. My observation teaches me that there is a decided difference in favor of a mild winter.—M. MAHIN.

Yes, if more active. It all depends upon the activity of the bees. Bees may be irritated and active in the cellar. They are in mine, when the temperature gets below 35°,F.—A. J. COOK

In the climate of Kentucky, where I am located, they do not, unless they commence to breed earlier, on account of the mildness of the winter and forwardness of the spring, in which case the stores are profitably consumed.—G. W. DEMAREE.

Much depends upon their quietude, and whether the bees are wintered in the cellar or on the summer stands. The question cannot be answered in one word.—THE EDITOR.

The Terms When Keeping Bees on Shares.

Written for the American Bee Journal

Query 629.—1. I have some bees out on shares, and I furnish all the Langstroth hives, sections, crates, etc. I am to receive one-half of the honey and increase of bees, and the other party is to pay for his share of the hives, sections, crates, etc. What is a fair price to value them at? 2. I would like to know the usual terms when putting bees out on shares.—Virginia.

Your terms are all right.—WILL M. BARNUM.

I am not prepared to answer either of the above questions.—M. MAHIN.

1. *Your market* price. 2. I think that you have about the fair and square plan.—A. J. COOK.

1. Whatever they cost. 2. I do not know. But my terms would be, "Keep them at home."—EUGENE SECOR.

1. Whatever can be agreed upon. 2. About as you have given.—G. M. DOOLITTLE.

The "fair price" would depend upon what they originally cost, with the "wear and tear" deducted.—J. P. H. BROWN.

1. You should be able to judge that better than I. 2. The terms vary greatly, but the result is generally dissatisfaction.—H. D. CUTTING.

I give it up, and will let others who have had experience, answer it.—C. H. DIBBERN.

1. What they would cost the party, if he obtained them from a supply dealer. 2. I think that your agreement is about right.—MRS. L. HARRISON.

I would not put them out on shares, and the querist will not do so, after he has once tried it. They should be valued at what they will sell for at the time of invoice.—J. M. SHUCK.

1. Much depends. What would be fair with me, might not be fair with you. 2. I have never put bees out on shares.—J. M. HAMBAUGH.

1. At the usual cost of such goods. 2. The terms stated I believe to be fair to both parties, and are the terms usually given in putting out bees on shares.—G. L. TINKER.

1. If I understand the question, you want to know what he should pay for his share of the hives, sections, crates, etc. Why not value them at their actual cost? 2. They are about as various as the number of cases.—C. C. MILLER.

1. Consult some good price-list issued by some responsible supply dealer; this will enable you to fix a price that will be just and fair. 2. There are too many things "depending," to give a general answer to this part of the query.—G. W. DEMAREE.

1. This question cannot be satisfactorily answered, in my judgment, by any one. 2. Some one must answer who has had experience. I think, however, that it would require years to solve the problem.—J. E. POND.

I do not know that I understand your question. I should suppose they would be valued at the same price as they would had, you not put them out on shares, and that price would depend upon the market in your locality.—R. L. TAYLOR.

1. Just what they are worth, and that depends upon the style of hives, sections, crates, etc.; whether old or new, and how far from where such could be bought, etc. 2. In this locality (Toledo, O.) one furnishes the bees and the hives they are in, and the other takes care of them. Each is to half the expense of extra hives, supers, sections and crates, etc., and each has half of the increase in bees and half the surplus.—A. B. MASON.

1. The value of the hives, sections, crates, etc., should be just what they cost, including freight, if unused. If used, deduct "for wear and tear." 2. Your "terms" are about right, but be sure to have every detail in writing, for the usual outcome of such transactions is dissatisfaction, especially on verbal contracts.—THE EDITOR.

Convention Notices.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at Tarbell House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m.
H. M. SEELEY, *Sec.*

☞ The second meeting of the York and Cumberland Bee-Keepers' Association will be held in the Good Templar Hall, at South Waterboro, Maine, on May 15, 1889, at 9:30 a.m. A cordial invitation is extended to all. Matters of interest will be discussed. Bring your hive or some useful implement for exhibition. Hotel accommodations may be had in the village at reasonable rates. C. W. COSTELLOW, *Sec.*

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

CORRESPONDENCE.

MY SWEETHEART.

Written for the American Bee Journal

BY EUGENE SECOR.

My Love is fair,
With golden hair,
And eyes that shame the heavenly blue;
And I am sure,
If you but knew her,
That you'd admire and love her too.

Her artless smile
Doth oft beguile
The weary hours of toil and care;
And bliss is found
When she's around—
My happy dove, so sweet and fair!

Her hands are small,
And plump withal,
Her feet, as dainty as a flower.
Her perfect nose
No envy shows—
Her talk, refreshing as a shower.

Such teeth of pearl
No other girl
In all the wide, wide world can show;
The breath of June
Is hers, and soon
Its fragrance-laden warmth I'll know.

The bee ne'er sips
From lily lips
A sweeter draught than I from hers.
Her merry laugh
Is better by half
Than any potion the doctor "stirs."

Fond Hope's bright gleam!
A stray sunbeam
To cheer my heart when I am sad!
A happy sprite
To illume the night
Of discontent, and make me glad!

I hope some day,
Some morn in May,
When tulips plight their faith and wed,
That she'll redeem
My fondest dream,
When to Love's willing altar led.

Who is my Love?
My pure, sweet dove
That Tempts the Muse her charms to sing?
Now you'll not tell,
But keep it well?
Her name is—Baby—*our wee thing.*

TRANSFERRING.

How to Transfer, Italianize, and Increase Bees, Etc.

Written for the American Bee Journal

BY DR. C. C. MILLER.

The following letter was sent to me to answer in the AMERICAN BEE JOURNAL:

I have 8 colonies of German bees in box-hives, and have adopted the Iowa tiering-hive. I wish to transfer, Italianize, and increase my colonies, and at the same time secure all the comb honey that I can. I have no practical experience except with bees in box-hives, and wish to know the best time to begin, and how to proceed.—J. B., Missouri.

I am not sure what the "Iowa tiering hive" is, but I suppose that it is some good hive embodying the principles of the Langstroth. The old way to transfer is to cut out the combs about the time of fruit-bloom, and fasten them in the frames. Mr. Hedden has given us the plan of waiting till later, driving out enough bees with the queen to make a good swarm, and then, 21 days later, driving out the balance of the bees. As you want to get all the comb honey possible, and, moreover, have no experience with bees in movable-frame hives, it may not be the best way for you to try to make an entire change to Italians the first season.

About the time that bees begin to swarm, is a good time to operate. If you could hit upon the time *just before* queen-cells were started preparatory to swarming, that might be best. Turn the box-hive upside down, and over it place almost any kind of a box, so arranged that the bees can pass up into it, closing up any holes out of which the bees might fly. No great harm, however, will come from letting a few bees get out, and, indeed, after the driving has fairly commenced, they will not be likely to fly out, even if the opportunity is given.

Now with a stick of wood, hammer with some vigor, for a few minutes on the side of the hive. After waiting a few minutes to let the bees fill themselves, jar the hive again, and continue until most of the bees are in the driving-box, being sure to leave enough to protect the brood left in the old hive.

This driving will probably be done close by the old stand, upon which may be placed the new hive with movable frames partly or wholly filled with foundation.

The bees in the driving-box may now be poured down in front of the new hive, and allowed to run in, and the box-hive placed upon a new stand several feet away. You now have a strong swarm of bees with the old queen in the new hive on the old stand, and this may be counted on for good work on surplus, if the season is favorable.

About ten days later, drive out the bees again, as clean as you can, from the box-hive, in the same way as before. Then cut out the combs of the old hive, and save all those that contain worker-brood—and you will readily distinguish the worker from the drone brood by its smaller size. The worker-brood is also sealed over flatter than the drone-brood, and at this time you will probably find all the brood sealed. Fasten this comb containing brood in the frames, *cutting out all queen-cells*, and the balance of the combs may be melted up, or used as you think best.

If you care to take the trouble, you fasten in the frames all the straight worker-comb to be found, although, if full of honey, it is a mussy job to do anything with it.

Having put these frames into the new hive placed on the stand which the box-hive has occupied for the last ten days, run the bees out of the driving-box into the new hive, and drop among them the Italian queen, as they are running in. This queen you will have obtained in advance, and if you think best to have eight Italian queens, you will probably get what are called "dollar queens"—that is, fertile queens reared from pure Italian mothers, and you run your own risk as to whether they are purely mated.

In this way you have done nothing to lessen your chances for a crop of honey; half your colonies have Italian queens, and the next season, having all movable frames, you will have no great difficulty in Italianizing the rest.

Very likely some who have had more experience in this particular line, may make suggestions as to what may be done to improve the plan that I have here given.

Marengo, Ills.

A LECTURE.

Delivered at the Farmers' Institute at Bluffton, O.

BY JUDGE RICHIE.

I see by the programme that I am expected to talk on bee-culture. I presume that the committee recognizes the fact that every man has his hobby, or as some put it—every man is insane on some subject—when they selected me to talk on bee-culture.

The introduction of the movable comb hive and the Italian honey-bee has made apiculture practical, pleasant, and profitable. The movable hive enabled the operator to ascertain the exact condition of the colony at any time when the temperature will admit of opening the hive.

The Italian bee, unlike either of the native varieties, if not naturally so, has become thoroughly domesticated, and may be handled with ease without disturbing their equanimity or ruffling their temper. Not unfrequently have I taken a comb from a hive in which the queen was depositing eggs, and so little were they disturbed that the queen kept on laying while the comb was outside the hive, and the bees seemed not to be disturbed in the least in their labor.

* * * * * *

There is that in bee-keeping which should make it attractive, aside from the profit derived from its pursuit. Who can watch without interest the little pilgrims as they go forth in quest

of honey to store away for their successors to winter upon, long after they have died from exhaustion, or become food for the rapacious spider?

How strange the sight, when the old queen and almost the entire colony, without any apparent regret, leave the old home with all its stores of honey; its young, a part of which are but just cradled, and a portion wrapped in their night blankets, to sleep until they are old enough to take their place in the colony as nurse-bees, and go forth to form a new colony in a new home, with no capital save the energy of the army of little workers.

How strange that these little insects should know just how to build their combs, of just the shape which science has demonstrated affords the most room, while it affords the greatest possible strength, and with a mathematical precision that is unsurpassed by human skill; that they should know when it is necessary to rear a young queen, the kind of food that should be furnished for her full development, and how much room she must have to grow in! And a hundred curious things you see by studying the nature and characteristics or the honey-bee.

The caprice of the little creature is nowhere more fully proved than by the finding of a swarm in the carcass of the lion which Samson killed. Many are the curious freaks of this queer little insect, about the habits and needs of which too little is known. No more interesting subject for the study of the naturalist, especially if his beeship should take a notion to point the investigation, and "sit down" on the investigator.

Primitive bee-keeping was rude in its inception, and barbarous in its prosecution. The poor little insects were housed in a hollow-log or an inverted straw-basket, and left to shift for themselves; and failing to find an abundant store of supplies for the winter, they were doomed, if not to a "lake of fire and brimstone," at least to the fumes of combustion, that the proceeds of their toil might be enjoyed by others, who labored not for it. If the colony escaped the brimstone process, it was left to battle with the frosts of a long, dreary winter, upon the summer stand, unsheltered and uncared for.

Nor was the avarice of man and the severity of winter the only enemies of the little honey-gatherer, for its home was invaded by the bee-moth in summer, and by the rapacious mouse in winter, which burrowed and built its nest within the hive, while it fattened upon the honey and honey-gatherer. But the invasion of the mouse was the result of the grossest carelessness on the part of the bee-keeper, while the ravages of the bee-moth seemed to long baffle the skill and ingenuity of the apiarist.

Scarcely a farmer present who has not seen a "moth-proof" bee-hive, and listened to the lingo of the vender, who knew as much about bee-culture as a Digger Indian does of mental philosophy; and ninety-nine times out of a hundred the "moth-proof" hive was a grand success, for it housed the bees, if you ever got them into it, until the moth could hatch in sufficient numbers to devour both bees and honey.

The bee-moth is a sort of anarchist, and insists upon a division of capital, and is especially opposed to the accumulation of large stores of honey, unless she is let in for her full share; and her wages for a time seemed to permanently endanger profitable bee-culture, as our native bee seems powerless to repel the insidious attacks of this insidious pest.

But the Italian bee, though of foreign extraction (like unto most Americans), seems to have adopted American ideas, and is disposed to, and does, administer summary justice on every intruder of the moth-family upon the apparent motto, "Let no guilty one escape." So that, instead of resorting to any moth-catching process, all you want to insure against the moth-incursions is, a simple common-sense hive, and a vigorous, healthy colony of pure Italian bees.

There seems to be about as much difference in the disposition and intelligence of the different varieties of bees as there is in the different races of men; and of the varieties known here the Italian has the decided preference; although the large gray bee, sometimes called the German bee, is by no means without its very good qualities. But of all the varieties none equal the genuine native black bee. The real little Ethiopian, so inquisitive in its nature, and always at leisure, you have no trouble in becoming acquainted, getting on familiar terms without the formality of an introduction. Ever on the alert, you can scarcely come within ear-shot of a colony of this variety, until you are met by from one to a dozen of the little "darlings," each one so anxious to peep into your eyes, and, embracing the first opportunity, to nestle in your hair.

But attempt to manipulate a hive of this variety, and it is remarkable how quickly they impress you with the conviction that they are true Americans—even if they are a little "off color,"—by their ability to "repel invasions from abroad," while of you they make a second Arnold Winkelried.

Let bee-keeping once become thoroughly understood, and honey will be found on every table—even the sting of the bee will be utilized by our physicians as an antidote for rheumatism—and beeswax will be so abundant that, lacking a better use, it will be converted into "nice white wax," or to some other equally beneficent purpose.

EXPERIMENTS.

Small Loss in Weight—Hibernation and Ventilation.

Written for the American Bee Journal

BY EUGENE SECOR.

It is an old story to tell how the bees have wintered, but as I have tried some (to me) new experiments, it may be interesting to record them.

I began carrying the bees into the cellar on Oct. 19, 1888, and on Nov. 9 I finished the job. They were housed, as usual, in the cellar under the house where we live. Forty-five colonies was the number stored. The weather was beautiful, and continued so till after the holidays—indeed the whole winter was as mild as Texas, and bees could have flown, probably, every week from October until April.

Before cellaring them, I weighed every colony. On April 4, 1889, I began removing them from the cellar, and finished on April 10. I weighed all the colonies as they were taken out. I lost two, which were probably queenless in the fall. The shrinkage for the remainder was from 3 to 20 pounds—average loss, 10 pounds. The average number of days confined was 157.

The cellar was almost too warm, all winter, being difficult to keep the temperature below 50°, Fahr. A 6-inch sub-earth ventilator of common tile has its upper outlet in the bee-room, and its lower about 100 feet from the house, running under ground from 2 to 6 feet deep.

The bees came out in good condition, and it now looks as though I should not lose any in "springing" them. The colony that lost only 3 pounds was so quiet when removed, that the boys said they thought it must be dead, as it had not "waked up" when all the others were basking in the sunshine. To learn the facts, I took off the cover, and found a nice colony elevating their *hinder reminders* just as they do on a frosty morning in the fall, when the cover is suddenly removed. Let me see, who was it that said, "Bees never hibernate?" Perhaps he meant "hardly ever."

Hive-Ventilation in Winter.

Now in regard to ventilation: When taking the bees into the cellar I neglected to remove the entrance-blocks from two or three hives, as is my usual

custom; and in these was a mass of dead, moldy bees, clogging the entrance and obstructing the passage-ways between the combs. In a repository so warm as mine was, it would, unquestionably, be better to have ample ventilation below, at least.

Forest City, Iowa, April 20, 1889.

PREMIUMS.

Illinois State Fair Still Behind the Times.

Written for the Prairie Farmer
BY MRS. L. HARRISON.

The Illinois State Board of Agriculture met in Peoria a short time ago to make arrangements for the coming State Fair. I embraced the opportunity of going before this body to speak a good word for the busy bees.

I was cordially received, especially by Mr. Skeavington, superintendent of farm-products and pantry-stores. He said that it was an industry that ought to be encouraged, but that many members of the board were so interested in horses that they could not see it. He said that one of his neighbors, a sickly woman, was told by her physician that she must exercise in the open air a great deal, so she engaged in bee-culture, and from her small apiary of 25 colonies, one year she realized over $300. It was too late now, however, to make any changes in the premium list, as it was in the hands of the printer, but they would try to do more for us another year.

Mr. Skeavington seemed to think that it was an industry especially adapted to women, as they needed exercise in the open air to keep them in good health, and said his wife was quite interested in it.

One year I wrote to the Secretary of the State Board, complaining of the small favors to bee-keepers, and he said, "It is your own fault. Why don't you come to Springfield, lay in your claims, and represent your interests to the Board while in session?" This is no doubt true, and we should not grumble when we neglect our own interests. I shall do my level best this year to "lobby" for the busy bee, and with what success, time alone will tell. Illinois is far in the rear with her honey exhibits in comparison with some other States, while she is second, if not first, in honey-production. Let us arouse from our lethargy, gird on our armor, and show to the world what the great State of Illinois is capable of producing in choicest sweet. With this end in view, let one and all work with a will, and assist our busy workers in every possible way.

Those who expect to win the blue in the fall, in this State or any other, should be up and doing. If the premium lists are not already in the hands of the printer, see how they read. The premium list for the Illinois State fair of last year reads: "Largest and best display of comb honey, $5.00." Tell it not in Gath, neither in the streets of Askelon, lest the buckeyes, badgers and wolverines of the neighboring States rejoice. The premium should be, rather, on the best honey, *in the best marketable shape*.

Years ago, when the State Fair met at Peoria, the first premium on comb honey was awarded to a large glass vessel of comb honey, that had taken the bees two years to fill; consequently much of it was tough and discolored. I suppose it was given the blue on account of its novelty. Choice comb honey in sections, in the *best marketable shape*, could not be seen, whilst it was in the *foreground*. The first premium on extracted honey was given to a two-quart jar of *strained* honey. The woman who exhibited it, said, "I don't know what makes it look so cloudy; it was nice honey before I strained it through the cloth." In competition with this jar was a gross of Muth's one-pound honey-jars, filled with the choicest white clover honey, tin-foiled and labeled.

Who should be a judge of honey, bees, or supplies? Should he be a breeder of Normans, Holsteins, Essex pigs, South Downs, or of Bronze turkeys, pigeons, dogs or ferrets; or one whose bread and butter depends upon the little busy bee's work? Producers of honey, and dealers in the same, ought to know something of that commodity. A carpenter would be a poor judge of a bee-hive, though he could tell which was made the best.

I have seen hives at fairs which drew large crowds— and their glib exhibitor claimed that they were one of the greatest inventions of the nineteenth century—that an intelligent bee-keeper would not tolerate in his yard; hives with cunning little drawers —and how the glib exhibitor pulled them in and out, showing them to his delighted audience. A bee-keeper would know at first glance that when the hive was occupied with bees, those cute little drawers would be propolized so tightly that no power could get them out, except chopping the hive to pieces.

A judge of bees ought to be some one who has reared winged stock. How would the breeders of horses and cattle like Mrs. Harrison for a judge of their stock? They would soon say that she might be a good judge of babies, bread, pickles, and sauerkraut, but what could she know of the good points of a horse?

WINTERING.

Attending College and to Bees at the Same Time.

Written for the American Bee Journal
BY ALLEN LATHAM.

All the past winter I was intending to write some articles stating some of my ideas on wintering, fall honey, pollen, etc., but I never found the time to do so. Perhaps some one would ask, "How can you attend College and take care of 30 colonies of bees at the same time?" That was a problem which I had to settle, and I believe that I have settled it. I think, by using a non-swarming plan, and a few days out of my college hours, I can run the apiary also, when college is out, by June 20, which enables me to keep the busy colonies straight.

The Wintering Problem.

So many bee-keepers are still speaking about the "wintering problem," but I left that three years ago. It may look presumptuous in me to say that I have mastered the problem, but until I lose a few colonies, I shall still claim to have done so. I settled on a plan of wintering bees four years ago, and I have not lost a colony in wintering since that time. One of my neighbors adopted my plan, and has lost 3 colonies; but each case was one of *starvation*, and so must be ruled out.

Last fall I put my 20 colonies of bees into winter quarters, and left them, to go to my studies. The past week, when I was at home, they were "booming"—not a colony having been lost. I hope, before next fall, to put my method before the eyes of American bee-keepers in other words in the columns of the AMERICAN BEE JOURNAL; and thus let it be tried. I claim that there is no more need of losing bees in the winter, than of losing a horse—nor, indeed, so much need.

Combs Filled with Pollen.

About combs getting filled with pollen: When I began bee-keeping, I used to lament about having the combs filled with pollen; but now, when I find a comb packed with pollen, I say: "Won't that be a fine start for some weak colony next spring?"

The Amount of Winter Stores.

Mr. Pond, on page 250, says that a ten-frame hive is none too large when the colony is expected to store its winter food. In Lancaster, where I keep my bees, asters and golden-rod furnish the winter food for the bees, and at that time of the year, I do not want more than four frames of brood. No colony ought to eat more than 5 pounds

of honey, from the middle of October to the middle of March; and unless a person dislikes to disturb his bees in early spring, 15 pounds furnish a great plenty. I consider one of my colonies well supplied, when it has four frames a little more than half filled.

I am aware that when bees are put on short stores, spring replenishing is necessary. But are all aware of the benefit of spring feeding, where apple-blossom honey is desired?

Two weeks ago I put into each of my hives, two combs well filled with good, thick syrup, made from white sugar. Each hive warmed right up, and began to breed heavily. Apple-trees will be blossoming shortly, and then we will see if the 125 pounds of sugar that I fed, are not returned.

Cambridge, Mass., April 19, 1889.

EVOLUTION.

A Discussion of the Dzierzon Parthenogenesis Theory.

Written for the American Bee Journal

BY J. F. LATHAM.

Dr. C. C. Miller prefaces his strictures on my article on page 168 with an apparent misrepresentation; and seems to relish dealing in irrelevancy throughout his discourse, if I rightly construe it.

Notwithstanding the cautionary remarks of the editor, on page 198, at the close of the Doctor's article, I now would ask indulgence for a few remarks in response. If I am mistaken in regard to misrepresentation, I must acknowledge, with the doctor, that I am not scholar enough to understand his language, unless he surmises that I am hinting at the quality of queens from the egg, and queens from the larvæ. That was not the object of the first sentence in my article; but as my attention has been drawn to it by the doctor, I am more than willing to admit that "some instruction" might emanate therefrom.

With reference to the demure profession of inability to understand what I say; and the further modest desire for an interpretation in "plain English," candor prompts me to admit that I think the Doctor's perch is too elevated for his vision.

In his second paragraph, the Doctor asks, "What are the points in it that we are to know, to enable us to rear better queens?" As he has failed to profit by "instructions," I can only answer candidly, that is what I would like to know! But I *believe* the best queens are reared from the egg, during he swarming impulse, or soon after.

The doctor next takes a "round" with atrophied (food) glands, and parthenogenesis, and asks, "Now are we to understand that Dzierzon is all wrong, and that parthenogenesis, at its present stage of development, is not a very substantial reality?" etc. Yes; the hatching of an egg laid by a virgin queen *is* a reality; but from my diagnostic stand-point, the *substantiality* of the *reality* exists in its procreative value. If the existence of atrophied (food) glands in the queen-bee are conclusive evidence that at one period during the development of her species the requirements of mother and nurse devolved upon her, as specific duties in the perpetuation of her kind; while at the present time, the progeny of an unfecundated queen are represented in what I believe to be useless drones; the relative merits of the former and latter qualifications seem to be too well established to admit a radical response to the Doctor's query.

My experience warrants me in saying that Dzierzon is all right in teaching that the eggs of a virgin queen will hatch, and result in the production of drones only; but at this point in the economy of Nature, so far as I have been able to note, the procreative functions of the queen and progeny terminate, inclusively.

Here I would like to ask, if what is termed Dzierzon's theory, *i. e.*, parthenogenesis, was an original demonstration by Dzierzon. I have reason to think that the Dzierzon theory, so-called, was not original with Dzierzon, from the fact that glimpses of the idea crop out in writings that existed long before the race from which Dzierzon sprung, were known in history.

In his third paragraph, the Doctor again puts in the plea of inability to understand, and unburdens himself of what appears to be a misconstruction. Perhaps I have read the Bible as much as the Doctor, and my faith in the credibility of its teachings may be as genuine as his, also; but I have no recollections of having read a single passage in it in which it is purported that any part was drawn from Acadian and Turanian sources; and this is the first time that I have ever received an intimation that anyone believed, or taught, that the Bible, in specific terms, signifies that any of its contents were drawn from Acadian and Turanian sources. But I cannot comprehend why the records of events, which modern archæological research discloses to have existed in written narrative, ages prior to their compilement into the book of Genesis, should be any less a "direct revelation from God Himself," than after the narrative had been so compiled. If the attributes of the Deity are not omniscient, the idea of revelation, special and specific, might be readily comprehended, and easily reconcilable to the limits of a special providence.

There are many things in the open book of Nature, and signally so, in a colony of bees, when in the enjoyment of health and activity, that should prompt an observing mind to the fact that the visible is but a mirror of the invisible, and that the God of the Universe cannot be contracted to the limits of particularized environments. As the Doctor seems to not agree with me on this point, let us "agree to disagree," and drop the matter.

That there "are men who do not believe in the Bible as a Divine revelation," I have also long known; but from long association and dealing with those men, I am prone to the belief that they fill their place in the world as reputably as, what is termed, the best of those who *do* believe in "Divine revelation;" and would scorn to injure the most hapless of God's creatures, or cheat a fellow bee-keeper in the quality of his supplies—knowingly sell him a colony of bees infected with foul brood, or create a demand on his purse by recommending fallacies in his pursuit.

In his fourth paragraph, the Doctor inquires where those Acadian and Turanian records were, prior to their compilation in the book of Genesis. I am very willing that the Doctor should solve the problem himself, for I entertain no doubts but that he will find the task a pleasant and instructive one.

The last two paragraphs of the Doctor's article hardly merit a passing notice; but as I have no desire to falsify anything, or wound the sensibilities of any one, much less the contributors to, and readers of, the AMERICAN BEE JOURNAL, I will try to meet his asperity as succinctly as I can. In assigning a signification to the word "purported," the Doctor has my free consent to define it as he pleases; but to the candid readers of the BEE JOURNAL I will say, that I used the word only to express explanation, or signification. If my information is correct (and I have no reason to doubt its veracity), there exists in the lately-deciphered literature of the Assyrians, a narrative of the "creation," the Paradise, the flaming sword, the cherubim, the flood, the ark, the Tower of Babel, the dispersion, etc., which is purported, in my same information, to have been translated from the Acadian and Turanian dialects, or languages in which it existed as an epic, and had so existed 2,000 or more years B. C.

From the above date it is quite certain that the narrative of the "creation" was not original with Moses, or the Hebrew race; nor was it made a

part of the book of Genesis until after the Babylonian captivity. Now, Doctor, you have my position, in connection with the word "purported," as plainly as I can give it, and if my comprehension of the "Revealed will of God" does not assimilate with yours, I can see no reason why either of us can be blamed.

I also do not consider the pages of the AMERICAN BEE JOURNAL the proper place for "religious discussions." It was not with the intent to provoke "religious discussion," that my article on page 168 was framed as it is; nor does it contain a single phrase that can be construed with that import. What I drew from the book of Genesis was used to form a connection, of ancient modes of expression, with modern expressions in the teachings of geology, as comprehended in evolution, as I understand it; and if there are any in the ranks of the bee-keepers who cannot comprehend, intelligently, such a connection, but view its consummation with the holy horror of religious "cant," it seems reasonable that others who can should be allowed their privileges.

The expression in the closing sentence of the Doctor's article, viz.—"And when he goes out of his way to lug in to a parenthesis a fling at that which we should hold sacred," etc., looks, if I may be allowed the use of a very inelegant "Yankeeism," a "lee-t-l-e soft;" but if there *are* any in the bee-keeping fraternity, within the limits of the BEE JOURNAL'S circulation, who have been reduced to a state of commiseration by my depravity, I most respectfully solicit their leniency; and, if the Doctor feels that he can so condescend, I think it a duty incumbent upon him to do the same, for going "out of his way to lug into" his article "flings" and delusive allusions, misleading in their import, and absolutely uncalled for.

Cumberland, Me.

[A short reply from Dr. Miller will end this controversy in the BEE JOURNAL. It is uninteresting to the general reader.—ED.]

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 15.—York and Cumberland, at Waterboro, Me.
C. W. Costellow, Sec., Waterboro, Me.

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

Dec. 4, 6.—International, at Brantford, Ont., Canada.
R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bountiful Season Anticipated.—W. J. Cullinan, Kansas City, Mo., on April 15, 1889, says:

The white clover here is in excellent condition, and I anticipate a bountiful season. There are the best prospects for peaches for many years. I expect to go to Quincy, Ills., soon, to take charge of the apiary of the late Mr. C. H. Smith, whose demise was chronicled on page 179.

Horse-Mint Looks Promising.—J. N. Colwick, Norse, Texas, on April 15, 1889, says:

My bees are swarming, having commenced on April 2. I am expecting a good honey-crop, as I see that horse-mint is growing finely, and the crops in general look promising.

Killing off Drones, etc.—C. P. Hehry, Blooming Grove, Tex., on April 18, 1889, writes:

I began bee-keeping in 1888 with 2 colonies, and on examination I found one queenless. This being my first attempt at bee-culture, I was entirely at a loss as to what to do, and so I came very nearly losing the colony. I noticed that the strong colony was continually killing off bees, and I did not understand this—I supposed they were without stores; but I learned later on, that the queenless colony was trying to unite with them. After losing nearly all the weak ones, I learned that if a frame were given to them from the colony that had a queen, supplied with young brood, they would rear a queen. I gave it to them, and they started to work at once, and increased to a thriving colony in a very short time. I have increased my number to 6 colonies, and as it is very early in the season, I may yet have more increase. I have tried dividing colonies for increase and profit, and I find it a satisfactory plan. We do not need to put our bees into cellars in this latitude, as they do well on the summer stands, flying nicely all through early spring. When a lad, I dreaded bee-stings terribly, but now they do not have much effect on my flesh—something like a mosquito bite. A few days ago one of my colonies was killing off drones. I cannot account for it at this season of the year. Will some one please explain it? The AMERICAN BEE JOURNAL is a welcome visitor, and I could hardly do without it.

Results of Wintering.—John H. Guenther, Theresa, Wis., on April 12, 1889, says:

I put 40 colonies into the cellar last fall, and left 12 packed on the summer stands for trial. All except one that was queenless came out of the cellar alive this spring; but of those that were out I lost one colony from diarrhea, and the 11 colonies remaining have no more bees than 6 that came out of the cellar. The first natural pollen was gathered on March 16, and the first honey on April 8 from elm. In order to keep bees quiet for five months in the cellar, the ventilation must be right. Where all upward ventilation is stopped, I cannot keep them quiet. I have quilts on top, and in 48 hours after being put in, the covers will be wet. I have the hive-entrances open the same as in summer. The temperature for five months averaged 46°, and never was lower than 42°. The average loss in weight was 8 pounds per colony.

Producing Comb Honey.—John A. King, Mankato, Minn., writes:

On July 2, 1886, 2 or 3 swarms united, an unsuccessful attempt having been made early in the day to hive them separately. A greater question perhaps has not been offered, than how to work colonies in order to get the greatest amount of comb honey. Shall we tier up 4 or 5 **T** supers, and oblige the bees to go through a queen-excluding honey-board? My opinion would be adverse to this, and I can only tell just what I did do. Basswood had been in bloom a few days, and the rush was on. There were bees to fill over 100 one-pound sections all at once, just as quickly as they would fill 50 sections, provided that they have ample passage-ways to get into them. The hive and surplus arrangement were up to the very wants required. The hive was a full 2-story Doolittle hive, 24 inches long, 13 inches wide below the rabbets, and 10½ inches deep.

Nine brood-frames, including the two thin partitions, formed a square of 14 inches, with 5 inches across each end for surplus. I make a case holding 6 sections for the ends, tiering up 4 cases high. Another case holding 7 sections, and 6 cases being used, will just fill the space over the brood-frames, and between the end cases; 48 section in the ends, horizontal to and above the brood, and 42 sections being directly over the brood-frames. The sections are 5x4⅛x1⅞ inches, 6 of which weigh 7 pounds. Here is a very solid fact: Fifty-six pounds along side of that theoretical view, that bees work best over the brood. But see, the bees slide right and left like a base-ball player to the goal, under the thin partition into the first case, or climb up on the side of the hive and enter the second, third or fourth case, or at the ends of the 6 cases over the brood-frames, thus having access to every section from the ends of the hive. Every section was well finished, and taken off in a pile (105 pounds) just before all the white was changed to yellow at the close of July. I had other colonies with as good results, but they had more time.

Priority Right to Keep Bees.

—J. A. Proctor, M. D., of Union City, Ind., writes:

In his article on page 217, Mr. Pettit seems to think that our Constitution is not right, where it says that all men are born equal, and shall have the right of life, liberty, and the pursuits of happiness. It looks very strange to me, when I hear a man reason so inconsistently. If Mr. P's logic is true, when a man buys a farm and commences to raise corn, cattle, hogs, poultry, no other man should be allowed to come near him, and do the same. The idea of a man who keeps bees, and is making money, and his poor neighbor with his wife and little children must be prohibited from keeping bees that they might have some of their sweets, because the other man was in the business first, and there should be a law to prohibit him! "Oh, consistency, thou art a jewel." Why, it would be a usurpation of the right that our Constitution guaranteed to him! Mr. P's heart goes out in sympathy for the man that first kept bees, and so it must for the man that located the first farm, and first commenced to raise corn and stock. What a tender heart Mr. P. must have, for the prior man! I have read all of the discussions on this subject, but I never saw any foundation for them.

Subscribers who do not receive this paper promptly, will please notify us at once.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

DORÉ ART PORTFOLIO,

PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Honey and Beeswax Market.

HONEY.—We quote: White 1-lbs. 15@16c.; fall or dark, slow at 12c.; 2 lb. California white, 13@14c.; amber 11@12c. Extracted, in 60-lb. cans, 7½@8c; for white, 7@7½c.; for amber, in barrels or kegs, 5@6c. We think that our market will be cleaned up before new honey comes in.

BEESWAX.—18@20c.

Apr. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.

BEESWAX.—22c. for prime.

Apr. 22. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.

BEESWAX.—22c. R. A. BURNETT,

Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.

BEESWAX.—18@20c.

Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.

BEESWAX.—20@22c.

Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.

BEESWAX.—24c.

HILDRETH BROS. & SEGELKEN,

Mar. 25. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½@7 cts.; amber, 5½@6c. Comb, white 1-lbs., 13@14c.; 2-lbs., 10@12c. Demand for extracted is good; for comb, limited. Prospects are not as good for honey as in 1888.

BEESWAX.—Scarce, at 18@22c.

SCHACHT, LEMCKE & STEINER,

Mar. 15. 16 & 18 Drumm St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.

Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.

Apr. 23. BLAKE & RIPLEY, 57 Chatham Street.

DETROIT.

HONEY.—Best white 1-lbs., 15@16c. Sales slow. Extracted, 8@9c. Demand small, prices lower.

BEESWAX.—22@23c.

Mar. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 15@16c.; 2-lbs., 12@31c. Good dark 1-lbs., 12@13c.; 2-lbs., 10@11c.

Mar. 21. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

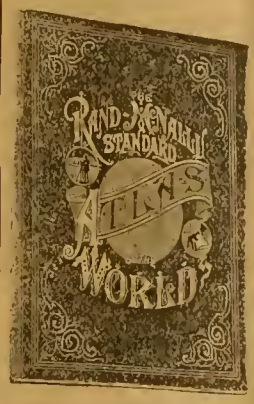
HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:



This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD.
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. May 11, 1889. No. 19.

EDITORIAL BUZZINGS.

Sweet Home.—The most perfect type of "sweet home" is the bee-hive.

The Poultry Weekly is the second title of the *Canadian Bee Journal* in last week's issue. There are two additional leaves (the cover being discarded), and 8 pages are each devoted to bees and poultry. The first page is much improved in appearance. We wish it success.

Vexatious Delays still hold back the trial of the case of Mr. Z. A. Clark, of Arkadelphia, Ark., in the Supreme Court of that State. He writes us that he expects to "get a hearing soon."

Mr. Clark wrote thus on April 27, about his bees:

My bees are doing well here now. They began gathering pollen on Feb. 2; swarmed on the last of March, and now are ready for the extractor.

Good Testimony.—At the meeting of the Erie County Farmers' Institute held at Holland, N. Y., on April 20, 1889, Mr. M. F. Varney, of North Collins, gave an address on "Grape Culture," at the conclusion of which Mr. Hershlser asked him this question: "Do bees injure grapes?" Mr. Varney replied: "I am confident that bees will not touch them, only when the skin is broken."

This testimony from an extensive grape-grower is very important. He positively asserts that the bees do not appropriate the juice of the grape until the skin is broken by birds or insects. That is *grand testimony*, and we commend it to all the grape-growers who have foolishly waged war against the bees.

Statistics of Our Industry.—After more than a year we record the first move on the part of the Department of Agriculture to obtain the promised statistical information—for which we obtained the names of correspondents in March, 1888. We have received a circular like the following, as have (in all probability) each of the persons whose names we sent the Department a year ago:

U. S. DEPARTMENT OF AGRICULTURE.
Washington, D. C., May 1, 1889.

Sir:—At the request of the officers of the National Bee-Keepers' Association, I propose to send out twice each year circulars to prominent bee-keepers in all sections of the country, to obtain accurate statistics of honey-production. Those engaged in this industry are particularly interested in having accurate knowledge of the general condition of apiculture, and early information as to the probable honey supply, in order that they may more intelligently market their individual product. The data obtained by these circulars of inquiry will be consolidated and published in the June and October crop reports of this Department, copies of which will be sent to all persons making returns. The present inquiries relate only to the general condition of the industry, but those in October will relate to comparative product of honey for the season, quality, etc. Trusting that you will fill up and return this blank at your earliest convenience, I am, very respectfully,

J. M. RUSK, *Sec.*

Name .....
Post-Office.....
County.....
State.....

1. How are the colonies in your county generally wintered? (In cellars, caves, out-doors or otherwise?).....
2. What percentage of bees survived the past winter?.....
3. Is there any foul brood?.....
4. What races of bees are generally kept?
.....
5. What are the present prospects for the crop of the coming season?.....
Remarks.....

We filled up the blanks, and wrote after the word "Remarks," that we were glad the Department had at last taken a step in the matter—but regretted that statistical information in reference to the number of colonies of bees in the fall of 1888 and in the spring of 1889 was omitted.

Our friend, Eugene Secor, wrote us a few days ago that he had also received the "first circular from the Department of Agriculture to correspondents, to obtain statistics relating to the condition of the industry of bee-keeping." He adds: "The questions asked do not cover the ground as thoroughly, perhaps, as they might, but it is a step towards recognizing the importance of the honey-bee."

As such step towards a recognition of the pursuit of bee-keeping, we hail it with pleasure. "Large bodies move slowly"—but generally "get there" in due time. This is the result of the committee appointed at the Chicago convention in the fall of 1887.

Catalogues for 1889 are on our desk from—

F. A. Salisbury, Syracuse, N. Y.—3 pages—Apiarian Supplies.

G. D. Black, Brandon, Iowa—16 pages—Seeds, and Italian Bees and Queens.

J. Van Deusen & Sons, Sprout Brook, N. Y.—4 pages—Comb Foundation.

Southern Comb Honey.—E. Israel, Oak Lawn, Miss., on April 27, 1889, sent us two one-pound sections of comb honey, with the following letter:

I send you two sections of comb honey. Please inform me through the AMERICAN BEE JOURNAL what you think of it. The colony that gave it, also gave me 56 one-pound sections this year. It had a hybrid Holy-Land queen; she mated with a black drone. I have others doing as well. It was gathered while black locust was in bloom; white clover also. We have a heavy honey-flow at present from white clover, poplar and blackberry. My bees commenced swarming on March 26. I have already had 80 swarms.

Do not put this honey in your Museum, but put it on the table, so that you can give a good idea of its quality. Friend Muth wrote me last year that he never saw any Southern honey light enough for his trade in comb honey.

We have eaten the honey, by the help of our family, and like its flavor. It is amber in color, has a good body, and is pleasant to the taste—the white clover flavor predominating. As long as the trade calls for *white* honey in the comb, this would not fill the bill, and that is what Friend Muth meant, no doubt, but we think the flavor more agreeable than much of the white honey, particularly the linden; the latter is excellent for its medicinal qualities, but many object to its peculiar taste.

A Correspondent asks to have these questions answered in the AMERICAN BEE JOURNAL, viz:

1. What are the dimensions of the Langstroth hive; also of the frame?
2. What size of the Langstroth hive is the best for all purposes, controlling swarming, etc.?
3. As I intend to produce both comb and extracted honey next year, and comb honey this year—would it be any advantage to use extracting supers for both, using a wide frame holding 8 sections 2 tiers high?
4. Is there any difference between the V-groove one-piece section and the open side section?
5. My supers are one-half depth, with bee-spaces between the top-bars, and also under all the frames; are they for tiering up?

1. The Langstroth frame in general use is 9⅛x17⅝ outside, and the hive for 10 frames measures 14x18⅜ inches inside, and is 10 inches deep inside.
2. The hive containing 10 frames is generally considered the best for all purposes, though some use only 8 frames, and like them well.
3. Wide frames are used, but are not as popular as they were some years since.
4. One-piece sections are made open on all sides when so ordered.
5. Probably—though the question is very indefinite.

Grafting-Wax.—As nearly all our readers are farmers, or interested in that pursuit, and often would be glad to have a good, yet simple, recipe for making grafting-wax, we give the following, which the New York *Voice* says is good:

Mix one part of tallow with two parts of beeswax and four parts of rosin.

GLEANS OF NEWS.

The National Centennial Birthday was enthusiastically celebrated from the Great Lakes to the Gulf of Mexico, and from the Atlantic to the Pacific oceans—on April 30—the centennial of the inauguration of Washington as the first President under the new Constitution of the United States of America.

Not alone in the civic and military display were the ceremonies noteworthy — but throughout the whole country earnest men, women and children gathered in all the churches and offered thanks for the manifold blessings consequent upon the labors of the men who had guided their country in the hour of peril, and had laid the foundations of its peaceful progress, and present glory.

This grand Republic has now entered upon its second century strong in its might, and conscious of its grand and glorious destiny.

On the next page we reproduce an engraving exceedingly appropriate at the present moment—showing the faces of Washington and his successors down to the present time.

The Outlook.—A correspondent in last week's Orange Judd *Farmer*, who has been traveling through the State of Illinois, expresses himself thus about the prospects for a good crop of honey for this season :

In our travels through Illinois, during the past month, we have found that bees have mostly wintered well, and colonies are stronger than they have been in April for several years past. Our own are unusually strong, and have large quantities of sealed brood almost ready to hatch. The abundance of the cherry and willow bloom has been an early stimulant, and we are looking for early swarming. The outlook for white clover honey is good, there being an abundance of white clover everywhere, uninjured by the winter.

Bees and Fruit.—In reference to the very important work done by bees in fertilizing the flowers, and thereby increasing the fruit, Mr. W. Styan, of San Mateo, Calif., writes to the *Pacific Rural Press*, under the above heading, the following interesting facts :

In addition to the very able letter written by your correspondent, W., in your last issue, regarding the fertilization of fruit blossoms by bees, we have in the same issue a letter signed J. R. Springer, Woodland, which is a proof of the efficacy of cross-fertilization undoubtedly performed by the agency of bees. Mr. Springer (speaking of almond trees) says : "I will say that the Standard and Languedoc, planted alternately, will yield double what they will if each is planted by itself. I saw that at Mr. W. W. Smith's at Vacaville last June. He had 12 trees in a row—6 Languedoc and 6 Standard—and where the two varieties were the nearest, the trees were the heaviest loaded, and the further away the lighter." The reason for the above is obvious : the bees working on the trees nearest together would naturally cross-fertilize more of their blossoms than those at a distance, hence the desirability of planting the two kinds together.

Many kinds of fruit depend entirely on the agency of bees in fertilizing the flowers to enable them to produce fruit at all. It is a well-known fact in the Eastern States that unless they have a few hours of sunshine when early cherries are in bloom they get no fruit at all. The reason is plain ; when the cold wind and rain storms prevail, the bees are unable to get out, and consequently the blossoms remain untertilized.

Bee-Stings to Cure Rheumatism.—James McNeill, of Hudson, N. Y., seeds us the following with these remarks : "The enclosed, cut from the *Christian at Work*, is somewhat humorous, if it possesses no other merit." Here is the "item" referred to :

Sufferers from rheumatism, says the London *Christian World*, will be delighted to hear that a cure has been found, which tried upon 173 patients has proved uniformly successful. The first feeling aroused in them by this good news may, however, be succeeded by a less ecstatic state of mind, when they learn what the cure is—namely, the sting of bees. A certain Dr. Tere is the hero of this notable discovery. The cure is somewhat prolonged, for we read that his 173 patients took among them no less than 39,000 stings—an average of about 225 stings apiece. This is a little disheartening, though Herr Tere avers that after the first dose the subsequent stings give less and less pain. Still, the "bee-cure" has rather a forbidding aspect. The agony might, perhaps, be shortened by substituting hornets for bees—say, one hornet for every 20 bees ; or, perhaps, a single scorpion might effect the whole cure. It would be useful to have a table drawn up something in this wise :

12 midges	equal	1 mosquito.
24 mosquitoes	"	1 bee or wasp.
20 bees or wasps	"	1 hornet.
10 hornets	"	1 scorpion.

There are, doubtless, some who would prefer to take the "scorpion cure," and have it over at once.

To laugh heartily at the general fear of stings is about the best thing to do.

Honey Comb 50 Years Old.—A strange discovery has just been made in England, says the *Public Opinion* of April 12, 1889, at the Cathays Yard of the Taff-vale Railway Company. Several copies have been sent us by our correspondents. The particulars are as follows :

A large elm tree, grown in Gloucestershire, was being cut up into timber, when, right in the very heart, a cavity measuring 8 feet by 7½ inches in diameter was discovered almost completely filled with the honey comb, together with a squirrel's skull. No means of access to the hollow was discoverable, neither was decay anywhere apparent, and around the cavity itself no less than fifty "rings," each ring denoting a year's growth, were counted, the outer bark being, too, without a flaw. The hollow was of uniform size throughout, and presented the appearance of having been bored with an auger, and, great though its dimensions were, it was practically filled with comb, proving that the bees must have been in possession for several years. Empty queen-cells also showed that they had swarmed.

How the bees got there can only be guessed, but it is surmised that a squirrel once occupied a decayed hole in the tree, cleared away the decay, occupied the cavity as its home, and there died. Then the bees entered into possession, and filled the whole with comb, when by some means the entrance, which must have been small, became stopped. Then for fifty years the growth of the timber went on. The entrance being absolutely obliterated, and the hole being hermetically sealed, the comb was preserved from decay for half a century, to be found at last in the way described. The find is of great interest to naturalists.

Bears and Honey.—Two large Bears were recently captured in Ulster county, N. Y., says the Kingston *Freeman*. It seems they loved honey too well, and this led to their capture. For months honey had been missed, and suspicious persons were accused of the theft. The *Freeman* gives the details thus :

On Monday morning a member of the family of Cornelius Palen saw what at first appeared to be a large black dog near one of the hives. Investigation, however, proved the supposed dog to be a bear. A moment later another large bruin made its way into the back yard. An alarm was given. Neighbors were called to the scene, but in the meantime the shaggy brutes had slunk to a neighboring woods. A hunting party, composed of quarry men, woodchoppers and farmers, was soon organized, and a search instituted.

Two large blood hounds, owned by Cornelius Palen and Luther Trowbridge, accompanied the party. The chase was a long one. The bruins led the hunters over hill and dale. Overlook mountain was reached, and the hunters were nearly exhausted. Still the trail was followed, which led from "the mountain" through Rattlesnake Hollow. Here the dogs, which were considerably in the lead, overtook the bears, and a lively tussel ensued.

The hunters were soon on the scene, and a few minutes later two shaggy brutes lay lifeless on the ground. The dogs were badly bruised and scratched. The largest of the two bears weighed over 325 pounds. The other tipped the scales at about 300 pounds.

The Echoes of our Centennial celebration had hardly died away before the Republic of France began to commemorate its centennial of the revolutionary struggle for freedom a hundred years ago. The Universal Exposition at Paris opened on May 5 with appropriate ceremonies and enthusiasm, to commemorate that event, and it promises to be a grand success.

Scientific Queen-Rearing, as practically applied ; being a method by which the best of queen-bees are reared in perfect accord with Nature's ways. This is the title of a new book of nearly 200 pages by G. M. Doolittle, of Borodino, N.Y.

In this book Mr. Doolittle details the results of his experiments in rearing queen-bees for the past four or five years, and is the first to present his discoveries to the world. It will be out in good time for every progressive bee-keeper to test the various discoveries which it details, during the present season. Send all orders for the book to this office. Price, $1.00, postpaid. The usual discount to dealers in lots of 10 or more.

Early Queens.—Those wanting such Queens, should note J. N. Colwick's prices on page 302 of this issue.

WASHINGTON AND HIS SUCCESSORS.

COMMEMORATING THE ONE HUNDREDTH ANNIVERSARY OF THE INAUGURATION OF WASHINGTON AND ADAMS—APRIL 30, 1789.

The Frost on the Punkin.

BY JAMES WHITCOMB RILEY.

When the frost is on the punkin, and the fodder's in the shock,
And you hear the "kyouck" and the "gobble" of the struttin' turkey cock,
And the clackin' of the guineys and the cluckin' of the hens,
And the rooster's hallylooler as he tiptoes on the fence;
Oh, it's then's the time a feller is a feelin' at his best,
With the risin' sun to greet him from a night of peaceful rest,
And he leaves the house barebeaded and goes out to feed the stock,
When the frost is on the punkin and the fodder's in the shock.

There's something kind o' hearty-like about the atmosphere
When the heat of summer's over, and the coolin' fall is here;
Of course we miss the flowers and the blossoms on the trees,
And the mumble of the hummin'-bird and the buzzin' of the BEES;
And the air's so appetizin', and the landscape through the haze
Of a crisp and sunny morning of the early autumn days,
Is a picture that no painter has the colorin' to mock—
When the frost is on the punkin and the fodder's in the shock.

The husky, rusty rustle of the tassels of the corn,
And the raspin' of the tangled leaves, as golden as the morn;
The stubble in the furries—kind o'lonesome-like, but still
A-preachin' to us sermons of the barns they growed to fill;
The straw-stack in the medder, and the reaper in the shed;
The horses in their stall below—the clover overhead—
O, it sets my heart a-clickin' like the tickin' of a clock,
When the frost is on the punkin and the fodder's in the shock. —*Selected.*

QUERIES AND REPLIES.

Sections Used With or Without Separators, etc.

Written for the American Bee Journal

Query 630.—1. When all other things are equal, what per cent. more honey will bees store in a two-pound section, 6x6x1⅝, without separators, than they will with separators in the 4¼x4¼ sections? 2. In open-top sections, to keep the bees from coming out, what do you cover them with? 3. Do you use glass on the end sections? 4. If not, how do you tell when the bees commence work, and when the sections are finished?—Ohio.

1. I do not know. 3. A quilt. 3. No. 4. Raise the quilt and look between the sections.—A. B. MASON.

1. Very little, if any. 2. Oil-cloth covers. 3. No. 4. Remove the cover from the corner, and *look*.—C. H. DIBBERN.

1. Very little, I think. 2. I use a board cover, just bee-space above the sections; that is all. 3. No. 4. Look into the ⅞-inch space above.—A. J. COOK.

1. Very little, if any. 2. Enameled-cloth. 3. No and yes. Partly, and partly not. 4. By examination.—WILL M. BARNUM.

1. I cannot say. 2. I mostly use a cloth—often a thin board. 3. Not often. 4. Tell by removing the cover. —J. P. H. BROWN.

1. Little if any difference. 2. I use wide frames. 3. No. 4. Pry the wide frames apart, or the closing board at the sides.—G. M. DOOLITTLE.

1. It is possible that they would store a little more, but I doubt it. 2. With the plain flat hive-cover, the section-case being so made that there is a bee-space between the sections and the cover. 3. No. 4. I raise the cover and look in.—R. L. TAYLOR.

1. Fully ⅛ more. 2. A burlap mat, and plain honey-board. 3. No. 4. By removing the plain honey-board and mat, and looking down between them.—J. M. HAMBAUGH.

1. I cannot say. 2. Cloth. 3. Where I use sections I do; where I use a case like Heddon's, I do not. 4. It is an easy matter to raise the cloth that covers the case, and one can see at a glance whether the sections are full or not.—MRS. L. HARRISON.

1. I do not think that they will store any more. 2. The top of the hive or cover; I also use enameled-cloth on many hives, and like it. 3. In one style of hive, I use glass. Give a puff of smoke, then look down through the openings on top.—H. D. CUTTING.

I do not think that any appreciable difference will be found. 2. Usually with thin strips of deal. 3. I use no glass in the hives at all, but examine from time to time to see what progress is made.—J. E. POND.

1. I am not sure that they will store any more. I have never used separators. 2. Any kind of board that may be at hand, or a shingle. 3. Yes, generally. When I do not, I remove the thin board that is in the place where the glass ought to be.—M. MAHIN.

1. Not any more. 2. I let them come out. I have a bee-space over the sections, and cover with a hive-cover. 3. No, certainly not. 4. If I wish to know when the sections are finished, I examine.—J. M. SHUCK.

1. One-third more. Bees hate separators. 2. Indian-head muslin. 3. I have wine-cases with glass at the sides. I do not like them. I want open-top sections, and to look inside I cannot always tell. Sometimes I take them off, look at the bottom, and then put them on again.—MAHALA B. CHADDOCK.

If the sections be 4¼x4¼x1⅞ inches, open-sided, and used with perforated wooden separators, bees will store fully as much (and probably more) honey in them than in a two-pound section 6x6x1⅝ inches, without separators; and I think so from having made this same test with the latter size of sections, but I shall never use it again. But if the smaller sections be closed-sided, and used with separators, the bees will store at least one-third more honey in the larger sections used without separators. 2. A section-case for open-top sections (and I think that no other kind are profitable to use) should have a bee-space above the sections, and the hive-cover should rest upon it. 3. I use no glass about section-cases, but can tell all about the work going on, by looking into the sections from the top, and sometimes using a little smoke.—G. L. TINKER.

1. I do not know, but I would not expect them to store as much. 2. Nothing. Let them come out. 3. Raise the cover, and you can see every section; raise the super, and you can see whether each section is finished.—C. C. MILLER.

1. If they begin in the sections without "sulking," as Mr. Hutchinson says, they will probably put the same amount in either kind. But they are more likely to "sulk" with the small sections and separators. 2. The oil-cloth and straw-mat. 3. We do not use glass; we look from above in the openings of the sections.—DADANT & SON.

1. That is a question that could only be answered by practical test on a large scale. 2. I use a bee-quilt made of enameled-cloth, or any clean cloth will do. 3. No; I only have to turn up the quilt, and look down through the openings between the sections, to tell at a glance what progress is being made in the sections.—G. W. DEMAREE.

1. Perhaps a little more, but what per cent. I shall not venture to guess. 2. The hive-cover. There should be a bee-space between the top of the sections and the cover, so that it does not touch the sections at all. 3. No. 4. Look down between the sections from above. You can tell more about the condition in that way, than the other. —EUGENE SECOR.

1. The difference is an unknown quantity. It is but very little, if any. 2. A cloth. 3. Yes; if the honey-rack is used. If not, no. 4. A look down between the sections will give the desired information.—THE EDITOR.

Convention Notices.

☞ The second meeting of the York and Cumberland Bee-Keepers' Association will be held in the Good Templar Hall, at South Waterboro, Maine, on May 15, 1889, at 9:30 a.m. A cordial invitation is extended to all. Matters of interest will be discussed. Bring your hive or some useful implement for exhibition. Hotel accommodations may be had in the village at reasonable rates. C. W. COSTELLOW, *Sec.*

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

CORRESPONDENCE.

WINTERING BEES.

Box-Elder for Hedges—Temperature in Winter.

Written for the American Bee Journal
BY A. C. TYRREL.

Cottonwood and box-elder trees are now furnishing an abundance of pollen, and the bees are once more busy preparing for the honey-flow, instead of robbing their weak neighbors, as was the case early last season; and not that alone, for they robbed every merchant in the city not provided with screen-doors. Whether or not the above-mentioned trees yield nectar, I am unable to say, never having the heart to kill a bee and examine its honey-sac.

Box-elder trees being indigenous to this State, they are very hardy, grow quite fast, are valuable for sugar, and furnish the first pollen. No trees with which I am familiar, have such dense foliage, or put forth leaves so early in the season, with the exception of crab-apple trees.

For hedges, all things considered, there is nothing better than box-elders, as they can be shaped into any form desired, and any amount of hacking at any season of the year, will not injure them in the least. The young shoots are so tender that trimming is accomplished with very little effort. The hedge in front of our residence is admired by all who view it, Bostonians, who have visited our city, not excepted.

Early this spring, before the trees blossomed, the bees left on the summer stands brought in flour from the mill every pleasant day.

Winter Temperature for Bees.

Our bees wintered well, every colony being alive when taken from the cellar. The winter before, one-third died, perhaps owing to improper ventilation.

My experience is widely at variance with Prof. Cook's; my bees are quiet at a low temperature, and restless at a high temperature. During the warm weather last fall and winter, I found it necessary to throw open both cellar-doors every night, to lower the temperature, and to admit pure air.

Place a number of colonies in a cellar, or an air-tight apartment under ground, and the air soon becomes poisoned, and the bees die sooner or later in consequence. The readers who have been in a packed audience in a room imperfectly ventilated, know how it is themselves.

I find that the bees wintered on the summer stands are in better condition than those kept in the cellar.

The experimental hive that I used, seems to be well adapted to a changable climate. One morning the thermometer registered 25° below zero, I placed my ear against the hive, and could hear a gentle humming, which proves that bees can be wintered in any climate where chaff-hives are successfully used.

I put a large sheet of blotting-paper over the brood-frames to absorb the moisture, and over that a strip of burlap, all of which was unnecessary, as the cover was air-tight. I examined the colony to-day, and find plenty of honey, and more brood than is usually found in June—fully ten times as much as in the hives stored in the cellar.

I have discovered that a newspaper placed over the burlap, when bees are taken from the cellar, is much better than oil-cloth; for it fits closer to the hive, and no heat can escape if the cover is pressed down firmly. It was all the covering used in a large number of my hives in the cellar, and I have yet to discover any injurious results arising therefrom.

Preparing Hives for Winter.

The simplest and best method that I have yet discovered for cellar-wintering of bees, is as follows:

Remove the bottom-board and cap of the hive, and draw a thick gunny-sack over the hive, put the cover on, and place the hive thus prepared on the shelf, and the work is complete. The advantages are manifold; light is excluded, and dead bees cannot clog the entrance and smother the colony; they drop in the sack, and not on the cellar floor to be trod upon, neither can they crawl out of the hives, never more to return.

If it is thought necessary to remove the dead bees, a small slit can be cut where the sack bulges, the bees taken out, and the slit closed with a pin.

By making use of this method, the hives are at all times well ventilated, and a high temperature can be maintained when necessary. The sacks can be used for many years, if kept in a dry place when not in use. I hope that bee-keepers will try this plan next winter and report.

Flattering Prospects.

Our prospects for this season are quite flattering. For pasturage I have 4 acres of Alsike clover, and 2 acres of melissa in fine condition, from seeds self-sown last season; besides, white clover in the city is well advanced. Sweet clover is a failure here.

Madison, Nebr., April 19, 1889.

HINTS.

Two Queens in a Hive, Shipping Bees, etc.

Written for the Prairie Farmer
BY MRS. L. HARRISON.

I traveled sixty miles on the railroad recently, and ten miles by carriage. All the way I kept looking for bee-hives, and only saw some at one place. I am afraid that Illinois has not bees enough to do the work required of them in fertilizing the flowers, and every year fruit appears to get scarcer. There are very few insects at this season of the year, and bees alone must carry the fertilizing powder from blossom to blossom to insure the setting of the fruit. Clovers would soon disappear from pastures and meadows without their friendly aid.

Two Queens in a Hive.

I visited an apiary the other morning, and saw the bees coming in, with their panniers heavily laden with the beautiful pale-yellow pollen. Box-elder, frequently called "ash-leafed maple," is a fruitful source of both honey and pollen, and those planting for timber or shade should not forget it.

While looking at the bees and admiring them, the proprietor remarked: "I bought three queens, of a distinguished queen-breeder last fall, and lost one while introducing her. I had removed one queen, and supposed that was all, as is generally the case, and introduced the new one, when she was destroyed." Two queens, or mother and daughter sharing maternal honors, are not so rare as may be supposed.

Dr. Allen, while attending the National Bee-Keepers' Convention at Lexington, Ky., was presented with a valuable imported queen, which he reported lost in a similar manner. So, those introducing new queens should be doubly sure that all old ones are removed, lest they be destroyed in like manner.

Shipping Bees.

Bees can be shipped long distances, if only precautionary measures are taken in order to confine them to the hive. They also need ventilation while in transit. Our hives are Langstroth with porticoes, and in preparing some colonies for transportation to Nebraska lately, good, strong colonies were chosen, in which the frames were securely fastened with propolis or bee-glue.

A couple of thicknesses of old blanket were wrung out lightly of warm water, and spread over the frames, plenty lare enough to reach

over the sides of the hives, and then a board nailed on. The dampness in the blanket served the double purpose of keeping the bees cool, and furnishing water while in transit. Wire-gauze was nailed securely over the front of the portico. Bees fixed up in like manner, missing their destination, and that were knocking about as freight for three weeks, yet finally arrived at their destination all right. The bees we shipped were sent by express.

Fresh Water for Bees.

Persons owning bees and not located near streams of water, should furnish them fresh water daily, as it will save time, which, to the bee, means honey, as it means money to us. The way they frequent wells and cisterns shows that they prefer water fresh to stale, and they appear to enjoy sipping it from gravel and sand. I have used milk-crocks filled with gravel and sand, but, on the whole, I prefer wooden kegs with cloths put in them, hanging over the sides, acting as syphons. The bees sip water from the sunny side of the kegs. The kegs should be washed out frequently, and one should be a little brackish, about a tea-spoonful of salt to a pail of water.

Starting an Apiary.

A correspondent writes to know how many colonies he should buy, in order to start bee-keeping; what kind of bees, and which is the best hive.

A person having no previous knowledge of bee-keeping should not purchase more than two colonies, and let his knowledge increase in the same ratio as his bees. If it is a good season, the bees will double, and much more, if allowed to follow their own sweet will. If a colony is allowed to swarm once, and no more, both will be strong, and able to store surplus. Much increase and honey cannot be obtained the same season, and a person can readily have which he prefers —bees or honey.

All bees are good, and persons can take their choice. The Italians are the most "fashionable" variety just now. Brown or German bees have their good points; they build up quickly in the spring, throw off enormous swarms, and have the reputation of sealing the whitest honey. Italians leave their hives earlier in the morning, and work later in the evening; they have stronger wings, and longer tongues than the common bees. This enables them to work on flowers which the common bees cannot.

The hive I use and prefer is the eight-frame Langstroth. There may be others just as good, but none better, in my judgment.

Peoria, Ills.

POETRY.

The Muses and their Literary Productions.

Written for the American Bee Journal

BY JAMES HEDDON.

It seems that bee-keeping is more of a poetical business than many other lines of production. Although some of the rhymes found in bee-periodicals, written by bee-keepers, are more of a jingle than poetry, still, it shows us that they are touched with the poetical sentiment, caused by the excitement and hustle of the apiary, with its hopes and disappointments, resulting from its greatly varied income, together with the fact that the work brings one in contact with Nature's scenery. But to a far greater extent does field sports bring one face to face with Nature's most beautiful scenes, and that, too, at a time when the fancies are heated with excitement, and the mind becomes as plastic as molten iron before it has cooled and hardened.

To illustrate what I mean by true poesy and "jingling" rhyme, allow me to present a poem from George Arnold, a second-rate English poet, entitled

SEPTEMBER.

Sweet is the voice that calls
From babbling waterfalls
In meadows where the downy seeds are flying,
And soft the breezes blow
And eddying come and go
In faded gardens where the rose is dying.

Among the stubbled corn
The blithe quail pipes at morn,
The merry partridge drums in hidden places,
And glittering insects gleam
Above the reedy stream
Where busy spiders spin their flimsy laces.

At eve, cool shadows fall
Across the garden wall,
And on the clustered grapes to purple turning,
And pearly vapors lie
Along the eastern sky,
Where the broad harvest-moon is redly burning.

Ah! soon on field and hill
The winds shall whistle chill
And patriarch-swallows call their flocks together,
To fly from frost and snow,
And seek for lands where blow
The fairer blossoms of a balmier weather.

The pollen-dusted bees
Search for the honey-lees
That linger in the last flowers of September,
While plaintive-mourning doves
Coo sadly to their loves
Of the dead Summer they so well remember.

The cricket chirps all day,
"O fairest Summer, stay!"
The squirrel eyes askance the chestnuts browning;
The wild-fowl fly afar
Above the foamy bar,
And hasten southward ere the skies are frowning.

Now comes a fragrant breeze
Through the dark cedar trees,
And 'round about my temples fondly lingers
In gentle playfulness,
Like to the soft caress
Bestowed in happier days by loving fingers.

Yet, though a sense of grief
Comes with the falling leaf,
And memory makes the Summer doubly pleasant,
In all my Autumn dreams
A future summer gleams,
Passing the fairest glories of the present.

A poem may be poetical from its sentiment, but it seems to me that it is with the descriptive that the poet finds his best opportunity to excel. I consider that there is no other field equal to that of description.

We should be able to fairly judge of a poem entirely independent of the reputation of its author, and now I will give one which I consider fully equal to the foregoing, by Frank Selden, of Modus, Conn., an obscure writer, who, so far as I have been able to learn, is a true field sportsman. Although his name is not great, any one who appreciates true poesy, cannot for a moment fail to recognize that he is great; and to meet him and make his acquaintance would be of vastly more pleasure to me than to meet any of the Presidents of the United States.

We will suppose that just before the shooting season, Frank and "Scout" are taking a pleasant stroll in the woods, and both becoming tired, Frank sits down upon a log, while Scout reclines by his side, and as their eyes meet, Frank addresses the noble animal as follows:

TO MY SETTER "SCOUT."

You are a tried and loyal friend.
The end
Of life will find you leal, unweary
Of tested bonds that naught can rend,
And e'en if years be sad and dreary
Our plighted friendship will extend.

A truer friend man never had;
'Tis sad
That 'mongst all earthly friends the fewest
Unfaithful ones should thus be clad
In canine lowliness; yet, truest
They, be their treatment good or bad.

Within your eyes methinks I find
A kind
And thoughtful look of speechless feeling
That Mem'ry's loosened cords unbind,
And let the dreamy past come stealing
Through your dumb, reflective mind.

Scout, my trusty friend, can it be
You see
Again, in retrospective dreaming,
The run, the woodland and the lea,
With past Autumnal sunshine streaming
O'er ev'ry frost-dyed field and tree?

Or do you see now once again
The glen
And fern, the highland and the thistle?
And do you still remember when
We heard the bright-eyed woodcock whistle
Down by the rippling shrub-edged fen?

I see you turn a list'ning ear
To hear
The quail upon the flower-pied heather;
But, doggie, wait till uplands sere
And then the Autumn's waning weather
Will bring the sport we hold so dear.

Then we will hunt the loamy swale
And trail
The snipe, their cunning wiles o'ercoming:
And oft will flush the bevled quail,
And hear the partridge slowly drumming
Dull echoes in the leaf-strewed dale.

When wooded hills with crimson light
Are bright,
We'll stroll where trees and vines are growing
And see birds warp their southern flight
At sundown, when the Day-King's throwing
Sly kisses to the Queen of Night.

But when the leaves of life's fair dell
Have fell,
And Death comes with the Autumn's even
And separates us, who can tell
But that, within the realm of Heaven,
We both together there will dwell?

PERSONAL.

Allow me to thank you, Mr. Editor, for your kind mention of my election. I really have reason to feel somewhat proud of it, as I desired neither nomination nor election; solicited no votes or poll-workers, and had a majority of 76 to overcome before my majority began. Our bright and rapidly growing little city is this year expending $40,000 for a thorough system of water

works, besides our regnlar out-puts, so my friends, among your readers, may know that I shall be a busy man for the coming year.

Dowagiac, Mich.

OHIO.

Report of the Fayette County Convention.

Written for the American Bee Journal

The first meeting of the Fayette County Bee-Keepers' Association was held on April 11, 1889, at the residence of J. W. Gillespie, at Washington C. H., Ohio, and was attended by quite a number of representative bee-keepers. After a bountiful repast served by the hostess, Mrs. G., the meeting was called to order by President Waters, who gave quite an interesting address.

After the usual preliminary business was dispensed with, the election of officers for the ensuing year was held, and resulted as follows:

President, D. Waters; Vice-President, Lewis Haines; and Secretary-Treasurer, S. R. Morris.

Mr. J. W. Gillespie was appointed as a committee of one to formulate the Constitution and By-Laws of the Association into pamphlet form, and have some new copies printed, after which a report from each member present who has bees, was heard with regard to their wintering.

Reports on Wintering.

J. H. Ferguson wintered his bees on the summer stands, starting in the winter with 2 colonies, and has them yet, but one is queenless.

Lewis Haines began the winter with 68 colonies, and now has 62 in good condition; he wintered them on the summer stands, a part in Root chaff-hives, and part protected otherwise.

Scott Hopkins had 15 colonies, and came through with 9 colonies; he wintered them on the summer stands without protection.

S. R. Morris began the winter with 66 colonies, and now has 60; wintering half of them on the summer stands, protected by sawdust cushions, and half in a winter repository.

D. Waters started into winter with 13 colonies, and came through with 8; wintering them on the summer stands without any protection.

After the reports were ended, a motion prevailed that the President appoint a committee consisting of one from each township, for the purpose of working up the interests of bee-culture, and the successful progress of the Association.

The following names will constitute the committee:

Concord township, Wm. Bay; Green, R. Binkley; Jasper, Levi Rice; Jefferson, G. M. Eichelberger; Madison, C. West; Marion, Wm. Clarkson; Perry, Lewis Haines; Union, J. H. Ferguson; Paint, S. R. Morris; Wayne, Joseph Bonham.

After a general discussion on bee-culture, the convention adjourned to meet at the residence of D. Waters on Thursday, May 9, 1889, at 10 a.m. Everybody interested is invited to attend.

The programme for the next meeting will be as follows: "Spring management of bees, for the purpose of obtaining a large yield of honey," by Wm. V. Bay; "What should be done with queenless colonies," by J. H. Ferguson; "Signs of failure in queens," by Lewis Haines; "The outlook for the coming season, with reference to the honey crop," by H. Ellis.

S. R. MORRIS, *Sec.*

MOVING BEES.

Shipping an Apiary by Freight 200 Miles.

Written for the American Bee Journal
BY WM. LOSSING.

There is no part of the AMERICAN BEE JOURNAL that I read with more interest than the letters from every State, and especially when written by some old and experienced bee-keeper.

Last fall I decided to change my location, so I moved to Howard Lake, Nebr., and employed a fellow bee-keeper, Mr. Andrew Quist, to see that my 203 colonies were properly placed in the cave, which he did in first-class order. On April 10 I arrived at Hokah on the midnight train, and by the next night I had 147 colonies out; the next morning I finished carrying them out; I lost 3 colonies outright, and 4 were queenless when put in, making 7 in all.

Then came the tug of war—loading all these bees in a freight-car for a ride of 200 miles, and to receive the "careful handling" of railroad brakesmen. When they arrived at Howard Lake, it seemed as though they would be a total wreck; but to my happy surprise, only 4 colonies had succumbed to the "gentle" knocks of a freight-train, and the balance came through in fine condition.

I placed the hives so that the combs would be parallel with the car. I did not nail the frames, but just left them as the bees had fastened them with propolis last fall. I left each hive with plenty of upward ventilation, and a little in front, so that if the combs of honey broke down, it might run out; but that part failed, for those that perished were broken down, and the bees, honey and all were in a mess together. I gave each colony plenty of water as I loaded them on the car.

This looks like a promising season. I am located 8 miles east of the apiary of Mr. Fayette Lee, who has reported this as a great place for honey. I will expect to be able to make a like report, as we have here plenty of basswood, white clover, golden-rod, asters, and in fact almost everything that grows in a Northern climate.

I have sold 50 colonies to one man, since I moved, so when I get through uniting weak colonies, I will have about 135 left, to make a joyful sound around our little home "out West."

Howard Lake, Minn., April 29, 1889.

BEGINNING.

An Experience in the Keeping of Bees.

Written for the American Bee Journal
BY M. RICHARDS.

Three years ago I had my first experience with bees. I was going to Hampton, Nebr., with a load of grain, when I saw an unusual throng of what I supposed were flies, in a cornfield by the roadside. I went to examine them, and to my surprise I found a huge bunch of bees hanging on a corn-stalk. I took a good view of them, and the next thing was to get them into a box to take them home, a distance of about 3 miles.

I went to the nearest house to procure a box, and the old gentleman who resided there, told me about his adventures with bees away back in Ohio, 50 years ago. I was somewhat interested in his history, but I was more interested in getting the box; so I urged my business a little harder, and he said he had no box, but that he could give me a molasses-keg. I thought that was good enough, so we got it ready, according to his ideas. He went with me, and placed the keg, as he supposed, in the proper way; then he told me to knock them down, when I slipped up near the hill of corn, and gave it a terrible blow with a stick, just below the bees.

I made my escape without getting stung, and after awhile the old gentleman went home, and I remained until dark, but the bees did not like to go into the keg. So I went home, and about 3 o'clock in the morning I returned, but found the bees still clustered on the side of the keg. It was pretty dark, and I was not very much afraid of them in the night, so I had

prepared everything to handle them, and I took a sheet and enveloped the whole thing—bees, keg, and all—and put them on a spring-wagon and took them home.

The next day the bees were determined to leave their new home, but by throwing water on them, pounding on pans, and making a great noise, we induced them to stay. I then obtained Prof. Cook's "Manual of the Apiary," after which I proceeded in a little better way, and those bees did remarkably well. The next season I took 4 colonies on shares, and as my colonies increased, I increased in the knowledge of bee-keeping. I cannot estimate the value of the AMERICAN BEE JOURNAL to me, as I have received so much valuable information from it. I cannot do without it while I keep bees, and I never expect to stop bee-keeping while I live.

My bees did tolerably well last year, considering the dry season, as I got about 2,000 pounds of honey from 30 colonies, which I sold in my home market at 15 or 20 cents a pound. I am looking forward to a more prosperous season this year. My bees have wintered well, and are in good condition for the coming season.

Aurora, Nebr., April 19, 1889.

MICHIGAN.

Report of the Ionia County Convention.

Written for the American Bee Journal

The Ionia County Bee-Keepers' Association met in annual session at Ionia, Mich., on April 18, 1889. The following officers were elected for the ensuing year: President, J. H. Robertson, of Pewamo; Vice-Presidents, Geo. W. Stanton, Sheridan; and I. A. Balch, Ionia; Secretary, Harm Smith, Ionia; Treasurer, M. Guernsey, Ionia.

The report of the Secretary showed the result of the year with the 18 members present, to be as follows: Fall count of colonies, 885; spring count, 784. Honey taken during the year, 8,891 pounds; pounds of wax, 101.

J. H. Robertson then delivered the following

President's Annual Address:

I am here as a member of this Society to assist as best I may, in throwing light upon the subjects brought before us for discussion. I am in hopes that we have passed the crisis in the history of bee-keeping in our county, and that all well-informed bee-keepers are aware of the fact that the time has passed when large and remunerative profits can be realized from the pursuit. It will not be my purpose to instruct those of you who are already experts in the business, whose lessons have been taught you by dearly-bought experience. Many of you, I think, with myself, have learned that it is not advisable to carry all your eggs to market in one basket.

I have found that one of the great difficulties we have to encounter is that bee-keeping is a charming pursuit, and that its beauties are many times magnified; while its dark or black side, with its many discouragements, is kept clear in the background.

"Springing" Bees.

We have now arrived at the season of the year when large colonies grow larger, and small ones smaller, robbing and dwindling being our greatest spring trial; and these I think, with even the expert, the hardest mile-post he has to make. Robbing being well under way, the colony is discouraged usually before the trouble even catches his practiced eye, and with dwindling he has but the queen and a small handful of bees, whereon the last examination was to all appearance a fairly prosperous colony. Teach us how to successfully spring our bees, and I think that the most of us could make a fair remuneration for our outlay in even such three poor seasons as we have just passed through.

Bees Ready for the Harvest.

The next point essential to success is to get the bees ready for the harvest. The flowers may bloom in vain, so far as securing a crop is concerned, if our colonies are not in that strong, populous condition, ready to take advantage of Nature's provisions. The apiarist must know his colonies, work hard early and late, and leave no stone unturned that will add one more pound of honey to his crop. Bees will store honey in a box, straw-skep or log-gum; but the time honey could be sold, taken from such a repository, has passed away. So that if we realize the most for our labor, we must compel our bees to store it in neat and attractive sections. This will lead to methods of which the first is contraction, whether vertical or horizontal, with the relative merits of each system. System would mean the hive, making it necessary, without large outlay, to adopt the system best suited to the hive we have in use.

Control of Increase.

An interesting topic being discussed through our papers is the control of increase, or to handle bees in such a manner as not to decrease the profits of the apiary colonies. Allowing a part to cast many swarms, or even to swarm at all, makes serious inroad in the profit of the stock. This I think a subject well worthy of your fullest consideration.

In conclusion, allow me to say that the prospects for a successful season were never better. Reports from all the Southern States are that their bees are booming, and that their prospects are better than for a number of seasons past; and we are enjoying the same state of facts.

In the growing industry that we represent, Ionia county ranks well in the production of honey. Our breezes are tempered by our great inland sea, and our soil is generous in foliage and flowers. We are strangers to extreme drouths and pestilential moisture. We are not in the path of the blizzard or the death-dealing tornado; and I sincerely hope that at our next meeting we can report to our Secretary that once more our favorite pursuit has returned us a bountiful harvest.

J. H. ROBERTSON.

W. Z. Hutchinson, of the *Bee-Keepers' Review*, was invited to address the fall meeting of the Association.

After a discussion of various pertinent questions, the convention adjourned to meet at the call of the Secretary, in the latter part of September next, at Ionia. HARM SMITH, *Sec.*

WINTERED WELL.

Good Outlook for Honey—Some Experience.

Written for the American Bee Journal

BY J. B. SYPHRIT.

I took my 19 colonies of bees out of the cellar on April 10, and found them in splendid condition; in less than two hours they were carrying in pollen. They are working very industriously on willows and peach-bloom. The outlook for honey is very good, white clover here being very promising.

I winter the bees in a cellar 18x32 feet, walled with stone; a diagonal tile runs through it, with tile ventilators in the end windows. I always have wintered my bees successfully. In 1887 the bees starved, but I fed them sugar syrup for wintering, and brought them through the winter; but in the spring of 1888, I lost 13 colonies by spring dwindling, being nearly all old bees. Last season I got a little honey from fruit-blossom, then I had to feed until sometime in August, when we had plenty of rain, and the bees accumulated nectar very rapidly. I got about 400 pounds from 10 colonies, in sections, and the lower stories were full, and they are still very heavy. I use

the 10-frame Langstroth hive, and have used nothing else for 25 years.

We are now having plenty of rain, and Alsike and sweet clover look well. This part of the country has plenty of linden, and almost all kinds of honey-plants that grow in the Northern States. I handled bees for more than 20 years with nothing to guide me except Langstroth on "The Hive and Honey-Bee." The last few years I have been reading new works on bees, with improved methods, and I find that I was just 20 years behind the times. I commenced handling bees when all that was necessary was to know how to make a box, and get bees in; then in the fall, to know how to build a sulphur pit, and put them on—that was all it required to be an expert bee-man. I now read the AMERICAN BEE JOURNAL, which comes to me every Thursday, nice and clean, and I hail it as a great treasure. I could not get along without it; it is the first paper that I open, and the first that I read. May it live many years to continue its mission of usefulness.

Newport, Iowa, April 19, 1889.

BUSINESS BEES.

Breeding Bees for the Honey-Gathering Quality.

Written for the American Bee Journal

BY FRANK COVERDALE.

Should we breed for quality in bees, as well as in other farm stock? I certainly must favor this, for two reasons, viz: First, because it is very reasonable; and second, because I know from personal experience in my own apiary, that through years of careful selection, from the most prolific and best honey-gatherers, I have reared a strain of bees much superior to what they would have been if allowed to increase at will.

Upon meeting a bee-keeper some time ago (who keeps, on an average, 100 colonies), and asking if he would have to feed any of his colonies for winter, he said: "Those that will not have enough honey to carry them through the winter, are not worth feeding; and I do not care whether I save them or not, for they are of no use to gather honey." I call this a very expensive method of weeding out the bad quality. I am inclined to think that a great part of our bee-keepers are rearing bees for beauty, and not giving enough attention to the honey-gathering quality and prolificness, which should go hand in hand.

I would not be understood as being one who would discourage the breeding of the beautiful bee, with the three distinct yellow bands; for from these I believe that an excellent strain can be bred. When visiting a beginner in bee-keeping, he will show his golden Italians, saying perhaps nothing about their honey-gathering quality; and he may continue breeding for the most beautiful, regardless of anything else, and thus be in the future a loser of dollars and cents. If we have the control of the drones, it is as easy to rear bees to produce much honey, as to rear cows to give much milk. Just so it is with disposition, whether in bees, cattle, horses, or whatever it may be; if it is possible to breed cattle for beef and milk; and horses for disposition, is it not just as much possible to breed bees for disposition and honey-gathering quality? I most assuredly answer, yes! Then if this be true, thousands of pounds of honey or nectar are wasted, because of so great a neglect.

Upon the foregoing points of excellence hang all the dollars and cents for the honey-producer. The idea that we must have our bees tempered like hornets, in order to have good honey-gatherers, is really preposterous!

Welton, Iowa.

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
May 15.—	York and Cumberland, at Waterboro, Me. C. W. Costellow, Sec., Waterboro, Me.
May 21.—	Northern Illinois, at Pecatonica, Ill. D. A. Fuller, Sec., Cherry Valley, Ills.
Dec. 4, 6.—	International, at Brantford, Ont., Canada. R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Expecting a Good Season.—Joseph E. Shaver, Friedens, Va., on April 25, 1889, writes:

The past winter has been a mild one, and bees have come through the winter in fine condition. The weather is very fine now; the peach, cherry and apple trees are in full bloom, and bees are gathering honey rapidly. One of my neighbor's had a nice swarm day before yesterday. Bee-keepers are expecting a good honey season this year, and they are rapidly discarding the box-system of bee-keeping, and adopting the modern system of apiculture. To all such, we wish hearty success; to wish success at this day, to the box-hive system, would be to wish success against hope; for I do not think that there is much hope for their success.

Well Satisfied with the Bees. John Haskins, Empire Prairie, Mo., on April 26, 1889, writes:

Bees have wintered finely, and most of them have an abundance of sealed honey. My bees in 1888 averaged about $17.00 per colony, spring count, from heart's-ease, as the white clover only yielded about honey enough for brood-rearing. I have lost no colonies the past winter, and gave them scarcely any protection. I had 7 colonies last spring, and now I have 30. I had lots of empty combs last year, and they were a great help to my bees. I am well satisfied. Peach, plum, cherry and apple trees are in full bloom. I have kept bees for many years, and I find there is lots for me to learn yet. The AMERICAN BEE JOURNAL is a great help to me.

Bees Wintered Safely.—T. Garion Fisher, Topton, Pa., on April 25, 1889, says:

I like the AMERICAN BEE JOURNAL better every week—in fact I cannot see how I could get along without it. I safely wintered 11 colonies of bees on the summer stands. Nearly every colony has 5 frames of capped brood to-day.

Successful Cellar-Wintering.—Rev. L. Lobeck, Knittel, Iowa, on April 18, 1889, says:

My 11 colonies of bees wintered in the cellar under the house, and did too well, as every colony is boiling over with bees. There was no ventilation in the cellar, but it is tiled, and of course that gives a sub-earth ventilation. I never lost a colony in the cellar.

Ants in the Apiary, etc.—Ira N. Lyman, St. Peter, Nebr., on April 22, 1889, writes:

In the BEE JOURNAL recently, I noticed an item in regard to ants troubling the apiary a great deal. One sure remedy is to place the hives on a bench with short legs, put those legs in fruit-cans or dishes, and keep them half full of water, or more; and as the ants are not good swimmers, they never trouble the bees. A long bench can be made, and several hives put on it. The hives could be close together, by facing every other hive the opposite way. My father used to do that way nearly fifty years ago, in the woods where ants were bad. My bees are working splendidly. I hope that we will have a good season for bees. They are working on willows and box-elders, and will soon

be working on plum-blossoms, if the weather keeps good. Grass is growing rapidly, and leaves and blossoms are coming out. Bees wintered pretty well, generally, last winter, though a few colonies were lost, as usual. I hope to get a good increase of colonies this year. I like the AMERICAN BEE JOURNAL very much, and would not do without it as long as I could get the small sum of $1.00 to pay for it.

Good Results in Wintering.—Samuel Flory, South English, Iowa, on April 22, 1889, writes:

I have wintered my bees in the cellar the last two seasons with very good results. In the fall of 1887 I put in 25 colonies, and all came through nicely. Last fall I put in 33 colonies for winter, and when I took them out this spring, only one was dead, and that one I did not much expect to winter. All are doing finely so far. I hope we will have a better honey season this year, than we have had for the last two years.

First White Clover Blossoms, etc.—Geo. W. Morris, Cornishville, Ky., on April 20, 1889, writes:

My bees wintered without the loss of a single colony, and are in a better condition than I have ever had them before at this season of the year. Drones have been flying for about ten days. White clover looks tolerably fair at present, and if not grazed too closely, I hope for a moderate crop of honey from this source. I saw a few white clover blossoms to-day—the earliest that I have ever seen them. Mr. J. E. Pond, on page 250, gives my idea exactly, in regard to the size a bee-hive should be.

White Clover Looking Well.—B. A. Manley, Milo, Iowa, on April 26, 1889, writes:

My 22 colonies of bees wintered without any loss, all in excellent condition, and are doing better than I ever knew bees to do at this time of year. Some of them are working in full force in the sections, gathering honey from fruit-bloom, which is abundant. The prospect for a good honey crop was never better; white clover is looking well, and the rains have come just as we need them. I have been supplying my bees with plenty of room, to prevent early swarming, and yet the indications are that we are to have plenty of early swarms. Drones have been flying for more than a week, and young bees are playing outside in fine condition.

Bee-Keeping in Texas.—G. F. Davidson, Fairview, Tex., on April 17, 1889, writes:

I have about 100 colonies of the meanest hybrid bees that I ever saw. A friend of mine bought 46 colonies last year, and let me have them to work, and I did the best I could with them. I saved 32 swarms, and produced only about 1,000 pounds of extracted honey. It rained so continuously last year through the spring, that the nectar was all washed out of the cat-claw and cactus plants. These are our main dependence for a spring crop of honey, and all that my bees gathered was from the flax or "broom-weed," in the fall.

1. Are you acquainted with the cat-claw and cactus honeys? If so, how do they compare with the honey of the North?

2. How long should combs be used in the brood-chamber?

3. Will some practical bee-man of Southwestern Texas, give, in the BEE JOURNAL, his management of bees both in winter and in summer?

[1. We are not familiar with the honey from "cat-claw" or "cactus." If samples were sent we could judge of its quality.

2. Combs will last a long time in the brood-chamber, but it would be desirable to melt them up and give the bees comb foundation, after 8 or 10 seasons—for the cocoons left in the cells, from brood, make them smaller after long use.

3. We request Judge Andrews to give us an article on management of bees in Texas, as desired by our correspondent.—ED.]

Bees Doing Well.—J. R. Lawton, Lafarge, Wis., on April 19, 1889, says:

Bees are doing well. I put them out of the cellar on March 26, and they found pollen the first day. All had young brood. If we have any honey for them to gather, I do not know why they will not do well. I have 42 colonies, and I want 100 pounds from each, of extracted honey.

Strong Colonies—White Clover—L. J. Waldo, Merrow, Conn., on April 24, 1889, writes:

My bees have wintered finely; I have not lost a single colony, and never saw bees so strong at this time of the year. I have some colonies so strong that they hang out on the hive as much as they do in July. The hives are just solid full of bees. I shall look for swarms as soon as apple-trees bloom. I think that this is going to be a fine year for honey in this part of the country. I believe that I never saw white clover come up any thicker than it has this spring. Bees are just booming on maples now. I winter my bees on the summer stands, part in Langstroth hives, and part in Bristol chaff hives.

A Large Colony of Bees.—Mr. Sanders Johnson, Odon, Ind., on April 17, 1889, says:

Bees are doing finely on fruit-blossoms. I have a fine colony of Italian bees on a 5-foot green, that I have had four years. It casts three large swarms every spring—a half-bushel measure would hardly hold the colony. I have been offered all prices, but no sale. I value the colony at $25, but that would not buy them. It was caught, or found, in the woods four years ago.

Bees Ready for Work.—Mrs. H. A. Gale, Shelby, Ind., on April 15, 1889, writes:

Last fall I had 20 colonies of bees, and all wintered well. I put 5 of them into the cellar as an experiment, and those on the summer stands did as well as those in the cellar. All are in good condition for summer work. On March 10 they gathered the first yellow pollen, and had a general rejoicing in gathering it, as it was new, and better than the old. The bees had a good cleansing out, and are now prepared to stow away for young brood. The elms are flowering and yielding plenty of pollen; also catkins and the willow, which yield abundant honey; and the maples and birches that skirt the banks of the Kankakee river are loaded with bees that come back heavily laden with the sweet nectar, to furnish food for the young bees that soon will hatch. From recent reports, bees in this county have wintered in good condition, with very small loss, and have plenty of honey until white clover comes, as everything is much earlier than last season. My bees paid me better than my cows last year. I have always found a ready market for my honey at home and abroad, and never have enough to supply the orders as they come in.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,

PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:

This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Guide	1 50	1 40

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white 1-lbs., 14@15c. Market is dull and lower, but not overstocked. Demand slow.
BEESWAX.—22@23c.
Apr. 30. M. H. HUNT, Bell Branch, Mich.

KANSAS CITY.

HONEY.—We quote: White 1-lbs. 15@16c.; fall or dark, slow at 12c.; 2 lb. California white, 13@14c.; amber 11@12c. Extracted, in 60-lb. cans, 7½@8c; for white, 7@7½c.; for amber, in barrels or kegs, 5@6c. We think that our market will be cleaned up before new honey comes in.
BEESWAX.—18@20c.
Apr. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Demand limited to local wants, which are small. We could sell some to country points in barrels and ½-barrels at 6½@7c. for extracted; in cans, 7½c.
BEESWAX.—22c. for prime.
Apr. 22. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX,—22c. R. A. BURNETT.
Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 6@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.
Apr. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNAT

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD.
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. May 18, 1889. No. 20.

EDITORIAL BUZZINGS.

May Fowers are coming,
The bees are humming,
And the small boy hankers for early fruit;
The skies are bluer,
The gales are fewer,
And the damsel is trimming her bathing suit.

Thomas Gavin, of Warburton, Ont., is dead. He was 31 years of age, and his death was caused by diabetes. He was one of our subscribers, and was an enthusiastic lover of bees.

We Regret to learn that Mr. A. J. Hatfield, of South Bend, Ind., unfortunately broke his leg last fall, and is now only able to get along with one crutch, but expects to be able to dispense with that soon.

Golden Bees.—Mr. W. P. Henderson has sent to us from his Tennessee apiary, some of the brightest yellow bees we ever saw. In fact, the black or dark is barely enough to discern. They are as yellow as the yellowest queens, and when on the wing, look much like bright yellow queens. They are docile, and Mr. Henderson says, they are fine workers, even if they are so grandly dressed.

Is He Reliable?—We often receive a postal card containing something like this: I want to ship some potatoes, berries, eggs, honey, chickens, fruit, or some other produce, and, naming some person, the question is asked, "Is he reliable?" or "Is it safe for me to ship to him?" Now while we desire to accommodate our friends, still it is quite a task to lay on us to answer such questions. The better way would be for those interested to step into a home Bank, and have the banker look them up, through Bradstreet's or Dunn's commercial agencies.

Saved by the Union.—How often, when requested to join "The National Bee-Keepers' Union," will some one ask, "What good will it do me?" The very fact of belonging to such an organization is of itself not only an honor, but also a power in the defensive! If a jealous or prejudiced neighbor finds that a bee-keeper belongs to a "Union" for the defense of the pursuit—he will *think twice* before rushing into a lawsuit.

Here is a case in point, and an excellent illustration of the moral effect of being a member of the Union: Rev. Robert Carver, of Manton, Mich., a member of the National Bee-Keepers' Union, wrote to the Manager that he was sued by a jealous neighbor to appear before a prejudiced Justice of the Peace, for maintaining a nuisance. The damage was placed at $100 for trespassing bees. Threats were made to drive him and his bees out of the village.

As Manager of the National Bee-Keepers' Union, we counseled him as to what to do and how to proceed; told him to hire a good lawyer, and assured him that the Union would *stand by him* as long as he was in the right, and defend his rights in a moral as well as a financial way.

The case was called, and an adjournment was made until April 29. Mr. Carver retained a lawyer, showed him the letter, and also the published "Reports" of the "Union." He read the latter carefully, went down town and talked with the opposite attorney, and some of those incensed against the bees. The result was that they were quite willing to compromise the affair.

By mutual agreement the bees were to be moved a few rods from the road, and the suit dropped, leaving the parties who brought suit to pay all costs.

Mr. Carver writes as follows: "A friend of mine happened in, when several of them were talking about the matter, and he heard the village marshal say to them that if they went on with the case, they would have all the bee-fraternity to fight, and would have their hands full."

This is another triumph for the Union. The counsel of its Manager, and the moral effect of being a member of an organization for the defense of the pursuit—caused the prosecuting party to withdraw from the field and pay all the costs!

Will our friends please chalk up another victory for the Union!

Uncapping-Knife.—A person signing himself "Inventor," asks if all bee-keepers are "satisfied with somebody's uncapping-knife, or is there a demand for a simply-constructed, easily-operated uncapping machine, that will do perfect work in one-half or one-third the time required with a knife? Such a machine would cost ten dollars."

We cannot answer for *all*, and therefore give any one a chance to answer the question. Perhaps the time has arrived for a machine to be invented. If so, it will be done, for all good and useful inventions come in just the right time.

In the Controversy concerning "large and small hives," between the Messrs. Dadant and Mr. Hutchinson, we shall not interfere—they are well able to discuss the matter intelligently and thoroughly. We desire, however, to make a few remarks about the article appearing in our columns, instead of the *Review*. To refuse to publish an article from the Messrs. Dadant, or any prominent apiarists, is more unpleasant to an editor than it is to the writer of the article—but there are occasions and circumstances when such an unpleasant duty is to be performed.

Some four or five years ago we received an article from the most prominent and popular apiarist in America, and one of the best of men the world contains. It was very faulty, and full of unwise suggestions and notions, and we deemed it best, both for the author as well as apiarists generally, not to publish it, and we wrote him a private letter to that effect. It was an unpleasant matter to us, and "mortified" our friend and correspondent considerably—but time has shown that our judgment was correct. He was saved from the "mortification" which would have ensued, and is now *glad that the article never was published!*

We fully agree with brother Dadant, that an editor should be "impartial" in giving full latitude to both sides of every question, and we fully believe that it is *the intention* of all editors of bee-periodicals to do so, but they are "frail" like other men; they err in judgment (at least we realize that we do, and judge others by ourself); they make mistakes, and have to act "on the spur of the moment" in deciding many questions, which, on more mature consideration, would have reversed the decision.

It is best, generally, not to judge our brethren of the press too severely—in fact they need sympathy more than censure—charity rather than rebuke!

We feel quite certain that Bro. Hutchinson will gladly re-publish Bro. Dadant's article with his reply, for we know that they all have none but the most kindly feelings towards each other. "Let brotherly love continue," is sound advice, and applicable to all ages and under all circumstances.

Bee-Enemies are numerous, and Mrs. S. E. Sherman, of Salado, Texas, asks if martins are among the number of bee-catchers. King-birds are often called bee-martins, and we presume these are what our correspondent intends to ask about. They are very destructive to bees, but seem to prefer the drones.

A Supplement to the *American Apiculturist* for May is received. Mr. Alley occupies seven pages in an article on "Rearing Queens in Full Colonies without Depriving the Bees of their Queen." It seems many have been experimenting in this direction at the same time, and probably without a knowledge of each other's experiments. Truly, this is a grand age of development.

GLEAMS OF NEWS.

Small Hives.—On page 124, Mr. B. Taylor, a Minnesota bee-keeper having 260 colonies of bees, stated that he had secured 7 tons of honey in the last poor season, and credited his success to the small hives he was using, and offered to describe them and detail their management in the AMERICAN BEE JOURNAL. He has sent one of the hives to our Museum, and has this to say respecting it:

The bee-keeper, like the farmer, secures his harvest with a reaper—the hives and fixtures are his harvester; the log-gum is the ancient "sickle;" the box-hive is the "cradle;" and the movable-comb hive is the "self-raking reaper" of the apiarist. The needs of 1889 now demand the "self-binder."

It must combine all the good points of all previous hives; must be cheap, and easy to make; suitable for breeding bees in summer, and keeping them safely in winter; convenient for hiving swarms, and moving in the home yard; and always ready and safe to move to out stations. It must be suitable to handle by whole hives, or by single frames, without any loose parts or complicated machinery; equally suitable for the securing of either comb or extracted honey, and to that end it must be capable of easy contraction, and of tiering up to any required height; with a bee-space, and no more, between the upper and lower frames of such tiered hives, whether with or without the queen-excluding honey-board between them.

Mr. Editor, I send you a sample hive that meets the above-mentioned needs. It is of the right size (1,000 inches of comb surface); the beveled rabbet of the top and bottom of the sides enables it to rest upon a plain bottom-board, and to have a plain, smooth board for a cover, without any ⅛-bee-spaces or other evils. The fixed frames give all the advantages of the closed-end frames, and the manner of suspending them in the hive avoids their faults, among which is, its inconvenience of handling by single frames.

I can remove a frame in any part of the brood-nest in this hive, with my naked fingers, without any prying or other force (after loosening the compressing screws), and return them with equal ease, without hearing the "bones" crack, as we do in returning other closed-end frames in a populous hive.

This frame is right for any depth, but you cannot reverse them. I once made them reversible, but soon found that, in the way I used them, the bees would build the combs solid in the frames, without reversing; and there is no other reason for reversing, as alternating secures all desirable ends.

I use the hives with two depths of frames, 8 inches inside for the full size, and 4½ inches for the double ones. They are exactly alike, except as to depth; and the small size has its frames suspended on a plain rabbet, as I do not expect to handle single frames much in this size. I use them large and small, in about the same way, and sometimes the two sizes together. I am as yet undecided as to which size is best, if but one was used; but I think I shall use the small size in the home bee-yard, and the large size in the out apiaries.

I do not claim anything new in this hive, only old things in new and improved ways. I am just finishing 300 hives, and 600 cases, for my own use the coming season, so it will be seen that I intend to get some honey, if there is any around.

With the editor's permission, in a future article, I will detail my way of using these hives, and handling my bees in these three ways, viz: with fair increase, with small increase, and without any increase.

I see that nearly all bee-keepers object to any kind of glass in supers. I shall offer no apology for the peep-hole in my hive. Others may remove a shade-board with its 15-pound stone every time they take a squint at the bees; but I will see all I need to know in ten hives, while they are uncovering one.

Mr. Taylor does *not* describe his management in the above, but promises it in another article. That is more like what was wanted—the key to the production of the "seven tons of honey in a poor season," would interest our readers much more than a description of the hive.

For all that we can discover, the hive is practically the same as other shallow hives, and has a wood and zinc slatted honey-board. It seems strange that he should have been using it for eight years, and yet at least two very similar ones have been invented and patented within the past three years.

This article is very appropriate under the heading of "Gleams of News."

Laying Workers.—Thos. M. Pierce, of Wickford, R. I., asks for information, and writes as follows:

Last fall I united 2 good colonies, and left the queens to settle their own claim; and this spring the hive contains a good, strong colony; but instead of a queen, a laying-worker. I do not know what to do. I have looked into all the books, etc., I have, and cannot make up my mind what to do. The thing is quite a conundrum to me. I am sure it is a laying-worker, as many cells contain three eggs, and the brood is in all frames, a few here and a few there. Young, small drones are running around on the comb, queen-cells are started, but the cells are never capped, as the grubs all die after a few days. All the capped brood in the worker-cells is rounded up like drone-brood, if anything more so.

The conundrum can be solved in about as good a way as any, by breaking up the colony, giving a frame or two to weak colonies to build them up. It would be difficult to get those bees to accept a queen while having these annoying pests—laying workers.

Nurserymen.—The Fourteenth Annual Meeting of the American Association of Nurserymen will begin at Chicago, Ills., June 5, 1889. Railroad tickets for the round trip, from any part of the United States and Canada, may be secured by any person, whether a nurseryman or not, at a rate of one-third fare for the return trip; a great opportunity for all who would like to visit the great metropolis of the West. Tickets are good for any train, going or returning; no crowd, no jam. Reduced rates are also secured at the Grand Pacific Hotel, Chicago, the head-quarters of the society.

This will be a notable gathering of distinguished nurserymen and horticulturists, and an interesting and instructive programme is offered. June 5 will be the most delightful season of the year for such an excursion—cool weather, delightful views, Nature adorned in her most attractive garments. For circular giving full particulars about securing reduced railroad fare, programme, etc., apply to Charles A. Green, Secretary, Rochester, N. Y.

Transferring Bees.—As many are now inquiring how to transfer bees from box-hives, we give the following from the *American Agriculturist* for May—just received:

A good bee-smoker is needed so that you can have full control of the bees. They should be smoked thoroughly before operations begin, and at frequent intervals before attempting to open the old hive. This will allow ample time for them to fill themselves with honey, which they never fail to do if thoroughly smoked. Turn the hive bottom side up, and with a cold chisel and hammer pry open and cut the nails from two sides of the hive. This will lay the combs bare, so that they may be reached conveniently. Lay the frame to receive the combs flat upon a board which has been previously guttered out one-half by one-half inches on every two inches of surface. This will allow a wooden needle to pass under the comb after it is fitted into the frame. By this means a cord of hard twine is drawn over the comb and around the entire frame and securely tied, spanning the frame every two inches. After the combs have all been removed, cut, fitted and tightly bound into the frames, place them carefully into the new frame hive and raise the old hive, which contains the majority of the bees. With a brush of soft material, or a stiff feather, gently remove the bees into the new hive, or to its entrance. In arranging the combs, place those containing the brood in the center, and see that the brood occupies a compact mass in the hive. In a day or two the bees will have fastened the combs in the frames, and will ultimately remove the twine fastening. They cannot do this if wooden strips or tin fastenings are used. Only combs that are straight should be used; fill the remainder of the frames with foundation, which I would recommend rather than crooked combs, but combs containing brood should all be used.

Making Comb Foundation.—F. C. Erkel, of Le Sueur, Minn., asks these questions:

I keep 50 colonies of bees, and desire to secure all the white honey possible (such as basswood and clover) in the comb, and to extract the dark and autumn-flower honey. I have over 200 empty combs, and 10 combs in each of my 50 Langstroth hives; the combs were built from starters, so that they are not as straight as they might be, and have some drone-comb in them. 1. With that number of colonies, would it pay to have a foundation-mill for my own use? 2. If I had a mill of my own, would it be advisable to melt up those combs and use full sheets with wired frames? 3. If I had to buy foundation, would it be advisable to melt up the poorest of those combs?

1. We do not think it would pay to fuss with and make foundation for 50 hives, when the prices of it, already made, are as low as at present.

2. We should not advise the melting up of any good combs—but the "crooked" and black ones should go to the melting pot—substituting comb foundation for them, wired or not, as you choose.

3. Our advice would be the same, no matter whether you had a "mill" or not.

A Nebraska Apiary.

The engraving on this page represents one of the many excellent apiaries found in the State of Nebraska—a State which is rapidly taking its place among those noted for its fine apicultural productions. The following is written by Mr. J. M. Yonng, the owner of the apiary shown in the illustration :

The photograph from which this engraving was made, is a very correct one, and I wish that I could show a better picture here ; but the engraver has overlooked, and has changed, things about somewhat, and from this fact the illustration is faulty.

I now have the entire apiary and buildings removed from the old stamping ground (at Rock Bluffs) to a new location, 1½ miles south of Plattsmouth. The hives are placed in their new location, as well as the building, in nearly the same way as they are seen in the engraving—in fact I have tried to make it about the same.

I hope some day to show a picture of my new location, as I have a very pretty site to work on ; and as I have already put on a title for the new location—"The Home of the Honey-Bees," we intend to make it the home of the bees for a great many colonies, at least as many as I can make profitable for one locality.

The large hives that are shown in the picture are the winter and summer chaff hives, the sides and ends of the lower story being packed with chaff when the hive is made. Since the first introduction of this hive, it has given excellent satisfaction in wintering.

The building in the background is the honey-house and work-shop combined. The upper part of the building is used principally for ripening extracted honey, the honey being packed in open vessels. The direct rays of the sun keep this part of the room of a heated temperature, and for ripening honey, I would desire nothing else better than this arrangement.

The engraver has put foliage upon the trees (which are fruit-trees), and makes it appear to the eye that the photograph was taken during the season when the leaves were on the trees; but it was taken during the fall, when all vegetation appeared winter-like.

Apiary of Mr. J. M. Young.

Chance for an American Girl.

The American girl may aspire to be Queen of England. Sir Edward Sullivan, who is a very serious Tory of the old Protectionist school, says so, and he is not to be confounded with Sir Arthur Sullivan, who sets Mr. Gilbert's nonsense romances to music. Prince Albert Victor, eldest son of the Prince of Wales, is 25, and his royal grandmother desires to see him married and settled ; but there seems to be no eligible Protestant bride for him on the Continent, and those unreasonable Radicals in Parliament will be certain to make themselves disagreeable when the question of settlements is raised in that body.

So the suggestion is offered in good faith by Sir Edward Sullivan, as appears from our cable letter, that he shall marry an American, and thereby promote an era of good fellowship between the two great branches of the English-speaking race. This is highly complimentary to the typical American girl, who may be pictured as blushing coyly at the novel idea.

Then there are doubtless millionaires by the score who stand ready to relieve an English Ministry of any and all financial embarrassments by dispensing entirely with Parliament votes in supply.—*New York Tribune.*

MAY.

The finches are singing,
The bright bees are humming,
The grasses are springing,
The Summer is coming,
For May is here.
With sunshine and shadow,
Refreshing and cheering,
How green is the meadow!
Where daisies appearing,
As stars, shine out clear.

The tree-tops are swaying,
With nests on their branches;
The rabbets a-playing,
Or sit on their haunches,
As striving to hear
The church bells' far pealing,
Now swelling, now sinking,
Through the wood, the stream stealing,
Seems joyously thinking
Glad Summer is here.—*Sel.*

QUERIES AND REPLIES.

How and When to Renew the Old Combs.

Written for the American Bee Journal

Query 631.—1. What is the best procedure for the renewal of old combs in hives which bees have occupied for 12 or 15 years? 2. When is the best time for such procedure?—Iowa.

1. Use full sheets of foundation. 2. Any time from April to September.—WILL M. BARNUM.

Cut them out before they are occupied with brood in the spring.—J. P. H. BROWN.

1. The Heddon method of transferring. 2. About swarming time.—C. H. DIBBERN.

1. Remove them and render them into wax. 2. In early spring.—J. M. HAMBAUGH.

1. Use sheets of foundation. 2. Any time, except during a good honey-flow.—MAHALA B. CHADDOCK.

Transfer about the usual swarming-time, *a la* Heddon; as described in my "Manual," on page 219.—A. J. COOK.

I have never had any combs too old in my apiary to be useful, and I have kept bees 20 years.—G. M. DOOLITTLE.

1. If you are satisfied that they *must* be renewed, cut them out and fill the frames with foundation. 2. After you get all the brood out, in June or July.—H. D. CUTTING.

I do not know that I fairly understand the question. 2. During fruit blossom, as a rule.—J. E. POND.

1. Melt the old combs into wax, and give frames entirely filled with foundation. 2. In the spring—perhaps about the time of apple-bloom.—MRS. L. HARRISON.

1. I do not know how to "renew" old combs. If it is desired to replace the old with the new ones, I should say that the best method would depend upon how surplus honey is secured. If to be comb honey on the contraction plan, and swarms are hived on empty frames with starters, and a queen-excluding honey-board is used, new combs will be secured. If the surplus is to be extracted honey, furnish the surplus frames with full sheets of foundation. 2. When securing surplus.—A. B. MASON.

I never renew them on account of age alone; but probably the best way to renew them is to melt them up, and replace with worker foundation.—C. C. MILLER.

1. I am not certain that they *ought* to be renewed. 2. If you are sure that they are worthless, select the time when they have the least honey and brood in, which would be in April or May.—EUGENE SECOR.

1. Take them out and replace them with new *worker* combs, or with comb foundation. But we would not remove them unless *very, very* old and thick. As long as the queen breeds in them, they are as good as new combs. 2. The best time is spring—April or May.—DADANT & SON.

1. If you must renew them, take out one or more at a time, as you can find them empty, and replace them by putting frames filled with foundation in the brood-nest as needed. 2. Such as you find empty, may be taken out at any time when bees can fly, but frames of foundation should only be put in when some honey is coming in.—R. L. TAYLOR.

1. My plan is to work out the old combs gradually at any time that it can be done with the least labor to myself, and disturbance to the labor of the bees. I sort out many poor combs in the spring, and many when making up nuclei for queen-rearing.—G. W. DEMAREE.

1. Drive or shake the bees upon foundation, and after the brood in the old combs has emerged, shake these new bees into the same hive with the others, and melt the combs into wax. 2. Any time when the combs have but little honey.—J. M. SHUCK.

1. Combs that have been occupied for 12 or 15 years do not need to be renewed. I would not care to use them more than 40 years, however. 2. If portions of them, from being moldy or from any other cause, become unfit for brood-rearing, they may be cut out at almost any time that may be convenient.—M. MAHIN.

1. Place them in the supers of hives, if they contain brood, till it hatches out; then extract the honey and melt up the combs. In renewing, take out alternate combs, and insert frames with full sheets of foundation till all the combs are renewed. 2. The above procedure may be carried out at any time in the season.—G. L. TINKER.

Exchange the frames of old combs (if they *must* be renewed) for frames filled with comb foundation. It can be done best in the spring, about the time of fruit-bloom.—THE EDITOR.

Central Michigan Convention.—W. A. Barnes, of DeWitt, Mich., the Secretary of the Association, sends the following report:

The Central Michigan Bee-Keepers' Association met in the Supreme Court Room on Wednesday, May 1, 1889, and the election of officers resulted as follows; President, Rev. J. H. Ashworth, of Lansing; Vice-Presidents, S. E. Vanetter, of Williamston, Miss Minnie Brindle, of Bath, and W. O. Wilson, of Okemos; Secretary, W. A. Barnes, and Treasurer, N. U. Goodnoe, of Lansing. The convention adjourned to meet with the State Bee-Keepers' Association next fall.

A Queer Hive.—Mr. E. L. Dickinson, of Central Point, Calif., writes to the Pacific *Rural Press* this item, under the above caption:

A very novel and curious bee-hive was discovered recently at Dutch Corners. It consisted of a straw-burning engine, which a swarm of bees had taken possession of as their home. Every attempt to dislodge them had failed. The engine was stored in an open shed, facing the road; hence it was very desirable to get rid of the bees.

The proprietor of the Dutch Corners' hotel, offered me the bees if I would take them. Accordingly I went at it, and in a few minutes had them safely hived in a box. I moved them 80 miles, and set them up. On being liberated they immediately went to work.

There were in the engine about 14 pounds of honey of a very fine flavor, and nearly pure white, from alfalfa, of which there were large fields near by. The means of capturing them was simply smoke and water. After capturing, I found the queen and clipped her wings, and all trouble was over.

CORRESPONDENCE.

BROOD-CHAMBERS.

Size of the Brood-Chamber—or Large vs. Small Hives.

Written for the American Bee Journal

BY CHAS. DADANT.

I desire to review the criticism written by Mr. Hutchinson, in the April number of the *Bee-Keepers' Review*, on Chapter IV of the "Langstroth Revised."

I write this article for the AMERICAN BEE JOURNAL instead of sending it to Mr. Hutchinson, because he refused to publish an answer that I sent him about one year ago. As my present criticism will bear on the same question—"the size of the brood-chamber"—I do not wish to expose myself to the same (to me) unusual mortification.

According to my notions, the publisher of a periodical devoted to improvements is bound to give, with the largest possible impartiality, both sides of every question. When he favors the writers whose views are identical with his own, by refusing or shortening the articles opposed to his ideas, or when he takes only a few words from a paragraph, to condemn what his opponent says, he is deficient in impartiality, which, to my mind, is the first quality indispensable to a reliable editor.

In his review of this chapter of our book, Mr. Hutchinson, after writing that, "through the chapter runs a vein of opposition to small hives," has omitted to quote several points given in our plea in favor of large ones—in fact he discarded every one of them!

For instance, he quotes thus from our book: "The harvest is in proportion to the number of bees in the hive;" and he starts from this member or phrase, to assert that it is of no matter whether the same number of bees is in one or in more hives. He does not copy one word on the causes of our preference, as given in the same paragraph, which reads thus:

"309. As the harvest of honey is always in proportion to the number of bees in the hive, and as a large colony requires no more labor from the apiarist than a small one, the hive should afford the queen sufficient space to deposit all the eggs which she is able to lay during 21 days, the average time for an egg to be transformed into a worker. Besides, it should contain a certain amount of food, honey and pollen."

The part of the paragraph omitted implies that if we have 100,000 bees, on the average, in one of our large hives, or one million in ten, we will get as much honey, with far less work than if the same number of bees is divided into twenty small colonies. As such theorem cannot be disputed, Mr. Hutchinson has deemed prudent not to mention it.

A little further on he writes that, "a large hive is more expensive than a small one." Nobody will deny it. But, if our large hive contains twice as many bees as his small one, our outlay is smaller, since our hive costs less than two small ones; even without putting in account the cost of queens, for he affirms "gravely" that they cost practically nothing to the bee-keeper; and without reckoning the extra number of empty hives required to receive the more numerous swarms that his small hives will not fail to give.

He does not contest that bees in large hives swarm less than in small ones; but he adds that they will swarm enough to need an attendant. How does he know that such is the fact? Did he ever try our system and our capacious brood-chamber? No! Never! For more than 15 years we have dispensed with watching the bees of our home apiary, numbering from 80 to 100 colonies. As the yearly number of natural swarms does not exceed two or three, the expense of such watching would be far above the profit.

He continues: "If the hives are too large, some of the queens will fail to fill all the combs with brood, leaving from $1.00 to $2.00 worth of honey in the outside combs as dead capital." He passes directly over our anticipated answer to this objection, in the following paragraph, 310, in which he did not fail to read, "This space must allow of contraction, according to the needs of the colony, by what is called 'movable division-boards.'" Besides, I could add that while we can reduce the capacity of our large hive, he cannot increase the size of his small one.

Mr. Hutchinson seems to be opposed to a great prolificness in queens, for he avoided to mention that, according to our idea, one of the qualities of large brood-chambers is to enable the bee-keeper to discern which of his queens are the most prolific, to be selected as breeders, to improve his bees; while such selection is impossible with small hives.

He adds that "he is surprised to see us assert that the honey-board has been discarded of late years." What we wrote is far from being so peremptory, for we said this:

"352. The oil-cloth, or enameled cloth, first applied to hive purposes by R. Bickford, is used over the brood-frames in the spring. It fits closely, concentrates the heat, and can be removed without jar or effort. When the surplus arrangement, or upper story, is put on, this cloth is removed and placed at the top. All apiarists, or nearly all, who have tried the oil-cloth and honey-board simultaneously, have discarded the latter forever, except in some cases of comb-honey production, when a skeleton honey-board is used between stories."

At last he writes: "In closing the chapter on hives, beginners are cautioned to be very careful in buying patent hives. Why, we ask, any more caution when investing in a patent hive, than in one unpatented?" I wonder why Mr. Hutchinson asks for an answer to this question. He can read it in the same paragraph, of which he took, as before, just what he intended to condemn, avoiding to quote our motives, for we wrote as follows:

"358. More than 800 patents on bee-hives and implements have been issued in the United States since January, 1873. Not ten of these have proved to be of any use to bee-keepers. The mention of this fact will suffice to show the small value of these 790 patents, and the loss incurred by those who have bought them before they were able to judge of their merits."

I may add that the buyer of a patent has to pay a royalty for the right of use, and that hundreds of beginners were victimized by patent venders, in paying for worthless implements which sometimes proved to be even real nuisances.

To sum up the criticism of Mr. Hutchinson: In perusing it, nobody could form a correct idea of our views, since it does not contain a word on the causes of our preference for large hives; although we wrote that it is based on a successful practice of more than twenty years, with several hundred colonies in different sized hives, used in producing comb and extracted honey; and although we quote reports from several noted bee-keepers of Europe, who praise the large hives, and have discarded their small ones, after serious comparative experiments.

Our friends, Newman and Root, can say that for years, the hives which are the most recommended by the editors, and the most advertised by the hive manufacturers, in the bee-papers published in the French language, have very large brood-chambers; some of them, such as the Layens, having it even more capacious than ours; while none of our opponents, Mr. Hutchinson himself included, can bring anything forward but their preconceived ideas.

We would be glad to see our book reviewed and criticized, since controversies would help us in redressing

errors ; as we do not consider ourselves infallible, we are ever open to conviction ; but we do not think we are too exacting in asking for honest impartiality in the criticisms.

Hamilton, Ills.

DRONES.

The Importance of Rearing Good Drones, etc.

Written for the American Bee Journal

BY F. F. GRAVES.

The first honey was brought in today. The season is very early, the trees are leaving out, and the red maple is now fairly in bloom, and is secreting a little honey.

It has been said that the willows produce some honey, but I have never been able to find any in the flower, or see evidence of it in the hive. It affords quantities of good pollen, and the bees have brought in so much the past week, that I have been obliged to take out one or two frames from each hive, many being so full that they are unfit for use, and can only be melted up. This has been my experience for the past ten years ; and if artificial pollen is necessary anywhere, it certainly is not in this locality.

For the past three or four weeks the weather has been very warm—no cold nights, and not a day for a month but what the bees have been out, consequently they are breeding very fast, and it is time that we are thinking, or doing, something about the strain of bees that we wish to breed from. We all know that race will tell, and the importation of queens into our apiaries has made a wonderful improvement in the prolificness, storing-qualities and fighting-propensities of our bees ; and those who do not care to purchase queens to supersede old ones, and to introduce into new swarms, should begin at once to breed from the best they have, as the male has as much or more to do with the disposition or traits of the progeny as the female.

We should commence by selecting the most vigorous and desirable young mothers, and from them rear all the drones for the whole apiary. This can be done by giving such an one a full hive of bees. A good and safe way to do this is to give them, from any hive which can spare them, a few frames of hatching brood ; then in the centre of the hive put one or two empty frames, in or near the middle of which are a few cells of drone-comb (anywhere from 100 to 200), and when the cells are capped over, the frames should be given to such colonies as you do not wish to rear drones from, and the place in the first hive supplied with similar combs, until every hive has a supply of drones.

If at any time drone-eggs are found in a hive, it will be safe to take them away and give drone-brood in any stage, from the selected queen. To rear drones is a natural propensity, but any colony will be satisfied with its quota, let it come from what source it may. If this is practiced, and every hive examined once in two or three weeks, and the heads shaved off from all drone-brood not wanted, and the frames having scattered brood taken out and put into a hive, the entrance of which is protected by a drone-trap, then they can be disposed of as they come out. In this way we can have pure and vigorous males.

We have not heretofore paid enough attention to the most important part of breeding. Many of our apiarists are also poultry fanciers, who have gained a reputation as successful breeders ; and I think that they all are more particular about the points of the male bird than they are of the mother. Why should we not be as particular about the character of the drone, as of the queen ? It is of much greater importance, for the queen is reared under the swarming impulse ; the egg is laid by a mother that is able to fill the hive with brood, and lead the swarm to seek a new home, while the drone may be the last egg laid by a decrepit old queen who has deposited her fifteen hundred thousand, and now has not enough energy or life to produce a fertilized egg, but is just laying from force of habit.

A queen is a queen only by accident; any one of the two or three thousand eggs that a queen lays in a day, may be made into a queen if circumstances require it ; the difference only is a larger cell, and more stimulating and nutritious food. If that will change a worker into a queen, give her more strength, greater endurance, and also a lease of life, not of weeks, but of years—if all this is done by care and condition, why is not the drone equally affected ?

Many of the drones that fly about the apiary were reared in colonies that were not able to take care of themselves, and were dying faster than the young bees hatched to take their places. In such hives the drone could not receive sufficient warmth in germination, proper care, nor enough of the requisite food to make a vigorous male, and his progeny would certainly suffer and be deficient of the qualities that make the best bees.

Waterville, Me., April 30, 1889.

SPRING.

The Management of Bees in the Spring.

Read at the Erie Co. Farmers' Institute

BY O. L. HERSHISER.

At no season of the year do bees need more careful management than during the first warm days of spring, and until they can gather honey from the fields. Losses are not usually heavy during the winter months, but from the latter part of March until fruit trees bloom, the fatality is sometimes great. It is not a difficult matter to winter bees, but to "spring" them successfully often requires much thoughtful attention to their needs and condition.

The first requisite is plenty of food. If this matter has not been looked to in the preceding autumn, preparatory to wintering, it should be on the first warm day of spring. Springs following years of failure of the honey crop, and especially failure of fall honey, are usually springs of heavy losses from starvation and dwindling. If each colony is provided with from 25 to 35 pounds of stores in the fall, they will in nearly every case have abundance to last until the flowers produce honey again.

A normal colony of bees will consume from 6 to 12 pounds of food from fall till April 1, and from this time till fruit trees bloom, about as much more. If they consume more than this, they are not in a normal condition, and are liable to perish. The less honey a colony consumes during the winter, the better will be its condition in the spring.

Feeding Bees in the Spring.

If bees are out of food, empty combs in the hive should be replaced by combs containing honey. If these are not accessible, syrup made from the best quality of granulated sugar may be fed. In feeding, be careful to allow as little loss of heat from the hive as possible. A strong colony will store several pounds of food a day.

A bee-feeder is desirable in feeding syrup. Some bee-keepers prefer to feed by replacing empty combs in the hive by combs containing sugar syrup. The combs are filled by laying them on a board and pouring the syrup into the cells with a dipper. They should be hung in the natural position and allowed to drip before placing in the hive. Feeding should always be done in the evening to guard against robbing.

If it is desirable to stimulate bees to rapid brood-rearing, a small amount should be fed daily, and the feeding

prolonged till the flowers yield honey. If bees have plenty of capped stores, brood-rearing can be greatly augmented by uncapping a part of the honey and place it back of a division-board. As often as the bees restore the honey, the operation may be repeated, until the bees can gather honey from the flowers.

Cleansing the Hives.

If many bees have died in the hive during the winter, they should be removed; this is easily accomplished if hives have loose bottom-boards. Get an extra bottom-board and exchange it for the bottom-board of the next hive, and so on. As nearly all the dead bees have fallen to the bottom-board, by scraping the latter you have pretty thoroughly cleansed the hive. This operation offers very slight disturbance to the bees, and it is but a moment's work to lift the hive and exchange bottom-boards.

If the hives have tight bottom-boards, or are in packing-cases, a part of the combs containing the fewest bees should be lifted out, and this portion of the hive cleansed; then move the remaining combs and bees to the clean side of the hive, and finish removing the dead bees, after which the combs first removed may be replaced.

If the hives are of the same pattern, and look alike, so that a change of hives will not confuse the bees, they may be cleansed by transferring the first colony into a clean hive, by simply lifting the combs and bees into the latter, and placing it in the position of the first hive; then scrape the hive just emptied, and transfer the next colony into it, and so on.

It is not always necessary to go through the operation of cleaning all the hives. If there are a few dead bees, the better plan is to allow each colony to clean its own hive. In the spring following a mild winter, during which the bees have had frequent flights, the hives will seldom contain many dead bees.

When there is an abundant crop of late fall honey, some colonies will store so much in the brood-chamber as to leave insufficient room for brood-rearing. Colonies left in this condition cannot increase rapidly in numerical strength. If the hive is overburdened with honey, some of the full combs should be exchanged for empty ones. Then by uncapping some of the remaining full combs, the honey will be rapidly transformed into brood. Uncapping the honey seems to create the impression among the bees that there is great demand for labor, and they consequently rear young bees as rapidly as possible to meet this apparent need. Thus these otherwise superfluous stores can be converted into full and strong colonies to gather the white clover and linden harvests when they come.

The matter of reducing the stores to the proper amount, should be looked to in the fall, and all honey, not needed for wintering, extracted. No more than 30 pounds of honey per colony should be left for wintering.

Queenless Colonies.

Very often colonies become queenless during the winter. As a rule it is poor economy to purchase queens early in the spring to re-queen them. If the colony is strong it may pay to re-queen. Queens in April are quite valuable, and usually cost about as much as an ordinary queenless colony is worth. If the queenless colony is strong, the better way would be to unite it with the weakest colony that has a good queen. The queen begins laying from the middle to the last of February, and the entire absence of eggs or larvæ in a colony after the middle of March or first of April is sufficient evidence that they are queenless, or that the queen is worthless.

Queenless colonies are liable to be robbed by other bees during the first warm days of spring. The bees seem to lose courage by the loss of their queen, and submit to the robbers with little resistance. Robbing can be easily detected by the great number of bees flying to and from the hive that is being robbed, and by the fine bits of honey-comb and rubbish about the entrance of the latter.

Robbing—Uniting Colonies.

When it is found that a colony is being robbed, the entrance to the hive should be closed for 10 or 15 minutes, to allow the robbers to secure their load of honey, and then opened to allow them to fly away with it. The robber bees that have collected to enter the hive, may be kept away with smoke, while the robbers that have been confined are leaving. After the robbers are out, the entrance should be closed until evening, and then, if queenless, the bees united with another colony.

In uniting, reduce the number of combs in the colony with which you wish to unite the robbed colony, and remove the remaining combs and bees to one side of the hive, and confine them there with a division-board. Place the robbed bees in the remaining space in the hive on two or three combs containing sufficient honey to last them two or three days. All means of passage between the two divisions of the hive should be closed for two or three days, and during this time the robbed bees should not be allowed to fly.

After this confinement they will go together with little or no fighting, and very few bees will be lost by trying to find their old home. They may be brought together by lifting out the division-board and properly arranging the combs. They can also be united by drumming both colonies for ten minutes, keeping the entrance closed; this frightens them, and they fill themselves with honey, when they lose all disposition to fight. This is probably the better way, if the hives are alike, and the two colonies to be united are side by side. But if unlike, and some distance apart, the former method is the best.

Each colony should be confined in space according to its numerical strength. Remove empty combs and use a division-board to confine the bees to the proper space. They should have no more combs than they can cover in moderate spring weather.

In handling bees at this season of the year, care should be exercised that they do not "ball" and kill the queen. "Balling" the queen is a very singular and annoying peculiarity; the bees seem to blame the queen for any disturbance in the home, and often try to kill her when the hive is opened for manipulation. If you notice a little ball of bees about an inch or less in diameter, tightly clustered, you may be sure the queen is in the centre of it, and in danger of being stung or smothered. Get the bees away from the queen as soon as possible, by smoking or throwing the "ball" into water. When the queen is secured, she should be caged in the colony for 48 hours, when she may be safely liberated.

Bees should be manipulated as little as possible. Sufficient food to last until fruit-trees bloom in the spring should be provided in the fall, so that no manipulation of the hive will be necessary until settled warm weather in the spring.

Bees will generally take care of themselves in the winter, if well prepared in the preceding autumn; but a few hours attention in the spring is well spent time, and may result in saving good colonies from starvation and dwindling, so that a few weeks later they will yield a handsome profit.

Big Tree Corners, N. Y.

BASSWOOD.

Wholesale Destruction of the Linden or Basswood Trees.

Written for the American Bee Journal

BY D. MILLARD.

The following paragraph was taken from the news items of a late issue of a Michigan newspaper :

A. W. Slayton, of Tecumseh, the basswood lumber king, has now so big a business that he will have to travel 12,000 miles during 1889 to look after it. He has sixty mills, which are cutting basswood in 29 counties, and his freight bills run in the neighborhood of $10,000 a year.

This shows conclusively that it is not the poor season alone that is making such inroads upon our surplus honey crop. Within the last 18 months, over 100 linden trees have been cut within easy reach of my bees. I have kept bees the greater portion of the time for over 40 years, and I have ever observed this, that whenever my bees were in anything like a fair condition, and with a good flow of nectar from the lindens, I never failed to get a good crop of surplus honey.

White clover usually furnishes a surplus, but a good yield from the lindens always insured me a full crop of this most beautiful and best of honey. I fear that unless something can be done to check the wholesale destruction of this most beautiful and useful of trees, that the profits of bee-keeping will become lessened to an extent that will cause many to abandon the pursuit.

Planting for Honey.

Much has been said and written of late, in regard to planting for honey ; but I am thoroughly convinced that it never will pay to plant for honey alone. Buckwheat, which has a value aside from its nectar, pays well in favorable seasons. Mint is extensively raised in this vicinity, and pays well for the oil extracted therefrom. My bees worked on it very busily for some time last fall, but it seems to yield nectar very sparingly, and of a quality and color about identical with that of catnip. The best thing to do, I think, is to

Plant Linden Trees.

Laws have been enacted by many of the Northern States, with a view to the encouragement of tree-planting—not only on private grounds, but along the public thoroughfares, parks, etc.

In this State, owners of real estate are allowed to apply a portion of their highway tax in setting trees by the roadside, but I regret to say that very few embrace this opportunity to thus erect living monuments to their memory, and further add to the beauty of the country and the enjoyment of the coming generations. If they would but do so, and but one-fourth of the trees thus set out and properly cared for were lindens, it would be but a few years ere this country might be truly a land flowing with "milk and *honey*."

If there is any profit in setting out trees for shade, there would certainly be a great profit in growing those that would yield honey as profusely as the lindens. They flourish best on low, rich soil, but will grow on almost any upland. If planted thickly in groves or with other timber, they grow slim, forming excellent timber ; but if isolated, they branch out and become more stocky, and make beautiful shade-trees. The trunks furnish a nice white lumber that is of great value for manufacturing purposes.

The leaves and tender branches are readily eaten by any kind of farm stock, and as a honey-producing tree it has no equal. I have a row of them growing on two sides of my farm, and also several hundred in a nursery, nearly all of which blossomed the past season at a heighth of from 4 to 5 feet, being six years from the seed.

How to Grow Lindens.

To produce them in large quantities, the seed should be gathered in the fall and dried ; then packed in boxes with alternate layers of sand, and burried just below the reach of frost. Plant in shallow drills in early spring, and give a light mulching to retain the moisture; keep the ground mellow and free from weeds, and you will get from 4 to 6 inches of growth the first season.

The following spring they should be transplanted into rows 18 inches apart, and 4 feet between the rows, and kept well cultivated throughout the entire season. The next spring each alternate shoot should be removed and placed 3 feet apart in rows, and 4 feet between the rows, and kept well cultivated during the forepart of the season ; later give a mulching of partially rotted straw to retain the moisture, and keep down the weeds. At the end of the fourth year, the larger ones will do to take up and permanently re-set.

If only a few are wanted they can sometimes be found in the open timber where stock have not been allowed to run, as stock of any kind will keep them grazed down close to the ground. These can be transplanted the same as those grown from the seed.

I have no faith in trees grown from shoots, slips, or cuttings ; they seldom make good trees, and are short-lived at best. Abundant evidence of this fact exists in apple orchards throughout the country. Seedling trees are frequently seen bearing heavy loads of fruit at any age that those grown from root-grafts would have been long consigned to the brush pile. The re-setting from time to time causes them to grow more stocky, also more thickly rooted and hardy, enabling them to better withstand the change of final setting. The tops should be cut back and evened up to keep them in good shape, and assist in making them more stocky.

How to Set Out Lindens.

This can be done at any time after they have shed their leaves in the fall, but early spring is much to be preferred. Prepare the ground by plowing and cultivating it the season previous. Never set them out in hard ground or sod, and leave them to take care of themselves. They should be set in rows from 2 to 3 rods distant from each other, and cultivated for at least two seasons, after which the ground may be allowed to grass over.

Start Lindens by the Roadside.

First, it is presumed that there is no risk of damage from stock, as they should never be allowed to run at large in any civilized community. Next select a place where the adjoining field is to be used to grow corn the next season. Remove the old fence, plow and fit the ground as for a crop ; the following spring set out the trees 7 feet from the road line, inside the highway. Plant corn alongside, and cultivate all together for the season.

The next season plant some root crop on either side of the row of trees, while the adjoining ground may be sown to oats or wheat. The third season, make the ground by the trees smooth by harrowing, and seed with Alsike clover, with about one-eighth part Kentucky blue-grass, or common June grass. This, in time, will form a sod after the Alsike runs out.

Next build a good iron fence on the road line, and you have made an improvement that will add greatly to the value of your farm, an everlasting beauty to the highway, and a source of profit through employment for your bees.

Mendon, Mich.

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary. — R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

May 21.—Northern Illinois, at Pecatonica, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.

Dec. 4, 6.—International, at Brantford, Ont., Canada.
K. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Rolling in the Honey and Pollen.—E. E. Ewing, Rising Sun, Md., on May 6, 1889, says:

I have had two Carniolan swarms—one on May 4, and one on May 5. They were ready to swarm a week before they did, having capped queen-cells several days ago, and young queens ready to come out; but the weather was cold and windy. To-day it is fine, and the bees are rolling in honey and pollen. Apple-trees are in full bloom. The hybrids are only getting started to work fairly.

Early White Clover Bloom.—W. J. Cullinan, Quincy, Ills., on May 2, 1889, writes:

Fruit-trees have been blooming in this locality for about two weeks, but owing to the dry, cool weather prevailing, bees have not derived the benefit that they should therefrom. White clover began blooming here on April 28, the earliest date at which I ever heard of its blooming in this latitude. Now for warm, showery weather, and we still may be able to send in a "bright side" report a couple of months hence, as a sort of diversion from the gloomy ones of the last two years. Bees, where properly prepared, have wintered well.

Colonies in Good Condition.—Jos. L. Flint, Marion, Iowa, on April 23, 1889, writes:

My 5 colonies of bees came out of the cellar on March 25, all strong and in good condition, with plenty of stores and some sealed brood. They have been carrying pollen every warm day since then, and some days they carried it so fast that they dropped on the alighting-board by the half dozen, so that they could not be counted. We have had 1½ inches of rainfall, so that white clover is "booming," of which there is an abundance. The fruit-bnds do not seem to be hurt by the winter frosts.

Working on Fruit-Bloom.—N. Staininger, Tipton, Iowa, on May 6, 1889, writes:

I have had no loss for three years in wintering. My bees came out in splendid condition this spring. I put them out about March 20. A few colonies were put in on Nov. 5, and taken out in April, being in 157 days; they lost 13 pounds each in weight, and came out in fine condition, there being not a spoonful of dead bees among them. I never saw bees so strong at this time of the year. To-day they were lying out like they do in the summer. They are doing nicely on fruit-bloom. The prospects are very good for a grand honey-season. I had plenty of drones flying in April, and I expect some swarms soon.

Good Crop Expected.—E. M. Showers, Pine Bluff, Wis., on April 22, 1889, says:

Never have my bees come through the winter better than the past winter. I had 22 colonies in the fall, and they are all right this spring. I wintered 14 colonies in the cellar, and 8 outside, in chaff hives, and the latter wintered the best. There are not many bees in this place. White clover does not look very promising, but there is a great deal of Alsike in this neighborhood, so I expect a good crop of honey this year.

Bees Doing Remarkably Well.—A. S. Crotzer, Lena, Ills., on May 7, 1889, says:

One of my neighbors had a fine swarm of bees yesterday. How is that for Northern Illinois? I have never seen bees do so well at this time of the year as they are doing now.

[That is good enough. Yes, every indication now points to the best honey-season for many years past.—ED.]

The New Bee-Veil.—Mrs. L. Harrison, Peoria, Ills., writes thus concerning the "New Bee-Veil:"

"What is that, Mrs. Harrison, that you have just received by mail—that square box?" asked a lady visitor who was contemplating bee-culture. "A bee-veil," I replied; and she watched me button the springs on the neck-band, and adjust the veil. When it was completed, I put it over her head—"O, my," she said, "I like this so much better than that wire hat you put on me in the honey-house; it is so light and airy." How crestfallen I was, to hear my wire gauze hat being cast in the "shade." It has so long been my joy and pride, and the more fun that was made of it, the more dearly I loved it; but now Thomas G. Newman & Son have eclipsed it entirely. "Light and airy" it certainly is, and a cool head-cap can be worn within it, when the mercury plays around the hundred in the shade. My objection to veils has been, that I could not protect my neck and chin, so but that bees could sting through; but these steel bows keep the veil so far away, that bees, mosquitoes and gnats are outwitted.

Only One Colony Lost.—C. H. Stordock, Durand, Ills., on April 17, 1889, says:

I finished carrying out my bees yesterday; and of the 102 colonies put into winter quarters, I took out 101 in good condition, though I may find a few queenless ones.

New Honey, etc.—John Boerstler, Vashon, Wash. Ter., on April 29, 1889, says:

I think that bees will do well here this year. I have had 3 swarms from one colony already, one on April 19, one on April 22, and one on April 26; also 2 pounds of new honey from the same colony.

Dry Weather, etc.—Wm. B. Ray, Alaska, Wis., on May 6, 1889, says:

My bees have wintered well, although the month of April was cold and windy, and the first four days of May was cold; but the bees are just booming now, although it is very dry. We have had very little rain within two months, and no snow to speak of. The last season was not as good for honey as the season before, and if we do not get rain soon, our prospects for this season will not be very good.

Evolution.—Dr. C. C. Miller writes thus concerning the discussion of this subject:

Mr. Editor, with your permission, I will allow Mr. Latham's article on page 282 to end the controversy between us. If I ever happen around at Cumberland, Me., I may ask him to explain some things to me; but I do not believe it is best to take any more room in the AMERICAN BEE JOURNAL. All the same, I hope he will rear the best kind of queens.

Early Swarming—Storing the Honey.—J. M. Young, Plattsmouth, Nebr, on May 3, 1889, writes:

The past winter has been so mild in Nebraska that bees have come through safely, and colonies are very strong in bees. I had the first natural swarm to-day. Who can report earlier swarming than this,in this latitude? My bees since my removal have been doing finely, and are storing considerable honey—sufficient to keep brood-rearing under good headway, and the hives are now full of brood. There are several large orchards near, from which the bees are getting their honey. The fruit bloom is good.

Good Prospects for 1889.—Frank A. Eaton, Bluffton, O., on May 4, 1889, says:

Bees are doing finely here, and I can report my first swarm—a fine prime Italian—this morning. Plenty of drones are flying. Prospects are good for a fine crop of honey.

Foggy Weather, etc.—Mr. Levi Reichard, Ellison Bay, Wis., on May 1, 1889, says:

I lost 3 colonies the past winter, and saved 4. We had a very poor season in 1888, and now there is so much foggy weather that the bees cannot fly much, but when they can fly, they are very busy on May flowers, willow and poplar, which abound here. The trees are not yet in leaf, but the buds are just ready to burst open.

Old Colonies of Bees, etc.—J. S. Barb, Bristolville, O., on May 3, 1889, writes:

Bees have not wintered the best throughout this vicinity—lack of honey being the main cause, and so much warm weather during the forepart of the winter, another cause, as the bees consumed a good deal more honey than they otherwise would. The last was a very poor honey season here, as it was too wet, and the two seasons before that were too dry. The prospect for a good honey crop the coming season is very good, as there is an abundance of white clover, and considerable Alsike clover raised; also, there is much basswood here, which will help the bees a little.

Some three or four years ago I wrote about an old colony of bees that I have in a very large box-hive, which I called the "Old Pioneer." Well, this colony is still alive, and in good condition. It was put into this hive on June 20, 1870, and has stood all the hard winters that we have had since then. It is from a stock of bees that was brought on this place by my father in 1836. It has stood close to the wood-pile where we haul, cut, and split wood every winter. I have an old log gum that was brought to this farm with a swarm of bees in it, when my grandfather, Gabriel Barb, moved here, in 1821. My uncle, Mr. Sager, has a few colonies of bees that are of a stock of bees that were brought on the farm where he now lives, by his father, over 80 years ago.

I have a lot of frames of comb in good condition; would it be a good plan to hive swarms on them? If so, how many should I use for each swarm? How soon should I put sections on after hiving the swarm?

[You can use the old combs if they are in good condition for swarms—but we prefer to use comb foundation, and think nothing would be gained by using the old combs. Melt them up for the wax.—Ed.]

Bees Wintered Poorly.—B. W. Peck, Richmond Centre, O., on May 4, 1889, writes:

I commenced the spring of 1888 with 45 colonies, increased them to 55, and took about 1,000 pounds of honey in one-pound sections. I have usually been successful in wintering bees, but on account of long confinement (from early in November until March 4) and black, inferior stores, I have lost 16 colonies out of the 55, leaving 39, and most of them are now in good condition. I expect a good honey season, and hope to make up my losses; I will try and do better next winter. Bees in this vicinity have wintered poorly; but 5 or 6 miles south of this place, bees wintered well.

Bees Doing Well in Texas.—A. W. Lamkin, Cotulla, Tex., on May 7, 1889, writes:

Bees here are doing well for the chance they have. I notice that a great many bee-keepers are trying the improved hive here; heretofore we have generally used dry-goods boxes, or gums cut from hollow-trees; or more frequently, just cut a bee-tree, get what honey that may be stored therein, and leave the bees to shift for themselves. This is a very thinly settled country, and few persons are trying to improve their bees. Those that have given their bees any attention, seem to do well with them. On April 27, I extracted from two hives (the property of Mr. D. M. Levels). I only extracted the top story of each (18 frames), and got 100 pounds of nice white honey. I have had quite a nice time this spring transferring about 30 colonies from dry-goods boxes—some of them had been in the boxes for three and four years; in some the comb had fallen down, and had lain in the box for a year or more. The outlook for honey here this year is good; grass and crops of all kinds look well, and all kinds of stock are fat.

Bees Doing Finely.—Dr. J. M. Hicks, Indianapolis, Ind., on May 4, 1889, writes:

Bees are doing finely in my new location. The State apiary has had two new swarms. The bees all wintered well, having lost none except by two-legged thieves, who relieved me of two of my best colonies during the winter, at my old home in Battle Ground, Ind. Honey is in good demand in my home trade here.

An Early-Reared Queen.—S. D. Haskin, Waterville, Minn., on May 7, 1889, says:

Tally one for Minnesota; for I have reared a queen this spring, which, on the first day of this month, was laying worker-eggs, all in good order, and bountifully. I think that the fertilization must have been by a drone reared in a worker-cell, for I had noticed a very few such (perhaps a half dozen) in one hive, and no other drones anywhere.

Carex or Sedge Grass.—J. M. Doudna, Alexandria, Minn., on April 27, 1889, writes:

Will you please name the sample of native grass that I send? It grows in the timber-lands, and yields a great amount of pollen; and blooms just after the willows and soft maples. Bees are in fine condition. I never had them winter better; most of them have from 5 to 8 frames of brood. They got the first pollen on April 6, from hazel. Last year the willows did not bloom until May 10.

The above was referred to Clarence M. Weed, of the Ohio Agricultural Experiment Station, who replies thus:

The "native grass" is a sedge of the genus *Carex*, and has been identified by Prof. L. H. Bailey, of Cornell University (our best authority on this group), as *Carex Pennsylvanica*.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,

PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Doré, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:

This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religions sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the lettiug down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amouut can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white 1-lbs., 14@15c. Market is dull and lower, but not overstocked. Demand slow.
BEESWAX.—22@23c.
Apr. 30. M. H. HUNT, Bell Branch, Mich.

KANSAS CITY.

HONEY.—We quote: White 1-lbs. 15@18c.; dark, 10@12c.; California white 2-lbs., 11@12c.; amber, 10@11c. Extracted, white, 7@8c.; dark, 5@6c. Our market is in good condition for the new crop.
BEESWAX.—20c.
May 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Extracted, in barrels, 6½@6¾. Excellent demand for clear, bright in barrels.
BEESWAX.—22c. for prime.
May 4. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX.—22c. R. A. BURNETT,
Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 18@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.
Apr. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNAT

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

THE AMERICAN BEE JOURNAL
CIRCULATES
ALL OVER THE WORLD
PUBLISHED BY
THOS. G. NEWMAN & SON,
CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXV. May 25, 1889. No. 21.

EDITORIAL BUZZINGS.

We have Received the annual report of the Experiment Station of the College of Agriculture, of the University of Minnesota, at St. Anthony Park, Ramsey Co., Minn. This is the institution now presided over by Prof. N. W. McLain, who is the professor in charge, and the director of the Station.

A Correspondent in Texas says: "I have 10 colonies of Cyprian bees crossed with hybrids, which make very vicious bees; at times they are almost unmanageable, but they are excellent honey-gatherers. What is the best plan of subduing them? I dislike to use tobacco smoke." We reply: To give them an Italian queen is the best advice we *can* give. We have no use for vicious hybrids, and there can be no excuse for crossing Cyprians with hybrids. It is a very dangerous proceeding, and is damaging to the pursuit. To subdue them is almost an impossibility.

Dragging Out the Brood.—A correspondent writes us that his bees are dragging out brood, and asks what to do to stop it. They must be short of stores. G. M. Doolittle, in the *Rural Home*, writes thus about the necessity of stores in the hives:

To secure the best results in brood-rearing, it should be known that each colony has honey enough to last them at least two weeks ahead, never letting them get nearer out than this. When a prospect of starvation in the near future confronts a colony, they always curtail brood-rearing so as to save their stores if possible till the flowers yield honey. If there is no danger of their supply of stores giving out, they carry on brood-rearing as fast as the weather will permit.

Secrets of Bee-Keeping.—On page 259 we noticed a new claimant for public favor, who proposed to send the "Secrets of Bee-Keeping" for a "nickel and a dime" sent to his address within two miles of the office of the AMERICAN BEE JOURNAL.

Since then the bee-periodicals have been after him in these words. The first is from *Gleanings*:

A "FISH STORY" AND A BAIT FOR NOVICES.—For several days back, correspondents have been forwarding on to us circulars from F. Andrews, Chicago. The circular bears the stamp of a "fish story." It advertises a new hive that will prevent swarming, that will set every idle bee to work, and that will store *twice* as much honey as any other hive made. Mr. A. further claims that it will cost nothing to keep bees, as they feed themselves; that a single colony will net from $25 00 to $60.00 per season. It closes up by offering to sell a book, entitled, "Secrets of Bee-Keeping," for 15 cents.

Bro. Newman, of the AMERICAN BEE JOURNAL, of course, was prompt to find out whether there was any such individual. In his last issue he says they have made four trips to the address of Mr. Andrews, but that he was "out" each time. A woman in an adjoining room said he was there only a few minutes each day, and that he expected to make a trip to California in May. Mr. Newman cracks his editorial whip over Mr. Andrews' shoulders in his following characteristic way. He says:

"It is useless for *us* to caution any one, for *our* readers do not send 'a nickel and a dime' for any 'secrets' of bee-keeping. They know better. It is the 'novices' he is after. The circulars seem to have been sent to postmasters, and by them distributed into the 'boxes,' to catch the unwary, and many $3.00 and 'nickels and dimes' for Mr. Andrews to go on a 'trip around the world.'"

P. S.—Since the above was in type, we have the following from friend Newman:

FRIEND ROOT:—After some six special trips to Mr. Andrews' advertised place, I have got a copy of his pamphlet, and mail it to you to-day. His hive is a Mitchell, and the extractor a McDougall. In fact, the whole pamphlet is mainly a copy of McGougall's, published in Indianapolis twelve years ago. He told the person I sent that he had no hives on hand—had sold none this year, and said it would take 10 days to get one made. He is doing nothing.
THOMAS G. NEWMAN.

The book kindly forwarded us, as above, is a pretty fair bee-book for only 15 cents, only it does not fill the bill at all, according to the circular. The principal illustration is one used years ago by N. C. Mitchell. Mr. Andrews, however, has dug out the "N. C. Mitchell," giving the hive a botched appearance. From the back cover we learn that Mr. A. sells patent medicines, etc. The engraving of the extractor is one made for us years ago by Stillman & Co., of Cincinnati, O. The word "Novice" is got rid of by some means.

The next is from the *Bee Hive*, by E. H. Cook, of Andover, Conn.:

Some three weeks ago our postmaster handed us a leaflet circular on bees, a number of which he was distributing to people as they came for their mail. It proved to be interesting reading; here is a sample:

It costs from $2.00 to $4.00 a stand to start with and you can realize from $25 to $60 per stand, etc.

On the back a "New Improved Hive," and a book, "Secrets of Bee-Keeping," were advertised. The address was W. Madison St., Chicago. We wrote to Mr. Newman, editor of the AMERICAN BEE JOURNAL, for light on this "secret" kind of bee-keeping, and the following is his reply:

We have made some six different trips to find Mr. Andrews, and only this morning (April 27) have we got the first copy of the "Secrets of Bee-Keeping," which he advertises. It is a small pamphlet printed in the cheapest and roughest style, a re-hash of the McDougall pamphlet, published in Indianapolis in 1877. The hive is the N. C. Mitchell, and the extractor the McDougall. It is behind the times, and in character it is the "Oklahoma boomer." He could not agree to fill an order for a hive in less than ten days—had made none this season, etc. Is going to California in about ten days.

Mr. Newman is ever working for the best interests of bee-keepers, of which this is only one instance of the innumerable "skinners" that he has exposed. Only novices and people unacquainted with bee-keeping would be caught by the circular.

A Very Bright Idea.—The *Canadian Honey Producer* gets off the following "joke" in its May issue, under the heading of "A Way to Get Apis Dorsata at Last:"

Some years ago Mr. D. A. Jones and others made great efforts to secure Apis Dorsata, but owing to the difficulty of transporting bees when secured, they have failed to get them to this country alive. We would suggest that the next enterprising individual take a package of Dr. Mason's egg-preservative with him, and secure not live ones, but drone and worker eggs, preserve them and ship them to America, where they might be put into strong colonies, the drone eggs first, and the fertilized egg later, and Apis Dorsata shall be ours. It is needless to add that we claim a moral right to the idea, but will sell it to any responsible party for a half interest.

The Doctor will take that "half interest," Mr. Holtermann, and "don't you forget it." He is always ready to *appropriate* such nice things. But how did you come to get such a brilliant idea? It entitles you to a long chalk-mark!

Hiving Swarms.—Ray Murray, of Ada, O., gives the following in *Gleanings*, as his method of hiving swarms:

When a swarm is about settled on a pear-tree, evergreen, or grapevine, I pick up my swarming-box, throw back the duck top, slip it under the swarm, and then give the limb a few small jerks. I then have about all in the cage. Next I throw back the duck top, and wait a little while, till the outside bees can hear, see and scent their little comrades in their wire cage. They will soon settle on the wires, and peep in, I suppose, to see "mother." I then pick up the swarm and pour it in front of the hive prepared for them.

In the Excitement of swarming, the bees fill themselves with honey before leaving the hive. An exchange gives these reasons for their doing it:

This is one of the wise provisions of nature. It gives them a start in their new home, and sustains them until they can get "organized" and at work once more. But this is not all, the main secret of why bees can be so easily manipulated when swarming lays right here. This is why we can shake them into baskets, and pour them out in front of the hive without their raising a disturbance in our "har!" In other words, a "full stomach" has the same effect on a bee as it does on a man—it makes 'em good natured!

GLEANS OF NEWS.

The Bee and Honey Show at Buffalo, N. Y., promises to be one of great interest. The Buffalo *Courier* makes these comments on tt:

Not least among the many new and attractive features of the Buffalo International Fair will be the bee and honey department, under the superintendence of O. L. Hershiser, who is a practical and scientific apiarist. This industry has hitherto received a very small and unequal share of patronage from the majority of large fairs, notwithstanding the efforts of bee-men to secure a more hearty recognition. Premiums have usually been so insignificant as to be no inducement to those who would with reasonable inducement make a representative display, and the products of the apiary have usually been forced into some out-of-the-way place, in space not desirable for other purposes.

The managers of the Buffalo International Fair have taken a long step in advance, and placed the "bee and honey" department on an equal footing with other industries. They have offered a handsome sum of money in premiums, and the department will be advantageously located in the main building.

The following are the "Rules" and "Premiums" of the Honey Show:

Exhibitors will not be allowed to remove honey from their exhibit during the Fair, but may sell from a reserved supply, for which no charge will be made.

Exhibitors who sell honey, must enclose it securely in paper or cartons.

Honey exhibited or sold must be this season's crop, and all honey must be the produce of the exhibitor.

Exhibitors competing for a single premium cannot be included in a display.

Colonies of bees must be exhibited so as to be readily seen on at least two sides.

A breach of these rules will forfeit all premiums that may be awarded, and the right to exhibit the following year.

Display of comb honey, largest and most attractive	$30	$15	$8
Display of extracted honey, largest and most attractive	30	15	8
Sample of comb honey, not less than 25 pounds in shape for retailing	10	5	3
Sample of extracted honey not less than 25 pounds, in best shape for retailing	10	5	3
Display of comb honey, by a lady	15	5	
Display of extracted honey, by a lady	15	5	
Largest collection of samples of different kinds of honey, from any source	15	8	
Display of beeswax, largest and most attractive	20	10	
Sample of beeswax, not less than 10 lbs., the produce of the exhibitor	6	3	
Honey-vinegar, not less than one gallon, displayed in glass	6	3	
Assortment of honey candies	6	3	
Assortment of pastry made with honey	10	5	
Assortment of fruits preserved in honey	6	3	
Colony of Italian bees in observatory hive	10	5	
Colony of Syrian bees in observatory hive	10	5	
Colony of Cyprian bees in observatory hive	10	5	
Colony of Carniolan bees in observatory hive	10	5	
Best collection of queen-bees, not less than one dozen, in such shape as to be easily seen	20	10	
Collection of honey-producing plants, properly named, pressed and mounted or in bloom	15	8	
Display of comb foundation, both brood and surplus, made on the grounds, quality to be considered	20	10	
Sample foundation for brood-chamber, quality to be considered	10	5	
Sample foundation for surplus, quality to be considered	10	5	

Largest and most complete line of bee-keepers' supplies, exhibited by manufacturer, quality of workmanship to be considered, Society's large Silver Medal.

Best bee-hive for comb honey, Diploma.

Best bee-hive for extracted honey, Diploma.

Best bee-hive for all purposes, Diploma and Medal.

Competent judges will carefully examine and pass upon any new and meritorious improvement or invention, and make such honorary awards as they deem just.

The superintendent of the bee and honey department, O. L. Hershiser, will furnish a premium list of the fair, and give any further information regarding the apiary department to all bee-keepers who may apply for it.

As Mr. Hershiser has induced the fair managers to make these liberal offers, we hope that the bee-keepers will give a hearty response, so that it can be shown to have been a good venture for the fair, as well as for bee-keepers.

Mr. Hershiser desires to make the following announcement to those who intend to exhibit:

Those who contemplate making exhibits in this department, should send estimates for the space they wish to occupy, at as early a date as possible. Space will be assigned in June. If application is made early, we can have all the space we can use. The bee and honey exhibit will be in the main building, where every visitor may see it.

Buffalo is a very central location for a bee and honey show for the Eastern and Middle States, and we hope that a magnificent exhibit will be made of the products of the apiary.

Such Shows are the best educators of the the people that can be made. We shall have (to all present appearances) the largest crop of honey in many years, and every means should be used to create a demand for its consumption. It must be eaten by tons upon tons—a little by everybody—and still there will be enough left for cooking and manufacturing purposes!

Educate the People to Eat Honey

Recipes for Colds.—Here are some recipes where honey is an ingredient for the cure of coughs and colds. The items were clipped from some paper and sent to us by Dr. A. B. Mason. Other papers are requested to copy them for the general good. Here they are:

In the changing weather of this month a great many are troubled with a hacking cough; a cold, taken in time, can often be checked. We keep aconite solution at our house, which, by putting a few drops in a little water and taken at short intervals during the evening, will break up a cold by morning.

A correspondent writes that a heaping tea-spoonful of honey stirred into a raw egg is a very good corrective for a cough, which should be continued for nine or ten mornings.

Another very good recipe is to put ten cents' worth of balsam of fir gum into a pint of whisky; as the gum dissolves, pour off the liquid and add to two-thirds honey one-third of the liquid. Take a tea-spoonful at a dose. We have used this in cases of very bad coughs. A severe cough should never be trifled with, nor allowed to run on.

A SONG FOR MAY.

BY EBEN E. REXFORD.

A song for May, whose breath is sweet
With blossoms glowing at our feet;
Her voice is heard in laughing rills
That ripple down the sunny hills,
O, happy, happy May.

The robin in the cherry tree
Is blithe as any bird can be;
And bubbling from his silver throat,
His wordless songs of rapture float.
O, happy, happy May.

Above the hills the firmament
Bends down about us like a tent,
And we, O, fairy-footed May,
Are dwellers in your tents, to-day.
O, happy, happy May.

Our hearts are glad with bird and bee
For what we feel and what we see;
O, would that life and love, we say,
Might always keep its happy May,
Its happy, happy May.

—*Vick's Magazine.*

Best Honey Weather.—A correspondent in the *Northeastern Farmer* makes these remarks about the best weather for the secretion of nectar:

It is my opinion that the best honey seasons are when it is comparatively dry weather. Frequent showers are beneficial to the honey-producing flowers. On a very warm day when the air is filled with electricity, but scarcely a cloud overhead, by taking notice you will see the bees bringing in the honey with all possible haste. Being loaded so heavily they drop upon the platform for a little rest before entering the hive.

The hurrying to and from the hive as though there was not one moment to lose, is a pretty sure sign of a shower "making up" in the distant horizon. Flowers secrete more at such a time. But after a shower, when the sun again shines forth, and a gentle breeze has shaken the rain-drops from the flowers, the bees are again ready to start out securing their sweets, but with less appearance of nervousness.

One who is not acquainted with these "little laborers" cannot understand the intelligence they possess. It is regarded as instinct. I am inclined to think it is a fair amount of understanding.

Scientific Queen-Rearing, as practically applied; being a method by which the best of queen-bees are reared in perfect accord with Nature's ways. This is the title of a new book of 176 pages, by G. M. Doolittle, of Borodino, N. Y., which is now ready for delivery.

In this book Mr. Doolittle details the results of his experiments in rearing queen-bees for the past four or five years, and is the first to present his discoveries to the world. It is published in time for every progressive bee-keeper to test the various discoveries which it details, during the present season. Send all orders for the book to this office. Price, $1.00, postpaid. The usual discount to dealers in lots of 10 or more.

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin now.

QUERIES & REPLIES.

Characteristics of Bees Transmitted by the Queen.

Written for the American Bee Journal

Query 632.—1. What is the difference in general characteristics between hybrid bees produced by a cross between an Italian queen and a brown German drone, and those produced by a cross between a brown German queen and an Italian drone? 2. What characteristics do you expect the queen to transmit to the workers, and in what will they resemble the drone?—Illinois.

I will let expert queen-rearers answer this.—C. H. DIBBERN.

1. As they average, very little if any. 2. About equal from each parent.—G. M. DOOLITTLE.

1. If you believe that prepotency is on the male side, you can answer your own question.—A. B. MASON.

1. I cannot say, as I think that I have only had the first-mentioned kind. They were cross, but good workers. 2. Let the "other fellow" answer this.—MRS. L. HARRISON.

1. I have had no experience with the progeny of Italian drones and black queens. 2. I refer you to Prof. Cook. —R. L. TAYLOR.

1. The bees of the first cross, in my experience, are the best honey-gatherers. Their general characteristics are nearly the same.—W. M. BARNUM.

1. There is no difference. What is the difference between a child of a white father and negro mother, and one from a negro father and white mother? 2. No possible rule can be given. Sometimes the male is prepotent; at other times the female.—A. J. COOK.

Friend "Illinois," unless some of the others know more about it than I do, you have come to the wrong place for information.—C. C. MILLER.

1. I give it up. I do not know. 2. A queen whose workers are extra honey-gatherers, is apt to have daughters whose workers are extra honey-gatherers also. The drones transmit color, and (probably) strength of wing, and power to smell.—MAHALA B. CHADDOCK.

1. The progeny of an Italian queen mated with a black drone, have always seemed to be more irascible than those *vice versa*. 2. From the mother, the markings predominate; from the drone, the disposition, if any observations are correct.—J. M. HAMBAUGH.

1. As a rule, the former are vicious, and the latter fairly gentle. 2. Exceptions will occur to any rules that may be laid down in the matter of heredity. But the rule is, that the queens transmit to the worker progeny any peculiarity in the comb-building faculty; that is, the manner of building and capping the combs. They also transmit size, and to the queen progeny, fecundity. The drones transmit the working quality, temper, color, and size to the drone progeny, which does not appear until the second generation. —G. L. TINKER.

"Illinois" please excuse me. I have never studied along this line critically. If the bees produce much honey, and are reasonably docile, I do not inquire who their grand-parents were.—J. M. SHUCK.

1. I presume that there may be as much difference as there is between a mule by a cross between a jenny and a stallion, and one from a jack and a mare. I have heard it maintained that there is a difference, but I do not know. 2. If the queen is pure, she ought to transmit *all* the characteristics possessed by the workers of her race.—EUGENE SECOR.

1. The black drone with an Italian queen makes cross bees; while the Italian drone and black queen are more gentle. That is my experience. 2. You can place but little dependence upon what the bees will be and do, until you get them.—H. D. CUTTING.

1. Crosses between Italian queens and black drones (I do not know anything about "*brown* German drones") are usually crosser, more pugnacious, and better honey-gatherers than the cross of a black queen and an Italian drone. 2. The most prominent characteristics are transmitted by the queen.—J. P. H. BROWN.

1. Who can tell? There are no characteristics that I know of, by which any cross can be known. 2. Who can answer this? I confess that I cannot, in fact. Crosses are so liable to sport that no positive deductions can be made.—J. E. POND.

1. In appearance, half-pure bees (there are no hybrids) resemble the queen more than the drone. A pure Italian queen that has mated with German or black drones, will produce bees that will nearly all be more or less yellow. A black queen and Italian drone will produce mostly black bees; only a few will have yellow bands. 2. The progeny of a black queen and an Italian drone are more gentle than the opposite cross.—M. MAHIN.

1. I found, many years ago, when handling the fiery Cyprians, that the queen transmits family traits so far as general appearance is concerned with the greatest regularity; while the drone (coward as he is erroneously believed to be) transmits temperament. Thus, the drones of a fiery race of bees, when coupled with queens of a gentle race, give fiery progeny. This answers the second part of the query, also.—G. W. DEMAREE.

It depends upon circumstances and conditions—there is no rule to judge by. Generally the latter cross are much more docile.—THE EDITOR.

CORRESPONDENCE.

BROOD-REARING.

The Proper Temperature Inside of the Brood-Nest.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

As the season for brood-rearing is at hand, something regarding the degrees of heat maintained inside of the cluster of bees which are rearing brood, may not be amiss; especially as I see, by what I read, that but few have a correct idea of what warmth the bees keep the larvæ, eggs, etc., during the time when they are rearing their young.

While Nature has so ordained that a good colony of bees can form a "living hive," as it were, so as to generate heat enough for brood-rearing inside of a crust or wall of living bees, still, in early spring weather, the capacity of a hive to retain warmth, the same coming in close contact with the bees, has much to do with prolific brood-rearing, and the getting of our bees in time for the harvest. The more heat we can retain in the hive, the more honey we can save; for all are aware that the fuel which the bees have to "burn," so as to raise the temperature of the cluster to where they desire it, is honey.

Again, the more fuel (honey) the bees burn, the quicker their life wears away, for it takes an effort even on the part of the bee, to keep the furnace (the bee) filled with fuel as fast as it is consumed. Hence we see the important bearing that a good, warm hive has in advancing our interests in early spring weather.

Why do I say in early spring weather? Because, that at this season of the year, the temperature outside of the hive is very much lower than that which is required by the bees to rear brood. If, as I saw in print not long ago, bees could rear brood with a temperature of only 55° to 60°, then there would not be so much need of a warm hive; for we have many spring days wherein the mercury goes as high, and even higher than that. If those figures were cor-

rect, then our bees could rear brood in April and May, here at the North, to good advantage, as they now do in July and August.

Again, I see that where the temperature inside of the hive reaches from 73° to 84°, the bees ventilate the hive, by setting apart a certain number of bees to fan at the entrance, in order that a higher temperature than 84° shall never be reached, as that is the highest temperature bearable by the brood. If this were true, then what would the bees do when the mercury stood about the "nineties" for days in succession, as we frequently have it, even in this locality? Would it be possible for them, by fanning the air, to give a less degree of heat than that very air contained?

Once more: I notice that some of our most practical bee-keepers say that we should not have the temperature of the lamp-nursery much above 85°; for if we do, the queens which we are trying to hatch in the same, will be killed; for that is about the temperature at which the bees keep their brood and queen-cells, when they have their own way. A very few allow that a temperature of 90° may be maintained, and yet have the queens hatch all right. Having a desire to know of this matter myself, I began to experiment as follows:

I procured a self-registering thermometer, and after placing it near the fire till it showed 125° of heat, the register was set, when it was carefully wrapped in a warmed woolen-cloth, and immediately placed in a medium colony, as nearly the middle of the brood-nest as I could guess at the center. This was on a very cool day, the latter part of May, on the night of which water was frozen so as to form ice nearly as thick as window-glass, I selecting such a time purposely.

The next day, at two o'clock, it had warmed up enough so that the bees were flying, when I took out the thermometer, and found that the coldest point reached in the brood-nest during that cold night was 92°. After this I tried the same experiment several times on both strong and very weak colonies, although at no time did it freeze as hard as at that time; in fact, I do not know that the freezing-point was reached outside the hive during any of the other experiments, yet in no colony that was rearing brood did the mercury register less than 92°; while some of the strongest colonies gave 95° as the lowest temperature inside of their brood-nest.

Being satisfied that 92° was the lowest point consistent with rapid brood-rearing, I next went about finding what was the highest point the bees allowed in their hive, when the mercury was playing about the "nineties." Accordingly, I placed the thermometer in a very strong colony, early one morning, when the day gave promise of being a very warm one, the temperature at this time being 78° in the shade. At two o'clock that day, the mercury in the open air was at 91°, while later on there was scarcely a hive in the yard but what the front was covered with bees "hanging out." At about sun-down, the thermometer was lifted from the hive, when I found that the highest point reached was 98° during that extremely hot day. With several other experiments tried along this line, I was not able to secure quite as high a temperature as that again, although one other time it was within less than one-half of a degree of 98°.

In this way I found that to rear brood successfully, the temperature of the hive must reach a point somewhere between 92° and 98°; and if this was the case, why should I not keep my lamp-nursery between those temperatures, if I desired to hatch queen-cells perfectly.

I am well aware that sealed brood, or nearly mature queen-cells, will bear a lower temperature than will larvæ, but that does not decide but what such would be better off could they have the same temperature which they enjoy in the hive. From the foregoing, I think that it will be apparent to all, that there is great advantage in helping the bees all we can in early spring, to maintain as warm a temperature as possible inside of the hive. This can be done to the best advantage by keeping the hive as tight as possible at the top, and contracting the same to suit the size of the colony occupying it.

Borodino, N. Y.

FOUL BROOD.

An Experience with this Disease —Fastening Foundation.

Written for the American Bee Journal

BY JOHN H. MANCHESTER.

I commenced bee-keeping about nine years ago, with one colony of black bees in a box-hive, which I transferred to a movable-frame hive, and Italianized them. They increased until I had 12 colonies, when I bought 2 colonies for $14.00. They had the foul brood, but not knowing it, I went on and exchanged frames, and gave the disease to the whole apiary.

I then began to cure them, and succeeded. I put them into a box and left them 24 hours, and then hived them on one frame of hatching brood and honey; this was taken from healthy colonies, and the rest of the hive filled with foundation. I extracted the honey and melted up the wax, burnt the frames, and steamed the hives. There have been no signs of foul brood since in my apiary.

I also treated some bees for one of my neighbors in the same way. He boiled the honey, and fed it back to his bees, and they had the foul brood the next year.

I have at present 43 colonies of bees, all in good condition. I prepared them for winter by packing them on the summer stands. My bees are in double-walled hives. Bees in this town have wintered nicely.

Fastening Foundation.

A good deal has been written about fastening foundation in sections, and so I will give my way of doing it:

Take a board 3 feet long, and 6 inches wide; to one side of this fasten 4 pieces, just half as thick as the boxes, and cut these blocks so that they will just fit inside of sections. Fasten these on the first piece of board about 8 inches apart; now place the board a little slanting, put the sections over these blocks, on the foundation, and place them in the section; have some melted wax in a basin, which is to be kept warm by placing it over a lamp. Have a small brush, and with one hand hold the foundation down to the top of the section, and with the other hand draw the brushful of melted wax along the lower edge of the section, and fasten all four of the edges before removing any of them, so that the wax can cool. When taking the section off, place them right side up. I think that if bee-keepers will try this, they will be satisfied with the plan.

Preble, N. Y.

QUEEN-CELLS.

When to Destroy Queen-Cells to Prevent Swarming.

Written for the American Bee Journal

BY EUGENE SECOR.

Good evening, Deacon Smith, what makes you look so smiling? Has Aunt Miranda taken the sweepstakes' prize for the best ten pounds of dairy butter at the International Dairy Fair? Or has her Plymouth Rock chickens hatched out thirteen to the dozen, without an incubator?

"Narry one. I'll tell you, neighbor, what makes me feel so good-natured to-night. When a fellow meets another who ought to know a good deal the most, and fellow number one finds out that fellow number two has to come to fellow number one to get the alphabet of what he ought to be graduated in, it makes fellow number one feel as

though he was of some use in the world, after all.

"It's queer that some folks go through this vale of tears with their eyes shut. As I was goin' along the road this mornin', farmer So-and-So hailed me, and wanted to know when was the best time to cut out queen-cells to keep the pesky bees from swarmin'. I thought he was trying to git some joke on me, and I told him the best time was when he found the bees buildin' cells. But soon I found out that he was in dead earnest.

"He thought the bees built the queen-cells in the spring, when they hadn't anything else to do. That was about the first of May, when the bees in these parts thought about as much of swarmin' as my two-year-old granddaughter does of gettin' married. Now, you know this man has about fifty hives of bees, and folks think what he don't know about 'em aint worth larnin'. But he don't take any bee-paper, and he hasn't any bee-book, and he lives too far from you to borrow, the way I have done. Some of his hives are half full of drone-comb. He never uses a smoker, and I reckon he don't see the inside of many hives but empty ones. But he is gettin' more enterprizin'. He wanted to stop swarmin'. And he thought if he could git me to go through and cut out the queen-cells before corn-plantin', it would be a wonderful savin' of labor.

"I told him that instead of bees being the wisest critters, they were the most cranky, hand-to-mouth animals I ever see. They never do nothin' because there's any reason for it, but because they don't know any better. They build queen-cells one day, and may be tear them down the next. They raise and feed a million drones when perhaps they don't need any. They stick their hives from top to bottom with bee-glue, when you have wintered them in the cellar for fifty years. They will nurse a worker-bee that lays drone-eggs, and kill the queen you try to give 'em.

"They will sting the hand that feeds 'em, just as quick as they will the fellow that robs 'em. They will leave the best hive on the farm to take up with some little hollow tree in the woods, where they are sure to freeze to death before spring. They are just as likely to swarm a few days before frost, if buckwheat gives any honey, as they are in basswood time. They are like some young folks that get love-struck, they will set up housekeepin' without any meal in the barrel, and a hard winter comin' on.

"After I had delivered myself after this fashion, all Mr. So-and-So said was, 'Well, I swan!'"

Forest City, Iowa.

SCHNEIDER'S ALBINOS.

Written for the American Bee Journal

BY M. R. CULLISON, M. D.

Mine vife she vend, dot uder day,
Ily neighbor Schneider's house
Ter see hees bees, and now she say
Mine bees are nix cooms ouse.

She dell me Schneider's bees are vite
Und yaller—like der gold;
Dhey vill nod shting, nor dry ter fite
Vhen by der vings der hold.

Hees hives—can leeft der dop ride off,
Dose bees dhey come nod out.
Dhey makes der combs weigh yust er bound,
Und minds vhat der about.

Und, Hans, dot Schneider vas er vitch!
I can nod undershtand—
Hees vife she said, *for sure* 'tis drue,
He shwarms dose bees by hand!

Und books—hee's more as I can dell;
He shtring 'em on der shelf,
Und say no mans can do so vell
What reads 'em nod heeself.

Und babers,—dhree er veek, I vow!
Reads just aboud der bees.
He say dod bees-ness is bud now
Sure in ids A B C's.

Und seex,—eight dousand bounds he sell
Vrom seexdy shtands—Shpring cound,
Made by dose vite and yaller bees
Vhat fly vor miles around.

Und hee's er kind or dwist machine
Vhat jumps dod honey kwick
Ride oud der combs! Mine hed got schwim
Dod honey bounce so shlick.

Now, all dose dhings,—und more as dot,
Mine vife just dalk er shtring—
Aboud dose bees vhat Schneider's got,
Dod vorks more as dhey shting.

I say, "Katrina, hold dod mondt;
I dakes nod vor der cute
Vhat cranky bee-mans say aboudt
Dhere bees more as der trute.

"Do'nd I kept bees nigh vordy year!
Vhile Schneider less as dhree!
Mine vodder keep bees all hees life!
Knows Schneider more as me?

"Und dose book-larnin—vhat ish dot!
Yust vooling dime avay;
Vhile I der hives rub mid der leaves
Vhat made der shwarms to shtay.

"Und all dose mans dod babers rides
Vhat comes dhree dimes er veek,
Sure bades dod hook,—und vools vhat bides
Makes fat dod peeg man's cheek.

"Und as ter shwarmin' bees by band—
I laft mine sides ter crack.
He make dose vite und yaller bees
Mid bowder on der back."

Und dod high-fangle dwist machine—
A sausage grinder shlick!
I vonder how dod Schneider vool
Katrine on dod so kwick.

I grind mine honey vonce mid dod,
Und squeeze der vax like vice!
(I nod led Kitty found dod oud,
She keeps no secred nice).

Und vor dod bee as vill nod shting
Dhere's *von, doo* dhings, or *dhree*;
He vas er dhrone, he vas er king,
Or else no good vas he.

Und vor dose hive der dops come off,
I nail mine on ter shtay.
Und vor dose combs vhat weighs er bound—
Shades ov Munchausen's day!

Und seex,—eight donsand bounds ter sell
Vun year ov seexdy shtands!
Der vorld nod ead so much. Vor sure
He weigh dod mid hees hands.

Bud more as all I laft ad vhat
Katrina sez ter me—
Dod none vas ever half so blind
As him vhat don't can see!

Adel, Iowa.

BEE-STINGS.

Treating the Wounds—Bees and Bloom, etc.

Written for the American Bee Journal

BY REV. J. D. GEHRING.

My apiary east the first swarm of the season on April 28. It was a large one, and very cross—owing, I think, to scarcity of honey.

The best precaution against bee-stings is, I think, cool and deliberate movements, a veil to protect the face, much patience, and pluck enough to "grin and bear" what stings cannot be avoided. I am often much amused when I hear and read of the various remedies and cures for bee-stings; for all of them, to say the very least, are very unhandy for a busy man. The idea of my running to the house, leaving an open hive behind me, to get an application of soda water or some such thing! Who, when he is in the midst of an interesting job, which requires both hands, both eyes, and all the attention of the mind, can stop to doctor a bee-sting?

The nearest to a success for stings that I have yet tried, is tincture of *Ledum palustre*. I used to carry a little vial of it in my vest-pocket, and apply a few drops to a bad sting; but I soon found even that too unhandy. As a remedy for the *pain*, it is pretty nearly a success.

For a very bad case of stinging, such as I had two years ago when a swarm of Italians got after me when I tried to hive them, and stung me on the neck, throat and head, I used the homœopathic antidote—"Apis Mel No. 3," internally, in drop doses in water; four or five doses, from one to two hours apart. I think this remedy, used intelligently and promptly, will always prevent serious results; and even death in the worst cases.

The Irishman said: "A man can get used to 'most everything that befalls him, if it lasts long enough—and that's the reason one can never get used to hangin'." With a bee-keeper, "stingin'" lasts long enough so that, in course of time, he gets used to it. It is so in my case. Bee-stings cause me very little pain, and generally no inconvenience, except when I allow them to "jag" me in or near the eye. I need my eyesight as much as my wits, in the apiary; and hence I believe in being "green" enough to wear a veil when circumstances require one.

I have never had so many drones in my apiary as this spring. I thought I had control of that part of the business by having excluded drone comb, and by cutting off the heads of unhatched

drones "in due time;" but they have somehow got ahead of me. I would like to catch about 5,000 of them, if I could. I thought to have only pure Italian drones. But a neighbor of mine has about 50 hives of blacks and hybrids, and takes no thought of drones. So I have concluded to give up the batttle for the time being, for an apiary of pure yellow bees. My young queens stand a very poor chance this season. The air, on warm, sunny days, is full of black drones.

Bees and Fruit-Bloom.

In regard to bees and fruit-pollen, I would like to say this: Bees have, no doubt, much to do with the fertilization of fruit-bloom; but I cannot believe that success or failure depends altogether upon bees, or other insects. Of course when it rains, or is too cool for bees to work, the pollen of the fruit-blossoms is not carried from flower to flower, and mixed, as it is when the weather is just right. But the fact is, if it all depended upon the work of the various insects, we would never see much fruit, "rain or shine;" for, when the blossoms are wet, and the weather damp, the pollen is damp also, and, hence, the wind cannot waft it about. This, more than the work of the honey-bee, accounts for the scarcity of fruit when blooming occurs during damp and rainy weather.

Moving Bees—White Clover.

Last year I moved my bees five times—once by rail, and four times by wagon. I did not lose one colony, though they were moved on a common truck-wagon, over a rough, stony road, and taken by freight to Kansas, when they were very heavy with honey. Of course the much moving did not do them any good; but I mention it to show that moving, like anything else in bee-manipulation, can be done successfully and safely, if done in the right way.

I have 20 colonies and 4 new swarms. All came through the winter nicely. They had brood in March, and plenty of drones in April.

White clover promises a rich honey harvest, if it does not rain too much! It is just coming into bloom here, but, as yet, it contains no nectar. The weather is too cool, and I fear the rains will be too frequent for an abundant yield from white clover here in Douglass county, Kans. I consider it rather unfortunate, than otherwise, that white clover comes into bloom so early, before the sun gives heat enough to secrete nectar in the flowers. June is, no doubt, the best time in this latitude.

Lawrence, Kans., May 12, 1889.

WINTERING.

Maple Sugar for Bees—Pear-Bloom Honey.

Written for the American Bee Journal

BY O. L. HERSHISER.

Bees have wintered better in this locality than for several years past. All colonies that had half a chance have come through in fine condition. My observation has been, that colonies deeply covered with snow-drifts, and those well shaded, have wintered the best, and are more vigorous now than those that have been exposed to sunlight. I contemplate taking a few colonies to some well sheltered place in the woods to pass the next winter, by way of experiment.

Feeding Maple Sugar to Bees.

There are many good ways of feeding bees, some adapted to one season of the year, and other methods to other seasons. Having occasion to feed a few colonies this spring, I tried maple sugar, and though I do not say that it is the best food, and the best way of feeding, I am confident that it is good, and the best I have tried. It is as follows:

Take a thin cake of the desired amount of sugar, raise the cloth covering the bees, and place the cake over the cluster. It is but a moment's work, and practieally no heat is lost. The bees will store it slowly, and thus stimulate the queen to lay. Enough may be given at one time to last the season during which it is desired to feed. Maple sugar can be bought in quantity in the Buffalo markets for from 7 to 9 cents per pound. No objection can be urged against maple sugar on the score of economy.

Honey from Pear-Bloom, etc.

The spring was favorable for brood-rearing up to April 26, after which followed a week of cold, rainy weather, during which the bees consumed much honey in feeding young bees. A few of the colonies starved during this week of inclement weather, but now, how great the change! Bees are working with as much vigor as I ever saw them in the best honey-flow. Pear and hard-maple trees began blooming on May 7, in this locality, and from this source some of my strongest colonies are storing several pounds of honey per day, while the weakest are making more than a living.

I never saw honey so plentiful in pear bloom. It glistens like dew-drops, as has been often observed in basswood bloom, and is very white and of a delicate flavor. The flow of nectar from pear bloom is constant. The contented hum of the bee is heard in the pear orchards from sunrise to sunset. Apple trees will bloom in a few days.

Before the week of cold weather, referred to before, a few of the strongest colonies began preparations for swarming. One colony had a queen-cell with a larva ready to cap, and several hundred capped drones. The drones are now on the wing, but the bees postponed the swarming, and destroyed the young queen-larva.

Big Tree Corners, N. Y., May 9, 1889.

LANGSTROTH

On "The Hive and Honey-Bee," as Revised by Dadants.

Written for the American Bee Journal

BY G. W. DEMAREE.

I have had in my possession this great contribution to modern bee-keeping for two months or more, and notwithstanding I have been more than usually pressed for time, owing to business matters, etc., I have not neglected to examine with some thoroughness this fascinating work on bee-culture.

"The Hive and Honey-Bee," by Rev. L. L. Langstroth, is a pioneer work in modern bee-keeping, and has done more for the cause than all else besides; and now to have it thoroughly revised and brought up to the front, cannot fail to give a new impetus to practical bee-culture.

It would be impracticable for me to undertake to more than mention a few features of the revised work, and these must be of a practical nature.

Contraction, Patent-Hives, etc.

The majority of the bee-keeping fraternity are of an enthusiastic temperament, and therefore prone to extremes. Brood-chamber contraction, patent bee-hives, and a multiplicity of bee-gear have been carried beyond healthy limits, and the conservative stand taken by the reviewers of this standard work, on these subjects, is timely, and backed up by practical experience.

On page 173, the revisers "caution" beginners against being trapped by "patent hives." It required some sacrifice and moral courage to speak out on this subject just now, no doubt, but we honor the man, or men, who have *principles* and dare to maintain them. Who knows how much hard-earned money and vexatious disappointment will be saved to beginners in bee-culture, by this timely warning; as the voice of warning in this direction has been smothered and drowned

out for a time by the clammers of the "patent-right man."

The revisers take a proper view of the "contraction system." We want a system that will give the best possible yield of surplus honey, and at the same time leave the bees in a normal condition. Extravagant contraction can never meet these desirable ends.

Feeding Bees.

What is said in this new book on "feeding bees," is sound and practical. There is nothing better and more economical than good sealed honey for winter stores, or for spring feeding. Sugar feeding should only be resorted to when it becomes necessary on account of scarcity of honey.

Queen-Excluding Honey-Boards.

I was much pleased to see what these practical authors had to say about the use of the "slat honey-board." This implement has been well spoken of by many practical apiarists; and while I believed that much of the praise bestowed on the "break-joint principle" applied to honey-boards, had its origin in a desire to please the inventor, I was slow to pass upon its usefulness till I had tested it in every sort of season, and under all circumstances wherein a honey-board might be useful.

With me the slat honey-board is an unnecessary appendage. In a good season it is stuck fast to the tops of the brood-frames in a most provoking way, while it does not prevent the queen from going into the upper story; and when she does go above, she will sometimes settle down into busy life in the upper story, entirely abandoning the brood-nest proper. I have met with this provoking state of things in several cases.

The break-joint honey-board is a fussy arrangement, and is a real impediment in the way of the bees, and there should be very many good points about its use to over-balance its many faults.

The perforated-zinc queen-excluders I have found very useful to keep the queens out of the extracting-cases, as I believe that the very best article of honey cannot be taken with the extractor, from combs containing unsealed brood; for the reason that such combs usually contain more or less thin nectar in close proximity to the brood, which, when mixed with the thoroughly evaporated honey, acts as a *ferment* to the whole lot of honey with which it is mixed.

The chapter on comb foundation is exceedingly interesting, both historically and in a practical way. But I must close this line of thought with the thought, what a book is this before me!

Christiansburg, Ky.

BOX-ELDER.

A Tree that Yields Pollen very Plentifully.

Written for the American Bee Journal

BY WM. L. DREW.

On page 295, Mrs. L. Harrison recommends the box-elder (*Negundo aceroides*) as a tree valuable both for pollen and honey. Now, while it may be unsafe to positively say that the box-elder, or almost any other plant, yields no honey, yet I do not regard its value in that direction of any consequence.

The flowers of this tree are dioecious, that is, the pollen-producing flowers are on one tree, while the fertile flowers, or those which produce seed, are on another tree. On this latter tree, where we would expect to find the nectar, if any were produced, I have never seen a bee at work. On the other hand, bees work in great numbers on the honey-producing tree, but from examination of the flowers, and careful observation of the bees at work, I feel quite positive that no nectar at all is obtained.

I would not undervalue this tree, however. Besides being a native here in Iowa, it is widely cultivated for shade and blooms, and produces an abundance of pollen at a time when pollen is of great value—much more than honey, in fact. The flowers opened this year about April 15.

There is no other single plant that I know of from which the bees gather so much pollen, as from the box-elder; but it must be remembered that only a part of the trees, the stamenate, are of any value. The flowers are beautifully adapted for fertilization by the wind, and probably its fertilization is seldom accomplished through any other agency. Here, at least, is a plant upon which bees work in large numbers, and the plant receives no benefit therefrom.

Iowa City, Iowa.

WISCONSIN.

A Great Honey-Producing State—Early Swarming.

Written for the American Bee Journal

BY W. A. HODGE.

I am of the opinion that Wisconsin will in due time become one of the leading States in the production of bees and honey, at least that portion of the State bordering on the great Mississippi Valley, as the river bottoms average about four miles wide the entire length of the State, and are usually one vast ocean of flowers of almost all kinds, from July until November. The honey-bee can be seen gathering sweets from these bottoms fully a month after all flowers are killed on the highlands; and also in the springtime (March and April) the honey-bee is usually found gathering a goodly amount of pollen and honey from the soft maple and willow, of which there is a great abundance.

So, taking the foregoing advantages, together with upland forage, such as the clovers and fruit-blossoms of several kinds, we, or at least some of us Wisconsin bee-keepers, are beginning to see that poor, cold, Wisconsin has something in store for us, not to be enjoyed by every one living on the broad and boundless plains.

Some Early Swarms.

Now, as to early swarming: William Valliant, living two miles from me, on the river, on April 30 had a natural swarm of bees that were all right, and are doing nicely. On the tenth day from that time, the second swarm came out all right, and it is doing well also. Who is ahead of this? I have kept bees in Wisconsin for 25 years, and never heard of bees swarming naturally in April; if any Wisconsin man has, I should like to hear of it. Our bees are rushing the season here.

Victory, Wis., May 13, 1889.

CONVENTION DIRECTORY.

1889.	*Time and Place of Meeting.*
Dec. 4, 6.—	International, at Brantford, Ont., Canada. R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bees are Booming.—Dr. A. B. Mason, Auburndale, O., on May 10, 1889, writes:

I did my first extracting to-day. I looked to see if the colonies were ready for the supers, and found that in one day some of them had filled everything nearly full of honey, and were capping it over, and building pieces of comb wherever there was a chance; I had to extract to give the queens room. There is "worlds" of fruit-bloom, and the bees are booming. It is so very dry that the white clover will be materially injured in a few days, if it dones not rain.

P. S.—May 11.—We had a splendid rain last night, and everybody and everything looks happy.

Susquehanna Co. Convention.—H. M. Seeley, Harford, Pa., Secretary of the Association, sends the following report:

The Susquehanna County Bee-Keepers' Association met at the Tarbel House, in Montrose, Pa., on Saturday, May 4, 1889. President E. B. Smith called the meeting to order, then the usual routine of business was attended to, after which was held the election of officers for the ensuing year, as follows: President, E. B. Smith; Vice-President, A. O. Warren; Secretary-Treasurer, H. M. Seeley. Various subjects pertaining to bee-culture were then discussed, and, taken altogether, it was very interesting, as well as an instructive one, being thoroughly enjoyed by all present.

Abundance of White Clover.—J. T. Wilson, Little Hickman, Ky., on May 13, 1889, says:

We are having copious showers now, which will give us an abundance of white clover; the ground is already white with it in places.

Early Pollen from Maples.—J. A. Williamson, Lake Station, Ind., writes:

I send a sample flower of what I call a "pollen-tree," because the bees gather pollen from it. Perhaps it has a different name, but I never have read of a tree of this kind, that the bees gather pollen from so early in the spring. They begin to work on it as soon as the frost is out of the ground, and it lasts till willows commence to bloom, making 5 or 6 weeks of blooming. The pollen is of a bright-yellow color. The tree is a rapid grower; the first year it makes a straight growth of 4 to 6 feet, and finally reaches the height of 50 or 60 feet. It is an ornament as well as a shade tree; its bark is of a drab or light grey color, and its tassels are from 1 to 2 feet in length.

[It is one of the maples, all of which yield pollen very early in the spring.—ED.]

Bee-Keeping in England.—Mr. Henry Neve, Warbleton, Sussex, England, on May 1, 1889, writes:

The last year here in England has been a most disastrous one to bees and bee-keepers; many thousand colonies have died from starvation and other causes, but principally occupants of straw hives. Very few colonies gathered sufficient during the past summer to carry them through the winter—some districts are entirely depopulated. The bees here are, as a rule, all wintered out-of-doors, cellaring of bees being unknown. Our spring is backward; the last week we have had a higher temperature, with much rain, so that the bees have not been able to do much. Here in the South, we have at the present time, blooming willows, dandelions, furze, and small fruit trees, which the bees are working on freely when the weather permits; no need for artificial pollen in my apiary in early spring—I suppose I have enough furze within half a mile, in full bloom, to supply 200 colonies with pollen. We are hoping for a better season this year; our sections, etc., are ready, for they are just as they were put on the hives last year, and taken off in the same condition. The AMERICAN BEE JOURNAL is a welcome visitor.

Hives Crowded with Honey.—James McNeill, Hudson, N. Y., on May 13, 1889, writes:

Bees have had a splendid time on apple-bloom. It was cold and rainy during cherry-bloom, so they got in only two days' work on that. But we have had real hot weather during apple-bloom, with the mercury up in the nineties some days, and before we knew it our bees, which were on seven frames, were crowded with honey. We had to "fly around" pretty lively to give them more room. The hot weather is bringing vegetation forward with a rush. The season is at least two weeks in advance of the average, and I never had my bees in such uniformly good condition at this time of the year. They will be in splendid condition for the harvest, which, of course, will depend altogether upon the weather.

Wintered Only One Colony.—W. H. Rowe, Bridgeport, Ind., on May 13, 1889, writes:

I have had very bad luck this spring. I left 8 colonies of my bees on the summer stands last fall, packed in leaves, as I thought in good condition, but I am sorry to say that during my absence from home, the bees starved, and out of 8 colonies I have only one left, and only saved that by chance. My bees stored no honey last fall, and I did not get a pound from them last year; but I think that we will have a good season this year, as clover looks well now, and is blooming some already. I started two years ago with 2 colonies, and did well until the past winter. The BEE JOURNAL is a welcome visitor, and I could not do without it.

Combs of Diseased Colonies.—Chas. D. Barber, Stockton, N. Y., on May 10, 1889, says:

The bees in this locality, as a general thing, wintered pretty well, but some bee-keepers lost nearly all they had. My loss was 8 colonies out of 11. All had plenty of honey, but they had the diarrhea, and one was queenless. Are the combs of these diseased colonies good to put other bees on again? The clover looks well, and the outlook for honey is very good.

[Yes; it will be quite safe to give the combs mentioned to the bees; they will clean out the dead bees, and use them without detriment—and will do it much better and cheaper than you can do it.—ED.]

Good Season Expected.—Jas. T. Fennel, Venice, Ills., on May 13, 1889, says:

White clover has been in bloom for about 12 or 13 days here—plenty of bloom, but the bees have not been working on it. They have been working on a yellow flower; but we had a rain yesterday, and I think they will go to work on white clover now. Bees wintered nicely, and I expect a good season this year. We have not had a good season here since 1886.

Working in the Sections.—Mr. Edward Margileth, Mt. Carroll, Ills., on May 10, 1889, says:

I put 53 colonies of bees into the cellar on Nov. 26, 1888, and took them out on March 15, 1889, without the loss of one colony. All are in good condition, and have plenty of honey. They carried in the first pollen March 17. At present the bees are working in the sections. The outlook for honey is very promising. White clover is now heading out.

Mineral Wax.—John C. Swaner, of Salt Lake City, Utah, writes as follows:

On page 259 is an item with comments, pertaining to ozocerite, or mineral wax. Utah has deposits of such a mineral, but as far as can be ascertained, they are not as yet very extensive. A company has been incorporated with the intention of mining it, but as nearly as can be ascertained, there has been only one carload put on the market. It can as yet only be found in one location (so I am informed), and that in not very large quantities. I examined some samples

in the Chamber of Commerce building in this city, but I could not get any, or I should have sent a sample to the office of the AMERICAN BEE JOURNAL. The article that I saw was as black as coal, and had a dull appearance. I am informed that it can be bleached white. It might be a fair substitute for beeswax in some instances, but I do not think that there need be any uneasiness on the part of bee-keepers, on account of it. The foregoing are all the points that I have been able to get in regard to it.

Good Prospect for Honey.—Orrin Maker, Westfield, Ind., writes:

On May 11 I attended the county bee-meeting, and all reported their bees in good condition. The loss through the winter was heavy—not less than 25 per cent. The prospect is good for a honey crop.

The White Clover, etc.—Lionel Brokaw, Summer Hill, Ills., on May 13, 1889, says:

White clover looks promising, and is beginning to bloom. We had a nice rain to-day, which was needed very much.

Swarming Early, etc.—Caspar Capser, St. Joseph, Minn., on May 4, 1889, says:

I wintered 32 colonies of bees in the cellar, the past winter. Last year I had 2,300 pounds of honey, mostly in one-pound sections. I lost no bees in wintering, and every colony is strong enough to cast a swarm this month. I had the first swarm on May 2, which is earlier than any I have yet heard of; it is doing well.

Bee-keeping in Alabama.—B. B. Toney, Padgett, Ala., on May 11, 1889. writes:

My bees are all doing well now. We have had one of the most backward springs for bees for several years. The peach-bloom was plentiful, but it secreted very little honey. The apple-bloom was scarce, and also secreted but little honey; and this failure caused the bees to consume all of their winter stores, and for a few days it seemed that we would have to feed to keep them increasing. But the first of this week the poplar opened, together with the white clover, and ever since then it has been a constant roar. The bees are now storing honey as rapidly as they did last year, and our prospects now are very fine. My bees are in care of a first-class hand (Mr. Hall), who is constantly busy preparing and putting on sections for surplus honey, as the bees have commenced to work in them. The present outlook in northeast Alabama is favorable.

Poplar and White Clover.—T. M. Edwards, Kerrville, Tenn., on May 13, 1889, says:

My 150 colonies of bees are now booming, and all are in fine condition. I took off comb honey all last week. I have one swarm that was hived April 17, that has filled 56 one-pound sections already. The poplar and white clover are fine, and the former is at its best; it never fails to give a good yield of honey. We are having quite a drouth at this time, and would be very glad to have rain.

Backward Spring—Gathering Honey.—Miss Helen Betten, Goodells, Mich., on May 13, 1889, writes:

In May, 1888, I bought 2 colonies of bees in box-hives, and placed them in the yard. In June and July I had 3 swarms from the 2 colonies, and the latter part of July I transferred the 2 old colonies to the Armstrong reversible hive, and used the T super. I secured 24 pounds of comb honey, and 12 pounds of extracted. In October I doubled two of the weakest colonies, leaving me 4 to winter, which was done successfully. I packed the bees for winter on Nov. 1, 1888, and I did not touch them until the last of March; when I opened the hives, I found them all well stocked with bees, brood and young bees, and they are gathering honey from fruit-bloom. I expect to have some swarms soon. We have had a backward spring, but the weather is warm and pleasant, and the bees are making good use of it.

Ruined by Paris Green.—John G. Smith, Barry, Ills., on May 15, 1889, writes:

The past winter was very mild in this locality, and bees have wintered well generally. I never had my bees in better condition up to within two weeks ago—in fact I was too much elated over the prospect of harvesting the largest prospective crop of spring honey that I ever saw; white clover never looked finer, or promised a greater yield of nectar, than it does at this time; but alas! the apple-bloom proved a "death-warrant" to millions of bees in this immediate neighborhood. One of my neighbors, owning an orchard of about 100 acres of apple trees, sprayed the trees with Paris green dissolved in water, just as the trees were in full bloom; and, lo, our bees got the full benefit. The result is, that about ten or twelve bee-keepers have been totally ruined, as far as getting a spring crop of honey is concerned. The young bees of the colonies that had never been out to the fields, came out of their hives by the thousands, and went hopping all over the grounds; the larvæ in all stages of growth, both drone and worker, were thrown out of the hives by the (I suppose) well bees. Yesterday I examined 4 colonies of the poisoned bees belonging to Mr. Charles Dodge, and I could not find any queen or freshly-layed eggs. I do not know whether the queens are all killed by the poison, or not. Truly, the path of the bee-keeper is a hard one.

Bees at Work Early.—S. D. Haskin, Waterville, Minn., on May 13, 1889, says:

Are my bees ahead this time? On the first day of this month I had a fertilized this-year's queen laying freely; and yesterday (May 12) I had a large swarm of bees, which I hived.

Prospects for Honey are Very Favorable.—Adolph Ott, Geneseo, Ills., on May 6, 1889, writes:

The weather is fine, and we had a nice shower last night. I have 10 colonies of bees, which are in good trim, and 4 of them are already working in the surplus sections. I am 37 years old, and have been with bees for 37 years, never being away from them. Father always had from 5 to 40 colonies, but never got any good out of them. I have had bees for myself for the last 14 years, but only commenced making a study of them about 4 years ago. I have them in such a shape now that I can handle them, and I find it pays. I wintered my bees in the barn, where I have a place so warm that it won't freeze in the severest of weather. I never lost any when wintered in the barn. The last two years were bad ones for bees in this part of the State; but this spring everything looks favorable for a large honey crop.

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of boney. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at **8** cents per pound for Amber and **9** cents per pound for White.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,

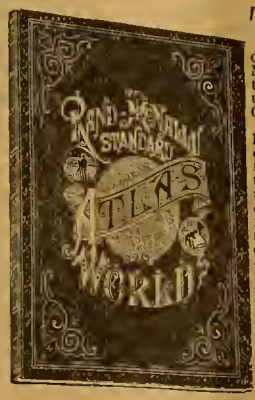
PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:



This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, $1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	$1.50	$2.00	$2.25
500 Labels	2 00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	*Club*
The American Bee Journal	1 00	
and Gleanings in Bee-Culture	2 00	1 75

Do not send to us for sample copies of of any other papers. Send for such to the publishers of the papers you want.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Triple Lense Magnifiers have been so often called for that we have concluded to keep them in stock for our subscribers to inspect bees, insects, etc. See page 212.

Price, by mail, 80 cts.; or the BEE JOURNAL one year, and the Magnifier, for $1.50.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

A high-toned Monthly Magazine for the

FAMILY AND FIRESIDE,

Published at $1.50 a Year,

will be clubbed with the American Bee Journal and both mailed to any address in the United States and Canada, one year, for **$2.00.** This low rate will be extended to all those who have already paid for the Bee Journal for 1889. To such the Illustrated Home Journal will be sent one year for $1.00 extra. See page 269.

Trial subscriptions will be taken 3 months for 40 cents each; or it will be clubbed with the BEE JOURNAL for a year at $2.00 for both. Agents, who are working for premiums, may take "trial subscriptions," and count 4 as one yearly subscriber. One sample copy sent free to subscribers of the BEE JOURNAL, upon application. That will tell you all about the "Premiums" offered for getting up clubs, and "Cash Prizes" for the largest clubs sent in before Sept. 30, 1889. "Good pay for good work" is our motto.

CONTENTS OF THE MAY NUMBER.

—:o:—

Press and Personal Opinions.

Never did the advent of a magazine for the Family touch such a responsive chord, or receive such a hearty welcome.

What the Other Periodicals Say of it:

The *Canadian Honey Producer* records its opinion thus: "Thomas G. Newman & Son, well known amongst bee-keepers and others, as the editors and publishers of the AMERICAN BEE JOURNAL, have taken in hand the publication of the ILLUSTRATED HOME JOURNAL, a periodical abounding with instructive and interesting first-class literature. There is too much poisonous literature at the present day, and we congratulate Messrs. Newman upon the appearance of their Journal."

The *Bee Hive* says: "The contents of the ILLUSTRATED HOME JOURNAL are varied and well chosen for instruction and amusement. 'One Hundred Years a Nation,' by the Editor, is an able tribute to our Nation's progress. Stories, current items, etc., follow—among which is an interesting sketch of Washington's Monument."

Personal Opinions Concerning it.

Mrs. L. Harrison, of Peoria, Ills., records her opinion in this language: "Many sample copies of various publications find their way to our desk, and soon are nestling in the waste-basket; but when the ILLUSTRATED HOME JOURNAL came, bearing the name of that well-known firm (Thomas G. Newman & Son), it met a very different reception. It was read and re-read, and its contents well noted, and then loaned to a neighbor. We wish it success, and predict for it a glorious future."

W. M. Barnum, of Angelica, N. Y., writes as follows: "The ILLUSTRATED HOME JOURNAL unexpectedly (but welcomly) found its way to our sanctum recently. It is a beautiful and intensely interesting Journal—well worthy of Publisher Newman's zeal. May it prove a success!"

J. M. Shuck, of Des Moines, Iowa, records his opinion thus: "The Illustrated Home Journal is a gem of the first water—appreciated as soon as seen."

James A. Green, of Dayton, Ills., expresses himself thus: "I am very much pleased with the Illustrated Home Journal. I wish and predict for it success. Interesting, instructive, typographically perfect, with ability and enterprise at the helm, it is bound to succeed."

J. M. Jenkins, of Wetumpka, Ala., writes: "The Illustrated Home Journal is received. We are all delighted with it. Success to it."

☞ A Sample Copy will be sent free, upon application.

The ILLUSTRATED HOME JOURNAL is a high-toned, moral and intellectual educator, invaluable in every library, and a very attractive and inspiring ornament in every drawing-room.

Its stories are elevating in tone, as well as charmingly thrilling and captivating; its historical and biographical sketches are fascinating and delightful; its Department for "Our Young Folks" is enticing and alluring; and its miscellaneous matter leads to the higher life, and the moulding of more beautiful thoughts and affections.

Reader, if you receive a number of the ILLUSTRATED HOME JOURNAL as a sample, you may know that it is sent to you expecting that you will be SO MUCH PLEASED with it, that you will subscribe for it at once. With a very little effort you can get your neighbors to join you, and thus get up a club, entitling you to a free copy, as well as one of our valuable premiums. Try it.

Send us the Names and addresses of those of your friends upon whom you desire to call to get their subscriptions, and we will immediately send them each a sample copy. In this way you can readily obtain them for your club, for all who see the ILLUSTRATED HOME JOURNAL will desire to subscribe for it.

The Articles offered as premiums are all purchased at lowest wholesale rates, and the club raisers get the benefit of the discount. In this way we are able to give premiums of greater value than if we gave them cash. New premiums will be enumerated in future numbers of the ILLUSTRATED HOME JOURNAL.

Premiums are due when the names and money are here, and may be taken at any time. You can have them right along as you earn them, or wait a little and have more together, and save a part of the cost of transportation.

Write your Name, Post-Office, County and State plainly, and if your Express or Freight office differs from your Post-office, give that too if you order anything by Express or Freight.

Each Order or Letter must be complete in itself, and not refer to something written a day or a week before, for that letter may be filed away with thousands of others, and very likely the person who reads your second letter never saw your former one.

How to Send Money.—As we do a Cash business only, nothing will be sent until we receive the money. We send nothing C. O. D. Money must be sent by Bank Draft, Post-Office or Express Money Order, or Registered Letter.

An Elegantly Illustrated Monthly Magazine

AT $1.50 PER ANNUM,

THOMAS G. NEWMAN & SON, PUBLISHERS

923 & 925 West Madison Street, CHICAGO, ILL.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white 1-lbs., 14@15c. Market is dull and lower, but not overstocked. Demand slow.
BEESWAX.—22@23c.
Apr. 30. M. H. HUNT, Bell Branch, Mich.

KANSAS CITY.

HONEY.—We quote: White 1-lbs. 15@16c.; dark, 10@12c.; California white 2-lbs., 11@12c.; amber, 10@11c. Extracted, white, 7@8c.; dark, 5@6c. Our market is in good condition for the new crop.
BEESWAX.—20c.
May 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Extracted, in barrels, 6½@6¾. Excellent demand for clear, bright in barrels.
BEESWAX.—22c. for prime.
May 4. D. G. TUTT & CO., Commercial St.

CHICAGO.

HONEY.—Our trade is light; no large lots on hand and what there is consists chiefly of dark comb, and not salable in quantities. Choice white comb, 1-lb. sections, 16@17c.; dark grades from 10@12c. Very little demand for extracted, but prices remain at 7@9c., according to quality and package.
BEESWAX,—22c. R. A. BURNETT,
Mar. 25. 161 South Water St.

DENVER.

HONEY.—White, in 1-lb. sections, 16@18c. Extracted, 7@10c.
BEESWAX.—18@20c.
Mar. 26. J. M. CLARK & CO., 1409 Fifteenth St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 14@15c. If damaged and leaky, 10@12½c. Extracted, white, in barrels, 8@8½c.; ½-barrels, 8½@9c.; amber in same, 7@7½c.; in pails and tin, white, 9@9½c.; in barrels and ½-barrels, dark, 6@6½c. The demand is fair.
BEESWAX.—20@22c.
Mar. 27. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—Market is bare of comb, except some small lots of buckwheat which is selling at from 10@12c. No buckwheat extracted. Cuba and San Domingo extracted, 67@70c. per gallon.
BEESWAX.—24c.
HILDRETH BROS. & SEGELKEN,
Mar. 25. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.
Apr. 23. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNAT

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12@15c. Demand is slow, and prices low.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 21. C. F. MUTH & SON, Freeman & Central Av.

EDITORIAL BUZZINGS.

"Let old and young unite
On faithful hearts to write
Firm loyalty.
In grateful mem'ry keep
Heroes in soldier sleep
On land, or in the deep,
For liberty."

We had a short but enjoyable visit from Mr. J. E. Pond, of North Attleboro, Mass., last week. He was on his way home from Minnesota, where he had been, for a few days, on professional business.

We Regret to learn that Mr. W. W. Cary, of Coleraine, Mass., is unable to attend to business, having been *sick* for some time. This information comes from his good wife. We hope for a speedy recovery, and a safe return to his usual good heath.

Memorial Day has come again and passed into history. To decorate the graves of the patriotic dead with flowers, once a year, is a fitting tribute to their memory, and should receive that hallowed tenderness at the hands of every patriotic citizen.

The Bee-Keepers' Pocket Companion is the title of a little book of 32 pages, with thick covers, just issued by the Crown Bee Company, Brighton, England. Besides a monthly calendar, it contains many interesting items of instruction for bee-keepers. The arrangement of the book, and the instructions are given by Mr. S. Simmins, the manager of the company, with whom our readers are familiar, as he is the author of the book entitled, "A Modern Bee-Farm, and its Economic Management."

It is Not True that honey in its purity is so scarce as some try to make out. The *Sanitary Era*, a paper published in New York, was sent to us sometime since by one of our readers, with an article marked, which, after stating that honey was an excellent remedy for many diseases, preserving fruit, etc., went on to say this:

The difficulty is to get honey, for love or money. It is almost useless to look for it outside of the native comb; and since the comb has begun to be made artificially to save the bees the trouble, there is no security that artificial honey of glucose and sugar, with a little bitter almond flavoring, may not take the rest of the business out of the mouths of these insects.

It is said that bee-keepers want a law similar in effect to that on the sale of oleomargarine. The manufacturers of artificial honey should be obliged to stamp their product so that the public will not be deceived.

No! No! The *Sanitary Era* is informed that bee-keepers do not want any law similar to the oleomargarine law. That law recognizes and legalizes an abomination, and would do the same with "artificial honey," if such a law were enacted.

Adulteration should be frowned down—not legalized! It should be crushed out of existence—not made respectable!

But the statement made by the *Sanitary Era*, that it is difficult to get pure honey "for love or money," is a glaring untruth. It can be obtained in all its virgin purity in almost any quantity, on a few day's notice, either at this office, or of any bee-keeper or honest honey dealer.

This is but another version of the Wiley lie. Comb is not made artificially to be filled with glucose and sold for honey! No, sir. Weed, in Detroit, tried to bolster up Wiley's lie by a poor substitute for comb, but it is safe to say that comb has never yet been made artificially, and we do not think it ever will be.

The *Sanitary Era* has been "sold" by the ever-flying falsehood, and now should give place in its columns to the truth—and thus counteract, as far as possible, its evil effects. If it is fair, and had an honest intention in writing as it did, it will gladly tell its readers the truth of the matter. We shall easily measure its stature by its action.

The First White Clover Bloom.—Allen Latham, of Cambridge, Mass., on May 18, 1889, wrote as follows:

I send the first blossms of white clover that I have seen this spring. They are good, healthy blossoms, and if they fulfil their promise, there will be a great honey year in this State. I never saw the clover more promising, nor the bees in better condition.

The blossoms came duly, and promise well for a good honey crop, if other conditions are favorable. The West greets the East upon its prospect, and hopes for a large harvest for the whole country—East, West, North and South.

"This is the first quarter of the honeymoon," remarked Jinks as he handed his bride twenty-five cents.—*Exchange.*

Jordan Springs, Va., is a famous watering place, and the hotel is kept by our friend E. C. Jordan. Mr. Wellington, who has just gone down there from East Saginaw, Mich., writes thus:

I have just spent nearly an entire day in the apiary of Mr. E. C. Jordan, who has a fine lot of bees in a splendid location. I arrived here on the morning of May 10, and found Mr. Jordan suffering greatly from a badly swollen right hand. Two or three days before he had been bitten by a squirrel, and the day that I came he was out; since then he has been confined to his bed, suffering intensely; and although he has been kept under the influence of opiates, he has gotten but little rest, and has taken hardly any nourishment for the past five days.

To-day (May 15) the attending physician lanced the hand, and predicted great relief; but seven or eight hours has passed, and the relief has not come. The prospect now is that Mr. Jordan may lose his hand.

Mrs. Jordan, a most estimable lady, has been constantly at her husband's bedside, and is nearly worn out. Although the family have been so greatly afflicted since I have been here, I have been most royally entertained. They are the kindest and most hospitable people I have ever met.

I have not been in this locality long enough to form much of an idea about the country, but what I have seen I like very much. Bees seem to do well here.

Later news, through Mr. J. H. Wellington, informs us that, on May 22, Mr. Jordan was a little better, but not out of danger. That baneful disease, erysipelas, has complicated matters by its presence—and, worse still, the strain on the nerves of his devoted wife and faithful nurse, has been too much, and she is now confined to her bed by a severe attack of neuralgia. We deeply sympathize with these afflicted ones, and hope for speedy restoration to health.

Judge W. H. Andrews, of McKinney, Texas, one of the best apiarists of the South, delivered four lectures on bee-keeping before the Texas Bee-Keepers' Association, at its late meeting at Greenville, Texas. The lectures covered every point in southern bee-keeping. B. F. Carroll, the chairman of the committee on programme, says: "It is believed by this committee that more light has gone out from its meetings than from any like body in America." That is saying considerable, but it may come pretty near the truth, "for a' that, and a' that."

The Judge will no doubt formulate his ideas, and give them to the public before long.

Red Ants are sometimes very troublesome, and a subscriber wants to know how to get rid of them. This can be done after finding their nests by sprinkling powdered borax around it, and when a rain comes, it will be carried down into the nest, and they will then remove to new quarters to get rid of the soapy borax.

The Rev. George Raynor, one of the most eminent English bee-keepers, died on May 3, 1889, aged 70 years. The cause of his death was, *angina pectoris.*

A Swarm of Golden Bees.

"That orbed maiden with white fire laden,
Whom mortals call the moon,
Glides glimmering o'er my fleece-like floor,
By the mid-night breezes strewn.

"And wherever the beat of her unseen feet,
Which only the angels hear,
May have broken the woof of my tent's thin roof,
The stars peep behind her and peer.

"And I laugh to see them whirl and flee,
Like a swarm of golden bees,
When I widen the rent in my wind-built tent,
Till the calm river, lakes, and seas,
Like strips of the sky fallen through me on high,
Are each paved with the moon and these."

—From "The Cloud," by Shelley.

GLEANS OF NEWS.

Prof. Cook's Lecture recently at Albany, is reported thus in the *Country Gentleman*, published in that city :

For years many of our best bee-keepers have urged that only specialists should keep bees. The last two years of failure have convinced many of these that it would be better to unite bee-keeping with some other industry. Bee-keeping is *par excellence* a pursuit to add to some other. It serves as recreation, and often gives a large profit. Farmers and fruit-growers, as the very successful experience of many has shown, are just the ones, it naturally fitted for the business, to add apiculture to their other cares. Thus the farmer may have better crops, and may save the nectar that otherwise would go to waste, and which may be the most profitable product of the farm.

The study which bee-keeping requires will be enjoyed, and may be made the means to interest the boys and girls in the farm. The speaker had known several such cases. But let the boys and girls know that the profits are to be theirs. Then bee-keeping, in conjunction with farming, can be made a great success. How will the product of such bee-keeping be put on the market in poor condition ? Unmarketable honey comes from the slovenly and the untidy, alike, whether he be a specialist or amateur.

The idea that the busy season with the farmer and bee-keeper is one and the same, need discourage no one. With proper thought and care the labor with bees in June and July may be reduced to small proportions, and can mostly be performed by a boy or girl. And here is a way to interest our girls, to give them air and sunshine, and a chance to earn money. Some of the best bee-keepers in the country are just such farm girls.

To work successfully,one must thoroughly prepare himself by studying a good book, reading one of the best bee-periodicals, and, when possible, spending a day or two with some well-informed and successful bee-keeper. In the farm home, during the long winter evenings, the books can be read aloud, and the business discussed by father and children. This keeps father and children just where they ought to be as night comes on.

Directions were given as to where and how to secure the bees, and the point was urged to go slow ; commencing with 2 or 3 colonies of bees, and increasing as experience, success and knowledge suggested. If no money was paid out after the first start, no great loss could be experienced, and usually such a course brought success, pleasure and satisfaction.

If the first purchase is made of some neighboring bee-keeper, we are likely to do better, and make a friend who will come to the rescue, if breakers confront us in our work in the bee-yard.

With proper thought, study and care it will be found that the new pursuit brings pleasure and profit, and its adoption by the studious and thoughtful man will rarely be regretted.

Tid-Bits from the pen of friend G. M. Doolittle, in the *Rural Home :*

If any one wishes a little keen enjoyment of his pets, the bees, let him put out some finely-ground corn-meal in some sunny nook in early spring, before any pollen can be had from the fields, placing a piece of comb in the same, so that the bees may be drawn to it. They will soon begin to pack the meal in their pollen baskets, and carry it to the hive. They will roll around in it like little pigs, and cut up all sorts of antics, greatly to the amusement of the children, and most of the older ones also.

When among the bees let your movements be deliberate, and do not appear to fear the bees ; quick, nervous movements the bees resent. If a bee is troublesome, and you wish to retreat, put up your hands quietly and shield your face, and as quietly retreat ; if you throw up your hands wildly and run, you may be sure you will lose the race, and the bees will leave you in a peculiar state of mind ; not a calm and peaceful frame I assure you, but perhaps one which will enable you to heed these instructions better than such a state of mind would.

Bees and Honey.—The *Sentinel*, Rayne, La., has this to say about our book entitled "Bees and Honey :"

Mr. Newman is a prolific writer on apiculture, is editor of the AMERICAN BEE JOURNAL, and is a well-known authority. The pretty bound book before us contains detailed instruction as to the management and care of bees, the preparation and shipment of honey to market, bee-pasturage, nutritive qualities of honey, etc. In fact, no lover of the industrious little insect should be without the book, or fail to subscribe for his well-known periodical, the AMERICAN BEE JOURNAL, which is one of our most valued exchanges.

Herr Emil Hilbert, of Maciejewo, Germany, has sent us two of his latest pamphlets. One is on "Foul Brood in Bees, its Cause and Cure," and the other is on "Chicken Cholera." He invites us to translate and publish the former, and if some good German scholar will take the trouble to read and translate the salient points for us, we shall be pleased to publish pretty full extracts. Herr Hilbert is good authority on bees. We met him at the bee and honey show and convention at Prague ten years ago, and had an excellent visit with him, and Dr. Dzierzon, Dr. Pollman (of Russia), the Baroness of Berlepsch, and many other prominent apiarists of Europe.

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

The Statistics, as gathered by the Honey-Producers' Exchange, are received, and show that the losses in the past winter were only about 8 per cent. ; the present condition of the colonies is good ; and the prospect for a honey crop was never better.

Japanese Buckwheat.—Prof. A. J. Cook, of the Agricultural College, Mich., says that the Japanese buckwheat is the best variety for grain and also for honey. He says farmers, and especially bee-keeping farmers, should sow it as a part of their crop. It is sown late in June. It is an excellent crop to precede corn on land that is infested with white worms. It seems to starve out these terribly destructive grubs. Again it is a profitable crop, often paying better than wheat. Not only this, it gives us the basis of our buckwheat cakes which with honey will tempt the most capricious appetite. The blossoms oftentimes furnish nectar for the bees when all else fails.—*National Stockman.*

Here are some more recipes where honey is used to advantage :

FOR WORMS.—Before breakfast take a table-spoonful of honey ; or a tea made of peppermint sweetened with one-half its bulk of honey.

HONEY mixed with flour into a paste just thick enough to run, will be found most efficient in the treatment of boils. Put it on as a poultice.

FOR CROUP AND HOARSENESS.—A gargle made of sage-tea sweetened with honey, or "pills" made of mustard, flour and water.

Why Advertise in the AMERICAN BEE JOURNAL ? Here are some good reasons for patronizing the advertising space in this bee-periodical :

1. Because it has a large and influential circulation in every State and Territory, Canada, and other foreign countries.

2. Because it is well-printed, and an advertisement in it appears neat and attractive, and invites a reading.

3. Because it reaches just the class of persons desired—professional men, lawyers, doctors, and the best of the rural population.

4. The rates are low as possible, and the returns from advertisements are satisfactory.

Catalogues for 1889 are on our desk from—

J. G. Aten, Jefferson, O.—6 pages—Bee-Keepers' Supplies.

Thos. L. Thornton, Dividing Ridge, Ky.—6 pages—Bees, Honey, and Apiarian Supplies.

Is that your Husband, ma'am ?

He be.

Is that your wife, sir ?

She be.

Ah, that's pleasant ; a he bee and a she bee can't fail to taste the sweets of life.—*Texas Siftings.*

PRESERVES.

All the summer weather,
Saying naught of "nerves,"
Toils a little house-wife
Making choice preserves.
How she does her cooking
Surely no one knows,
Tho' they watch her daily
While she comes and goes.

More than half her goodies
Go to pay her rent,
Yet in every season
She is well content;
And from noon till even
And from morn till noon
Even at her labor
Hums a pleasant tune.

Rose and lily syrup,
Richest clover jam,
Fill her tiny fruit-jars
Full as she can cram.
Now you've guessed my riddle,
And you'll all agree
That the name we call her
Always ends with *Bee*.
—*Youth's Companion.*

QUERIES & REPLIES.

Beverages with Honey as a Main Ingredient.

Written for the American Bee Journal

Query 633.—Please describe a good method of making mead, metheglin, lipeiz (a Russian drink), and any other desirable drink with honey as main ingredient.—Canada.

Pure water is the most desirable drink that I know of.—H. D. CUTTING.

I know nothing of the subject or matter.—J. E. POND.

I have had no experience.—J. P. H. BROWN.

I would not make any fermented drink of honey.—EUGENE SECOR.

I am not posted. We are cold-water people at our house.—A. J. COOK.

I never made any, and think that good, *pure water* is much better.—C. H. DIBBERN.

Cold water is the best drink for man, used with moderation.—G. M. DOOLITTLE.

Mead is made by sweetening water with honey until it is a little sweeter than maple-sugar water. Metheglin is the same honey and water after it has fermented.—MAHALA B. CHADDOCK.

The best methods are fully described in Thomas G. Newman's valuable little pamphlet entitled, "Honey as Food and Medicine."—G. L. TINKER.

I do not know. I do not approve of beverages simply to tickle the palate. —J. M. SHUCK.

You will find a good description of the methods for making these drinks in "Honey as Food and Medicine," by Thomas G. Newman.—MRS. L. HARRISON.

I think it is not desirable to make mead, metheglin, or any other fermentable substance.—M. MAHIN.

I have had no experience, and I have some doubt if any good drink can be made with honey as *main* ingredient. I surely would not call it a good drink if intoxicating.—C. C. MILLER.

None that you name are desirable drinks—do not make any of them. What a grand thing it would be, in an economical point of view, to say nothing of men's souls and bodies, if everything containing alcohol were doomed as a beverage.—R. L. TAYLOR.

The best wine that we ever made with honey and grapes was made as follows: To each gallon of grape-juice, add 2 pounds of honey that has been thoroughly boiled. Three pounds of honey to a gallon of water, boiled, with a very little grape-juice added, will make a splendid drink for dyspeptics, taken at meal-time with addition of water. It should be taken care of, like wines, and is best when at least three years old.—DADANT & SON.

I have experience only in making wine and vinegar from honey as a sweetener. I can make very fine wines by the use of honey, and the best of vinegar, but I am awfully "sot" on temperance, and this takes the enthusiasm out of me as to the wine; but the vinegar is all right. This department will not admit of space to give the methods employed to make wines, etc.—G. W. DEMAREE.

I do not know of any "desirable drink with honey as the main ingredient." The "main ingredient," and the most "desirable" in all the "drinks" I ever saw, tasted or heard of, is *water*. If some milk is added, it does not detract from its "desirableness" for my use. If you Canucks have not enough variety in "drinks," just send 5 cents (or rather, send the price of two "drinks") to Thomas G. Newman & Son, for a nice little work entitled, "Honey as Food and Medicine," and get over a page of "drinks" that have honey in them, and 27 pages of good reading besides.—A. B. MASON.

Our good editor says this in "Bees and Honey:" "Metheglin is made by mixing honey and water strong enough to carry an egg; let it stand three or four weeks in a warm place to ferment; then drain through a cloth, and add some spices to suit the taste." Also, we find the following in the same book: "Cheap Harvest Drink.—To those engaged in harvesting and other occupations tending to create thirst, we recommend the following preparation, which makes a very palatable and healthful drink in hot weather: Take 12 gallons of water, 20 pounds of honey, and 6 eggs, using the whites only. Let these boil one hour; then add cinnamon, ginger, cloves, mace, and a little rosemary. When cold, add one spoonful of yeast from the brewer. Stir it well, and in 24 hours it will be good."—WILL M. BARNUM.

The first edition of "Honey as Food and Medicine" contained a large variety of recipes for making honey-wines, mead and metheglin—as used in the various countries of Europe. The later editions contain only the recipes for harvest drink and metheglin quoted by Mr. Barnum, and the following recipe for making "wine mead:" "To make mead, not inferior to the best foreign wines, put three pounds of the finest honey to two gallons of water, two lemon peels to each gallon; boil it one-half hour, and skim well. Put in the lemon peel while boiling. Work this mixture with yeast, and then put it in a vessel to stand five or six months; then bottle for use. If you choose to keep it several years, add four pounds of honey to a gallon of water." As all good people should be temperate in their habits and life, they are not expected to use intoxicating drinks, and this will account for the omission of the recipes before mentioned. In answering the question therefore, as to "how to make," no one should imagine that it is advice to manufacture or use any intoxicating drinks.—THE EDITOR.

CORRESPONDENCE.

HIVES.

Large vs. Small Brood-Chambers Considered.

Written for the American Bee Journal

BY W. Z. HUTCHINSON.

I desire to reply here, instead of in the *Review*, to the argument of Mr. Dadant in favor of large brood-chambers, on page 311, as I wish *all* the readers of the AMERICAN BEE JOURNAL to hear both sides of the discussion.

It is true that I declined to publish and article from our Illinois friend, but I was not actuated by any motives of partiality. I could, of course, tell *why* it was refused; but while I sincerely desire to stand well in the opinions of the AMERICAN BEE JOURNAL and its readers, I prefer to be misjudged by those who cannot take my simple word in the matter, rather than still further wound the feelings of so honorable an opponent. I will say this much, however, that the article which appeared on page 311 of the BEE JOURNAL would have been accepted with pleasure.

To review a book containing so much valuable information as is to be found in "Langstroth on the Honey-Bee, Revised by Dadant," and attempt to give, in a few short columns, the gist of the volume, at the same time criticising, praising or condemning, as the occasion seems to require, is a very difficult task. Others may be better fitted than myself for this work, but I *do* strive, and that most earnestly, to do the author no injustice.

Mr. Dadant thinks that I did not do quite the fair thing by not giving the *reasons* why he preferred large brood-chambers. He gives a paragraph from which I quoted a sentence. He thinks that it would have been better if I had quoted the whole paragraph, which reads as follows:

> 309. As the harvest of honey is always in proportion to the number of bees in the hive, and as a large colony requires no more labor from the apiarist than a small one, the hive should afford the queen sufficient space to deposit all the eggs which she is able to lay during 21 days, the average time for an egg to be transformed into a worker. Besides, it should contain a certain amount of food, honey and pollen.

Let us investigate this idea that "a large colony requires no more labor from the apiarist than a small one." I believe that the *forte* of my opponent is that of producing extracted honey; can he extract the honey from a large colony with as little labor as from a small one?

The advocates of large hives assert that their bees are housed more cheaply in large hives. I say *no*. Large hives are not only more expensive in proportion to their size, but the width of lumber needed for their construction, is more expensive. But I think that there is little difference, so far as expense for hives is concerned.

With large hives, and the use of the extractor, I know that swarming can be well-nigh overcome; but not so in producing comb honey.

In speaking of large hives, Mr. Dadant says: "This space must allow of contraction, according to the needs of the colony, by what is called 'movable division-boards.'" He still further says: "Besides, I could add that while we can reduce the capacity of our large hive, he cannot increase the size of his small one." Beg pardon, Mr. Dadant, but the small hive that *I* use and prefer, can be at once the smallest or the largest hive, simply by adding or removing sectional parts.

But this is not exactly the point under discussion. Mr. Dadant advocates, and uses, a large brood-chamber—one so large that the most prolific queen will never be cramped for room, so large that some of the queens do not fill them with brood, and the space at the sides must be filled with combs of honey, or else the brood-nest must be contracted with division-boards; while *I* advocate and use a brood-chamber that is no larger than an ordinary prolific queen will keep full of brood in the forepart of the season. We are discussing which *size* of brood-chamber is the better; and *not* which could change over to the *other* size the most readily, although I should be willing to discuss the latter point.

I am still in doubt as to Mr. Dadant's exact views in regard to honey-boards. He quotes a paragraph in which he admits that a *skeleton* honey-board is sometimes used in comb-honey production; but there is another paragraph in which he says: "331. The *movable honey-board*, between the brood-chamber and the upper stories, has also been discarded of late years." Dr. Miller suggests that Mr. Dadant has reference, in paragraph 331, to the old obsolete honey-board, that was really a *board* having holes bored through it, and upon which honey-*boxes* were placed. I shall be glad to know that Mr. Dadant does not condemn the modern, slatted, break-joint bee-space inventions.

In reference to patents, Mr. Dadant thinks that I ought to have published the paragraph in which he gave his reasons for cautioning bee-keepers against investing in patent hives. Here is the paragraph:

> 358. More than 800 patents on bee-hives and implements have been issued in the United States since January, 1873. Not ten of these have proved to be of any use to bee-keepers. The mention of this fact will suffice to show the small value of these 790 patents, and the loss incurred by those who have bought them before they were able to judge of their merits.

During this time that 800 apiarian hives and implements have been invented and patented, many others have been invented that were *not* patented. I fail to recognize their superiority over the patented articles. The patenting of an article does not add, neither does it detract, one iota of usefulness.

My opponent calls attention to the point that many have been led to invest in patents upon worthless articles. True; but the pittance paid for a patent is a mere drop in the ocean, compared to the mistakes of adopting an undesirable hive; and the mistakes will be none the less grievous, be the hive unpatented.

Mr. Dadant complains because I did not mention that he had arrived at his conclusions in regard to the best size for brood-chambers, after an experience of twenty years with hives of different sizes. Of course it would have been perfectly proper to have done so, but then I should have been in duty bound to have mentioned others who had experimented in a similar manner and arrived at *opposite* conclusions. Instead of simply giving our experiences, let us strive to learn the *reason* for things.

I cannot close without thanking Mr. Newman for his kind editorial on page 307, upon this discussion and the preceding circumstances. I feel like saying "amen" to the whole of it. Until I commenced publishing the *Review*, I did not fully realize the many difficulties and delicate tasks that fall to an editor. Not the least of these is that of declining articles, especially when they come from prominent personages. I have several times thought it necessary to do this, but never without wishing that I might, for the time being, change places; and I sincerely hope that I have lost the friendship of no one by doing what I believe is for the best.

Flint, Mich.

TEXAS.

Report of the Texas State Bee-Keepers' Convention.

Written for the American Bee Journal

BY REV. J. N. HUNTER.

On May 1, 1889, the eleventh annual session of the Texas State Bee-Keepers' Association was held at Vice-President W. R. Graham's apiary, at Green-

ville, in connection with a May-day picnic.

At 11 o'clock a.m. an invocation was offered by Rev. W. K. Duff, of Greenville, and a speech of welcome was then tendered by Hon. J. S. Sherrill.

Dr. W. K. Marshall, of Marshall, Texas, was introduced and delivered an excellent address on the happy surroundings of the day, and the moral education of the rising generation. The Doctor's speech was a splendid effort, and we trust that it made a deep impression. A sumptuous repast was spread at noon, to which all did ample justice.

After dinner, at 2 p.m., the convention was called to order by Vice-President W. R. Graham. Judge W. H. Andrews, of McKinney, Texas, was introduced, and gave a lecture on the following points in bee-culture: Importance of bee-culture; implements of bee-culture; hives, frames, etc.; bee-keeping as a specialty; uncertainty; honey-plants of Texas; races of bees—the best and most beautiful; handling of bees; and their propensity to sting.

Dr. W. K. Marshall then drew a graphic contrast of modern bee-keeping with the past methods, now becoming obsolete.

The convention then adjourned to meet the next morning at 9 o'clock.

SECOND DAY.

The convention met on Thursday, May 2, at 9 a.m., and called to order by Vice-President W. R. Graham.

Judge Andrews was introduced, and continued his lecture on bee-culture; on rearing and introducing queens. The lectures were of vital interest to bee-keepers.

On motion, the officers of the Association were elected for the ensuing year, as follows: W. R. Graham, of Greenville, President; J. P. Caldwell, of San Marcos, Vice-President; J. N. Hunter, of Celeste, Secretary; and G. H. Wilson, of McKinney, Treasurer.

Greenville was selected as the place of the next meeting.

J. N. Hunter, *Sec.*

APIS DORSATA.

Climbing Trees to Get the Large Bees of Java.

Written for the Australasian Bee Journal

BY T. J. MULVANY.

Confining our attention for the present (as we have done in preceding papers in regard to South America and to Africa) to that portion of the tropical zone which extends abou 10° north and south of the equator, and tracing this belt eastward from the coast of Africa, it will be found to take in, first, the island Ceylon and the extreme southern part of India proper, and next, the so-called "East India Islands" in the Malay Archipelago; then passing by the northern extremity of Australia to New Guinea, and to the least important of the island groups in the Pacific Ocean. North of this narrow belt lie those districts of Arabia, India, and Eastern Asia, which were amongst the earliest inhabited parts of the globe, and into which the honey-bee had found its way, and where the use of honey and the traffic in both honey and beeswax seem to have been established long before the earliest pages of history were written.

Climbing After Apis Dorsata.

The Egyptian bee (*Apis fasciata* of Latrielle) appears to be the variety which extended itself most extensively eastwards, through Arabia, Central Asia, north of the Himalayas, and into China. The peninsula of India proper, south of the Himalayas, is said by Dr. Gerstaecker to possess three indigenous species of the genus apis, named by Latrielle *Apis indica*, *A. sirialis*, and *A. dorsata*; but a closer inquiry seems to indicate that these are not separate species, but only varieties of the *Apis mellifica*. I do not know if this point is as yet quite settled to the satisfaction of scientific men; but at all events, the *Apis dorsata*, of which we hear most in Southern India, in Ceylon, and in the eastern islands, is a very remarkable insect, and seems to differ more in size, character and habits from the European honey-bee, than any other variety we have heard of.

It is now some eight or nine years since Mr. D. A. Jones, of Canada, took steps to ascertian the practicability, or the reverse, of importing the East India variety of the honey-bee. Mr. Benton, who was sent out by him to Ceylon, in his first report wrote: "*Apis dorsata* is a wonderful bee, whether it can be domesticated or not. It builds in the open air on branches, often making combs six feet long: and I have good authority for saying that *thirty natives have each taken a load of*

honey from one tree." In 1883 the Indian Government published the result of investigations that had been going on for some years in all parts of India, in connection with the popular treatment of bees in that country. From this source we learn that the chief honey district in Southern India is about Coorg and the Wynaad near the Neilgherry Hills, which is about the nearest part of continental India to Ceylon, where Mr. Benton met the *Apis dorsata.*

In Coorg, it is said, "the wild bees build their combs in the trees, and as many as a hundred combs are occasionally found in a single tree. An average of 8 pounds of honey is obtained from each comb in this district, and the bees are driven out by smoking torches applied to their nests." One case is mentioned of a "large mango tree, some 20 feet in girth, standing on the boundary between Wynaad and Mysore, where the natives in each district exercise the right of collecting the honey from the as far as I know, without success up to the present.

Mr. A. R. Wallace, in his work entitled "The Malay Archipelago," published in 1868, mentions bees, honey, and beeswax as met with, especially in the great island of Borneo, in Celebes, and in Timor. They are no doubt common in all, or nearly all the islands of this group, though not specially mentioned, the principal objects of Mr. Wallace's pursuit having been the birds of paradise and other gorgeously feathered denizens of that interesting region.

At Maros, in the Celebes islands, he notes, "the flies and bees were abundant, and of these I daily obtained new and interesting species;" but he does not describe the species or varieties of bees met with. However, when at Timor, he speaks, as we shall see further on, of the *Apis dorsata*, and in the following extract, the manner in which the honey-bee of Borneo is described, leads to the conclusion that it is the same as at Timor. After describing the many uses to which the bamboo cane is applied in Borneo—the building of light suspension bridges across rivers, etc.—he says :—

The Manner in which Apis Dorsata Build their Combs.

branches overhanging their own territory." These bees would appear to be of the same variety as those found in Ceylon, but unfortunately no particulars are given as to their size, color, the size of their combs or its separate cells, nor about the separation into different "nests" or colonies of the large number of combs found in one tree.

One of the reporters, Mr. Morgan, Deputy Conservator of Forests in the Wynaad, comes to the conclusion that "only one kind of bee, the *Apis indica*, is capable of domestication, and that only in hilly districts, not on the plains;" but he does not say why, nor give any special description of this variety. A very large sort of bee, which they call "large cliff bees" (building in cliffs and under ledges of rocks), are represented as "so ferocious in habit, and furnished with such deadly stings, as to be dangerous to both men and beasts coming within their neighborhood." Whether these dangerous insects are *A. indica* or *A. dorsata*, or some other sort, does not appear. Mr. Jones, of Canada, has since made personal acquaintance with the *A. dorsata* in Ceylon, and endeavored to import some to America, but

One of the most striking uses to which the bamboo is applied by the Dyaks, is to assist them in climbing lofty trees, by driving in pegs in the way I have already described at page 55. This method is constantly used in order to obtain wax, which is one of the most valuable products of the country. The honey-bee of Borneo very generally hangs its combs under the branches of the Tappan, a tree which towers above all others in the forest, and whose smooth cylindrical trunk often rises a hundred feet without a branch. The Dyaks climb these lofty trees at night, building up their bamboo ladder as they go, and bringing down gigantic honey-combs. These furnish them with a delicious feast of honey and young bees, besides the wax, which they sell to traders, and with the proceeds buy the much-coveted brass wire, ear-rings, and gold-edged handkerchiefs, with which they love to decorate themselves.

Thin, long jointed bamboos form the Dyaks' only water-vessels, and a dozen of these stand in the corner of every house. They are clean, light, and easily carried, and are in many ways superior to earthen vessels for the purpose....Salted fruit, or fish, sugar, vinegar, and honey are preserved in them instead of jars or bottles. At Timor also, describing a photograph given of two natives, he remarks, "The covered bamboos probably contain honey for sale."

At Timor he gives the following account of the manner in which the natives climb the tall trees there and take the honey-combs of the *Apis dorsata*. The description is so graphic and interesting, especially to the different means adopted by these natives as compared with those of Borneo, climbing the tall smooth trees, that I am induced to give it at full length.

The beeswax is a still more important and valuable product, formed by the wild bees (*Apis dorsata*), which build huge honey-combs, suspended in the open air from the underside of the lofty branches of the highest trees. These are of a semi-circular form, and often 3 to 4 feet in diameter. I once saw the natives take a bees' nest, and a very interesting sight it was. In the valley where I used to collect insects, I one day saw three or four Timorese men and boys under a high tree, and looking up, saw on a very lofty horizontal branch three large bees' combs.

The tree was straight and smooth—barked and without a branch, till at 70 or 80 feet from the ground it gave out the limb which the bees had chosen for their home. As the men were evidently looking after the bees, I waited to watch their operations. One of them first produced a long piece of wood, apparently the stem of a small tree or creeper, which he had brought with him, and began splitting it through in several directions, which showed it was tough and stringy. He then wrapped it in palm leaves, which were secured by twisting a slender creeper around them. He then fastened his cloth tightly around his loins, and producing another cloth wrapped it around his head, neck and body, and tied it firmly around his neck, leaving his face, arms, and legs completely bare. Slung to his girdle he carried a long, thin coil of rope; and while he had been making these preparations one of his companions had cut a strong creeper or bush-rope 8 or 10 yards long, to one end of which the wood-torch was fastened, and lighted at the bottom, emitting a steady stream of smoke. Just above the torch a chopping-knife was fastened by a short cord.

The bee-hunter now took hold of the bush-rope just above the torch, and passed the other end around the trunk of the tree, holding one end in each hand. Jerking it up the tree a little above his head, he set his foot against the trunk, and leaning back began to walk up it. It was wonderful to see the skill with which he took advantage of the slightest irregularities of the bark or obliquity of the stem to aid his assent, jerking the stiff creeper a few feet higher when he had found a firm hold for his bare feet. It almost made me giddy to look at him as he rapidly got up—30, 40, 50 feet above the ground; and I kept wondering how he could possibly mount the next few feet of straight smooth bark. Still, however, he kept on with as much coolness and apparent certainty as if he were going up a ladder, till he got within 10 or 15 feet of the bees. Then he stopped a moment, and took care to swing the torch (which hung just at his feet) a little towards these dangerous insects, so as to send up the stream of smoke between him and them. Still going on, in a minute more he brought himself under the limb, and in a manner quite unintelligible to me, seeing that both hands were occupied in supporting himself by the creeper, managed to get upon it.

By this time the bees began to be alarmed, and formed a dense buzzing swarm just over him, but he brought the torch up closer to him, and cooly brushed away those that settled on his arms and legs. Then stretching himself along the limb, he crept towards the nearest comb and swung the torch just under it. The moment the smoke touched

it, its color changed in a most curious manner from black to white, the myriads of bees that had covered it flying off and forming a dense cloud above and around.

The man then lay at full length along the limb, and brushed off the remaining bees with his hand, and then drawing his knife cut off the comb at one slice close to the tree, and attaching the thin cord to it, let it down to his companion below. He was all this time enveloped in a crowd of angry bees, and how he bore their stings so coolly, and went on with his work at that dizzy height so deliberately, was more than I could understand. The bees were evidently not stupefied by the smoke, or driven away far by it, and it was impossible that the small stream from the torch could protect his whole body when at work. There were three other combs on the same tree, and all were successfully taken, and furnished the whole party with a luscious feast of honey and young bees, as well as a valuable lot of wax.

After two of the combs had been let down, the bees became rather numerous below, flying about wildly, and stinging viciously. Several got about me, and I was soon stung, and had to run away, beating them off with my net, and capturing them for specimens. Several of them followed me for at least half a mile, getting into my hair, and persecuting me most pertinaciously, so that I was more astonished than ever at the immunity of the natives.

I am inclined to think that slow and deliberate motions, and no attempt at escape, are perhaps the best safeguards. A bee settling on a passive native probably behaves as it would on a tree or other inanimate substance, which it does not attempt to sting. Still they must often suffer, but they are used to the pain, and learn to bear it impassively, as without doing so no man could be a bee-hunter.

Timor is nearly the most eastern of the East India islands, and that nearest to the northwest coast of Australia, from which it is, however, more than 300 miles distant. The *Apis dorsata* never made its way across that sea, as neither it nor any of the European varieties of the *Apis melifica* was known in Australia until the latter were introduced by the white settlers. It is well known that there is an extraordinary and very marked difference between both the fauna and flora of continental Asia and those of Australasia; and naturalists point out, as the abrupt boundary between the two, a narrow strip of deep water which divides the shallow seas on each side of a line passing between the islands of Bali and Lombock, and through the Macassar Straits, between Borneo and Celebes.

Some of the western species of birds, and some insects—the *Apis dorsata* among the latter—have made their way or been carried to some of the islands east of that line of demarcation, but no further, in a southeasterly direction, than Timor, as above mentioned. As bees are plentiful in Celebes, and there are several large and small islands scattered between it and the great island of New Guinea, which might serve as stages in the eastward spread of the insects, one would expect to find them also in the latter place; but I have not seen any mention of bees or honey in the meagre accounts of New Guinea, which I have chanced to come across. Of the Pacific islands in this equatorial belt, the Caroline, Marshall, Gilbert, Ellice, and Phœnix groups, New Britain, and Solomon Islands, etc., but little is known. They are, no doubt, destitute of any species of the honey-bee.

With regard to the more important and better known groups in the southern tropical region—New Caledonia, New Hebrides, Fiji, Samoa, the Friendly, Cook's, and Society groups, etc., it is greatly to be wished that information on this subject could be collected from parties who may have visited them. In the principal of these islands now inhabited by Europeans, apiculture will, no doubt, have been already introduced to some extent, and it is to be hoped that some among these pioneers of the industry may be readers of the *Australasian Bee Journal*, and may be induced to favor us with the information desired.

TRANSFERRING.

How to Transfer Bees from Box-Hives.

Written for the Orange Judd Farmer

BY JAS. POINDEXTER.

Fastening combs in frames by wrapping strings of wire around, slipping clasps over frames and combs, or running melted wax between the pieces of comb, etc., to hold them in place, have all proven unsatisfactory with me.

The only plan by which I have been entirely successful is by the use of sticks to hold the combs right where I want them. This is an old method, but I will give it as I practice it at the present time. Use two boards the size of the frames, a lot of sticks 1-6 of an inch square and ½ inch longer than the frame is deep, some small annealed wire (copper is best), about the size of an ordinary needle, a straight edge, a knife and a table. Then we are ready to operate.

If the combs are to be taken from a hive with bees in, give the bees a smoking, invert the hive, place another of the same size over it, and rap on the hive a few minutes, when most of the bees will ascend into the empty hive which may then be set to one side. Then take off that side of the hive which is parallel with the combs, cut out the combs, smoking occasionally to drive the remaining bees to the further side. The combs are carefully placed in a box, and taken to a room where the temperature is 60° or upward. On one of the boards above mentioned, place an empty frame. Take one of the largest straight combs, and with the straight-edge cut so as to fit snug in the frame, then fill out the frame with smaller pieces, keeping in view two very important points:

To have the frame filled solid, so there will be no openings between the pieces, and that there are no crooked pieces put in, no matter how small they are cut to avoid it. Lay as many sticks on, extending ⅛-inch above the top, and ¼-inch below the bottom of the frame, as are necessary to hold the combs firmly in place. Lay the other board directly over the frame and on the sticks. Invert and remove the first board used. Lay on as many sticks as were placed on the other side and even with them. Now with the annealed wire wrap once around the end of the upper stick, then down under the lower one and back twice around the upper. The wire may be cut in pieces of right length before using. After the ends on one side are secured, the others are fastened in like manner.

When combs with brood are transferred, a frame with cloth tacked on is used instead of one of the boards, to prevent the capping of the board from becoming bruised.

When empty combs, and those with little honey are transferred before puting on the sticks, I lay the other transfer board on the combs and frame, lay on the floor, and place a 244-pound weight on all by stepping thereon. This reduces the comb to ⅞-inch, the thickness of my frame, and the proper thickness of worker combs. The bees will strip off the bruised ends of the cells.

If there are not combs sufficient to fill the hive, a division-board is placed in the vacant space until other combs are secured. The hive is then returned, and the bees shaken at the entrance.

The best time for transferring is when there is the least honey and brood in the hive, and when the bees are busy and not inclined to rob. During fruit-bloom and at the commencement of white clover harvest are favorable seasons. If the work is done when the bees are idle and liable to rob, it should be late in the evening, or the hive and bees removed to a room during the operation, and until all the loose honey is cleaned up. The sticks are left on until the combs are thoroughly welded together. I have in a few instances left them on a year without apparent harm to the bees. All the new, straight drone-comb not used as guides in sections, I transfer to frames to be used in hives for extracting. I have a set of drone-combs used for 14 years.

BEE-HIVES.

My "Ideal" Hive is the Coming One.

Written for the American Bee Journal

BY J. W. TEFFT.

I take pride in being a good bee-keeper, and knowing my trade thoroughly. I will give some of my ideas of what a perfect bee-hive should be. The subject-matter may not be of interest, and then again it may be of great interest. If no one receives instruction from reading it, I certainly will have the pleasure of amusing them.

In the year 1883 I received much pleasure, information and instruction in examining a bee-hive that was imported from Rodheim, Germany, in 1830; also in the book giving a history and description of the hive, by the inventor, Rev. J. L. Christ, published at Rodheim in 1783, over 100 years ago. The illustrations gave me a subject for thought. Previous to this I had been using the Langstroth and Quinby hives, as well as reading their books, and other good bee-literature.

Comparing the three books and the three hives, and carefully comparing the fine points in the hives and books, I was impressed with the similarity; then I conceived that the ideas of the three men were of the same intent, but had worked up their hives at opposite ends. This impressed me with the idea that if the three hives could be combined into one solid one, some serious obstacles could be removed, and would be of advantage. These ideas were carried out in 1875, and introduced to parties in New York city; and in 1876 they brought the hive out under the name of "Chaff Eclectic." When I saw the hive I was wofully disappointed, for they had ruined my expectations by substituting ideas of their own, and it was not much of any advance over the Langstroth and Quinby hives.

To say the least, I was far from being contented to let the very best thoughts of the three great inventors remain in that shape. I concluded to take the matter in my own hands, and arrange things as they should be. I commenced ten years ago, striking out old things and substituting new ones—my idea being to work out of the ruts. The ten years have been employed in experimenting, perfecting and putting things to practical tests, and they have proved beyond a doubt that my convictions were right.

The good features that I desired in a bee-hive were these: The permanent packing, or hollow walls of the ends of the brood-chambers 21 inches wide, from side to side; roomy, for single movable-comb frames, and the movable division-boards; these three things are indispensable, and I saw nothing more that I desired to retain in our modern bee-hive.

I want to see the same advancement in the future bee-hives that we see in our flouring mills, and receive the same results as the roller mill has achieved over the old French burr stone process.

In order to do that, we must have the brood-chambers larger from side to side, with movable division-boards, so that the brood-chambers can be enlarged or contracted at the will of the apiarist, to suit any large or small colony of bees, be they strong or weak, as necessity requires. The ends of the brood-chambers must be hollow-walled, or permanently packed, for the prevention of any sudden changes from heat or cold, or *vice versa;* from interfering with the workings of the bees inside the hive, at any and all seasons of the year.

The bottom-board of the brood-chamber should be double thickness, and tarred paper put between, and nailed fast to the brood-chamber to prevent insects or dampness from the ground passing through, as well as for warmth. The sides, back, and ends should be 11 inches high, and on the outside, near the upper parts, one inch from the upper edges, a ledge should be nailed all around the brood-chambers for strength, and for the middle rim to rest upon.

The middle rim should have no top or bottom, and be 11 inches high. Its functions in connection with the brood-chamber, are numerous, such as securing shade, ventilation, protection from heat, storms and cold; also for its capacity for packing for winter. Bees will not quit the sections when thus protected. Think of it!

The cover should rest in the same manner as the middle rim rests on the brood-chamber, the side of the cover to have 4½ inches rise; where the shell of the hive is thus constructed, its functions is to protect the movable inner hive, such as shade, ventilation, warmth, and numerous other good things.

Ventilation of the Hives.

When the combs over the bees are in working order, and the division-boards in place, a space is found between the shell and the division-boards; the division-boards should be ¼-inch from the bottom-board; and the air as it enters the entrance of the hive will pass under the division-board into the space and out through the four ventilating holes. This keeps the bees quiet, the comb free from moisture, and insures healthy bees, and pure honey. The fetid air passes away into the packing in winter, and into space in the summer. This is a certain remedy to prevent bee-diarrhea.

Making Hives.

The division-boards, frames and middle rim should part flush with the top of the brood-chambers, to insure every manipulation. The cover should part flush with the top of the surplus chamber. The brood-chamber, middle rim, top, and surplus chamber and stand, are all to be made from ½-inch lumber, planed on both sides, and must be strong, durable, light and suitable for any climate or out-door wintering, as well as a summer hive for the North as well as the tropics. We want a bee-hive for business, to do all that has ever been done, and a great deal more. We do not know the working capacity of bees yet.

The hive must be so constructed that any and all kinds of manipulation can be practiced, as well as to take any and all kinds of surplus chambers; to practice the tiering-up plan as others; and secure comb honey or extracted; but we want, if possible, to avoid T-tin rests and metal corners on frames, and adopt something new, so that we can remove sections as fast as finished, more than one at a time, before the whole case is finished, and have the surplus case so arranged for the lateral movement that a frame of sections can be removed, and an empty frame of sections inserted in its place, and not disfigure the cappings; thus do away with wide frames. This, I think, would enable us to get more finished comb honey at the end of the season. Then the comb should be attached to all parts of the inside sections, and nearly free from wax, bee-glue or propolis. By this arrangement one can get all the surplus honey in sections, if he does not want to use the extractor.

The bee-hive proper is to be inside the shell, all parts of it movable, and in separate pieces, and all interchangable to any hive about the apiary. The frames and division-boards must be flush with the top of the brood-chamber, and rest ¼-inch from the bottom-boards of the hive, for obvious reasons, but I will only mention a few, viz:

When the hive is adjusted, and the bees at work, the space between the inside hive and the shell, form an air space, and young bees will occupy and be out of the way of the workers, and not hang out on the front of the hive, to be run over by working bees. They will be protected from storms also; then at night, when the workers are all at home, I have seen this space crowded with bees, and also on rainy, cold days. To feed bees a better con-

trivance cannot be imagined than this space. For winter, this space is splendid for packing with chaff, peat, moss, or forest leaves, or any absorbent material. Then one can ship bees the world over. Such a frame of comb full of honey the extractor cannot injure in the least.

Then again, they should be constructed so that they can be used the same as the Langstroth frame at all times. This frame must be reversible, so that it can be used for all known methods—an all-purpose frame, if you like. The same frame, when empty of brood-combs, is to be used to hold two tiers of sections. The inside dimensions of the frame should be constructed on the metrical measurement, in order that the frame will take sections, say 4 two-pound, 6 one-pound, 8 ¾-pound, 12 half-pound, 24 quarter-pound; and be able to run all sizes of sections at once, or separate size, and extracted, just as one wishes. Thus we have a frame that is universal in its application, as well as interchangable—side-storing, tiering-up, etc.

The frame should be cheap, simple, and effective, universal for all purposes, and in harmony with the instincts of the bees; so that they can turn out finished honey remarkably fast. These frames require no bracing, wedging, or thumb-screws; a single one will stand alone, and can be put down anywhere, and not crush bees or combs. Bees can be brushed or shaken off readily, and no fear of smashing things.

The bees cannot glue these frames fast to the hive, and it requires no machine to loosen them. There is much more about the frames, but I will now speak of separators, which should be thin, and the full size of the outside brood-frame, and reversible.

The surplus chambers should be constructed with the view to use them for other purposes, than merely to store comb in; then if the swarm should come out unexpectedly, one can put frames of foundation in, and hive his bees into it; and so that they can be used two or six stories high, if desired; or to ship nuclei in them. A hive thus constructed and adjusted is storm-proof, winter-proof, summer-proof, as well as at all times ventilated and shaded.

The frames of a hive must be made of wood, and all frames alike. They must answer for brood-combs, and for holding sections; one inch and a half wide at the ends, for the purpose of spacing themselves; recessed from the four corners on both sides, so that the top-bars, bottom-bars, and end-bars will be 1⅛ inches wide, for passage-ways for the bees, and the natural thickness of comb.

The top-bar is to be slit from end to end, through the centre, for the purpose of inserting foundation quickly; to thus avoid wired frames, wired foundation, melted wax, and other time-provoking experiences. Then when a frame full of foundation is placed in the brood-nest, the combs will become of an even thickness, no varying, crooked, warping, or sagging, broken combs; and no break-down, if the foundation is all wax, and not adulterated.

The top and bottom bars must be the same, so that the combs will be attached to all parts of the inside of the frame, and to be impossible to tell which is the right side up. Then when placed in the hive, 8 or 12 of them, and the division-board in place, one can move or ship a colony of bees, and the frames will not swing in at the bottom like a pendulum, and crush the bees or combs. They will be as firm as the hive itself, when a wedge is inserted between the division-boards and the shell.

As a surplus chamber they excel, and the manner of construction is too simple to speak of. They have no bottom or top, both sides are movable, which allows the frames to be taken out laterally. They can be made to hold 3, 4, 6, 8, 10, 12 or 14 frames, but the 6 frame is the best, that holds 36 one-pound sections, or 144 quarters. Then one frame of finished honey can be removed at will, and an empty one inserted, or one side-storing frame of sections can be lifted, bees and all, to fill a surplus case, and not disturb the working, but rather increase the honey and retard swarming by the interchange, etc.

These surplus chambers have no intermediate honey-board or zinc queen-excluder between the honey-boards, therefore there is an unbroken passage-way for the bees from the entrance of the hive to the top of the sections. The section-frames and brood-frames are just bee-space apart. There are no brace-combs; the surplus chamber can be lifted at any time without removing a frame, which makes it very easy to get at the brood. I have no **T** tins or other hinderances; it is so simple that any one can manage it.

My sections have four open sides, and I use 6 one-pound sections in each frame, two tiers high, and so arranged that one frame at a time, as the honey is nearing completion, can be reversed if needed in order to have plump full sections, and the comb attached to all parts.

The 4 open-side sections have a charm for me, as the bees are not divided off, but they are all together in a mass, and they seem to work better. Why it is so I do not know, but they do, all the same. I like this style of section very much, as it avoids the bad corners and accomplishes the same results. I wonder if any one has tested this section: if so, I would like to learn how they can be made in one piece, or 4-piece dovetailed. They pack in a shipping-case better than the other 4-open-side sections with paste-board between the rows.

Should we want the bees early to work in the supers, by these interchanging frames and parts, we can put them up by raising the side-storing sections, bees and all; also at times a frame of ripe brood, bees and all, to start them up; and thus we will control swarming, and get the bees up at work in the sections long before one can possibly do it by the old method of waiting for the spirit to move the bees up in the sections.

I want to and do take away finished sections before my neighbor has his bees in the sections. We want bees to work all the time gathering during the season; and to be able to say to those men—who, after trying all plans for non-swarming hives given, with no success, have settled down in the old rut, and have come to the conclusion that such a thing does not exist when working for comb honey, and even if it did, they doubt if as large a yield of honey could be obtained as by the use of non-swarming hives—that swarming can be controlled at will; and that one colony of bees will produce surplus honey as much as they possibly can by the use of three small single-walled swarming hives, and that at less expense, time, and labor, and more simply.

Wintering bees should be done on the summer stands; the brood-combs should be reduced to four frames, the surplus chamber be placed above, holding four solid frames of honey. Bees do not look or go sidewise for their stores, when clustered, but only up, there the honey being above the unbroken continuous passage-ways.

When thus adjusted, and the peet, moss, or forest leaves are packed solid into the space formed by the inside hive and outside shell, bees live, they "hold the fort," if properly attended to in time; and the time to commence is as soon as they are unpacked in the spring.

The space between the division-board and the outer walls can be filled with packing and absorbents of moisture, which keeps the combs clean and free from mildew.

With such a constructed hive, we accomplish all that has been done, or is being done. The bees are at all times comfortable, and are ready for business a month sooner than my neighbor's bees in the spring. I never,

in one of these hives, had a case of spring dwindling, nor bees diseased in any way so far. I feed no sugar, nor remove any pollen.

Again, those reversible frames pay me, if used for no other purpose but to winter bees ; for if the brood-frames contain honey, place the honey part up, and in surplus chambers reverse the honey part down, to match the one in the brood-chamber ; then the honey parts of the eight frames will be together, one above the other.

The whole hive is constructed with the view of giving the queen full power of reproduction, and hereby hangs the whole "law and gospel" in bee-keeping. The mother-bee must have room as fast as she wants it ; we must be able to give her that room, and if not able, we lose control over the bees, and swarm they will. We must be able to make our increase as necessity requires, ourselves, and not be at the mercy of the bees, to do it when not necessary.

Keep the bees in one strong colony until after the honey harvest ; keep the brood-frames full of brood, and no honey in them during the harvest ; by so doing the bees have no place to store honey but in the sections. Make your aim, and make the bees work for you in one colony, and do as much as your neighbor's bees do in four or even five single-walled, small hives.

My object is to make a chaff hive, and yet not a chaff hive ; and to part flush with the top of the brood-frames, so that I can get at things, and push things.

When those who manufacture bee-hives take all these points into consideration, and unite them with the best points in the hives of Rev. J. L. Christ, Rev. L. L. Langstroth, and Moses Quinby, we will have the next great invention in apiculture, of great economic value, and one that is needed as well as now called for by honey-producers, queen-breeders, etc. It will be as revolutionary in its effects as the application of the movable-comb frame was forty years ago. I do not make or sell hives, or any other kind of bee-supplies.

Collamer, N. Y.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Dec. 4, 6.—International, at Brantford, Ont., Canada. R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

We will Present a Pocket Dictionary for two subscribers with $2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

SELECTIONS FROM OUR LETTER BOX

Queen-Rearing.—Newton Johnson, Ficklin, Ills., says :

I have received the book, "Scientific Queen-Rearing," by Mr. G. M. Doolittle. It is intensely interesting, besides being very profitable.

Destroying Drones and Brood.—R. R. Stokesberry, Clinton, Ind., on May 16, 1889, says :

Last fall I had 57 colonies in good condition, except one that was queenless, which died during the winter. All the rest came out in good condition, and built up fast, until two or three weeks ago when the cold, dry weather checked them, and they began killing off the drones and pulling out young brood. It seems to me that we are going to have another failure to record for this year, which, with the past two, is very discouraging. If I knew of a good location for bees I would be tempted to move to it.

Early Spring, etc.—C. Theilmann, Theilmanton, Minn., on May 17, 1889, writes :

The Doolittle book on "Scientific Queen-Rearing" is very interesting, and contains many new ideas not found in other bee-books or periodicals ; and they come from one of our most (if not *the* most) and best experienced bee-masters in America. We had rather bad weather for bees to make their living for quite awhile ; they are getting plenty of pollen, but very little honey, and have to be fed. The colonies are strong in bees. We had some glorious rains lately, which were badly needed. Spring crops look remarkably good after the rains, and corn is coming up—the rows can be seen in some fields. This is earlier by two weeks here than ever before.

Early Swarming, etc.—J. M. Peck, Wyoming, Wis., on May 19, 1889, writes :

I see reports of early swarms from Ohio, Indiana, and other localities, but I want to say that Wisconsin is not behind the times, if we are much further north. On May 4 I had a large swarm, and I have had 7 swarms so far. I would have had many more, but it has been very dry for the last two weeks, and with the exception of the last four days, it has rained most of the time. Bees did nothing the past week but kill off drones ; but everything bids fair for a good honey-flow now. White clover is just commencing to bloom. My bees are in fine condition, and I am expecting swarms every day. My report for 1888 is as follows : I commenced the season with 15 colonies, increased them to 47, and took 2,500 pounds of extracted honey, and 300 pounds of comb honey in one-pound sections. I also had 400 natural combs built in brood-frames.

Bees Dwindling and Dying.—J. A. Bence, Hamrick, Ind., on May 16, 1889, writes :

On page 283 of the AMERICAN BEE JOURNAL for 1888, Mr. R. M. Rawlins, of Arkansas, exactly describes my situation in regard to bees dwindling and dying. Some of mine died that way last season. They ceased dying in the fall, and wintered all right. They went to work on fruit-bloom, and seemed to do well, but now there is but little for them to get, and some of the colonies are dying off very rapidly. Their abdomens are much swollen, and full of a thick, yellowish matter. They will lie struggling several days on the ground before they die. I have watched ever since Mr. R's article was published, hoping that some one would give the cause and cure. Will some one please do so ?

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white 1-lbs., 14@15c. Market is dull and lower, but not overstocked. Demand slow.
BEESWAX.—22@23c.
Apr. 30. M. H. HUNT, Bell Branch, Mich.

KANSAS CITY.

HONEY.—We quote: White 1-lbs. 15@16c.; dark, 10@12c.; California white 2-lbs., 11@12c.; amber, 10@11c. Extracted, white, 7@8c.; dark, 5@6c. Our market is in good condition for the new crop.
BEESWAX.—20c.
May 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Extracted, in barrels, 6½@6¾. Excellent demand for clear, bright in barrels. Dark, 5¾@6c.
BEESWAX.—Scarce at 23c. for prime.
May 22. D. G. TUTT & CO., Commercial St.

NEW YORK.

HONEY.—Market is bare of comb. We have not seen honey cleaned out so well for several years. As to extracted, there is no white clover, basswood or buckwheat in this market. New Southern honey is arriving freely, and brings from 65@70c. per gallon. New Florida orange-bloom honey brings from 7½@8c. per lb.
BEESWAX.—Scarce, at 26½@27c. for good.
HILDRETH BROS. & SEGELKEN.
May 24. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—We quote : Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.
May 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 11@16c. Demand is fair. Arrivals are plentiful of new comb and extracted honey from the Southern States, where the season had a most prosperous beginning.
BEESWAX.—Demand is good—20@24c. per lb. for good to choice yellow, on arrival.
May 21. C. F. MUTH & SON, Freeman & Central Av.

AMERICAN BEE JOURNAL
ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,

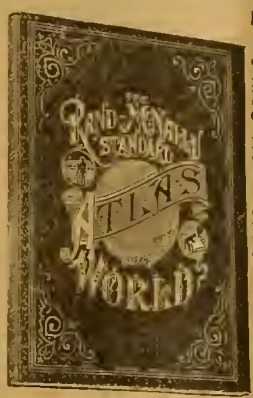
PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Doré, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:



This ATLAS contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Triple-Lense Magnifiers for the inspection of bees, insects, etc. They are invaluable in the conservatory, or if for only a very few plants. For boys and girls, they make very pleasant studies, and arouses in them a laudable enthusiasm for investigation. Price, by mail, 80 cents; or the AMERICAN BEE JOURNAL for one year, and the Magnifier, for $1.50.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin now.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Bee-Convention can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble.

Money in Potatoes, by Mr. Joseph Greiner. Price, **25** cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

EDITOR.

Vol. XXV. June 8, 1889. No. 23.

EDITORIAL BUZZINGS.

The Cold and Rainy Weather during the latter part of May, has been very depressing. The bees have been unable to leave their hives for hours together, some days, on account of the rain and cold weather. White Clover blossoms are seen, but many colonies have to be fed to prevent starvation. The following lines from friend Eugene Secor, entitled, "Hope On," are very appropriate for us all just now:

Why cloud thy horizon with evil forebodings
When the blossoms of Hope seem not to unfold?
The mists that obscure thy sad heart's ardent longings,
May vanish like dew in a sunlight of gold.
Hope on, doubting brother, thy Father is guiding,
The future is His, He knoweth thee best;
What seemeth to thee like Infinite chiding,
Is only thy faith and devotion to test.

Music suitable for Decoration Day will be found in this issue. We promised to give another, and here it is—a beautiful song.

Some One wrote from Darrtown, Ohio, asking us to send Bee-Keepers' Union blanks, but forgot to sign his name. Will he please to try it again?

Poisoning Bees.—On this subject Prof. A. J. Cook wrote us the following on May 26, 1889:

DEAR FRIEND:—I have been fearing such reports of poisoning bees as occurs on page 331 of the AMERICAN BEE JOURNAL. I have urged in emphatic words **that no spraying be done till all blossoms fall from the trees.** To do so earlier is criminal, foolish, and without excuse. Please assert this again in full face type. I have written a "caution" to the New York *Tribune* to-day.

Let this *caution* be heeded by everybody. To spray trees while in bloom is very reprehensible indeed, and should never be done.

Experiments in Apiculture.—The Ontario Agricultural and Experimental Union is now engaged in making experiments in apiculture. The following has been issued as a circular, and has been sent to many of the prominent bee-keepers:

BRANTFORD, May 15, 1889.

DEAR SIR:—The Ontario Agricultural and Experimental Union have taken up experiments in apiculture. The desirability of securing a method which will prevent swarming, and at the same time not lessen the honey crop, is so great that any experiment in this direction will doubtless meet with the approval of bee-keepers at large, and a hearty co-operation on their part.

Chloroforming bees when under the swarming impulse has been experimented with slightly, and apparently with a measure of success to prevent swarming. The colony is to be treated as follows: A colony which has queen-cells started, and will apparently swarm, is to be treated with chloroform, and results noted as per list of questions. Another colony is to have the swarm returned and treated. More colonies may be treated, numbering 1, 2, 3, etc. A sponge with some drops of chloroform upon it may be inserted into the nozzle of the smoker, and the fumes of the drug driven in at the entrance of the hive or under the quilt, the same as smoke.

When the bees are in such a condition that they will not fly from the combs when the hive is severely jarred, the process is complete, and no more chloroform need be given.

The results will be given to each experimenter at the close of the season, and you are invited to assist in the work and fill out the list of questions, sending the answers to R. F. Holtermann, Brantford, Ont., Sept. 1.

Kindly let him know at once if you will undertake the experiment.

Yours very truly,
E. A. RENNIE.
R. F. HOLTERMANN.

The Blank mentioned in the circular is as follows:

After Swarming.	Before Swarming.
	No. of Colonies.
	Date of Treatment.
	Did honey-flow continue after treatm't
	Did colony swarm after treatment.
	If so, what date?
	Did you give the colony more room after or immediately before treatment?
	Did the bees appear to work with their usual vigor?
	Did your other colonies swarm after these were treated?
	Did you consider this method a success?

The results of these experiments will be duly given to our readers, when they are received and tabulated.

A Story of Thrilling Interest to all classes of readers, and constituting one of the most important contributions to our national history that has ever appeared in a magazine, is Col. Richard J. Linton's account of "John Brown and his Men, before and after the Raid on Harper's Ferry," in the June number of *Frank Leslie's Popular Monthly*, just out. The value of this notable paper is enhanced by the illustrations which accompany it, including portraits of Owen Brown, Richard Realf, and others, together with reproductions of the only existing contemporaneous pictures of the scenes at Harper's Ferry and Charlestown, where John Brown was tried and executed.

The S. W. Rich appeal has just been vigorously argued in the Circuit Court, and the Judge has reserved his decision until the next term of court in September. We have reason to think that the decision of the lower court will be reversed.

The facts in this case were briefly stated in the last report of the National Bee-Keepers' Union in these words:

Mr. S. W. Rich, of Hobart, N. Y., was sued by a jealous and disagreeable neighbor for $1,200 damages, and also to compel him to move his home apiary outside the city limits. Bee-keepers from several States attended the trial, which was held in October before Judge Boardman, at the Delaware County Court. About forty witnesses were called.

The plaintiff asked for $1,200 damages for injuries inflicted by the bees upon his person and property, but the jury, from which every person having bees was excluded, gave him but *six cents* to cover wounded feelings and damaged property!!

This virtually declared that the bees were *not* a nuisance. The result is an overwhelming defeat for the enemies of the pursuit of bee-keeping, and another victory for the National Bee-Keepers' Union.

But as the award of even 6 cents as damages carried with it costs amounting to $468.04, the case has been appealed to the Superior Court, which will cost about $500 more. Judge Boardman ruled against the bees every time, and in charging the jury compared the bees to a pig-sty and a slaughter-house.

This was the first case with one exception ever tried in the State, and the Judge having no law or precedent to go by, ruled just as *he* thought right, with the above result.

It will not do to let bee-keeping be likened to a pig-sty or a slaughter-pen! It is an honest and honorable pursuit, and its rights must be preserved. This appeal will be heard this fall, the Union having engaged lawyers, and guaranteed the expenses of the new trial. Had the Judge been inclined to be as *fair* as the jury, this would have been unnecessary.

Questions for Discussion at the French Congress of Bee-Keepers in 1889, are thus enumerated from *L'Apiculteur* in the *British Bee Journal* for May 9. Two or three of the subjects for discussion will cause a smile among American apiarists. The subjects are thus stated:

1. What are the bases of rational bee-keeping?
2. Should the management of bees be conducted on the same plan in different localities?
3. Is the production of wax the main object of keeping bees?
4. By what means may foul brood be prevented?
5. What influence have certain manures on the development or neutralization of nectar in flowers?
6. Is it possible to produce honey in France at a price as low as the cost of production in America?
7. In the absence of official statistics, is it possible to determine approximately the proportion of honey and wax derived from hives with movable combs, and hives with fixed combs?

Zinc Honey-Tank.—J. R. Eskew, of Iowa, asks this question: "Is zinc a suitable lining for a honey-tank? If not, why not?" We reply that a zinc tank is not even *suitable* for water—much less for honey. It is as *unsuitable* as a lead tank.

QUERIES AND REPLIES.

Results of Bee-Sting Poison in the Human System.

Written for the American Bee Journal

Query 634.—Does a person's system ever retain any of the poison from bee-stings, so as to come to the surface in the form of carbuncles, blood-boils, felons, etc.? My experience for 15 years says that in some cases it does, and it may be a secondary, if not a primary, cause.—New York.

I think not. My experience has been the reverse of yours.—EUGENE SECOR.

From my own experience and observation, I should say no. —MRS. L. HARRISON.

We do not believe that it has any such lasting effect. We never had a carbuncle, boil, or felon, and have had lots of bee-stings.—DADANT & SON.

I think not; but a medical expert could answer this question better.—C. H. DIBBERN.

I do not think that I have ever experienced anything of the kind.—C. C. MILLER.

I do not know, but I am rather of the opinion that your idea is right, or at least partly correct.—JAMES HEDDON.

I have no personal experience in that kind of a phenomenon, though I have read of it.—J. M. HAMBAUGH.

My experience would say no. I have had small pimples with suppuration to appear a few hours after being stung, but they very soon disappeared.—M. MAHIN.

My experience says not, in any sound and healthy persons. No doubt that in any one affected with scrofula, etc., it may have the tendency to produce such.—P. L. VIALLON.

A physician at my elbow says that he never knew any secondary consequences to come from the poison from bee-stings.—R. L. TAYLOR.

No. I have never seen any evidence that bee-sting poison will cause the maladies named. The worst cases of carbuncles, boils, etc., that I have treated, were in persons who were probably never stung by a bee.—G. L. TINKER.

I have never experienced any trouble of this sort, nor have I known any one who has. Mr. Langstroth, Mr. Heddon and some others suffer from bee-poison.—J. M. SHUCK.

I think not. You know that bee-stings are recommended as medicine for "dropsical conditions of the cellular tissue, skin, serous and mucous membranes, and the glandular system." Ahem!—MAHALA B. CHADDOCK.

I have never known any instance of this kind; and I believe it safe to say that bee-poison (formic acid) is never a *primary* cause.—WILL M. BARNUM.

It is possible for a person, from repeated application of the sting, to become inured to the action of the poison; and it is quite likely that there are persons with some idiosyncrasy of constitution where such symptoms may manifest themselves, although I have never met such cases.—J.P.H. BROWN.

I think not. Through some impaired condition of the body, stings may be more severe in their effects, and the body suffer from various diseases and maladies; but I doubt if one causes the other. The enfeebled body suffers more from both.—A. J. COOK.

I do not know. I never knew a *bee-keeper* to be troubled that way, unless he was pretty well filled with beer or whisky, and then he blames the bee-stings. I have had my wrists so filled with poison from bee-stings, as to be almost paralyzed, and I never had a carbuncle, a boil, or a felon.—A. B. MASON.

I think that you are mistaken. Previous to my keeping bees I used to have boils, etc., but for the last 20 years, having received thousands of stings during that time, I have not had a single boil or anything of the kind. I am pretty well satisfied that the sting of the bee does not have any effect on a person whatever, aside from the smart and swelling caused at the time. —G. M. DOOLITTLE.

I do not think that a positive answer can be given, based upon any certain proofs. In my opinion, however, the bee-poison is not so retained in the system, as to produce any permanent or constitutional effect. How can it be a secondary cause of blood-poisoning, when it is antiseptic in its nature? —J. E. POND.

I would suggest that a healthy "system" by the assistance of "nature," is capable of throwing off all acid poison that it is likely to absorb from the honey-bee. I have observed, however, that at certain seasons of the year, I have felt a peculiar sensation at times; as, for instance, a stinging "twitch" in certain parts of the body that forcibly reminds me of a bee-sting; but these sensations are of a nervous character, and may result from some other cause.—G. W. DEMAREE.

It is not a primary or secondary cause of boils, etc. When the system is deranged or diseased, the sting often causes much trouble, and sometimes death.—THE EDITOR.

CORRESPONDENCE.

THE LOCUSTS.

Interesting Facts about the 17-Year Locusts.

Written for the American Bee Journal

BY PROF. A. J. COOK.

I have received the following letter from Mr. J. T. Wilson, of Little Hickman, Ky., who desires a reply in the AMERICAN BEE JOURNAL:

The 17-year locusts are making their appearance here just now. I would like to have you write an article for the AMERICAN BEE JOURNAL, and tell all you know about them. We know that they come every 17 years, and lay their eggs in twigs of trees. Now where are they, and in what state are they, until they appear again?

The cicada 17-decim—17-year cicada (locust, though a common name, is yet an improper one) are very curious insects. First, they come once in 17 years, because it takes them nearly that long to develop as larvæ. Again, they come in great numbers, so that they attract much attention.

Thirdly, they make a whirring, shrill noise, doubtless their love-song, which, when they are very common, makes the trees ring; so that it is not possible to hear much else when a swarm of these cicadæ appear. It is hard to visit under trees when cicadæ are abundant, and are holding a concert to charm their mates.

Lastly, they cut into twigs and branches of fruit and other trees to lay their eggs; and so they do great harm at times.

The 17-year cicada is a black, robust insect, with strong red-colored veins to the wings. The males have a strange musical apparatus at the base of their wings. They come from May to August, depending upon the latitude. After pairing, the female cuts into limbs and twigs to lay her eggs, thus often injuring orchards quite seriously. When the eggs hatch, the larvæ fall to the ground, and enter the earth, where they feed on roots of plants for over 16 years. They then come forth from the earth, crawl upon some stem or branch split open on the back, and the beautiful cicadæ come forth to celebrate their nuptials with song and merry-making.

Why are they so long in the larval state? Is it not because they dig deep into the earth, and so growth and development are retarded by the cold? This would also explain why they do so little harm. They grow so slowly, and are so inactive that they eat but little, and so we mind not the damage, even though they are sucking the root-

letts of our valued plants dry of sap. We have the analogue of this in our bees—they are quiet in the cold of winter, do little, and do not eat much.

The same mail that brought Mr. Wilson's letter, also brought one from Geo. E. Boggs, of Waynesville, N. C., asking how to protect against these destroyers. I can give no answer to this. Though these cicadæ are very unscientific pruners, they usually do not wholly destroy a tree, though they often injure trees greatly.

We can get comfort in the fact that they come only four or five times in a lifetime, unless there are separate broods in our region. We never have these cicadæ here; though a similar one (cicada tibicem), with green veins to its wings, is often seen and heard. This latter is only a few years in maturing. Very likely it works nearer the surface of the earth.

DIVIDING.

Experience with Dividing Colonies for Increase.

Written for the American Bee Journal

BY C. P. HENRY.

I began the season of 1889 with 9 colonies, all having been wintered on the summer stands, and came through seemingly in good condition. Having read so much on dividing colonies for increase, I decided to try both plans to satisfy myself as to the better one, and I am now prepared to give a few items from experience.

While I find that those colonies left to swarm as nature intended, have not increased as rapidly as I would have them do, they are all strong and thriving colonies, ready for the harvest at any time the honey flow may come; while, on the other hand, those worked by dividing, are greater in the number of colonies, but shorter of stores, and not half so populous.

Still another objectionable feature that accompanies dividing, is the starting of robbing, which I have had to contend with to my own vexation, almost causing me to fully decide in favor of increase by natural swarming; by this means, we will—if we are awake to our duty, and keep all colonies queened, allowing no weak ones in our apiary to give robbers a start—exclude robbing to a great extent.

My bees were so very deep in the rut of robbing at one time this spring, caused by nothing more nor less than dividing colonies, that I could hardly go into my apiary without getting stung, or at least being told by some angry robber bee that my presence was very offensive; and in the meantime they were killed in front of the entrances in great heaps. I soon saw that this must be stopped, therefore some speedy work must be done.

With the foregoing views before me, I proceeded to shut up all weak colonies, but this did not answer, for the robbers proceeded on some of my strongest colonies, and then came the "tug of war"—dead bees were strewn all over the earth around the apiary. What must I do next, but close all entrances of hives that showed the least signs of being robbed, to a bee-space, and cover the hives with wet cloths, and throw wet weeds and grass over the entrances? By this means I kept the hives cool, and to some extent, excluded the robbers from the entrance.

After going through all this trouble and vexation, I am very glad indeed to say that my bees, at the expense of many lives, have decided to behave themselves, and get about their business. I hope never to experience another such a "riot" among my bees; and in order to do my duty to prevent it, I hardly think that I will ever divide another colony of bees. Perhaps some of my readers will think that I have changed my mind in this direction very suddenly, which indeed I have, I must admit; but in answer to this I will say, of what use is purchased experience, unless one profits thereby? Mine cost me dearly.

Blooming Grove, Tex., May 17, 1889.

BEE-LIFE.

How Long do the Bees Live Ordinarily?

Written for the American Rural Home

BY G. M. DOOLITTLE.

Picking up a paper recently, I noticed an item which was undoubtedly set a-going by some newspaper reporter who did not care whether he was telling the truth or not, to the effect that bees were very short-lived insects, and that the average life of the worker-bee during the summer season was but thirty days. Surely, no one need be ignorant on this subject when one experiment would tell them the truth in the matter, and convince them that the average life of the worker is about 45 days, or one-third more than was given in the item which I saw.

Take a colony of black or German bees, for instance, and about the 10th of June take their queen away and introduce an Italian queen, keeping record of the date on which this change was made. In 21 days the last black bee will have emerged from its cell, and if the Italian queen went to laying immediately, the first yellow bee will have made its appearance; which fact should be jotted down also. At the end of 45 days from the time the last black bee hatched no black bees can be found in the colony. At 40 days plenty of them can be seen, they growing less and less each day, so that on the forty-fourth, it will be very few indeed that are left.

This is for the summer months, but does not apply at all for those of the winter. The life of the bee depends on the work it does, thus when it labors the most its life is the shortest. Hence it comes about that through the inactivity brought on by cold weather, the bee can live from seven to eight months. This is proven by changing the queens as before, only it is to be done this time about the middle of September. Soon after the first of October, the last black bee will be hatched, but I have often found a few black bees on the first day of June the next year, in a colony so treated.

Also, when spring opens, or about the first of April, there will be very few yellow bees in this hive, which shows that very little brood is reared from October until April, as well as to tell us that more bees die in two months in the spring than during six months of winter.

The life of the drones is regulated very largely by the workers, for they are usually killed or driven off by the workers long before they would die of old age. Any sudden cessation in the flow of honey from the fields is often considered sufficient reason for their being driven out to die, or the killing of them by stinging, if they are persistent in staying in the hive, so it is hard to tell just what age they may attain to, were they allowed to live to a good old age.

More apiarists think that they would live about the same length of time which the workers do, but I am of the opinion that they are little shorter lived. It is a rare thing that any drones are allowed to stay in the hive after the honey harvest is over in the fall, still we have a few reports of drones having been wintered over.

The average life of the queen is about three years, although some have been known to live five years. They live also in proportion to the work they do, or according to the number of eggs which they lay, as egg-laying is the only work which they do.

Under our present system of management, we coax the queen to lay as many eggs in one year as she usually would were she in a tree or an old box-hive in two years; hence most apiarists think that all queens should be replaced after the second year, with

those which have just commenced to lay.

However, I do not make this a practice, for I find that the bees will supersede their own queen when she gets to be too old to be of service to them; so I trust the matter to them, believing that they know what is best for them along this line better than I do.

Borodino, N. Y.

TEXAS.

Concerning Bees and Honey in that Large State.

Written for the American Bee Journal

BY A. C. ATEN.

Bees have been doing well in this part of Texas so far this spring. I left too much honey in my hives in the fall, and although I gave them plenty of room, they swarmed some in April, beginning about the first of the month. I have never been troubled much with my bees swarming, for the last five years, and under such favorable circumstances, I had only 8 swarms that I know of from 140 colonies. I attributed my success in keeping down swarming, to giving plenty of room.

Horse-mint Looks Promising.

We had a fine rain three days ago, and bees are now booming on horse-mint and wild marigold. There is a fine crop of horse-mint this season, and everything is now favorable for a good honey harvest. Wheat and early oats are ripe, and being harvested; and corn is on an average waist high.

House-Martins and King-Birds.

I expect that Mrs. Sherman (see page 307) wishes to know if the common house-martin will destroy bees. It is affirmed by some intelligent bee-men that they will, and for this reason I have never put up any martin-boxes. There are but few king-birds here, but I saw one in my home apiary a few days ago, catching bees as usual.

Laying Workers and Drone-Laying Queens.

I will say for the benefit of Mr. Thos. M. Pierce (see page 308), that the most effectual way of getting rid of laying workers, or of a drone-laying queen, if you cannot find them, is to shake the bees all off the frames, and out of the hive, on the ground a couple of rods away. The bees will mostly get back, but the laying worker or queen will not; then give them a frame of eggs or a queen-cell, and give them a chance to rear a queen.

They should be given a frame of brood almost ready to hatch, for if they are all old bees in the hive, they may kill the young queen when she returns from her wedding flight.

Keeping Bees in Texas.

I will say to the friend that inquires in regard to bee-keeping in Texas, that bees never perish from the effects of cold here, and if they have plenty of stores, and are in anything like a good condition, they will get through the winter.

From some cause or other, I did not have a queenless colony this spring in my apiaries of 140 colonies. One drone-laying queen was the nearest to it. I have sometimes had over a half dozen in a less number of colonies. Was it because they had so much honey?

Another thing that I will call attention to, is this: There does not appear to be a queen but what is prolific—all the colonies have immense quantities of bees. I have long thought that most queens would lay enough eggs under favorable circumstances, and this appears to confirm it.

I have had to sell most of my honey for 6 cents per pound for the extracted; but when I consider that the whole amount of work that my bees received last year to produce and extract 11,000 pounds of honey, was only six weeks, it was not so bad after all. My bees are in Travis county.

Round Rock, Tex., May 20, 1889.

VERMONT.

As a Honey-Producing Region It is Excellent.

Written for the American Agriculturist

BY SAMUEL CUSHMAN.

Addison county, Vermont, celebrated for its pure-bred Merino sheep and horses, also stands high as a honey-producing region. The heavy clay soil favors an abundant growth of white clover, which usually yields large quantities of the finest honey. Basswood trees also abound. The surplus honey yield being of short duration and very heavy, allows quick work by the bees, which insures delicate white comb and, with good management, completely filled boxes. This, with its fine quality, gives Addison comb honey its justly-deserved reputation.

Numerous farmers and a few specialists scattered about the county keep bees. In some cases 200 colonies are kept in one yard with good results, while from 40 to 100 is the usual number. Many, with no love for the pursuit, but who have engaged in it simply for the dollars and cents to be made by following the instructions of leading bee-masters, have found it as profitable, or more so, than any other branch of their farm work, and now market their ton or two of comb honey yearly. The specialists who run a number of large yards in different locations, and make it their principal business, have also been successful in securing from 10 to 20 tons of honey in a single good season.

The most extensive apiarist in this section, and probably the one having the largest number of colonies in New England, is Mr. A. E. Manum. He commenced in 1870 with 2 colonies, and, although like other bee-keepers, he soon found that a good season was usually followed by a poor one, his success led him to extend the business, and in the spring of 1885 he had five different yards of 470 colonies. That season was an unusual one, and he obtained from them 19 tons of comb honey, and 3 tons of extracted honey, and an increase in bees, making 850 colonies in the fall.

This large crop was nearly all gathered in 12 days, and one of the best colonies on scales at Yard No. 2, while working on basswood, gathered in one day 33 pounds, and in four days 124 pounds. The largest yield from one hive was 228 pounds of comb honey. His greatest yield in 1883 was 312 pounds of comb honey from the bees in one hive.

As an offset to this and the previous good years, each season since 1885 has been a poor one, and his bees have not paid expenses. With a few exceptions in favored localities, bee-keepers everywhere have fared the same, although three such poor seasons in succession are unparalleled in the history of the industry in this country. Mr. Manum's out-apiaries are from 2 to 16 miles from the home yard.

The Hive Used by Mr. Manum.

At the start, Mr. Manum tried all the different hives, and studied and experimented to get the best for practical work. By combining, modifying and inventing new features, he turned out that which met his ideas, and which, with a system of management suited to it, is now used in all his apiaries and many others. The hive is double-walled, and consists of a stand, inner hive or brood-chamber, and an outer case. The entrance is through the stand underneath the brood-chamber, and cannot be clogged by snow; is protected from rain, and by means of a slide it can be graduated from 2 inches long by $\frac{3}{8}$ of an inch wide in winter, to 14 inches long by 2 inches wide—the full summer width when the slide is removed.

The outer case is movable, and is in three separate sections. The roof is of clapboards. In each gable is a 2-inch

auger-hole for ventilation. This is protected by a wire-cloth funnel projecting outward, which allows the bees to leave one at a time, but not to enter. This is an important proviso when bees are hastily shut in, or when surplus honey is removed. The 3-inch space between the walls is filled with chaff or sawdust, which is allowed to remain during the winter and summer. When damp, it can be readily replaced.

Having so many loose parts, the hive can be moved without heavy lifting, and, when properly packed, is sufficient protection from Eastern winters. The hive-stands rest on two lengths of joist to keep them off the ground, and are set perfectly level. Hives once located are not afterward moved unless carried away from the yard.

The brood-chamber is covered by a board, when the sections for honey are not in place, and contains 12 hanging frames, 12 inches long by 9½ inches deep.

The surplus arrangement consists of cases, at one end of which are a "follower" and a wood screw, by which the sections are tightly clamped together. Each section is supplied with a full sheet of foundation, and between each row are placed thin wood separators to insure perfect combs.

Mr. Manum was probably the first to make white-poplar dovetailed sections, which are now so much used. Previous to this they were of pine, and made to nail. These sections, put together with glue, are not only the strongest, but the neatest sections in use. Two of the Bristol clamps cover the brood-chamber, and can be tiered up as high as desired. Mr. Manum has lately discarded all but one-pound sections.

When filled with finished combs, the cases are disconnected from the brood-chamber, and before they are removed to the honey-house, the bees find their way out at the bee-escape in the gable. A cord and a simple device allows the hive-cover to be tipped back instead of having to lift them off bodily when opened.

Caring for Several Apiaries.

The hives are 5 feet from each other, in rows 12 feet apart. To prevent upsetting by heavy storms in winter, a large cord is thrown across the roof and fastened to a stake driven in the ground on each side. During the winter everything needed in the summer campaign is prepared ready to be quickly supplied to the different yards by the teams which are then constantly on the road. In the spring, at certain intervals, Mr. Manum and his assistants spend a day in each apiary, giving the aid to colonies which is so important. These rounds are made more and more often until the swarming season is about to commence, when one competent person is placed in charge, and is in constant attendance for 6 or 8 weeks, or until the honey season is over.

Board is usually obtained at the farm-house near which the yard is located, and the help are continually employed in hiving swarms, putting on or taking off sections, and in attending to other necessary details. As experienced men are not always to be had, many knowing nothing of the business must be taught, and as they usually commence for themselves as soon as really competent, this instruction must be given again and again. After a few weeks' instruction, some are able to do nicely the remainder of the season with occasional looking after. Women are also employed, and one who did not know a queen from a drone when she commenced, took charge of 116 colonies the second season.

Keeping a Record of Colonies.

At each apiary there is a building containing a honey-room, where "clamps" of honey are temporarily stored, and a work-room where fixtures not in use are also housed. In each yard one hive stands on scales, of which a close watch is kept after the clover and basswood blossoms open.

On the front of every hive in plain black figures is the colony's number, while inside is a record of the colony, its origin, age of queen, date of each examination that season, and their condition when examined. This is written in abbreviated characters on a piece of section or smooth board, and laid on the packing. The apiarist also keeps in a book a list of the colonies casting swarms, and of those requiring special attention at a certain time.

Hiving the Swarms.

The wings of all queens are clipped to prevent their going off with the swarms. When the latter attempt to leave, they are caught by an arrangement consisting of a wire-cloth cage fastened to a pole. It is made to stand anywhere by two legs, which fold up when not in use. A sufficient number of these are always at hand. When a swarm issues, the queen is caught on the ground near the hive and placed in the cage of the catcher, which is stood or held in the midst of or near the flying swarm, and the bees soon settle upon it. They are then left, and attention is given to the others, which usually issue at about the same time.

If the swarm has gone some distance, or clustered in the top of a tall tree, it will soon return, as it is without a queen. So the catcher containing their queen is placed in front of the hive from which they came, and as they return they find her and cluster upon it. To make this more certain, the entrance of the old hive is covered with a cloth. This plan differs from that of most bee-keepers, and enables Mr. Manum to quickly handle many swarms.

In hiving, when time is more plenty, about a third of each swarm is shaken back in front of the old hive, and the balance of two or three swarms, with one queen, is hived in a new hive. As this makes a powerful working colony in the new hive, abundant room in sections is immediately given.

Marketing the Honey.

A close watch is kept of the apiary, and more storage room is added as fast as used to advantage, and the filled clamps are removed as soon as they are completely sealed. A large crop can be cut off from communication with the brood-chamber in a short time, and when free from bees is carried to the honey-room, and afterward carted to the central honey-house. It is then scraped clean of propolis by women and girls, and, after being graded, is stored in the honey-room to ripen.

In the fall, wood sides of white poplar, instead of glass, are fastened to each section, and they are shipped to market in white-poplar crates, holding two one-pound sections. Sections full of nice white comb, those full of darker combs and those light in weight, are each crated separately, and the crates are marked "Green Mountain," "Comb Honey," and "Light Weight," according to contents. A few of the very best and most perfect are selected from the first quality, and go as the "Snow Flake" brand.

Feeding the Bees for Winter.

As most of the crop is secured as surplus, and but little is gathered after its removal, that remaining below is no more than the bees need during the season. Therefore, to keep them alive until spring, each colony must in early fall have its ration of sugar syrup. This season 28 barrels of the best granulated sugar were required to insure sufficient winter food.

For feeders, maple-syrup cans with small holes punched in their bottoms are used. Three short legs of tin raise them enough to give the bees room to get at the holes. These cans are filled with syrup, and put over holes in the cover of the hive, and are renewed until the proper amount of food is consumed.

After the honey season, instead of a constant attendant at the out-yards, frequent visits are made, as in the

spring, and are continued until the bees are snug for winter. Then an occasional trip is made on a warm day when the bees can fly, to see that all the entrances are clear.

Moving Colonies, etc.

Mr. Manum has, at present, about 700 colonies in eight different yards. The number in each is limited to 125 in the fall. The colonies in excess of this number are either sold or carried to a new location. For this work a double and single team are used. By the use of racks which hold a second tier, the former takes 50 colonies and the latter 23 colonies. Before loading, the frames are immovably fixed, and a sheet of muslin is tacked over the brood-chamber to give air, while in very warm weather a rim covered with wire-cloth is necessary to their safety.

Mr. Manum's bees are mostly Italians, although in some apiaries there is a trace of the black and Holy-Land races. He is about to test a few Carniolan queens. The working bees are reared from the best Italian colonies, which are selected out of this large number as possessing unusual excellences. I saw many fine, large queens, a shade darker than the average Italians, having very plump and thick-set bodies.

In each yard, distributed among the regular hives, were many nucleus colonies—the temporary quarters of surplus queens.

Mr. Manum has planted honey-producing crops on a limited scale, but he is not yet certain that they can be made to pay.

SWARMS.

The Proper Time to Have Increase.

Written for the American Bee Journal

BY L. W. LIGHTY.

"A swarm in May is worth a load of hay," and so on, as the jingle goes, should go with the gum and box-hive. The time to have swarms depends upon the latitude, and upon the season. The bee-keeper should know when his surplus honey-flow commences, and then he can work to an advantage.

Fruit-bloom and very early spring flowers will tend to encourage the bees to rear much brood, and, if not properly managed, they will often swarm right after fruit-bloom; and that is to be deplored, with me.

When the bee-keeper sees that the bees incline to swarming, or are crowded, he should give them room in the brood-chamber, and hold back the swarms as much as possible; but get everything crowded with brood; then, when white clover and locust comes, crowd in the brood-chamber and put on sections, when a swarm will shortly issue. Hive that on the old stand, and it will be in trim to get honey, and will be "worth a load of hay," even if it does not jingle with June.

Swarms right after fruit-bloom, when the honey is scarce, generally do no good for me, but spend their time in building drone-comb, and often crooked comb; putting propolis where I did not want it, and were a general nuisance. By the time that clover was ready, they were not in a condition to work; the old bees had considerably dwindled, and the young ones were not yet ready to work.

Fruit-bloom honey can be secured by doubling up colonies, but it is hardly worth the while, as the honey is generally inferior. It would be better to get ready for the fine white honey harvest.

Mulberry, Pa.

The Boon of Sleep.

Written for the American Bee Journal

BY JOHN ANDREWS.

The boon of sweet, refreshing sleep,
Unbroken by an anxious care,
Where sweet repose its vigils keep,
And peaceful quiet everywhere,
Is treasured still, and while we rest,
Contentment reigns within our breast.

We feel no toil, we see no ill;
We grasp the present, ask not why;
Nor have we aught within to chill
The moments, as they pass us by,
As we have sweet and calm repose,
Unharmed by passion or its woes.

'Tis sweet to let all care go out,
And take in place unharmed repose—
Unmarred by any fret, or doubt,
Or clouded by the least of woes;
A peaceful sleep, of harm bereft,
Restoring Nature's balmy gift.

Patten's Mills, N. Y.

EXPERIENCE.

The Success with One Colony in Nebraska.

Written for the American Bee Journal

BY FRANK S. JOHNSON.

Years ago my father used to keep bees on the farm in Wisconsin, in box-hives, and let them winter or not, as it happened. Although Mr. Jonathan Grimm, of Jefferson county, Wis., was then a very successful bee-keeper, most of the farmers who kept bees paid no attention to them, and all of my father's bees finally died.

Ever since then I have wanted to try my hand at the business; so, two years ago, in July, I received a three-frame nucleus with a tested Italian queen, from Michigan, costing me $6. I read "A B C of Bee-Keeping," and as I studied and watched my bees, I became enthusiastic. I made a hive, and the bees filled it the first season. I took only one frame from them, leaving nine American frames of solid honey for their winter food.

During the first winter I put a large box over them, and as the weather grew cold, I put them into the cellar; but I think that it was too warm, for they were very uneasy, and tried to get out. As soon as the weather became a little better, I put them back on the summer stands.

During the next summer (1888) they did finely. I gave them plenty of room in a new chaff hive, packed with ground cork, and they stored over 200 pounds of honey. I sold honey to the amount of $23.00, besides having 15 pounds for spring feeding, and eight frames of solid honey in the hive.

They wintered nicely on the summer stand, in the chaff hive, with a thick cushion over them, and were so strong in bees this spring that I was afraid that they would swarm; so I gave them a sheet of foundation in the middle of the brood-nest, and as soon as there were eggs deposited in the cells, I divided them, placing the new swarm in a chaff hive in the place of the old hive, and removing the latter a few feet. In a few days there were a dozen fine queen-cells started.

Early this spring I obtained a colony of hybrid bees from a farmer here, in exchange for two hives, which I made for him. I took them out of the box-hive in April. In a short time they were rearing brood rapidly.

On May 17, as the queen-cells in my other hive were about to hatch, I divided the hybrids, giving them one frame from the other hive, having a fine cell. They all seem to be working well, and I am delighted with my success, so far.

I mean to work my two Italian colonies for honey this season, and the hybrids for increase; then in the spring I will Italianize all hybrid colonies.

I am experimenting with them during my spare moments out of the store, and I find it very interesting, besides being profitable and instructive.

I think that those bee-keepers who let their bees starve in the spring, are like some farmers that I have known, who allow their cattle and horses to become so poor that they die in the spring. If my bees should be hungry, I would feed them the same as if my cow or horse was hungry; and I shall continue to leave the hive solid full of honey during the winter, for if it is not used, it will come handy in

the spring, provided, of course, if it is good, healthy feed for the bees.

I read the AMERICAN BEE JOURNAL with great interest, and if my experience with my little apiary will give encouragement to other beginners, I will be very glad. My reported success has caused five of my neighbors to have me purchase 7 colonies of bees for them, for their own use only; and if I could spare any of mine, I could get from $7.50 to $10.00 per colony. In fact I have been offered $10.00 for a colony several times.

Campbell, Nebr., May 20, 1889.

LAYING WORKERS.

How I Manage to Get Rid of these Pests.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

Where a colony has been a long time queenless, some of the workers aspire to motherhood and lay, but their eggs invariably produce drones. Laying workers lay very irregularly in worker-comb, and build out the cells to accommodate their huge bodies. Their presence can be told at a glance, as the cells are scattered here and there, and not joined together as they would be if the queen were a drone layer. Laying workers cannot be distinguished from other workers, as they look alike, so they cannot be destroyed. They are a nuisance in a hive, for they will destroy a queen as soon as introduced. And, even if they allow a young queen to emerge from a cell, they will destroy her on her return from her bridal tour. As many as a dozen laying workers have been seen upon one comb.

There are several ways of getting rid of these pests. One way is to carry the hive away, and put another in its place. The combs in the laying-worker hive can have the bees brushed off and returned to the hive on the old stand, and accept a fertile queen, while the would-be queens will not.

The way that I manage a colony that has laying workers is as follows: I take out all the combs excepting the two outsde ones; then I go to a strong colony and remove a frame or two, as the strength of the colony may warrant, covered with bees, being careful not to remove the queen, and put them into the laying-worker colony, and fill their place with the combs taken from the laying workers.

If I have no queen to introduce, I let them rear one. These new bees that are introduced will have no nonsense, and will dispose of the laying workers in their own time and way.

Prevention is better than cure, for just as sure as a colony of bees is left without a queen, or the means of rearing another, for two weeks, the pests will appear. When I have a queenless colony that I have given eggs and larvæ to rear a queen, while she is being reared, every four or five days I give them a fresh comb containing eggs and larvæ, which gives the bees employment, and seems to keep up the the strength of the colony. If one is given them about the time the queen emerges from the cell, it will furnish them the means of rearing another, if she is lost on her bridal tour.

Peoria, Ills.

FREAKS OF BEES.

Race Peculiarity, or Freaks of Some Bees.

Written for the American Bee Journal

BY S. D. HASKIN.

The following are some of the freaks of bees that have occurred under my own observation: On one occasion three swarms clustered together, and were hived in two hives; but one hive had probably two-thirds of the bees, and they showed that they had a preference to one hive. As soon as they were inside, they were located, and all seemed lovely until the next morning; when the one with the most bees manifested much discontent, or uneasiness, and about 12 o'clock (it being quite warm) it swarmed and clustered. It was hived all right, and did nicely, having a queen; one was in the other hive, and did equally well. These were all first swarms.

As it is quite common that bees swarm but once, I have often let them have their own way about it, and in case of a second swarm, I locate them close by the parent colony for a day or two, and then cut out queen-cells, and place the young swarm on top of the old colony, and generally they will go below and stay with the old bees; on two occasions the young queen passed down through the old colony and became fertilized, returned, and set up house-keeping; and, as far as I could determine, they did just as well as though on separate stands. There was but one entrance, and that was in the old hive.

The summer and fall of 1887 was very dry, so that there were no young bees for wintering, but had the following spring been as early as usual, I think that bees would have done tolerably well; but it was very backward, wet and cold, so that the old bees mostly died before they could rear young bees to take their places; so I doubled up the little clusters left, as best I could, and late in the season there were two, I thought, to unite, standing side by side; I placed one upon the other, and about this time they began to build up a little. I watched them closely, and they did so well that after a while I separated them again, and they did well last fall, and have wintered nicely. The young swarm that I had May 12 is building up finely.

Waterville, Maine, May 17, 1889.

NEW HONEY.

How a Youthful Bee-Keeper Secured Early Honey.

Written for the American Bee Journal

BY W. A. HODGE.

I want to tell how a young hand at the business has "played it" on some of us older heads. I shall personate him as Charley Lawrence, of Victory, Wis., who has some 53 colonies of bees that were given to him by his aged father, who is now deceased.

Charley wintered the 53 colonies in the cellar, and this spring, early in March, he took them out, all strong and roaring. Their first drive was to the islands of the old Mississippi, and they came home loaded with pollen and honey; so Charley concluded that they meant business, and he sent at once to the AMERICAN BEE JOURNAL office for a lot of sections.

The sections came on short notice (as does everything ordered from that office), and with all possible speed he put them on, long before any of us thought of putting on sections. Now what has been the result? Why, Charley came to my house the other morning with the broadest smile on his face that you ever saw, and in his hand he held a new, white, one-pound section of honey, and said to me, "Look here, old man, don't you want some new honey for your breakfast?"

I will admit that I was somewhat surprised, and said: "Why, Charley, where did you get that?" "Oh," he said, "I just took it off the hive." I said, "Yes, you did!!"

"Well," said he, "if you don't believe it, just go down with me and see. I have between 1,500 and 1,600 one-pound sections nearly capped, and will be ready to come off inside of a week."

Why, this idea of letting a young lad come to the front with 1,600 pounds of new white honey, this early in May, and that away up in cold Wisconsin—why, surely, I for one take a back seat, and call this a "connndrum," and say, Charley, go it while your young!

Victory, Wis., May 25, 1889.

Doing Remarkably Well.—G. M. Whitford, Arlington, Nebr., on May 28, 1889, writes:

My bees came through the winter without the loss of a single colony. All but 4 colonies were placed in the cellar on Nov. 17, 1888, and were taken out on April 9, 1889. Those that were packed upon the summer stands consumed less stores than those in the cellar. Although the nights are too cool for the secretion of nectar, the bees are doing remarkably well. I have had two swarms, have divided one colony, and have several more ready to divide.

Plenty of Rain, etc.—Geo. G Scott, Wadena, Iowa, on May 28, 1889, says:

I have had several swarms so far, which is very early for northern Iowa. The dandelion bloom was abundant. White clover is beginning to bloom. We are having plenty of rain, with frosty nights.

Bees Bringing in Honey.—Mr. H. A. Cunningham, McLean Co., Ills., writes thus:

Please state in the AMERICAN BEE JOURNAL if bees show by their appearance when they are carrying honey into their hives. If so, how?

Prof. Cook thus answers this question by our request:

There is no way to tell or to guess, only by their air of work and more plump appearance. Of course pulling them apart and finding a full, plump honey-stomach is conclusive.—A. J. COOK.

Very Peculiar Swarm.—H. C. Mosely, Charleston, S. C., on May 21, 1889, writes:

I would like to ask for some information from the experienced correspondents of the BEE JOURNAL, in regard to a colony of Italian bees that swarmed on April 2, 18 and 20, and I secured all the swarms. The swarm of April 20 being rather small, I put it into a hive about one-third smaller than the usual size; they went to work finely, and proved to be rapid workers. On the eighth day after being put into the hive, I noticed that they began to carry in pollen, and increased rapidly in this deposit from day to day. On May 19 they began tearing the young bees out of the comb, by the wholesale; I counted 25 in about 15 minutes that they flew out of the hive with. This being May 21, it is now three days, and they are still vigorously taking them out. I omitted to state that they have filled the hive about half full of nice, white comb honey. Will some one give a cause for this strange and apparently unnecessary cruelty on the part of the bees, to their offspring? I would like to know a remedy for it. The swarm that I allude to is the one issued on April 20.

White Clover—Cold Weather.—W. H. Graves, Duncan, Ills., on May 28, 1889, says:

We have an abundance of white clover, but it is so cold that bees are doing but little on it; mine are just beginning to swarm. If it would only turn warmer, I think that we would have a good flow of honey. I have 11 acres of Alsike just coming into bloom.

Killing off Drones.—P. Sheridan, Perrinton, Mich., on May 27, 1889, says:

My bees came through the winter and spring all right. I had 11 colonies protected on the summer stands, and part of them are killing off the drones. They worked well on fruit-blossoms and spring flowers, but they are doing nothing at present. I would not like to do without the AMERICAN BEE JOURNAL, as it is a help to any person, even to those old fogies who know so much about bees!

Severe Frosts—Wintered Well.—I. N. Rogers, Jackson, Mich., on May 27, 1889, writes:

Upon examining my bees last Saturday, I found them in a nearly starving condition. In the early spring they built up rapidly, and I expected early swarms, but a drouth setting in, and high, northerly winds prevailing the greater part of the time, the flowers secreted nectar only in limited quantities; even during apple-bloom bees brought in only enough to keep up brood-rearing. There were three quite severe frosts here the past week, doing some damage to vegetation, but not to fruit. Raspberries are just ready to blossom, and with suitable weather, honey will be coming in in a few days. I have heard of no swarms so far this spring. Bees came through the past winter with very little loss in this locality.

Flattering Prospects.—C. G. Ridout, Hutchinson, Minn., on May 25, 1889, says:

We are having splendid weather here now, and crops are looking well—plenty of rain, but none too much. We had a hard frost last Wednesday night, that killed some garden vegetables, and froze potatoes half to the ground. It is warmer again now, however, and I think that frost will be no more this spring. Bees are swarming, and prospects for a good honey harvest are flattering.

Bees in a Starving Condition.—C. Theilmann, Theilmanton, Minn., on May 25, 1889, says:

We are having cold, cloudy weather, which is bad for the bees. As far as I can learn, they are in a starving condition. I have fed over 700 pounds of sugar already, and there is no sign for much honey to come in for 2 or 3 weeks yet.

Too Cold for Honey-Secretion.—T. F. Kinsel, Shiloh, O., on May 26, 1889, says:

Colonies are very strong in bees. They are working on locust blossoms. Raspberries will soon be in blossom. It has been too cold lately, but it may change in a few days to hot enough. My expectation is big, on this year's prospects for surplus honey. Is it not a pity—at least on some things—that our "foresight" is not better?

Bad Weather for Bees.—A. Sherington, Dutton, Mich., on May 27, 1889, writes:

We have mixed weather for the bees. It was rather cold last week, as we had four frosts, and on the night of May 21, we had a snow-storm. The corn that is up is badly frozen, and the garden-truck is also frozen; but white clover looks well, and commenced to bloom about one week ago. There have been a few swarms here, but this weather will put them back again. Young colonies will starve, if not fed. My bees came through the winter in first-class condition. I put 12 colonies into winter quarters in 1888, and took 11 out this spiring, one having died with the diarrhea. Linden is full of buds, but the leaves are nearly all eaten off.

Catalogues for 1889 are on our desk from—

Horace Banks, Reisterstown, Md.—4 pages—Scotch Collies.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 — OLDEST BEE PAPER IN AMERICA

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for $1.50.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

New Subscribers can obtain the full numbers for 1888 and 1889 for $1.80, if application be made at once, before all the sets of 1888 are gone.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, $1.00 per 100, or $8.50 per 1,000.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

In order to pay you for getting *new subscribers* to send with your renewal, we make you this offer. For each yearly subscriber, with $1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a **premium.**

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

DORÉ ART PORTFOLIO,

PRICE, 50 CENTS,

Will be CLUBBED with the AMERICAN BEE JOURNAL, at the low price of $1.25, postpaid.

This magnificent Art Portfolio is in size just 11x14 inches, and besides a picture of Gustav Dore, the great French Artist, it contains the following beautiful engravings: Expulsion from the Garden of Eden—Entering the Ark—Noah Cursing Ham—Samson and Delilah—Ruth and Boaz—Death of Saul—The Judgment of Solomon—Daniel in the Lion's Den—Daniel Confounding the Priests of Baal—The Nativity—Christ Healing the Sick—Sermon on the Mount—The Disciples Plucking Corn on the Sabbath—Jesus Walking on the Water—The Agony in the Garden—Death of the Pale Horse. Seventeen handsome full page plates under one cover.

Standard Atlas of the World.

To any one sending us, direct to this office, **Five NEW Subscribers** for one year, with $5.00 (renewals not to count), we will *present* this beautiful Atlas, by mail, postpaid:

This ATLAS contains a large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, showing the wealth, the debt, the civil condition of the people, chief productions, the manufactures and the commerce, religious sects, etc., and a superb line of engravings of historical interest and value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise history of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), $4.50.

Triple-Lense Magnifiers for the inspection of bees, insects, etc. They are invaluable in the conservatory, or if for only a very few plants. For boys and girls, they make very pleasant studies, and arouses in them a laudable enthusiasm for investigation. Price, by mail, 80 cents; or the AMERICAN BEE JOURNAL for one year, and the Magnifier, for $1.50.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Simmins' Non-Swarming System, and the AMERICAN BEE JOURNAL for one year, for $1.25. The subscription to the BEE JOURNAL may begin now.

Scientific Queen-Rearing, as practically applied; being a method by which the best of queen-bees are reared in perfect accord with Nature's ways—by G. M Doolittle, of Borodino, N.Y. 176 pages.

In this book Mr. Doolittle details the results of his experiments in rearing queen-bees for the past four or five years, and is the first to present his discoveries to the world. It is published in time for every progressive bee-keeper to test the various discoveries which it details, during the present season. Send all orders for the book to this office. Price, $1.00, postpaid. The usual discount to dealers in lots of 10 or more.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for $3.50, and it can be obtained at this office. Postage 10 cents extra.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

Alfalfa Clover.—For cultivation of this honey-plant, see page 245, of 1888.—We supply the seed at the following prices:—Per lb., 22c.; per peck, $3.00; per half-bushel, $5.50; per bushel of 60 lb., $10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: $8.00 per bushel; $2.25 per peck; 25 cents per lb. *White Clover Seed:* $10.00 per bushel; $2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed:* $6.00 per bushel; $1.75 per peck: 20 cents per lb.—by express or freight.

A Modern Bee-Farm and its Economic Management, by S. Simmins, of Rottingdean, Brighton, England, is the title of a new book of about 200 pages, printed on excellent paper, and nicely bound in cloth. Price $1.00. For sale at this office.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble.

Money in Potatoes, by Mr. Joseph Greiner. Price, 25 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white 1-lbs., 14@15c. Market is dull and lower, but not overstocked. Demand slow.
BEESWAX.—22@23c.
Apr. 30. M. H. HUNT, Bell Branch, Mich.

KANSAS CITY.

HONEY.—We quote: White 1-lbs, 15@16c.; dark, 10@12c.; California white 2-lbs., 11@12c.; amber, 10@11c. Extracted, white, 7@8c.; dark, 5@6c. Our market is in good condition for the new crop.
BEESWAX.—20c.
May 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Extracted, in barrels, 6½@6¾. Excellent demand for clear, bright in barrels. Dark, 5¾@6c.
BEESWAX.—Scarce at 23c. for prime.
May 22. D. G. TUTT & CO., Commercial St.

NEW YORK.

HONEY.—Market is bare of comb. We have not seen honey cleaned out so well for several years. As to extracted, there is no white clover, basswood or buckwheat in this market. New Southern honey is arriving freely, and brings from 65@70c. per gallon. New Florida orange-bloom honey brings from 7½@8c. per lb.
BEESWAX.—Scarce, at 26½@27c. for good.
HILDRETH BROS. & SEGELKEN,
May 24. 28 & 30 W. Broadway, near Duane St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 18@20c.; best 2-lbs., 17@18c. Extracted, 8@9c.
Sales have been checked a little on account of maple sugar and syrup being so plentiful. Sales of honey are very slow.
May 22. BLAKE & RIPLEY, 57 Chatham Street.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 11@16c. Demand is fair. Arrivals are plentiful of new comb and extracted honey from the Southern States, where the season had a most prosperous beginning.
BEESWAX.—Demand is good—20@24c. per lb. for good to choice yellow, on arrival.
May 21. C. F. MUTH & SON, Freeman & Central Av.

☞ The International Bee-Keepers' Association will meet in the court-house, at Brantford, Ont., Canada, on December 4, 5, and 6, 1889. All bee-keepers are invited to attend, and State and District bee-keepers' societies are requested to appoint delegates to the convention. Full particulars of the meeting will be given in due time. Anyone desirous of becoming a member, and receiving the last Annual Report bound, may do so by forwarding $1.00 to the Secretary.—R. F. HOLTERMANN, Sec., Brantford, Ont., Canada.

Cheap Extracted Honey.—We have a keg of DARK HONEY, weighing 164 pounds, net, suitable for feeding to bees, which we will sell at **6 cents** per pound, delivered on the cars here.

Vol. XXV. June 15, 1889. No. 24.

EDITORIAL BUZZINGS.

The National Flower of America is now receiving attention. Bee-keepers should vote for the Golden-rod.

England boasts of glorious weather just now, with heavy bloom everywhere, and the bees are gathering honey rapidly. The *Record* is rejoicing over the fact.

The Western Apiarian is a new bee-paper published in Placer county, Calif. It contains 16 pages and a cover; and is published monthly at 50 cents a year, by S. L. Watkins and F. E. McCallum.

The Present High Price of Sugar will help the price of honey, if it continues a little while longer. Honey may be used to advantage in place of sugar—nay, it is vastly superior to it for preserves, and in making many kinds of cake, palatable summer drinks, as well as in cooking. Let bee-keepers see to it that it shall be thoroughly introduced, and its use secured in every available manner, both by housekeepers and manufacturers of mead, candies, pastry cooks, etc.

A Painted Bee.—Mr. W. F. Kennecott, Lax, Wis., sent what he called "a queer looking bee taken from an Italian colony." Prof. Cook remarks thus concerning it:

The bee sent by Mr. Kennecott is simply covered with red paint. I had always supposed that bees had too good sense to practice these questionable methods. But this is a genuine worker bee, and the brilliant carmine seems genuine. Either some one has been trying experiments, or else this bee got into a tight place with paint all about.

An Appalling Calamity has overtaken the inhabitants of Conemaugh Valley, Pa. On Friday afternoon, May 31, the dam gave away up in the mountains, and a flood of water rushed down the valley, sweeping everything before it. The villages were destroyed—buried beneath 40 feet of water. Over 13,000 persons were drowned. There was no time for escape. Before the irresistible deluge houses, stores, factories, public buildings were torn to fragments and swept away.

The stone railway bridge below the city, on the Conemaugh river, resisted the pressure of the flood; its arches became choked, and there a huge mass of *debris* accumulated. The many hapless ones on the rafts, and in floating houses, on that angry flood, were burned in the fire, which ignited from the fires and lamps in the houses. The horrible torture of that doom is appalling.

An unknown man rode down the valley, mounted on a big bay horse, just before the flood, shouting, "Run for your lives! Run to the hills!" The people were awe-stricken. But few comparatively fled, for in a few moments there came a cloud of ruin down the broad streets; down the narrow alleys, grinding, twisting, hurling, overturning, crashing, annihilating the weak and the strong! It was the charge of flood wearing its coronet of ruin and devastation, which grew at every instant of its progress. On and on raced the rider, and on and on rushed the wave! Dozens of people took heed of the warning, and ran up the hills. Poor, faithful rider! It was an unequal contest. Just as he turned across the railroad bridge, the mighty wave fell upon him, and horse, rider and bridge all went out into chaos together.

The whole country is touched in sympathy, and from East, West, North and South financial aid, food and clothing are pouring in to the relief of the stricken inhabitants left in the valley. Our people are noted for giving full-rein to the most generous promptings of practical sympathy. This gives strength to our confidence in humanity.

Sweet Clover.—Mr. C. H. Dibbern talks about sweet clover, in the *Western Plowman*, and gives his way of management in these words:

This year our three-acre field of sweet clover will be no good, that is for the bees, as we have sown it in oats. I have experimented a good deal in the past ten years with sweet clover. How to get a good stand of clover every year has been the problem, and I have come to the conclusion that it cannot be done. I think I have hit on a better plan.

I think that no biennial plant can be made to flower on the same piece of land every year. In the case of melilot or sweet clover it is, perhaps, best to sow it with oats early in the spring, and that season a crop of oats will be harvested. After it is cut the clover will take possession of the land. The next season it will simply be immense, and grow taller than one's head, and blossom profusely. It will so shade the ground, however, that nothing else can grow, even the seeds scattered by the sweet clover will germinate during the fall. Now it is evident that nothing for the bees will be produced the following year, and the use of the land would be wasted.

I have decided to utilize the land during these off years by going over it with a disc harrow and thoroughly cutting up the stalks which also works the soil up nicely by going over it several times, and again sowing it with oats. Of course the ground is covered with the sweet clover seed, and will take care of itself.

If it is desired to have a crop of sweet clover every year, two pieces of land will be necessary, and keeping it alternately in oats and clover. Land treated in this way, if ever so poor, I believe, will be greatly benefited, as the great quantities of rotting stalks are about as good as a coating of manure.

Foul Brood among bees, in England, seems to be rampant. The *British Bee Journal* for May 23 has this to say about its spreading, and the negligent stupidity of those who are responsible for its ravages:

This appears to be one of the perpetual troubles of bee-keeping. The chief difficulty lies in the fact that although all the bee-keepers save one in a district may take every precaution to eradicate the disease, that very one, either by his negligence or stupidity, may again poison the whole district. Can any of our readers say whether it is a legal offence to sell bees suffering from foul brood, even when no guarantee is given?

Much obloquy has been cast upon expert work on account of some unprincipled men ignoring even the most rudimentary safeguards. We say most emphatically that it is unjust to thus condemn experts as a body for the sins of the few, but we do desire some means of so dealing with the black sheep, that they may for ever afterwards be prevented from demoralizing that which is a most honorable calling when properly conducted. We have reason to believe that some of these black sheep positively conceal the fact of foul brood being in existence lest they might lose custom. Was there a more short-sighted policy? Could the committee of the British Bee-Keepers' Association consider this question in all its bearings?

Fruit Bloom.—Mrs. L. C. Axtell, of Roseville, Ills., in the *Farmers' Review*, remarks as follows about the bees, and fruit blooming all at the same time:

Since fruit-trees have been in blossom, the weather has been so cool and cloudy that most of the time bees have gathered very little honey, and as bees at this time of the year consume large amounts of honey in brood-rearing, many colonies will run out of stores unless fed. A few pounds of syrup fed now will pay the bee-keeper in large returns in a short time. Use the first time or two, sugar syrup, then add cheaper syrup as the bees learn to take it. This year is the first time I ever noticed the peach, cherry, and apple trees in bloom at the same time.

Peach Honey.—Mrs. L. Harrison remarks thus in the *Prairie Farmer* about the honey gathered this spring from peach blossoms:

The bees had a rare treat this spring—peach honey. There has been no bloom on peach trees in this locality since 1883, and it was a welcome sight. An older settler said to me lately: "I well remember the time when peaches were so plenty in Peoria that boys wouldn't steal them; nice ripe peaches would fall from the trees to the sidewalk, and no one cared to pick them up."

GLEANS OF NEWS.

The Book.—"Doolittle on Queen-Rearing," has received a thorough review in several of the publications devoted to bees. The *Bee-Keepers' Review* gave a digest of the contents of the book, beginning with these words:

Queen-breeders have no cause for complaint in regard to the supply of literature devoted to their delightful branch of apiculture. A few years ago, Mr. Alley, one of our oldest queen-breeders, published a book largely devoted to the rearing of queens; the present year has witnessed the birth of the *Queen Breeders' Journal;* and now that old veteran, G. M. Doolittle, has written a book of 176 pages, devoted wholly to "Scientific Queen-Rearing." The price is $1.00; and when we say that the publishers are Thomas G. Newman & Son, Chicago, Ills., no more need be said in regard to the typographical neatness, and general make-up of the book. It contains twenty illustrations, besides the best-looking picture that we have ever seen of its author.

Upon our desk lies a copy of this book, just fresh from the press; and all are invited to step up and look over our shoulders.

Mr. Doolittle says that he has secured, on an average, $500 per year in rearing and selling queens; and, while he does not say whether he would have made more money had he devoted his whole time to honey production, he does say, in substance, that the queen business is too fascinating to be abandoned. We know exactly how he feels.

After subjecting every chapter of the book to a thorough examination, and differing from the author in some few points, Mr. Hutchinson concludes with the following:

There are, of course, a great many points that it is impossible to notice, even in so extended a review as this (*all* details are necessarily omitted), and we will close by most heartily urging all queen-breeders to read the book. Address the publishers.

Gleanings in Bee-Culture criticises Chapter III, on "Nature's Way *versus* Man's Ways," and avers that "friend Doolittle deviates considerably from nature when he makes artificial cells, fills them with royal jelly, and finally deposits therein an egg or larva. We do not deny but that first-class queens, and good queens, can be produced in this way; but is it altogether in accordance with *nature's* way?"

Friend Root then sums up Chapter VII, around which all the chapters centre, and the author's new method of queen-rearing, and the making of his queen-cups, etc., and says:

On page 50 is a nice engraving representing a lamp, above which is a small tin vat for holding melted wax. Beside the lamp is a cup of water. Three little sticks of wood (old rake-teeth) are lying upon a little block of wood. These teeth are taken from a common hay-rake, the teeth being whittled and sandpapered so as to be as near the shape of the inside of the queen-cell as possible. Three of these sticks are dipped successively into a little of the melted wax, above the lamp. The film is cooled in the cup of water, and is then dipped again. The operation is repeated a number of times, until the cell of wax has the proper thickness, when it is slipped off from the end of the rake-tooth, and more cells are made in like manner. After a sufficient number have been made, the end of the cell, or the end opposite from which the queen hatches, is stuck on to a little strip of wood by means of melted wax. After a dozen cells are fixed, this strip of wood is fastened horizontally into an old comb, the space below the strip being cut out so as to allow plenty of room for the cells. On page 56 is a nice engraving showing the cells when fully capped over by the bees.

Friend Root begins his review with this compliment to the publishers:

A neat little work of 176 pages, bearing the above title, fresh from the publishers' hands, Messrs. Thomas G. Newman & Son, has just come to hand. The work is well printed, and, as usual, comes up to the standard of Messrs. Newmans' publications.

And in conclusion makes these remarks concerning it:

For full particulars, as also a discussion of many important matters connected with queen-rearing, we will refer you to the work itself. The book is full of valuable hints, and will be worth all it costs to any queen-breeder. Price, $1.00 by mail.

The *Canadian Bee Journal* speaks of the book as follows:

"Scientific Queen Rearing" is the title of the latest addition to apicultural literature, by G. M. Doolittle, than whom no one is better qualified to speak on this subject. The volume consists of 176 pages, is well bound and printed, and as a frontispiece has the photograph, which, by the publishers' permission, we are enabled to reproduce.

The first chapter details his first struggles in learning the art of bee-keeping, and though Doolittle senior kept bees on a small scale, his son was not stricken with the bee-fever until confined to the house with a gashed foot, when he devoured all the bee-books in reach.

On the importance of good queens, Mr. Doolittle writes strongly, for, as he says: "Upon no other one thing does the honey part of the apiary depend so much as it does upon the queen." To show what can be done in having all the queens in an apiary as near perfection as possible, he notes on page 17, that the "variation of yield of honey from different colonies has grown less and less, till, at the present time, the average yield of honey from each colony in the apiary is very nearly alike, while fifteen years ago some colonies would give 75 per cent. more honey than would others."

The finest queens are reared at a time when the old queen is not destined to live much longer, and in the writer's opinion these are the superior of those reared under the swarming impulse. Says our author: "I have no hesitation in pronouncing queens thus reared of the highest grade," and our experience is the same.

Bearing this important fact in mind, Mr. Doolittle, with that perseverance and continued application for which he is noted, studied for six long years to find a plan for rearing queens of quality. That plan he has now perfected, and this valuable book tells just how it is done, in language so terse and simple that any apiarist can follow it successfully.

Then follows a statement of the contents of the several chapters.

The *American Apiculturist* has this to say about it:

The work is nicely printed and bound. Until we can find time to look it over, the only opinion we can give of its value is the reputation of the author. When one can get nearly two hundred pages of bee-matter from the pen of such an author and bee-keeper as Mr. Doolittle, our advice is to lose no time in securing the work.

The *Canadian Honey Producer* gives it this notice:

DOOLITTLE ON QUEEN-REARING.—This work written by G. M. Doolittle, and published by Thomas G. Newman & Son, Chicago, Ills., is a credit to author and publishers. It is written in Mr. Doolittle's most pleasing style; modestly and simply does the author give us the results of his long and extensive experience. Any one wishing a book upon this branch of apiculture will do well to secure a copy.

Honey Statistics.—Under this heading, *Gleanings* for June has given six questions and several answers from persons in every State, showing the present condition and future prospects. The questions are introduced, answered and commented upon thus:

We herewith present our first installment of statistics for 1889. Our correspondents are located in such a way as to cover the entire United States. The average date at which the statements are rendered is May 10. The questions to which they reply are as follows:

a. What per cent. of your bees have wintered?

b. What per cent. of the bees in your locality do you estimate have wintered?

c. What size of brood-frame is used most largely in your locality?

d. What frame do you prefer?

e. What per cent. of an average crop of honey has been secured in your locality up to date, as nearly as you can estimate?

f. What are the prospects for a honey crop this year?

ANSWERS SUMMARIZED.

A summarized averaged statement for the entire United States, we find stands as follows:

a. Of the bees owned by the special reporters, 91⅛ per cent. have wintered.

b. Of the bees in the localities of the reporters, 83 3-20 per cent. have wintered.

c. Seventy-five per cent of the localities reported are using the Langstroth frame exclusively, and the others use odd sizes, no one frame in particular.

d. The frame used by the reporters themselves is about the same as stated in *c.*

e. Where honey has been coming in, a full average has been secured up to date.

f. The prospects throughout the United States are universally good—never better.

Now let us go back and see what the statistics mean. To question *a* we find the average of 91 per cent. is considerably better than the average for about the same date for last year, the ratio standing 91 to 84; but remember this rather has reference to those who reported on *their own* bees. The percentage of loss for the *localities* (bee-keepers, good, bad, and indifferent), is also much less this year—the ratio standing 17 to 33 in favor of 1889.

Observe that the reporters (who are in most instances the best and most successful bee-keepers we could select for the localities), have had much better success than the mediocre bee-keepers—those who cannot afford to own a good text-book or take a good bee-paper. The first-mentioned class lost only 9 per cent.; the last mentioned lost 17 per cent. This point was clearly brought out in the statistics for last year.

The answers to question *c* prove conclusively that the Langstroth frame is the universal standard throughout the length and breadth of our country. There are three times as many Langstroth frames, according to the reports, as all the rest of the frames put together, odd sizes included.

BIOGRAPHICAL.

MR. T. S. BULL.

A face, familiar to those who attend conventions in and around Chicago, is presented to our readers in this issue of the AMERICAN BEE JOURNAL. It is that of Mr. T. S. Bull, of Valparaiso, Ind., who is an enthusiastic bee-keeper and extensive honey-producer. We have also secured the following account of his life, which will be read with interest by all :

Theodore S. Bull was born in Cayuga county, N. Y., on March 20, 1829.

MR. T. S. BULL.

When about four years of age, he went with his parents to Onondaga county, and in 1850 from thence with his parents to Porter county, Ind., where he still resides.

Mr. Bull was reared on a farm, and receeived a good common school education. He became interested in bees when seven or eight years of age ; and one day, upon hearing some older members of the family telling of a bee-tree having been cut, he learned where the tree was located, and after preparing a box, went in search of the bees. He secured about a quart.

Not knowing how to winter the bees, he was advised to bury them, as they would live without food. They all died. His interest survived, however, and grew with him. When there were bees in sight, he gazed at them as long as eye could see.

When he was about 16 years old, his father, seeing his great love for bees, bought a colony, and also about this time a patent hive, containing three brood-chambers, one above the other, all interchangeable. From this time until he removed from New York, he spent all his leisure hours in studying and examining the work of the bees.

Some two years after coming to Indiana, he saw a swarm of bees going into a hollow tree. He managed to secure them, and kept them in a box-hive, with fair success, until the fall of 1871, at which time he saw the movable-frame hive (called the "Cottage Bee-Hive"), and became very enthusiastic. He had the bees transferred the same fall—5 colonies during the forepart of August, and one colony in September. They all wintered successfully.

The next spring he purchased 3 colonies—the only ones he ever bought. In the fall of 1872 he had 17 colonies, which increased (never losing a colony in wintering), until he had nearly 100 colonies. Since that time his losses have been light. He now keeps about 100 colonies, which produce several thousand pounds of excellent honey annually. His honey being of the finest quality, it is exported to most of the Northern States, and is sold in all the home markets.

Mr. Bull is an energetic farmer, having a pleasant and commodious country residence, and a large farm, gained by industry and good management.

He was married on Sept. 20, 1855, to Mrs. Ann M. Mason. There were born to them ten children, seven of whom (five sons and two daughters) survive ; all but one are married, and, with his ten grandchildren, are living within a few miles of the paternal roof.

Mr. Bull is of medium size, of sanguine, nervous temperament, and fond of reading solid literature, especially that on bee-culture, of which class he takes the principal periodicals. He is a pleasant conversationalist, but has never had any taste for writing or composition.

Send Us the Names of bee-keepers in your neighborhood who should take and read the AMERICAN BEE JOURNAL, and we will send them a sample copy. In this way we may obtain many regular subscribers, for thousands have never seen a copy, or even know of its existence. This is one way to help the cause along.

QUERIES & REPLIES.

Combs Filled with Pollen for New Swarms.

Written for the American Bee Journal

Query 635.—When the bee-keeper has combs filled with pollen (otherwise good combs), are they suitable to put into the brood-chamber for new swarms?—Ont.

Yes.—A. B. MASON.

Yes.—R. L. TAYLOR.

Yes.—MAHALA B. CHADDOCK.

Most assuredly, *very suitable*.—A. J. COOK.

They are as good as any.—P. L. VIALLON.

I think so.—C. C. MILLER.

Yes, if not moldy; but we would not want many such in a hive for a swarm. —DADANT & SON.

I never tried it, but if I had such combs, I would not hesitate to use them for new swarms.—G. L. TINKER.

I would use them in the brood-chamber for new swarms, if necessary.—J. P. H. BROWN.

Yes; but I never saw a comb *filled* with pollen. Did any one?—G. M. DOOLITTLE.

Really, I do not know. I have used them, but I am not satisfied that the practice is economical.—E. SECOR.

I should certainly use them, and I think myself fortunate in their possession.—J. M. SHUCK.

Yes; the bees will arrange the pollen to suit themselves.—C.H. DIBBERN.

Yes, the bees will soon clean out the old pollen.—MRS. L. HARRISON.

Yes, sir; the bees will take care of the old-pollen business.—JAMES HEDDON.

I would rather not use them, though a small quantity of pollen will do no harm.—J. M. HAMBAUGH.

Yes. If the pollen is dry and hard, it is well to soak the combs until it is soft; and much of it can be thrown out with the extractor. If soft, the bees will clean it out in a very little time.—M. MAHIN.

Take a tooth-pick and stir up as much of the pollen as you can, turn the comb over, and jar out as much of it as you can. Treat the other side the same, and the swarm will take it more quickly than they would gold!—WILL M. BARNUM.

If the combs have been well kept during the winter, so as to keep the pollen sound and sweet, as many as two such combs may be profitably used in each hive proposed for swarms. Such combs may also be profitably used in the brood-chambers of all good colonies in the early spring, instead of feeding meal, etc., as a substitute for pollen.—G. W. DEMAREE.

Most certainly they are, unless so completely filled with pollen as to give the queen no room. In this answer I assume that the pollen is all right as such. Ample cell-room must be given, both for eggs and storage.—J. E. POND.

Yes; they are suitable, and will be readily appropriated by the bees.—THE EDITOR.

Evaporating Water from Honey in the Cells.

Written for the American Bee Journal

Query 636.—Do bees evaporate water from honey or nectar, after it is placed permanently in the cell preparatory to sealing?—Nebr.

Yes.—DADANT & SON.

Yes.—J. M. HAMBAUGH.

I suspect that they do.—C. C. MILLER.

Yes, through the warmth of the hive. The honey evaporates continually till sealed, and often still later.—A. J. COOK.

Yes, and that same honey may absorb water, or evaporate it, after it is sealed.—JAMES HEDDON.

I think that they do. It seems clear that the evaporation does take place. The heat of the cluster appears to hasten it.—EUGENE SECOR.

If Mr. G. M. Doolittle has seen straight, and guessed correctly, we might say no; but I am "kinder 'fraid" he is mistaken.—A. B. MASON.

Yes, they do evaporate honey or nectar, just as you please to call it.—J. P. H. BROWN.

Yes, and may even after it is sealed, by means of the heat of the colony.—R. L. TAYLOR.

Yes. Instinct teaches them not to seal it till it is sufficiently evaporated to keep.—C. H. DIBBERN.

Yes. The heat of the hive keeps up evaporation as long as the air in the hive has access to the honey.—M. MAHIN.

Yes. The circulation that is kept up in the hive takes the moisture out of the honey as long as it is unsealed. —MAHALA B. CHADDOCK.

Chemically, honey and nectar are two different things. Nectar is principally cane-sugar, and contains no glucose; while honey is principally natural glucose, and contains no cane-sugar. Nectar is gradually transformed into honey by the action of formic acid, incorporated into it by the bees. At the stage referred to in this query, there may still be some of the sugar not entirely transformed, and, no doubt, there are both nectar and honey.—P. L. VIALLON.

Probably; but the bulk of all nectar carried in is co-operated from the bodies of the bees during the night of each day succeeding a flow of nectar. —G. L. TINKER.

Only as the heat from the hive does it, the same as would be done in a warm room. The bees do their part in evaporation by manipulation.—G. M. DOOLITTLE.

No more than is evaporated by the heat of a colony; honey sealed or unsealed, if kept in a warm room, gradually becomes thicker.—MRS. L. HARRISON.

Yes. The quiet humming so often heard upon hot days and nights, is caused by the bees circulating a current of air through the hive. Other bees stir the honey with their tongues or trunks.—WILL M. BARNUM.

Nectar, when first gathered, is quite thin and watery, and if then sealed up, would prove insipid, and speedily becomes sour from fermentation. Leaving the cells unsealed, allows the watery excess to evaporate, thus "ripening" (as it is called) the nectar, so that it becomes the honey of commerce.—J. E. POND.

I think not, except as they may contribute to this end, by their heat and the circulation of air produced in the hive by their movements. That the bees do *handle* the nectar and thus reduce it, I have no doubt. After the bee puts the honey into the cell to stay, and labels it with waxen caps, after-evaporation must be trifling.—J. M. SHUCK.

According to my observations, nectar in the flower varies in density, or what we call "thickness," in precise relation to the condition of the atmosphere at the time the secretion of nectar is going on; and when the nectar is quite "thin," the bees, guided by instinct bordering upon judgment itself, spread the nectar over as wide a comb-surface as they can command, to hasten evaporation; and as the nectar "thickens," it is transformed to the cells at the tops of the combs where the evaporation goes on till "thick" enough to be finally sealed. How much more rational are these practical facts than is the "digested nectar" theory! —G. W. DEMAREE.

Evaporation of the water in the honey takes place in the hive, and is caused mainly by the heat and air therein—and these are controlled by the bees.—THE EDITOR.

CORRESPONDENCE.

BEE-GLANDS.

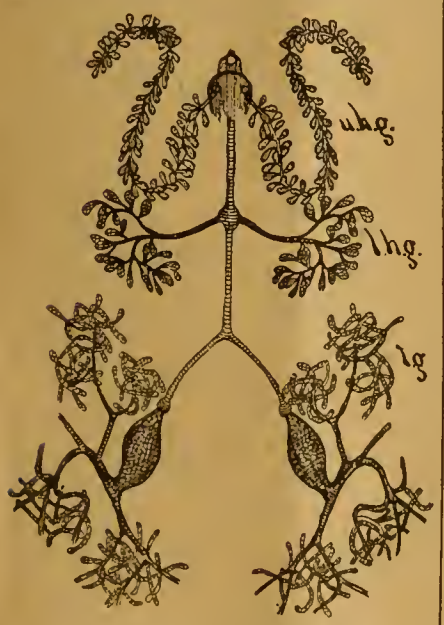
Some Facts about the Glands in Honey-Bees.

Written for the American Bee Journal

BY PROF. A. J. COOK.

A "gland" is an organ which takes elements from the blood of animals, or juices of plants, and forms from these a liquid called a secretion. Thus nectar in flowers is a secretion formed by the glandular cells of the blossom. Our own livers are glands which secrete the bile.

The essential structure of a gland is a membrane with epithelial cells on one side, and blood on the other. Such



The Glands in Bees, Greatly Magnified—Modified from Cheshire.

a simple structure is called a "membranous" gland. Such glands line all the closed cavities of the body, as the joints, the thorax, abdomen, etc. Often this membrane dips, and we have bags, pocket-like, or follicles. Such glands are called "follicular."

We see examples of follicular glands in the lining membrane of the mouth. Often these pockets are prolonged into tubes, and we have "tubular" glands, as seen in the lining coat of the stomach. Most frequently the tubes branch and re-branch, like a twig, and resemble a bunch of grapes (see Fig.), and are then known as "racemose" glands. All of our salivary or spittle glands are of this kind.

Our bees are in some respects the most remarkable of animals. Their larder, unlike that of most animals, is not filled with a single kind of food. They subsist on pollen—a very hearty nitrogenous food (a regular pork-and-beans diet), and on nectar, a highly-flavored dish of carbo-hydrates. To find these, they have a nose of exquisite performanee, situated in the antennæ, or horn-like organs attached to the head. To keep this very sensitive nose always clean, and to collect their food, they have a development of mouth organs and legs that are not surpassed even in the trunk of the elephant, or the still more marvelous human hand.

Again, in the rapid development of the bee from the egg to imago, and in the wondrous accomplishments of the queen—which lays often double her weight of eggs daily—we see what good food can do. To accomplish this, requires an alimentary system of very high development; and so, in the digestive tube of the bee, we have a perfection unequaled, I think, in the whole animal kingdom.

Passing those wonderful structures—the tongue, mouth, honey-stomach, stomach-mouth, and true stomach—let us study the position, structure and function of the several glands of bees.

There are three pairs of glands well developed in the worker-bees. The first pair (u. h. g. in the Fig.) are high up in the head, and consist each of a tube with appended follicles. They are packed within or between the compound eyes, and empty on the side of the floor of the mouth, just where their secretion could mix most readily with pollen, when eaten by the bees.

The next glands are the lower head-glands (l. h. g. of the Fig.). They are situated in the head, below the others, are racemose, and empty into a long duct, which comes from the third, or thoracic, glands. These latter (l. g. in the Fig.) are situated in the thorax, are also compound racemose, and, with the lower head-glands, empty just at the base of the tongue, where their secretions would surely mix freely with nectar as the bees gather it from the flowers.

Thus from the position of the mouths of these duets, no less than the admirable demonstrations of Schœnfield, we are very sure of the functions of all these secretions. The secretion from the first is undoubtedly to digest the pollen. These glands are rudimentary in the queen, and absent in the drones, which shows that the queen and drones are fed in part by the workers. These are best developed in the young workers. This is as we should expect. The young workers may be said to digest the albuminous food for larvæ, queen and drones; to digest this pollen, and form the rich jelly, they need the upper head-glands, and in them we find these glands the largest, and very active. It seems likely that the queen is not fed in winter. If this is true, it shows again the probability that bees when rather quiescent, need no more nitrogenous food than is already in their blood and tissues.

The probable function of the secretion from the other four glands, is to digest the nectar—to change the cane-sugar of nectar to the grape-sugar of honey; for all honey is completely or partially digested nectar. As honey is not all fully digested, we see why the drones and the queen need these glands. They take honey, and unless the honey is fully digested, they need this secretion to complete it.

I have little doubt but that the reason why some honey, like basswood, contains more cane-sugar, is because it is gathered very rapidly, and so the nectar is only partially digested. When bees gather from 10 to 30 pounds of nectar a day, as a colony often does from linden, we do not wonder that some undigested nectar is emptied into the cells. This also accounts for the great variation of honey in its composition—in relative amounts of cane and and grape sugar—and the reason why the ray of polarized light shifts so astonishingly from left to right, or *vice versa*; and why chemists are so likely to pronounce pure honey, adulterated.

There is another interesting fact connected with this subject, viz: When we eat cane-sugar, we have to digest it, while honey is already digested for us. I have heard good physicians say that some of our worst diseases of the liver and kidneys were, they believed, caused by eating cane-sugar; that such diseases were now more prevalent than of old, is because cane-sugar is more eaten now. If this suggestion is true, then in persuading people to eat honey we are lifting from the labors of their digestive organs—are causing the bees to do for them what the bees do for their own larvæ, and are so conserving the health of the people. Thus the inspired writer in commending honey, was wise beyond the science of his day.

Agricultural College, Mich.

NEW YORK.

Report of the First Erie County Convention.

Written for the American Bee Journal
BY OREL L. HERSHISER.

At the call of Mr. Charles Penton, of East Aurora, N. Y., several prominent bee-keepers of Erie county assembled at his house on the afternoon of May 29, 1889, for the purpose of perfecting an organization.

Mr. Penton stated briefly the objects of the meeting, which were, to bring the members of the bee-keeping fraternity into closer relations for social and intellectual purposes; to impress upon its members the growing importance of the honey-industry; to bring more prominently before the public the healthfulness of a common commodity, both for domestic and manufacturing purposes; and to educate the honey-producers in the latest and most approved methods of the production of the purest and most delicious of sweets.

On motion by Hiram P. Hopkins, Charles Penton was chosen chairman of the preliminary meeting, and Mrs. Chas. Foville, Secretary.

After considerable discussion, it was decided that the society be known as the "Erie County Bee-Keepers' Association." The election of permanent officers for the ensuing year resulted as follows:

President, Charles Penton, of East Aurora; 1st Vice-President, Robert Meatyard, of Ellicott; 2nd Vice-President, L. D. O'Dell, of Protection; Secretary, Mrs. Foville, of South Wales; and Treasurer, Mr. S. S. Sleeper, of Holland.

A Board of Directors was selected as follows: T. S. Johnson, of Morilla; J. D. Havens and J. McMillan, both of East Aurora, and Ralph Evans, of Brant.

By special resolution, Orel L. Hershiser, of Big Tree Corners, was chosen special correspondent. The yearly dues were fixed at 50 cents per member, by the payment of which all bee-keepers, and others interested in bee-keeping, may become members. Ladies were exempted from the payment of dues.

Orel L. Hershiser was elected a delegate to represent the Association at the International Bee-Keepers' Association, to be held at Brantford, Ont., Canada, on Dec. 4, 5 and 6, 1889.

After a vote of thanks to Mrs. and Miss Penton, for their generous hospitality, the new-born association adjourned to meet in the village of East Aurora. N. Y., on June 15, 1889.

THE BUTTERCUPS.

Written for the Farmers' Home
BY NELLIE F. O'NEILL.

They laugh and dance all through the day,
They nod and smile in winsome way,
No other flowers are half so gay—
The merry-hearted buttercups.

Atop the verdant hill they dwell,
Adown the grassy slope as well;
They lift their heads within the dell—
The golden-crested buttercups.

They stand beside the river deep,
And at their shadows gayly peep;
They smile upon the refuse heap,
The lowly-hearted buttercups.

The mansion's lawn they scatter o'er,
Like bits of gold on emerald floor;
They blossom by the beggar's door—
The simple-hearted buttercups.

They 'fore the grand cathedral wave,
The prison yard in sunshine lave;
They nestle on the baby's grave—
The tender-hearted buttercups.

They glow and glisten everywhere,
In city parks, in meadows fair.
Ah! well their regal crowns they wear—
The kingly-hearted buttercups.

BEE-SMOKERS.

The Best Kind of Fuel to Use in Bee-Smokers.

Written for the American Bee Journal
BY T. F. BINGHAM.

On page 230 is a query on this subject, and the answers to the same. I was much interested in them, as an interested party, and also as having experimented considerably with various kinds of fuel, etc.

The query, while one of a specific kind, does not specify in what smokers the fuel is to be used. This feature makes all imaginable difference—so far as the facts are concerned—and precludes the possibility of the real value of answers. Generally the answers seemed to indicate that the correspondents used direct-draft smokers, as sound stove-wood and also rotten wood was regarded as valuable.

If the querist will bear in mind that none of the "cold blast" smokers have draft sufficient to burn sound wood, the answers will be plainly misleading, if applied to them; but if to the direct-draft smokers, no confusion will occur, as almost any kind of material will burn in them.

While rotten wood is valuable as a quick means of kindling a sound-wood fire in the direct-draft smokers, it is much more trouble to control and keep burning steadily than sound stove-wood. The sound wood also makes a much stronger smoke; *i. e.*, it is not *steam* and air mixed, but clean, strong, pungent smoke, containing very little creosote, and freer from condensation. Especially is this true if the stove-wood is placed in the sunshine, on sunny days, to dry it perfectly. It cannot be too dry, nor dried too often. It does not burn faster for being dry, neither slower. With long, dry sticks, the direct-draft smoker is simply a base-burner—that is, sound wood burns only at the bottom, close to the grate, and this is one of several valuable features peculiar to sound wood.

Here it may be well to specify a weakness or two incident to rotten wood. One of them is, that it does not last long; the reason why it does not is, that it takes fire all over, and so, while yielding a cloud of smoke and steam, puts the operator to the needless trouble of refilling so often.

Of course, if you have a smoker in which only rotten wood and rags can be made to burn, the question of fuel decides itself. On the contrary, if your smoker will burn anything combustible, you have a wide field to select from, and convenience in obtaining may be to you the feature of all others determining which is best.

I trust that the above may aid in the convenience and comfort of selecting bee-smoker fuel.

Abronia, Mich.

CANADA.

Report of the Haldimand, Ont., Convention.

Written for the American Bee Journal
BY E. C. CAMPBELL.

The Haldimand Bee-Keepers' Association met at Nelles' Corners on Tuesday, May 28, 1889. The minutes of the previous meeting were read and confirmed.

The President read a number of postal cards relative to securing a lecturer for the meeting, and the reasons why one was not secured.

Best Package for Comb Honey.

The President said that the first thing was, to get the honey in pound sections, and well finished in the hive; they should then put the sections in cases holding a dozen, glassed on both sides, so that the sections can be seen without opening the case. He also said it was important that the sections should be all of good quality, both front and back.

Best Package for Extracted Honey.

The President said that for shipping in large quantities the 60-pound tin-can was the best he had used; and for small packages, the 10-pound pail was preferable. The pail was useful after the honey was taken out; and for re-

tailing in stores, he preferred the pint glass-jars, and jelly-glasses with screw tops.

Mr. Kindree agreed with the President as to the packages for shipping honey, but for show purposes he preferred glass. Several other members expressed themselves in similar terms.

Eighteen members present reported an aggregate of 445 colonies last fall, and 397 colonies this spring.

It was decided to make the same offer as last year with reference to prizes to be offered for honey and apiarian supplies at the Cayuga, Jarvis and Rainham shows, and delegates were appointed to attend to the matter.

The next meeting will be held at Fisherville, on the last Saturday in August, 1889.

E. C. CAMPBELL, *Sec.*

BEE-HIVES.

"The Coming Hive" is Already Here and in Use.

Written for the American Bee Journal

BY J. E. POND.

Mr. J. W. Tefft, in his article on "The Coming Hive," on page 346, gives some tiptop points, and two paragraphs on page 348, from the article, are so much to the point, that I quote from them as a text. He says that the coming hive should be "constructed with the view of giving the queen full power of reproduction, and hereby hangs the whole 'law and gospel' in bee-keeping." Again, he says: "Keep the bees in one strong colony until after the honey-harvest," etc.

Now in the above, Mr. Tefft hits the nail on the head squarely; the point he makes is correct, and cannot be gainsaid or denied. The point, however, remains—what is the size of hive that will accomplish just this? Do different localities require different sizes? To the latter question I unhesitatingly say, No! and, further, that were it not for an evident desire on the part of many to be "cocks of the walk," we should have less bother in regard to size of hives, and hear less in regard to this, that or the other claim of originality or improvement.

The matter of protected hives need not be considered in this connection at all, as any size of hive can be protected by chaff or dead air-spaces, in its manufacture, or by any outer covering when needed, if needed at all; the point simply being what interior size of hive will best accommodate the varying requirements of a colony of bees with an ordinarily prolific queen, during a given or any season. The discussion on this point has taken a wide range in the past; and at times, I am sorry to say, some ill-temper has been displayed, but certain *proofs* have been set out in the way of statistics, that must stand as such for all time.

Now what is the evidence? The ordinary "Langstroth hive" (and I now speak of the interior dimensions of that Langstroth hive that carries a frame that will take in length four 4¼x4¼ sections, and being 14¼ inches wide), has given the best general results, and to-day stands unrivalled as an "all-purpose hive." It is large enough for any queen; it can be contracted to any required size; it can be made double-walled, filled with chaff or not, or can be protected with an outer covering, as desired; and it is free from any patented complications. Now what more can be desired? I have used this hive for years; none has been found better, and I have tested about all; none can be found that in the hands of the ordinary bee-keeper, will prove more profitable, or practicable.

I speak with positiveness on this subject, for the proofs sustain me; and till statistics show differently from their present aspect, I shall stick where I now stand.

North Attleboro, Mass.

DRONES.

The Rearing of Drones from Pure Queens.

Written for the American Bee Journal

BY L. STACHELHAUSEN.

On page 260 is reproduced some parts of Mr. Doolittle's new book, in which is stated the idea that, "a pure queen, however mated, must produce a pure drone of her own variety," is a theory only derived from the fact that a virgin queen can lay eggs, which will produce drones; and he says that the drones of a mismated queen are not pure at all. Although Mr. Alley and some other bee-keepers are on his side, nevertheless it is a mistake.

That those drones are pure, is no mere theory, but a proven fact. When Dr. Dzierzon introduced a single Italian colony into Germany, he reared at once many queens, which were of course mated with German drones. In the second year he used the drones of these queens exclusively. *He never received another queen*, nevertheless his Italian bees remained pure, and were even improved in color and working-qualities, by careful selection. For years he always received the first premium for his queens in competition with queens directly imported from Italy. Many other experiments have proven that those drones are pure.

Mr. Doolittle explains at some length that he is willing to prove his view. I may ask here, has he ever made this experiment? If we take into consideration that he sells Italian queens, it does not seem probable that he kept only black drones in his apiary. He may have experimented in an out-apiary, but how far was this from any other colony? What certainty have we that not a drone of any other colony mated with one of his queens? The way in which Mr. Doolittle recommends to have drones of a certain race only in an apiary, will do very well for practical purposes—for rearing queens for the market; for a large percentage of the queens will be purely mated; but for an experiment of this kind, it is much too uncertain. Somewhat better is the so-called "Koehler's method," but hereby too some few queens may be mismated.

Italian bees have been introduced in this country for many years, and consequently it is nearly impossible to say that any colony is entirely pure black. Six years ago I introduced the first Italian queen into this locality, and now a bee-keeper six miles from my apiary has among his over 200 colonies, not a single one certainly pure black, and no other Italian queen was introduced here except by me.

By Mr. Doolittle's experiment, any one of the colonies which are selected to rear these drones, may supersede the queen unknown to the bee-keeper, and then produce half-pure drones. If in this or any other way, a little trace of the yellow race is in the stock, some yellow queens will appear. If from these queens more are reared, and always selected in the color line, the black traces are more and more bred out; some queens may be mated with hybrid drones again, and you have real hybrids.

So we see that this experiment gives occasion for so many mistakes, that it is no proof at all. If very carefully conducted, I know that it will result to the contrary of Mr. Doolittle's view.

The idea that these drones are not quite pure, has its origin in the experience of queen-breeders, that some of the queens reared in the apiary are darker than other ones and their mother, and produce darker workers; but this is nearly always so, because the Italian bee is far from being a quite pure race. The idea that every queen imported from Italy is necessarily pure, is a great mistake generally made in the United States. If, now, some darker queens are bred, the bee-keeper thinks that some black "blood" originates from these drones;

but this black "blood" was at first in the imported queen.

Not everywhere in Italy are yellow bees, and the bee-keepers there rear queens for the trade, and select in the color line in just the same way as we do here in the United States. More than this, Italian bee-keepers introduced Cyprian queens to better the color of their bees.

It is well known that the progeny of a mismated queen is not uniformly marked—some of the bees seem pure yellow, some pure black, and some show mixed "blood." This is quite different from other animals, and makes it possible, by careful selection, to breed a purer race, and even from hybrids we could rear pure Italians, by selecting for a long time in the yellow line; and we could rear pure black bees, if we select in the black line. But here and there one bee will show some markings of the other race, and in this condition is the Italian bee just now.

Therefore it is necessary to breed in the color line, if we want pure Italian bees; but the beauty of the bee should not be the only reason to select a queen to breed from, and in-breeding should be avoided.

If I cannot agree in this respect with Mr. Doolittle, I think that he is correct in saying that the appearance of the drone many times will lead to mistakes. I have often observed that the drones of a queen which should produce hybrid drones, look nicer and more yellow than really pure drones. If we find some drones with two broad, yellow or red bands, similar to those of the workers, we can be sure that they are "half blood;" pure Italian drones are darker in appearance, and have small golden rings only; but the only sure way to select good drones, is to look at the worker progeny *of their grand-mother* for color as well as working-qualities.

Selma, Texas.

MAINE.

Report of the Western Maine Convention.

Written for the Bee-Keepers' Advance.

The Western Maine Bee-Keepers' Association met at the residence of J. B. Mason, at Mechanic Falls, Me., on May 7, 1889. The President being absent, at 7 o'clock p.m. the convention was called to order, and J. Pike, of Livermore Falls, was elected President *pro tem.*

The larger part of the evening was spent in the regular business of the Association, after which a letter was read from Mr. E. M. Dunham, of Freeport. His bees had not done so well the last few years as formerly, but he believes that he will now succeed better.

The convention then adjourned to meet at 9 o'clock the following morning.

On May 8, at 9 o'clock the convention was called to order with J. Pike in the chair. J. S. Fuller, S. H. Stockman and Wm. Holden were appointed as a committee on exhibits. J. B. Mason was selected as a committee to act with the committee of the Maine State Association in making arrangements for the exhibit at the State Fair, and in procuring a speaker to deliver an address on apiculture at the State Fair. Mr. Mason was instructed to draw on the treasury for such sums as, in his judgment, were advisable to procure the speaker for the occasion.

The convention then adjourned to meet at 1 p.m., at which time the following were elected as officers of the association for the ensuing year:

President, J. B. Mason, of Mechanic Falls; Vice-President, J. N. Dyer, of Durham; Secretary, J. F. Fuller, of Oxford; and Treasurer, J. Pike.

The first subject discussed was "The sale of virgin queens." The sense of the convention was, that the sale of virgin queens through the mails, was not to the best interest of bee-keeping.

Prevention of Increase.

"The best method to prevent increase was next considered. Mr. Pike hives the new swarm beside the old colony, placing the new where the old stood, and removing the stand from the old to the new; in five days he shakes all the bees from the old hive in front of the new one, and repeats the shaking until all the bees are hatched out; thus all the working-force is kept in one hive, and although they swarm and are hived, no increase is obtained.

How to Secure Increase.

The next question was, "The best method for securing increase." J. B. Mason would make swarms by drawing combs of capped brood, nearly ready to hatch, one from each of the seven hives, and shaking all bees back into their own hive, then remove an eighth hive to a new stand, and place this new colony on the eighth hive's stand, giving the colony a laying or virgin queen, or a queen-cell, or even let them rear their own queen; but in the last case, a frame of bees just hatching should be substituted for one of the frames of brood. This plan gives satisfaction, as it is very nearly faultless, and the new colony is strong, although but a small amount is taken from any hive at one time.

In regard to the effect that the past poor seasons had on bee-culture, it was thought that they would redound to the best interests of those good bee-keepers who continue in the business; that the unreliable and shiftless ones had been sifted out; and that the markets would be cleaned up, ready for the new crop of 1889. It was thought necessary to have a poor season occasionally, in order to clear the market of the poor grades of honey.

The Secretary was instructed to prepare a programme for the next meeting, to be sent with the notice of that meeting.

The committee on exhibits reported that they had examined the Root and Heddon hives, and the smokers of Messrs. Bingham and Quinby, and the Mnth Cold-Blast smoker.

The convention then adjourned to meet at the residence of J. Pike, at Livermore Falls, Me., in September, 1889. J. F. FULLER, *Sec.*

FEEDING.

Bees Starving—The Rearing of Early Queens.

Written for the American Bee Journal

BY CHAS. A. BUNCH.

For the last week or ten days the bees have had a pretty hard time, unless they had honey in the combs that was left from their winter stores. White clover is in bloom, but the weather is cool and cloudy, with some rain, so that the bees have gathered but little nectar for some time. Their winter stores are mostly used up for brood-rearing, which caused me to feed full colonies this late in the season, for the first time since I have been keeping bees.

The handiest way that I can feed my bees, is to give brood-combs of honey, if I have them; if not, I use granulated sugar made in a syrup flavored with honey. This syrup I have warm in a tea or coffee can, and I go from hive to hive, lift out a frame that is empty, and pour the syrup into the comb, which can be done nicely by holding the comb about two feet below the can of syrup. Colonies whose hives have tight bottom-boards, can be fed in the evening at dark, by tilting the hive back a little. A tin separator pushed in the hive at the entrance, will serve as a trough to pour the syrup on, which will run into the hive and disturb the bees but little. I do not claim that there is anything new for old bee-keepers in these ways of feeding, but it may help some beginner in bee-keeping.

As I almost always have my hives full of bees and brood some time be-

fore white clover blooms, I thought that I could spare some bees for queen-rearing early in the spring, to see how it would result; so April 9, I removed a Syrian queen and 6 brood-combs with brood in them, and gave them a brood-comb with eggs from one of my best Italian queens, with some more combs of honey.

About April 29 three queens hatched out of five cells that were built; the cells were placed in nucleus hives a day or two before they hatched, and in due time the queens were laying, and doing finely, as far as I could see. So far this season I could get only five or six good cells built in full colonies of bees.

I agree with Mr. Chas. Dadant, as given on page 311, that large brood-chambers are the ones to test the prolificness of queens; for I place considerable value on a queen-bee that is prolific, and first-class in other respects.

La Paz, Ind., May 29, 1889.

BEES' HUM.

Spring Work—Cleaning up the Hives, etc.

Written for the Country Gentleman

BY GEO. A. STOCKWELL.

The honey season of 1889 has begun. The flow of nectar is not in a swelling stream, but leak as little as it may, it encourages the bees, and the great family begins "to rock a thousand cradles," and to knead a thousand loaves of pollen-honey bread for the occupants.

This returning to the business of life is an interesting feature in bee-keeping. Like impatient children kept in by illness or bad weather, the bees appear to fret and to contend with themselves in their eagerness to rush forth. Early in the season, in sunny, mid-day hours they frolic and play, we know not how many games, in the porch of the hive. Every hive should have a porch. The bees appreciate it as much as the bee-keeper enjoys his veranda.

The first work of spring is to clean house. The hive with movable bottom now shows its convenience. The body is lifted aside, and the bottom-board swept. This is not enough. Every frame in the body of the hive should be taken out. Dead bees, and wax-litter from the uncapping of the cells may lodge between, mold, and spoil the comb if not removed.

Will not the bees remove dead bees and all litter? They will, and one man whith a wheelbarrow will carry off a mountain in time. If a dead bee be lodged and secured between combs, the bees will carry it away by piecemeal.

But there is work to be done more satisfactory than tugging all summer at the uncleanliness of a hive. Ten minutes work of the bee-keeper places the hive in good condition, and the occupants have only to brush up, repair a little comb, and go about their regular business; until the time comes to put on the surplus boxes, the bed-spreads and comforters should be kept on, and well tucked in. The bees cannot be too warm up to June 1.

At mid-day set a table before them, place a feeder under the quilt filled with warm honey. The colony may be strong, but the object in feeding is to encourage the queen that she may lay many eggs, that comb-cradles may be full, and full-grown workers may be numerous when the flood-tide of honey comes.

Bee-keeping has been discouraging for two years, but it cannot be that a third will follow in succession. Let every farmer—every one—remember that the more bees we have the greater will be the distribution of the fructifying pollen, and the greater will be the yield of all plants.

Providence, R. I.

CONVENTION DIRECTORY.

1889. *Time and Place of Meeting.*

Aug. 31.—Haldimand, at Fisherville, Ont.
E. C. Campbell, Sec., Cayuga, Ont.

Sept. —.—Maine, at Livermore Falls, Me.
J. F. Fuller, Sec., Oxford, Me.

Dec. 4, 6.—International, at Brantford, Ont., Canada.
R. F. Holtermann, Sec., Brantford, Ont.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Rolling in the Honey.—J. W. Eckman, Richmond, Texas, on May 28, 1889, says:

Bees are rolling in the honey very fast from wild China and horse-mint. Everything bids fair for a large honey-yield in this part of Texas. My bees gathered no surplus last season, on account of too much rain. All crops are fine this season. We have been eating roasting-ears for two weeks.

Bees in a Starving Condition.—Jas. W. Tefft, Collamer, N. Y., on June 3, 1889, writes:

I have reared one queen this season, and have 3 colonies to work in the sections—this was previous to May 15; since that time it has been cold and rainy, and the bees could not go out to gather from white clover, raspberries and other plants in full bloom. On June 1 I examined every colony, and found them full of young bees, from 6 to 8 frames full of brood, and some drones; but I do not think that there is 10 pounds of honey in the apiary, which is something remarkable for this part of the country at this season of the year. I shall feed only those colonies that throw ont brood. On June 2 and 3 bees were working lively, although it rained, and there was a high wind. I examined 10 colonies of bees of my neighbors, and found them all in a starving condition. This is rather discouraging, is it not?

Dry Weather in Minnesota.—Wm. Enke, Rochester, Minn., on June 1, 1889, says:

The season here is very discouraging. The continued dry weather killed most of the clover, so that now but little is to be seen. Bees are now gathering some honey-dew, which just keeps them breeding well. The prospect now is that we will not get any white honey except from basswood. We have frost two or three times a week.

Snow-Storm and Frost.—A. H. Lind, Calumet Harbor, Wis., on May 31, 1889, says:

This morning we had quite a snow-storm, enough to make the ground white for about an hour. I fear that if the weather does not change very soon, our crop of white honey will be very small. Corn, potatoes, beans and grapevines have been damaged the last week by frost, and I am afraid for the linden blossoms. Clover is coming into bloom, but yields no honey. I put 17 colonics of bees into the cellar last fall, took out 14 in good condition, and sold one, leaving 13 for the season's work.

Colonies Short of Stores.—W. D. Markham, Hart, Mich., on June 3, 1889, writes:

Having kept bees for 25 years or more, I never before have had this experience, and being warned by Mr. Doolittle and others quite often to look to the bees right away after apple-blossom, and having been cold and wet for about two weeks, I began to be uneasy, and on investigation I found reason to be a good deal alarmed. In walking around among them (I have about 100 colonies), I saw at the entrances of a few hives an unusual amount of dead bees. I quickly

removed the cover (I thought it was too cold before to look after them much), and I found that 4 colonies had given up entirely, and 5 more that still had life, which, with some warm honey poured over them, soon started them on the buzz again. This was on May 27. I soon got about three gallons of food ready, and decided that it was not too cold and wet to see if my bees were about to starve, for they had always been pretty good to me. I found, on investigation, about 25 colonies getting pretty short of stores, and now every day or two I am dishing them up a good square meal. It is still raining now (Monday morning), and I shall have to continue to feed, or the number will increase. Bees have not been able to be out for more than two hours in over two weeks; before this they were doing so well, and I began to have visions of swarms. I think that we will have a good season, as this wet time will make white clover in abundance. I am located in the fruit-belt of Michigan. Peaches and plums are not injured by frost, and the trees are very full.

Simple Swarming Device.—J. B. Wilcox, of Manistee, Mich., deseribes a very simple swarming device as follows:

Take a piece of board about 2 inches wide, of the desired length, and a dish-pan with large wire ears; cut a notch in the end of the board, or pole, so that the wire on the ear of the pan will just go through the space between the two. With the pan on the pole, hold it just under the cluster, and give the limb a shake, then take the pan down quickly, and pour the bees in front of the hive. If this does not get the queen, it should be repeated.

Unfavorable Weather.—Joshua Bull, Seymour, Wis., on June 1, 1889, writes:

The early part of the spring was very encouraging for bee-keepers in this vicinity. March was remarkably fine for that season of the year, in this latitude. April was, on the whole, quite favorable, and the forepart of May was exquisitely fine—all that even the most fastidious could expect or desire. Fruit-bloom commenced on May 4, and continued up to about the middle of the month, with the weather warm and fine; the bees were just booming, and the strong colonies persisted in building queen-cells, and preparing to swarm. White clover blossoms began to appear on May 15, and were quite numerous by May 20; our expectations were running high in anticipation of an early and bountiful honey harvest; but our warmest hopes received a severe chill, when on May 22 a series of frosty nights, interchanged with cold rains, set in, and have continued up to the present time; since which bees have done nothing, being confined to the hive the most of the time. The fruit crop is ruined, or at least greatly injured by the frost; white clover blossoms have all disappeared, and vegetation is at a standstill. I do not know whether the bees are hibernating, or generating, or meditating what to do. We shall think it a boon if the clouds depart soon, so that the sun can once more shine through.

Good Prospect for Basswood.—Green R. Shirer, Greene, Iowa, on June 2, 1889, says:

Bees have not done much for the past two weeks, on account of cold weather—wind from the north, with frost last Friday morning. White clover is just beginning to bloom. Basswood will be very full of bloom.

Heavy Frosts—Feeding Bees.—Rev. Stephen Roese, Maiden Rock, Wis., on June 1, 1889, writes:
