I commenced keeping bees in the fall of 1894, with 10 colonies. The next season I sold honey to the value of over \$14 to the colony, and increased by dividing to 41 colonies. I commenced using dove-tailed hives with full sheets of foundation, and still use full sheets, and right here is where I think my success lies.

I have 160 colonies in hives well painted, with frames wired and full sheets of foundation in every frame.

EDW. SCOGGIN.

**"Drove of Wild Bees Swimming."**—Mr. J. M. Burch, of Whiteside Co., Ill., sends us the following somewhat flowery quotation from a recent novel, which will be quite amusing to bee-keepers:

"The king sat in his private garden in the shade of a potted orange-tree, the leaves of which were splashed with brilliant yellow. The velvet hush of the midday hour had fallen. There was an endless horizon of turquoise blue, a zenith pellucid as glass. The trees stood motionless; not a shadow stirred, save that which was cast by the tremulous wings of a black-and-purple butterfly, which, near to his majesty, fell, rose and sank again. From a drove of wild bees swimming hither and thither in quest of the final sweets of the year, came a low, murmurous hum, such as a man sometimes fancies he hears while standing alone in the vast auditorium of a cathedral."

Surely, a "drove of wild bees swimming" would be quite a "novel" sight—seen only in a novel.

**Geo. W. Brodbeck—Additional Notes.**—Last week we gave a biographical sketch of Mr. Brodbeck, written by Prof. A. J. Cook. Since then we have received the following from J. M. Hambaugh, who also knew Mr. Brodbeck well:

Geo. W. Brodbeck was loved and respected by all who knew him, and he had the entire confidence of the bee-keepers of the Sunny Slope. His heart was in the work, and he labored early and late to place the apian interests on a higher and more lucrative plane, the last two or three years of his life, as president of the California National Honey-Producers' Association.

The bee-keepers of the Coast and Nation have lost a faithful and sincere friend, and the name of Geo. W. Brodbeck will long be remembered as one of our brightest and most distinguished lights of the industry in California. May his spirit be at rest. His wife and family have our heartfelt sympathy in this their dark hour of sorrow.

J. M. HAMBAGH.

Mr. Hambaugh also enclosed a letter dated March 23, written by Mrs. Brodbeck, from which we take the following paragraphs:

"My husband's birthplace was Lawrenceburg, Ind. He grew to years of manhood in that town. He was married there, Dec. 3, 1878. He removed to Edinburg, Ind., where he resided about 5 years, going from there to Indianapolis. In that city he became interested in bees, and owned a small apiary. In October, 1889, he came to Los Angeles, where he resided until the time of his death.

"In January, 1904, he had a severe attack of pneumonia, and for days it was thought he could not live. He rallied from that some-

what, but never gained much strength. The effects left by that terrible disease were such that he could not recover, and he gradually grew weaker until death ended his sufferings, Feb. 6, 1905.

"He was an earnest Christian, and was entirely willing to go, but would have preferred to get well for my sake. His love for the bees and the welfare of the bee-keepers is well known. He loved the work he had chosen with unselfish devotion."

The Farm Journal has in its May issue, in a very prominent place, an excellent article written by Mr. Wm. A. Selser, one of the members of The Honey-Producers' League, on "The Honey-Bee and the Truth About Honey." Mr. Selser sets forth some real facts about honey and its nectar origin.

Also, in the same issue, appears this paragraph, in the department called "Heart Problems," conducted by "Aunt Harriet," who, in the April Farm Journal, wrote the statement about honey that we copied on page 291:

I have had a number of letters in reference to an item which appeared last month, advising me that my statement in regard to adulterated honey was overdrawn, and is liable to injure the bee-industry. The attention of the Editor of the Farm Journal has also been called to the matter, and he wishes me to say that bee-keepers need not fear but that the Farm Journal will set the matter right if a mistake has been made.

**The Chick Book.**—The successful methods of rearing chicks; 80 pages 9x12 inches. A book of thorough and reliable instruction on rearing chicks. It includes chapters on condition of the breeding stock; selecting and incubating the eggs; brooding, feeding and caring for the chicks from the time they are hatched until they are ready for market or breeding pen. By following the instructions in this book, the poultryman can avoid mistakes and secure the greatest profit, whether raising chicks for market or fancy. If your chicks do not live and thrive, consult this book, and learn better methods. It is a guide to success. Price, 50 cents, postpaid, or given free as a premium to a paid-in-advance subscriber who sends us one new yearly subscription to the American Bee Journal with \$1.00; or clubbed with the Bee Journal one year—both for \$1.30. Address the American Bee Journal office.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food", written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey". It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy.

PRICES, prepaid—Sample copy for a two-cent stamp; 50 copies for 70 cts.; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

**Some Facts About Honey and Bees.**—This is the subject of an article written by Mr. J. E. Johnson, and published on pages 581-82 of the American Bee Journal for Aug. 25, 1904. We have republished it in 4-page leaflet form for general distribution, and furnish it, postpaid, at 35 cents per 100 copies. Send all orders to the office of the American Bee Journal

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get them subscriptions, for which work we offer valuable premiums in nearly every number of this Journal. You can aid much by sending in the names and addresses when writing us on other matters.

## Producing Section Honey With and Without Separators

BY WM. M. WHITNEY

On pages 20 and 21 there appear some expert opinions respecting the production of section honey. To the question "Can marketable sections of honey be satisfactorily produced without separators?" a large number of emphatic "Noes" were the response. Other, and more guarded replies, admitted the possibility of its being done.

It is seldom that we find two bee-keepers surrounded by the same conditions and having exactly the same difficulties to meet and overcome, and this fact, it seems to me, may be one of the prime causes of the diversity of opinion among bee-keepers on nearly every branch of the business. My bee-keeping has been carried on, on comparatively a small scale—25 to 50 colonies being the limit—and having plenty of time to devote to details, I have given more attention to experimenting in a general way than I otherwise might have done had there been a larger number of colonies to look after; yet I believe I could have managed as many as 100 colonies just as well.

It is not the farm of the largest number of acres that is farmed the best; nor is it the largest apiaries that show the best results in every respect.

Having made a trial of wood separators, and having been troubled so much with brace-comb, which invariably, with me, spoiled the section, that only in exceptional cases has it seemed advisable to use them. Were unfinished sections, or those from which the honey had been thrown out; or, sections 1 7/8 to 2 inches wide to be used, on even my style of hive, separators should be used. It is unnecessary to explain, even to an ordinary bee-keeper, why they should be used in the first two cases mentioned, but perhaps it's well to give a reason why they should be used in the last. All sections 1 7/8 to 2 inches wide, if well filled, without the use of separators, weigh more than a pound. If separators are used, there results two bee-way spaces between, the combs instead of one; consequently, lessens the thickness and weight of the sections just that much, bringing them within the weight required by nearly all dealers; but with 7-to-the-foot sections, if properly manipulated, the same results are attained without separators.

Allow me to explain my practice, and pardon minute details in doing so, for, often, mistakes are made, and disappointments and disasters follow, because of lack of attention to seemingly unimportant details in management.

My hives are 2-story, double-walled to the top of first story, with thin outside shell for second story. Section cases may be tiered up three high under the cover, having a dead-air space around the entire outside of the cases. The outside sections are kept, practically, at the same temperature as those in the center of the case. In early spring, the hive-stands are leveled as accurately as possible, and on all hives where the colonies are strong enough to bear the treatment, supers of brood frames of comb, or foundation, are put. Just about fruit-bloom time, or a little later, depending upon the weather and honey-flow, the colonies are examined; supers on all such as are strong in numbers are removed; bees shaken from the frames in front of the hive, and supers taken, if containing brood, to such colonies as may be comparatively weak—such may be found in nearly all apiaries having a number of colonies;—if none such are found, new colonies may be formed in the usual way.

Cases containing 7-to-the-foot, 2-bee-way 3/4 sections with full sheets of extra-thin foundation are put on all hives strong in bees; sometimes two cases, if the colony is very strong, are put on at once, and within two hours—sometimes, in much less time—the cases will be filled with bees from side to side, with not a vacant section to be found. With the dead-air space around the cases, the outside sections are worked as freely as others, and the combs are carried down parallel, with a single bee-way space between them, and as true as the best worker-comb one ever saw. Not infrequently

the cases are surrounded with bees clinging to the sides nearly an inch thick. This condition could not obtain were it not for the outside wall.

Now, my theory is, that owing to the great fluctuation of temperature, often between midday and midnight, in our northern localities, the double-wall hive is a better one for the production of comb honey than the single wall, for the reason, as I have thought, that comb-building is carried on more extensively at night, bees in the outside sections in the single-wall hive, are checked in their operations during chilly nights; hence, the necessity for the use of separators in such hives to prevent the bulging of the comb in the sections. In more southern localities this condition may not prevail, but in northern localities there seems to be this trouble; or, is it my imagination? It seems to me, that if outside sections are kept as warm as inside ones, and the hive is strong in bees, that work would be as likely to be done there as elsewhere. While I've never had anything but limited experience with single-walled hives, this theory seems plausible to say the least.

But, I imagine I hear some one saying, "This is all a pretty word-picture; it looks well on paper; sounds musical, but I'd like to know whether it is all so, or not." Well, try it. Some one says, "It's just possible you are not a judge of what constitutes a marketable section of honey." Well, I'll not say as to that, but let the honey speak for itself. A dealer who handles it in one of our large cities reports that he has handled honey in the same place for 16 years, and that this honey—non-separated honey—is the finest that he ever saw; that he sent a case to a lady who wanted a choice article, and that she sent it back because she thought it was manufactured; said she never saw comb so true and so nice in her life, and that she knew that it was never in a bee-hive. After being convinced that it was all right, she requested the grocer to return the honey to her home.

My honey has been shipped to St. Louis, Kansas City, Chicago, Oak Park, and to other places, at \$3.75 to \$4.00 per case of 24 sections (f. o. b.), and I'm unable to supply the demand. Of course, it is put up just as nicely as I know how to do it, and I intend that no section back of the front row shall suffer from a comparison with any one of those just behind the glass.

Now, whether it takes an expert or not, to produce that kind of honey without separators, I'll not admit that I cannot do it. Taking the extra expense of separators, the trouble of cleaning them, and the brace-comb that is so often built that spoils the section, I'm not so certain that I cannot do it as well without separators, and with as little trouble, as with them.

I have said that I'm experimenting a little in a general way. What we read in books and journals of course is of use to us, and sets us to thinking, which should prompt us to do a little testing of theories, so that we may know for ourselves; and, if done intelligently, this gives us positive knowledge, which is essential for every person in any line of business or employment to have. In this way, and only in this way, are we likely to advance along any line of research. I am planning to try a different style of separator from anything that I have seen, to be used with the various kinds of sections, and if I meet with success I shall give the results of my experience to my brother bee-keepers. If I fail, well—what? Why, "Try, try again." Walworth Co., Wis.

## Governor Folk's Veto Message

BY DR. G. BOHRER

ON page 261 appears the Veto Message of Governor Folk, of Missouri, in which he gives what he calls his reasons for not approving the Apiary Bill passed by the Legislature of that State.

In the second paragraph he refers to the provision in the Bill for the inspector to make a second visit to an apiary diseased, which is the only real shadow of a valid reason set forth in the entire document, that can serve as a real plea of justification in support of his inexcusable blunder.

The law should be so formed as to require the appointment of a person for inspector who is well skilled in the habits and management of honey-bees, and well-versed in the diseases of bees and the successful treatment of the same. When called upon to visit and inspect an apiary in case foul brood, pickled brood, or black brood is found, he should prescribe an effectual remedy for a radical cure. If the owner or manager of the bees refuses to permit the

inspector to treat the disease or fails to apply the remedy himself, the inspector should proceed to destroy all diseased colonies, together with everything about the premises infected in a manner liable to spread the disease. As a rule, one visit will be sufficient to mark out the course to be pursued by the inspector, and he should be the judge as to whether or not more than one is necessary.

In the third, fourth, and fifth paragraphs of the Message, the Governor proves that he (like millions of other well-meaning people), knows nothing about the bee-industry, except, possibly, the superstitions and false reports sent over the country through the press, all of which have their origin in ignorance, and are cradled in superstition, to the serious detriment of a very important industry. For thousands of good people, many of whom are women and invalids, are securing a comfortable support through the scientific support of bees, and many other thousands are keeping a few colonies which supply their tables with honey, the most welcome sweet obtainable from any source.

In the fifth paragraph he states that the principle of the measure is *paternalistic*, and not in accord with the democratic theory of government, which expression had its origin in the brain of some trust magnate, and is used to prejudice the minds of the unthinking and unsuspecting, but confiding, public, and has no legitimate place in the consideration or discussion of any question like the one before us. If I am in error in taking this view of the case why should any of the states enact laws to prevent harboring and spreading glanders among horses, small-pox, yellow fever, and other ailments among the human family? The Governor has assumed ground wholly untenable, and he should lay aside all such slang expressions when considering questions which deserve the candid and sincere thought of a real statesman.

Missouri, like other States, has many intelligent bee-keepers, who are confronted with the deadly disease of foul brood among bees, which is being harbored by the careless, ignorant and superstitious persons who own them, and who are not only careless but egotistical, as well as superstitious, and unwilling to accept the advice of anyone who may be disposed to help rid them of the disease. In view of what the governor says—"leave the matter to the owners of the bees themselves"—why not, Governor Folk, call legislation against railway train-robbing *paternalistic*, and advise the railway companies, the people, and the robbers, to settle the matters of robbery among themselves?

That Governor Folk has in time past done some very good things is a fact, but in vetoing a bill for the suppression of a great source of injury to an important industry, under the tame reasons he offers, he has done wrong. Let us hope that he will not do it again.

Lyons Co., Kans.

## A Large Increase—How to Secure It

BY G. M. DOOLITTLE

A LETTER lying before me reads thus: "I see that you are answering questions in the American Bee Journal, and so am led to ask you to tell me how I can increase my bees more rapidly than I did last summer by natural swarming. During the winter of 1903-04, I lost nine-tenths of my bees, and thought to get the unoccupied combs covered with bees again, by natural swarming, but as few swarms issued, I was obliged to sulphur the combs to keep them. Now can you tell me how I can increase what few I have so that I can get the combs all in use again?"

I have tried many plans of rapid increase of bees, all of which would work to a greater or less extent; but I will give the one which suits me best, taking everything into consideration:

Get out as many boxes as you think you will want (I keep ten on hand), large enough to hold from three to five pounds of bees. For this purpose there is nothing better than an ordinary 20 to 24 section shipping-case, nailed up and leaving off the side-strips that hold the glass. On one of the open sides nail on a piece of wire-cloth, and for the other side, make a frame to fit, to which you will nail wire-cloth, the same as you did to the box. Now with hinges and a hook or latch, fasten this to the opposite side of the box, when you will have a door that you can open at any time you may wish.

Next get a tinsmith to make a great, big funnel, which should be eighteen inches across the top, with the usual slope of side, coming down to a 2½ inches upright, or outlet, which should be about two inches long. If this outlet

is much less than 2½ inches in diameter, the bees will clog in it, instead of readily passing down through, when the bees from a frame are shaken into the funnel.

Having the funnel made, squeeze together at the top, till you have an oval funnel about a foot wide and 22 inches long, in diameter of the two ways across the top. This will collect the bees in better, when the frame is shaken, than it would if left in the ordinary funnel shape.

Next bore a hole in the top of the "nucleus box" (that is what I call this box), which will just let the small or upright part of the funnel down into it, and fix a little door of some kind to cover this hole when the bees are in and the funnel is out. Next put in a section partly filled with honey, left over from last season, putting the same near one end of the box, and fasten it in place by means of a screw, clamp or spring, so that the bees can have something to live on while in the box. This completes all the box part.

Now crowd the colonies you have in the spring, toward full colonies, just as fast as possible, using any or all the plans with which you are familiar, or those given in the bee-books, for keeping them warm, stimulating, etc.; and as soon as any one of them gets strong enough, prepare it for queen-rearing, according to the plan given in "Scientific Queen-Rearing," and continue to rear queens from this colony, as you may require, for you can do this and not hinder this colony from contributing its share of bees for the increase you wish, as well as the others, as the queen is laying all the time in it.

As soon as any of the colonies are full of bees, so they can spare bees from two frames, or from half a pound to a pound, without injuring their future prospects, and you have ripe queen-cells, take the cells out and put them into the queen-nursery to hatch. Now, as soon as the queens are one or two days old, go to any hive that can spare bees, take out two frames, being sure that the old queen is not on either of them, and shake the bees from them down through the funnel into the box, doing this about 10 o'clock, a. m.

Having the bees in the box, set them in some darkened room, leaving them there till the next morning, when you will get one of the young queens from the nursery, put her in a cage having a stopper in it filled with queen-candy to an extent that it will take the bees about half a day to eat it out and liberate her. Now take the box of bees to some place where it is light so you can see, and suddenly set it down on the bench or floor, when all the bees will fall to the bottom. Now quickly open the funnel hole, put in the queen-cage, and secure it so it will stay about an inch or so below the top of the box, by means of a wire shut in between the little door and the top of the box, in closing the hole again.

After having things thus fixed, set the box away again where it was before, leaving it to near sunset the following day, when you will find the bees all contented with their new queen, and hanging to the box like a swarm. At this time go to any hive that can spare a frame having some brood in it, say from 1/3 to 1/2 full, and take such a frame, shaking the bees off, and replacing it with a frame of empty comb. Put this frame in a hive placed where you wish a colony to stand, together with two of the combs you wish to stock with bees, each having enough honey in them to insure the little colony from starvation, placing the one having brood in it between the two having honey in them, and all near one side of the hive. Now get the box of bees, open the large door to the same, lowering it down into the hive, when with a quick, jarring motion you will shake all the bees on the bottom of the hive. At once set the box outside and draw the combs along the rabbets of the hive till they are next the side of the hive where you have shaken the bees, put in a division-board to keep them on the three combs, and keep all warm, when the bees, in running up, will be immediately on the combs, and will fly out and work just the same as a natural swarm of the same size would.

If your work is so that you can not put them in the box at 10 o'clock a. m., as given above, the little swarms can be made at any time, but by doing the work as above you will get a greater proportion of young bees in the box than you would did you do this work when the working force of bees was mostly in the hive.

As you wish to make more little colonies, fix the box back as it was when making this first one, and using the whole ten, or more if necessary, in the same way, and proceed with all the same as with the first. As the season advances you can make one such little colony from each full colony twice a week, and take the same from your colony rearing queen-cells, too.

Keep a good lookout for the combs, if the moth is likely to trouble them, using those each time that may show any

signs of moth-worms, and in this way you will not need to sulphur any that were not treated that way last year, or from which the bees may have died the past winter.

When the honey harvest arrives, keep plenty of combs on the strongest colonies, so that plenty of stores can be stored in these for wintering, and, as the season advances, use more bees each time in making the colonies; and when fall arrives, if you do not have all the colonies you wish, and you have plenty of sealed combs of honey for stores left, take bees from several hives, thus forming a strong colony at once, and hive them on these frames of sealed stores. I have so formed colonies in September, many times, and had them prove as good as any the next season.

If you have some honey in the combs from which the bees died, and you work to the best advantage in securing honey in the combs when the flow is on, you can increase seven or eight colonies in the spring to 100 in the fall, easily, by this plan, without any feeding or without any outlay in cash for queens, feed, or anything of the kind; and if the season is a really good one you can secure some surplus besides.

With the nucleus-box plan, you can do almost anything you wish by way of making colonies for any purpose you may desire, and the beauty of it all is, that they will stay as contented and work as nicely as any natural swarm. Of course, it is understood that the empty combs are to be added to these little colonies as soon as the queens get to laying and they can cover more, till the hives are full, and the combs are all used.

Allow me to say that the main secret of a rapid increase, is in not commencing operations till the colonies are strong, nearly enough so to swarm, and then not robbing them of bees till they are too weak to work to the best advantage; using few bees for each colony the fore part of June, and more and more as you go along, thus having all come up to full colonies in August and September.

I have had to be brief with this in order to get all in one article, but I think I have been sufficiently explicit so the questioner, and all others, may understand. If not, I am open for more questions at any time. These nucleus-boxes have become an absolute necessity with me in my apiaries; for with them I can handle bees with about the same ease I can potatoes in the bushel boxes.

Onondaga Co., N. Y.

## Our Sister Bee-Keepers

Conducted by EMMA M. WILSON, Marengo, Ill.

### Bees Do Not Puncture Fruit

Those who read the letter of Miss Wheeler, on page 204, will doubtless be interested in the outcome of the investigations instituted by her to find whether bees were the culprits in the case of certain injuries to apples. A letter from her dated March 1, is as follows:

DEAR MISS WILSON:—As promised, I send Prof. Stewart's reply, also Prof. Parrott's comments on bees *vs.* apples. Prof. Benton's opinion, being practically the same, reads as follows:

"We have no record that I am aware of regarding puncturing of over-ripe apples by bees. My own observations do not lead me to think that bees ever do this. When apples and other fruits are broken open by any means whatever, honey-bees go in to suck the juices, and even when the skin is broken, take hold of the edges of the latter in such a manner as to permit them to enter the cavity, then to continue the sucking of the saccharine juices of the latter from the pulp."

He refers to the Annual Report of the U. S. Department of Agriculture, 1885, pages 336-339, and Gleanings in Bee Culture Feb. 1, 1901, pages 91-92, which shows where careful tests have been made both by himself and others, and also the trial in court and decisions in fruit *vs.* bees. All of which tend toward the conclusion that bees do not take the initial part in puncturing fruit, but follow after insects that do the mischief, and the bees reap the benefit.

I must, of course, bow to the decision of men so thoroughly competent to decide in this matter, and who have made a study of the subject. And of course it is quite a relief if our bees are innocent of injury to fruit.

Clinton Co., N. Y.

Prof. Stewart reported as follows:

We have made a careful microscopic examination of the brown spots on the Talman sweet apple which you gave me, but have been unable to determine definitely what caused the spots. In a great ma-

FRANCES E. WHEELER.

majority of cases we found no traces of fungi but occasionally there was a little fungus present. Probably the spots have not been caused by fungi and I am unable satisfactorily to account for them. After talking over the matter with our entomologist, Mr. Parrott, I very much doubt that the bees could have caused this trouble. It is contrary to accepted beliefs in the matter. Mr. Parrott will, I think, write you on the subject.

F. C. STEWART, *Botanist.*

And this is the letter of Prof. Parrott:

MISS FRANCES E. WHEELER—

Dear Madam:—Upon his return, Mr. Stewart has informed me of your interesting observations upon the work of bees on apples. Similar reports have been made of the work of these insects upon grapes and other fruits. While it is thought by some that they are able to puncture fruits, it is now generally believed by apiculturists that the bees cannot gain entrance to the fruits except as the skin may be broken by other agents, as wasps and birds, etc. As we have paid very little attention to this group of insects, I have written to Prof. Benton of the Department of Agriculture, Washington, D. C., who is a specialist in this line, for his advice. His reply is sent enclosed. I am sure it will be of interest to you. When you are through with this, will you please kindly return it to me?

P. J. PARROTT, *Entomologist.*

Accompanying the foregoing documents was a private word from Miss Wheeler, asking that judgment might not be too severe upon her for having arraigned the bees for trial. Why, bless your good heart, Miss Wheeler, instead of having any grudge against you, bee-keepers owe you a vote of thanks for having done them a distinct service.

It is no light matter to have secured the verdict of two such able men as the botanist and entomologist of the New York Agricultural Experiment Station, not only because of their ability but because of their disinterested position. No matter how much more Prof. Benton may know about bees, there is some danger that having been a practical bee-keeper all his life he might be thought to have a kindly leaning toward the bees in rendering a verdict. Professors Stewart and Parrott are outside the ranks of bee-keepers, thus adding weight to their verdict, and we are indebted to Miss Wheeler that they have thus committed their weighty influence on the side of right and the bees.

I am sure that the sisters will join me in hoping that Miss Wheeler's keen eyes may be further used in watching the busy bees, and that we may often learn something from her as to that watching.

### Honey as a Bee-Sting Cure

That "like cures like" is fully demonstrated by the fact that one of the best cures for bee-stings is honey. As soon as possible after being stung remove the stinger which the bee usually leaves and cover the afflicted part with honey, either in the comb or extracted. If used soon enough it is, as far as I have known, a sure cure. I have an acquaintance who was so badly stung that his arms, face and head and even feet, for he had low shoes on at the time, were literally one immense sting. The honey was applied and the following day he felt no ill effects whatever except a slight weariness.—ALLENE LANGFORD, in *Vick's Family Magazine*.

### Indian Cough Cure

W. T. Mundy sends the following recipe for a cough cure which he obtained from an Indian woman in Mississippi, and which he says cured him of a cough of 20 years' standing:

Take Indian turnips and slice them up thin, put into a jar and cover with honey, and then let stand 24 hours. Common turnips will do. Dose, a tablespoonful before meals and at bedtime."

Mr. Hasty's  
Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B Rural, Toledo, Ohio.

#### CAPT. HETHERINGTON AND HIS BEE-KEEPING EXPERIENCE.

The excellent sketch of J. E. Hetherington by Mr. Elwood shows that the greatest bee-keeper in the world was not so much of a recluse as some of us imagined. Had been President of his State association, and also of the National. The fact that we seldom saw him in print and seldom heard of his being at a convention somehow made me assume that he never did these things. Not a fact. And if any one has set it down as selfishness, or lack of public spirit, that kept him so much out of sight and out of mind among our fraternity, the reading of these live pages from the pen of a personal friend is likely to bring an entire change of opinion.

A humorist would say that bee-keepers are distinguished by the mark that somehow every one invented everything. Hetherington's invention of everything rather scoops the rest of us by reason of the fact that he was so early in the field, 1852, and had a very inventive

mind as well. First man in America to depend wholly on bees for a support. Takes 3,000 colonies, it seems, to give one the title of largest bee-keeper in the world. Somebody will go higher now just for the sake of doing it. Heavy wintering losses he had for some years; but for the last dozen years his success was quite good. We may remark, by the way, that the cellar-wintering of 3,000 colonies of bees is not exactly the same problem as wintering 100. To the good is 30 times as much animal heat; and to the bad is 30 times as much carbonic acid gas. More call for ventilation than to sweeten things up. Pages 137-142.

#### NO QUEEN-REARING SYSTEM IMPROVES BEES (?)

Our "Hutch" seems to be running for the office of champion heretic. Not content with contemplating all our bee-papers sealed up in their tombs, he proceeds to say: "There is no system of queen-rearing that will improve a strain of bees." Did you ever? Now it may be that a short-lived and non-prolific queen will usually transmit to her daughters the good qualities that her parents were endowed with—that is, transmit them without *very much* loss. I'm not ready to say there would be no loss at all. 'Spects she would not have been short-lived and non-prolific had she been properly reared. And had she been properly reared I should expect her to lift up a little instead of pulling down a little on the desirable qualities of her descendants. It is quite possible that the upbuilding power of queen-breeding pure and simple may have been very greatly overrated. If that is so perhaps we should be thanking Mr. Hutchinson for calling our attention to it, instead of scolding him for getting a wheel off the track. Undoubtedly wise observation and selection extended to a large number of colonies amounts to a good deal more than any arts of mere breeding. But let us not throw away our dimes because gold pieces are worth more. Improvement of a strain of any living creature often gets on very slowly; but also sometimes (we know not why) advances with a sudden long leap, which it is our business to seize and hang on to. We wouldn't be hanging on properly unless we bred in the best method we know. Page 150.

#### BEES IMMUNE FROM DISEASE.

When a fatal disease has had wide range and long prevalence, and individuals never exposed are few or none, nature gradually builds up an immunized strain. Thus, Prof. Harrison says, the sheep of Algiers have become partly immune to the disease called anthrax. He also thinks the bees of Europe have become partly immune to foul brood, on the same principle. I don't feel so sure of that as one might; but it would account very well for so many sure cures brought from over there proving nearly worthless on this side. Page 151.

#### DO BEES FREEZE OR STARVE?

As to those seemingly dead bees on page 163, I incline to introduce a third theory to account for death when it actually comes in such cases. They certainly did not starve to death, for they were not dead; neither did they freeze to death, for the same conclusive reason. But had they been left alone long enough they would have been dead—which cause then? Neither (let us say). Starvation comes from lack of nourishment; and organs that have ceased to act do not need nourishment—that is, do not come to need it any worse than they did when they ceased to act. Quite likely there is still some little remnant of invisible action somewhere—as long as life remains; but the amount of nourishment needed to support it would be correspondingly small. And one would say (though with some possibility of a big mistake) that it would take weeks, if not months, to starve a thoroughly chilled bee. As to freezing, a bee frozen for two hours is not dead. What more can freezing do after the first two hours? It is not easy to see. So I'll mildly conclude that certain chemical changes proceed quite well below the freezing point; and that they finally disorganize things and extinguish the vital spark. But the whole of this is theoretic. Practically the way to save just such a colony in the future is to give them more food to start in with. In some cases warmer quarters would cause the bees to eat less food, and so have enough. Matter of food in both cases.

Doctor Miller's  
Question-Box

Send Questions either to the office of the American Bee Journal,  
or to Dr. C. C. MILLER, Marengo, Ill.  
☞ Dr. Miller does not answer Questions by mail.

#### Transferring Bees

I have 6 colonies of bees in home-made hives with home-made frames. These I wish to transfer to new hives (S-frame) with Hoffman frames. I also desire to procure new brood-combs for each hive. I do not want increase; besides, I am not keeping bees for profit, neither do I sell any honey, but all is turned to our personal use. I intend to furnish the new hives with starters, and then shake the bees from the old hives in front of them, and thus combine transferring with swarming.

1. Is this method practicable or advisable, and, if so, when should I do it, during swarming-time (about the end of May and beginning

of June with me) or when they have queen-cells? or could I do it before there are any indications of swarming?

2. Could I transfer in the above manner during fruit-bloom, and, if so, will any swarms issue from colonies transferred in this manner?

3. Can I use only starters in the new hives, or must I use full sheets of brood foundation?

4. Could I use the brood-combs from the old hives in extracting-supers? I intend to run 3 colonies for extracted and 3 for comb honey.

5. By transferring them in the manner outlined, would not the greater part of the honey from white clover (which blooms in this locality from the beginning of May) go into the brood-chamber rather than into the sections?

INDIANA.

ANSWERS.—1. The method is practicable, and under the imposed conditions perhaps advisable. If you do the work before swarming-time, there is danger that you may hinder the best development of the colony on the one hand, and on the other hand that if there is no such hindrance there is likely to be swarming when swarming-time comes. It will be safer to wait till swarming-time, and it may save some work if you let the colonies swarm naturally, hiving them on the new frames.

2. If you operate in fruit-bloom, and if you don't give the bees too much of a set-back by it, they will be likely to swarm. If you operate in swarming-time, they will not be likely to swarm.

3. You can do either way, but you're likely to have so much drone-comb with starters that it may be cheaper in the long run to have frames entirely filled with foundation.

4. Yes, they will do nicely, giving you 2 stories of extracting-combs for each of your 3 colonies.

5. No, you will probably find that the first thing the queen will do will be to fill the frames with brood, giving way to honey later in the season.

The following plan may be worth your consideration: When the colonies become strong, but before any have swarmed (it may be well to even up in strength by giving sealed brood from stronger to weaker) treat 3 of them after this fashion: Put the empty hive of foundation in place of the old hive, put a queen-excluder on, and set over this the old hive. Find the frame with the queen, and shake off bees and queen at the entrance. Over this, for a third story, set a story of brood from one of the other 3 hives, shaking the bees upon foundation. The 3 colonies with the 2 stories of brood above the excluder will become very strong, will not be likely to swarm, and will do fine work for the extractor. The other 3 colonies will not be so strong, but will do fair work in sections. If you would like the stronger force to work on sections, you can make the exchange in 10 days or so. Lift off the 2 stories of brood; put in their place the sections, bees and all, from one of the other hives; brush off all the bees from the brood, and put the 2 stories of brood where you took the sections from.

### Surplus Combs for Hiving Bees

I have some surplus combs. Is it best to hive bees on these or on foundations? I run for comb honey.

MISSOURI.

ANSWER.—Some prefer foundation, but I think most bee-keepers would rather have the combs.

### Rearing Queens in Different Ways

How can I rear queens in different ways?

WISCONSIN.

ANSWER.—I'm not sure that I know enough to tell you all the different ways that are used to rear queens, but some of the ways most in use are the Doolittle plan, the Alley plan, and the old plan of making a colony queenless and allowing it to select its own larvæ from which to rear queens. Another way is to encourage a number of afterswarms for the sake of securing a queen from each. Possibly I don't get at the right drift of your question. If not, please ask again, and I'll try my best.

### Prevention of Swarming

I have been reading and studying your book, "40 Years Among the Bees," all winter and hope to profit by it the coming summer. I have only recently become a subscriber to the American Bee Journal, and so I don't know whether you have ever made any report in it as to your success, or lack of it, in practicing your "foundation method" of treating bees preparatory to swarming. I note that you say in your book that the first two years this method was successful, but in 1902 it was not so much so. How did the seasons of 1903 and 1904 serve you in this practice, or have you some better method now?

MASSACHUSETTS.

ANSWER.—I'm not sure that I gave the foundation plan any further trial, because, even if it did nearly always succeed, I'd rather have something always successful. During the past two years the following plan has had the right of way:

As soon as there is danger that there may be preparation for swarming, the search every 10 days or so for queen-cells is begun, as given in "Forty Years Among the Bees," page 184. When cells are sufficient in number, and sufficiently advanced, to show that the bees are not to be balked in their attempt to swarm, the cells are destroyed and the queen removed. About 10 days later all cells are again destroyed and a young laying queen given. If she is found laying all right at the next visit there is no need to go into that colony again

during the rest of the season. Sometimes a colony swarms unexpectedly during our absence, and at the next visit we find that it has swarmed by the absence of young brood, the clipped queen having been lost. We destroy queen-cells, and at the next visit give it a young queen, after killing all queen-cells. Sometimes we have no young queen ready, in which case we give them back their old queen, or any other queen available. If an old queen is given the colony needs further watching, for although it generally does not swarm, sometimes it does; whereas when it receives a queen of the current year's rearing, there is practically no danger.

### Using Combs and Honey from Hives Where Bees Died

1. Will it do to put a nucleus in a hive where the bees died and left considerable honey? And would it do to give this nucleus a couple of frames of brood and bees from a strong colony to help build the nucleus up, or would they fight and kill the queen?

WEST VIRGINIA.

ANSWER.—The plan you propose will work all right if you do not give too many strange bees at a time. Not that the bees are likely to fight at this time of the year, but there might be danger to the queen of the nucleus. Don't give more than one frame of brood with adhering bees at a time, and even with all that number there might be danger with a very weak nucleus. In that case, don't give the frame of brood, but just shake in a few bees.

It is only fair to warn you that unless you have very strong colonies from which to draw, the damage done to the colony from which you draw will be likely to overbalance the benefit to the nucleus.

### Breeding Queens of Different Races

I am interested in making some experiments in breeding queens of different races. I expect to have queens of Carniolan, Cyprian and Caucasian races the coming summer. Now I want to know what would be the best method of managing the drones. I am going to select a mating-ground where I may be reasonably certain of immunity from the races I do not want to cross with. I want to manage this mating business so as not to be obliged to take whole colonies of bees to the place. The queen-side of the proposition is, of course, simple. I am going to use the "baby nuclei" for the queens.

My question is, can I trap out a sufficient number of drones and unite them with the baby nuclei containing the queens to be fertilized, and feel reasonably certain that I will succeed? Or would it be a more certain method to take the drones of the race that I want to use for crossing in a colony of that race? I want, as far as possible, to keep from interfering with the work of whole colonies, and besides that, I want to handle the mating problem with my horse and buggy, and not be bothered with a wagon.

This may seem a silly question to ask, but I want the benefit of your wisdom and ripe experience in these things, so that I may not spoil the whole equipment at the very outset.

I put away 25 colonies last fall, and all came through nicely, and are building up in good shape now (March 31). I followed your advice given in "Forty Years," where you said that if you were as good a bee-keeper as you would like to be you would have frames of honey stored away for feeding in the spring. I had 50 or more fine, straight combs of honey to slip in where they were needed this spring. It is quite a satisfaction to be able to put them in, too.

ILLINOIS.

ANSWER.—It's all very well for you to talk about my "ripe experience" and all that sort of thing, but when you come at me with a question outside the range of any experience of mine, either ripe or green, what is left for me but to say, "I don't know?" I can only say what I do or don't think. I don't think you will make so good a success with drones in baby nuclei as in full colonies; but it will be so much easier to manage with the nuclei that I believe I would run the risk of a larger percent of failures and not have the bother of the full colonies. At least you can afford to make trial at first with the "babies," and if they don't work satisfactorily you will still have enough of the season left to do the other way. On the face of it, one would be inclined to think there could be no question in the case, the nuclei are queenless, and queenless bees cherish drones, so drones in the nuclei must be all right. But exceptions occur sometimes in weak nuclei. For instance, queenless bees, if they build comb at all, build only drone-comb. Yet a queenless nucleus will build worker-comb if weak enough. So unless some one has tried it and knows, I should have just a little fear that a nucleus might kill off its drones if weak enough. Trial, however, may show that there is no ground for the fear. Let us hope so. In any case it will do no harm to make the nuclei just a little stronger than is necessary without any drones.

**A Queen-Bee Free as a Premium.**—We are now booking orders for untested Italian queens to be delivered, in May or June. This is the premium offer: To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us one new subscription with \$1.00 for the Bee Journal a year. Now is a good time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

## Reports and Experiences

### Fastening Transferred Comb in Frames

In a recent issue of this Journal directions are given for fastening combs in the frames when transferring, by winding strings around the frames and combs. I like the plan of using splints a little longer than the depth of the frame—splints made from straight-grained wood that will split readily, they being about 1/4 inch wide and 1/8 inch thick. Place as many sticks on a smooth board as will be needed to hold the comb in place. Lay the frame on top of the sticks, then lay the pieces of comb on the splints, placing other splints opposite the splints under the comb; tie each pair together at the ends outside of frames the lower end to project as little as possible. When the bees have fastened the comb to the frame and the pieces of comb together, cut the strings at the upper end and work the splints out.

WM. CLARK.

Livingstone Co., N. Y., April 11.

### New Mexico Foul-Brood Law—Honey Prospects

A foul brood Bill has just been passed by the New Mexico Legislature and is now a law. While it lacks much of what we desired it is a public recognition of the bee-keeping industry and a big step ahead of no law at all.

Section 1 provides that all bees, hives and fixtures be kept properly disinfected and free from foul brood and contagious diseases.

Section 2 makes it a misdemeanor to keep bees or fixtures infected with foul brood or contagious diseases, and imposes a fine of not less than \$10 nor more than \$50, or 30 days in

the county jail, or both fine and imprisonment for the violation of this Act.

Section 3 provides that when any competent person makes a written complaint before a Justice of the Peace where foul brood exists, the Justice of the Peace shall issue a warrant for the arrest of the offender and try the case in the usual manner.

Section 4 states that upon conviction the Justice of the Peace shall declare all bees, hives and fixtures infected to be a nuisance, and issue a writ to the constable or sheriff for the immediate destruction of the same by burning.

Section 5 provides that Justices of the Peace shall have all jurisdiction under this Act, and that costs be assessed as now provided by law.

In Northwest New Mexico rains have been abundant and prospects for bee-pasture are the best. Alfalfa, sweet clover, and cleome, our main dependents, can hardly be failures under the conditions. The coldest weather was 1 degree above zero, and the bees have had about the usual number of winter flights. Bees with stores and free from foul brood are in fine shape now. A few colonies were lost through starvation, on account of poor conditions last year.

The dearth of honey last season because of the weakness of the bees when the harvest did arrive, will have a tendency to boost the price this year.

A railroad now in process of construction to this country will open up new markets, give us a way to reach them, remove many of the disadvantages in securing supplies, and promote a big increase in orchards, small fruit, ranches and alfalfa fields. Hauling honey or supplies to or from a railroad station 50 miles distant, over rough mountain roads, would cause many of our eastern friends to quit the business. It isn't a snap. With sugar way above the 87 mark at wholesale, and choice comb honey retailing at 8 1/2 cents, we are in no danger of being persuaded to feed our bees sugar; so they will manufacture unadulterated honey for our customers. Cleome and alfalfa are hard to beat, but if we could induce our bees to mix in some of New Mexico's glorious sunshine, you bee-men of the land of fogs would be left as badly in the cold as you were this winter.

W. A. BALLINGER.

San Juan Co., N. Mex., March 18.

Swarming—Wasp's Nest in a Bee-Hive

My bees commenced swarming last season June 5, and cast 3 swarms each. I have four colonies, 2 of which I wintered on the summer stands, and the other 2 in the house, and all are doing well. One of those inside has built 3 square inches of comb.

I have been experimenting for the past year, and find that when a colony of bees robs another colony they unite, and when a

natural swarm flies over the land they go like a flying martin. I lost 2 swarms last year, and one the year before. Last year 2 that left returned, and one of them tried to go into the hive from which I had lost a swarm. It seemed to know where it belonged.

One day my father found a swarm of bees on a bush, bived them, and took them home. I went back with a box to get the bees that were left. Father said they would do nothing without a queen, so I got a wasp's-nest and put it in with my bees, and waited until they hatched out, then I called papa, but he hardly thought they were the right kind of "queens," so I quit.

I think I heard my papa say when I was a little boy that I had a great-uncle named Dr. C. C. Miller, who was a mighty bee-keeper.

**JAMES L. A. MILLER.**

Gasconade Co., Mo., March 14.

### Small Winter Loss—Good Prospects

Though we have had one of the most severe winters since 1880-81, I lost only one colony and had 2 queenless out of 39, and I had them all on the summer stands except 13, which I have at my home in town. They were in a basement for about 3 weeks in February, but those on my farm were on the summer stands throughout the winter. I looked them over about 3 weeks ago, and find they have plenty of stores.

This is about the nicest month of March we ever had. The wheat and grass are looking fine, and there is a good prospect for another good crop of honey. I fed my bees well last September, and now they are very strong.

**L. A. HAMMOND.**

Washington Co., Md., March 27.

### Bees Wintered Well

The bees having wintered well packed in oats in winter cases, began to bring in some pollen to-day, and on examination I found some had larvæ already. I do not believe I will ever try another way to winter bees than by packing the hives in winter-cases, in chaff, oats, or similar material.

I read the American Bee Journal with great pleasure and profit. There has been practically nothing in it, the smallest letter not excepted, that has not taught me something. It is not only instructive, but is also inspiring and encouraging to one's advancement in bee culture. I believe that with its help I shall make a success in bee-keeping.

(REV.) **J. G. BAERMANN.**

Osceola Co., Iowa, March 31.

### Select Tested Queens—Carniolans, Italians and Blacks

In 1902 I bought a select-tested Italian queen. I could not wish for better-marked drones, but the workers vary from one to 3 bands. She could not have been purely mated. Her daughter in the old hive mated with a drone from the old hive—in fact there were no other drones but black ones to mate with. This

## Tested Queens by Return Mail, —\$1.00 Each—

We have a large number of Choice Tested Queens, reared last September and October, and wintered in 4-frame nuclei; these queens are vigorous and prolific, and of our fine strain of Three Band Italians. Just the queens to build up weak colonies. Try them. Send for circular.

**J. W. K. SHAW & CO.**

13Atf LOREAUVILLE, Iberia Par., La.

queen's drones are half black. In the spring of 1904 the select queen ceased to lay, and the colony dwindled to nothing, so I lost it, with over 25 pounds of sealed honey in the hive. I never have had one pound of honey in the sections from those Italians until last summer, when 8 sections were filled by a prime swarm which issued June 30.

I have had 2 second swarms leave for the woods, one in 1903 and another in 1904. I have one colony of Italians now, and the queen is the daughter of the select-tested queen.

I think a tested queen should breed both workers and drones so that all should be marked alike. I don't see how breeders get so many different grades from one breeding queen. As I look at it there are but two grades, one must be pure, and the other impure.

After testing the queen from Breeder No. 1 I bought three queens from Breeder No. 2. The drones from 2 of those queens had 3 bands, one having a few darker drones, but the workers from all 3 were well marked. Those 3 queens were superseded in the spring of 1904. I bought them in August, 1902. The young queens in the 3 hives where the supersedures took place are truly mated with Carniolan drones, but the daughter from the mother that produced drones is half black.

I have 4 young Carniolan queens that breed 3-banded drones. I supposed the queens were Italians, but was told after I bought them that they were Carniolans. I had heard that they were great swarms, so I bought lumber and made 16 hives, 17x11 inches deep, with 8 frames. I have had those bees two seasons, but have not had a swarm from them yet. These are the colonies that gave me my surplus honey, all No. 1 white. They are peaceable, and I can walk or stay any length of time about the hive without getting stung.

I put 27 sections on each of 3 hives—two Carniolans and one black. I set the sections on the honey-board, with 1/2-inch slat-fence between sections. By June 20 the Carniolans had their sections filled, and the blacks a few days later. I now saw that I had made a

mistake. How was I to take off those sections without getting stung? They were across the hive, with glass front and back. My folks kept asking me when I was going to take the honey off, expecting to see a fracas, and I expected the same. I got to work and removed one light of glass. No fight. I lifted one section with my knife, and with a turkey-wing feather I brushed the bees off on the front of the hive. I removed every section in this way, but in taking off the last 3 sections I struck the one I had in my hand against another, and was stung.

From the other Carniolan colony I had been taking out brood for queen-rearing, so on its hive I put 6 sections crosswise of the hive, with two lights of glass. Inside of a week those 6 sections were plump full of bees working on the strips of foundation. So I made a super with 9 frames holding 3 sections each, had 2 frames to put those 6 sections in and removed the glass, picked up the 6 sections and bees, placed them in the frames, and hung the frames in the super. Not a bee tried to sting—they were too much engaged in comb-building. Every time I took off sections from the black colony I got stung.

We had white clover from June 15 up to the 1st of September. I saw one lonely black bee gathering from it. The blossoms were plentiful on the roadsides, in the fields, and anywhere one might look for it. The basswood yield was good. In a big basswood tree near by bees could be seen going home after sundown. We could see the nectar in the blossoms, and I should judge that one flower's nectar would be all that a bee could take in one load.

I have 5 Carniolan colonies, 1 Italian, and 3 blacks. I have not lost any yet this winter.

E. TUCKER.

Watertown, Conn.

**New York.**—The annual spring meeting of the Fulton and Montgomery Counties Bee-Keepers' Society will be held in Amsterdam, N. Y., at the Central Hotel, on Tuesday, May 2, 1905, at 10 o'clock a.m. All are invited.

West Galway, N. Y. T. I. DUGDALE, Sec.

**Next National Convention at San Antonio, Texas.**—For years Texas has been asking that the National Bee-Keepers' Association hold its convention within her borders, but there has always seemed to be some reason why the meeting should be elsewhere. There is now no reason why it should not be held in Texas this year, if it is ever to be held there. Texas is the largest state in the Union, and stands at least second, if not first, in honey-production, while she has a good list of members in the National Association. Considering all of these facts the Executive Committee has decided upon San Antonio as the place for holding the next convention. The exact date has not yet been decided upon, but it will probably be the latter part of October, after the busy season is over with the bees, when the weather is comfortable, even in the South, and when cheap excursion rates can be secured.

W. Z. HUTCHINSON, Sec.

**SINGLE COMB BROWN LEGHORNS**

Noted Winter-Laying Strain. Cockerel Mating, headed by Rochester Prize-Winner; Eggs, \$2.00 per 13. Pullet Mating, headed by pullet line; pedigreed; Exmoor males, \$2.50 per 15. ## Honey and Beeswax

CHICAGO, April 18.—A carload of comb honey, (said to be from Colorado) came on the market about the first of the month. It was placed with a firm that does not make a specialty of honey, and to some extent has upset prices when looked at in print. It is put up in 24 section flat cases with wood slides instead of glass, and is more or less candied. Choice white comb brings 12½c; No. 1, 11@12c; amber, 8@10c. Extracted, white, 6@7c; amber, 5½@6½c; price being governed by quality, flavor and package. Beeswax 30c if clean and of good color.

R. A. BURNETT & Co.

CINCINNATI, April 20.—The conditions of the honey market to day are not encouraging. The consumption is lacking, although we are looking forward to brighter days in the honey market. We continue to quote amber extracted in barrels and cans, 5½@6½ cents; white clover, 7@8c. Fancy white comb honey, 12@13c. Beeswax, 28c. THE FRED W. MUTH CO.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c. HILDRETH & SEIBLEN.

PHILADELPHIA, April 19.—There has not been much call for honey in the last two weeks. Prices remain unchanged. We quote: Fancy white, 11@12c; No. 1, 10@11c; amber, 9c. Extracted, white, 6@7c; amber, 5½@6c. Beeswax, 28 cents.

We are producers of honey and do not handle on commission. WM. A. SELSER.

BOSTON, March 9.—The demand for comb honey still continues light with heavy stocks on hand. Fancy white, 15@16c; No. 1, 14c. Extracted, 6@8c, according to quality. BLAKE, SCOTT & LEE.

KANSAS CITY, March 31.—The honey situation does not improve. While there is a little better movement the prices seem to be lower. Fancy white brings \$2 a case; No. 1, \$1.75; amber and lower grades from \$1.25 to \$1.50. Extracted, 4½@6c. Beeswax, 28c. C. C. CLEMONS & Co.

CINCINNATI, O., April 18.—The large stock of comb honey, yet offered with hardly any demand caused lower prices. I quote fancy water white at 12c; other grades in proportion, lower. Extracted is in the usual demand for this time of the year; quote amber in barrels at 5½@5¼c; in cans, ½c more; white clover, from 7@8c. Beeswax, 28c. C. H. W. WEBER.

ALBANY, N. Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candles or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6½c; white, 6@6½c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c. H. R. WRIGHT.

SAN FRANCISCO, April 12.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted white, 5½@6 cents; light amber, 4@5c; amber, 3@½3c; dark amber, 2½@3c. Beeswax good to choice, light, 29@30c; dark, 27@28c.

Stocks on the local market are not heavy and mostly common amber grades. The demand is slow. The new season being near, handlers are awaiting arrivals of new crop, which are expected to put in an appearance early in May.

## IN THE HEART OF MICHIGAN

“There’s no use crying over spilt sections.”  
 You won’t have to if they are  
**LEWIS’ SECTIONS**

You are not taking chances when you order Lewis’ Sections.  
 Our name is on every crate.

These are Lewis’ Sections. Aren’t they Beauties?  
 Read what others say about them:

G. B. LEWIS CO., Watertown, Wis. Deerfield, Iowa.  
 Gentlemen:—I want to say that I consider your make  
 of sections the nearest perfect of any I have ever had. I  
 have folded packages of 500 without breaking one and I can-  
 not say that of others I have used.  
 Yours truly, GEO. BROWN.

G. B. LEWIS CO., Watertown, Wis. Centralia, Kas.  
 Gentlemen:—Everybody wants Lewis’ sections.  
 Yours truly, A. W. SWAN.

Grand View, Iowa, June 3, 1904.

G. B. LEWIS CO., Watertown, Wis.  
 Gentlemen:—I have received those sections in good

shape and I am well pleased with same. They are all right  
 in every way. I shall recommend your bee-supplies to other  
 bee-keepers. I think you make better goods than any other  
 firm in the world. Accept my thanks.  
 Yours truly, GEO. B. MCDANIELS.

Kenton, Ohio, May 4, 1904.

G. B. LEWIS CO., Watertown, Wis.  
 Gentlemen:—The goods are simply fine in every re-  
 spect. We have compared a few of the No. 1 sections  
 bought of another firm which we carried over from last sea-  
 son with your No. 2 and find that the No. 2 are superior.  
 Yours truly, NORRIS & ANSPACH.

Lewis’ Sections have made the Lewis Co. famous. They are for sale all over  
 the world.

# Root's Goods in Chicago.

For the saving of freight for our western trade, as well as to give much quicker delivery, we opened a branch office in Chicago, Oct. 1, 1903. The following taken from our catalog of last year, explains the transfer then made:

The business for many years conducted by George W. York & Co., at 144 E. Erie Street, as agent for The A. I. Root Company's supplies, is this day transferred to The A. I. Root Company, to be conducted as a branch office. Please note change of name to avoid confusion in our work. THE A. I. Root Co. October 1, 1903.

### To Our Customers and Friends:

In transferring back to The A. I. Root Company the bee-supply business, which we took over from them some years ago, we do so with regret, as we have labored hard to build up a large and honorable trade in bee-appliances, and value beyond expression the valuable patronage accorded us during the years.

We trust the same will be continued to our successors in the business. GEORGE W. YORK & Co. Chicago, Ill., Oct. 1, 1903.

The conveniences offered by the branch office were evidently appreciated by the bee-keepers of Illinois, Wisconsin, and other States beyond, for the business done by the branch was much beyond our expectations. During the rush season—April, May and June—orders came in so fast that, in spite of frequent orders to the factory for another car of goods, the stock ran low, and some delays and annoyances thereby were caused. Some little confusion because of change of name and manner of conducting the business (from agency to branch office), but these have all been overcome. We are better than ever prepared to handle your business carefully and promptly, and solicit your patronage.

## Low Freight and Quick Delivery.

A glance at any railroad map will show the superiority of Chicago as a shipping-point. Because of the great number of railroad and steamboat lines centering in Chicago, and the large stock of goods we carry, we can give you the best of service. This office is in constant touch with the factory and home office, and in many cases can give your order quicker attention and earlier shipment than the factory, to say nothing about the saving in time and transit and lower transportation charges.

## Wholesale and Retail.

We are prepared to furnish goods at wholesale and retail, the same as the home office.

## Terms.

Our terms are cash with the order. We pay cash for material, and pay our

helpers cash every week for their work; therefore we must have cash in advance for the goods furnished. Do not ask for credit.

## Beeswax Wanted.

We are in the market for good beeswax the entire year, and pay the same prices as quoted by our home office in each issue of GLEANINGS IN BEE CULTURE. Send your wax direct to us for cash or in exchange for supplies.

## Extracted Honey.

In the course of a year we use large quantities of extracted honey, and are pleased to get sample and prices from parties who have honey to exchange for supplies. We are also prepared at all times to furnish first-class honey to any one who is in need of same, either bee-keepers who have a demand for more than they can furnish, or from dealers. Get our prices before you place your orders elsewhere.

# DANZENBAKER HIVE.

"Facts About Bees", a 64-page book written by Mr. F. Danzenbaker, giving a complete description of his famous hive and directions for using. Full of valuable information. Sent on receipt of a 2-cent stamp to pay the postage. Send for it.

## The Danzenbaker Hive

THE COMB-HONEY HIVE.  
Three Points of Excellence:

### QUALITY

You can produce better-looking honey.

### QUANTITY

You can produce more of it.

### PRICE

You can get more per pound for it.

### SPECIAL NOTICE.

The great popularity of the Danzenbaker hive has brought the shallow brood-frame and the tall plain sections into prominence. It must be remembered that no other hive contains the essential features of the Danzenbaker. The success of this system depends on having everything JUST RIGHT, so you should place your order for the Danzenbaker hive with our office, or any of our branches or regular agents.

## Editorial Notes and Comments

### The Honey-Producers' League

Many of those who have become members of this new organization of bee-keepers have added encouraging words when sending in their dues. Some of them read as follows:

I think this scheme of advertising honey is a grand step.—R. S. CHAPIN, of Michigan.

I believe the League is the proper thing, and is going at it in the right way.—E. A. DONEY, of Iowa.

The Honey-Producers' League meets with my hearty approval. I will do what I can to help it along.—J. A. GREEN, of Colorado.

I think the League, if conducted rightly, will be of more benefit to bee-keepers than any other organization yet started.—GEO. E. GOODWIN, of Michigan.

I welcome The Honey-Producers' League with pleasure. I think it is one of the best movements ever made for the apiarists of the United States, as advertising is an absolute necessity if we expect to keep abreast of the times.—C. H. HARLAN, of Minnesota.

It seems to me every person that produces honey to sell should become a member of the League. If the League should raise the price of honey only one cent a pound, or even a half cent, I shall think I made a first-class investment when I became a member of the League.—D. I. WAGAR, of Michigan.

If those interested will fall in line so as to secure enough money to push the advertising, there is no doubt but what great good will result. We know it to be a fact that the masses do not buy honey, because it is not brought to their attention. Other things are pushed so hard—brought to their attention continuously by the various methods of advertising—that honey is crowded to the background and forgotten. Even if the groceryman has a nice line of honey in a very prominent position in his store, sales are not what they should be on account of his customers calling at the store so seldom (where they could see the honey), the majority of orders from groceries being either taken by 'phone or the grocery solicitor, who probably seldom mentions honey. This is especially so in the larger towns and cities.—A. G. WOODMAN, of Michigan.

With such hopeful expressions, it seems that there should be no delay in lengthening the League's membership list. It will take a good deal of money to advertise honey efficiently. If it can not be done on a large enough scale of course the results will not be what they might be if it were done in proportion to the real need to the large number of bee-keepers, and to the enormous quantities of honey to be sold annually in the United States.

But if the selling price of honey could be raised even a half cent per pound, as one member suggests, or if the price can even be kept from declining still lower, the value of the League to bee-keepers, and the wisdom of its creation, will be fully justified. But even if the largest success is not attained, the attempt is worth the making.

### The Right Name for Honey

A friend in an eastern city offers me some very good suggestions in regard to the general belief that comb honey is adulterated. He says, in substance, that the general public mean one thing by comb

honey while we mean another. The common conception of comb honey is what bee-keepers would term chunk or broken honey, generally kept in pans, the honey running loose among the combs. It is hard to see why this could not be mixed with glucose as well as if the comb were absent. But bee-keepers restrict their idea of comb honey to that in sections. Newspapers are rapidly admitting that honey in unbroken combs is necessarily genuine. Instead of calling the mashed-up stuff "honey in the comb," he would call it "comb in the honey." This is well worth thinking about.—"STENOGR," in Gleanings in Bee Culture.

There is some weight in the argument, if the premises are correct. But is it true that the public generally considers the term "comb honey" to mean "chunk or broken honey, generally kept in pans, the honey running loose among the combs?" Possibly, in special localities, hardly in general. Take Chicago, for instance. For every pound of such honey found on the market there will be found thousands of pounds of section honey, and the probability is that to the average Chicagoan the term "comb honey" suggests honey in sections. In the broken mixture spoken of, the part that is comb honey is genuine honey, whatever the surrounding liquid may be, and if any special name should be given to the stuff, it should be called "comb honey in liquid honey" rather than "comb in the honey," which would suggest empty comb submerged in honey. In any case, what is needed is to have the truth known.

### The Honey-Producers' League and Canada

The following letter from Mr. R. F. Holtermann, of Canada, contains his estimate of the League, and also involves a question:

FRIEND YORK:—I have been much interested in The Honey-Producers' League. It will undertake a line of work for which I have seen much need, and along which I have been trying to do some work. If you can give me the assurance that the organization will work on this side of the line as well as in the United States, you can have my membership fee any time. I hope the bee-keepers will rush in their fees. I have carefully read over the Constitution, and it appears to me it is well thought out, and I can see no place for improvement.

Yours truly,

R. F. HOLTERMANN.

In reply, we may say that the organizers of The Honey-Producers' League thought best not to include Canada, believing it would be better for our esteemed northern neighbors to form such a league themselves, if they so desire. If United States bee-keepers succeed in raising all the funds necessary for the honey advertising that should be on this side of the line, they will do well. Then, we believe, there is very little honey passing back and forth between the two countries, on account of the duty imposed upon it. So we United Statesers would hardly care to pay for advertising honey in Canada, and no doubt few of the Canadians would feel like helping to pay advertising bills over here.

We see no good reason why Canadian bee-keepers should not organize similarly to our League, and make it a great success.

### Certificate for Inspectors of Apiaries

N. E. France, the Wisconsin State inspector of apiaries, has kindly sent us a copy of a blank which he furnishes to every bee-keeper whose apiary he inspects, also a carbon copy to the Governor with his monthly report. Bees for sale often require such certificate also.

On the back of the certificate, which is about  $3\frac{3}{4} \times 5\frac{1}{4}$  inches in size, are printed the laws of Wisconsin on the appointment of a State inspector of apiaries and his duties, also as to the sale of a diseased apiary, etc. The blank portion reads as follows, excepting the name

and address of the inspector at the bottom, which can be printed, or may be signed in each case:

No. \_\_\_\_\_

**Wisconsin State Inspector of Apiaries**

Date.....

I have this day inspected the apiary of—

Mr.....

P. O.....

No. of colonies in apiary.....

Last winter..... { In cellar ..... Loss.....

Remarks.....

**No Adulterated Comb Foundation, and Why**

Referring to the charge by Dr. Wiley that comb foundation is adulterated, Gleanings in Bee Culture says:

At first we thought we would pay no attention to it, as we did not think there was one bee-keeper in ten thousand who would believe it; but as two of our brother editors have denied that such practice has been going on on the part of foundation makers, it now seems pertinent for us to say that, out of between 300,000 and 400,000 pounds of foundation made annually in the United States, we will guarantee there is scarcely a pound of it adulterated. I say *scarcely*, because foundation makers are huying wax from everywhere, and they might, in spite of their careful inspection, allow a single cake of adulterated wax to get in with the good, with the result that a single sample might show a very slight adulteration. The makers of foundation in this country know that, if they wish to ruin their business, and that right speedily, the quickest and easiest way to do it would be to begin to adulterate their goods. Paraffin and ceresin foundation are something that can be detected by bees and bee-keepers almost instanter. Again, the modern methods of making foundation will show up adulteration in the wax very quickly. Indeed, it is practically impossible to make adulterated foundation on Weed machinery. The reason why we know is because we once tried making some sheets of wax and paraffin for the dental trade that called for it, and had to giveit up as a bad job.

**Don't Leave Wax Unwatched on the Stove**

Especially to beginners is commended the following by J. A. Green, in Gleanings in Bee Culture:

When melting beeswax on a stove, especially if there is any water in the vessel in which it is being melted, do not go away and leave it for even a minute. If you must go away, set the wax off the fire until you get back. The fire may be hotter than you think, or something may make you stay away longer than you expected to. A pan of wax boiling over on a hot stove may make a serious blaze. Last year neglect of this precaution cost one bee-keeper in this valley, his dwelling-house, and another a good honey-house with contents, including about a ton of honey.

**Miscellaneous  
News \* Items**

**Freight-Rate on Jacketed Honey-Cans.**—From a letter dated April 20, received from General Manager France of the National Association, we take the following:

**FRIEND YORK:**—Yeaterday, while in Chicago, I secured a fourth-class freight-rating on my 5-gallon jacketed honey-cans. This applies to all railroads in the Western Freight Classification. The cans are bail-handled, flat top, entire can enclosed, and with a 3-inch screw cap underneath. I feel this is another victory for bee-keepers. Now add

the help of The Honey-Producers' League, and certainly bee-keepers should be better able to market honey.

I also saw a nice tin shipping-case for comb honey that is no-drip, and when empty will be nice to use in the pantry for holding bakings, etc., as no ants, dust, or other foreign material, can get inside.

In connection with the League's help to bee-keepers, I am planning some showy honey-labels for the National members at cost. They are in three colors, and much like some showy syrup-labels. Marketing is the cry now, and it looks as if the Association and the League will solve that.

The National has just secured another city ordinance victory in Toledo, Ohio. Yours truly, N. E. FRANCE.

**The Honey-Producers' League Incorporated.**—Only a little over a month after the League was organized the final incorporation papers were received by the Manager from the Secretary of the State of Illinois, Jas. A. Rose. The date of organization was March 15—date of incorporation, April 21, 1905.

Mr. N. E. France, who had been selected as a member of the Executive Board, decided that he had already "too many irons in the fire," and so could not serve. In order that the incorporation might be completed as soon as possible, the remaining members of the Board selected, in place of Mr. France, Mr. Robt. A. Holekamp, of Missouri, who did so much toward getting the Foul Brood Bill passed in that State recently.

**The Fourth Annual Report** of the Illinois State Bee-Keepers' Association is now ready for mailing. Any one can have a copy of it by sending 15 cents in stamps to Jas. A. Stone, Rt. 4, Springfield, Ill., the Secretary of the Association. Besides considerable other interesting matter, it contains a report of the last Illinois State convention, also a full report of the meeting of the Chicago-Northwestern Association last fall, and a number of pages on "Foul Brood and Other Diseases of Bees," by N. E. France, Wisconsin's popular foul-brood inspector. The Report contains 192 pages.

**A Tariff on Cuban Honey.**—The Southwestern Ohio and Hamilton County Bee-Keepers' Association, through its Secretary, Henry Reddert, sends us the following on the tariff on Cuban honey:

The recent agitation of the increase of tariff on Cuban comb honey is quite spirited, judging by the favorable replies this Association has received.

We learn from a responsible source that all foreign honey is taxed by this Government 20 cents per gallon, at 12 pounds to the gallon, no distinction made as to comb honey; but on all honey coming from Cuba a rebate is allowed of 20 percent off the tariff amount, leaving the tariff rate on Cuban honey 16 cents per gallon. All honey-producers know it requires more honey to produce comb honey than it does to produce extracted honey, hence comb honey is rated too low.

At the time the tariff rate on honey was fixed no doubt there was little if any comb honey on the market, hence the single rate. We understand it is rumored that a revision of the tariff is to be undertaken at the next session of Congress; if so, then will be the time to bring a proper Bill regulating the tariff as to each kind of honey, comb and extracted.

Mr. Sereno F. Payne, the chairman of the "Ways and Means Committee," we judge, is the man to whom this Bill should be presented; however, this is only a suggestion. If the Executive Committee of the National Bee-Keepers' Association knows of a better way to bring it before Congress, it is their liberty to do so, but we must not delay it, as we have but a limited time before the next session of Congress in which to do this work.

We suppose it would be a good idea to discuss this question at the next convention of the National Bee-Keepers' Association.

Very respectfully,  
S. W. OHIO AND HAMILTON CO. BEE-KEEPERS' ASSOCIATION.  
Per HENRY REDDERT, Sec.

We think the suggestion a good one, that this subject be considered at the next meeting of the National, in San Antonio. Perhaps Secretary Hutchinson will request some one to be prepared to introduce it for discussion.

**The A. I. Root Co.**—It was our privilege to visit The A. I. Root Co., at Medina, Ohio, the latter part of March, for about 6 hours. But that was too short a time to take in all there is to be seen. It had been about 10 years since last we visited them, and we were astounded to see what a wonderful transformation and development had taken place during the decade.

Mr. A. I. Root began, some 40 years ago, in a little room above a jewelry store with a one-foot-power buzz-saw, but that small beginning has expanded into a big plant that covers acres and acres of ground. Massive brick buildings and warehouse 2 and 3 stories high, protected by the latest fire-apparatus, peopled with skilled workmen, and supplied with the latest automatic machinery, mammoth lumber yards—all are in evidence over the grounds. A 400-horse-power steam-plant, a 100-horse-power electric plant, a water-works plant, an organ-

ized factory fire-fighting crew, a pay-roll of \$2000 a week, daily shipments of goods by the car-load to all parts of the world, are also prominent features of "The Home of the Honey-Bees."

Immense lumber-sheds, capable of holding at one time anywhere from \$50,000 to \$75,000 worth of lumber, have been erected so that timber of the right season and dryness may be used for the exacting demands of bee-hive work.

In order that The A. I. Root Co. might perfect its already large equipment, and thus serve its customers better, the capital stock was increased in 1904 to \$300,000, all paid up.

Few people can realize what it means to build up and conduct a business of such proportions, and especially on the results of the work of so small a creature as the honey-bee.

On the first page we give some pictures of this great factory and the officers of the company responsible for its management.

Mr. A. I. Root is getting somewhat along in years, and yet he tries to keep a watchful eye on all that is being done around him. True, he devotes a good deal of his time in the spring and summer to the raising of "garden sass," but he is ever on the lookout that things are kept straight. And then he has two sons and two sons-in-law to "see to," besides their increasing families, so it is no wonder that he is kept "on the trot" about the place pretty much of the time.

Ernest R. Root, as nearly all our readers know, ably edits the bee-department of *Gleanings*, and is as royal a man and friend as one would wish to know.

John T. Calvert is the hustling business manager of the concern. He knows how to "make a good bargain," and also sees to it that his firm's share of the apiarian trade is secured.

Arthur L. Boyden is not only secretary of the company, but also looks after the advertising in *Gleanings*, as well as that done elsewhere by the firm. He is affable and kindly, also a good entertainer, for we were invited to dine at his hospitable board while there.

We must not omit the mention of W. P. Root, who conducts, under the *nom de plume* of "Stenog," a department in *Gleanings* known as "Picking from Our Neighbors' Fields." "W. P.," as he is also familiarly known, has been with the Root Co.—well, a quarter of a century, we should say. But he seems to "renew his youth" as the years pass on. Really, he seems to look younger now than when we first saw him 10 years ago. He is what might be called "a jack at all trades" and master of all. What he can't do, from typesetting up to proof-reading and translating a dozen or so of both dead and living languages into modern English, is hardly worth mentioning. The word "versatile" best expresses him. He's "all right." Nothing at all the "matter with him." (We didn't ask him, but would be willing to believe that middle initial "P." in his name stands for "Prohibitionist.")

We were not in Medina long enough to take in the whole of The A. I. Root Co.'s extensive plant and business, but we saw enough to convince us that they are doing business—they know what they are there for without being told. They have built up a great institution by energy, industry, and push—and the end is not yet.

citizen of our country. I believe he measures as with a correct top-line, and that all his criticisms may well lead us to pause and ponder. After a lapse of several years he has visited us again, and, as before, he pens a graphic picture. He calls attention to one of our most serious perils. This is municipal corruption. That word "graft," as now used, like the social evil, may well make us shudder for what is, and tremble for what may be. Honesty, like purity, is a transcendent virtue, and it behooves us all to magnify its importance, and we should begin with our little ones as soon as they begin to prattle.

I am led to these remarks from a letter received from one of our most respected bee-keepers, who uses this same word "graft" regarding one of our Southern California bee-inspectors. I know nothing of the merits of the case in question; but I do know what is required, and what we should and must demand.

Our California law, thanks to Mr. J. M. Hambaugh more than to any other one man, is well-nigh perfect. If it does not give good results it is because the bee-keepers themselves are asleep to their duty and privilege.

The good points of our law are: It makes the supervisors appoint upon the petition and recommendation of the bee-keepers themselves. It pays good wages—\$4.00 per day—which ought, and will, command ability, honesty and energy—a most-needed trio. It gives the inspector power to exterminate the disease wherever found.

It is now up to the bee-keepers to nominate the right man—such men as the author of our Bill. They must know that he is a student, and will keep informed as to the very latest and best known regarding the nature and cure of this and kindred diseases. They must be equally certain of his absolute integrity, and must know him to be most thorough and energetic.

The inspector must be fired with enthusiasm in two directions. He must be determined to find all cases of the disease in his district, and must act with the keenest energy to stamp out the disease wherever it has gained a foot-hold. He must be just as eager to save expense to the county. He can often plan his work so as to make a horse unnecessary for days at a time, and thus save both hire and keep. He can often enlist the aid of the bee-keepers themselves, and thus accomplish much more in a given time, and at the same time the bee-keeper is gaining just the knowledge and experience that every capable bee-keeper should possess. By working in a locality continuously till apiaries of the region are all examined, and so far as necessary treated, he will save a vast expense. He will not object to offered entertainment, or to permit any bee-keeper to transport himself and his equipment to the next apiary, as this will save expense to the county, and will reduce his bills, and make his work more popular. Nor will such courtesies on the part of the bee-keeper be really an imposition. He will often receive rich pleasure and very helpful instruction in the company of the inspector; indeed, it ought to be worth more to him than the cost of entertainment and other courtesies rendered. He will also gain in the fact that the work will not be so likely to be criticised and cut short if the expense account is held down. We are all interested that the work shall be thoroughly done, and that no foul-broody colony be overlooked.

There is just one more duty that the bee-keepers are bound to keep in mind. If they find that they made a mistake, and recommended the wrong man for appointment—one who is not competent, one who does not watch carefully to save to the county, one who is not full of energy and telling enthusiasm in his work—then it is their duty to petition, yes, demand the supervisors or appointing power to remove the incumbent, and replace him with one competent for the duties and demands of the position.

With such an admirable law as we now have, we should reach almost complete success, to the saving of untold thousands of dollars to our bee-keepers. Let us do our part, that the best possible results may be secured. I believe other States can do no better than to copy substantially our California law. But when we have the statute we must not think our work is all done. We must insist that we have the right man, and that he works with the best skill and energy, not only in extirpating the dread malady, but also in whittling expenses to the very minimum.

EARLY FLORA IN CALIFORNIA.

In this charming climate of Southern California we have two reasons to rejoice in the abundance of rain, warmth and sunshine that have gladdened our hearts and landscape the present winter. They not only offer almost certain promise of abundant prosperity along all agricul-

Foul Brood Law—Early Honey-Flora

BY PROF. A. J. COOK

TAKE the country over and foul brood is one of the three serious evils that go to form the most menacing trio that stands in the way of successful bee-keeping. As I size up the situation, these worst enemies are, Uncertain Markets, Winter Losses, and Foul Brood. I believe foul brood is the equal of either of the others in the heavy hand that it lays in the way of our progress. Yet we know that, like the others, we can face it and down it if we only fashion and use the right weapons. These weapons are intelligence and action.

Mr. James Bryce, the great statesman and writer of England, is very brainy and possessed of a most catholic spirit. He knows a whole lot, and his judgments are as kindly as they are reliable and accurate. His great work, "The American Commonwealth," should be read by every

tural lines, but they have carpeted the fields and roadsides with a wealth of green and bloom that is a delight to behold. I have, in all my 11 years in this place, never seen so many flowers at this early date as now gladden the vision of any one who strolls forth over the plains and hills for air and sunshine.

The phacelias are out, and swarm with bees, as do the orange and lemon trees, and the great live-oaks which are now in full bloom. The white and black sage are now pushing out new growth, and will be early in bloom to attract the bees, and swell the profits of the bee-keeper. The gilias are thickly spread, and are also attractive to all nectar-loving insects. Some of the gilias bear blue pollen, and it is not uncommon to see bees with their full loads of this blue proteid which they are carrying for bread to the hive.

At present the whole air is perfumed with the scent from the citrus bloom. No doubt but we would get much orange honey except that at this early season the bees are few, and thus the harvest of orange honey is never great.

Los Angeles Co., Calif., April 3.

## Using the Langstroth Hive Advantageously

BY LOUIS H. SCHOLL

MUCH larger hives are necessary in the South. There are many advantages for using them, but not so many bee-keepers know it. The trouble is that the Langstroth hive, which is almost universally used, is too large in one way and too small in another. This statement might cause many to say that I was condemning the Langstroth hive, or that I am not showing proper respect to its inventor. Not so, however, but I do say that the best results can not be obtained with the regular Langstroth hive in a locality with the honey-flows and the other existing conditions as given in my previous articles.

### THE 10-FRAME THE SOUTHERN STANDARD.

The 10-frame Langstroth is mostly used in the Southern localities here, but even it is not large enough—at other times of the season, again, it is too large. That is the objection I have to this hive. A satisfactory hive must be so constructed that it can be enlarged or contracted at will, and this can hardly be done with the Langstroth. The result is that many valuable manipulations that would be worth much to the bee-keeper in critical times are unknown, or even unthought of, by the majority of the users of this hive.

### ENLARGING THE LANGSTROTH HIVE.

I have always been an advocate of large hives—large hives at the right time; large hives in the proper shape, other conditions being equal, mean rousing colonies of bees. They prevent swarming; and a large crop of surplus is the result. The 10 frame hive as commonly used, with only a single brood-chamber, is not quite large enough for the best results in brood-rearing in the spring. For this reason I enlarge the brood-nest by a super of shallow combs above. Some will say that another hive-body could be added, but that would be adding too much room for the majority of the colonies. In such hives the brood is generally scattered too much, while in the former it is all in a compact form. If the colony is an extra-strong one an additional super can be added, and that without the danger of giving too much room at a time. By using hives so, and breeding the bees in accordance therewith, the problem of swarming will be reduced to a minimum.

### PROVIDES ADDITIONAL BREEDING ROOM.

The queen has used the shallow combs of the super for egg laying, the brood has been hatching out, and the honey that has been coming in in excess of the amount required by the bees, has been stored in place of it.

### AN EXTRA SUPER OF HONEY.

In this way an extra amount of surplus honey is obtained. All honey that is not used by the colony goes into the shallow extracting-super, whereas it would have to go into the brood-chamber otherwise, or perhaps not be gathered at all. If it is stored in the brood-chamber it clogs the brood-nest and crowds out the queen. It also places honey along the top-bars above which the bees are loth to store during the main flow when the comb-honey supers are given. The shallow extracting-super prevents this. Its use brings the colonies in a Langstroth brood-chamber to the best condition by the beginning of the honey-flow, for

the brood-nest extends up to the top-bars of the chamber. There is no honey along the top-bars. The colony is in an ideal shape for the comb-honey supers.

### CONTRACTION DURING THE HONEY-FLOW.

Now I do not mean to contract the brood-chamber to 4 or 6 frames, and place a lot of dummies in the place of those taken out. Such practice has always seemed like a "dummy" to me, and I never liked it, although I tried it repeatedly.

When the time comes for putting on the comb-honey supers, the extracting super, now filled or nearly so, is simply raised up and placed above the empty super put on. This places the colony in a shape by which immediate storing in the comb-honey super is obtained if the honey-flow is on. The bees take possession of the supers at once, and there is no need of bait sections and other methods for coaxing them up.

The extracting-super is left on until the first super given is partly filled. Then, when the second super is added underneath it, the extracting-super is removed to be extracted.

### THE ADVANTAGES THAT ARE GAINED.

The advantages that are obtained by using a shallow extracting-super as outlined can be summarized about as follows:

First, it enlarges the hives. This means prevention of swarming, rousing the colonies of bees, and large surplus crops.

Second, extra storing-room is provided for honey not needed by the bees. It prevents the clogging of the brood-nest, and an extra amount of surplus is obtained.

Third, the brood-chamber is in the best condition for the comb-honey supers when the main flow comes. There is no sealed honey along the top-bars above which the bees are loth to store, but the brood extends up to them.

Fourth, contraction of the right kind can be practiced with great advantage and without extra trouble. Placing the extracting-super above causes better work in the comb-honey supers, and the extracted honey is ripened better while left on. In this way the bees are used to working in the supers, and the trouble about them not entering the comb-honey supers is done away with.

Brazos Co., Tex.

## Convention Proceedings

### The Illinois State Convention

The 14th annual session of the Illinois State Bee-Keepers' Association was held in Springfield, Nov. 15 and 16, 1904. The proceedings of that meeting are published in a pamphlet, as mentioned on page 324 of this number of the American Bee Journal, from which we take the following:

#### CO-OPERATION AMONG BEE-KEEPERS

Your invitation to me to attend our annual State Bee-Keepers' meeting and deliver an address has been duly received, and I would gladly comply with your request were it not that the date conflicts with that of another congress—the Upper Mississippi River Improvement Association—which is of very great interest to the cities along the big river, and for which I am delegated by our city. I trust that, in view of the importance of the matter, our bee-keepers will excuse my absence.

I believe that the most important matter before the bee-keepers of the country at the present time is the matter of coöperation. The methods of bee-culture have been so improved in the past 50 years as to make the production of honey an easy matter for all practical men. The old fogy bee-keeper and the "gum" have been relegated to the background. The moth-trap has been put away with the spinning-wheel of our grandmothers, and neither of them is brought to light, except as a relic of the past. The essential questions today are: How to market our honey, and how to protect ourselves against damage, either through the contagious disease, foul brood, or through the ignorance or dis-

honesty of those who oppose our interests? The comb-honey manufacture yarns, the spraying of fruit-trees in bloom, the prejudice against bees because of the untrue accusation that bees damage flowers or injure sound fruit—all these and many others are to be warred against. To do it safely, we must unite.

We hear on every side of the success of the great trusts which are formed in the manufacture of everything, and of the enormous profits derived by coöperation. The truth is, that association is the key-note to success today. I dare say that of those who will hear this paper read, there are very few, if any, who do not belong to some association, for profit or comfort. The life insurance and fire insurance companies are nothing but trusts for our benefit. The secret societies, for mutual help—Masons, Odd Fellows, etc., are all in the direction of coöperation. Our bee associations, no matter how insignificant and weak they may be, are all evidences of the need of association for mutual information, and ultimate increased comfort.

Some of our State associations have already secured some very positive benefits from association. A number of States have efficient foul-brood laws and foul-brood inspectors, who help keep down this disease, which is really the only disease that nature has put in our way. As bees increase in numbers throughout the country, the danger of epidemics increases, and therefore the precautions against all possibilities of disease should increase. When bee-keepers lived 25 miles apart, and bees existed only in the forests, an epidemic was soon stopped, like a fire without fuel, by want of something to feed on. But since bees are becoming one of the institutions of the farm or of the suburban garden, there is an increase of risk which must be warded off.

I notice the same danger in other lines. A small vineyard runs less risk of black-rot than a large one. A farm yard containing a couple pigs is in less danger from hog cholera than one containing a couple hundred. So, as we become more and more numerous there is more and more need of coöperation, to defend ourselves by mutual understanding and instruction. It is necessary to obtain laws in each State regulating the control of foul brood, and sustaining the honest producer against the adulterator who tries to sell a manufactured product as a product of the farm.

There is also need to advertise our business so as to help the sales of a healthy and pure product; there is need of placing before the masses a very plain statement showing that the canards concerning the alleged manufacture of comb honey by machinery are all a fake. For these purposes, and for many others which do not come to my mind now, and also for purposes of which we have no present adequate idea, it is absolutely necessary that we should unite—coöperate.

The National Association, which a few years ago numbered only as many members as met together each year at one selected spot in the United States, now numbers something over two thousand members. Although this is a great increase, it is nothing compared to the possibilities of coöperation, whenever we convince our brother bee-keepers that it is to their interest to unite for the common good. Instead of two thousand, we must have twenty thousand members. Each State must form a nucleus, sending its delegates to the meetings of the National congress, and the Association must sooner or later send its ramifications to every spot where bees are kept, in the length and breadth of the land. When this is done, our bee-keepers will no longer go to their town groceries and ask them what prices they pay for honey, but each will be posted from headquarters, and will go to the retailer with a statement something like this:

"Our sales headquarters state that the crop is short in such and such States; that the honey is expected to be in demand in such or such localities; and that the prices, considering prices of other sweets, may be expected to range about so much. Therefore I have placed the following prices on my honey."

Let no one think that this is impossible. An impossible thing is to get a fancy price for your product, but there is not the shadow of a doubt that a plain understanding as to the resources and the demand will bring about the securing of fairly profitable prices. No one can produce anything at cost, or below cost, and keep it up. At present we have many friends who produce honey and sell it at less than the cost of production, because they are working individually without any information as to the value of their product. We may expect paying prices for our crop, if, when we put it on the market, we know just what to expect, and if we feel that there is a distributing point from which our surplus may be handled at the lowest possible cost.

I know that some of our members may consider this as romance, but let me tell them that this romance is based on facts. We see thousands of plain evidences that an understanding of conditions and an increase of facilities for distribution is productive of great benefits to all. The cost of coöperation is insignificant, compared with the results. The only thing that may discourage some of those who hope for success is that large coöperative combines are not built up in one day. We must unite and stay united until we succeed.

It is not only in progressive America that the ideas of union are taking root. Even in our pursuit of bee-culture, we see this principle taking the lead a little more every day. The bee-papers of nearly all foreign countries are discussing association and coöperation. In Belgium, in France, there are some tangible steps taken. The October number of the Italian "L'Apicoltore" contains an address from Mr. Capponi, before the third National Congress of Bee-keepers, on "Protection to the Bee-Industry," in which he urges his brother bee-keepers to unite, as "no great results can be obtained if we do not act as '*viribus unitis*'—united men."

The United States of America are a living example of what can be done by "united men." C. P. DADANT.

## Our Sister Bee-Keepers

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Lady President of the British Association

The Baroness Burdett-Coutts has been unanimously re-elected president of the British Bee-keepers' Association for 1905, a position she has held for some time. Who says bee-keepers do not honor their women?

### A Busy Sister Bee-Keeper

The letter from Prof. Parrott, which appears in this number, when sent by Miss F. E. Wheeler, was accompanied by a delightful private note, and one part of it will appeal to so many of the busy sisters that Miss Wheeler will just have to forgive its introduction here:

DEAR MISS WILSON:—My, but I'm busy! The bees are pretty quiet, but we will get them out soon now. Snow is gone, but we have high, raw, chilly winds. I will start two incubators to-morrow morning, sending off a White Holland tom, receiving 10 from Indiana for myself, bossing my man's house-cleaning and mother's dress-making. Can you beat that in a day's work, and add correspondence and some work on an article? FRANCES E. WHEELER

### Honey as a Health-Food

Honey is a medicament which can be used for various purposes. Dyspeptics whose real treatment consists in a strict food regimen, should use it as dessert in place of cake, fruits and nuts, such as almonds. Honey has still one more advantage, which is that it acts as a mild laxative, and that is a valuable property for habitual constipation which gives rise to many disorders. Without doubt it is to this double action that honey owes its reputation.

As a narcotic it may be recommended for sleeplessness. Two spoonfuls of honey in a glass of water will suffice to induce sound sleep all night. It is probable that honey in such cases serves to displace indigestible foods, which, retained in the stomach, disturb the nightly rest.

That is not all. Honey mixed with water serves as an excellent gargle, and has the merit of being very agreeable to the taste, either swallowed by accident or on purpose, for honey mingled with water is delicious. And the ancient Gauls thought such a beverage was a drink of the gods, and termed it "hydromel."—Medical Talk.

### That New York City Park Bee-Keeper Contest

Miss Haggerty, the lady who was so successful in passing the examination for the position of apiarist at Bronx Park, New York City, and who was so unsuccessful in obtaining the position, writes:

MY DEAR MISS WILSON:—The American Bee Journal has been sent me. I thank you very much for your kind notice, and wish to say you are right in surmising that politics, and not the fact that I am a woman, stood in the way of a position. This fact did help Mr. O'Mara, inasmuch as when Commissioner Schrader filled the vacancy, he worded his request for a "male apiarist." This barred me out,

and made room for the fourth on the list, as only three were to be considered.

As to the examination, all credit of my passing should be given to my excellent teacher, Mr. W. L. Coggsball.

Very respectfully, EMMA V. HAGGERTY.

Of course there is some satisfaction at having been able to diagnose the situation so correctly; but our good friend, Mr. Coggsball, will no doubt protest against taking so large a share of the credit for passing the examination.

## Honey Paste for the Teeth

Eight ounces of precipitated chalk, 4 ounces of powdered castile soap, 4 ounces of powdered orris root, 40 drops of oil of sassafras, 80 drops of oil of bay, and honey enough to form a paste.—MME. QUI VIVE, in the Chicago Record-Herald.

## Bees and Fruit-Puncturing

As a further contribution in the case of the bees on trial, Miss Frances E. Wheeler sends the following letter written by the entomologist of the New York Agricultural Experiment Station:

MISS FRANCES E. WHEELER:—I have read your letter with a good deal of interest, and understand your position as I did not before when your observations were given me second-hand. The prevailing opinion is, of course, that bees are not able of themselves to puncture the skin of fruits, but as regards your suggestions that they may deliberately sting the fruit as the first step in feeding, I can only say that I have had no observations to sustain such a theory. I fully appreciate the stinging abilities of these insects, and can understand that if they so willed they could puncture the fruit in the manner described. This is a point that could easily be determined, and I know of no better place where suitable observations could be made than in your own orchard. If this year the bees frequent the fruit as they did last year, I should consider it a great courtesy if you would call my attention to the same, that I may make observations to settle this point.

Thanking you for your interest in this matter, I am,  
Yours truly,  
March 7, 1905.

P. J. PARROTT,  
Entomologist.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B Rural, Toledo, Ohio.

### LIGHT-WEIGHT SECTIONS OF HONEY.

So a grocer of 10 years' experience thinks the swindle of light-weight sections is responsible for much of the falling off in consumption. Hit the mark that time. Not necessary to suppose that grocers generally lie about the weight, or that purchasers generally believe sections weigh a pound when they do not. But when a man buys a so-called pound section, and pays for 12 ounces the price that should have sufficed for a pound, he will ruefully kick himself about it afterward. Among other things he will tell himself then that it didn't weigh more than 10 ounces. And it will be quite a while before he buys any more. Page 229.

### SPRING AND FALL PRICES OF BEES.

On the price of a colony of bees, fall and spring, 6 of the 29 experts do not try to answer the question as it is given. Among the remaining 23 there are obvious causes of decided scatteration. Some live where farm sales of neglected bees are common, with resulting depression of prices. Some live where the winter problem is nothing, with the result that the two prices are the same, or nearly so.

We'll take \$5.00 in spring and \$4.00 in fall as the comparison figures. Three name these sums exactly and nothing else. Five more give answers that agree thereto, but with more or less of "frills" attached. So these prices have the assent of over one-third of the respondents. Three more name the same price in the spring but cheaper in the fall. Nine name them cheaper both fall and spring—lowest in Kentucky and Texas, where they are sometimes \$2.00 or lower. Two name them higher both fall and spring. If you glance over and compare these ballots you will most likely conclude that (by popular suffrage) the comparison figures are at least a shaving too high. Page 245.

### EXTRACTED-HONEY EXHIBITS—BEESWAX.

So Utah exhibited its best honey in great 100-pound glasses with the result that it didn't seem to be very white. The light amber honey in one-pound glasses looked whiter than the best honey did. Reminder for future exhibitors.

One of the things for us to find out when we get around to it is about the wide abnormal variations of beeswax. These affect both color and odor; and when we consider the world as a whole, they are by no means rare, it seems. These peculiar waxes seem local.

Whether they really are so or not is part of the problem. One might surmise that some local species of plant or tree serves as the real cause—were it not that most of our numerous divergences in bee-pasture seem to count nothing except as to the honey. A peculiar race or species of bee is without much doubt liable to have its own peculiar sort of wax. These peculiarities cropped out in the wax-exhibits at St. Louis. Nicaragua had a black, wild beeswax. Mexico showed a chocolate-colored wax. Madagascar showed a yellow wax with a very pronounced odor. Although none seems to have been at St. Louis, Jamaica has a cherry-red wax with a very penetrating fragrance. Yet, as a general proposition, we are in the habit of considering that blacks, Italians and Cyprians all make the same wax—and all the same whether from clover or buckwheat, willow, aster or polygonum. Somebody rob bumble-bees' nests enough to get a visible cake of wax from them. That would show individualities, I'm pretty sure. Page 199.

### A PUBLIC HONEY MARKET.

Nice to have a 2-days' public honey market every fall, as in the Swiss city of Neuchatel. But, considering our prices, 2 cents a pound to pay for selling extracted honey would kind of strike us in the neighborhood of the solar plexus. Taken out of their figures (from 16 cents up to 20) we would stand the blow. Page 245.

### INCORPORATION OF THE NATIONAL.

Sixteen of the experts favor the incorporation of the National, 7 oppose it, and three dodge the question. Page 200.

### HEAVY LOSS OF BEES IN 1903-04.

We know the winter of 1903-04 was a bad winter on bees; but Canada seems to have caught it worse than the rest of us, according to the figures on page 205. To lose 115,000 colonies of bees out of a total of 190,000 is certainly a startling loss. But such sweeping losses often make some desirable returns. The bee-keeper that harbors foul brood—won't take pains to cure it, and yet won't quit the business and let the territory become clean, is sometimes put out of commission by an extra-severe winter.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

## Bee-Hives Made of Cedar and Redwood

I have seen offered for sale bee-hives made of Washington cedar and California redwood. Are they any good? CALIFORNIA.

ANSWER.—I have had no personal experience with them, but I think some have reported favorably of these woods.

## Sections Protected All Around—Wide Frames

I am sending you under separate cover "top and bottom" of a section taken from one of my T supers. I would not want to say that all sections from my T supers are so stained. In my travels I occasionally come across a man who wants his sections protected all around while in the hive. At our bee-keepers' meeting a year ago there was not one who was in favor of it. I would like to know whether you think it would be desirable to have the tops of sections protected. G. M. Doolittle, a few bee-keepers near Syracuse and myself, seem to be all the "old fogies" who stick to wide frames. What is the matter with us? NEW YORK.

ANSWER.—Your samples have been examined and discussed by myself and assistant with much interest. We have had sections as badly daubed, but not many. When honey is yielding nicely, bees are not much inclined to propolize. They will glue cracks and angles to some extent but that is all. Late in the season, at least in this locality, they will plaster glue on plain surfaces, and if a T super of sections is left on for some time after the harvest closes, the bees seem to have it on their consciences to decorate the tops with propolis over the entire surface. They do not do this with wide frames—cannot—they can only get at the edges. So if a T super and a super of wide frames, side by side, be left on some time after the harvest, the sections in the wide frame will be much the cleaner. While the harvest is on, the difference is the other way. We take on thousands of sections in T supers that scarcely need any scraping. With wide frames on at the same time, the bees think it the right thing to glue the cracks, and it is wonderful how far they can crowd in the glue between the top-bars of wide frames. So on the whole there is probably less trouble with T supers than with wide frames in the matter of gluing.

After what I have said, you will not be surprised that my answer to your question is that I do not think it desirable to have the tops of sections protected, because the protection, while efficacious at the central part, invites propolis at the edges.

In the samples sent I note that you have the locked corner of the

section at the top; most likely an exceptional case, as a section looks better the other side up. I note also that on the bottom there is little glue, nine-tenths or more of the material being pure wax; in this particular case apparently an unprofitable degree of crowding.

It is nothing very strange that some adhere to wide frames. I have a very kindly remembrance of the fine crops of honey I secured with them. Given a complete outfit of any kind of surplus arrangements, and a man is not warranted in changing to something a little better; it should be much better. There's the expense of the change. Then he's used to the old, and the new is troublesome. I think some who have tried T anpers have failed to get the right benefit from not knowing how to use them. While looking at the daubed pieces you sent, my assistant said, "Sections like that can be scraped so as to be nice, and I'd rather have the trouble of scraping, if it was necessary, than to have the extra trouble of handling the wide frames."

Transferring and Hives—Clearness in Answers

1. I notice when beginners ask about transferring bees from box-hives, you quite frequently advise them to wait until the colony swarms, and then 21 days after that do something. You do not seem to take into consideration the fact that the bees may not swarm. It would be too bad to advise a beginner to wait until the bees swarm, and then they don't swarm until the second year, when he wants to transfer them before the first season. I have often thought about this when reading some of your answers.

2. Also, one questioner asked as to the value of the Danzenbaker hive for comb honey, and you told him you preferred the "dovetailed." Perhaps you forgot that the Danzenbaker hive is also a dovetailed hive, the word "dovetailed" referring to the way the corners are made. So they are both dovetailed hives. I do not know how to distinguish them unless you should say that you prefer the "regular Langstroth dovetailed" hive. Pretty near all the hives made now are "dovetailed," as you know.

I am simply after clearness in your answers, which might be confusing to a beginner if left as you give them sometimes.

A READER.

ANSWERS.—1. Your exception is well taken. At the very least, something should be said as to possibilities. The great probability is that the colony will swarm. In case it does not swarm, the probability is that in most cases it does not swarm because the season is so poor that it can not afford to swarm, in which case the advice may remain good, "Wait till the colony swarms," even if you have to wait till the next year. Especially is this true because in most cases the inquirer is a beginner who will do well not to tinker too much with bees in a poor season. After all this is said, there may be cases of a different character. A colony may be so little inclined to swarm that it may go through a good season without swarming, especially if it be in a large hive.

Suppose, then, we put the answer in something like this form: Wait till the colony swarms, give the swarm in your movable-frame hive, setting it on the old stand, and putting the old hive on a new stand. Twenty-one days later drum the bees out of the old hive, put them in a new one, leaving it on the same stand. That will give you 2 colonies. You may, however, prefer not to have any increase; in that case give the swarm as before, putting it on the old stand with the old hive close beside it, and 21 days later drum out the bees and give them to the swarm. In case the bees do not swarm until 2 or 3 weeks after other colonies are swarming, and the colony in question seems in a prosperous condition, you may take the matter into your

own hands and transfer in the old way in the manner directed for transferring in your book of instruction.

2. Strictly speaking, there is no such a thing as a dovetailed hive; yet, by common consent, the manner of locking the corners of a hive together now in general use is called dovetailing, and that use of the word is likely to continue.

Wm. McEvoy is a Canadian, not an American. True, he lives in America, but custom makes the word "American" apply not to every one who lives in America, but only to those who live in the United States.

The Danzenbaker hive is not a dovetailed hive. True, its corners are dovetailed just as much as those of a dovetailed hive, but the custom of years makes the name "dovetailed hive" apply not to every hive with dovetailed corners, but only to those containing frames 17x9. There may be a certain inconsistency in this, just as there is in saying that a Canadian is not an American, but established custom controls, and any other understanding of the name "dovetailed hive" would throw out of gear the catalogs and bee literature in general. A beginner may be confused, but instead of saying to him every time "regular Langstroth dovetailed hive" (which to many beginners would need further explanation), it may be just as well to use the concise form, and let him learn what "dovetailed hive" means, just as it is well to let him learn what "American" means.

Please don't understand from this that I take any exception to your strictures. It would take a whole lot of italics and capitals to let you know how heartily I thank you for what you have said, and if you will only do so some more I'm sure it will be helpful all around.

The Rietsche Press—Making Foundation

1. Would it pay to have a Rietsche press for 100 colonies (I use shallow extracting-frames and sections on each colony), or would it pay to sell the wax and buy foundation?

2. Will the same press make different thicknesses of foundation?

3. How much could one make in 10 hours, and will each sheet have to be trimmed by hand?

4. Please tell your readers all you know about the Rietsche press.

5. What size and shape pans are best to mould beeswax in for market?

OREGON.

ANSWERS.—1. I doubt that you could easily make foundation with a Rietsche press that would be satisfactory for section honey. For brood-frames you can make foundation with it that would be entirely satisfactory. Whether it would be advisable to make or buy depends upon circumstances. If you are somewhat at leisure part of the year, it might pay to buy a press, especially as the cost is not very much.

2. Yes, but as before said, you can hardly make it light enough for surplus foundation.

3. I must refer this question to Mr. Getaz, who doubtless answers it in his circulars, or will give the information privately on request.

4. I know nothing about it from personal experience. Mr. Getaz, who makes the machines, is a man in whom I have much confidence. He is the first, I think, to make any serious effort to introduce them in this country, but a large number of Rietsche presses—I think something like 20,000—are in use in Europe. Pretty good proof that they give good satisfaction there; but it is also true that it is not so easy in Europe to be sure of getting a pure article when you buy foundation.

5. That's a matter chiefly of your own convenience; only it should be a vessel that is at least a little flaring, so the wax will easily leave the vessel when cold.

Place Your Orders Now. ITALIAN QUEENS EITHER GOLDEN OR HONEY QUEENS

Our Golden will come up to any other Golden Strain. Our Honey Queens are what some term "Red Clover Queens." We always call them Honey Queens.

Table with 3 columns: Item, Price 1, Price 6, Price 12. Rows include Untested, Warranted Tested, Tested, Select Tested, Breeders from \$5 up, and 2-frame Nucleus (no Queen).

When Queens are wanted with Nuclei add price of any Queen wanted. We guarantee safe arrival of all Queens and Nuclei. Our breeders may be returned after 30 days, if satisfaction is not given. Cash must come with all orders. Orders are booked and filled in rotation. We book orders for next season. Safe arrival guaranteed of all stock. We ask a trial order.

Reports and Experiences

Bees Wintered Well

Bees have wintered well here. I wintered 20 colonies outdoors and over 100 in the cellar without loss, except from failure of queens and a few small queen-rearing nuclei that ran short of honey. The hives outside were covered with snow during the coldest of the weather. J. L. STRONG.

Page Co., Iowa, March 29.

Clipping Queens—Water for Bees—Ant-Proof Bee-House

I have just finished clipping my queens. I clipped 57, and will tell how I did it. I made a wire-trap, winding small wire around a flat wedge-shaped piece of wood. When the wood is removed it is just big enough for the queen, and is cone-shape, but flat at the bottom. It is nearly 2 inches wide. I open the hive and when I find the queen I set the trap over her, and as soon as she runs up in the small end I put my thumb on the bottom. In clipping I

run the point of the scissors under one or both wings, and clip. Then I let the queen run back on the same frame about the center, when I can see that the bees begin to feed her and that she is not molested, after which the frame is put back in the hive. I use a queen-trap because in so doing the queen does not get the scent from my fingers, and is not so likely to be balled.

The bees are now storing some honey, as the orange-trees are beginning to bloom and the pears and olives are in full bloom.

Some one wrote of bees needing water during the past month. My bees used over 2 large pailfuls of water. I keep it in several places for them, as they need it during brood-rearing.

Most of my colonies are in a bee-house, and I wish I had room for all of them there, as it is so fixed that no ants can get in to molest the bees. The sills rest on brick and cement piers with a space filled with water.

I am expecting to go back to Ohio in April to see how the bees there are getting along. There has not been a day that those I have here have not had a flight, although there were a few mornings that were very cold, but the afternoons were warmer.

I secured about 2 tons of honey last season.

year, and our friend and able commentor, Mr. Hasty, commented on the same.

I do not wish to go into detail on the subject this time, any further than to emphasize to honey-producers the fact that they must cater to the demand for honey by inducing the common class of people to buy their product, as my experience also teaches me that it is this class of people that consume the most honey. But they are under the impression that they are not getting their money's worth when buying it, especially the light, underweight sections.

But I believe besides giving them a full-weight section there is considerable room for educating them as to the value of honey as a food and medicine. I tried a little experiment in the last-named direction a year ago last fall, spending between \$15 and \$20 for local advertising, clothing the advertisements in bee and honey talk. I had 100 gallons of extracted honey to sell, for which I expected \$1 per gallon, but when shipping it to the larger cities it would net me no more than 75c. Well, it didn't net me much more at home after deducting the expenses for advertising and writing the same. But it brought the honey right where it belonged, that is, to the consumer.

But, again, it was not entirely satisfactory to me. Being of a selfish disposition as I am, and advertising honey as a health-food in general, it benefited others who sold in the same market nearly as much as it did me, and, finally, I concluded I would not "go it" alone again.

A. C. F. BARTZ.

Chippewa Co., Wis.

**Bees Wintered Well—Rain Needed**

Bees on summer stands came through the winter in fair condition, but those wintered in cellars and caves came through better. There has been considerable spring dwindling both with outdoor and cellar wintered bees. Spring opened up very early and bloom has made a good start, but this morning the mercury stood at 10 degrees below freezing.

There seems to be an abundance of white clover starting, but we are needing rain to make it grow and bloom well.

alsike clover produces as much honey as any plant grown in this region, and the honey is of the same quality as that of white clover. It is a fine pasture grass, and produces about twice the forage both for stock and bees as does the white clover. It is very hardy, does not easily winter-kill, will produce a good crop of hay on wet or medium land, and may be sown at any time when the land can be worked. It produces lots of seed, and consequently the seed is cheap. It is of a dark green color, and is very small.

As compared to alfalfa, it produces all the time, whereas alfalfa has seasons. Sweet clover is slow in starting, and after it blossoms is not good for hay. Buckwheat has a short season, and the honey is of a poor quality. Basswood has a short season, and in a prairie country is almost out of the question. So I might say that white clover is the only plant which may be compared with alsike, but while it is equal in some respects it will produce only about one-half as much honey per acre, and not one-third as much hay. Therefore, I would give alsike clover first place as an all-around grass for honey, hay and pasture.

R. A. MORGAN.

Clay Co., So. Dak.

## Prospects for a Good Season

Bees have wintered splendidly here with very little loss. Prospects are good all along the line. The weather is fine; everything in the fruit and vegetable line is growing and blooming, and if the weather continues good we will have the best and earliest spring in years. I look for a good season for honey, as white clover is coming on fine. I have 160 colonies to start with.

W. S. FEEBACK.

Nicholas Co., Ky., April 3.

## Bees Wintered Well—Dry Weather

My bees wintered well. I have 30 colonies that are good and strong, and one that is somewhat weak, but I think it will pull through. I lost one during the winter. Fruit-blossoms will be out in a few days, barring cold weather. The bees have been gathering pollen for about 3 weeks from elm, box-elder, and cotton-wood, with occasionally a day they could not fly because of the cold. It is quite cold to-day with north wind. Ice is on water in tanks or pails out-doors this morning.

Bees in this locality came through the winter in pretty good condition with not more

## HONEY-JARS.

For a limited time we offer No.25 Honey-Jars, porcelain cover, metal screw cap, holding one pound of honey net, one gross in case complete in 5-gross lots, \$4.00 per gross; less quantities, \$4.50 per gross, f.o.b. New York. If you want to secure some, let us know at once.

than average loss. The season so far has been dryer than last but we look for rain soon. Farm crops are in good condition—spring grain all in, and farmers are waiting for corn-planting weather to get to work at that.

J. M. LINSKOTT.

Gage Co., Nebr., April 14.

### Bees in Good Condition

Bees have wintered very well up to date; in fact, I never saw bees show so little signs of dysentery when they were placed on the summer stands as they did this spring. I have 160 colonies.

Success to the American Bee Journal.

WARD LAMKIN.

Cayuga Co., N. Y., April 4.

### Last Season a Very Poor One

The season of 1904 was a very poor one for honey in this locality. I commenced in the spring with 18 colonies, and my honey crop was about 400 pounds. I now have 31 colonies. My bees are coming out on cold days and dying on the snow. I have kept bees for 30 years, and never had so many come out on cold days before. I packed them on the summer stands better than I ever did.

Putnam Co., Ind., Feb. 20.

C. JOB.

### Bees Wintered Splendidly in a Cave

The last was a poor season in this locality. Not very much surplus honey, but the bees built up in good shape for winter. I put 51 colonies in a cave 6x10x6 feet, and took out 49 and one queenless, there being only one dead colony. I think this excellent, considering the crowded condition.

Last year my better half did most of the hiving of swarms, my professional work keeping me at the office almost all of the time during swarming-time. I intend to quit practicing in a year or two. I am going North, and intend to keep about 200 colonies

## SINGLE COMB BROWN LEGHORNS

Noted Winter-Laying Strain. Cockerel Mating, headed by Rochester Prize-Winner; Eggs, \$2.00 per 13. Pullet Mating, headed by pullet line; pedigree; Exmoor males, \$2.50 per 15. Flock on range, headed by 2d Wis. State Fair winner, and others of equal quality, \$1.00 per 15. Hens in all pens result of 15 years' scientific breeding.

Single Comb Buff Orpingtons. The grand new breed. No better quality in existence. \$2.00 per 15 eggs.

Mammoth Bronze Turkeys. Hens up to 23 pounds each. Not inbred. Eggs \$2.50 per 19; 25 for \$5.00.

G. G. PIERGE, Kilbourn, Wis.

of bees. I think we will increase to 80 this year. I am going to try to ship my bees when I go away. W. H. ELLIS.  
Calhoun Co., Iowa, March 25.

**Bees Doing Well—Good Market for Honey**

I have 12 colonies of bees, all in the cellar, which seem to be getting through the winter all right. They had a flight Jan. 31, and seemed to be very strong; they tried to rob each other.  
Last season I secured from 7 colonies 285 pounds of comb honey in 4 1/4 x 4 1/4 x 1 1/2 plain sections. I use the 8-frame kind with gable covers.

I am in the heart of a town of 6000 inhabitants, and you know how long 285 pounds of nice, white honey would last in such a place. I sell all my honey at 15 and 17 cents per section, and I would sell very much more if I had it the whole year around. I have 2 colonies of pure Italians, the first I ever had. I am completely "struck" on them, as they are very prolific.

There are about 50 colonies of bees in this town, owned by 8 different bee-keepers, so you see that we do not hurt each other's business. There are only two of us who take the "Old Reliable." I have loaned my Bee Journal to some of my neighbors, and think perhaps I will be able to get them to subscribe.  
S. W. STALEY.

Franklin Co., Pa., Feb. 27.

**Bees Wintered Well—Home-Made Bee-Supplies**

I started with 4 colonies of bees 3 years ago, and they stored 300 pounds of surplus honey the first year, but last year they did very poorly. I had 10 colonies, and secured only 70 pounds of surplus honey. The bees wintered well, as I lost only one colony each winter. I now have 14 colonies, which I took out of the cellar two weeks ago, all in good condition.

I am a common laborer and have no capital to start with, so I make my own hives in my spare time. I think the bees are a poor man's friend, as they can be handled with small means. I have made a bee-veil out of the cover of a tobacco pail and a screen. I cut out the center of the cover just enough to let the crown of my hat through and nailed the screen all around it, and sowed a thin cloth on the bottom.

I also have a little trick for nailing brood-frames. I take an inch board 20 inches long and 8 1/2 inches wide, make a side on each end of the board by nailing on a pair of cleats and a piece of band-iron for a spring to hold in place the end-pieces of the frame. Then I nail the top-bar to the top of the board. I next turn the board over and nail on the bottom. This makes the frame stiff and true. A little boy can nail frames together just as well as a man. This plan may help some novice.  
A. L. OLIVER.

Benton Co., Minn., March 9.

**The Big Song Success**

"Dreaming of that Old Kentucky Home." Tremendous hit with all who hear it. In order to introduce will send a copy on receipt of 10 cents. This offer good for a short time only. Cut rate in music. Send for catalog.

## Honey and Beeswax

CHICAGO, April 18.—A carload of comb honey, (said to be from Colorado) came on the market about the first of the month. It was placed with a firm that does not make a specialty of honey, and to some extent has upset prices when looked at in print. It is put up in 24 section flat cases with wood slides instead of glass, and is more or less candied. Choice white comb brings 12½c; No. 1, 11@12c; amber, 8@10c. Extracted, white, 6@7c; amber, 5½@6½c; price being governed by quality, flavor and package. Beeswax 30c if clean and of good color.

R. A. BURNETT & Co.

CINCINNATI, April 20.—The conditions of the honey market to day are not encouraging. The consumption is lacking, although we are looking forward to brighter days in the honey market. We continue to quote amber extracted in barrels and cans, 5½@6½ cents; white clover, 7@8c. Fancy white comb honey, 12@13c. Beeswax, 28c.

THE FRED W. MUTH Co.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.

HILDRETH & SEBELKEN.

PHILADELPHIA, April 19.—There has not been much call for honey in the last two weeks. Prices remain unchanged. We quote: Fancy white, 11@12c; No. 1, 10@11c; amber, 9c. Extracted, white, 6@7c; amber, 5½@6c. Beeswax, 28 cents.

We are producers of honey and do not handle on commission.

WM. A. SELSER.

BOSTON, April 24.—The demand for honey is light and the supply is, we would consider, heavy for this time of the year. Without question, much will be carried over to another season as the sales have been, generally speaking, light through the entire year. Fancy white we quote at 16c; A No. 1, at 15c; No. 1, at 14c. Extracted, from 6@8c, according to quality.

BLAKE, SCOTT & LEE.

KANSAS CITY, March 31.—The honey situation does not improve. While there is a little better movement the prices seem to be lower. Fancy white brings \$2 a case; No. 1, \$1.75; amber and lower grades from \$1.25 to \$1.50. Extracted, 4½@6c. Beeswax, 28c.

C. C. CLEMONS & Co.

CINCINNATI, O., April 18.—The large stock of comb honey, yet offered with hardly any demand, caused lower prices. I quote fancy water white at 12c; other grades in proportion, lower.

Extracted is in the usual demand for this time of the year; quote amber in barrels at 5½@5¾c; in cans, ½c more; white clover, from 7@8c. Beeswax, 28c.

C. H. W. WEBER.

ALBANY, N.Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6½c; white, 6@6½c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c.

H. R. WRIGHT.

SAN FRANCISCO, April 12.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted white, 5½@6 cents; light amber, 4@5c; amber, 3@3½c; dark amber, 2½@3c. Beeswax good to choice, light, 29@30c; dark, 27@28c.

Stocks on the local market are not heavy and mostly common amber grades. The demand is slow. The new season being near, handlers are awaiting arrivals of new crop, which are expected to put in an appearance early in May.

## IN THE HEART OF MICHIGAN

## PURE ITALIAN BEES

The most beautiful, most prolific, best workers, and since long-tongued the best honey-gathering strain of bees. Highest award at St. Louis Universal Exposition. Extra Select Breeding Queens, \$3; 6 for \$16; doz., \$30. Selected Queen (young Tested), \$2; 6 for \$11; doz., \$20. Special prices on 50 or 100 Queens. Payment is to be made by Postal Money Orders. If by chance a Queen arrives dead, she is to be returned at once, with a post-office certificate, and another Queen will be sent free. Address,

**ANTHONY BIAGGI,**

Pedeville, near Bellinzona,  
Italian Switzerland.

### BEE-KEEPERS' SUPPLIES.

We are now able to quote lower prices than ever before. Highest quality guaranteed. We handle the G. B. Lewis Co's goods. Italian Bees for sale in dovetailed hives. Send for my 88-page Catalog, and lend for beginners. They are free.

44Ett W. J. MCCARTY, Emmetsburg, Iowa.

Please mention Bee Journal when writing Advertisers.

## Why! the Little Rascals!!

That's what you will say when you read our little book, "Bee Pranks." This pamphlet is compiled from newspaper clippings and contains many strange and laughable accounts of the doings of the busy bee. It also gives you in a nutshell what the great writers have said about this wonderful little insect.

Price  
10 cents

**GIVEN FREE**

For the names and address<sup>s</sup> of five bee-keepers in your vicinity. If you have not read this little book, be sure to secure a copy at once for this offer, holds good only while they last. Published only by

**G. B. LEWIS COMPANY,**  
Manufacturers of Bee-Keepers' Supplies, WATERTOWN, WIS.

The A. I. Root Company offers unexcelled advantages to the bee-keeper.

**Prompt Shipments! Full Stocks! Quick Time! Low Freight!**

Now is the time the average bee-keeper wants Supplies, and wants them quick! Now is the time the advantages offered by the A. I. Root Company are most apparent. With branches and agents in all principal bee and railroad centers the time consumed between the mailing of the order and receipt of the goods is reduced to a minimum. Write to the nearest branch or agent for Catalog. Remember our prices are as low as consistent with good goods, and that we are the leaders in improvements. Complete information on request.

### The Latest Improvements in Honey-Extractors

ROOT'S AUTOMATIC 8-FRAME HONEY-EXTRACTOR CONNECTED TO RUN WITH A SMALL GASOLINE-ENGINE

The long-wished-for practical Automatic Reversing Extractor has at last been found. The Root Automatic solves the question completely. No complicated mechanism; it is simplicity itself. All orders for 4-frame Cowan or larger will be fitted with the Root Automatic at the regular price of the Cowan.

When a bee-keeper has a large amount of extracting to do, requiring a large machine, an Engine for running the Extractor is almost a necessity. To furnish power in such cases we are prepared to supply a small Gasoline Engine, specially built for this work. If you are interested write for complete description and price.

#### Best Book for Beginners

Arranged in the form of an encyclopedia so that any information can be found in an instant. The subjects are completely covered, and brought completely up to the times by constant revision. The book is beautifully illustrated by the finest half-tones. 100th thousand. 1905 edition. Price, \$1.20, postpaid.

#### Bees and Queens

We are prepared to furnish Nuclei and full colonies of Italian Bees. Also our Red Clover and Honey Strain of Italian Queens, as well as Imported Queens. Upon the queen depends the prosperity of the colony. See to it that your queens are young and vigorous, and the honey is sure if there are flowers. Write for our price-list.

### IMPORTANT NOTICES

**THE SUBSCRIPTION PRICE** of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

**THE WRAPPER-LABEL DATE** indicates the end of the month to which your subscription is paid. For instance, "dec 15" on your label shows that it is paid to the end of December, 1904.

**SUBSCRIPTION RECEIPTS.**—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

**ADVERTISING RATES** will be given upon application.

### National Bee-Keepers' Association

Objects of the Association

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

**Annual Membership Dues, \$1.00**

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

### The Honey-Producers' League

(INCORPORATED)

#### OBJECTS:

1. To create a larger demand for honey through advertising.
2. To publish facts about honey, and counteract misrepresentations of the same.

#### MEMBERSHIP DUES

1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.
2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-paper publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.

GEORGE W. YORK, Manager,  
334 Dearborn St., CHICAGO, ILL.

#### Queen-Bee Free as a Premium

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1904, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is a good time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

## Editorial Notes and Comments

### The Honey-Producers' League

Since the last report the Manager has received the following memberships with annual dues as indicated:

H. G. Acklin.....	\$ 14
D. I. Wagar.....	3
T. P. Andrews.....	4
A. G. Woodman.....	15
Geo. E. Goodwin.....	4
E. F. Tiedt.....	5
C. H. Harlan.....	4
R. S. Chapin.....	3
Nellie Love.....	2
Thomas Meyers.....	1
E. A. Doney.....	1

Previously reported.....	1223
<b>Total.....</b>	<b>\$1341</b>

In the first column on this page the reader will find something about the League, its objects and dues. We trust more of our subscribers will become members at once. Active work will be commenced just as soon as there is a sufficient fund in the treasurer's hands.

### Some Newspaper Glucose Yarns

Thanks are due Jos. M. Hynek for translating into English some of the things said about bees in a periodical published in a foreign tongue, in the following letter:

EDITOR YORK:—I read an article a few days ago in Hospodar, of Omaha, Nebr., stating this:

"People in large cities think, when they buy sealed comb honey, that it is pure honey, but it is not always so. There are many professional bee-keepers that have their bees work all summer to store glucose honey. The glucose is placed close by the bees in open barrels purposely prepared for the bees to store it and seal it. The bees will not go a long distance to look for nectar when they can get the glucose near by. There are cases of merchants in large cities who keep a few hives of bees on their roofs, and have glucose

near by to make it into honey. These bees in large cities never see a blossom of any kind, and if they were transferred to the country they would get scared over different kinds of blossoms and flowers all full of nectar."

Now, Editor York, is it possible to keep bees on glucose all the year around? I am a beginner with bees, and know but very little about how to manage them, but I don't want any one to run down comb honey, or to run down professional bee-keepers. I could not call them professional bee-keepers who sell glucose for honey.

Please give us some information on this subject in the American Bee Journal. I am well pleased with the American Bee Journal. Sank Co., Wis. JOS. M. HYNEK.

The Hospodar is no doubt innocent of originating the statements made, having probably copied them from some paper possessed of a reporter with an imagination in lively working order. It may be that it will be glad to make a few statements possibly not quite so sensational, but at least having the virtue of being entirely truthful. The following statements it may safely make without fear of contradiction:

There are not many—there is *not one* professional bee-keeper—in the land who has his bees working all summer storing glucose, for the simple reason that bees could not be induced to do so. Only under stress could they be induced to take glucose in limited quantity for a short time.

If glucose, honey, or any liquid sweet were placed near the bees in an "open barrel," and if the bees should attempt to take it, the barrel would simply be filled with drowned bees.

If a thousand barrels of glucose were placed close by a colony of bees, and the nectar of flowers were to be reached by going 2 miles, the 2 miles would be cheerfully traversed, and not a bee would touch the glucose. Their natural instinct makes them prefer nectar, or its product—honey—to any other food that could possibly be offered them.

Quite a number of bee-keepers in the large cities keep bees on roofs or elsewhere, and these city bees produce tons of honey just as sweet and pure as that gathered by their country cousins, and they make it from precisely the same material—the nectar of flowers. Some of them may have to go quite a distance to reach the flowers, but they are

sure to find them unerringly, and nothing less than Nature's product will satisfy them.

Will the Hospodar kindly give its readers the benefit of the preceding facts?

### Invention of the Movable-Frame Hive

It is a bit amusing to find that "locality" plays a part even in the matter of credit for the invention of the movable-frame hive. The average American bee-keeper will tell you that it is the invention of Langstroth, with probably no thought that any one in the wide world should have any other idea. The German bee-keeper will tell us that we are indebted to Dzierzon for the movable frame, and likely he has never heard the name Langstroth. L'Abeille Domestique, a late French text-book, utterly ignores both Dzierzon and Langstroth, and names Della Rocca as the inventor. Langstroth modestly disclaims entire credit, saying it was the work of more than one; but if Langstroth had never given us the movable frame in its present form, it is not so very likely that very many of us today would be using it. Dzierzon, who deserves undying fame for having given us the Dzierzon theory—parthenogenesis—can hardly be said to have invented a movable frame, because he had only a top-bar, cutting away the sides of the comb each time a comb was taken out, and for years he stoutly adhered to this, having no use for end-bars or bottom-bar. Still less practicable was the invention of Della Rocca.

### Bee-Keeping—Farmers' Bulletin 59

This bulletin, first issued by the U. S. Department of Agriculture, at Washington, D. C., in July, 1897, was revised in March of this year by its author, Frank Benton, who is in charge of apicultural investigations by our Government. Like other publications of a similar nature, copies may be had on application to any Senator, Representative, or Delegate to Congress, or to the Secretary of Agriculture, Washington, D. C.

Considerable new and very interesting matter has been added to this revised edition of "Bee-Keeping," Bulletin No. 59, from which we quote these paragraphs:

#### COMB FOUNDATION.

Comb foundation is now manufactured with extra thin septum or base, and with the beginnings of the cells marked out by somewhat thicker walls which the bees immediately thin down, using the extra wax in deepening the cells. This is not artificial comb, but a thin sheet of wax having the bases of the cells outlined on it. Complete artificial combs have never been used in a commercial way, although there exists a widespread belief to this effect, which is founded on extravagant claims that have appeared from time to time in newspaper articles.

#### NO MANUFACTURED COMB HONEY.

Owing to the appearance of statements of a sensational character to the effect that complete honey-combs are manufactured by machinery and filled with sweets lower in price than honey (glucose, cane-sugar, or mixtures of these), then sealed over and sold in the market as genuine honey, a strong suspicion exists regarding the comb honey commonly offered for sale. Wide circulation has been given to these wild stories by sensational newspaper writers, and even monthly periodicals, usually far more discriminating and accurate, have repeated them. Some writers have even tried to locate the "comb-honey factories" in given cities, but investigation has always shown that the locations

were mythical. The forfeit of \$1000 which a reputable firm has had standing for 15 years past for a pound of manufactured comb honey of a nature to deceive the buyer still remains unclaimed.

The National Bee-Keepers' Association, at its annual convention held in St. Louis in 1904, offered also a like forfeit of \$1000 for satisfactory proof of the existence of such a thing as manufactured comb honey. But no claimant has come forward, notwithstanding the \$2000 which awaits his proof. The fact is, there is no truth in the "yarn," and no one has thus far shown the thing possible. The comb honey in the markets is pure and wholesome—a healthful and nourishing sweet, easier to digest than cane-sugar or any of the syrups so commonly sold. It is worth a place on the tables of all who can afford to use it.

#### LEGISLATION AFFECTING APICULTURE.

Many States have in recent years passed laws having for their purpose the eradication or suppression of contagious diseases among bees. State and county inspectors have been appointed under these laws, whose duty it is to go about and ascertain where diseased colonies of bees are located, and recommend the treatment to be given, or, in some cases, to carry out this treatment, even to the complete destruction of colonies or apiaries where the virulence of the attack seems to warrant it. Where these laws have been conscientiously and energetically executed, much has been accomplished toward freeing the apiaries of the given State from disease.

Some States have passed laws making it a misdemeanor to spray fruit-trees during the time of blossoming, since thereby bees are poisoned, and besides the injury to the apiarist the pollination of the fruit-blossoms is seriously interfered with.

Laws against the sale of adulterated goods as genuine, known commonly as pure-food laws, are in operation in some of the States, and where bee-inspectors or bee-keepers have taken the pains to have these laws applied to the marketing of honey, a check has been put upon the selling of adulterated honey in the liquid form, which has been practiced to

a greater or less extent, and still occurs in some of the city markets.

In general, the rights of bee-keepers to own and cultivate bees, either within the limits of cities or on farms adjoining those devoted to grazing and general stock raising, are becoming more clearly defined through decisions of supreme and county courts. In this connection the work of the National Bee-Keepers' Association should receive mention.

This organization is in no sense a trades union, but has for its purpose the defense of its members against unjust attacks upon their legal rights, the suppression, in so far as possible, of the sale of adulterated honey, the securing of legislation for the protection of its members and favorable to the general advance of the industry, as well as the dissemination among its members of advanced ideas in bee management and information regarding the marketing of aparian products. The membership fee of one dollar per annum entitles every honey-producer to membership and participation in all of the benefits enumerated, as well as to the published report of the annual convention held by the association. The membership numbers nearly 2000 at the present time, and the influence of this large body of intelligent bee-masters is already being appreciably felt in the general advance of the industry in this country.

### Foul-Brood Legislation in England

Foul brood is reported to be on the increase in some parts of England, and probably will so continue so long as ignorant and careless bee-keepers have no fear of legal restraint from scattering the seeds of the disease. Legislation does not seem very near at hand, and, strange to tell, the chief hindrance is the apparently hopeless disagreement of bee-keepers. In this country scarcely any practical bee-keeper opposes legislation, the only trouble being to get legislatures to move in the matter.

## Miscellaneous News Items

Chairman R. L. Taylor, of the Board of Directors of the National Bee-Keepers' Association, writes us that by a practically unanimous vote the General Manager of the National will hereafter receive 20 percent of the receipts from dues as his annual salary. But even that amount will be small pay for the services of a man like Mr. N. E. France.

**How to Keep Bees** is the title of "a handbook for the use of beginners, by Anna Botsford Comstock, B. S.," and published by Doubleday, Page & Company, of New York, N. Y. The price is \$1.00 net, or \$1.10 post-paid. It is cloth-bound, with 226 pages, 32 of which contain photographic illustrations. The preface contains these words:

"It is not intended to be a complete treatise for the professional apiarist, but rather a handbook for those who would keep bees for happiness and honey, and incidentally for money. It is hoped, too, that it will serve as an introduction to the more extended manuals already in the field."

**New French Bee-Book.**—"L'Abeille Domestique" (The Domestic Bee) is the title of a work of 350 pages, duodecimo, published in France, written by Lucien Iches. It is printed in clear type, with 132 illustrations, and for a book of its size seems well filled with up-to-date information. It is divided into four parts: I. The Apiary. II. Anatomy and Physiology of the Bee. III. Management of the Apiary. IV. Products of the Bees.

French readers may obtain the work for 3 francs from Garnier Freres, 6 Rue des Saints-Peres, Paris.

Mr. A. B. Carpenter, of Tulare Co., Calif., writing us May 1, said:

"With me swarming is getting late, probably on account of cool weather. Bees are filling every nook and corner of their hives with honey. I think some of going to extracting, regardless of swarming, only partially, however. Appearances indicate a good honey season."

West Florida Bee-Keeping seems to have had a setback according to the following from Mr. J. B. Hunter:

"Just as we were getting ready to take the tupelo crop of honey, a fearful rainstorm set in and cut the crop off almost entirely."

Mr. and Mrs. Thos. Wm. Cowan, of London, England, passed through Chicago Saturday, April 29, en route to their California home, in Monterey County. Mr. Cowan, as most of our readers know, is the honored senior editor of the British Bee Journal.

It is Mr. and Mrs. Cowan's intention to remain in California until late autumn, then visit British Columbia, and after that return across the continent through Canada on their homeward journey. They have crossed the Atlantic seven times, and think that once

more may be the last crossing. They expect to reach London again about Jan. 1, 1906.

Mrs. Cowan had contracted a severe cold on the Ocean, so was not very well when she arrived in Chicago. But Mr. Cowan was looking and feeling first-rate; in fact, even better than two years ago when he was here, we think.

Mr. and Mrs. Cowan are delightful people to meet, and we regretted that we were not permitted to see more of them. They have been in our country so often, and for so long a time heretofore, that they seem more like our own people than foreigners.

We, as no doubt all who know them, wish them a pleasant summer in their home in "Sunset Land," and then a safe return to their native and far-away England.

On the front page we present one of Mr. Cowan's latest pictures, which we think is a very good one.

The Minnesota Association, through its Secretary, sends the following for publication, which is of interest to Minnesota bee-keepers:

EDITOR AMERICAN BEE JOURNAL:—The Secretary of the Minnesota Bee-Keepers'

Association is authorized by the Executive Committee to deny the statements made in a recent circular sent out by the so-called "Committee on Co-operation," in so far as they relate to the connection of that Committee with the Association. At the annual meeting held Dec. 7, 1904, the chair ruled that the Committee was not appointed by, nor as a part of, the Association, and, therefore, had no standing in the meeting. An appeal to the house being taken, the ruling was sustained by a decisive vote. In view of these facts, the Association does not wish to be placed in the false light of appearing to endorse, or be responsible for, the statements in the circular referred to. Yours truly,

MRS. W. S. WINGATE, Sec.

May 1, 1905.

## Contributed Special Articles

### Home Marketing of Honey—Unripe Honey

BY S. B. SMITH

ON page 51, those who could sell more honey than they can produce right in their home market, are invited to tell how they do it. As I belong to that class, I will tell how I do.

The first and most important of all is good, ripe honey. The second requisite is neatness. Prepare the honey for market in such a manner that it will be attractive, pleasing to the eye. I work mostly for section honey, and the propolis is all scraped off and the sections are neat and attractive, and every section has my name stamped on it.

I have some extracted honey every year; this I put up in one-pint fruit-jars, holding one and one-half pounds, and in this locality they are more salable than larger quantities.

Some bee-keepers advocate peddling honey. There is no objection to that method of disposing of honey, provided they like it, but I don't have to peddle mine. There is a merchant here that takes all of it, and would take more if I produced it. I get 14 cents per pound for section honey and 15 cents per pint jar for extracted honey—or 10 cents per pound and he furnishes the jars. This man has taken my honey for the past 8 years, and I have established such a reputation for it that sales are readily made.

If any of the neighbors want my honey they can get it at the same price the merchant pays me, but I am not much troubled with neighbors' custom, as honey is peddled at 10 cents per pound for section honey, and 6 to 8 cents for extracted. I have no complaints to bring against men who sell under market price—it is a privilege they have, and I shall enter no protest, but I will relate a little incident that happened last season.

Lady No. 1 bought a quantity of extracted honey of Mr. A. for 10 cents a pound. Lady No. 2 went to Mr. A. to buy honey, but when told that the price was 10 cents a pound she said, "Mr. B. is selling honey for 7 cents a pound, and Mr. C. for 6 cents." The result was that she bought honey of Mr. B. at 7 cents.

As time passed Mr. A. dined with lady No. 1, and she had some of his honey on the table, and when she passed it she remarked that there was a great difference in honey. Your honey is thick and good-flavored. I was at lady No. 2's the other day, and we had some of Mr. B.'s honey, and it was thin and watery, and of very bad flavor.

The readers of the American Bee Journal can draw their own inferences, but Mr. A. went home without any enmity against the 7-cent honey man.

A good name is greatly to be desired, and I think more of a good name than I do of many pounds of unripe extracted honey. My honey is all ripe when taken from the hive, whether in sections or extracted, and I will say that the man who always puts good, ripe honey on the market in a neat, attractive manner will never lack for customers. The advantage or disadvantage of putting your name on your honey is a matter for each to decide; with me it is an advantage.

I will give my opinion on extracting unripe honey. There seems to be a strife among bee-men in this vicinity to see who

can get the largest amount of extracted honey. The hives are closely watched, and as soon as the combs are well filled with honey, with little or no capping done, the honey is extracted. Those who follow this method obtain a large amount of thin honey of a poor quality, thereby doing great harm to the market.

I was very much interested in the report of the convention of the National Bee-Keepers' Association held at St. Louis, especially what is said about "extracting unsealed honey," on page 61 of the American Bee Journal, and I approve Mr. France's idea about extracting unripe honey. I say, let it remain on the hive until it is ripe. Perhaps the quantity of well-ripened honey will be a little less than that of unripe honey, but the quality is much better, and it is quality, not quantity, that I want. Honor is the foundation upon which every man should build, and let that honor be unsullied.

There is much complaint about the poor quality of extracted honey, and it will be thus until some bee-keepers learn that it is to their advantage to have a good article of honey instead of a poor one in the market. Let us deal honestly with ourselves and our fellowmen. It takes a little longer to do a piece of work well, than only half do it, and it takes a little longer to produce good, ripe honey than it does the unripe, but it pays better in the end, every time.

Mille Laes Co., Minn.

### The Deterioration of Races of Bees

BY ARTHUR C. MILLER

FROM time immemorial until a comparatively recent date it was the custom among the so-called Christian peoples to "take up" or destroy their heaviest colonies of bees, which meant the killing of the most virile, and left the less suitable to perpetuate the race. The evil results of this practice at last became apparent, attention possibly being called to it by information from Eastern peoples; at any rate, bee-keepers in the 17th century began to practice "taking up" the weak and medium colonies, and leaving the best for stock.

Also, there were soon begun efforts and devices for securing part of the honey without destroying the bees. The evil results of the long-continued practice of "selecting the unfit" for breeding were not to be overcome in a season, and until after the introduction of the yellow races we find frequent references pointing to weak stock.

The yellow bees came from the followers of Mahomet, who are forbidden to take animal life except for food, and whose practice was to deprive the bees of only a part of their honey, which gave opportunity for the law of the survival of the fittest to work untrammelled by the hands of unwise men. Despite their sojourn in Italy, this Eastern blood seemed virile enough when it reached here, and its superiority to the native stock was quickly seen.

The introduction and spread of the yellow bees from Italy, and the benefits derived therefrom, are too recent history to need repetition here, but not long ago evidences of weakness began to appear in this race in various parts of the country. Contagious diseases spread with alarming rapidity, and reports of less serious ailments came from all sides. These conditions have been ascribed to various causes, but there is a disagreement as to which one is the most important. Possibly the publicity given the subject of bee-diseases accounts for the recognition and reporting of many cases, but while this would explain the increase of reports, it does not shed light on the conditions upon which the reports are based.

The existing state of affairs is strikingly like that existing before the introduction of the Italian bee, the natural inference from which is that the stock has been losing its vigor.

What we may properly consider a further support of this belief is, that not many years ago many bee-keepers began reducing the size of the brood-chambers of their hives and calling for smaller hives. Their queens were not keeping the 10 Langstroth frames properly filled, and the size of the hive was blamed. Perhaps the blame was rightly placed, and then again perhaps it was not.

Most of such reports came from bee-keepers following well-defined lines of instruction and practice. The spread of diseases and the gospel of small hives have followed not far behind the heels of the "transferred-larvæ" system of queen-rearing; just far enough behind to give strength to the suspicion that they are related. The system was well exploited, judicious advertising increased the sale of queens reared by the system, and the evils have increased also.

It is idle for the advocates of that system to say the queens are as fine as any that can be produced by any method, until they can show that the above-mentioned evils have no connection with that system.

The system as taught and practiced, together with the confining of the young queens in cages on candy food, makes impossible the fulfilling of the natural laws of developing. I make this statement knowing full well whereof I speak, and knowing also that it will probably raise a storm of contradiction. Now and then queens may be found reared by this system, that are all that could be desired, and it would be strange if among the thousands reared some were not found which chanced to dodge the evils. But they are the exceptions.

Providence Co., R. I.

## Ezera Thrasher and His Bee-Keepin'

BY WALTER S. POWDER

**M**Y name is Thrasher—Ezera Thrasher—and I drove to town to look after some of your gums and other fixens made for bees. My boys is gettin' big enough to work, and I am going to take it easier. I am nigh 50 years old, and I am going to make a business of keepin' bees. I believe I like the business better than anything that I know of, and I have found out that bees work for nothin' and board themselves, and that is the kind of help that I have been wantin'. The boys is now big enough to tend the place, and they are good workers, 'specially when Manda—that's my wife—gets out and helps 'em. I have 'leven swarms in good box-hives, and I 'low to make just as many more swarms this season as I kin. You see, some time ago they dropped our post-office where I used to go to rest up, and now they have a rural route through my neighborhood, and I was so lonesome for a while that I hardly knew what to do, but since I got in the bee-business I am glad to stay around with my bees. I've been told that Tim Smith, our old postmaster, was about to be fired anyhow for closing the office on Ground Hog Day. You see he 'lowed it was a holiday, but he found out afterwards that it was no holiday at all."

In this manner Ezera Thrasher introduced himself to the clerk in a bee-supply store in Indianapolis. He purchased no supplies on this trip, but took home with him a quantity of honey, both comb and extracted. He explained that the neighbors seeing his bees, often wanted to buy a few pounds of honey, but that he had none on hand. Returning, he continues thus:

"Well, I now see my way clear to handle the honey-business in Indianapolis, both wholesale and retail *next year*. This coming winter I will buy a good many sections and an extractor. Say, you fellers told me that beatin' on tin pans did no good towards stopping a swarm. I want to say to you that it does bring 'em down, for I have tried it. Why, I could tell by the way the bees acted that they intended to lite out, so I runs for Manda's dish-pan, and as soon as I commenced to beat they began to lite on an apple-tree. Manda scolded like everything about having her dish-pan beat up, but I saved a fine swarm.

"Well as soon as they commenced to lite I sent one of the boys over for my neighbor, Silas Alving. Silas and I had always been good friends, and he had never seen a swarm settled in a tree before, but, blamed me, if Silas and I didn't have a fall out right there about those bees. It was this way: I got up in the tree and tied Manda's clothes-line around the limb, and I was to saw the limb off and let bees and limb down to Silas. Just as I hollered for Silas to be ready, the limb swung down and brushed off most of the bees, but the limb was not cut clear off. The first thing I did was to push away the leaves so I could look 'down and see what Silas was doing, and what I see just beat all, for there was Silas running just as fast as he could right through Tom Jamison's

wheat-field. By this time them bees was getting thick around my shoe-tops, and cllimbing right straight up. I climbed down as fast as I could, and then I started after Silas, he being heavy-set and me not very limber, but I soon caught up with him, and you just ort to see us a fightin' them bees—seemed like we both got excited, and I hate to say it, but from that day to this Silas has not spoke to me. *Next year* I am going to belong to that big bee-association and have some protection."

Mr. Thrasher called on us again in November, and his enthusiasm had not subsided in the least.

"I know three fellers that are makin' a heap of money off their bees; one at Alexandria, one at Peru, and one at Winchester, and I reckon that there are plenty others doin' as well, and if they can do it I can, too. Some of my bees are pretty weak, and some are scarce of honey, but I 'lowed that a swarm that don't make enough to keep 'em is no 'count. I have 2 or 3 hives that have no queens yet, but I thought I would get queens for them next spring."

Mr. Thrasher called on us again in the following February.

"Here, you fellers, is 6 pounds of beeswax; give me what it is worth and that settles the bee-business with me. The hogs upset some of my best hives during that last cold-spell, and the weak ones, too, are all dead. I am goin' back to farmin' again, and will keep one or two more cows, for Manda likes to help with the cows. My oldest boy is coming to town to get on the street-cars as motorman, and this will leave a heap of hard work for me. Recollect that last crate of honey you sent me? Well, I did not do well with that crate. It was put off at stop No. 13 on the Interurban Line all right, but it 'peared like everybody in our destrict went and took a look at it, and when I went to sell it they all wanted to know if I didn' buy that honey in Indianapolis instead of gittin' it from my own bees. I was stumped, and I have a good deal of it on hands yet. You will find that wax all right, but Manda has scolded a heap about me spoiling her copper-bottom wash-boiler. Manda is always pokin fun at me, too, and asking me what I am going to do *next year!*"

The last we heard about Ezera Thrasher he was down at the State House making an effort to lobby against a whipping-post Bill.

Marion Co., Ind.

## Convention Proceedings

### The Illinois State Convention

The 14th annual session of the Illinois State Bee-Keepers' Association was held in Springfield, Nov. 15 and 16, 1904. The proceedings of that meeting are published in a pamphlet, as mentioned on page 324 of the American Bee Journal, from which we take the following:

#### REPORT OF THE STATE INSPECTOR

*To the Illinois State Bee-Keepers' Association I submit the following report:*

In making this my first annual report of State inspection, I will say that the work to be done in this State is far more important than the best-informed on this subject can imagine. *Bacillus alvei* (foul brood) I have found to exist from the counties bordering on Lake Michigan to the banks of the Mississippi River.

In my work I visited bee-keepers in 32 counties, and found foul brood in most of them. I also found the infection had been brought by buying bees and queens from diseased apiaries and careless dealers. Any one buying queens should be very careful. The trouble may be avoided by removing the queen from the cage upon arrival into a clean cage, and burning the cage and attendant bees that came by mail. I believe that the best way to get rid of the disease is to educate the bee-keepers through the bee-papers, agricultural and horticultural publications.

A great many mistake chilled or pickled brood for foul brood. It can be easily distinguished from foul brood, as pickled brood, or chilled brood, occurs after the larva has passed the 13th day from the egg. The young bee takes on the nymph form, that is, the formation of legs, wings, etc.,

while the larva infected with foul brood dies in the pupa state about the 10th day. After a few days it settles back into the bottom of the cell and turns into a putrid, ropy state, and can not be shaken from the cells, while the pickled and chilled brood shrivels up and can readily be drawn from the cells intact.

I find that the practical bee-keepers are, as a rule, their own inspectors—the trouble comes from the novice or persons who never have seen the inside of a hive of live bees. In my visits with the bee-keepers, I find them all anxious to learn to know foul brood, so they can take care of their own and neighbors' bees. As a rule they are intelligent above the average, and very pleasant ladies and gentlemen.

In my work last season I inspected over 4000 hives, and although last year was a very poor honey year, the bee-keepers were not discouraged, but are looking forward to the coming season for better results.

I believe that good results could be attained, as Mr. N. E. France, State Inspector of Wisconsin, suggested in his report, by bringing together the farmer bee-keepers at the winter Farmers' Institutes, and having there a talk on bees and their diseases; also distributing to bee-keepers the old, reliable McEvoy treatment, which never fails to effect a cure. I find that a number of bee-keepers have the wrong idea regarding the treatment and costs, as in their letters they want to know what the cost will be to have their bees inspected.

I appointed Mr. Herman F. Moore my deputy last year, to look after the disease in Cook and adjoining counties. He visited a number of apiaries, and I herewith give his report for work done:

PARK RIDGE, ILL., July 11, 1904.

MR. J. Q. SMITH, Lincoln, Ill.—

*Dear Sir:*—I have finished my 30 days of inspection of apiaries. I visited about 125 yards, and found foul brood in about 12, containing 88 hives of bees. Possibly one-half of the 88 are diseased more or less. These figures show the importance of the work, and the need for a better law. The work has been very interesting.

HERMAN F. MOORE,

*Deputy Inspector of Apiaries.*

In my treatment and instruction to others I have used the McEvoy treatment. I have never burned a colony of bees where there was a fertile queen and bees enough to form a nucleus, which can soon be built up by adding combs of brood from strong colonies; the hives can be used again by boiling in strong salt or lye water. Care should be taken in removing the bees from the diseased combs, so that no robber-bees can have access to the combs. The work should be done at night while no bees are flying, or, if in daytime, in a tent or well-enclosed building.

J. Q. SMITH.

Lincoln, Ill.

WINTERING BEES

The subject of wintering bees is one which has perhaps been discussed and written upon as much as any other topic of apiculture, and it is of paramount importance to the bee-keeper to know how to bring his bees through, from the close of one honey harvest to the commencement of another, in good condition, so as to get the full benefit of the yield, whether it be large or small. This is especially an appropriate time to give the matter our consideration so as to refresh our minds for the approaching winter. If we were asked the question as to what was the principal cause of bees not wintering well, and their reduced condition in spring, and later when it occurs, I would answer. Cold and the unfavorable condition of the bees to withstand it. With this view, then, what are some of the favorable conditions conducive to successful wintering?

First, on the summer stands, to start with strong colonies. Second, plenty of well-sealed stores of good quality in the same combs on which the bees are clustered. Third, protection against winds. Fourth, a double-walled hive or its equivalent by packing. Fifth, ventilation so as to keep the inside of the hive dry, but no draft through it.

As to hives being shaded or standing in the sun, it depends upon the kind of winter. If warm, shade; if long-continued cold, like the winter of 1872-3, 1877-8, 1881-4-5, we would give the hives the benefit of all the sun's warmth possible.

During some of those extremely cold winters we have saved the bees, as we believe, by covering the hives with snow. In all such cases we ventilated the hives above so as to allow the moisture to escape through the upper chamber.

For outdoor wintering of bees we believe that colonies should be allowed to increase to their full capacity of strength during the summer season. In fact, for other purposes we think the expansive system, or giving the queen and bees full room, is more profitable than the contracting and manipulating plan, for Illinois. While with proper care bees may be wintered with comparative success on their summer stands, but for the 8 or 10-frame single-wall Langstroth hive, a cellar or building so constructed that it will be not only frost-proof but not easily affected by outside temperature, is much more desirable. With part of our bees stored in such a repository we have time and again wintered them with a loss of not more than 3 or 4 per cent.

During the past thirty years, with but two exceptions, we have had almost perfect success in cellar-wintering, while those colonies wintered on the summer stands have suffered more or less especially during the coldest winters. Our conclusion is that the chief point to be kept in mind is the protection of the bees from cold, from the time it commences in the fall, until warm weather in spring has come to stay.

JAS. POINDEXTER.

Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

Some Difficulties of a Beginner

I bought 5 colonies of bees last spring and was all last year learning the different bee-traits. These bees were in the Hilton double-walled hives containing 8 Hoffman frames to a hive.

1. I notice that the bees have built the comb out so far that it is impossible to remove the frames. How shall I go about remedying this mistake? My idea was to take a new hive and put a frame with brood and honey from another hive in the center of the hive and put frames with new foundation on either side of the one containing brood, and brush the bees into the new hive, putting the old frames one by one on the top of the frames to let the bees remove the honey. Will I lose too much brood in so doing, or is there a more simple, practical plan, and when must I do this to get best results possible?

2. Also, at what temperature must comb honey be kept during winter to have the best results?

3. One of the colonies is not as strong as I should like, and a stranger who keeps some bees, suggested that the queen was not very vigorous, and also suggested a new queen. There is plenty of honey, and also brood hatching. The thought occurred to me that I could take a frame, later on, from my finest colony containing a queen-cell, and exchange it for one of the others, kill the old queen, and let the bees rear a new one, or put on a queen-catcher and let the queens battle it out themselves. Is this practicable, or would it be economy to buy a new queen? I have a bump of curiosity on my head, and should like to carry out an experiment with one colony if some one who knows how thinks it might work.

I must mention that the 3 colonies that have the brood-frames built so full were in that condition when I bought them, and I did not know what to do, and so left them in. I know better how to do now if I can only get out of my present difficulty.

The stranger before mentioned told me I had wintered my bees finely, and especially

for a beginner. And to be sure they are all in good shape with the exception of the above difficulty. I have the Hilton double-walled hives, as I have mentioned, and last fall I turned all the entrances to the south and put all the hives in a row and packed them all around the backs and sides with leaves. I kept the entrances clear from snow all winter, and before putting on the cushions in the fall I put cut-loaf sugar on top of each hive to make sure they had enough to eat. Each hive contains a great abundance of honey now, but the bees seemed to prefer a change of diet, as they ate about three-fourths of the sugar.

MISS SUBSCRIBER.

1. Please don't think of such extravagance as to waste all the brood, as you would do by the plan you propose. It would very likely cut in two the profits of that colony. Just what is best to be done depends upon the actual condition of the combs. You say "the bees have built the comb out so far that it is impossible to remove the frames." If you mean by that that the septum or center of each comb is in the right place in the center of each frame, and the bees have made the comb so thick in places that the combs can not be drawn out, then the remedy is easy. Select what looks to be one of the straightest looking combs, take a long-bladed knife, and slice off the part that bulges, so that you can lift out the frame, and that will give you room to get out the other frames, when you can slice off any bulges on them. Then instead of returning the frames just as they were, reverse

every alternate one, and the bees will not renew the bulges.

You may mean, however, that the bees have built crooked, making a comb from one frame into another frame. Even that case may be managed as above directed, providing the work is not too crooked.

If you can not possibly get out any frame for a starter, you would better proceed another way. Get a frame of brood from another colony, put it in an empty hive, fill up with combs, foundation, or empty frames, and set this hive over the faulty one. Now drum the bees up into the empty hive, pounding good and hard on the sides of the hive below. When nearly all the bees are in the upper hive, set it off, then move the old hive off the stand, put on the stand the new hive into which you have driven the bees, put over it a queen-excluder, and the old hive over that. In four days look for eggs in the lower hive, and if you find none you may know you failed to drum the queen up, and you must drum again. Twenty-one days after getting the queen into the new hive the worker-brood will be all out of the cells in the upper story, when you can remove it if you like.

Another way is open after you get the bees drummed out. Take a knife with a long blade, or a hand-saw, and cut down at each side, so as to sever any comb fastened to the sides. Now turn the hive upside down, and with a little jarring you can jar all of the contents out of the hive and lift the hive off. Then you can cut loose attachments so as to get one frame after another separate from the rest, and if the bees have not made too crooked work you may be able to crowd each comb back into its own frame.

2. Summer heat is the best temperature, but as that is hardly practicable, keep it as much above freezing as you can.

3. Don't be in too much of a hurry about condemning that queen. She may be as good as any other, and not to blame for the weakness of the colony. If she keeps filled with brood and eggs all the comb the bees can cover, that's all you ought to ask of her. If after a reasonable time you find that she is not bringing up the strength of the colony,

and decide to give a cell from another colony, dispose of the queen a day or two before giving the cell, or the bees may destroy it.

### A Place for Stimulative Feeding

The country here is perfectly lovely after the unusual rainfall, and all prospects for bees and honey seem good. Anyway, the bees are swarming. Five swarms of bees settled in the garden of a friend of mine in San Diego in less than two weeks. My bees in Colorado never swarm till June.

By the way, a few weeks ago it was asked whether there were many localities where bees could fly out and rear brood for a month before they could get flowers to work on. They certainly seem to do so with us in Western Colorado. We are over 6000 feet above the sea, and the vegetation depends upon extremes of cold or heat, of course. The nights are bitter cold well on into the spring, and there is seldom anything for the bees before the middle of March, when they are thick on the elm trees. The sun, however, is usually strong even in midwinter, and the bees get frequent flights, and begin to take bran or flour early in February.

REBECCA HALLEY.

San Diego Co., Calif., April 8.

Here seems to be a place where, if anywhere, stimulative feeding ought to be a benefit. Please tell us how that is.

### Honey-and-Salt Croup Cure

The following is given in the Herald and Presbyterian: Give frequent doses of salt and honey, giving at each dose a teaspoonful of salt mixed with a tablespoonful of honey.

It may be said here on general principles that it is not always advisable to give honey in connection with other ingredients so as to make a very disagreeable combination. The temporary benefit may be overbalanced by the distaste acquired for so wholesome an article as honey for daily food.

*canis* would fit the dachshunds, and *Microcanis* the little pocket poodles, and *Megaecanis* the St. Bernards and Danes, and *Velocianis* the hounds, and *Mordeocanis* the bull dogs. If we ever do get our science of bee-names right, the largest possible specimen of *Mordeocanis sebitem* should be set to stand off the meddlers. Page 214.

### LONGEVITY OF WORKERS AND DRONES.

With positive evidence that work shortens the lives of the worker-bees, one would think that the "idle drone" should live the longer for his idleness. It seems, however, that the queen-breeders do not succeed in keeping them quiet 45 days, when they put a supply of them in a queenless hive. That seems conclusive, or nearly so. Riotous bumping in search of sexual service shortens life a little faster than honest labor does, apparently. Page 215.

### DARK AND MEALY BEESWAX.

So the localities where the beeswax inclines to be dark are simply the localities where there is iron in the water; and it would be a simple cure if rain-water were always used in rendering. Sounds sensible. Mr. Dadaut is likely right, that too much boiling turns wax into meal; but I feel pretty well assured that too much honey in the water is also one cause of the mischief. Page 216.

### EVAPORATING HONEY IN THE HIVE.

For insisting on the real *modus operandi* of evaporating honey in the hive, in place of a venerable but non-existent one, Arthur C. Miller is to be commended. Page 217.

### "Feeding Back"—A Distinct Branch of Bee-Keeping

At the St. Louis convention the matter of the profit in feeding bees sugar that it might be stored in the sections was quite thoroughly discussed. The position was taken by some that it was folly for people to say that the bees were fed sugar that they might make it into honey, that there was no profit in it. Dr. Miller asked: "If I feed sugar at five cents a pound, how much must I sell the product for to get my money back?" No one could tell him, and, if there could have several persons answered him, there would have been as many different answers as there were persons. It was finally voted that Louis Scholl, of the Texas Experiment Apiary, should make some experiments and report.

Let me say that the feeding of sugar or honey, that it be stored in the sections, is as distinct a branch of bee-keeping as that of commercial queen-rearing. Mr. Doolittle once made some experiments in feeding back honey that it might be stored in sections, and reported a decided loss. I have fed thousands of pounds in which I secured three pounds of comb honey from the feeding of four pounds of extracted honey; and there you are. It depends upon the weather (the temperature), the strain of bees, the strength of the colonies, the size of the hive, the consistency and temperature of the feed, and a whole lot of details too numerous to mention. An experiment in this line will prove little, or nothing, as almost any results can be secured. Although I have made a decided success of "feeding back," I am not inclined to advise it for the general bee-keeper.—Beekeepers' Review.

### Bee-Keeping in Bosnia

The last speaker at the great beekeepers' meeting held in Dornbirn was Franz Gloessl, who reported the condition of apiculture in Bosnia, the extreme southern province of Austria bordering on Turkey. He said rational bee-keeping had made advances only very recently. The movable-comb hive had been introduced by the immigrants from Germany, Hungary and Tivol. In 1899 he had organized a beekeepers' society, which had at the end of the first year eight hundred members, mostly Turks. The society soon made an appeal to the government and succeeded in receiving material grants. For instance, no tax was to be levied on such hives as contained movable combs and removable supers. Beekeepers were furnished lumber gratis for constructing their hives. To further bee-keeping, soldiers and policemen were taught bee-keeping, etc., and were urged to keep bees whenever possible.—American Bee-Keeper.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### CANADIAN BEE-WINTERING EXPERIMENTS.

The wintering experiments at the Canadian Experiment Farm seem to show that when the hive is raised by 2-inch blocks on one side it winters better than when bottom and entrance are left in outdoor style; also, that with 3-inch blocks it does a little better yet. With wet sand below them and a wet sheet over them they were less quiet, but no very great harm seemed to follow. Interesting to see that colonies wintered wholly on sugar syrup, while they did about as well as those wintered on refed extracted honey, used nearly 2 pounds more of it per colony. I should have guessed that they would eat a little less if restricted to syrup of granulated sugar.

Now as to outdoor wintering. Of 2 colonies tolerably well protected with building paper and dead air space, one of them died and one of them went through in moderately good order. We've seen the like of that before. Of 4 colonies packed in a tenement with 6-inch spaces, and the spaces filled with cut straw, all came out in good order. Pages 208 and 209.

### SAINFOIN AS A HONEY-PLANT.

Here's a kick at the Canadians about their sainfoin experiment. The hay-producing part of it was splendid. Incidentally they call it a honey-producer; so I suppose we infer that they saw some bees on it. But, surely, they might have had the grace to tell us how constantly and to what extent bees were seen to frequent it. Those points are of decided interest, and also in dispute. Give us a little

more English, brethren—and don't let the taciturnity of the northern Ojibways affect you so. Page 209.

### SPECIES OF BEES.

The human disposition to find out about things is on the whole a praiseworthy one. We want to know about the North Pole, and about the South Pole; and quite a good few thousand dollars can be had to spend in exploration almost any time. And it kind o' seems to me that mankind should care as much to know just how many and what species of bees the world contains as they do to know what islands (if any) are adjacent to the North Pole. If the authority quoted by Prof. Cook could be called sufficient and complete, we might say the world has nine species of bees. Probably, however, Dr. Ashmead does not claim that his information is complete; and very likely some of his nine will have to undergo considerable discussion before their right to stand as separate species is conceded all around. So, for the present, we have to be satisfied to say that the social bees, akin to the domestic bee, are somewhere near nine in number of species. As to dividing up the genus *Apis* into three genera, I do not at all claim to be a competent judge; but on cat-look-at-a-king principles I will say what I think. I think that the fact that a man is a great scientist does not save him, alas, from the temptation to indulge in mischievous tom-tinkering just because he thinks he can! How many genera and species of dog should we have, if every dog not only had his day but his Latin titles and credentials? *Longi*!

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to Dr. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### Preventing Afterswarms

According to Heddon's method of preventing afterswarms, as explained on page 6 in "A B C of Bee-Culture," how many days from time of first or prime swarm until the young queen will be laying in the parent colony again?

MISSOURI.

ANSWER.—The young queen is likely to be laying somewhere in the neighborhood of 18 days from the issuing of the prime swarm. That time, however, may vary no little. The issuing of the prime swarm may have been hindered one or more days by bad weather, in which case the time will be just that much less than 18 days. The young queen may be slow about meeting a mate, or she may be slow about beginning to lay, making the time longer.

### Alfalfa Honey—Wintering Bees—Extracted vs. Comb Honey

1. Is alfalfa honey of stronger flavor than white clover? I have never sampled both at one time, and the alfalfa honey of Colorado and New Mexico seems to taste much stronger than the (Ohio) white clover product.

2. A hole dug in a bank here and roofed in is far drier than any eastern cement affair. Would it pay to try cellar-wintering? Mercury seldom goes below zero, and bees can usually have a flight every few days during winter, and the honey harvest comes late in the season.

3. For outdoor wintering would it not be easier to number hives (bodies) rather than have the stands numbered?

4. Where extracted honey sells for as much as or more than comb, is a fellow a fool when he produces comb honey? NEW MEXICO.

ANSWERS.—1. There must be a good deal of difference in honey of the same name in different localities. I have eaten a good deal of Colorado and Utah alfalfa, and it is much less pronounced in flavor than white clover.

2. Cellar-wintering would probably not do at all with you.

3. It is convenient to have the same number on the same stand, but also to have the number on the hive-body, changing the number if the hive is put on a different stand.

4. He would seem to lean in that direction.

### Tar Paper—Packing Bees for Winter—Using the Dummy—Comb vs. Extracted Honey

1. Do you think that tar paper used on hive-tops will taint the honey in the hive? I had some honey last year that had such a smoky taste I could not eat it. Do you think the tar paper was the cause?

2. I have been thinking of packing my bees in winter quarters after this with a shallow super over the brood-chamber having a piece of canvas nailed on the top edge of the super, and then pack chaff over that. Would that be too much air-space over the brood if the hive is well packed with a foot of chaff all around?

3. I have some 10-frame hives that will take 10 frames and leave about  $\frac{1}{2}$ -inch to spare for a dummy. Would you crowd a thin dummy into that space, or leave out one frame and use a dummy? or would that then leave too much space behind the dummy?

4. Do you think there is more money in comb honey than extracted, counting the comb you must give with the honey (and which the bees must make again), separators, sections, etc., and also counting, on the other

hand, the cost of extracting-frames, extractor, uncapping-can, storage-tanks, tins and jars, for extracted honey?

I am a young man, and equal to all the necessary conditions of either side of the business, but I wish to find out which is going to pay the better. Personally, I am in favor of comb honey, as the bees put it into a package without any extra work in comparison to extracted. I wish also to say that I consider the privilege of asking Dr. Miller worth double the subscription price of the "Old Reliable." ONTARIO.

ANSWERS.—1. Depends somewhat upon how the covers are made. If there is a board surface or other surface between the tar paper and the bees, there ought to be no trouble. If the tar paper is down next to the bees, it might affect the honey.

2. That air-space full depth of the super ought surely to do harm. Why not nail the canvas on the underside of the super?

3. Put in the dummy—as long as you can. No danger of comb being built behind it.

4. The man that lives inside your clothes is the only man in the world that can settle that question for you. There are veterans who have fairly tried both; and they are very sure they can make more clear money with comb. Other veterans who have given just as fair a trial are equally sure they can make more with extracted. And both are right. The pasturage has something to do with it, and the market. The man has also something to do with it, and your preference for comb makes a difference in your case. Now that's not a very satisfactory answer to one who speaks so kindly of this department; but you see that's one of the things I don't know.

### Preventing Propolis on Sections

I have some old Simplicity hives with section-holders having tin on their side, and find that there is a small space between the top of the section and top of the section-holder. If I should cut the top flat off and trim the end-bars down so they will be even with the sections, and place a super cover over all, will not that stop the bees from propolizing the tops of the sections? Can you suggest a better way? DELAWARE.

ANSWER.—I'm afraid the proposed remedy will hardly work as well as you expect. If you leave no space, you'll find it a hard thing to get the sections in, and still harder to get them out. And no matter how little space you leave, you'll probably find the bees will crowd in some propolis. After "rastling" with that sort of thing for years, I found a remedy in adopting T supers, which leave both the tops and bottoms of sections entirely open. In this locality, at least, bees put less propolis on an exposed surface than where just a crack is left.

### Using Honey from Empty Hives—Robbed Colony—Moths in Hives

About 4 weeks ago I bought out an apiary and all the fixtures pertaining thereto. There were about 25 colonies, with extra hives, supers, shipping-cases, etc. In the unoccupied hives there are a great many frames almost full of nice, clean honey, and I don't know what to do with it. The hives are the 8-frame Langstroth, and there are also a number of partly-filled uncapped sections.

1. Will it be all right to put the supers on with these sections just as they are?

2. Would it be well to put new swarms into these hives, leaving the honey in them?

3. How can I keep this when the hot days come?

4. What ought I to do with a colony when it has been robbed? Last night I found one that had been robbed and gave it a frame of honey, and this evening it is all gone.

5. What will keep the moths out?

WISCONSIN.

ANSWERS.—1. No, indeed.

2. Yes, only not more than a fourth of the comb capacity should be filled with honey.

3. The hot days will do no harm to the honey, only they will encourage the worms that almost surely will be in the combs, and these you must fight with bisulphide of carbon or sulphur. If the combs are kept in a cool, dry cellar the worms will hardly do much harm before time to use the combs for swarms.

4. Generally it is just as well to let them entirely alone, for the colony is likely to be queenless, and the bees so old as to be of no value. If, however, a good queen is present, as shown by the brood, and if there is a fair population, it will be worth while to try to save them. Close the entrance so that only one bee can pass at a time; pile hay or straw close in front and around the hive a foot or so deep, and keep it soaking wet so long as the robbers seem inclined to trouble.

5. Bees; keep your colonies strong, and the bees will keep out the moth, although Italians are better at it than blacks.

### Roaches in Hives—Starters—Salt and Water for Bees—Covering for Brood-Frames—Moving Bees

1. When opening the hive the other day I noticed a number of roaches in the upper story. Is that an indication that anything is wrong?

2. In putting starters in brood-frames, does it make any difference if they are not all of the same width?

3. I notice that some bee-keepers give their bees salt and water. Ought the two to be mixed, or should the salt be given in one dish and the water in another?

4. Would not a white cloth over the brood-frames do as well as a honey-board?

5. I must move my bees a short distance, and they now have a fence in front of them about a foot from the hives. Would you think it necessary to put this fence in front of them when I move them? IOWA.

ANSWERS.—1. The roaches find it warm and comfortable over the hive, and so they like to stay there, but it is not likely they do any harm, for the bees will not allow them among the combs.

2. No, only it would not be best to have one frame filled clear down and another only a very slight starter. It is, of course, better to have all frames entirely filled.

3. Mixed; but if they have plenty of water, they can get along.

4. Yes, only the bees gnaw holes in the cloth. Nowadays neither cloths nor honey-boards are used as much as formerly. Many prefer to have simply a quarter-inch air-space between top-bar and hive-cover.

5. No.

## Reports and Experiences

### Putting Weak Colonies Over Strong Ones

I notice in the item on page 307, in regard to putting weak colonies over strong ones, that the assertion is made that the upper colony loses its field-force not only once but twice. Now I wish to disagree. In theory possibly it does, but in practice it does not. I was one that gave it a trial last spring, and if I remember rightly there was only one other man at the Chicago-Northwestern convention who reported having given it a trial,

and he gave it only a partial one, I believe. It seems to me that if it were so that a colony loses its field-force twice in the same spring a man having the apicultural standing which Mr. Alexander has, instead of having practiced it for 20 years, would have discarded it long ago. He advised practicing it in the following way:

The 2 colonies are back in their normal condition from 15 to 20 days before the first fruit-blossoms open. Then if proper precautions are used it is possible to move colonies a short distance at any time during the season with very little loss. My bees have not had flights this month to exceed 20 hours all told, and today is April 30. The editor of the Review says that the strong ones lost as much as the weak ones gained. I can not entirely agree with him there, as I think that the 2 colonies placed one above the other would be able to keep the inside of the hives at a higher temperature than when placed on their separate stands, as part of the heat of the strong one would, in place of going out of the entrance, help to keep the upper one warm, and the same amount of bees would be able to cover and rear more brood in that way than when on their separate stands.

Then there is another great advantage in protecting the weak colonies from being robbed, which, as every large bee-keeper knows, means something in the spring when the bees have nothing to do but to look for mischief. As for the loss of queens, I think that will be very slight, if proper attention is paid to it, for out of the 36 colonies I treated last spring I didn't lose one. I was very much pleased with the practice, and while I am not as enthusiastic as Mr. Pearce seems to be, I am sorry that I can not give it a further trial this spring, as my colonies are all very strong. But I will certainly give it another trial at the earliest opportunity, and hope that a goodly number of bee-keepers throughout the country will do so this spring. H. F. STRANG.

Oceana Co., Mich., April 30.

### Baby Nuclei

This subject has presented itself as one worthy of consideration through the answer given me by Mr. Hasty, on page 104. I am ready to admit that if queens were reared in baby nuclei they would be poorer queens than those reared in the old way, and those that are hatched in baby nuclei are never better.

### ITALIAN

## Bees, Queens and Nuclei

Choice home-bred and imported stock. All queens reared in full colonies.

But few who use the baby nuclei advocate giving them even ripe queen-cells, and I think it can be done to advantage only when the weather is warm. The man who uses the baby nuclei to advantage is he who *mates* queens in them. The vitality of a queen is not made to depend upon her mating, but upon her rearing.

For the benefit of those who are using, or expect to use, the baby nuclei, I will give our plan. We have cells built in full colonies, and when sealed we place them in a nursery cage in a full colony where there is a laying queen, between 2 frames of brood. Here we have warmth and moisture sufficient to hatch them properly, and they will be fed by the young bees through the wire gauze. Here they should remain until old enough to mate. The reason for placing the cage in a colony with a laying queen is that if it is placed in a queenless colony when the queens are 4 or 5 days old the bees will ball the young queens through the wire and kill them.

I claim that a queen mated in a baby nucleus is the safest queen, and I am not alone in this. Mr. Gill, of Colorado, tells how he lost \$200 through a shipment of queens he re-

ceived, the queens having been taken from full colonies, when they were at the height of egg-laying. If they had come from baby nuclei where they never had an opportunity to reach their full capacity in egg-laying, no doubt they would have proved satisfactory.

While southern queen-breeders are benefited by the use of baby nuclei, I think we have shown that the buyers are benefited also. While queen-rearing is our leading pursuit we have not lost sight of the fact that our success depends upon the quality of the queens that we sent out. We know that the baby nucleus is now receiving its criticism, but the more criticism it gets the more favor will come to it from the investigations drawn out by its users. Be sure it has come to stay. We hope it may prove beneficial also to northern bee-keepers. JOHN W. PHARR.

Goliad Co., Tex., Feb. 19.

## Prospects in Mississippi

Farming operations are moving nicely. Corn is being worked and cotton planted. Melons are up, tomatoes are put out in the field, and peas are being shipped. Cabbage prospects are promising, some beginning to head.

I have had two swarms of bees this spring, one coming out to-day. We keep only a few colonies for our own use. There are so many bees in this part of the country that honey does not sell very rapidly in the local market, often going at 5 cents per pound. Here we also have an abundance of home-made sugar-cane syrup, which to the average southern palate is far superior to the honey.

D. G. ASHLEY.

Copiah Co., Miss., April 23.

## Shook Swarms—Foul Brood

I have read so many things in the American Bee Journal that I feel like writing something to try to help some of my brother beekeepers. I am surrounded by foul brood, and boil everything thoroughly that the bees have used.

I shake my bees every other year, or half of them every year, getting my increase from the other half by natural swarming. I commence on the strongest as early as I think

## Tested Queens by Return Mail, —\$1.00 Each—

We have a large number of Choice Tested Queens, reared last September and October, and wintered in 4-frame nuclei; these queens are vigorous and prolific, and of our fine strain of Three-Band Italians. Just the queens to build up weak colonies. Try them. Send for circular.

**J. W. K. SHAW & CO.**  
LOREAUVILLE, Iberia Par., La.

13Atf Please mention Bee Journal when writing.

they can make a living. I put the brood of the 2 strongest colonies on the weakest one, and so on till I am through. I always put all the bees in the new hive. It saves time and I do not have to look for the queen.

I now have two-thirds of them finished, with no danger of getting foul brood. I will shake the young bees again in 3 weeks. Being shaken so early they have plenty of young bees of their own when the main honey-flow comes. The weak ones are very strong after being shaken, because of the brood that is given to them, so the colonies are all strong in time for the main honey-flow.

When I shake the second time I take out the combs from which brood has hatched, and take them to the honey-house to be extracted, putting the unhatched brood on the weakest colonies as before. If there is any foul brood I lose only the brood on the last one. If there is none I set to one side and shake again in 3 weeks. I run no risks from foul brood. I have shaken 14 colonies this spring, and have seen no signs of it yet. A. T. BAIN.

Tillamook Co., Oreg., April 10.

## Adulterated Honey

I suppose all bee-keepers know that comb honey can not be adulterated in the frame or section, but tons of glucose, with a small piece of comb in it, are sold in Missouri. It is always on sale here in my own town, and has been for years. I have talked with people that had bought it, and they say it has a brassy taste, not fit to eat. No doubt some will say they wouldn't think it could be sold with good honey in other stores close by. Well, I can't explain it, but it is here for sale. I visited a town last year 10 miles from home and found it for sale in two stores. It comes from the wholesale grocers at Kansas City.

If we want to stop such stories as that in the New York Tribune, we probably will have to stop the sale of the stuff. I have never had a sample analyzed, but I am confident that it is glucose. I think the stuff and the blame the bee-keepers bear on account of it

## SINGLE COMB BROWN LEGHORNS

Noted Winter-Laying Strain. Cockerel Mating, headed by Rochester Prize-Winner; Eggs, \$2.00 per 13. Pullet Mating, headed by pullet line; pedigreed; Exmoor males, \$2.50 per 15. do a great deal of harm. We have a very  
strict pure food law here, but as far as the  
bee-keeper is concerned it is a dead letter.

Linn Co., Mo., April 12. IRVING LONG.

### Snowstorm in April—Sweet Clover

We are having a snowstorm to-day, which  
is coming on the fruit-bloom and lots of green  
and tender things that would be better for  
having sunshine.

I have been putting in sweet clover for 2 or  
3 years, and I had begun to feel quite proud  
of my acres of it until I read of the man with  
400 acres. That knocked me right over back-  
ward, for I realize now that I am a very  
"small potato." I have about 40 acres, most  
of which is last fall and this spring seeding,  
so that not more than 1/4 will bloom this sea-  
son. I am not entirely sure, but I think there  
is no blank time here from fruit-bloom till  
frost, and I am quite sure that if all our de-  
pendence was upon white clover I should go  
out of the honey-business. W. H. MILLS.

Boone Co., Nebr., April 15.

### Hiving Swarms—Hoffman Frames

I notice on page 88 an item on sawing off  
swarms. I will give the system I use, which  
never has failed me yet.

In 1903, when swarming was a daily occur-  
rence, upon coming home one night my wife  
met me at the gate with a smiling face. She  
led me into the back yard, and showed me a  
hive under the best peach-tree. I immediately  
realized that the bees had swarmed, and she  
had succeeded in hiving them, which she  
knew pleased me very much, as I have always  
devoted my leisure time to the bees. But,  
dear me! the beautiful peach-tree was a total  
wreck. (I live in town, and have only a few  
nice fruit-trees.) She had made several at-  
tempts to get the bees before she was success-  
ful. But I put on a bright face over it, and  
was thankful that with so much rough hand-  
ling the bees did not get angry, for about 40  
"kida" of the neighborhood had gathered  
around to witness the performance, but no  
one had been stung.

The next swarming occurred on a Sunday  
when I was at home. The swarm settled in  
an apple-tree where it was almost impossible  
to get to it without sawing half the tree down.  
I picked from a hive a double black cloth  
about the size of the hive, which had been  
used as a sort of quilt over the bees, and was  
saturated through and through with propolis.  
I wrapped this around a pole long enough to  
reach the cluster, then shook all the bees off  
at once, and held the pole there, and all set-  
tled on it. I shook them in front of the hive,  
and all went merrily in. This pole set up in  
a tree near where the bees are likely to settle  
when they are swarming, causes them to  
sometimes alight on it, or if it is held where  
they seem to be getting ready to settle, they  
will settle there at once. It has never failed  
with me, and I would like some one else to  
try it, and let me know with what success it  
is used. I am sure it will save many a nice  
fruit-tree, lots of dangerous climbing, and  
much time.

On page 108 I notice an article on Hoffman  
frames. I have used many different kinds of  
frames, but will discard all but the Hoffman  
just as soon as possible. I have only one fault  
to find with them, which I have overcome, so  
I consider them the best I have used yet. In  
handling colonies in summer when time is  
money, things must go quick. I find in first  
removing the frames I have some trouble in  
getting particular frames out quickly, and in  
putting them back I find, especially in large  
colonies, that as many as 7 or 8 bees can be  
crushed. I have about remedied the trouble  
in both cases by removing about 3/4 of the  
bearing space of the beveled bar, leaving at  
the bottom about half an inch and the same  
at the top. It does not change the spacing a  
particle. The frames are very easily removed  
anywhere in the hive without any trouble,  
and it lessens the bee-killing qualities about  
95 percent. I think if the frame was made in  
this way it would meet with much greater  
favor—at least none go into my hives without  
this change. FUS MONR.

## Honey and Beeswax

CHICAGO, April 18.—A carload of comb honey, (said to be from Colorado) came on the market about the first of the month. It was placed with a firm that does not make a specialty of honey, and to some extent has upset prices when looked at in print. It is put up in 24 section flat cases with wood slides instead of glass, and is more or less candied. Choice white comb brings 12½c; No. 1, 11@12c; amber, 8@10c. Extracted, white, 6@7c; amber, 5½@6½c; price being governed by quality, flavor and package. Beeswax 30c if clean and of good color.

R. A. BURNETT & Co.

CINCINNATI, April 20.—The condition of the honey market to-day are not encouraging. The consumption is lacking, although we are looking forward to brighter days in the honey market. We continue to quote amber extracted in barrels and cans, 5½@6½ cents; white clover, 7@8c. Fancy white comb honey, 12@13c. Beeswax, 28c. THE FRED W. MUTH CO.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c. HILDRETH & SROELKEN.

PHILADELPHIA, April 19.—There has not been much call for honey in the last two weeks. Prices remain unchanged. We quote: Fancy white, 11@12c; No. 1, 10@11c; amber, 9c. Extracted, white, 6@7c; amber, 5½@6c. Beeswax, 28 cents.

We are producers of honey and do not handle on commission. WM. A. SELSER.

BOSTON, April 24.—The demand for honey is light and the supply is, we would consider, heavy for this time of the year. Without question, much will be carried over to another season as the sales have been, generally speaking, light through the entire year. Fancy white we quote at 16c; A No. 1, at 15c; No. 1, at 14c. Extracted, from 6@8c, according to quality. BLAKE, SCOTT & LEE.

KANSAS CITY, March 31.—The honey situation does not improve. While there is a little better movement the prices seem to be lower. Fancy white brings \$2 a case; No. 1, \$1.75; amber and lower grades from \$1.25 to \$1.50. Extracted, 4½@6c. Beeswax, 28c. C. C. CLEMONS & Co.

CINCINNATI, O., April 18.—The large stock of comb honey, yet offered with hardly any demand, caused lower prices. I quote fancy water white at 12c; other grades in proportion, lower.

Extracted is in the usual demand for this time of the year; quote amber in barrels at 5½@5¾c; in cans, ½c more; white clover, from 7@8c. Beeswax, 28c. C. H. W. WEBER.

ALBANY, N.Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6½c; white, 6@6½c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c. H. R. WRIGHT.

SAN FRANCISCO, April 26.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted—white, 5½@6 cents; light amber, 4@5c; amber, 3@3½c; dark amber, 2½@3c. Beeswax—good to choice, light, 29@30c; dark, 27@28c.

There are no heavy quantities on the market but more than can be placed at full current rates. A shipment of 150 cases was made by steamer to Belgium and 68 cases to Germany.

## Prompt Shipments! Full Stocks! Quick Time! Low Freight!

Now is the time the average bee-keeper wants Supplies, and wants them quick! Now is the time the advantages offered by the A. I. Root Company are most apparent. With branches and agents in all principal bee and railroad centers the time consumed between the mailing of the order and receipt of the goods is reduced to a minimum. Write to the nearest branch or agent for Catalog. Remember our prices are as low as consistent with good goods, and that we are the leaders in improvements. Complete information on request.

### The Latest Improvements in Honey-Extractors

ROOT'S AUTOMATIC 8 FRAME HONEY-EXTRACTOR CONNECTED TO RUN WITH A SMALL GASOLINE-ENGINE

The long-wished-for practical Automatic Reversing Extractor has at last been found. The Root Automatic solves the question completely. No complicated mechanism; it is simplicity itself. All orders for 4-frame Cowan or larger will be fitted with the Root Automatic at the regular price of the Cowan.

When a bee-keeper has a large amount of extracting to do, requiring a large machine, an Engine for running the Extractor is almost a necessity. To furnish power in such cases we are prepared to supply a small Gasoline Engine, specially built for this work. If you are interested write for complete description and price.

#### Best Book for Beginners

Arranged in the form of an encyclopedia so that any information can be found in an instant. The subjects are completely covered, and brought completely up to the times by constant revision. The book is beautifully illustrated by the finest half-tones. 100th thousand. 1905 edition. Price, \$1.20, postpaid.

#### Bees and Queens

We are prepared to furnish Nuclei and full colonies of Italian Bees. Also our Red Clover and Honey Strain of Italian Queens, as well as Imported Queens. Upon the queen depends the prosperity of the colony. See to it that your queens are young and vigorous, and the honey is sure if there are flowers. Write for our price-list.

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., MAY 18, 1905

Vol. XLV—No. 20

THE AMERICAN BEE JOURNAL is absolutely an independent publication, and not connected with any bee-supply business whatsoever. It stands entirely upon its merits as an educative force in the field of bee-keeping, and as a medium for legitimate advertisers in apicultural or other lines. It is the oldest, and only weekly, journal of its kind in America. Its publishers believe that it deserves to be in the hands of every would-be progressive successful bee-keeper in the land. It is in its 45th year, and to-day is acknowledged to be better in every way than at any time during its long and honorable history.

## Editorial Notes and Comments

### Bee-Keeping Being Recognized

More than ever before is bee-keeping being recognized as a rural industry that deserves consideration on the part of those who are seeking a healthful as well as fairly remunerative outdoor occupation. We are led to this remark on account of the large space recently devoted to instructive illustrated articles on bees and bee-keeping in such magazines as *Country Life in America*, *The House Beautiful*, *Country Calendar*, etc. The last-named publication is a new one beginning with the May (this month's) number, and the large edition printed was sold almost before it was off the press.

So it seems that bee-keeping is just beginning to be appreciated. Like poultry-raising, only within a few years has it been developed, and to-day see to what wonderful proportions it has grown.

As our country grows in population, more and more will the smaller rural industries be developed, and so bee-keeping will come in for its share of the increased interest and consequent enlargement of its borders.

All this should increase the general demand for honey as much, perhaps, as it will augment the size of the crop produced. But what is most needed is that those who are led to embark in bee-keeping through the recent published articles shall be impressed with the necessity of thoroughly informing themselves on the subject if they expect to make a success of the work. Otherwise they will simply invite failure, and thus become disgusted with the pursuit.

By avoiding too high an idea of the financial possibilities of bee-keeping, many will save themselves a far and rapid fall, with its resultant bump.

The thing for all new recruits to do is to "make haste slowly," and thus be more likely to differ from the mushroom in their growth and lasting qualities as bee-keepers.

### Unripe Honey—Quality vs. Quantity

Mr. R. A. Burnett, of R. A. Burnett & Co., of this city, who has had over 25 years' experience in handling honey, writes as follows:

I have just read the article by Mr. E. D. Townsend, on "The Importance of Having Ripe Honey When it is Put Upon the Market."

In the autumn of last year we sold a barrel of honey to a man who would use about 500 pounds per week. We had sampled one of the barrels of the lot and found it to be well-ripened honey, but as the lot was from different producers, having been consigned to us by a dealer, the barrel which he got proved to be of a low quality in flavor, wholly from the standpoint of having been extracted when the honey was not cured sufficiently to give it flavor, or prevent its separating so that there was about half a gallon of water in the barrel that had been exuded during the candying process. This caused the man to return the package, and the so-called water in a can. We endeavored to satisfy him by offering to substitute another package for it, but he felt that he could not afford to risk it, and said he had great difficulty in getting honey outside of one producer, whom he knew always had good honey. The result of it was, we lost a customer for honey, and the man who sent us this unripe honey missed the sale of several hundred pounds of his product.

It is our opinion (which we have voiced for some years) that unripe honey has had more to do with the curtailment of its use by people generally than any other things combined, for when a person gets a coarse-grained, flavorless extracted honey, he does not like to throw it away, nor to return it to the vender, but keeps it around until everybody in the family tires of seeing honey, and gets out of the habit of using it, sometimes for years.

If we fail to give people a good article, it will be time thrown away to try to convince them they should buy more of it. Producers of honey should be free from commercial selfishness to the extent that they should seek quality before quantity. We will venture the opinion that if the honey to be gathered in 1905 will be allowed to ripen in the hives before being offered for sale, the consumption of honey will be greatly enhanced, and also, if that is kept up without variation for the next five years, the amount consumed will be double what it has been in the past five years.

It seems to me the remedy is very simple, in the fact that it lies wholly in the producer's hands.

In conclusion I will say this: That beginning with the crop of this season, any unripe honey that comes to us will not be offered for sale, but held subject to the owner's orders. It might be that a unanimous understanding to this effect among honey-dealers would be a most effective means of stopping the unwarrantable greed of the producer who endeavors to market a product that will bring him money at the expense of all intelligent and honorable producers.

R. A. BURNETT.

We think that Mr. Burnett's suggestion is a good one, that all honey-dealers agree not to receive unripe honey. Certainly they have it in their power to stop the shipment of such honey, and by all means should do so. Of course, no sensible bee-keeper would think for a moment of bottling unripe honey for the retail trade. If he did so, he would soon have no demand for it. And not only that, but such stuff will always kill the desire for any more honey of any kind. Unripe honey disgusts the consumer, and, in the end, is a loss to all concerned.

This danger is one that must be considered should the National Association ever furnish labels to its members. It could not afford to allow its name and guaranty to be used by any bee-keeper who is such a fraud as to put unripe honey on the market, knowingly.

### The New Honey-Producers' League

Under this heading Editor W. H. Putnam, of the *Rural Bee-Keeper*, has this to say:

Bee-keepers and farmers have been for a long time learning how to produce honey. The industry has reached a critical point, where the supply seems to be greater than the demand. We, as bee-keepers, have been producing, we have sold our product for what it would fetch. Certain natural conditions have arisen which have brought up the price of supplies. Bee-keepers all over the land have entered a protest, and all agree that the price of supplies is too high compared with the price of honey.

All dealers and manufacturers have heard so much about this subject that they have looked about for a remedy. They find that very few people comparatively are users of honey, and a great many do not even know its taste. They find cheap syrups (composed mostly of glucose) in every retail store, and flaming advertisements declaring that this poisonous concoction is better than honey. Many farmer bee-keepers are letting their bees go to the woods rather than buy hives and supplies at the present scale of prices.

As every manufacturing industry must depend upon the prosperity of the consumer or producer, and one upon the other, the con-

sumer of bee-hives being the producer of honey, it was lately decided by some leading manufacturers and bee-journal publishers and honey-producers living in the vicinity of Chicago, Ill., that something must be done. The following article from the Secretary will explain what has been done. The next step will be, will the bee-keepers of this land take interest enough in their own business to cooperate with those who have taken the initiative in this movement to increase the demand and the price of honey? You will notice from reading the Constitution that the burden falls heaviest upon the manufacturers of supplies, and you will notice that they will do their utmost to support this movement. Why? These manufacturers are constant advertisers; they know the benefits to be derived from advertising, and they are willing to spend their money in that direction. We all know that there are approximately 100,000 people engaged in honey-production to one manufacturer of supplies. The manufacturers and editors can act only as a nucleus. The bee-keepers must swarm to make this movement—their movement—a success.

The selection of George W. York, of Chicago, as General Manager of this League is very opportune. Editor York is an advertising specialist, and a careful business man. We may all rest assured that our money will be well invested in advertising.

W. H. PUTNAM.

Then follows a copy of the Constitution and prospectus as they appeared in these columns a few weeks ago. We are glad the League is to have such hearty support as Editor Putnam indicates in the foregoing. We trust that, as he suggests, the bee-keepers will come to the defense of their own business, and join The Honey-Producers' League by the thousand. Surely, something needs to be done to stimulate a more general demand for honey.

### Best Hive-Entrance for Bees

"Swarthmore" says in the American Bee-Keeper:

Bees prefer a one-inch auger-hole to all other forms of entrances. This may be proven by boring a hole into the back of any hive having a slot entrance at the front.

It might be worth while to know whether this is really the case; for, other things being equal, it is well to concede something to the preferences of the bees. Have any tried the experiment of boring a hole into the back of a hive having a slot entrance in front? and, if so, with what result? Yet if the bees should not take kindly to the new entrance at the back, it would hardly be proof that they have no preference for a round hole, for bees are creatures of habit, and are more likely to continue using the old entrance from habit, even if the new be better. If, however, they should show a preference for the new entrance, there would still remain the question whether the preference was due to the shape or the location of the entrance. A number of different experiments might be necessary to decide as to any positive preference.

Mr. C. G. Chevalier, of Maryland, sends us the following, taken from the Philadelphia Press, under the heading, "Nothing Serious:"

Farmington—Ah! there's that old poem about husking bees. I always did like that. Dumley—Husking bees? What do you mean?

Farmington—Why, were you never in the country during the season of husking bees?

Dumley—No. How in the world do you husk a bee?

It seems to us that it might be something "serious" were one to try to "husk a bee."

## Miscellaneous News Items

Mr. Geo. E. Bacon, representative of The G. B. Lewis Co., when in Chicago on business last week, made this office a brief call. He reports a good business in bee-supplies at their factory.

**A New Bee-Editor.**—Arthur C. Miller has made his editorial bow in the American Bee-Keeper as associate with Harry E. Hill, who, for more than seven years, has occupied alone the tripod. Mr. Miller is well known as a vigorous writer, and the editorial utterances of the American Bee-Keeper, which have been by no means of the insipid order, are not likely to fall off in interest because of the new associate hand at the helm.

**The W. T. Falconer Mfg. Co.,** of Jamestown, N. Y., are the largest manufacturers of bee-keepers' supplies east of Ohio. We had the pleasure of visiting their splendid establishment last November. We began our tour of visiting some of the bee-supply manufacturers early last fall, and the Falconer Company was the one we closed our trips with at that time, though there are several more of them in the West that we want to see a little later on.

We were received by Mr. Falconer and Mr. Merrill with true Eastern cordiality. The former devoted all his time to us while we were there, taking us through the large factory, and showing us a great deal of their work in detail.

Besides bee-supplies, they make a great many advertising novelties and school sup-

plies. They seem to be equipped to make almost anything and everything in wood. And their workmanship is simply superb. We believe we saw the most highly polished sections and some other articles that we ever saw anywhere. They were "as smooth as glass."

Mr. Falconer gave us quite a number of samples of their goods—in fact, he would have loaded us up like a country pack-peddler had we not declined most of his generous donations of samples. They were all so unique and beautiful, especially the advertising novelties and school appliances. We have since been able to make very happy several of our friends among the neighbors' children to whom we presented the samples, unfortunately not having any living children of our own. But we can assure The Falconer Company that their kindness to us we endeavored to "pass on" to others, and it was appreciated all along the line.

We are glad to be able to present to our readers the pictures of Mr. Falconer and Mr. Merrill, and also of their factory. We wish we could tell something more about the two gentlemen personally, but our repeated requests for biographical matter were good-naturedly declined, and so we and our readers will have to be satisfied with their pictures, both of which we think are excellent.

Should you ever go to Jamestown, N. Y., don't fail to call on The W. T. Falconer Mfg. Co., located at "Falconer," a delightful suburb about 3 miles east of Jamestown. You will receive a hearty welcome and most generous treatment. We did, and hope to go again some day.

## Some Expert Opinion

### Fresh Comb Foundation vs. Old

**Ques. 26**—How much better is fresh foundation than that which is a year old?

ADRIAN GETAZ (Tenn.)—None at all.

G. M. DOOLITTLE (N. Y.)—Not an iota.

L. STACHELHAUSEN (Tex.)—No better at all.

O. O. POPPLETON (Fla.)—In my practice, no better.

R. C. AIKIN (Colo.)—I never could tell any difference.

JAS. A. STONE (Ill.)—Very little, if kept from dust and light.

EUGENE SECOR (Iowa)—I don't believe there is much difference.

J. M. HAMBACH (Calif.)—No better, if you will steam the old foundation.

E. D. TOWNSEND (Mich.)—No difference, other conditions being the same.

MRS. J. M. NULL (Mo.)—No better if the latter has never been on the hive.

MORGAN BROS. (S. Dak.)—There is no difference if kept in a warm, dark place.

N. E. FRANCE (Wis.)—No better, if the old is tempered or warmed a little before using.

C. P. DADANT (Ill.)—Not a particle. On the contrary, the latter may be a little more firm.

R. L. TAYLOR (Mich.)—But little if any better if the old has been carefully kept from dust, etc.

ARTHUR C. MILLER (R. I.)—None, if the latter has been kept in a close package away from the air.

E. E. HASTY (Ohio)—I don't know, but as a matter of business I would pay 10 percent more if buying.

REV. M. MAHIN (Ind.)—I have not noticed any difference between that just made and that several years old.

WM. McEVoy (Ont.)—I never found the fresh any better than the old when I dipped the old in water not too warm, just before using it.

P. H. ELWOOD (N. Y.)—When well kept in sheets, not very much difference. After having been on the hives, with us, as a rule, it is better to use fresh.

PROF. A. J. COOK (Calif.)—Practically I could never see much difference. Of course I should prefer fresh foundation, but I am not sure that it is any better.

G. W. DEMAREE (Ky.)—I really can't say, but I used last year some foundation over 5 years old, and it gave perfect satisfaction, but it had been in a close box all the time.

DR. C. C. MILLER (Ill.)—I suppose the fresh ought to be a little better, but hardly enough to notice the difference. I've used

sections that had been filled with full sheets of foundation for five years, and they seemed to be as good as any.

E. WHITCOMB (Nebr.)—I have not been able to notice any difference. What we might call "fresh" may have been made a year or more before we came into possession of it.

C. H. DIBBERN (Ill.)—If it has not been exposed to light and air, it is no better. If the foundation is in the sections, and has been more or less soiled by the bees, it is not so good.

C. DAVENPORT (Minn.)—I don't believe

there is any difference. I have some that will be 2 years old this season, and I would not give a cent a pound to exchange it for fresh-made.

S. T. PETTIT (Ont.)—I have used it at different ages up to 7 years old, and could see but little difference, if in the meantime it had been kept wrapped or boxed up from exposure to light and air.

J. A. GREEN (Colo.)—Guided by my bees' preferences, I prefer the fresh foundation, but it would be difficult to say how much difference there is. If the foundation has been left packed as it came from the factory—

protected from air, dust and light—the difference is very slight. If it has been exposed to these agencies, it may be considerable.

Dr. J. P. H. BROWN (Ga.)—Pretty hard to determine the percent of "how much better?" Bees take quicker to the fresh foundation because it is softer than the old. If the old is warmed and softened bees will work it quite as readily as the new.

E. S. LOVESY (Utah)—If it is made of pure beeswax, and if rightly made and nicely packed and preserved, I know of no difference. The greater portion of the foundation I used last year was 5 years old, and I never used any that gave me better satisfaction.

### Hive-Buying and Hive-Making Symposium

#### A Few Opinions on this Important Subject

##### MAKING OR BUYING HIVES.

I have been interested in the controversy regarding making or buying hives. I made 8 hives with 2 supers each, and the same cost me \$12.05 in the knock-down, where last year hives of better material and one super only cost me \$1.15 each, freight paid. So, hereafter, when I want any hives some manufacturer will get my order.

Henry Co., Mo., May 5.

F. P. DAUM.

##### HOME-MADE VS. FACTORY-MADE HIVES.

This, like any other question, has two sides to it. Judging from the recent articles in the Journal the question seems to be nearly settled in favor of factory-made hives.

I believe that for the man who has from 10 to 15 colonies, and has not previously had some kind of power and machinery on hand, it would certainly pay him to buy his hives from the factory. I do not think a man could make more than one 10-frame hive complete in a day with frames, bottom-board, cover and dummy, unless he had some kind of power and machinery. Counting that man's time worth, say \$1.50, and the lumber and nails which will amount to 50 cents more, he has a hive which costs him \$2.00, and very likely when he tries on the cover of some other hive, or its frames, he would sell his hand-made hive for \$1.00.

But I think, on the other hand, that for the man who intends keeping bees as a business, and has from 25 colonies up, it would certainly pay him to buy a saw and some kind of power, and manufacture his own hives. By taking care in regard to gauges and measuring all parts before they are nailed together, he would have as good a hive as he can get from the factory, and I know from experience that one man can cut out material enough for 10 hives in one day. Counting that man's time as before at \$1.50, and the lumber and nails at 50 cents per hive, he has a hive which costs him about 65 cents. The difference in this price from factory-made hives would soon pay for a man's machinery.

To sum up: I think a man with a few colonies (as it would not pay him to install machinery) would better buy his hives. But a man with from 25 to 50 colonies would save a good many dollars in buying the necessary machinery to build hives.

Of course, there are such things as sections, separators, etc., which it would not pay us to try to make, although I may just add I saw-cut my own plain separators.

Ontario, Canada.

TOM THOMPSON.

##### MAKE HIVES OR BUY—WHICH?

"How are you, Mr. Smith? Did your bees go through the winter well?"

"Yes, Mr. Brown, they came through all right, but I hear everything is so high in the bee-supply line that I have decided to sell out."

"Yes, it is true there has been lots of talk on the subject in the bee-papers. I always try to look on both sides of a

question, and especially on this one, as I have kept bees myself for the past 25 years. Of course, Mr. Smith, when you come right down to it, they've 'got us' on sections, and the less we say about that the better. We pay \$5.00 a thousand for them, and get 70 pounds of wood which we sell at all the way from 10 to 20 cents a pound along with our honey. Suppose we get only 10 cents a pound for it, we receive \$7.00 for what we pay \$5.00, and we are \$2.00 ahead on it at that.

"Last week I had to go up in Wisconsin to see my daughter, and as I happened to be near a town which has a large plant devoted to the manufacture of bee-supplies, I thought I'd just take a run up there and go through it. I was surprised to find so much lumber piled up all around. There must have been thousands and thousands of dollars worth there lying in a pile. Well, sir, I went through the factory from beginning to end, and watched about a hundred men at different machines, each man doing his little part. I saw one machine used just for piercing end-bars for Hoffman frames, and they tell me the cost of such a machine is about \$500. One thing I noticed particularly, and that was the packing department. I saw three or four girls doing nothing but packing up nails. They do this all day long, and these nails are sent along with the hives to nail 'em up with. Why, I remember the time, years ago, when all we got to our hives was a lot of boards, supposed to be parts of the hive, and then a lot of frames were thrown in with these boards, and then when you got 'em you didn't know what you had. The lumber was poor and knotty. Nothing was marked to show what fit on what, and when you did put 'em together they wouldn't fit. Why, land of goodness, man, nowadays when a bee-keeper gets a hive from one of these big factories you'd think he was expecting a piano. If there's one-eighth inch difference in any one part he kicks, and they told me up there that a lot of these people ship the goods right back if they happen to be a sixteenth of an inch out of the way, and they aren't very often. When a man gets a hive nowadays he receives nice, clear white pine, every part marked and done up in packages, and then he gets a set of directions for putting the parts together, so that he couldn't make a mistake if he wanted to. His frames and inside furniture are all systematically put up. He is furnished tin and wire nails and everything he can need, even directions which tell him how many nails to use in every board. In fact, he gets everything, as a fellow told me the other day, but the hammer to nail 'em up with. And in the catalog all this means a hive.

"Yes, I know hives nowadays cost more than they used to, and some say they have doubled; but when I got on the train I was more perplexed than ever over this bee-supply proposition, only this time I couldn't figure out how they can afford to sell 'em as cheap as they do."

JOHN ALLEN.

Lake Co., Ill.

##### MAKE OR BUY HIVES—WHICH?

I consider the American Bee Journal entirely right and most wise in recommending bee-keepers to buy their hives. (See editorial, page 291-292.) Yes, even to recommend that the "man who is exceptionally skillful in the use of tools, who makes hives in times that would be spent in the corner grocery, so that really nothing would be counted for his time," to buy his hives ready to nail together, rather than to make his own. Take a 2-story hive for comb honey, and there will be from 92 to 452 pieces in the completed hive. Now each and every single piece must be accurately measured, nearly every piece measured separately, which takes a great amount of time and is excessively tedious. I am considering the matter from the standpoint of making every hive in the apiary exact duplicates, so that any single piece of any hive will absolutely and perfectly fit any other hive, which, I think, every one will agree is what ought to be done by hand—another tedious job; then each piece must be planed on all four

of its sides; and it will take an exceedingly careful and an extraordinarily good carpenter to make 100 pieces anywhere near mathematically alike. Even if he is so clever as to be able to do this, I still hold that he is wasting his time, for so expert a laborer could obtain the biggest kind of wages for his work, enough in a week to enable him to buy 30 or 40 hives.

No, sir! the best carpenter—the best cabinet-maker—using the best lumber to be had, is still wasting his time in making his own hives; and the better workman he is the more he is wasting when he tries with hand-labor to compete with machinery in turning out exact duplicates of anything. It takes too much time, entirely.

I would not think of making all my own hives, though I have the necessary tools and ability to do so, but will continue to buy till present prices are at least doubled, and I don't know that I would make my own even then. *Buy your hives* with every part accurately cut—to fit perfectly where each is meant to go, and to be interchangeable with any and every hive in the apiary. And this even without considering the question of cost. For the manufactured hives all cut by machinery are so far ahead of any that can be made by hand that they should be, and are, worth more money.

I can, and have, made exact duplicates of the manufactured hive, but at such a cost in time and labor, without counting the cost of the lumber and the waste of lumber, that I decidedly consider the hand-made hive, *when made as accurately as the machine-made hive*, to be absolutely prohibitively expensive. "A BEE-KEEPER IN VIRGINIA."

Augusta Co., Va.

P. S.—I have no connection with *any* manufactory, nor any supply-house, and am in no way concerned with the sale of any single appliance used by bee-keepers.

#### HOME-MADE BEE-SUPPLIES.

I have been quite interested in the controversy relating to bee-keepers making their own bee-hives, supers, etc., some claiming the manufacturers are charging too high a price for their goods, others that they can be made for less, and that, besides, one does not make as good an article as the factories turn out.

I have made my hives and fixtures for two years, and I am sure it pays me *well* to make them. I do not make them all by hand. I made a machine which cost me \$3.00 for foundry work, and \$2.00 for two 8-inch saws—\$5.00 in all. It is very much the same as the foot-power machines advertised, only mine has the table rigid. I raise and lower the saw by a treadle, with stop to prevent cutting beyond the proper depth, and when through it drops below the table out of the way. Or the saw is made rigid by tightening a thumb-screw, holding the saw-frame solid between the legs of the machine. My saw is run by a power wind-mill 16 feet. The saw makes as many as 5000 revolutions a minute, and cuts as smooth as a plane.

To make 4 supers, I take one board 10 inches by 12 feet—second clear lumber, costing \$26 per 1000 feet, which would make the one board cost 26 cents; 8 flat tins 4 cents—total, 30 cents, or 7½ cents per super. These are listed in most of the catalogs at 10 in the flat for \$4.00. The same things cost me 75 cents. Of course I have made no account of work, but as I could cut out 300 supers a day, that would not increase the cost very much, even if my time was very valuable, which it is not. This estimate applied to hives holds equally as good. Thus, it would seem that there is a fine profit for somebody. Of course the large bee-hive concerns probably get their lumber cheaper than I do, but they are to an enormous expense for machinery, skilled labor, and many other items which go to swell the amount.

I am not finding fault with the prices quoted by any manufacturer of bee-supplies. I simply claim that it pays one to make his own hives and fixtures as far as he can. There are some things that it is better to buy than to make, such as sections, fences, and wond or tin separators. I would not want to make my own hives by hand-work alone, but would rather pay the prices asked than to tackle that, as it makes me nervous. I tried it once. I should like to hear through the American Bee Journal from others who have tried making their own hives.

A. D. HUSON.

Sheboygan Co., Wis., April 24.

**Some Facts About Honey and Bees.**—This is the subject of an article written by Mr. J. E. Johnson, and published on pages 581-82 of the American Bee Journal for Aug. 25, 1904. We have republished it in 4-page leaflet form for general distribution, and furnish it, postpaid, at 35 cents per 100 copies. Send all orders to the office of the American Bee Journal

## Season of 1904—Swarming Management

BY C. DAVENPORT

THE honey crop here last year was light, and the word "light" in this case may be used in a double sense, as the crop was light in quantity and color. Hardly any dark or amber honey was gathered last fall, and last winter, or rather spring, there was a severe loss of bees. With one exception I never had bees spring dwindle like they did last spring. What caused it is more than I know. The weather and early spring flows were not very favorable. But I have seen the conditions worse, when no spring dwindling to amount to anything occurred. The previous fall enough fall honey was gathered to keep brood-rearing up in good shape, so it was not the lack of young bees that caused this loss last spring.

I have noticed that a good many think that if no fall honey is secured to keep up brood-rearing late, so that the colonies go into winter quarters without many young bees, that spring dwindling will, or is apt to, result. This looks very reasonable, and may be the case in most instances.

But I well remember one fall when no fall honey was gathered, and brood-rearing stopped earlier than I ever knew it to do before or since. I expected that there would be a heavy loss the next spring, but I never had bees come through the spring, or build up better, than they did.

I think that it was 10 years ago last spring that there was the most severe spring loss of bees around here that there has been in my time. The late Mr. B. Taylor, the most prominent apiarist in our State at that time, in writing about his severe loss, said that it was his Waterloo. Mr. Taylor thought that the great loss was because not enough young bees were reared late the previous fall; but in my own yards enough fall honey was secured to keep brood-rearing up late, so in neither case was it a lack of young bees that caused my own severe loss of bees by spring dwindling.

Now, owing to the loss of bees last spring, and the light crop gathered by what were left, the season was, in a financial way, the poorest I have known in a good many years. In other ways though—"those things we would not sell for money"—it was far different.

In the first place, I have finally found a *practical* way to render comb into wax and secure all the wax, no matter how old the comb is. I have spent what is, for a bee-keeper, a large amount of money, besides a large amount of work and time, over this problem, and I am glad to say that I have solved it. No machine or screw press is used, yet I can render more wax from *any* kind of comb and leave less wax in the slumgum than can be done with any press machine that is made, or can be made and operated by one man.

But this is a small matter compared to what I learned, or rather verified last season in regard to artificial swarming. As a good many who will read this know, I am a specialist, and devote my whole time to our pursuit, and that I have for a good many years practiced artificial swarming. Some 10 or 12 years ago, in the American Bee Journal, I described my method, which was, in brief, to remove all the brood. Not much attention was paid to it at the time, and what comment there was about it was unfavorable, but of late this matter has been given a good deal of prominence in all our journals under the names of "shook" or "brushed" swarms. Of course, it makes no difference whether the bees are shaken or brushed, the essential principle is to remove all the brood, for if all the brood is not removed, the colony, if it has contracted the swarming fever, will be very apt to swarm in a few days if only one frame is left. I preferred this method to natural swarming, but one very great objection to it is that a colony swarmed by this "shook" or brushed plan is very apt to swarm out again the next day, and sometimes they will swarm out a number of times before settling down to work; and in some cases, if they do not swarm out, they sulk or refuse to work much for a number of days. And, again, others "swarmed" in this way *never* work with any vim or energy.

But the swarming out is the worst part, for in a large yard, where a large number of colonies have been swarmed one day, the next day there may be a dozen swarms all out in a snarl together. Here, just as sure as fate, if a colony is swarmed by this method, after they have a queen-cell sealed they will swarm out. I never knew an exception to this in all the years I have practiced swarming in this way. There must, though, be a difference—shall I use our old stand-by, "locality?"—in regard to this swarming out, for some have reported through the journals that they had no trouble in this respect, while others have had, and last fall, while at our State Fair. I met a good many bee-keepers from this State, and also a number from Wisconsin, and I talked with all of them about

this, and every one of them that takes a bee-paper had tried this shook-swarm method. Some had trouble with swarms deserting, and some because they would not work, and I met only two who called the method a success.

I have for years, during the swarming season, thought, studied, worked, and even dreamed nights, about some plan or way that colonies could be swarmed so as to overcome the objections I have named, but even in my dreams I never hoped or expected to obtain the success I have secured. In reality, though, no credit is due me, for it was not any of the countless plans, methods, or devices I tried with this object in view that was the means of my discovering this method—a method or plan which is such a singular success that I suppose but few will believe what I shall say about it. At least I, who have spent practically all my life with bees, would not believe what I shall say if I had not the proof of my own experience.

A year ago last summer I was going to "swarm" a colony, but upon examining the bees I saw they had two or three queen-cells, so, as I knew that they would swarm out the next day anyway, they were not swarmed in the regular way; simply in order to save work they were handled in a different way, and I expected, of course, that they would swarm out, but they did not, though I could hardly believe the reason was on account of the way they happened to be treated. But the fact remained, that instead of swarming out they went to work with all the vim and energy of a natural swarm that is fully satisfied with its new home.

Southern Minnesota.

(Concluded next week.)

## Best Bee-Hive—Prices of Bees

BY DR. G. BOHRER

ON page 21, Mr. Latham asks what is the best bee-hive, and uses all his argument in support of two objects, one being the closed-end frame, and the other a frame hanging crosswise of the hive.

If there is any advantage in favor of the closed-end frame the standard Langstroth can be made in that way, or the Hoffman can be made with the entire end closed quite as easily, and at little, if any, more expense than the way we now have it. In wintering on the summer stands a closed-end frame may afford a slight advantage, but I doubt it, for the reason that if the walls of a hive were made so as to have two or even three dead air-spaces the combs would be covered with frost in cold climates, if left on the summer stands over winter.

The first and most important point to be looked after in outdoor wintering is to keep the bees from rain, snow and wind. Then with sufficient honey for their subsistence within easy access, they will winter through several weeks of zero weather. But if they are cut off from their stores by frost they will starve out. The crosswise frame as used by Mr. Latham has no advantage over the standard Langstroth frame, except possibly a very slight one which is in the matter of its being 2 inches deeper, and of course will put the

honey directly above the bees. What the Langstroth frame lacks in depth it a little more than makes up for in length for honey space, which, with the rear end of the hive being raised 2 to 4 inches higher than the front makes the honey about as accessible to the bees, if not fully as much so, as it is in the crosswise frames.

I talked to both Mr. Langstroth and Mr. Quinby concerning the difference between the length and depth of their comb frames. Mr. Langstroth took the ground that the depth and length of his frame, with 10 frames to a hive, afforded about as much space in the brood-nest as the average queen and colony could populate, and yield a profitable surplus to their owner, and that the space on top of such a hive was ample for storing a large surplus. Mr. Quinby held that in New York, where he lived, and north of that, the winters were severe and protracted, and that he felt that to add about 2 inches to the depth of the Langstroth frame, and one inch or more to the length, would make the matter of wintering on the summer stands somewhat safer than would be the case with the shallower frame. He, of course, like Mr. Langstroth, advised that the rear end of the hive be raised several inches, which would place the stores more nearly directly over the cluster of bees.

The cost is admitted to be greater in the crosswise hive, and also that it takes more time to handle the frames. As to a greater current of air having access to the bees in the Langstroth hive than in the crosswise-framed hive, there is certainly little, if anything, in favor of the crosswise frame. For during cold weather the entrance of either should be contracted so as to admit only sufficient air to afford the colony good ventilation.

Hives of every conceivable shape and many different depths have been tested, but none of them has ever displaced the old standard frame invented and given to us by that greatest of all bee-keepers and hive-inventors.

But I wish to say that there is one apparently unsurmountable difficulty in regard to the Hoffman frame, namely, it will cause many bees to be crushed. I have tried to be as careful as it seems possible to be in handling them, and have never been able to avoid killing more bees than are killed by the plain standard Langstroth frame spaced, with staple driven in the end-bar or top-bar near the end.

### SPRING AND FALL PRICES OF BEES.

On page 245, widely different spring and fall prices of a colony of bees are given. Let us consider it.

An 8-frame 1½-story hive, nailed and painted, with one-inch starters, is quoted in catalogs at \$2.65; add to this for freight 35 cents; honey on March 1, 15 pounds \$1.50; bees on March 1, \$1.50, making a total of \$6.00. In the fall add 15 pounds more honey at \$1.50, and this will make the fall price \$7.50. I think \$1.50 for the bees of a colony is a very moderate price, and honey at 10 cents per pound—that is, honey suitable for wintering bees—is not an over-estimate, and 30 pounds for wintering a good colony of bees in an 8-frame hive is also a fair estimate, it seems to me, and certainly not by any means an over-estimate.

Lyons Co., Kans., April 1.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### The Wonderful (?) Cotton "Controllable" Hive

About 25 years ago a hive with a woman's name attached was somewhat extensively advertised for which large claims were made, and no little was said in the bee-papers about Mrs. Lizzie E. Cotton and her Controllable hive, the general belief seeming to be that there was very little of any woman in the case beyond a man using his wife's name. Little has been heard of Mrs. Cotton and her hive for some years, but lately it seems to be coming to the surface again.

A circular about "The Controllable Hive, Improved Bees, and New System of Bee-Keeping," is to hand, which starts out by saying that owing to poor health Mrs. Cotton has

transferred her interest in "The New System of Bee-Keeping" to her husband, C. B. Cotton. But just as great things can be done with the hive now as 25 years ago. Get the improved bees in the Controllable hive, and "your success in the end, and your profits of the first season are greater from one swarm of these bees in this hive than from 6 swarms of bees in any other hive." Hive with outfit ready to receive a swarm of bees, \$6.00. The same with a "full swarm of Improved Bees," \$20. That's only \$14 for the bees alone!

The following letter has also been received:

MAINE, Dec. 24, 1904.

MISS WILSON:—Should like to introduce the Controllable Hive and Improved System of Bee-Keeping to the people of Illinois. If you will favor me with your order for a Con-

trollable hive and complete outfit on receipt of this letter, I will furnish you on receipt of \$4.00—regular price \$6.00—providing you will recommend to your friends, if hive pleases you, as I am certain it will.

I refer to F. G. Adams, of —, Iowa. Mr. Adams has had the hive in use more than 20 years.

Don't delay if you want the hive and outfit at this reduced price.

Yours truly,  
C. B. Cotton.

To which has been sent the following reply:

Dear Sir:—In reply to your recent letter, I would say that it is considerable trouble to test unknown things, and would suggest the following arrangement: You send me free, with all charges for carriage prepaid, your complete \$6.00 outfit of hive, etc., together with \$2.50 to pay for the trouble of testing, and if upon trial its great superiority is shown, I will cheerfully recommend it to my friends.

EMMA WILSON.

The strange thing in the case is that after 25 years of publicity such a wonderful hive would need to be introduced "to the people of Illinois," or of any other State. Strange, too, that not a man of those who make their

bread and butter by producing honey seems to have gotten hold of this great improvement by which their profits could be increased sixfold!

### Delightful Weather for Bees

We are having delightful weather, and the bees are enjoying it most thoroughly. They are in fine condition, no weaklings this spring, just strong, vigorous colonies. Plums and cherries in full bloom May 3, with the thermometer at 85 degrees. Pretty good weather for bees, but then we may be having frost ere many days—can't tell.

### Honey as a Soap Substitute

Honey is said to be as good as soap for cleansing the hands. Directions are to rub it on when the skin is dry, moisten a little and rub again, use more water and rubbing, and finally wash thoroughly when the hands will be as clean as though the strongest compound of grease and lye were used.—The Farmers' Review.

I did not have very much faith in the cleansing properties of anything as sticky as honey, but concluded to give it a fair trial. Say, it works better than you may think it would. Give it a trial and see.

### A Sister's Well-Ripened Honey

Mr. A. I. Root, in his notes of travel, gives an interesting account of the success of a sister bee-keeper in northern Michigan. She not only takes the entire charge of between 50 and 60 colonies of bees and secures good crops of honey, but adds to that the honor of producing a *very superior article*. Score one for the sisters. Mr. Root says:

"It was my privilege to stay over night at the home of Mrs. Morrow, who has between 50 and 60 colonies of bees, but as neither her husband nor one of the children take to bees, she manages them entirely herself. She has secured good crops of honey, and, strange to tell, her honey never candies. It is stored in sap-pails with a cloth tied over the top; and on a frosty morning you can turn the pail of honey upside down and not spill a drop, it is so thick, and yet it is just as clear as glass. For quality it suited me so well I took a bottle of it home to show our Medina folks what good, thick honey is like. The

only explanation she could give for the fact that her honey does not candy, while the raspberry honey of that region is celebrated for candying solid as soon as cold weather comes, is that her extracting is all done late in the fall. She just piles the hives up one story on top of another, so as to give the bees room. When extracting time comes, the combs are taken into a warm room, and kept there long enough to get well warmed through. The room is kept at a pretty high temperature where the extracting is done, because the honey is so thick it is a pretty hard matter to throw it out.

"Of course, there are other bee-keepers, many of them, working on this plan. The honey is better ripened, a good deal, than the average comb honey, especially comb honey that is taken from the hive before it is soiled by the bees tramping over it. And I for one do not want any more comb honey so long as I can get Mrs. Morrow's extracted. I have submitted my sample to a good many people since then, and they pretty much all agree with me. The honey is so thick it is difficult to get it out of the bottle without warming, or letting it stand in a warm room. Of course, such thick honey ought to bring more money than the ordinary liquid honey on the market; but I for one would be willing to pay for it."

### A Little Sister's Report

DEAR MISS WILSON:—I will answer Dr. Miller. He wanted to know where his little Abel girl was. I am sorry to tell you that my sister "Hope" died on Aug. 16, 1904. She was 10 years, 8 months, and 3 days old. The queen that she ordered is still alive. She is rearing brood, and is in the strongest colony. We have 16 colonies. We lost one colony the past winter. We had a very long and cold winter. Papa had all the bee-hives opened on April 20, and all are in good condition. The weather is changeable, one day freezing, the next day warm, and the next day raining. My sister got that queen from Mr. York on Aug. 13, but she never saw it. Now I must help papa in her place. I will be 9 years old Sept. 16. My papa's name is E. W. Abel.

FLORENCE M. ABEL.

Northampton Co., Pa., April 22.

Thank you very much for your nice little letter. Write again; we are always glad to hear from the girls. I am sure the sisters will all unite with me in extending our sympathy for the loss of your sister. "Papa" is to be congratulated that he has another little girl so willing to fill her place.

(that's what human beings would do, of course), but who can tell time and place where bees ever actually did that? Page 262.

### PUTTING WEAK COLONIES OVER STRONG ONES.

That sub-head on page 262, "Uniting weak colonies in the spring," is wrong. It means putting weak colonies over strong ones without uniting—a kink decidedly off the old, familiar track. What about it? It seems that two of the Michigan folks who tried it largely like it. The apparent advantage is that a queen, which in all probability would have been lost, is saved. The apparent disadvantage is that the lower colony's heat is used and much of it liable to be wasted. None seem to report any fighting, which is curious. Presumably some of the upper colony's bees desert when put back to the old stand, but not nearly enough to offset the gain realized by three weeks of parasite life. I suppose they not only go through the premises of their stronger neighbors, but help themselves to much that they find there. And according to page 307, bees from below often come up and help in the work. But don't forget that the inventor (E. W. Alexander) warns us that queens will be killed if such pairs are kept together too long.

### DO BEES EVER SMOTHER?

Bees never smother, eh? The backer of that, George E. Hilton, seems inclined to push Hutchinson in the heresy contest. The essential fact in this connection is that excited bees need a great amount of air, and if they can not have it they very speedily perish, while perfectly quiet bees will do very well with no more air than will go right through ice, or bricks, or boards. Whether a colony lives or dies is very often a mere matter of feeling and deportment with them. No harm to shut bees in unless the bees themselves object to it—but if they do, then look out.

In somewhat similar manner banking with snow is good—unless—unless it sets them to breeding, as it frequently does. If this takes place look out—look out and see a "blasted hopes" apiary. I imagine that the air which filters through snow is too stimulating—too much ozone in it. Page 263.

### CROSSING CROSS BEES WITH CYPRIANS.

So "South Carolina" crossed his cross bees with Cyprians, thinking to make them gentle! Next he'll be crossing his hens with Dominiques to make them non-sitters. Some eminent bee-folks have the "gall" to claim that pure Cyprians are gentle; but I think they mostly give it up about the mixed bloods. Page 265.

### Feeding Bees in the Cellar

Sugar syrup may be given to bees in the cellar with the regular division-board feeder of the Doolittle type. It would be advisable, as you suggest, to put the feeder in the middle of the brood-nest; but a better way would be to give the bees cakes of hard candy. The candy should be made by boiling granulated-sugar syrup, with a little honey in it, so that, when cool, it will form into a hard-translucent cake. A two or three pound brick of this when put on top of the brood-frames will be enough to take care of any colony short of stores.—Gleanings in Bee-Culture.

### Comb Honey in Confectionery

I have been unable to learn anything further about the way in which comb honey is used in confectionery, owing to the absence from home of the friend who sold the honey for this purpose; but I imagine that, like most soft candies, it is made with but a moderate amount of cooking and a great deal of stirring, especially just after it is removed from the fire. In this manner the wax is thoroughly mixed through the candy, and helps a very soft candy to keep its shape instead of melting down and becoming sticky with the changes of temperature and moisture. Paraffine is sometimes used for this purpose; but the comb honey, containing wax in about the right proportion, already finely divided and well mixed through the mass, is probably less trouble, besides being superior in other respects.—J. A. Green, in Gleanings in Bee-Culture.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### WINTERING OBSERVATORY HIVES.

Dr. Miller was not the only one to be surprised at Allen Latham's success in wintering observatory colonies. Well for us to inquire a little into the why of this success. Mr. L. himself thinks it's partly owing to stimulation late in the fall—that is, into October. This is reasonable; yet I do not feel absolutely sure that extra-late breeding counts for very much. I conjecture that the all-along *prosperity* of the colony (as shown by their swarming) is the main element. Page 261.

### THE BEE-KEEPERS' HIVE-TOOL.

Apropos to F. Greiner's new tool made of a piece of buggy-spring, it is apparently better than the prevalent putty-knife as a lever; but it does not remedy the worst short-coming of the putty-knife for the work of removing burr-comb. As human knuckles must have room to move along in, the operating edge is continually being crowded down in spite of us against the wood of the frames—and snub

right into the wood. Can't you have the tool made a little longer, with one end drawn to a screw-driver shape for the lever work, and a bend of 30 or 40 degrees put in it two or three inches from the broad end?

Oft we want to remove wax and burrs from combs that are not in the possession of bees. It naturally occurs to one that an old table-knife is the proper tool to do it with. You try it and get mad. Even a very dull knife won't travel in beeswax if it can find wood to plunge aside into. One of the queer perversities of materials and tools. Page 262.

### HIVING BEES ON FULL SET OF DRONE-COMBS

I think some one has said that bees are decidedly inclined to leave if hived on a full set of drone-combs. Mr. Greiner goes on record that they don't always do it, but sometimes go ahead and rear a lot of worker-brood in the drone-comb. Curious. Old bee-writings sometimes tell of bees tearing down drone-comb and rebuilding in worker size

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to DR. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### Preventing Swarming

Given a 10-frame Langstroth hive and 3 supers of 8 combs each, at clover time, raise 4 frames of brood to the first super, place 4 combs in their stead, and over this place a queen-excluder. Will such a colony be apt to swarm? MISSOURI.

ANSWER.—I don't know, but I should expect swarming in a minority of cases, if everything is closed except the entrance. With an opening at each story, allowing abundant ventilation, there might be no swarming.

### Corn and Sumac Honey—Hoffman Frame Honey Capacity—Melting Combs Containing Honey

1. Does corn yield honey? If so, is it not of poor flavor?
2. What kind and of what grade is sumac honey?
3. How much honey does an ordinary Hoffman frame hold when there are 8 in an 8-frame hive?
4. How do you melt combs with honey in? perhaps you'll say, just like any other comb; if that's the way, where will the honey go? NEBRASKA.

ANSWERS.—1. Sometimes it yields nectar in the axils of the leaves; but I don't know about the quality.

2. I don't know. In this part of the country it is in such small quantity that it would probably be impossible to get a sample of it pure.

3. I think something like 5 pounds.  
4. Not at all "like any other comb," if you want the honey saved in good condition. You must melt it very slowly, so the heat will not spoil the honey. Put it in a crock on the hot-water reservoir of the cook-stove, where it will take several days to melt; or put it in the oven if you are sure it will not get too hot; or set the crock in a dish of water on the top of the stove, with a chip or piece of shingle, or something of the kind, under the crock.

### Keeping Queens—Swarming—Foul or Black Brood

1. We are told that when we have a queen we do not want to use at present, to put her into a nucleus until we do want her. How are we to have these nuclei on hand just when wanted, and what are we to do with them after we take the queen away?

2. When rearing queens, when are the cells put into Titoff cages—as soon as the prepared cells are put into the hive, or when cells are sealed up?

3. How soon are cells sealed after given to bees?

4. What is your opinion on the Alexander method of controlling swarming, described in Gleanings of April 15?

5. How are queens reared in a baby nucleus? I often see it mentioned in the Bee Journal, but never saw any directions on the subject.

6. Does "baby nucleus" mean simply an ordinary hive with a few frames in, or a small hive full of frames?

7. Some of my bees that died last winter, and also some which did not die, had small patches of dead brood. It was not sunken into a brown mass as described in foul brood, but retained its shape. Some of it was black and some brown, but all was very soft and seemed decayed. Is it foul or black brood, and if not, is it ever likely to turn into either?

8. Would 1½-inch sections, with plain separators, hold a pound of honey? If not, how much would they hold?

9. Do you think it likely that some disease would be the cause of 47 colonies dying last winter and spring in one apiary of about 60 colonies? This was the case with one apiary in the county. All had plenty of honey.

10. Would it be advisable to call in the inspector? ONTARIO.

ANSWERS.—1. I know of no way of having nuclei but to make them; one way being to fasten one or more frames of brood with adhering bees in a hive for 2 or more days.

2. Cells are not usually caged until nearly time for the young queens to emerge.

3. They are sealed 5 or 6 days after the larva hatches from the egg.

4. The plan seems to be good if you can, as he says, have 2 good, strong colonies in the place of one, ready to commence work on your clover harvest.

5. Just about the same as in larger nuclei.  
6. Any nucleus with a very small number of bees is a baby nucleus; but the term is usually applied to a nucleus in a small hive, with one or two very small frames.

7. It may be neither. It will not turn into foul or black brood unless it was foul or black brood in the beginning.

8. There is no such thing as a given weight of honey in a section of a given size. The section you name would sometimes hold a pound of honey, and sometimes more.

9. Possible, but hardly probable.

10. It would do no harm.

### Prevention of Increase

1. If one has all the bees he wishes for, and does not care for any increase, how would it do, about the time bees are ready to swarm naturally, to destroy all queen-cells and put on a super so as to give them more room? Do you think the plan would generally be successful?

2. Does a second swarm generally leave the hive the next day, if fair, after the first piping of the queen the evening before? NEW HAMPSHIRE.

ANSWERS.—1. In the majority of cases it would merely defer the time of swarming. Something, however, depends upon the character of the bees. With colonies given to swarming it would nearly always prove a failure; with those little given to swarming it would often prove a success.

2. Yea.

### Clothing for Bee-Work—Bottom-Boards—Frames Full of Honey—Lemon-Juice in Sugar-Syrup—Dead Bees—Mice and Snakes in the Hives

1. I think it is a pity that a man who has done so much to help others should be so slow as to wear cotton clothing in hot weather, and suffer with the heat and perspiration when light wool clothes are so much cooler. They let the air through and are less clinging. Try it, and if you don't enjoy yourself better this summer, provided you get light-weight wool, light gray in color, I will let you go back to your old white cotton.

2. Why do you put a false bottom-board in the hives with the deep bottom-boards in summer?

3. Some of the hives seem to be almost full of honey. Perhaps it was robbed out of other hives. Would it be well to take away part of this and give empty combs instead?

4. All of the colonies except one are gathering pollen every fine day. This one has a good-looking and lively queen, but no brood. Will she begin laying?

5. One man says to put lemon-juice in sugar-syrup and make it as good as honey for the bees. What do you think of it?

6. There are a great many dead bees about some of the hives and not nearly so many about others, and yet it seems to me that the colonies with the great amount of dead bees are about as populous as any. How do you account for this?

7. Some colonies that I thought in pretty good condition in the fall are dead. Not from cold or hunger, but there are very many dead bees in and under the hives with a hole in the middle of their backs, and all the inside eaten out of that part of the bee. It looks like too small work for mice, and, in fact, I had contracted the entrance too narrow to admit a mouse, and yet I can not find it. What do you think it is?

8. Last fall and this spring there have been a great many small snakes around here. I do not know whether it is to eat bees or because the hive makes an excellent shelter for them, or because they are after mice. Do you think they are friends, or enemies? I used to kill them, but don't any more for I think they eat many mice. NEBRASKA.

ANSWERS.—1. There's just one fatal objection to the woolen clothing; bees sting worse.

2. Because the bees in summer would fill the space with comb.

3. It might be well to do so if you find that the queen has not room to lay, but you will find the bees will use up a good deal of honey in brood-rearing.

4. The likelihood is that a queen with no brood, when others have plenty, is of no value.

5. It would be better without the lemon-juice.

6. A very strong colony might have a good many more dead bees than a weak one merely because it had more old bees to die from old age.

7. In spite of appearances to the contrary, you may be sure that mice are the culprits.

8. I have seen snakes in hives a number of times, and have always supposed it was merely to have a comfortable place.

### Transferring Bees—Foundation Splints—Moving Bees

On page 297, in answering "New York" concerning transferring bees, you thought it would be better to wait till they swarmed, and 21 days later break up the old colony.

1. What should be done with the bees at the end of 21 days?

2. Would it be a good thing to move the box-hive to another part of the yard so as to deplete the number of bees as much as possible before breaking up the old colony?

3. Four different times I have tried upsetting the hive and then drumming, as is recommended in bee-books; but it did not work well. We drummed an hour each time, looking at intervals under the box to see if they were up. About a pint was all we could get. What was the matter?

4. What are foundation splints that you use instead of wire? How are they used?

5. Would it be better to move bees 45 miles by wagon than to have to change cars with them? MICHIGAN.

ANSWERS.—1. One way is to drum out the bees and unite them with the swarm at the end of the 21 days, making kindling-wood of the hive, and wax of the combs. Another is to transfer into a new hive, and keep the 2 colonies separate. Still another way is to do nothing further, leaving the colony in the box-hive to build up and cast a swarm again the next year.

2. Yes, you are to move the old hive to a new stand a week or so after swarming.

3. I don't know. Possibly you were too gentle in smoking and jarring. It is also possible that there were so few bees in the hive that you could not get up a stampede.

4. Little sticks of wood about 1-16-inch square and ¼-inch shorter than the inside depth of the frame. They are boiled in wax,

and with a pair of tweezers lifted out of the hot wax and imbedded vertically in the foundation by means of the wet edge of a little board.

5. It's rather a question as to which will cost less. Changing cars need not be a serious matter.

### Italianizing Bees

I want to Italianize 2 colonies of blacks in double hive-bodies, Danzenbaker size, by giving capped cells.

1. How would it work to put a queen-excluder between the 2, with the old queen in one and the cell in the other?

2. Should the cell be above or below?  
3. Could I not put the cell below with one entrance also below, and get the young queen fertilized and laying before removing the old queen? or, would it be better to have an opening for the upper story?

4. Wouldn't they be likely to swarm if the old queen could get out?

5. Would the bees destroy the cell if not placed in a cell-protector?

Of course, if the first question is not practical, the others need no answer. I got the idea from an article by Doolittle on queen-rearing, where he has cells completed in a hive with a laying queen. My idea is to do this just before the honey-flow begins, and I want to keep the old queen at work as long as possible, you see. NEW YORK.

ANSWER—Please allow me to answer your questions in a bunch. I have been able to have a young queen fertilized in one story while the old queen is laying in another, but generally she turns up missing about that time, although there is no trouble in having a young queen mature in that way. I'm not sure what becomes of the young queen after she is a few days old. You will not generally find that the colony will swarm on account of the presence of the young queen. I think you would not come very far from what you desire in something like this way: Put a cell in either upper or lower story, with the queen in the other story, and a separator between. When the young queen is 3 or 4 days old remove the old queen and the separator.

## Reports and Experiences

### Bees in Fine Condition

Bees are in fine condition for this time of the year, as I never saw them winter any nicer. Out of 112 colonies I lost only 2. They are commencing to bring in pollen, and otherwise enjoying themselves after their long winter's nap.

I enjoy reading the American Bee Journal, and look forward to every Thursday, as I know that is the day it will come.

WARREN H. WINCH.

Delaware Co., Iowa, April 3.

### Cool Weather for Bees

It is too cool for bees. There was a 50 percent general loss of bees this spring. I lost about 15 percent. White clover is in abundance.

H. W. HECKLER.

Keokuk Co., Iowa, May 8.

### Georgia as a Honey Country

In reply to the request for information concerning the eastern part of Georgia as a bee and honey country, I will say that bee-keeping is profitable in the eastern part, and there are many locations where the business would be very paying. These localities would be found mostly in the south-eastern portion.

We get our surplus honey mostly from the following sources: Gallberry, poplar, gums, bolly, sumac, and golden-rod. With these plants in a location, bee-keeping is paying.

I would be glad at any time to furnish more information concerning Georgia as a honey-producing State.

J. J. WILDER.

Doody Co., Ga., April 24.

### Wintered Well and Good Prospect

The bees have wintered very well, and the prospect is fairly good for a honey crop.

B. KENNEDY.

Winnebago Co., Ill., May 1.

### A Beginner Heard From

I am a beginner in bee-keeping, having purchased the first colony last June. They were Italians, and showed that they were expert swarmers. They swarmed 5 times, 2 swarms

absconded, and the mice killed one colony the past winter. I now have 3 good, strong colonies.

I got 75 pounds of comb honey last season. I can sell all I can produce at 15 cents per section, at home. Alfalfa is the source of most of our honey. There is a 60-acre field of it within 20 rods of my small apiary.

One seeding of alfalfa here will last from 5 to 10 years, and yield from 3 to 4 crops per year.

We usually have mild winters, but the past one was a little severe. Almost all of the beekeepers around here report that their bees wintered very well with little or no loss.

I think it will pay any one who keeps bees, no matter how few, to take the "Old Reliable" right straight along.

ROBT. A. JEFFREY,  
Harlan Co., Nehr., April 24.

### Loss in Wintering

Bees are mostly wintered on their summer stands in this locality. There has been considerable loss in some yards the past winter. We have our bees in double-walled hives covered with flax-straw. We have lost 11 out of 74 colonies, mostly the weaker ones. There is a good prospect for white clover around here.

M. ZAHNER.  
Johnson Co., Kans, April 17.

### Bees Wintered Well

Bees have wintered well in this locality. They seem to be healthy and strong. Section honey is dull at 12½ cents per pound. Beekeeping is growing rapidly in this locality.

Davis Co., Iowa, May 3. W. M. RAY.

### Good Prospects for Bees

Fruit-bloom is good. Bees are getting along fine. Clover is in fine shape.

J. W. JOHNSON.  
Stephenson Co., Ill., May 4.

### Bees Wintered Well

I have 11 colonies this spring, having wintered all that I put into winter quarters last fall; but a year ago I lost 16 out of 21 colonies. The few that were left did well last

2-frame Nucleus (no Queen).	2.50	14.00	25.00

When Queens are wanted with Nuclei add price of any Queen wanted. We guarantee safe arrival of all Queens and Nuclei. Our breeders may be returned after 30 days, if satisfaction is not given. Cash must come with all orders. Orders are booked and filled in rotation. We book orders for next season. Safe arrival guaranteed of all stock. We ask a trial order.

D. J. BLOCHER PEARL CITY, ILL.

Do not send personal checks unless you add 10 cents for collection. 16Etf

#### BEE-KEEPERS' SUPPLIES.

We are now able to quote lower prices than ever before. Highest quality guaranteed. We handle the C. B. Lewis Co's goods. Italian Bees for sale in dovetailed hives. Send for my 88-page Catalog, and lenthet for beginners. They are free.

41EU W. J. McCARTY, Emmetsburg, Iowa.

## QUEENS

Best 3-band Italian Bees free from disease for -Untested Queens, early in May, 75 cts.; 2-frame Nucleus, with Queen, \$2.25. Eight years' experience.

Chesley Presswood,

McDONALD, Bradley Co., TENN.

14A4t-13E2t Please mention the Bee Journal.

summer. Three of them stored over 100 pounds of section-honey, one stored 125 pounds, and the other 2 over 50 pounds each. I live in the timber, with lots of basswood, white clover and other wild flowers, plenty of fruit and pickle blossoms in their season, and but few bees. E. E. KENNICOTT. Cook Co., Ill., April 20.

#### Bees Swarming

Bees are swarming now, and have increased a little. Prospects for the season are good. May the Honey-Producers' League prosper. Inyo Co., Calif., April 27.

WM. MUTH-RASMUSSEN.

#### Bee-Locations in Virginia and Maryland

In answer to Mr. John H. Oren, page 234, I would like to say: I should not consider either Virginia or Maryland specially good States for bee-keeping. You say you hope "to do better where the summers are longer and the winters less severe." I should strongly advise your going further south than the above-mentioned States. I append some statistics of winter weather here for the years mentioned:

- 1889—Jan 31, 4 degrees; Feb. 8, 2; Feb. 9, 11; Feb. 10, 7; Feb. 11, 0; Feb. 12, 1; Feb. 13, 1; Feb. 14, 14; Feb. 16, 12; Mar. 7, 15
- 1901—Jan., 13 degrees; Feb., 14; March, 7; December, 1.
- 1902—Jan., 13 degrees; Feb., 8; March, 15; Dec., 13.
- 1903—Jan., 8 degrees; Feb., 1; March, 23; Nov., 10; Dec., 8.
- 1904—Jan., 6 degrees; Feb., 5; March, 18; Dec., 9.
- 1905—Jan., 5 degrees; Feb., 1; March, 24.

The minimum temperature for each month is given for the last 5 years.

Try Texas for your "longer summers and winters less severe," and you will also get many more honey-producing flowers and

#### SINGLE COMB BROWN LEGHORNS

Noted Winter-Laying Strain. Cockerel Mating, headed by Rochester Prize-Winner; Eggs, \$2.00 per 13. Pullet Mating, headed by pullet line; pedigreed; Exmoor males, \$2.50 per 15. Flock on range, headed by 2d Wis. State Fair winner, and others of equal quality, \$1.00 per 15. Hens in all pens result of 15 years' scientific breeding.

Single Comb Buff Orpingtons. The grand new breed. No better quality in existence. \$2.00 per 15 eggs.

Mammoth Bronze Turkeys. Hens up to 23 pounds each. Not inbred. Eggs \$2.50 per 19; 25 for \$5.00.

MRS. MILLIE HONAKER, Viroqua, Wis. 15-17-18A3t Please mention the Bee Journal.

#### THE ELGIN HIVE

That's the hive which can be knocked down and put up by any one in a few minutes. No nails or dovetails needed. Iron attachment holds the same together perfectly air tight, and keeps it from warping. Send for Circular. Address, G. H. KIENZLE, E. end Kimball St. Bridge, ELGIN, ILL.

19A4t Please mention the Bee Journal.

#### The Rietsche Press

Made of artificial stone. Practically indestructible, and giving entirely satisfactory results. Comb foundation made easily and quickly at less than half the cost of buying from the dealers. Price of Press, \$1.50—cash with order. Address,

#### ADRIAN GETAZ,

KNOXVILLE, TENN.

44At J. G. Goodner, of this State, writes me that he "prefers to pay \$25 for a Rietsche Press than do without it."—A.G.

Bee-Supplies in exchange—delivered here.

H. M. ARND, Manager.

plants than you will in the States mentioned  
above.

Our main honey-flow is from white clover,  
which comes in about the middle of June and  
lasts till about the middle of August. There  
is a considerable fall flow in some years from  
a great variety of wild flowers, but this flow  
is very uncertain. I am sure there would be  
no difficulty in purchasing a small farm that  
would be suitable for an apiary, and do not  
suppose there would be any difficulty in a  
Northerner establishing an apiary, or apiaries,  
on other people's farms. I would be glad to  
answer other questions if in my power, or go  
into more minute particulars if desired.

Don't come either to Virginia or Maryland  
under the delusion that you are coming to  
"The Sunny South." You must go lower  
down on the map for that. There has been  
no winter in the past 15 years that I have not  
had plenty of use for my heaviest and longest  
fur-lined overcoat.

While I believe I am right in saying there  
are very few, if any, large apiaries here, there  
are numerous small ones, (mainly of the com-  
mon black bees) scattered about. But I do  
not consider this State to be anything like  
half stocked with bees.

"A BEE-KEEPER IN VIRGINIA."  
Augusta Co., Va.

### Prospects for a Good Season

We are looking forward to a large honey  
crop, as white clover will be a fine crop.

We are readers of the American Bee Jour-  
nal, and derive much valuable information  
from its pages. J. F. W. WEBER & SONS.  
Marion Co., Ill., April 25.

## For Queens

SEND TO  
JOHN W. PHARR  
Berclair, Tex.

He will furnish at same prices as last year:  
Tested, \$1; Untested, 75c; 5 for \$3.25; 10 for  
\$6; 15 for \$8.25; 25 for \$12.50; 100 for \$45. He  
breeds Goldenes, Carniolans and 3-Band Ital-  
ians. Also 1, 2, and 3 frame Nuclei, and full  
colonies. Prices given on application. Pharr  
pays the freight, and guarantees satisfaction  
on all Queens. To do justice and judgment is  
more acceptable with the Lord than sacrifice.

## Honey and Beeswax

CHICAGO, May 8.—With April about all the trade in comb honey ceases so far as this market is concerned; occasionally a case sells, but no lots, so that prices now are practically without change, pending the new crop. Extracted is exceedingly slow of sale; white ranges from 5¼@7c, and amber 5¼@6c, according to flavor, quality and package. Beeswax in active demand at 30c.

R. A. BURNETT & Co.

CINCINNATI, May 8.—The demand for honey has increased quite a bit since our last quotation, which is due, probably, to the concessions made in prices to affect sales, as well as the awakening of the spring trade. We quote amber extracted honey in barrels at 4¼@6¼c, according to quality. White clover and fancy extracted honey at 6@7¼c. Comb honey has seen its season. Beeswax 29c cash.

THE FRED W. MUTH CO.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.

HILDRETH & SEGELKEN.

PHILADELPHIA, May 8.—The season is about over for the sale of comb honey. There are so few sales that the market is not established enough to quote price. Extracted honey has met with some demand, and prices are as follows: White, 6@7c; amber, 5¼@6c. Beeswax, 28 cents.

We are producers of honey and do not handle on commission.

WM. A. SELSER.

BOSTON, May 9.—There is no change to note in the condition of the honey market from our quotations of April 24.

BLAKE, SCOTT & LEE.

KANSAS CITY, March 31.—The honey situation does not improve. While there is a little better movement the prices seem to be lower. Fancy white brings \$2 a case; No. 1, \$1.75; amber and lower grades from \$1.25 to \$1.50. Extracted, 4¼@6c. Beeswax, 28c.

C. C. CLEMONS & Co.

CINCINNATI, O., May 8.—The large stock of comb honey yet offered, with hardly any demand causes lower prices. I quote fancy water-white at 12c; other grades lower, in proportion. Extracted is in usual demand for this season of the year. We quote white clover 7@8c; amber in barrels at 5¼@5½c; in cans, 5¼@6 cents. Beeswax, 28c.

C. H. W. WEBER.

ALBANY, N.Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6¼c; white, 6@6¼c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c.

H. R. WRIGHT.

SAN FRANCISCO, May 3.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted—white, 5¼@6 cents; light amber, 4@5c; amber, 3@3½c; dark amber, 2¼@3c. Beeswax—good to choice, light, 29@30c; dark, 27@28c.

The steamer City of Peking, sailing Saturday last, took 85 cases for Belgium. Movement on local account is light. Buyers are holding off, anticipating arrivals of new crop at an early day.

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

45th Year

CHICAGO, ILL., MAY 25, 1905

No. 21

THE BIGELOW EDUCATIONAL HIVE AND MANNER OF SETTING BEFORE A WINDOW,  
WITH SASH RAISED AND ENTRANCE CUT IN TEMPORARY BAR

## JUST LOOK

Carefully at the illustration below. Did you ever see a more perfect lot of sections? Notice the fastenings. Aren't they fine? Take a microscope if you wish and you can find few flaws. Yes, they are the product of the Danzenbaker hive. We have long been TELLING what this hive could do; now we SHOW you. The Danzenbaker hive excels in the following main points: 1. Yield of honey. 2. Percentage of fancy sections. 3. Wintering. "Facts About Bees" gives the REASONS WHY. A new edition just off the press. Send a 2 cent stamp for a copy.

The A. I. Root Co.,  
*Gentlemen*.—Swarming opened here May 1; sections ought to have been put on some hives April 15. How is that for bees on Danzenbaker Frames, and wintered on their summer stands?  
 QUIRIN-THE-QUEEN-BREEDER, Ohio, May 6, 1905.

The A. I. Root Co.,  
*Gentlemen*.—I am very enthusiastic over the Danzenbaker hive. I wintered my colonies in this hive and they came out as strong as if not stronger than, any colony wintered in chaff hive. I wintered 23 colonies without any loss, all on summer stands.  
 T. B. HAYES, M. D., Pa., April 29, 1905.

### National Bee-Keepers' Association

Objects of the Association

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

### The Honey-Producers' League

(INCORPORATED)

#### OBJECTS:

1. To create a larger demand for honey through advertising.
2. To publish facts about honey, and counteract misrepresentations of the same.

#### MEMBERSHIP DUES

1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.

2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-paper publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.

GEORGE W. YORK, Manager,  
334 Dearborn St., CHICAGO, ILL.

#### Queen-Bee Free as a Premium

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is a good time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

## Editorial Notes and Comments

### Some Facts About Honey

Under this head occurs the following clipping from the Liverpool Post and Mercury in the British Bee Journal:

Honey is the only sweet that may be eaten in any quantities and for a long time without interfering with the action of any of the vital organs. Its food value is twice that of pork, pound for pound, and it has been noticed that persistent honey-eaters are not nearly so liable to diseases of the respiratory organs as those who do not use it at all. It is calculated that the entire honey product of 60 bees during their entire working life will not amount to more than one pound of honey, an amount that a man with a good appetite would eat in a day without thinking much about it.

No bee-keeper is likely to dispute the "fact" that the entire honey product of 60 bees during their entire working life will not amount to more than one pound of honey. But in reading the statement given, the ordinary reader will be likely to understand as a "fact" that the life product of 60 bees will amount to as much as a pound of honey. Let us try a little figuring on that. Take a colony that has produced 100 pounds of honey. If each pound required the work of only 60 bees, there would be needed only the work of 6000 bees for the 100 pounds.

Again, figure from the standpoint of the number of bees in a colony. It would be hardly more than a moderate estimate to say that during a season 60,000 bees of a colony put in their lives at storing honey during the course of a season. If every 60 of them brought in a pound of honey, that would lead us to expect from each colony in a fair season not less than 1000 pounds of honey.

It is a nice thing to have the general press give facts about honey; but if the Post and Mercury would be a little more careful how it gives the facts contained in the last sentence, the public would be likely to put more faith in its other facts.

### Side Springs for Brood-Chambers

Recognizing the need of constant pressure in a brood-chamber containing frames spaced automatically, the use of springs has been suggested. Some hives are used with dum-

mies; some have none. With no dummy, and with the bees strenuously endeavoring to crowd glue between the frames, there is danger that there will be not only fixed distances, but fixed frames as well. The case is better with dummies only in so far as there is more room to fill up. Given time enough, and glue enough, and the dummy is likely to become fixed. As a help against this it is recommended, when closing up a hive, always to crowd the frames together hard, so as to squeeze out the glue between the frames. If this be faithfully done, and if the points of contact between the frames be small, there will be a minimum of trouble. But no hurried crowding together will do. The frames must be crowded together with force, and held in that way some little time, to allow the glue to be squeezed out. That time would be saved with springs.

The springs would also continue to work after the closing of the hive. The constancy of the pressure would also be a stand-off against the hundreds of little tongues constantly trying to crowd in glue between the frames; and this constant effort of little tongues, especially in a gluey region with such frames as the Hoffman, is no little matter.

With some frames and in some localities, springs in brood-chambers might not be worth while; in other cases they might be well worth while.

### "Be a Booster"—for the League

In Gleanings in Bee Culture for May 15 we find the following paragraph written by J. A. Green, one of the department editors:

#### BE A BOOSTER.

Join The Honey-Producers' League, and lend your money and your influence to the first organized effort to improve the condition of the honey market by the use of modern business methods. Your help is needed. Lay aside your selfishness, and do not be afraid to help yourself because in so doing you may help others.

Just read that over again, please. The League is, as Mr. Green says, "the first organized effort to improve the conditions of the honey market by the use of modern business methods." Then why not become a

member, and help to get the League to work on its special and important mission?

It may be you have some objections to something or somebody connected with the League. Well, it is quite possible that everything and everybody in connection with it are not perfect, but we can assure our readers that it is a sincere, honest effort to try to get all who are interested in honey—either its production or sale—to co-operate, and endeavor to create such a demand for honey as shall promptly take every pound produced, and at a fair and just price. Surely, its objects are praiseworthy, its need is pressing, and its membership list should soon be crowded.

It is an opportunity offered to bee-keepers to help themselves. The question is, Will they do it?

We believe they will.

### More Bees—More Honey

A Wisconsin subscriber, in a private letter, referring to advertising honey, says this:

"I consider honey a luxury which a great many people can not afford. The cry with you writers is, Keep more bees—produce more honey! How can we expect the price to keep up?"

If the writer of the foregoing will refer to the back numbers of the American Bee Journal we do not think he will find that we have advised keeping more bees, although, wherever a bee-keeper *thinks* he can make it *pay*, he will certainly "keep more bees," and thus "produce more honey," whether advised so to do or not.

Our advice to bee-keepers has been, for years, to organize and advertise, so as to get a better price—a more just price—for the honey already produced. After that is accomplished, we believe it will be time enough then to arrange to "keep more bees and produce more honey." We may be wrong about this, but that is the way it looks to us.

True, honey is now considered a luxury. But why should it be so considered? Surely, the price is low enough now so that any family could afford to buy it if they only knew about it. With meat regularly at 18 to 20 cents a pound, and butter about 30 cents, it seems to us that honey can be afforded pretty often at 15 to 18 cents, especially when its high value as a food is considered.

We verily believe that if honey were brought to the attention of the consuming public as are many of the breakfast foods, the demand for honey would be greatly increased. We know of no better way to do this than to *advertise*. Do you?

### Baby Nuclei with Common Hives

It is perhaps too early yet to say whether, all things considered, it is a very great step in advance to be able to have virgin queens fecundated with a very small number of bees; and so far it is the specialist in queen-rearing rather than the every-day bee-keeper who has made any trial of the plan. One reason for this is the fact that as yet few honey-producers take any special steps toward queen-rearing; leaving the matter entirely to the whim of the bees. Another reason is that it is some trouble to make ready the little hives needed. If ordinary hives were used, it is likely that more bee-keepers would have tried

the baby nuclei. Of course it would be expensive for those who rear queens on a large scale to use full-sized hives; but the honey-producer is likely to have always on hand extra hives, and these he can use without extra expense.

Dr. Miller had a number of queens fecundated in common hives, using for each nucleus only enough bees to cover well a pound section of honey, and the process seems very simple. He says:

"I took an empty hive, closed the entrance entirely, put in the hive a section filled, or partly filled, with honey, putting the section in a shallow wide frame, or even on the floor in one corner of the hive; then I took from any hive convenient a frame of brood with adhering bees—of course being careful not to take the queen with the bees—shook into the nucleus hive the bees from the brood-comb, and immediately dropped into the hive, on the floor, a virgin queen just emerged or only a few hours old, and as quickly as possible closed the hive. Three days later I opened the entrance large enough for a single bee, and in most cases I found the queen laying when 10 days old. It is possible older virgins would do. In some cases I used queen-cells well matured."

It will be noted that queenless bees were not necessary, and that the queen was drop-

ped right among the bees with no precaution whatever as to introduction. Mr. Sladen, in the British Bee Journal, says it is a very valuable point "that a virgin queen, even several days old, is readily accepted 4 to 6 hours after the nucleus has been formed, provided that there is no brood in its combs." Dr. Miller did not wait even "4 to 6 hours," but it is not certain that he would have succeeded with virgins "several days old."

### American the Best Linden for Honey

The bee-keeper who knows the great value of the linden, or basswood, and knows that more than one variety of linden exists, is likely to be interested to know whether some other than the common variety may not be better. Prof. Frank Benton has had exceptional opportunity for comparative observation. Lindens have been extensively planted in Washington, in the parks and for miles on both sides of many of the streets and avenues, and he says in Government Bulletin No. 59, "Several species of lindens are included in these plantings, but none yields more than our common American linden, or basswood (*Tilia americana*)."

## Miscellaneous News Items

**Foul Brood in Texas** is to be wiped out. Mr. H. H. Hyde, of Bexar County, informs us that the State Legislature has appropriated \$1600 to begin eradicating foul brood. We hope that the good work may be kept up until that dread bee-disease may be wholly cleaned up in all the land.

Mr. J. T. Calvert, of The A. I. Root Co., and also Mr. Frank Spellman, both of Medina, Ohio, were callers at this office last week when in Chicago on a business trip. Mr. Calvert reports a rushing business in bee-keepers' supplies, and looks for a large crop of honey throughout the country this year. If his prediction proves true, bee-keepers will need to do a lot of advertising in order to dispose of the honey produced at a fair price.

**Lecture to Cincinnati Bee-keepers.**—The Executive Committee of the Hamilton County Bee-keepers' Association announce that they have secured the services of Mr. W. Z. Hutchinson, of Michigan, to deliver a lecture to bee-keepers and friends of the honey industry in Cincinnati and vicinity, in the Convention Room, Grand Hotel, 4th Street, Monday evening, May 29, at 7:30 p.m. The subject chosen is, "The Comforts and Conveniences of the Apiary" in their relation to modern bee-keeping and honey-production. A great treat is in store for bee-keepers and others, as seldom such an opportunity is presented as this to hear one of the recognized authorities of the United States on this growing and important industry.

Mr. Walter W. Somerfield, of Cuba, has promised to be present also and talk on bee-keeping as practiced in the "Pearl of the Antilles." Production of his apiary in 1904 amounted to 140,000 pounds of honey.

Ladies, heads of families, grocers, school teachers and pupils of the public schools have been invited to be present and enjoy the interesting and instructive lectures. Admission will be free.

**Jonathan Stewart**, an old resident of Stephenson Co., Ill., and also well known for years in bee-keeping circles in that region, died at his home, Saturday, April 29, after nearly four years of suffering from paralysis. He was 78 years old, having lived in Stephenson County for about a half century. He was a regular attendant at the sessions of the local bee-keepers' association, of which he was also an officer. He was a member of the Presbyterian church, and a faithful and upright man.

**A Big Hive and Handy Honey.**—The Graphic-Herald, of Webster City, Iowa, gives the following account of a colony of bees in a house:

#### A HOME APIARY.

Mr. Thos. McDermott has a unique apiary at his home in the south part of the city. For two or three years past a swarm of bees has been housed in between the ceiling and floor, finding an entrance through crevices in the brick wall. Several swarms have come and gone in there each year until there is an awful mess of bees. Mr. McDermott tried to have them removed at one time, but without success, and the floor was taken up and several wash-tubs and boilers full of honey removed. Afterwards the floors were removed each year and the surplus honey taken out. Now he has arranged a set of frames that fit in between the joists, and when new honey is wanted it is a simple matter to remove the carpet, take up the floor and take out any quantity of honey needed in neat frames, setting back the empties, to be refilled. A perfect "apiary" in every shape, and the bees are quiet and gentle, and seem to like their home. Several hundred pounds of fine honey was the yield last year.

### The Bigelow Educational Bee-Hive

BY EDWARD F. BIGELOW

**I**NSECT STUDY—BEES IN PARTICULAR.—It is in the world of insects, vast and varied, its members innumerable, beautiful, and almost miraculous in transformation, that the naturalist revels. The entomologist proclaims the attractions of his favorite pursuit as does no other naturalist, and no other disputes his claim. The most exuberant language fails to do full justice to the subject. Kirby and Spence, years ago, wrote as follows:

"Were a naturalist to announce to the world the discovery of an animal which, for the first five years of its life, existed in the form of a serpent; which, then, penetrating into the earth and weaving a shroud of purest silk of the finest texture, contracted itself within this covering into a body without external mouth or limbs, and resembling more than anything else an Egyptian mummy; and which, lastly, after remaining in this state without food and without motion for three years longer, should, at the end of that period, burst its silken garment, struggle through its earthly covering, and start into a day a winged bird—what, think you, would be the sensation excited by this strange piece of intelligence? After the first doubts of its truth were dispelled, what astonishment would succeed?"

"But you ask, 'To what do all these improbable suppositions tend? Simply to arouse your attention to the *metamorphoses* or *transformations* of the insect world, almost as strange and surprising, to which I am now about to direct your view—miracles, which, though scarcely surpassed in singularity by all that poets have feigned, and, though actually wrought every day beneath our eyes, are unheeded alike by the ignorant and the learned because of their commonness and the minuteness of the transforming objects.'"

All this, bear in mind, is in praise of what is already known. Of the charm of discovering these facts, the entomologist James Rennie wrote:

It can never be too strongly impressed upon a mind anxious for the acquisition of knowledge, that the commonest things by which we are surrounded are deserving of minute and careful attention.

If it be granted that making discoveries is one of the most satisfactory of human pleasures, then we may affirm without hesitation that the study of insects is one of the most delightful branches of natural history, for it affords peculiar facilities for its pursuit.

"If you speak of a stone," says St. Basil, one of the Fathers of the church, "if you speak of a fly, a gnat, or a bee, your conversation will be a sort of demonstration of the power of Him whose hand formed them, for the wisdom of the workman is commonly perceived in that which is of little size. He who stretched out the heavens and dug up the bottom of the sea is also He who has pierced a passage through the sting of a bee for the ejection of its poison."

This very large order of animal life which, Prof. L. O. Howard states, "comprises nearly 30,000 described species; but the enormous number of undescribed species. . . . would probably swell this number to more than 300,000."

Of this vast number of insects, the one pre-eminent in human interest is probably the honey-bee. Says Morely, "Both ends of the honey-bee have always been of singular interest to us, and this for exactly opposite reasons. It is a double-ender—one end the friend—the other the enemy of man."

This supreme interest in the bee, Prof. John Comstock expresses less humorously, but no less truthfully when he says:

"The honey-bee, through its useful products, has been known and cared for by man for centuries. Philosophers have written about it, poets have sung its praises, and naturalists have studied it during past ages, until there is probably no other insect with which man has such an intimate acquaintance."

In face of this overwhelming interest, the study of the honey-bee, so far as apparatus is concerned, has fared the worst of all at the hands of the scientists or the educational naturalist. They have sold the master study, and relinquished chief title in it for a bag of gold. In the hands of commercialism bees have fared well. Father Langstroth lifted out the honey; Bingham and Root smoked out the bees; Coggsall and Dixie brushed them off; Porter kept them out of their home; Cowan whirled out the liquid honey, and Danzenbaker and others made it convenient to capture comb and all. Alley caught the queens and drones;

Doolittle, Miller, and Boardman said, "Let us feed them when they are weak, so they can work better for us;" Herzhiser and Mason bottled the honey, and Sturwold exhibited it to the public, all saying, in effect, "Bring up your money, and eat." Then they all shouted in chorus, "There's money in it! keep bees, and get rich!"

One manufacturer tells of "millions and millions of dollars' worth of honey taken from bees annually," boasts of a plant with a working capital of \$300,000, and pictures the honey product in the United States every year as "making a solid train-load" 50 miles long. Where, all this time, is the educational naturalist who *loves the bee* as well as its product? Resting quietly, and perfectly willing, apparently, to let commercialism dominate the entire subject.

He will spend his money on elaborate bamboo rods, nickel-plated heads of ingenious devices, with fine mesh nets for the flying insects, approved drag-nets, and devices for water-insects, elaborate breeding-cages, collecting boxes; plaster of Paris, and glass and other mounts; costly storing-cases, and other elaborate paraphernalia. He will devise ingenious methods for observation of ants, as have Comstock, Fielde, and others. But what will he do for the bee, the charm, the supreme interest of entomology? Nothing. No catalog of entomological supplies with which I am familiar, though picturing a great variety of breeding-cages for other insects, has one word to say in favor of studying bees, or even a device to show for facilitating the investigation of their habits. That has been left to commercialism, and commercialism cares for nothing but the money of the arrangement.

In a life devoted more or less to the study of bees as a *Nature Study* topic of supreme merit, I have more and more felt the need of an *educational bee-hive*.

This need has presented itself to me in the twofold relation of workmanship and convenience. To remedy this defect I have devoted all my spare time for several months past. Let us examine these needs.

1. **WORKMANSHIP.**—A leading book on *Nature Study* in the school-room and home, pictures of a clap-trap dry-goods box affair that would not for a moment be tolerated as an apparatus for the study of physics in any laboratory in the land. Even those who cry the loudest for home-made apparatus in physics would not accept such a crude thing as that. A poor farm-house would demand better workmanship in a box to put behind the stove for holding fire-wood—it surely would if the photographic illustration does the subject justice. A prominent magazine devoted to life in the country has two or three times pictured arrangements for holding a single frame of bees in a window. If we are to judge from the illustration, it must have been the poorest piece of furniture in the house. The tone of the article, and the appearance of the illustration, convey the impression that the writer felt a pride in the fact that the whole thing was cheap and home-made. But why cheap and home-made? Is the subject unworthy our attention? or is it unworthy our best treatment?

Why does that periodical not publish articles on "How to Make a Dog-Kennel Out of a Dry-Goods Box;" "How to Make a Cage for Your Canary Out of Old Umbrella Ribs;" "How to Tear Up Old Rags into Ribbons for the Neck of Your Pet Cat"?" or—but why argue further? The articles admit the interest in bees as a home ornament. Then why insult the bees with anything short of the best?

In a leading university and in a prominent museum I have seen a crude "observation hive" visited by greater crowds of people than were the show-cases of specimens, and have heard them excite more exclamations of interest and wonder. Yet the glass in one of the doors cost more than the entire hive; indeed, the hives in both places were such ramshackle affairs that an up-to-date bee-keeper would hardly consider them worth a place in his back-yard apiary. The probabilities are that such an apiarist would chop them up for kindling-wood. Yet why this "economy" of the university or the museum? Are not live bees of more interest than pinned beetles or skeletons of muskrats? If they are, give them a "case" at least as good.

2. **IN UTILITY AND CONVENIENCE.**—The so-called "observation hive" has consisted of 8 or 10 frames with glass on both sides, with or without covering doors, exposing usually about two-thirds of one side of the outermost comb. The real work of the bees is on the inner combs; but, waiving that disadvantage, a hive that exposes to observation from one-twelfth to one-fifteenth of its comb surface (the glasses at the end are useless) is not an observation hive; it is an *aggravation* hive.

Another form of so-called "observation hive" has been a simple affair with glass sides for holding one frame of

comb temporarily removed from a hive, with the bees upon it. For temporary exhibition of one comb this has its place; but as an observation hive it is a misnomer and a failure. From their unnatural surroundings, and from the fact that they have no facilities for clustering between protecting combs for warmth, and especially since the bees soon die in it, my opinion is that the contrivance would better be named a tribulation or *devastation* hive. Another apparatus, originating in England, and intended to secure the desired result, has been made of two series of frames with four or five in each vertical row! Could anything be more absurd as a matter of ingenuity, or further removed from the natural condition in the natural hive? I can imagine nothing.

These facts, united with the belief that the honey-bees are unexcelled in interest from the nature-study standpoint, have impelled me for months to study the subject, and to plan what now seems to be an ideal educational bee-hive, and I have intrusted its manufacture to The A. I. Root Company, who have had extensive experience in building hives for the honey-gatherer; and who are in full sympathy with the nature-study conditions, and who, furthermore, have unexcelled facilities for fine workmanship. The hive is to be made in finely finished pine, ash, or oak, and glazed in first-quality glass.

The essential feature is an *observation chamber* backed by a force of bees in regular body hive with glass sides.

As the physicist has a battery or motor from which he takes out electricity for such experiments or observations as he may desire to make with special apparatus, so here the bee naturalist is provided with the ability to make observations and experiments.

The chamber is supplied with a padded division-board, which serves to divide it into two hives, and which is also useful as a background for photographing results obtained in either apartment. The bees may be readily isolated as a separate colony in either section for artificial feeding, for rustic comb-building, or for other purposes. The chamber is deeper than the body of the hive, so that the entire extent of the regular frame or other comb-support may be seen or photographed.

Under each half-chamber is an ingenious arrangement of slot and bee-escape. When the thin metal cover is drawn entirely out, bees go in or out freely; when half in, the bees go out only, and the chamber is soon cleared. Push the metal plate entirely in, and the bees go neither in nor out, but may be instantly removed to another hive for experimental purposes. Not a bee can then take flight to freedom, and there is not the slightest possibility of being stung. By using one or both of these sliding covers, the hive is readily made into two or three hives. Holes in the top are supplied with caps and with jar feeders.

**OBSERVATION SUPER.**—A regular Danzenbaker super with 32 4x5 sections is the third story of the hive. This is supplied with observation sides, which give clear exposure from the top to the bottom of the outer sections.

**REMOVABLE HIVES.**—Above this are two traveling hives for temporary exhibition. Bees are let into this by slot and escape device (as is done with each half of the observation chamber), so that bees may be carried from place to place or be used for class exhibition, or for nuclei experiments, and without the slightest danger of loss or injury either to the insects or to the apiarist. Both have the regular mouth opening for use as a single isolated hive. Many experiments that can not be made in the divided observation-chamber can be performed in these removable hives.

**MAGNIFYING FEEDER.**—This is on the end opposite the mouth of the main hive, and is so arranged that the observer, looking through a powerful lens, faces the window at which the whole hive is located. The top and back of this feeder are of glass. Diluted honey or simple syrup is put in small quantities in a trough one-eighth of an inch wide. Bees stand on an elevated glass shelf, and each one takes the sweets from the narrow space between the two glasses, as it takes the nectar from the flower. Collectively they have the appearance of "feeding at the trough like little pigs."

The powerful lens slides back and forth so as to give a view of any portion of this trough, wherever "the best feeding" is in progress. The lens is set one-eighth out of center from top to bottom, so that by turning the supporting-block, a range of adjustment of one-fourth of an inch up or down is given. A delicate focusing adjustment is provided by a screw with a range of three-fourths of an inch. This lens shows the heads and proboscides of the feeding bees in a wonderfully interesting manner.

The bottom of the feeder is provided with slot and slide as an escape device, previously described, and the whole is easily taken from the hive by the slides and carried to a window for closer observation, or it may be passed around to members of a class or to visitors.

**ARTIFICIAL FEEDING.**—Between this magnifying-feeder and the end of the hive which has the mouth opening there are two jar feeders with perforated caps. These are so arranged that one is over each half of the observation chamber. The hive is also provided with a Doolittle division-board feeder that may be placed in the main hive, in either observation chamber or in the one or two removable hives. From these last the cover may be taken off and the feeder put in without the escape of bees, provided the sliding cover is previously pushed in half way, so that the portable hive is cleared through the Porter escape.

**FLYING CAGE AND OBSERVATION BOX-HIVE.**—This attachment, like the magnifying-feeder, is not supplied regularly with the hive, but is regarded as an extra. It will be found very serviceable in a variety of experiments. Three sides are of glass. The other has non-rustible wire-netting. This netting is placed next to the main hive in place of the tube entrance. A long slot through the lower part of the frame matches the mouth opening of the main hive. The purpose of this flying cage is to provide a place in which the bees may fly when the hive is set up in a room away from a window for observation, instruction, or exhibition. This will be found very serviceable for use in fairs, and for temporary exhibition in schools, also for advertising purposes, and when placed with the entire hive in the show-window of a store.

This cage is hive-size, and takes on the top the regular cover, the feeding-board, with the main hive or supers. At the upper and lower portions are places for feeding. The inside of the hive is regularly fitted with supports for regular frames, or for rustic sticks. In this manner it may be used in imitation of the original bee-trees, the whole being covered with paper, cloth, or other material for making the interior dark. When this covering is removed, the entire inside of the bee-tree with rustic cross-sticks may be readily seen.

When the cage is not thus used in connection with the main hive, it is turned around so as to face in the same direction as the other hive, and both are then side by side at the window, with two tube entrances as two separate hives. A large base-board is provided for the hives when used in combination. This cage is so designed that it may readily serve many other natural-history purposes. It is unexcelled in convenience as a transforming-cage for lepidoptera or for aquatic insects. For the last-mentioned purpose bowls or dishes of water to hold the aquatic specimens are placed in the lower section.

When used as a larval feeding-cage, pots of earth with growing plants, or broken branches placed in bottles of water which are set in the earth in the pots, may be placed in the lower section.

The main hive is fitted with the Danzenbaker entrance-stops. The bottom-board is clamped to the main hive by the Van Deusen hive-clamp.

The alighting-boards of the tube entrances take Alley's queen and drone trap, bee-guards, etc. It is recommended that the Root queen-rearing outfit be purchased in connection with the hive.

Another very useful accessory is an observation lens five inches in diameter.

With the complete hive, the magnifying-feeder, the flying-cage, and observation box hive, the Root queen-rearing outfit, and the observation lens, facilities are afforded for every phase of apiarian observation, experiment, instruction, pleasure, or exhibition. At last we have an observation hive worthy the subject. The optical parts are by one of the most famous and extensive manufacturers of lenses in the world. The woodwork and bee-appliances are by the largest manufacturing establishment of apiarian apparatus.

I have not tried to produce a cheap or simple hive, but rather one which the bees and their friends have long merited. I am confident that all concerned will be pleased.

Contrary to the advice of many friends who have known of my prolonged study and work on this hive, I have refused to take out a patent. On the contrary, I have arranged with the manufacturers to have the hive and all its accessories placed on the market at the cost of production. Considering the detail and workmanship, I regard the price as barely covering cost of labor and materials. I am confident that the hive-manufacturers must look for profit to the sale

of their regular goods to the new converts which I am sure this hive will bring to the fascinating field of apiculture.

Profit and the spirit of commercialism in no wise enter into the production of this hive. I have regarded the labor spent upon it as a labor of love. To my fellow-students and lovers of Nature I cordially bestow and heartily commend "The Bigelow Educational Hive." May the study of these wonderful insects afford you as much pleasure and instruction as they have afforded me.

## New Method of Artificial Swarming, Etc.

BY C. DAVENPORT

(Concluded from page 359.)

THE event I described in my previous article in regard to a new method of making artificial swarms, took place late in the season after most of the swarming was over, so I had a chance to test this plan on only a few colonies that season, but most of these I allowed to have sealed queen-cells before I swarmed them. None of them appeared to swarm out, and all went to work with all the vigor of natural swarms.

Last year, as I said, was a poor honey season, but more than enough was secured to keep up brood-rearing, and swarming was excessive. Nearly all medium to strong colonies made preparations to swarm. And now, to be brief, I swarmed by this new plan last season over 200 colonies, many of which had sealed queen-cells.

And, now, what will be hard to believe is the fact that not one of these swarmed out, and all worked fully as well as natural swarms.

Another fact that I expect few to credit is, that I can swarm a colony by this plan, and secure more honey, than if they were allowed to swarm naturally, or than would be secured if they had stayed together with no desire to swarm, and this without regard to whether the colony is weak, medium or strong. That is, I can, here in the North, with our short flow. There is, though, in spite of all I have said, one disadvantage about this method, and that is, that so far I have not been able to devise any way by which this method can be used to unite two swarms. Here, with our short flow, more honey—especially comb—can be secured if two swarms are united, but there are possibilities about this method that I have not yet fully developed or worked out, and I wish to experiment and handle the matter alone another year before giving it to the bee-keeping world.

### REMOVING BEES FROM CELLARS.

I would now like to say something about removing bees from cellars in the spring that may be of benefit to some who have not been engaged in our pursuit long, and possibly it may to some who have. The credit for this belongs to a Mr. West, who lives somewhere in the East. It was about removing bees from cellars in the evening, or at night, and since reading what he said in regard to the matter, I have put a good many of my bees out in the evening. I tried the plan in a small way at first, for it seemed to me that after bees had been confined so long they would, if carried out at night, fly out the next day without regard to what the weather was, but I found that such was not the case. The only trouble I have ever found in this respect—and I remember that Mr. West mentioned this—is, that if it should snow before they have a chance to fly, and then turn warm suddenly, some bees may be lost in the soft

snow. I have had this occur, but I do not think the loss of bees was very serious.

Sometimes bees become so restless and uneasy by spring in cellars where conditions are not right that as soon as light is admitted the air becomes thick with flying bees that seem crazy to sting somebody or something as soon as they get out.

A year ago last spring a man came some distance and said he would pay me almost any price I might ask if I would get his bees out of the cellar either dead or alive, he did not care much which. He had about 25 colonies in large box-hives in the cellar under the house where all the fruit and vegetables were kept, and had been disturbed more or less all winter until they had finally gotten so that none of the family dared open or go into the cellar.

I told him he could remove them at night without trouble, but he said they were as bad or worse at night. This man knew practically nothing about bees. He had bought them late the previous fall, of a neighbor who had moved away. I mention the matter partly because, although these bees were wintered in a cellar under very unfavorable conditions, I have seen but very few bees in as good condition in the spring as they were. Most of those large hives were fairly crowded with bees. The cellar was very warm, and the great roaring they made was what made him think they would fly at night.

But even in a case as bad as this there need be no trouble in removing them at night, for after the window and outside door had been opened for some time they were removed and wheeled some distance on a wheelbarrow without any bees leaving the hives.

But often the greatest advantage about removing bees at night is in regard to robbing. After colonies have had their first flight in the spring I never have any trouble or pay any attention to robbing. I keep the hive-entrances of weak colonies contracted according to their strength, and if they can not defend themselves robbers are welcome to take them. But I have never yet lost one colony by robber-bees, that was worth saving, and I throw out broken combs or leave honey out to be cleaned up any time it suits me to do so.

I have, though, met with some serious losses by having colonies robbed when they were first put out. Bees seem to make no effort to defend their stores when put out in the daytime until they have had a good flight. And if only part of the bees in a cellar are put out, and a number of days elapse before the rest are removed, those first put out may remove nearly all the stores from a large number of those just put out. But when this is the case there is no fighting and loss of bees on this account, for, as I said, they make no effort to defend their stores, and if no honey is in the fields they of course soon starve to death unless close watch is kept and those robbed are fed.

Now, for some reason, when they are carried out at night they defend their stores. They fly more slowly, and seem to keep guard and be on the lookout for robbers. Robbing, though, under these conditions, can be prevented if they are put out in the daytime. All that is necessary is to give the colonies first put out a good smoking just before putting out the rest. But I prefer to put them out on pleasant evenings, because it saves opening and shutting the cellar-door for every hive, and no precaution has to be taken to close the hives, for the bees will scarcely attempt to fly out, no matter how roughly they are handled, at least when the evenings are cool as they always are here in early spring. Southern Minnesota.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Trip of a French Bee in a Bouquet

[The following sketch, written by a sister of sunny France for the French bee-journal, L'Abelle de L'Aisne, and translated by our good friend, Mr. C. P. Dadant, will no doubt be enjoyed by the readers of this department. am told that there is a Mr. Denner who is

editor of a bee-journal, and it is not unlikely that Mrs. Lucie Denner is his wife.—E.M.W.]

A few days ago I was unpacking a box of exotic flowers sent to me from Nice by a lady friend, when, in the calyx of a blossom, I found a small honey-bee numb and almost inanimate. Poor little one, victim of your zeal, you had been gathered with the blossoms on which you foraged! Seized with pity, I at-

tempted to revive it, and while warming it with my breath, I laid it by the window in the rays of a March sunshine.

I then indulged in the charming occupation of admiring the rich assortment of blossoms that the surprise box contained. The table was soon covered with them. Anemones with bright and varied colors, white and yellow jonquils, Parma violets, orange blossoms and white lilacs, gigantic mignonettes and branches of mimosa, the fine and sensitive leaves of which had folded themselves during the trip to take on a new life at the contact of water and air. This blossoming world evoked the picture of the sunny and perfumed South of France. It is this rich flora which supplies the distillers of Grasse with the penetrating perfumes they make. I read, only a few days ago, in the Belgian Bulletin of Arboriculture a very interesting report, showing that the perfume of mignonette costs

\$3700 per pound, and that it takes 16 tons of those flowers to produce a pound of perfume. The essence of violet costs a still greater price, and it requires 33,000 pounds of these blossoms to produce a pound of essence. These wonderful figures caused me to deplore the fact that so many acres of blossoms were sacrificed to satisfy the demand for a matter of vanity and luxury when the same fields would be of great use to our little bees and the common good.

While I was thus pondering, my little immigrant had become warmed by the pale sun of Alsace, and I soon heard it buzzing gaily and striking against the panes, already hungry for air and probably labor. Poor little one, how you will wonder and wander in vain through our cold country seeking for flowers and plunder! How foolish you were to allow yourself to be thus packed among those flowers. If I were to turn you free you would die of cold, or would be killed by your Alsatian sisters. What shall I do?

I then thought, as an anchor of salvation, of the queen-cage, so ingenious and practical. I introduced my little ward in one of these with a few drops of honey. I was anxious to see whether the little French bee would be accepted. But how could I know? I was determined to watch the hive that was to contain it. I had recourse to the coloring recommended by our friend and bee-master, Mr. Kraemer. I entrusted to the more experimented hands of my husband the task of decorating the corselet of our little friend with a bright red spot.

The cage has been opened and the prisoner released. Yesterday, in a fine sunshine, I had the pleasure of seeing the little southern bee flying out of the hive among its companions of Mutzig, and shortly coming back with a load of pollen evidently gathered on the alder-bushes near by.

And now, dear little winged worker, have courage. Be contented with the Alsatian flora. If it is not as rich and as varied as that of the romantic Riviera, it is yours all the same, and you can harvest from it some delicious honey.

I do not know whether this page will please my readers, but I found that trip of a bee in a bouquet so pretty and so unique that it has seemed to me worthy of being mentioned.

MRS. LUCIE DENNLER.

No "Colored Line" in Bee-Keeping

MISTAH EDITOR:—Ise now gwine to write to you 'bout de Sistahs' department. My good wife Dinah wants to know if dar is any objeksun to a cullahed lady jinin' de cirul ob de Merican Bee Journal sistahs? If dare is no cullah line, den how much does Sistah Emma charge for a sistah jinin? Will you

please refur de foregoin' quesshuns to Sistah Emma to be anshured in de Sistahs' department ob de Bee Journal, and oblege?

Well, as dis am de fust time dat I rote to de Merican Bee Journal, I speeks dat I better tell de bruddern who I is. My maiden name is "Jeems," but de boys all call me Jim. I speeks I is more dan 40 yeas old. I had been keepin' bees fo' ni on to 25 yeas. Obcese we keep only de cullahed bees, as dey seem mo' in harmony wit de things around us, but Dinah says dey had mose too warm a tatchment too de childun, as dey am so familliah wit deir biznes ends.

My daughtah "Arrovis" srys to tell you dat aldo she is not quite 16 she is very sweet, specially when she is helpin' wit de honey.

If our huney crop turns out as well as we spect this faul, me and Dinah speeks to jine de Nashington 'Sociation in a body. Dar am some people here that come from China, and they call huney "sting-bug juice."

It hab bin ssaid dat dar am aphin imposible; but dar am, because it would be imposible to make my son Eb's mouf widah wiotout fust settin' his eahs back.

We hab a nectah plant heah called allumweed. De huney from hit am so stringent dat a spoonfull giben to a comon chile wit pucker up hits mouf so hit can't baul fo' seben hours; but hit takes two spoonsfull fo' Eb.

Oh, yes, I like to fogot to tole you dat I is a cripple. Dey say dat I was bawn dat way—crippled in de hed, or, as Dr. Sea Sea Miller would say, "Crippled in de upper story of de anatomy of de cullahed jentleman."

From your confectaconaire brudder—Whitman Co., Wash. JEEMS SMITH.

There is no colored line that Sister Dinah can not easily climb over to get into the charmed circle of the Sisters' department, and she will be welcome at any time to join "in a body."

Honey for Sleeplessness

Honey has been reported as very helpful in cases of sleeplessness, and it is well known that milk helps to put to sleep grown-ups as well as babies, but why has not the combination of the two been thought of as a remedy for insomnia?

Recently a Sunday-school institute was held in Marengo, and the absence of one prominent in both Sunday-school and public-school work was much regretted. From a letter just received, the following is taken:

"I had planned to attend, when, for some unknown reason, I became a victim of insomnia, being unable to sleep for three weeks ..... Honey and sweet milk before retiring brought back my natural sleep, so I am now recuperating rapidly."

that we are guilty of some things that we are seldom flogged for. Even The Tribune did not tell them—because it did not know of them. I have seen exposed for sale at a grocery in Toledo alleged comb honey, sections that had no cappings on at all, and the lower portion of the comb was not yet built out to full thickness. This is a rare piece of bee-man's wrong doing; but there are some things not rare that we ought to be flogged for. As we can't make our adversaries quit their meanness, suppose we go to work and quit ours. Suppose The Tribune had said, "If comb honey is never adulterated how came this taste of soap in it?"

SHORTER HOURS FOR MICHIGAN BEES!

Why, Comrade Bingham, if you didn't push too far we might be induced to grant that the air of Michigan may have something languid in it, inducing laziness in man and bee—but only two hours, out of the long June day, for bees to gather—we feel that you must have overdone your job somehow. Your trade union hardly wants you to lesp from the 8-hour day to the 2-hour day all at one step. Page 278.

SEALING HONEY WITH HEAT OF HIVE.

That's a queer question on page 279 about sealing up honey with the heat of the hive still in it. Not likely that such a practice would (*per se*) do any harm. The trouble is that the heat of the hive is not enough to do any good particularly. Seal up honey when it is as hot as your hands can well bear. Considerable time must be given the minute floating particles and air bubbles to rise, and the attempt to utilize natural heat would prevent this.

DECOY HIVES WITH WORK IN THEM.

About decoy hives, Dr. Miller, what do you think of this? Don't have the combs and floor too clean—hive rubbish on the floor and combs calling for considerable work. The idea is that when a swarm enters a hive voluntarily it is almost always because they have become attched to that hive by doing lots of preliminary work in it. How can they go and work day after day in a hive where there is no work to do? This is apropos to your answer to "Michigan," on page 281. I am not sure a perfectly clean decoy would be any the less attractive for its cleanliness; but I suspect that scouts on first visit would go away much quicker if they found nothing to do, and therefore be less likely to return.

CALIFORNIA'S VARIABLE HONEY PROSPECTS.

Yum, yum! Sure prospects now of lots of California honey on the market—unless something new under the sun transpires—or again unless an almost unprecedented succession of cold winds continue all the time through the time of harvest. Page 282.

BIGGEST HONEY-YIELD—SMELTER GAS.

That was a splendid honey-yield of Mr. Lovesy's, related on page 284—one strong colony increased to six, and made to yield close to a thousand pounds of surplus. Pity those 384 sections were not weighed. We can hardly assume that they weighed 383 pounds without a little more evidence of it. I am a little inclined to think that this is the most satisfactory and best authenticated approach to the 1000-pound yield that this continent has had published so far.

Probably where bees suffer in winter from the gas of distant smelters, it helps them a little to be in a 4-story hive—supply of pure air inside. Where winters are severe and air perfectly pure, I think all needless extra space inside is more or less of a damage. When the hives are so few why not winter them on a high, 4-posted platform—providing the roof of a building can not be fixed to answer? Bees should live wherever human beings can, if they are kept as far from the ground.

Introducing Queens

I have many times introduced queens—both virgin and mated—by using flour as a pacifier. When removing a queen from nucleus for a customer, I introduce another at once, sprinkling the bees with a little flour, and

Mr. Hasty's Aftershoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

PATENTS AND SO-CALLED MANUFACTURED COMB HONEY.

Provoking, but very decidedly interesting, is the language of that patent mentioned on page 276. Seems to show that, notwithstanding rules, a man may get Uncle Sam to give him a patent on an impossible invention. Examiners are human and finite—and may be about as lacking in bee sense as the private citizen we are oft amazed at. As a natural result they don't always know what is possible, and what is impossible; and they give the man who wants a patent the benefit of the doubt. Somebody invent and patent a machine for taking a certain leading misrepresenter of comb honey and making him into a somewhat different sort of man. The finished product of this machine would try to compensate old wrongs instead of adding to them. Said product would realize

what great wrongs he had done in the past to a section of the people he is paid to serve. Therefore, said product would not put out words sounding like the words of a lawyer paid to do more of the same mischief—as much of it as possible without out-and-out untruth.

And the New York Tribune, mainly right, and all along leaning on apparent evidence, still loses sight of the main thing—as human beings usually do when they argue. The main thing is that a company of honest people in an honest calling are confronted everywhere with the charge that their product is completely fraudulent. And that charge is not a fact, and there is no danger of its ever becoming a fact, yet The Tribune will not say so in a way to count as it should.

Still, when we get flogged for what we are not guilty of, it's a good time to remember,

also the queen, then dropping her in among the bees, or letting her run in between the frames, and in nearly every case she has

been accepted. This is a great saving of time to the bee-keeper.—W. WOODLEY, in the British Bee Journal.

hive, or can a swarm be put in a hive, without any honey or comb, or even foundation starters, or is it best to put comb in a hive when transferring or hiving a swarm?

7. How is beeswax made? Should it be a bright yellow color, or rather dark? In what shape should the cakes be made for sale?

8. How much brood-comb should there be in an ordinary 8-frame hive about the first of May?

9. Would it be best to get a frame of brood and put it in the hive, or put starters in the frames?

10. Would having no queen cause them to swarm? If so, will they swarm again?

11. Will bees build comb in a brood-frame at all without starters? INDIANA.

ANSWERS.—1 and 2. Yes, bees are constantly dying off from old age, and all the worse in a colony which was queenless last summer or early fall, as there are none but old bees.

3. I don't know. Perhaps you mean a bee-moth, or wax-moth, which is a common-looking moth of a dull, grayish color.

4. Not before fruit-bloom.

5. About 21 days after the issuing of the prime swarm, for that allows the prime swarm practically to transfer itself. If you don't want to wait for that, transfer in fruit-bloom.

6. A swarm will generally stay all right in a hive entirely empty, but in transferring the combs go with the bees.

7. Melting the combs and separating the wax from the other parts makes beeswax. Unless it is burned or injured in some way it should not be very dark color. It doesn't matter about the shape of the cakes.

8. The 8 frames should be entirely full of comb in the fall, and of course there will be just as much comb the following May.

9. If you mean, when hiving a swarm, it is better to have the frames entirely filled with foundation, and many think it advisable to give a frame containing brood and honey to a swarm.

10. Yes, a colony in the case you mention would be more likely to swarm out if queenless, and still more likely if also short of stores. In that case they are likely to swarm out again.

11. Yes, but they may not build it just where you want it.

If you have not already secured a book of instruction about bees, you could not more profitably invest a dollar or so than in that way.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to Dr. C. C. MILLER, Marengo, Ill.  
 Dr. Miller does not answer Questions by mail.

### Diseased Bees

We have 20 colonies of bees, 4 of which are diseased, and we do not want the disease to spread.

The colonies are pretty strong, have frames full of brood, and have plenty of honey. The larvæ die in various stages, some while quite young and others just before being sealed and after being sealed. Some die while they are white, some turn brown and black. Those that are black are large, but both turn black, sealed or unsealed. Some of the larvæ come half-way out of the cell and stick there. There is a sour smell on combs and larvæ, but no ropiness in the larvæ.

1. Do you think it is pickled brood, or foul brood?

2. Can we feed the honey back to the bees?

3. We have shaken the bees into new hives on new frames and foundation, and let them fly. Have we done right?

4. What causes the pickled brood, if it is pickled brood?

5. Do you think the cold, frosty nights did it?

6. We hear there is some foul brood in our township, but none closer than 4 or 5 miles, that we know of. If this is foul brood to whom should we send a sample?

ILLINOIS.

ANSWERS.—1. It may be pickled brood.

2. No, the honey will very likely carry the disease with it. If it is nice honey it will be all right for the table.

3. It would probably have been better if you had waited till bees were busy storing.

4. A microbe, but just exactly what microbe does not seem entirely settled.

5. Not if it's anything like pickled brood.

6. General Manager N. E. France, Platteville, Wis. Put in tin or wood, so it will not be mashed in the mail.

### Swarming Affected by Hive-Color

At the State Bee-Keepers' meeting yesterday Allen Latham said bees would not swarm from a hive painted a dark color and set in the shade. Does the color of a hive have any effect on swarming when in the shade?

CONNECTICUT.

ANSWER.—I. I don't understand why color should make any difference in the shade. Possibly he meant that shade would lessen the likelihood of swarming, even if the hive was dark.

### Queens Missing and No Queen-Cells

This spring I sent to one of the queen-breeders for 2 queens, which I introduced into 2 good, strong colonies. One week later I opened the hives and found both queens all right and both were laying. I put a feeder in each hive, and began feeding a little every night. Two weeks from the time I introduced the queens I looked for them again, and found them without any trouble, as the bees were black and the queens Italians. A few days later I looked for the new queens to clip them, but could find neither of them. Do you think the bees killed them, and if so what was the cause?

I waited a week and then looked again, but there was no queen in either hive, and the eggs had all hatched. I could find no queen-cells started yet, so I waited a week and looked again, shaking the bees off the combs

and looking very carefully for queen-cells, but there was no sign of one started. I have since given each colony a frame of eggs and brood, and still they do not start queen-cells. The brood is all sealed except that in the frames I have given them the past week. What can I do to get them to start cells?

MINNESOTA.

ANSWER.—The case is a very unusual one, and I don't know what to think of it. Sometimes a queen is accidentally killed by the bee-keeper when a hive is opened, and sometimes the opening of a hive makes the bees kill a queen, but it would seem strange to have it happen with 2 colonies, and then to have neither colony start cells. If they persist in refusing to start cells, you might try swapping frames of brood and bees with other colonies.

### Strong Colonies for Winter

1. Does it pay to work for strong colonies of young bees to go into winter quarters?

2. Can it be done by feeding in the fall to cause brood-rearing?

3. When would you begin feeding for that purpose, and how long would you feed?

MINNESOTA.

ANSWERS.—1. It pays to have such colonies, and it sometimes pays to work for them.

2. Yes, if there is no yield of honey in late summer and fall.

3. Generally I wouldn't begin at all, for generally nature takes care of the matter; but if there is an absolute absence of nectar I would perhaps begin toward the last of August and continue 2 or 3 weeks.

### Bees in a Nail-Keg—Moths—Transferring—Swarming Rendering Beeswax, Etc.

I have a small colony of bees which I kept outdoors all winter in a nail-keg. When I hived them last fall they seemed to be a large colony, but they have been dying until now there is only about a quart of bees in all. On March 16 I changed them to an 8-frame hive which I had made. While I was transferring them the weather got cooler, the temperature going to 40 degrees above zero. I put a good roof over them and a carpet over this. They had nearly enough brood-comb to fill one frame, and only about 4 square inches of honey. They have never seemed to be satisfied since I changed them, and did not appear to be gathering any honey or pollen, although the apple-trees are in bloom, and several days ago, while still in the keg, they were gathering in a great deal of pollen. Yesterday—8 days after I transferred them—the whole colony left the hive. I followed them 150 yards, and they clustered on a limb. I put them in the hive again, and they seemed to be better satisfied. I don't think they have a queen. She probably got killed while I was transferring them. I have never seen her, although when they swarmed I looked carefully for her.

1. Is the loss I mention natural?

2. Should there be a constant loss of bees in winter through dying and falling to the bottom of the hive?

3. What does a honey or comb moth look like?

4. How early is it safe to transfer, taking climate, etc., into consideration?

5. What is the best time to transfer?

6. Can a colony of bees be transferred to a

### Sunken Brood Cappings, Etc.

1. When the cappings of the brood-cells are sunk, is it always an indication of disease, or are the cappings of healthy brood sometimes sunk?

2. Of what use to the bee are the 3 black spots (thus . . .) seen on the back of the head of the larvæ about the time the eyes begin to get dark?

3. Is there any reason for bees so often holding their hind legs straight down instead of using them to hold on with when they cluster?

4. I had 4 queens come out with a swarm, and, as far as I know, it was a prime swarm. How would you account for that?

TENNESSEE.

ANSWERS.—1. I don't know that the cappings of healthy brood are ever sunk, but dead brood might have sunken cappings without any disease being present; and, of course, dead brood could hardly be called healthy brood.

2. I don't know unless it be the three single eyes.

3. They are likely to have a good reason for everything they do, but I don't know what the reason is in this case. If you mean when they cluster in festoons, it would seem that the hind legs ought to hang down free so that the next bee below could hang onto them.

4. The old queen may have been lost in some way (possibly accidentally killed, possibly she issued with a swarm, was unable to fly, and the swarm returned), and when the young queens matured a number were allowed to go out with the swarm.

# BEST BEE-SUPPLIES

Lewis' Goods at Factory Prices.

Root's Smokers and Extractors, Dadant's Comb Foundation, Bingham Smokers.

Dovetailed hives with the famous COLORADO COVER. The best cover ever put on a bee-hive. Hives (if entirely complete) cost you no more with this cover than with other covers, but they are far better. WHERE DO YOU LIVE? We will quote you a price with freight paid to your station if you send us your list of what you intend to buy. We ship goods each year into every State east of the Rocky Mountains; let us ship to you.

## Reports and Experiences

### Swarms Entering Empty Hives

I notice on page 281 a question about getting swarms to enter empty hives. I would like to know how it is done. When the bees swarm I place an empty hive wherever I have cut a bee-tree. The places are about a mile apart. JAMES L. A. MILLER.

Gasconade Co., Mo.

### Moving Bees

I have seen a great deal about having trouble in moving bees a short distance. I moved my bees about 300 feet without any trouble on Feb. 20, and they had two flights before I moved them. I don't think any one would have trouble if it were done right.

W. H. HOBERT.

Muscataine Co., Iowa, April 20.

### Giving Afterswarms Combs of Brood

In reply to G. M. Doolittle's advice to a beginner to give to a second or afterswarm a comb of brood, that it is all right from the mother colony where no eggs are to be seen, or he may find that virgin queen right in front of that second swarm, killed by its own bees. It might work with genteele Italians, but not with cross bees. I give brood to first swarms to insure their remaining. I never allow eggs where a queen is to mate, not even in baby nuclei, and they generally finish the best queens of all.

I have been a bee-keeper for 40 years, and for 16 years have secured my living from them. One don't need 100 colonies to support a family, when he knows how to handle bees. JOHN H. GUNTHER.

Wood Co., Wis., April 19.

### Honey Sold in Light-Weight Sections

I have sold goods (groceries) for over 20 years, and it is my observation that 9 out of 10 people will say that they don't believe there is a pound of honey in a section, and it was only by weighing it for them that it was possible to make a sale, and not always then. But I very seldom failed to make a sale when the section weighed a full pound.

Henry Co., Mo., May 5. F. P. DAUM.

### Selling Light-Weight Honey

As to selling honey by light weight, when I first commenced with section honey I used 1 1/2 sections, and found that the bees did not build in all sections alike. One-half bulged

(H. H. HYDE, Successor)

1 Dtf SAN ANTONIO, TEXAS.

Please mention Bee Journal when writing

so badly that I could not case them. About this time the fence separator made its appearance. On examination I found that a 1 1/4 section and the fence just filled the 1 1/4 slats. I find that a 1 1/8 section filled when the fence is in will average 15 ounces right through. I put 15 sections in a 12-pound case and sell it at \$1.50. That is as cheap as dirt.

I would not do anything with the bees if I could labor, but I am crippled with rheumatism so badly that I can't get about to do other work. I think that Mr. Morgan is right. When I fill up what few empty hives I may have on hand, I let the rest go if I can not double up.

D. C. WILSON.  
Linn Co., Iowa, March 24.

**Fastening Foundation**

No doubt Mr. Doolittle can do all he says he can in making bee-fixtures in the winter, but he did not inform one how he works his wax. He no doubt has a shop which he can make comfortably warm and that is sufficient to take the brittleness out of the foundation. Then very likely he uses knife and wire-imbetter, as hot as hot water can make them, to work it.

We tried every way we could learn of to stick foundation, without much satisfaction, until we stumbled on using hot beeswax, and the way to do it.

In our shop the ground is the floor, and we dig a pit in the center and build a fire in it sufficient to warm it, and the smoke goes out of the open places. We have no snow, and a small amount of freezing weather. We then have an oil-stove to heat water, tools and wax. We use a discarded frying-pan to heat water in and set in this a miner's small coffee-cup filled with wax to be melted. Next we must have a stop to put on the frames, to stop the foundation in the center of the frames. We take a stick larger than the top-bar of a frame

**STAR DYES**

and cut out a piece the size of the top-bar, only a shade thicker, so we can wedge the frame. Then cut a piece a half-inch thick, and nearly the length inside the frame, and nail it on the first piece so the edge will come nearly to the center of the top-bar. Then the foundation will be in the center of the frame, then wedge so the top-bar will fit up to the last piece. The foundation can be set on the bar and pressed down tight with the fingers, so the melted wax will not run under it. Then take a frame and foundation in the hand, and hold it at an angle of 45 degrees, more or less. Take a spoon and dip up the hot wax. We soon learn the proper amount, and put it at the upper corner pouring it out so it will run down the corner of the frame and wax. It soon cools. Then turn the frame and serve the other side in the same way, being careful to keep the foundation resting on the wire when turning. Patience and perseverance soon enable one to make a good job.

We prepare a quantity of foundation, one side of which *must* be made straight with a straight-edge, and a hot knife out of a frying-pan of hot water. Heat the wire-imbedder in the same place.

We never were so well prepared for swarming-time as we are now, having done all our work of making hives and frames, and wiring and putting in foundation last winter. The bees are late in commencing to swarm here. In the orange orchards they were swarming several days ago.

If my description of putting in foundation will help out some beginner in bee-keeping I shall be satisfied. A. B. CARPENTER.

Tulare Co., Calif., April 28.

## Putting Out Cellar-Wintered Bees

The spring problem with cellar-wintered bees has been solved by me in the following way:

Seven years ago I put some bees out on March 23, to save them. They did so well that I have ever since put all the bees out the first fine day in March, with very good results, compared with the years previous to that time, when I waited for settled warm weather.

I made a bad-weather case by sawing a large shoe-case through the center, after nailing laths on each side of the proposed cut. I then put 4 to 6 feed-sacks over each hive, and put the case over all. Close the entrance all but a small space, and all is well.

The cases and sacks are also used in cold weather to get the bees to stay in supers one night. At the time of our harvest in the fall the nights are so cold that every bee will leave the supers, and I can lift them off in the morning without escapes, leaving me with thin and uncapped honey.

JOHN J. McRAY.

Ontario, Canada, April 19.

## White Clover, But No Nectar

Bees are doing poorly. They wintered well and built up well early in the spring, but they have been living on stores they had from last fall, or what has been furnished them in the shape of combs of honey saved over for the purpose of feeding from last year. There is lots of white clover in bloom but it seems there is no nectar in it. May be when it stops raining every few days the bees will do better.

ROBT. A. HOLEKAMP.

St. Louis Co., Mo., May 16.

## Balled Queens—Values the American Bee Journal

I have been trying to get some new subscribers to the American Bee Journal, but every one I spoke to side-tracked me in some way. One man laughed at me and asked me if I believed there was such a thing as foul brood.

On March 13 I visited a man who was taking out honey. I asked him if he was not robbing the bees, but he said that the bees would never eat all that honey, and besides they could live all right from now on, any way. He had about 40 colonies in box-hives, and was cutting down into the brood. It looked to me as though he needed the Bee

Journal, so I gave him one, and told him how it taught us of the decided advantages of the new hives over the box-hives. He said he had been getting along with his bees for about 20 years without the help of a bee-paper, and guessed he didn't need any.

For the last 12 years I have been a blacksmith, and in the spring of 1903 I bought 4 colonies of black bees from one of those haphazard bee-keepers. They were in some kind of movable-frame hives, but the comb was built in all kinds of shape. I wanted to Italianize them, but waited for them to swarm. I sent for a couple of queens—first subscribing for the American Bee Journal—cut out the crooked combs and divided 2 colonies. I then got a bee-book and went to work. But I want to say that I give one copy of the American Bee Journal the whole credit for saving the life of one of my queens. Every time I looked into the newly divided colonies after putting in the caged queens, I hoped to see the queens crawling around among the bees. At last the bees freed the queens and balled one of them. Now I was at a standstill, and started a letter to one of my friends to find out what to do. As luck would have it the Bee Journal came that night, and I began to look through it when I noticed a heading about balling queens. The good man that wrote it told how to drop the ball in a pan of water to get the queen out. I could hardly wait until the next morning, when I "baptized" that ball of bees in great style. I got the queen, and put her on the top-bar, and that was the end of my trouble in introducing. I worked after the instructions of the Bee Journal and "A B C of Bee Culture," and built my 4 colonies up to 13 last year, have brought them through the winter in good condition, and they are working nicely. J. D. PASLAY.

## Honey and Beeswax

CHICAGO, May 8.—With April about all the trade in comb honey ceases so far as this market is concerned; occasionally a case sells, but no lots, so that prices now are practically without change, pending the new crop. Extracted is exceedingly slow of sale; white ranges from 5½@7c, and amber 5¼@6c, according to flavor, quality and package. Beeswax in active demand at 30c. R. A. BURNETT & Co.

CINCINNATI, May 8.—The demand for honey has increased quite a bit since our last quotation, which is due, probably, to the concessions made in prices to affect sales, as well as the awakening of the spring trade. We quote amber extracted honey in barrels at 4¼@6¼c, according to quality. White clover and fancy extracted honey at 6@7¼c. Comb honey has seen its season. Beeswax 29c cash. THE FRED W. MUTH Co.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c. HILDRETH & SBOELKEN.

PHILADELPHIA, May 8.—The season is about over for the sale of comb honey. There are so few sales that the market is not established enough to quote price. Extracted honey has met with some demand, and prices are as follows: White, 6@7c; amber, 5¼@6c. Beeswax, 28 cents.

We are producers of honey and do not handle on commission. WM. A. SELSER.

BOSTON, May 9.—There is no change to note in the condition of the honey market from our quotations of April 24. BLAKE, SCOTT & LEE.

KANSAS CITY, May 12.—The honey situation is a little stronger, and there is but little honey left in the hand of the dealers. Best honey bringing from \$2.25 to \$2.50 a case; amber at from 25@50c a case lower. Extracted, 4¼@6c. Beeswax, 28c. C. C. CLEMONS & Co.

CINCINNATI, O., May 18.—The large stock of comb honey yet offered with hardly any demand causes lower prices. I quote fancy water-white at 12c; other grades lower, in proportion. Extracted is in usual demand for this season of the year. We quote white clover 7@8c; amber in barrels at 5¼@5¾c; in cans, 5¼@6c. Beeswax, 28c. C. H. W. WEBER.

ALBANY, N. Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand; Buckwheat, 6@6¼c; white, 6@6¼c. Buckwheat most in demand, as the Jew sh people will have no other. Beeswax, 30@32c. H. R. WRIGHT.

SAN FRANCISCO, May 3.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted-white, 5¼@6 cents; light amber, 4@5c; amber, 3@3¼c; dark amber, 2¼@3c. Beeswax-good to choice, light, 29@30c; dark, 27@28c.

The steamer City of Peking, sailing Saturday last, took 85 cases for Belgium. Movement on local account is light. Buyers are holding off, anticipating arrivals of new crop at an early day.

5. Vice-Pres. Dr. E. Gallup  
6. Treas. N. C. Mitchell

# ESTABLISHED IN 1861

# AMERICAN BEE JOURNAL

## THE OLDEST BEE-PAPER IN AMERICA

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., JUNE 1, 1905

Vol. XLV—No. 22

THE AMERICAN BEE JOURNAL is absolutely an independent publication, and not connected with any bee-supply business whatsoever. It stands entirely upon its merits as an educative force in the field of bee-keeping, and as a medium for legitimate advertisers in apicultural or other lines. It is the oldest, and only weekly, journal of its kind in America. Its publishers believe that it deserves to be in the hands of every would-be progressive successful bee-keeper in the land. It is in its 45th year, and to-day is acknowledged to be better in every way than at any time during its long and honorable history.

## Editorial Notes and Comments

### First National Bee-Convention

Dr. G. Bohrer, on another page, gives a most interesting account of the first attempt to organize a bee-keepers' association in the United States. Being a member himself he speaks as an eye-witness. He gave something along the same line at the opening of the St. Louis convention last September, but the reporter failed to get it. We regretted it very much, as it was an extremely interesting address, and being of historical value we felt that it should have been preserved. So, afterward, we requested Dr. B. to write it out as nearly as he could recall, and so we have it for our readers this week.

In addition to the contribution by Dr. Bohrer, he has kindly furnished a picture of a group of men who helped organize the first bee-keepers' association in America, which we present on the front page. We believe the only members of that group that are still living are Dr. Bohrer, of Kansas, and M. M. Baldrige, of Illinois. If any of the others are still with us, we would be pleased to announce it.

We are sure Dr. B.'s article will be greatly appreciated by all our readers.

### The Honey-Producers' League

We believe that so far practically all the bee-papers of this continent have approved this new organization in the main. Of course, it would be expected that some of the details would not suit all, though the few objections that have been advanced by some are not insurmountable, but can be met and corrected later on. What we mean is, that any slight defects in the constitution or management of the League can easily be rectified at the annual election next March, if by that time it is thought best to make any changes. What is needed now is to put the League in a

position to do some effective work for bee-keepers before, or by the time, the new honey crop begins to come on the market. If during the next 30 days a sufficient number of bee-keepers would send in their annual dues, the Executive Board could plan a great advertising campaign that could be put into active operation so as to prepare the public for the reception and consumption of this season's crop of honey about as rapidly as it comes on the market.

We may say that practically all the United States bee-papers have published in full the Constitution and Prospectus of the League, just as we gave it on page 259.

The Modern Farmer and Busy Bee had this to say about it:

The latest candidate for favors among the bee-keepers of the United States is The Honey-Producers' League. Its object, as expressed in the Constitution, is to create a large demand for honey by popularizing its use among the consuming public through advertising in newspapers and magazines its great value as a food, and by such other methods as may be considered advisable by the Executive Board. Also, by publication of facts concerning the production of honey to counteract any misrepresentation of the same. . . . The aim of the League is a good one, and the indications are that it will receive the hearty support of the leading bee-keepers of the United States.

Editor Craig, of the Canadian Bee Journal, in his May issue, writes as follows:

The Honey-Producers' League, recently organized in the United States, is, we believe, going to be one of the most useful movements yet inaugurated among bee-keepers. We understand that for the present at least the effort will be confined to the United States. Perhaps by and by the organization will see its way to extend its border and take in Canada. At any rate, we will be helped indirectly. Something of this sort may perhaps be taken up in connection with our Ontario Association. If space permits we will next month give the text of the Prospectus and Constitution.

"A York County Bee-Keeper," in the same paper, expresses himself thus:

When reading over the Constitution of The Honey-Producers' League, the thought came to me, "They can fight successfully honey adulteration, but how are they going to get at the producers of unripe honey?" While this organization has plenty of difficulties in the way, I think the one mentioned will be one of the most formidable. What's the matter with The Honey-Producers' League, anyway? We think it a splendid idea, and hope that in some way arrangements can be made for us Canucks to take part in the benefits. What say you, brethren?

Surely, such expressions of confidence and encouragement are appreciated, and should result in bee-keepers coming forward with their dues and thus aid in the proposed effort to help themselves through a general advertising of honey among the public.

On another page of this number Mr. J. E. Johnson offers some good suggestions and friendly criticisms. We hope his whole article will be read carefully. What the bee-keepers in his locality propose to do about selling their honey crop should be followed by the bee-keepers of every locality. And that should be done *in addition* to the advertising that the League is organized to do.

Mr. Johnson seems to think that the organizers of the League have made some mistakes. But let us see about that.

First, we think it is not likely that a bee-supply manufacturing concern that does a business of say \$100,000 or more a year, is going to raise prices in order to pay its small annual dues as members of the League.

As to what Mr. Johnson thinks is a second mistake, we may say that the League has not definitely decided to offer a \$10,000 reward. It may offer none at all.

As to the third mistake, there is no danger of starting out too big in the advertising line, for even \$5000 would be too small an amount with which to do big advertising. But we must start in a way that will impress the people that bee-keeping is more than a two-by-four business. And then, having started the advertising it should be continued several months in succession in each publication used.

It may not be known to many, but a single cream separator firm spends over \$50,000 a year in advertising; several single poultry incubator firms spend \$10,000 or more a year. We believe there is a certain stock food firm that spends over \$100,000 a year in advertising. A full-page advertisement in the Ladies' Home Journal costs about \$1000 for just one

time. But it goes every month into over a million homes. Think of it! But the League would perhaps take only about one-eighth of a page in that Journal, if it went into it at all. It would not pay to take say a one-inch space in such a publication.

Let us assure bee-keepers that the Executive Board of the League will not do anything rash, or without due consideration. They all desire only the best interests of the pursuit of bee-keeping, for, their own success, like that of the honey-producers, depends upon the prosperity and success to be derived from the production and sale of honey.

### Use of Springs in Supers

Super springs are found on the list of bee-keepers' supplies; but it is doubtful that they are used as generally as they would be if their advantages were known more fully. The common way of wedging up a super of sections with a straight stick may seem quite satisfactory to one who has never given the matter much attention, because when the

wedge is first put in the sections are pressed together very tightly—more tightly, indeed, than the springs—but sections have a way of shrinking, especially when wet before being put together, as so frequently they must be to prevent breaking, and so it often happens that by the time the supers are put on the hives the wedges have dropped down. Springs accommodate themselves to this shrinking of the sections, and although the pressure is not quite so much, there is no entire cessation of pressure as with the wooden wedges—if straight sticks can be called wedges.

Another thing: There is no little variation in the size of wedge needed, and it is not convenient to have wedges of varying size; the result is that some supers are too loosely wedged, and some so tightly that there is danger that the supers may be pulled apart at the corners; the springs accommodate themselves to these different sizes.

The springs are easier put in; easier to take out.

It is an easy thing to try springs in a few supers. If they prove an advantage the number can be increased.

## HISTORICAL

### The First Convention of Bee-Keepers Held in the United States of America

BY DR. G. BOHRER

During the summer and fall of 1870 the matter of calling a convention of bee-keepers of the United States and Canada was agitated, and resulted in the decision that it should be held in the city of Indianapolis. It was held Dec. 21 of that year. Mr. N. C. Mitchell, who was then publishing what was known as the Illustrated Bee Journal, in Indianapolis, was one of the prime movers in arousing interest in favor of a convention of national character. His efforts were seconded by such men as Adam Grimm and A. H. Hart, of Wisconsin; E. Rude and A. F. Moon, of Michigan; Elisha Gallup, of Iowa; M. M. Baldrige, of Illinois, and others of that State whose names I can not now recall; Aaron Benedict, of Ohio; T. R. Allen, of New York; Dr. Hamlin, of Tennessee; Gen. D. L. Adair and J. H. Nesbit, of Kentucky; Mr. Atkins and his wife; and Mr. Scofield, Mr. Barber and myself lent the movement our support in Indiana. There were some others in Indiana who favored it, and Seth Hoagland and R. Bickford, of Pennsylvania, also supported it. R. C. Otis, of Wisconsin, attended the convention. He was the owner of much of the territory covered by Mr. Langstroth's patent. He came to examine the different hives there for the purpose of finding out if any were infringements on the Langstroth invention, and nearly or quite all were, although but one or two of the exhibitors in attendance would admit it.

A delegate to this convention from Utah, whose name I have also forgotten, purchased 100 colonies of Italian bees from Mr. Grimm while at the convention, paying him \$1500 for them. This was probably the largest deal in bees that had ever occurred in this country up to that time.

At this convention A. F. Moon was elected president, and I think there was also a secretary elected—M. M. Baldrige, of Illinois. The proceedings of this convention were similar to those of bee-keepers' conventions nowadays, except that very little was said about hives, further than to agree that to successfully manage bees the combs must be movable. There was, however, quite a feeling of anxiety on the part of most of the owners of the different patterns of movable comb hives, it being generally believed that the presence of Mr. Otis meant unfriendliness toward them, which might end in prosecution for infringement on the Langstroth patent, which Mr.

Otis then controlled in most, if not all, of the States and Territories.

On motion of R. C. Otis, Rev. L. L. Langstroth was made an honorary member of the Association.

During the afternoon of the first day's proceedings a telegram came to the convention from H. A. King, of New York, which read as follows, or nearly so:

"Officers and Members of the Bee-Keepers' Convention at Indianapolis, Ind.:—You are earnestly requested to meet with your bee-keeping brethren at Cincinnati, Ohio,"—giving the date, which, I think, was in February following. The convention then in session was called the "North American Bee-Association."

Mr. King was the maker of the "American" hive, and while he was selling a straight-out infringement on the Langstroth patent, he had not admitted it up to that time, and was selling more hives than any other one dealer in the country. He was a most persistent advertiser, and sold a bee-book which was quite a help to the beginners in bee-keeping.

After some discussion it was decided to accept the invitation to attend the convention at Cincinnati.

Mr. King's reason for not attending the convention at Indianapolis came out in the following statement, which he made through the press:

"The convention has been called to meet at Cincinnati because it is centrally located, free from local influences, and near the home of Mr. Langstroth, whom we want present."

Most of the bee-keepers at the Indianapolis convention were friends of Mr. Langstroth and his invention. Mr. King knew this, and also knew that most of those that were not were friends to the "Buckeye" hive, of which Mr. N. C. Mitchell was the inventor.

When the time for the election of officers for the ensuing year was announced, Mr. Otis moved that in view of what Mr. Langstroth had done in promoting the interests of bee-keeping, not only in this but in other countries, he be crowned with the honor of being the President of the North American Bee-Keepers' Association for the ensuing year. The motion was warmly seconded, and Pres. Moon was authorized to cast the unanimous ballot of the Association for him.

Mr. Langstroth was present at the Cincinnati convention, also H. A. King, A. I. Root, Mrs. Ellen S. Tupper, and nearly all who had attended the Indianapolis convention. A motion was made by Mr. King on the second day of the convention that the bee-keepers present be requested to donate a liberal sum of money to Mr. Langstroth. I opposed the motion on the ground that it would be humiliating to the man who had done so much for the interests of bee-keeping, and that every one who was deriving benefit from his invention had not paid for the right to use it, as I had done, or Mr. Langstroth would not stand in need of donations from any source. I also stated that I had not to exceed a thousand dollars with me, and might run short of funds in case I gave Mr. Langstroth such a sum as all present ought to give if the benefit was to amount to much. Rev. F. W. Clarke, of Canada, supported my statement, saying that he had heard something about Mr. Langstroth, and that among other things he had learned that a number of persons had fared sumptuously as a result of having sold to a great extent hives that embraced the Langstroth invention, and suggested that they be requested to disgorge and divide profits with Mr. Langstroth, which would probably relieve his wants. This about killed the donation move, and Mr. A. I. Root afterward wrote that at the time he censured me for having blocked this move, but that after more mature thought he concluded that I was not far wrong.

After a two days' session devoted principally to the usual subjects, this convention—called the American Bee-Keepers' Association—adjourned to meet one year later at Cleveland, Ohio, it being agreed by the bee-keepers that they would meet at the above-named city at the same time and place, disband as separate organizations, and organize as one body. There was no cause or feeling of any sort to prevent such a union, as the masses of bee-keepers had no bone of contention. The feeling that existed between King, Mitchell, and other patent-hive men was left for them to adjust either in the courts or among themselves. Mr. Quinby, the author of "Mysteries of Bee-Keeping Explained," was present, and was made temporary chairman. The late Capt. Hetherington, of New York, and Dr. J. P. Kirtland, of Cleveland, were at this convention, and also Prof. A. J. Cook, then of Lansing, Mich., but now of California. Dr. Kirtland was one of the first men of talent and rare scientific acquirements to make note of Mr. Langstroth's invention, and call public attention to its great worth.

I made a motion for the election of a treasurer, which was seconded by Prof. Cook, Rev. F. W. Clarke, and others. It was antagonized by Mr. King, on the ground that it was likely to result in loss to the members, and that at best it would involve a membership fee. This last statement was a cunning dodge, and was largely shared in by the bee-keepers present, so that the motion was lost. I then moved that a record of the proceedings of that convention be kept, and that they be published. This motion was carried without opposition—then questioned the convention as to where the money was to come from to defray the expense of publishing the proceedings. At this stage the motion to create a treasury department was about to be renewed, when King again came to the front and stated that he would publish the proceedings free of charge. He published a periodical, the name of which I do not remember, and on the strength of this offer received a number of subscriptions. One year later this new organization (now called the National Bee-Keepers' Association, if memory serves me correctly) met at Indianapolis. This was during the winter of 1872-73. I never attended another meeting of this body until the fall of 1904, at St. Louis, as I moved to Rice Co., Kans., in 1873, and kept no bees from 1873 to 1903.

Mr. Langstroth did not participate very extensively in the discussion of subjects brought before the convention. He was depressed in spirit to quite an extent, owing to the recent death of his son, James Langstroth. Besides, he could not have been very favorably impressed with the motion that was made to collect money from the bee-keepers present for his benefit—that is, if he knew about it.

He was not present when the motion was made. He afterward wrote an article concerning proposed charitable donations for his benefit, that had anything but a friendly tone. He was not at the Cleveland convention—in

fact, I never saw him after the Cincinnati convention, which occurred not very long after the Cleveland convention. He wrote me concerning the loss of his wife, when she died, and during 1872, I think, he wrote me

from Washington, D. C., stating that Mr. Samuel Wagner, then editor of the American Bee Journal, had died that morning of heart disease. This was the last time Mr. Langstroth ever wrote to me. Rice Co., Kans.

### "The Honey-Producers' League," and Why It Should Be Worthy of Our Support

BY J. E. JOHNSON

HAVING sent in my dues some time ago to become a member of The Honey-Producers' League, I would like to offer a few suggestions and criticisms.

The League was organized very suddenly, the bee-keepers not being consulted or even notified, and thereby not being permitted to offer any suggestions or having any say whatever as to who should be the officers, and are asked to contribute their dollars to help advertise honey, but have no voice in the matter of how it should be done. I don't believe the organizers of this League can blame bee-keepers very much if they think as I did when this was first brought to my notice. In fact, it seemed to me that these men did not think the bee-keepers knew enough to do business for themselves, but would contribute their money if they furnished the brains and carried the money-bags. However, I am personally acquainted with Mr. York, Mr. Hutchinson, and Dr. Miller, at least to the extent that I am sure they were doing what seemed to them to be necessary, and I am sure they all have the interests of the bee-keepers at heart. No better men could have been chosen on the Executive Board.

Let me give an account of some experiences I have had in organization.

Five years ago I began trying to organize a farmers' mutual telephone system in this locality. I first began talking it up among neighbors. Oh, yes, it would no doubt be a fine thing, but they would not take one just yet. Some would not be on a line that had any other 'phone on, and each had an idea of his own as to how a line should be constructed, and nearly all differed from each other and from me. I had spent considerable time and study on the telephone question so as to adopt the proper method and be sure to get started right.

Well, I finally appointed a time for meeting, notified all my neighbors, and we met, that is, 10 of us did, but we could not agree on many points, so it was decided to have another meeting, and in the meantime we would all seek for more information and get others to come.

At our next meeting there were only 5 present, and some lived nearly 10 miles apart, so it all fell through, and they gave it up. But I was determined to get the thing started, so I went to a telephone constructor and made an agreement with him to furnish everything except poles, and build the line complete and install 'phones for \$25 each, providing I could get subscribers near enough together so that each subscriber should furnish 16 poles, 60 steps apart, and thus pole the line.

I then went to my neighbors with a contract to that effect, and I guaranteed them that if after having the 'phone 30 days in their houses it proved unsatisfactory, they need not pay a cent.

Well, at first only 6 'phones were installed, but the system has now grown to something over 200 'phones, and we have absolutely free service with something like 25,000 'phones. We now pay only \$2.00 per year at our home switch. Even the large cities are willing and anxious to give us free exchange, as they charge the city people 15 cents when they call us up, so they make money in that way. We just got a letter from the Peoria Independent Telephone Company, and they want to exchange with us, and I don't think any one of us would give up his 'phone for \$100.

Now, I did not do all this myself, but I hit the ball the first real hard lick, and it has been rolling ever since. The organizers of The Honey-Producers' League have hit the

ball a whack in their own way, and it has begun to roll. Let's help it along.

To the bee-keeper with from 20 to 100 colonies, I want to say your dues are not very much, and if you are benefited only a very little you will receive more than you give. And the specialist with 500 to 1000 or more colonies should not hesitate to pay his share pro rata, as he is in a critical period. If we have a big honey crop this year, with prices already very low, and lots of old honey left over, where will you be? It is very much harder to get honey to take a raise in price than it is to let it go down.

We have a bee-keepers' association in this locality called The Western Illinois. It has been growing in membership and interest ever since it was started, and our next meeting will be Sept. 20, at the Court House in Galesburg, Ills. We expect to discuss the honey-selling problem more than any other question at our next meeting. It is our intention to make arrangements to get the merchants to allow us to display our honey to the best advantage in their stores. The daily papers have sent their reporters to our convention each time, and have given a fine report of it, with large head-lines on the first page. They have treated us well, and we intend in turn to treat them well, and shall do some advertising of our home product. We shall wait on the merchants and get them to handle our product first, and if they refuse to do this we shall put a man in the field to canvass our honey from house to house, and sell in case lots in this and other cities, if we have an abundant crop (and indications are quite fair for an abundant crop).

A few years ago there was lots of honey shipped from Chicago to these small cities, but it will be the duty of our association to help sell our own crop first. Many other localities are forming local organizations and will adopt similar plans, perhaps. Thus Chicago and other large cities will not buy nearly so much honey, as it has been customary for Chicago firms to sell honey to many smaller towns in this and adjoining States. If the demand becomes less in the large towns, and the supply of honey should be large in the Western States this year, what will be the result? And I would say to the specialist, as The Honey-Producers' League offers an opportunity where both the specialists and the small bee-keepers can join hands and help each other in this matter, don't neglect your duty, but let us all pull together now, and at once. You with 1000 colonies are asked to contribute \$50. That seems a great deal, but 50 bee-keepers with 20 colonies each, also contribute \$50, and they probably all sell all their honey to neighbors, and near home, while you put nearly all of your honey in competition with others.

To the officers of the League let me say that I have read very carefully the account of your Chicago meeting, and the regulations or by-laws adopted, and as written by Mr. Hutchinson, and, in my judgment, one of the most unwise things in it is that you decided not to advertise until the treasury contained \$5000, although you all admit that work in this line is urgently needed at once. This seems to indicate your lack of confidence in the bee-keepers themselves.

Don't blame the bee-keepers if they think in return that the supply manufacturers expect to make a future raise on supplies in order to get the money back they have contributed. A small raise would more than make it up. That would throw all the expense on the bee-keepers, with the manufacturers carrying the money-bag and using as he or the Executive Board sees fit. The manufacturer contributes one-fifth of 1 percent. The bee-keeper is asked to contribute \$1.00 per 20 colonies, which, counting colonies to be worth \$3.00 apiece, is one percent, or five times the rate of the manufacturer. So, don't hold too tight a grip on that money-bag, but get to work and show the bee-keepers what you can do, and they will give this cause their general support.

Mistake No. 2 is for an organization with a capital of \$5000 or less to offer a \$10,000 reward, or twice as much as they have on hand. That is too much on the *cure-you-right-away* plan. Mr. Hasty's plan, as given in his "Afterthoughts," is certainly a much wiser one, and worthy of consideration.

Mistake No. 3 is to pay big money for a half-page advertisement in the daily newspaper with big letters, as if the people were all deaf. Don't start out too awfully big.

Start moderately, and spend the greater part of the money after you have become accustomed to the harness, so it will be used to the best advantage.

The men who started the League are deserving of praise. We surely must adopt up-to-date methods in finding a market for our product, and I am sure the leaders in the League are safe men to tie to, and if they had not started in their own way probably nothing would ever have been accomplished. They offer to do this work without salary, and I think we should not hesitate to pay our allotted share.

There is a growing antagonism between bee-keepers and bee-supply manufacturers; also between the small bee-keepers and the specialists. This should not be so. And now, as the manufacturers have planked down their money, and invited the bee-keepers and all to join in and aid the cause of the most importance to bee-keepers, let us all meet each other half way. We are all interested in the welfare of the bee-keepers—all rests upon the proceeds of the honey crop.

Probably my criticism has been rather plain and to the point, but it is meant for the good of all.

Knox Co., Ill.

## Some Remarks on Wintering Bees

BY HENRY ALLEY

**A**BOUT this time of the year the bee-keeper can go into the apiary on warm days on a tour of inspection, for the purpose of seeing where mistakes were made in preparing his bees for winter.

A few colonies will be found that have perished from starvation, not because the combs were not filled with stores the previous fall, but because the bees clustered too near one side of the brood-nest, and during a long, cold spell could not reach the food stored in combs at the opposite side of the hive.

Very large colonies are not apt to be caught in such a trap, but the weaker ones, if they happen to cluster in the early winter at either side of the brood-chamber, almost invariably die from this cause. Sometimes the bees select the combs for wintering and clustering upon that contain the least honey. There is but one way to help the bees out when this is likely to happen. Remove the empty combs at the side of the hive, and replace them by inserting full combs—that is, alternate the full and light filled ones so far as they will go. This work, of course, should be done as soon as the bees cease to store fall honey, as it can not be safely done during cold weather.

As soon as the honey-flow is over, bees should be packed for winter, and not disturbed thereafter.

A good way to winter bees is to let them alone from November to April. I mean by this, that under no circumstances should the interior of the hive be disturbed. Hardly anything can be done during cold weather that will in the least be beneficial to the colony, unless it be to carefully clear the entrance of the hive of dead bees.

Now a word about snow around and over the hives. During the winter of 1903-04, here in Massachusetts, we were buried in snow for four months. I spent much time digging the snow away from the hives, especially around the front ends, thinking each time that a warm day would soon come so that the bees could take a cleansing flight, which they seemed much in need of before the winter was half gone. But the warm day did not come—not one favorable day from December to March 20.

The mistake I made that winter cost me the loss of many colonies of bees. During the past winter, instead of digging the snow away from the hives, I spent my time in that direction in covering the entire hive with snow. In doing this I paid no attention to the entrances of the hives, but tried my best to seal them all up as tight as a fruit-jar. When the warm days came, which was Jan. 1 and Feb. 21, I dug the snow away from the fronts of the hives and gave the bees a chance to fly all they desired. Result, bees came through in fine condition.

In the spring of 1904 the best colony I found was in the yard of a man some six miles from my place. This colony was a swarm hived in a shallow hive-cap the previous June, then the box was placed upon two sticks of wood and directly upon the ground. This box of bees was not seen by the owner from November to April 10 the following year, and the hive contained nearly bees enough to swarm.

If a good, big blizzard comes your way, and covers your hives all over, my advice is to let them alone. Colonies in

that condition need no attention, and will surely come out all right when spring opens.

As a matter of fact, a good colony of bees needs but little packing to insure safe wintering. All should use hives having outside or winter-cases, and then the snow can do the bees no injury. Some coarse material, such as burlap, over the frames is about all the protection needed in winter. Upward ventilation without much draft is a great advantage to the bees.

I recently read in the American Bee Journal a good article from the pen of Mr. Latham. I can not agree with him that a large entrance is sure to winter bees. The large entrance is all right, and actually necessary, but many other things are required to insure their safe wintering.

Two years ago I purchased 10 colonies of bees from a woman in a near-by town. When I packed the hives, I remarked to the lady, that, had those bees been in my yard the previous winter they would have died, as I did not see how the bees got out of and into the hives, as the only entrance I saw in at least two of them would admit of only one bee at a time. Yet those 2 hives of bees were in as good condition as any of the 10 colonies.

I took the bees home, and during the summer managed to enlarge the entrances of all the hives. The next winter was the hard one of 1903-04, and notwithstanding the fact that each hive had a large entrance, several of those colonies died; but the loss was not caused by the size of the entrance. It was dysentery, caused by poor food and long confinement.

Bees having poor stores for winter must have frequent flights, or many of them will die.

As a rule, I have found that 100 days, or three months, is about as long as bees, either on the summer stands or in the cellar, can stand confinement here in Massachusetts.

There is within a half mile of my apiary 200 acres of goldenrod. Just so sure as the weather during the month of September is dry, warm, and pleasant, the combs in all my hives will be packed with fall-gathered honey. The quality of such honey is not first-class, certainly not for winter food for the bees. Frequent flights of the bees in winter generally bring my bees through the winter safely. When long confined, say of two months' duration, if entire colonies do not die, the hive is greatly depleted by the bees continually getting out when the sun strikes the hive during the warm part of the day. From this it will be seen the importance of darkening the entrances with snow, or in some way to keep the bees quiet.

A good queen put in not later than Aug. 1, plenty of good honey, the hive well prepared for winter, and absolute quietness, will generally bring a colony safely through to spring.

Essex Co., Mass., March 18.

## How Bees Find a Future Home

BY G. M. DOOLITTLE

**D**O bees select a future home before swarming?" is a question frequently asked. As this has quite a little to do with a start (to many) in the bee-business, it might not be amiss to talk about the matter a little.

My opinion is that where one colony knows where it is to go before it swarms, five know nothing of the kind. The reasons for such an opinion are based on the following:

First, the majority of swarms cluster within 2 to 5 minutes after coming out in the air, and then send out scouts to find a place to go for a home. This is easily proven by allowing a swarm to hang on a limb for 2 or 3 hours. Now take them from that limb or place, hiving them a rod or two away, and you will find from 10 to 50 bees hovering around that limb for from hours to days. I have often seen them about such a limb 3 days after such swarm had been hived, while, if the swarm is hived at once, no bees will be seen hovering about the limb 10 minutes after the swarm has been taken from it.

Next, I have known of swarms hanging on limbs 2 or 3 days at a time till they have built quite a little comb there, and then go off to a tree, or into some old empty hive that had been left standing in some apiary. From my own observation and that of others with whom I have conversed in this matter, five out of every six swarms alight and send out scouts in search of a suitable place for a home. If the scouts fail in finding such a place within 2 or 3 miles of where the swarm is clustered, the swarm moves off from 4 to 10 miles, when they cluster again, and again send out scouts, thus clustering and sending out scouts until a suitable place is found for a home. If a rainy day or two comes

on while they are clustered out on a limb, they build some comb; and if the weather is warm, and plenty of honey is found near when it clears up again, they may cease to look further for a home, making a home of a limb, rearing brood and storing honey, the same as if in a hollow tree, a cleft in the rocks, or a hive; for the cases are by no means isolated where colonies have been found with plenty of combs, brood and honey for wintering, with nothing to shield them from the elements save the twigs and the few leaves above them. A few years ago a friend living in New Jersey sent me a queen taken from a colony which was found in October having combs and honey enough for wintering on the underside of a grape-vine. And she proved a queen above the ordinary value, too, living and doing good work for 2 years after I received her.

But there are colonies which send out scouts to look for a future home before said colonies swarm, as is often proven by swarms going from the hive to such selected home without clustering at all, or staying not more than 10 or 15 minutes after clustering. When but a boy I remember seeing bees searching all up and down the body of large trees, and wondered what they were doing, and later on I saw quite a number going in and out of a hole in a very large tree that stood on the edge of the woods near where we had a field of corn in which I was at work. And this continued for several days, so that I should have thought there was a small swarm in there had it not been that the bees worked through that hole only from about 9 a.m. till 4 p.m. A few days later a swarm came from one of the few hives which my father kept at that time, and went straight to this tree without clustering at all.

About this time a person about 4 miles from me purchased some Italian bees, the first that had come into this part of the country, and, being interested in the same, I often went to see them. One day, on going to see him, he told me that at an out-apiary which he was working, which contained only black bees, he had noticed in the forenoon Italian bees at work cleaning out an old hive which was left there by the person of whom he bought the bees, the same having some empty comb in it. As this was something new to him, he seemed considerably excited over the matter, and said he should keep watch and see what became of it. I was also much interested and told him what I had seen, as related above.

The next time I went to see him he told me that the bees which he saw cleaning the hive were his own, as a few days later a swarm came from one of his Italian colonies, and, after circling around a few times, they started off in the direction of this out-apiary. Having a fleet horse near at hand, and being a fearless rider, he jumped upon it, and in a moment was going at railroad speed for his out-apiary, arriving there in time to see his swarm rushing pell-mell into the hive that the bees had been cleaning out. As he kept the wings of all his queens clipped, he knew that he could soon tell for a certainty whether these were his bees or not, although he had no reason to doubt that they were; for if they were, he had their queen at home in a cage, and sooner or later they must return to her unless they had come across some queen in their flight. In about half an hour they became uneasy and began to leave the hive, seeing which, he returned home only to find them coming back and running into the hive from which they went, and clustering about the cage containing the queen which he had left at the entrance of the old hive. Wishing to see more of the matter he liberated the queen, allowing her to return back with the bees. The next day they swarmed again, and again went to this hive at the out-apiary, the same as before. This they kept up for 4 or 5 days, the bees going to that hive which they had cleaned out, without clustering at all, each time they swarmed. After he became satisfied that colonies did select a home before they left their old home, and becoming tired of having them swarm so much, he divided the colony, thus putting a stop to their swarming.

A neighbor to whom he told this circumstance, took advantage of it by way of procuring some hives and a few frames of empty comb, which he placed in these hives and put them in trees and out-of-the-way places, till he soon had an apiary of his own, without even so much as having a single swarm.

Bees seem more inclined to go into places where there is a little comb than into places with no comb; but where combs are left in hives for such purposes, said comb must be free from pollen and spread well apart, or the moth will lay eggs in them, and they be eaten up with worms unless the bees happen to take possession of them before the larvæ of the wax moth do. Onondaga Co., N. Y.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Unreliable Bee-Information

A good friend in Michigan sends a clipping from that excellent periodical, *The Epworth Herald*, which emphasizes anew the fact that it is not a safe thing for any other than a bee-keeper to publish matter about bees without first submitting it to some practical bee-keeper. The article is styled, "Safeguarding the Queen," is reliable in the main, and written in an interesting manner, but some of the items would hardly be endorsed in their entirety by a two-thirds vote of the sisters. For example:

"Indeed, it is practically impossible for an intruder to enter a strange hive without discovery. And discovery means instant death and dismemberment."

And yet thousands of bees, upon returning from the fields, have entered wrong hives and received a kindly welcome. Did any of the sisters ever observe a case of "dismemberment," as mentioned?

"These honey-gatherers are not permitted to feed the queen direct. When they enter a hive they must give a mouthful to two drones waiting on guard. If the sample proves satisfactory the bees carry the nectar to the storeroom, where it is mixed with what the other workers have gathered. When the hive-cells are full, the workers and drones sample the mixture again, and then seal up the cells."

That leaves us all gagape for fuller informa-

tion. During the weeks when no drones are in the hive, what is done with the mouthful that should be given to the "two drones waiting on guard?" What weapons of offense or defense do those "two drones waiting on guard" use? "If the sample proves satisfactory the bees carry the nectar to the storeroom," but if the "two drones" do not O. K. it, what is done with it? Is there not danger that the "two drones" will be overworked when the workers are pouring into the hive with their loads at the rate of a hundred or more in a minute? When the cells are full, and the mixture is sampled again, do the same "two drones" do the second sampling?

Other questions may be asked when the foregoing are answered.

### An Austrian Sister "Skirts" Bees

The following account of what one of the sisters did in Austria is from the *American Bee-Keeper*:

"Jungklaus also tells how a young woman captured a swarm of bees. Being on a tramp, she found a swarm of bees hanging on a bush. Wishing to secure it, she took off one of her skirts, tied up one end, and, by the help of sticks, spread it out in such a way that she could have the swarm into it. After the bees had all moved in, she tied up the other end of the skirt and thus carried the swarm several miles to her home. ('Well done.')

We have twice had a somewhat similar experience. Once on our way to the Hastings apiary—which is about 5 miles distant—when about half way there we were offered by one of the neighbors a small swarm of bees which hung on a willow-tree by the roadside. Dr. Miller thought it would not pay to bother with them, as we had no way of carrying them, when I suggested my bee-hat—a broad brimmed straw-hat with a veil sewed around the outer brim, having a rubber cord run in the lower edge. He rather thought it might work, and as the bees were hanging on a convenient lower limb, we commenced operations at once.

Dr. Miller trimmed everything down as close to the swarm as possible, then carefully cut off the limb with the swarm, and while I held the hat upside down and stretched the rubber cord as much as possible, he slipped the swarm inside, while the veil was secured about the limb above the swarm, and we started on our way once more, I carrying the swarm by the end of the limb. When we reached the apiary we got a hive full of empty combs ready and let the bees run in, and I once more had possession of my hat.

Once later, when we had occasion to have a small swarm at some distance from the Wilson apiary, we used the hat again in preference to carrying a hive that distance.

### Wintering Bees—Good Prospects

I want to report on my good luck in wintering the bees last winter, as it was very cold. I was away from home last fall when I ought to have been packing my bees, so I left them on the summer stands. The stands are from 8 to 24 inches from the ground. I lost 3 colonies out of 21, so I now have 18, all in good condition. The 3 that died were late swarms, and they did not store honey enough to feed them. We did not have a very good honey crop last season. A hail-storm ruined the

first crop of alfalfa. I got 500 pounds of comb honey, and increased from 14 to 21 colonies. We have a good prospect for the

season, if all goes right. Success to all beekeepers. Mrs. BEN FERGUSON. Ford Co., Kans., May 8.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### AMOUNT OF CAPPED SECTION-COMB SURFACE.

Some of our expert answers to questions are a little depressing to the apicultural student by the amount of disagreement in opinion which they show. The student aforesaid may be reassured by the answers to question 25. Out of 29 respondents 22 either say the whole surface of a section should be sealed, or all except the cells next the wood. None of the other respondents lean in any other direction very strongly. One answer would tolerate 15 percent unsealed in *second-class* honey; another would allow 5 percent in first-class; and that's about the extreme in that direction. Page 293.

### CHEAP SECTIONS—FOUL BROOD.

"Lickin' good, Sal, why don't you get you some?"—as the bumpkin remarked to his girl about the stick of candy he purchased. Greiner's worse than that. Sal could, and probably did, buy the stick of candy; but we can't buy a nice supply of two-dollar sections to be kept as an emergency reserve.

Sure enough! If our appointed eradicators of foul brood at times become distributors of foul brood, and carry it into territory previously unpolluted, it surely becomes us to "look a little out." Page 294.

### A CORRECTION ABOUT PROF. HARRISON.

Lumber and literature both liable to "nots!" In the former always detrimental; in the latter often beneficial. Vide the not that turned up missing in the first line of my third caption, page 296. Also, when the knots of lumber drop out they always leave a hole to tell the tale; but no hole is left to hint that Prof. Harrison is *not* the objectionable bee-doctor he is there alleged to be.

### NOTICING "STRANGE" BEES.

The phrase, "I have noticed strange bees," seems to suggest that a less careful observer might have failed to notice them. That would hardly be the case with an onslaught of robbers. The peculiar language made me wonder a little if "Illinois" was not mistaken about what he saw. Possible to mistake extra-faithful guards for robbers. Sometimes guards galore get well out on the alighting-board, running at every bee that alights, saying, "Halt, there, and give the counter-sing." And the bee thus rudely collared says,

"I haven't the last countersign with me; but here's something just as good;" and thereupon uncorks something from the inside pocket. Page 297.

### DAUGHTERS OF BEST QUEENS AND OTHERS.

The fact Dr. Miller alludes to on page 297, is one of the most trying ones with which we have to deal. Left entirely to herself, the best queen in the apiary will die and leave but one daughter; while the most undesirable one of all will leave a host of daughters. If it wasn't for this one ugly fact one might almost object to breeding queens, and advocate systematic letting alone.

### WEAK NUCLEUS BUILDING WORKER-COMB.

"Curis!" Curious how much we don't know—some of us. Dr. Miller says, on page 313, that a queenless nucleus will build worker-comb if weak enough. I wonder greatly *why* extreme weakness should make such a change—in a rather mysterious thing. In my journeys through the forests of Ignotum, I don't think I ever encountered that little fact before. Thanks, Dr. Miller!

### PREPARING FOR SWARMS THAT DIDN'T COME.

So E. Tucker made lots of hives to be prepared for the excessive swarming of his Carniolans—and not a swarm for two years. I suppose that that quaint proverb, "The unexpected always happens," applies a little more frequently to bee-keeping than to almost any other vocation. Page 317.

### ADVERTISING HONEY IN CANADA.

The great publications of the United States have many readers in Canada, I believe, while Canadian publications circulate but little here. It follows that when honey comes to be advertised heavily the Canadians will have "a snft thing of it;" can just do nothing, and in so doing get a good share of the results. And if they choose to organize and put some ads. in their own papers, it will come in as additional and cumulative, and count much more than the same would if put in just now. They're all right anyhow. And also our folks were right in not trying to run two nations in the same advertising League. Otherwise they would have speedily heard that the Canadian [newspaper] widows were neglected in the daily ministrations. Page 323.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does *not* answer Questions by mail.

### Starters—Fastening Foundation— Painting Bottom-Boards

1. In Bulletin No. 133, Department of Agriculture, telling about the value of foundation in comb-building, only one end of the starters is fastened to the sides of the section. Is this best, or should it come against both ends? I bought some super foundation the other day that measured  $1\frac{1}{2} \times 3\frac{3}{4}$  inches, and as I use  $4\frac{1}{2} \times 4\frac{1}{2}$  plain sections, it will not nearly make 4 starters, the width of the section.

2. How does the Parker foundation fastener fasten one-inch starters to sections, that is,

are they held by wax or simply pressed against the sides?

3. Is it best to paint the bottom-board all over, or only that part which the bees do not come in contact with?

4. Does it not need anything to keep supers and covers from blowing off of dovetailed hives? MISSOURI.

ANSWERS.—1. If a single starter is put in a section, it must be fastened only at the top. If fastened only at the bottom, the foundation is likely to sag enough to make it bulge out to one side. Your foundation, when cut in four pieces, will leave a space of about half an inch at the bottom. The result will not be

much different if the space were only half as much. But the better plan is to have a  $\frac{1}{8}$ -inch starter at the bottom.

2. Simply pressed hard into the wood.

3. Usually only the outside part is painted. It would do no harm to paint all, but the bees are likely to paint their part well enough.

4. In the early spring, when bee-glue is hard, if the hives are in a windy place, it is well to have a small stone on the cover, unless the cover is otherwise fastened. At other times there is no need.

### Rearing Queens—Keeping Italians Pure

1. When I want to rear queens, and I put the prepared cells into Tifoff cages, do I put the cages into a queenless colony, or is it all right to put them in the upper story of a queen-right colony?

2. After the queens are hatched out is it all right to leave the queens in the cages in the queen-right colony until needed?

3. How am I to keep my Italian bees pure? Suppose I have two Italian colonies, and the queens I rear from one colony are to be mated. Do I have to take the virgin queen some distance away, and the drones of the other Italian colony with her, to be sure she is mated with an Italian drone? Please describe how I am to arrange the matter so as to be sure of pure mating. ONTARIO.

ANSWERS.—1. They are more sure of proper attention in a queenless colony.

2. No, before they are needed for use they must be kept where they are free to fly out to meet the drones.

3. You may as well make up your mind first as last that under ordinary conditions you can not be sure of keeping pure blood. Some claim success by confining the queens and drones during the hours of the day when drones fly, and then by feeding to induce flight at a later hour in the day. You can succeed without question if you have your queen beyond the flight of any but the desired drones; but that means, according to some good authorities, that they must be 4 or 5 miles away from other bees.

### Indian Turnip

On page 312, there is a recipe for a cough cure by W. T. Mundy. What is Indian turnip? May be it is those roots we call Indian potatoes, the stalks of which grow up to a height of 3 to 4 feet, with yellow flowers on top. MINNESOTA.

ANSWER.—No, it doesn't grow 3 to 4 feet high; it is less than a foot high. It is a 3-leaved affair, and the blossom and fruit have over them a hood which gives the plant its other common name, jack-in-the-pulpit. The botanical name is *Arisaema triphyllum*. If you bite a little piece of the bulb or root, it doesn't seem just at first to have a very strong taste, but after a second or two it begins to bite and burn your mouth, and keeps it up in quite a painful manner.

### Wintering Bees—10-Frame Langstroth Hives—Shaken or Driven Swarms

1. I am greatly interested in using the 10-frame Ideal super as a hive-body for swarms. Do you think I could winter a colony in one of these 10-frame supers in this locality?

2. Would the 10-frame super full of honey (if I used one super) be enough for them to winter on, or ought I to leave enough empty combs for them to cluster on?

3. I have 10-frame Langstroth hives. Do you think I would do better with them in this locality? There has been a very poor honey-flow in the last 4 years.

4. I made a second drive of newly-hatched bees last season, 19 days after making the shaken swarm. After all of the bees in the second drive had entered I placed an entrance queen-excluder to control drones. The next morning I found nearly all of the bees dead,

and almost completely clogging up the entrance. Do you think this second drive is a success generally? MAINE.

ANSWERS.—1. Two ought to winter well, and possibly one might.

2. The one story of frames filled with honey would be enough, but a second story, or something in place of it, must be under to give the bees room to cluster. I am not entirely sure about it, but I think an empty super would do without any combs in it.

3. You can try the change on a small scale, making a comparison of the two side by side.

4. So far as reported, second drives are usually successful. Your experience hardly has anything to do with the success or failure of the second drive. The death of nearly all the colony would seem to have been due to affocation on account of the entrance having been too much closed, and it might have been the same if there had been no drive.

**Preventing Leaky Hive-Covers**

We find it very difficult to keep our hive-covers in a condition so that they will not leak. If you know of any paint, or other preparation which we can use to prevent the leakage in question, please give directions for its preparation. MICHIGAN.

ANSWER.—It is a very difficult thing to make a cover water-proof with any kind of paint if there are joints or cracks in the cover. The better way is to cover the wood with something that will not leak. Some of my covers are covered with a paper and the paper painted; another lot is covered with tin and painted; and what perhaps is the best, another lot is covered with zinc, unpainted. How long the last will do without paint I don't know.

**Putting on Supers—Feeding Bees—Queens Humming**

1. When shall I put on the first supers? The colonies have much brood now.

2. What time will the bees swarm this month, when the brood is as much in my hive as I mentioned above?

3. I am still feeding them equal parts of sugar-water, and they take it all. Is this right?

4. What makes the queens hum so loudly for about 5 minutes at a time, then rest a little while, and begin again? WISCONSIN.

ANSWERS.—1. When you see bits of very white wax plastered on the top-bars or upper part of the combs. Or, as you are in a white clover region, watch sharply for the very first white-clover blossom that puts in an appearance, and put on supers a week or so later.

2. I don't know; and your telling me that they have "much brood now" does not help very much to decide. But it is not at all improbable that they will not swarm at all in May, the month in which your questions are written. You can only tell anything in advance about their swarming by looking in the hives and seeing when queen-cells are started.

3. It will probably do no harm, but it ought not to be necessary to feed when fruit is in bloom.

4. I don't know; I never before heard of anything of the kind.

**Strengthening a Weak Colony**

How would it do to set a weak colony of bees in the place of a strong colony, so that the worker-bees of the strong colony would go into the hive of the weak colony, thereby strengthening the weak colony? CALIFORNIA.

ANSWER.—The plan is hardly advisable on account of danger to the queen from the entrance of strange bees. A safer way is to take a frame of brood with adhering bees from the strong colony and give it to the weak. I have given hundreds of frames of brood in that way without injury to the queen. An entirely safe plan, and one that

is a very little trouble, is to exchange a frame of sealed brood for one containing unsealed brood and eggs, of course taking the mature brood from the strong and giving to the weak.

**Separators—T Supers**

1. Do you use separators between two bee-way sections, and if you do, what kind of separators?

2. Are you still using the old T super? I am using 4 1/4 x 4 1/4 x 1 1/2 two-bee-way sections, with top and bottom starter, without separators. This is my second year of bee-keeping. ILLINOIS.

ANSWERS.—1. I use loose wooden separators one-sixteenth inch thick.

2. I am still using the T super, after having tried others. For home use you need no separators. If you pack in shipping-cases, you will need them. Even in the home groceries, unless you use separators, you will find the grocers, in handling, will break the cappings more or less.

**Sulphur for Mice in Cellars**

Will sulphur hurt the bees if I sprinkle it in the cellar in the winter to keep mice out? MINNESOTA.

ANSWER.—Not a bit.

**Prevention of Swarming—Queenless Colony—Increase—Transferring**

1. I am a beginner, and have 8 strong colonies in good hives. I have timber work, to which I am afraid I will be obliged to give my attention the last of this month and all of next. I don't know how to manage the bees to keep them from swarming during the day, as I leave early in the morning and get in about 8 or 9 o'clock at night. I furnish timber for a coal-mine which is shut down now, but there is talk of starting it up again, and if this is done I can not watch my bees. Should I neglect the timber I would lose more than the bees are worth. How can I keep them from swarming and getting away from me?

2. This spring I had a colony in a box-hive which I transferred to a frame hive. I found they had no queen, but a little brood all sealed, and two queen-cells. This was about the first of April. The queens hatched but disappeared. The bees worked all the time bringing in pollen, but tried to build cells or cups for queens. I let them go until about the middle of April, then gave them a frame of brood from another hive. They took care of the young bees from the eggs up to the bees, but made no attempt to build queen-cells. I tried another frame of brood and eggs. After a week I took a peep and hardly knew the frame, as it was an empty frame to start with, in each end of which I had fastened two pieces of comb. I then gave it a strong colony which patched it up and built it about half way down. The queen followed up closely, and seemed to lay eggs in the cells as fast as they were built. They had had it only about 3 weeks, and had it full of brood and eggs. I gave the frame to the queenless colony (as before stated), and after about a week I took a peep, and to my surprise found it built nearly to the bottom, the brood nearly all out except a patch which was eggs when I put them in, but no cells started. I gave them another frame of brood and eggs and left it 3 days, then took a peep, and just as I expected, no cells were started. I think I could have the patience of Job if it were necessary, but I thought I had fooled long enough, and so put the frames back in the other hives. Then I took the bottom off and set them on another hive, aiming to unite them. I had tried them with 3 frames, one of brood and two of comb on each side to one side of the hive, and had tried them with 4 and 5 with the same result. Why did not these bees try to rear themselves a queen?

3. I wish to have as many colonies as possible to start with next spring. I have thought of starting a number of nuclei, taking brood from old hives and building them

up gradually as they grow in strength, to take care of the brood, and I have thought of going through them each week to look for queen-cells, and when I find them I will suppose they are getting ready to swarm. Then I shall divide them, giving one colony the cells and the other the queen. And I have thought of clipping the queens' wings so they can not fly.

4. Neighbor No. 1 had neighbor No. 2 transfer a colony about the last of May from a log hive into a frame hive with a comb where other bees had died from starvation, but he did not transfer the brood. The bees left the hive, and No. 2 says the bees won't stay without their brood. Is he right? ILLINOIS.

ANSWERS.—1. One way is to have queen-traps on your hives, so the queen will be caught when the bees swarm, and then you can shake the bees on frames of foundation. Another way is to go through your colonies every 8 or 10 days, and shake the swarm when you find queen-cells started. You may shorten the labor by shaking the whole 8 colonies as soon as one or two start queen-cells.

2. I don't know. I only know that sometimes bees refuse to start queen-cells, especially those that have been queenless a long time. When a colony is queenless early in the season, it is generally better to break it up than to try to have it rear a queen. If it does succeed in rearing a queen she is very likely to be worthless.

3. It is all right to clip your laying queens (of course not virgin queens), for then if a colony attempts to go off you can lose only the queen, and not both queen and bees. You can probably make your plan work all right. Here's another way, one which will give you increase and save watching for swarms: As soon as the first colony starts queen-cells, go to each colony, take away its queen with two frames of brood and adhering bees, being sure there is some honey in the frames, and put in an empty hive on a new stand. A week later take the old hive off its stand, and put in its place the hive with the queen. Then divide the old colony in two, and put each half on a new stand (one of them may be put on the stand from which you have just taken the queen), being sure that each half has a good queen-cell. If queen-cells are started in any colonies before the queen is taken away, then you must make the division sooner, or there may be danger that a swarm will go off with a young queen.

4. A colony transferred without brood is more likely to desert than one with brood. If he transferred the bees into the hive, and then set the hive just where the log-hive had been, the bees would stay ever so much better than if he set the new hive in a new place.

## Reports and Experiences

### Bees Doing Well

My bees did poorly last season, but have done well so far this year. They began swarming in fruit-bloom. White clover is very thick on the ground. S. G. KILOORE. Madison Co., Ohio.

### Selling Light-Weight Sections

The question of light-weight sections has many sides. Some grocers about here much prefer to buy comb honey in the case by weight. Where the sections hold but 13 or 14 ounces they of course sell these same sections by the section. In this State to-day grocers buy No. 1 white clover comb honey, delivered, at 17 cents per pound by the case, and sell by the section at 18 cents. The most of their profit comes from the 3 ounces short weight of each section sold. Last fall they bought the same honey at the same price, and sold it for 20 cents or 21 cents per section, thus making a very good thing of it for themselves. HERBERT W. DENIO. Hampden Co., Mass., May 8.

### A Beginner's Outlook

I have just started in bee-keeping, and have 35 colonies. I have the native bees crossed with Italians. I have one colony that is extra good. They resemble the blacks, except that they are longer and are shaped more like a queen. What kind of bees are they, and what are their value? There are hybrids in the same hive. They work better than any bees I have seen, coming in heavily loaded and they don't seem to want to swarm, but are busy storing honey. I have given them an entrance  $\frac{3}{4}$  x 12 inches, but they crowd that space in going in and out. They are in an old-fashioned box-hive. Christmas week it weighed 106 pounds, the hive itself weighing perhaps 25 or 30 pounds. I have placed this old hive on top of a new one, and let them pass through the new one to go up into the old one. I think I can get them in a new hive in this way without much trouble.

I have just sold some comb honey to a lady whose home is in Birmingham, Ala. She said she could not buy honey there, as what was sold for it did not taste like honey, and the comb seemed to be a good substitute for chewing-gum, so she had to taste of my honey before buying it. She intends to ship some to her children at Birmingham. She said she was glad of the opportunity to purchase comb honey made by the little bees.

D. R. PHILLIPS.

Jackson Co., Ga., May 16.

### Dovetailed Hive—Making One's Own Supplies

In reference to the talk between "A Reader" and Dr. Miller, page 329, I believe Dr. Miller should have said the "Langstroth hive" instead of the "dovetailed hive." He says that custom makes the name "dovetailed hive" apply only to hives containing frames  $17\frac{3}{4}$  x  $9\frac{1}{2}$ , and that any other understanding of the word "dovetailed hive" would throw out of gear the catalogs and bee-literature in general. According to this we have no "Langstroth hive," the nearest approach to it being a dovetailed hive having the Langstroth dimensions. If the catalogs and bee-literature are at fault, they should right themselves. The name "Langstroth hive" rightfully belongs to the common single-walled hives containing frames  $17\frac{3}{4}$  x  $9\frac{1}{2}$ , whether the corners are dovetailed, halved, or otherwise. It should be the pride of every bee-keeper to perpetuate the memory of Father Langstroth. How can we do this better than to have a hive bearing his name?

For my part I want a real "Langstroth hive"—a dovetailed or any other tailed hive

does not satisfy me so far as the name is concerned. In short, let us not call it the "dove-tailed hive," but the "Langstroth hive."

Mr. E. E. Hasty's article on the bee-supply manufacturers' trust, page 248, is a stroke straight from the shoulder, and it struck the key-note. That there is such a trust most bee-keepers know, and we should speak and write of it in such a plain way that the trust may know that we know it. "Actions speak louder than words." Let those that can and have the time, make their own hives, frames, etc. This can be done in winter and on rainy days, when there is but little else to do.

I started in bee-keeping in 1900, by buying one colony of Italians in a box-hive. With the exception of that box-hive I have never owned a hive or a frame that I did not make. I use the 8-frame Langstroth. I have two small circular saws—one for cutting off and one for ripping or cutting lengthwise. They are run by hand-crank power. The hives I make are halved cornered. The frames have the double saw-kerf. With this outfit it is easy to make hives, frames, covers, bottom-boards, hive-stands, supers, section-holders, shipping-cases, etc. In fact everything needed except sections and separators. I am well-informed on the prices of bee-supplies, and I save money by making my own hives, etc.

L. V. RICKETTS.

Whitman Co., Wash.

## Bees in Good Condition—Fair Crop Last Season

Bees wintered poorly here last winter, my neighbors losing from one-half to all of theirs. I packed mine carefully last fall, and saved 38 of the 45 colonies that I packed in winter quarters. What colonies I saved were strong, all had plenty of honey, and have built up so that they will be in good condition for the honey-flow when it comes.

I had a fair crop of honey last year, 38 colonies giving me 2200 pounds of honey and in-

**THE ELGIN HIVE**

That's the hive which can be knocked down and put up by any one in a few minutes. No nails or dovetails needed. Iron attachment holds the same together perfectly air tight, and keeps it from warping. Send for Circular. Address, G. H. KIENZLE, E. end Kimball St. Bridge, ELGIN, ILL.

creasing to 46 colonies, but then I am the only bee-keeper in this neighborhood who takes any bee-papers or buys any bee-books. D. E. ANDREWS.

Monroe Co., Ind., May 5.

## Great Honey-Flow in California

We are having the ideal conditions for a great honey-flow here at the present time. I know a man who has kept a colony of bees on the scales for years, and has the record this year. He secured 22 pounds one day last week, and 24 pounds the next day. We have had some very warm days, and the bees have been wild with their opportunity to work and store. I have never seen the like of bloom that now decks our fields, canyons and hills. The black or ball sage is in bloom and the white is just beginning to open. Both of these incomparable honey-plants give rich promise of a great yield of honey this year. The plants show a growth and vigor that only our abundant rains will explain.

The salvias also are out in force, and are very attractive to the bees. One of these, *Salvia carduacea*, is a wonderfully beautiful plant, and I have wondered that it is not in cultivation, the world over, for ornament. It has a ball of exquisitely beautiful lavender flowers, and the stem passes through this, and then there is another ball of the bloom, and so on there may be five in extreme cases. The foliage is woolly, and the flowers are as fine as any sage bloom that I have ever seen. The foliage looks like that of the thistle, and hence the scientific name which means "thistle *Salvia*."

We have another *Salvia* of like habit, which is far more common, *Salvia columbarie*, and though not as showy as the other, it is a good bee-plant and helps the bee-keeper not a little.

We also have many phacelias, all of which attract the bees and add to the stores in the hives. I have wondered if we might not plant more of the winter blooming acacias, and eucalypts, so as to give more winter work for the bees, and thus have brood-rearing com-

## ITALIAN Bees, Queens and Nuclei

Choice home-bred and imported stock. All queens reared in full colonies.

- One untested queen..... \$ .90

## A Standard-Bred Italian Queen-Bee Free!

For Sending One New Subscriber.

As has been our custom heretofore we offer to mail a fine, Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year

2. Sending your own name with the \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a

new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

We will book the orders as they come in and the Queens will be mailed

Will you have one or more?

If you cannot get a new subscriber, and want one of these Queens, we will send the American Bee Journal a year and the Queen—both for only \$1.50. Address,

GEORGE W. YORK & CO.,

CHICAGO, ILL.

mence so early that the bees would be strong for the orange bloom. There can be no question but that the citrus bloom is rich with nectar, else it would not fill the entire atmosphere with such delightful perfume. I have not any doubt but the honey from this source would be of the very best flavor. This year not a little has been gathered. I believe that more attention to this winter bloom might be wisely given. The reason that we have it is that we bring Australian trees here, and as they come at bloom in our winter, they continue the habit after they are brought here. Our genial winters make the trees slow to change the date of blooming. A. J. COOK.  
Los Angeles Co., Calif., May 18.

## Bees Wintered Well

My bees were taken out of the cellar about 3 weeks ago, and I was very well pleased with the way they wintered. I put away 36 colonies and took out 35 in fine condition, the one that was dead (I find by referring to my record) being queenless last fall.

The colony in which I put a queen, secured last fall, stored 30 pounds of comb honey after that, and it is good and strong now. She is a fine one. Wm. H. ROOT.

Wayne Co., Nebr., May 2.

## Ideal Spring for the Bees

This has been an ideal spring for the bees. Since fruit-trees began to bloom there has not been a day but that the bees could work. They seem to have plenty of brood, but are not very strong in supplies, so that I will let them clean up a lot of second-class sections.

I am starting in with a spring count of 25 colonies. S. C. REARICK.

Wood Co., Ohio, May 9.

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

GEORGE W. YORK & CO.

334 Dearborn Street, CHICAGO, ILL.

## Mount Union College

ROOT'S GOODS

At Root's Factory Prices

## Honey and Beeswax

CHICAGO, May 8.—With April about all the trade in comb honey ceases so far as this market is concerned; occasionally a case sells, but no lots, so that prices now are practically without change, pending the new crop. Extracted is exceedingly slow of sale; white ranges from 5¼@7c, and amber 5¼@6c, according to flavor, quality and package. Beeswax in active demand at 30c.

R. A. BURNETT & Co.

CINCINNATI, May 8.—The demand for honey has increased quite a bit since our last quotation, which is due, probably, to the concessions made in prices to affect sales, as well as the awakening of the spring trade. We quote amber extracted honey in barrels at 4¼@6¼c, according to quality. White clover and fancy extracted honey at 6@7¼c. Comb honey has seen its season. Beeswax 29c cash.

THE FRED W. MUTH CO.

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12¼@13c. Extracted, from 6@8c, according to quality.

BLAKE, SCOTT & LEE.

PHILADELPHIA, May 19.—The season is about over for the sale of comb honey, with so few sales that the market is not established enough to quote price. Extracted honey has met with some demand, and we quote as follows: White, 6@7c; amber, 5¼@6c. Beeswax, 28c. We are producers of honey and do not handle on commission.

WM. A. SELSER.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.

BILDRETH & SEIGELKEN.

KANSAS CITY, May 12.—The honey situation is a little stronger, and there is but little honey left in the hand of the dealers. Best honey bringing from \$2.25 to \$2.50 a case; amber at from 25@50c a case lower. Extracted, 4¼@6c. Beeswax, 28c.

C. C. CLEMONS & Co.

CINCINNATI, O., May 18.—The large stock of comb honey yet offered with hardly any demand causes lower prices. I quote fancy water-white at 12c; other grades lower, in proportion. Extracted is in usual demand for this season of the year. We quote white clover 7@8c; amber in barrels at 5¼@5½c; in cans, 5¼@6 cents. Beeswax, 28c.

C. H. W. WEBER.

ALBANY, N. Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6¼c; white, 6@6¼c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c.

H. R. WRIGHT.

SAN FRANCISCO, May 3.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted—white, 5¼@6 cents; light amber, 4@5c; amber, 3@3¼c; dark amber, 2¼@3c. Beeswax—good to choice, light, 29@30c; dark, 27@28c.

The steamer City of Peking, sailing Saturday last, took 85 cases for Belgium. Movement on local account is light. Buyers are holding off, anticipating arrivals of new crop at an early day.

# IS THE BEST TOO GOOD FOR YOU?

Lewis' goods are the best your money will buy and are worth every cent they cost you. Whether you receive them in the dead of winter or at the height of the honey-flow, or **when your bees are swarming**, they will fit accurately, admit of being put together quickly, and will be found to be made of the finest material. This saves you time; this saves you trouble; this saves you honey; and time, trouble and honey mean money to you. Your honey put up in good shape will bring higher prices, and the demand for it will be increased from year to year. This factory's reliable goods have started many a man on the road to success.

As is customary with all large concerns we have agencies or jobbers in different parts of the United States, where our goods are carried in stock. If you are located near any of those named below it will save you time and freight charges to send your order to them. Where the distance is not so great from Watertown to the agency, these jobbers sell the goods at our regular list prices.

No. 2.—Patch of Buckwheat in Bloom.

# ESTABLISHED IN 1861

# AMERICAN BEE JOURNAL

THE OLDEST BEE-PAPER IN AMERICA

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., JUNE 8, 1905

Vol XLV—No. 23

PUBLISHED WEEKLY BY

**GEORGE W. YORK & COMPANY**  
334 Dearborn Street, Chicago, Ill.

### IMPORTANT NOTICES

THE SUBSCRIPTION PRICE of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

THE WRAPPER-LABEL DATE indicates the end of the month to which your subscription is paid. For instance, "dec 05" on your label shows that it is paid to the end of December, 1904.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

ADVERTISING RATES will be given upon application.

### National Bee-Keepers' Association

Objects of the Association

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00

General Manager and Treasurer—  
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

### The Honey-Producers' League

(INCORPORATED)

#### OBJECTS:

1. To create a larger demand for honey through advertising.
2. To publish facts about honey, and counteract misrepresentations of the same.

#### MEMBERSHIP DUES

1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.

2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-paper publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.

GEORGE W. YORK, Manager,  
334 Dearborn St., CHICAGO, ILL.

#### Queen-Bee Free as a Premium

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is a good time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

## Editorial Notes and Comments

### Short Stores—Warning to Beginners

As a matter of fact the warning is needed by many who are not beginners. A good many colonies will be lost after this paragraph appears in print, and by those who have not dreamed of danger. It seems to take a good many years of experience to gain an adequate idea of the amount of honey used up in rearing brood in the spring. A colony has a good supply of honey when overhauled in April or the first part of May, and the owner thinks it entirely unnecessary to give any further attention to the matter of stores. If he would look into the hives just before the harvest begins, he would be surprised at the bareness of the larders.

A critical time often comes just before time to put on supers, when the immense amount of brood makes heavy demands on the stores, and little or nothing is coming in from the fields. If stores give out entirely, it means not only the cessation of all egg-laying, but as well the destruction of all unsealed brood. In other words, it means the loss of eight or more days of the queen's work, and that at a time when such work counts at its highest value. Especially remember that starvation may come *after* the fields are white with clover, for there may be no nectar in the blossoms.

### The Glucose-Honey Story Again

Rene Bache, in the Saturday Evening Post for May 20, contributes an article on "The Whimsical Consumer: Color, Not Quality, is What He Seeks in Food." After saying, "Appearance counts for vastly more than taste in rendering any food product marketable," reference is made to bright red apples, large strawberries, brown-colored eggs, yellow-skinned chickens, etc., all of which, it is alleged, are preferred regardless of *taste* or *quality* by the consumer.

"As far as practicable, things should be big, uniform in size, shapely, and done up in convenient and showy packages," it is said. This may be the case in exceptional instances, but we can not believe that the housekeepers, purveyors, etc., of this country—those who perhaps buy nine tenths of all the eatables used—prefer appearance to quality and taste.

But the paragraph in Rene Bache's article that is of greatest interest to bee-keepers is the following:

"Glucose, made of appropriate consistency, suitably colored, and containing pieces of genuine honey-comb, is bought by many people in preference to real comb honey. Honey is supposed to be light yellow, and, if darker, it finds a less ready sale. On the other hand, California comb honey is looked upon with suspicion in the East on account of its almost colorless appearance, the whiteness of the wax, and the perfect filling of all the cells. Purchasers frequently reject it on the supposition that it is machine-made, comb and all—the idea that comb honey is ingeniously counterfeited, and to some extent manufactured being, notwithstanding its absurdity, one of the most widespread of popular delusions."

We do not think that many people prefer a mixture of cheap glucose and pieces of honey-comb to "real comb honey." They may be inveigled into buying it through its sale being pushed by extensive advertising and otherwise, but never from a real preference if they can get first-class comb honey—the product of the bees. Talk about a combination of glucose and wax outranking the thick, delicious, well-ripened honey! It is ignorance of the genuine bee-product that prefers the glucose compound. Certainly no one who is familiar with real or best-quality honey—either in the comb or out of it—would prefer glucose, if in his right mind, or unless he has an unnatural, vitiated taste.

So "the idea that comb honey is ingeniously counterfeited," "machine-made," is still a "popular delusion." And the more beautiful the genuine article is in appearance, the more it is thought a counterfeit. Well, that's pretty rough on apicultural progress from beehive honey to that of tempting sections of virgin whiteness.

The next thing for bee-keepers to do is to displace the wrong idea that the public has of honey with the correct and true idea. Until that is done the finest product of the hive will be in disrepute among a large portion of our population. What a shame!

The Honey-Producers' League was organized to undertake the education of the public concerning honey. It's a big job, we know and will need the earnest co-operation of all

bee-keepers and others who are interested in the production and sale of honey. But it can be done by a persistent, united effort.

### A Glowing Account of a Honey-Flow

Arthur Laing gives in the Canadian Bee Journal the following account of a honey-flow from logwood in the island of Jamaica that is enough to send a thrill to the heart of any genuine bee-keeper:

I noticed unmistakable evidences of an almost universal bloom, and about 10 days later it came out in all its glory. It was truly a magnificent sight, and although the house was about 500 feet from the apiary, the roar of the bees passing to and fro was a sound to make glad the heart of any bee-keeper. I went down to the apiary one morning about 6 o'clock, and if I live to be 100 years old I never expect to see a more stirring scene in any apiary than I looked upon in that yard of 250 colonies. The bees seemed to be fairly wild with joy, and I must say it gave me a similar sensation to watch them. They kept up this pace for 4 days, which brought us up to a Saturday evening. I told my partner I should have to put on a lot of extra suppers on the following Monday morning, but, alas! it rained that Saturday night, and next morning the logwood blossoms were as brown as though they had been burnt, and the flow was over. Six thousand pounds for the 4 days was the record.

But the thrill is likely to become a chill when later on he says:

Prices we received ran from a small fraction below 2 cents per pound for dark to a small fraction below 3 cents per pound for the best, which was one of the finest samples on the island.

### Hushing Up Presence of Foul Brood

Mr. A. E. Hoshal is reported in the Canadian Bee Journal as saying:

I have wondered why it is we desire to keep this thing covered up so thoroughly as we do. My bees had the disease a while ago, and I wouldn't like to be considered a criminal because my bees had it. It is no disgrace.

Mr. Hoshal is right. There is no more sense in hushing up a case of foul brood than there is in hushing up a case of small-pox. In both cases the welfare of others demands publicity.

### Send Questions in Time

Now and again some one sends a batch of questions to be answered in the American Bee Journal, with the curt request, "Answer in this week's Journal," when a very little knowledge of the publishing business would make the sender understand that compliance with such a request was an utter impossibility. Quite possibly the questions are such as have not arisen from any sudden emergency, but could have been asked a month sooner just as well as not.

It would be a real pleasure if every question could be answered in such manner that within 24 hours the answer should be received by the one who sent the question, and it is a painful feeling to know that sometimes when the best efforts have been made the answers are so late in being received as to cause disappointment. Although our postal system is a marvel of accuracy and dispatch, still it does sometimes happen that a letter is delayed, and in rare instances lost. There is also the possibility of loss in some cases before the letter reaches the post-office; and if not lost, delay. So there must be counted time, and

sometimes overtime, for a letter to reach Chicago. Then it is a matter of time to get the letter to Dr. Miller, whose province is to answer questions. Just so far as it is possible to do so, he always answers such questions very promptly; but it must be remembered that he is a practical bee-keeper, and work in the apiary may be crowding so that he can not at once answer. After he has sent the answer to Chicago it takes time to get it into type and into press. Possibly the columns of the Journal are so crowded that a postponement of a week is inevitable.

If all these things are taken into considera-

tion, it will be seen that the sender of a question can not reasonably expect to find his question answered in the next number of the paper.

If an answer is desired as speedily as possible, it is always well to send the question direct to Dr. Miller. The delay of a day or two from sending the question first to Chicago will sometimes make no difference as to the time it appears in print, and at other times it may make a delay of a week or two.

But be assured that it is the desire at this end of the line to make just as little delay as possible.

## Miscellaneous News Items

### Mr. Benton After Foreign Bees.—

We have received the following from Miss Jessie E. Marks, who is an assistant in the section devoted to apiculture, of the Bureau of Entomology, in the Department of Agriculture at Washington:

"The Apicultural Investigator of the United States Department of Agriculture, Mr. Frank Benton, is about to start on a tour of exploration in the interest of apiculture. The purpose of the trip will be to secure new and valuable types of honey-bees for testing (under control) in this country, more especially the giant bees of the East, *Megapis dorsata* (*Apis dorsata*), and also any honey-producing plants which might prove of value in this country, particularly such as would at the same time serve as forage crops.

"He intends to go by way of England and across the continent to Constantinople, thence to the Caucasus, where he hopes to obtain a good supply of the gentle Caucasian queens; across the Caspian Sea to Bokhara, and from there southward over the long stretch of some 800 miles across Afghanistan (by caravan since there are no railroads in that region) to the Punjab in India, thence eastward through the northern part of Hindustan to Calcutta, whence the route will be by steamer via Singapore to Manila."

We trust Mr. Benton will keep the bee-papers of America informed concerning his foreign investigations, so that they in turn can pass the information on to their readers, who will be greatly interested in the proposed trip and its results.

### Invention of the Movable-Frame Hive.—

It is a pleasure to have the following explanation from one who is so thoroughly familiar with bee-keeping in Germany, and who stands as authority on both sides the ocean:

To the notice on page 340, I have to make a few remarks. This matter has been discussed very often, nevertheless some mistakes remain to be corrected. The different opinions can easily be explained if we distinguish movable frames and movable combs.

Nobody in Germany claims that Dzierzon invented a movable-frame hive, even the movable comb attached to a bar was known long before him, among others Della Rocca using this bar. But it is claimed in Germany that Dzierzon was the first who made such bar-hives fitted for practical bee-keeping, because his hive opened on the side, consequently the combs could be cut off from the ends more easily than in the top-opening hives used before him. Certainly his hive caused remarkable progress in practical bee-keeping in Germany.

Baron Berlepsch is considered as the inventor of the movable frame in Germany. He invented his frame with the bee-space all around it, and very similar to the Hoffman

frame (lately recommended in the United States), at the same time that Langstroth invented his movable-frame hive. Certainly both inventions were made public the same year, and not one of these inventors knew anything of the other. The two hives are so much different that nobody can doubt that each invention was made independently of the other.

The Berlepsch hive is still in general use in Germany, like the Langstroth hive in America. Of course both are considerably modified at present.

Certainly we should perceive and honor the merits of all these men, just in the way they are entitled. L. STACHELHAUSEN.

Bexar Co., Tex.

### The Apiary and Buckwheat Pictures

on the first page are described by Mr. Murphy as follows:

I sent two pictures, one is a patch of buckwheat in bloom, and the other my apiary. I was a beginner in 1904, and had only 4 colonies, which I united this spring to 3.

The buckwheat pictured is the silverhull, and I sowed it broadcast June 1, 1904. It bloomed for 25 days, and I let it stand and fall off by the midsummer rains, when it sprouted up again and bloomed, with a good flow of honey till frost, which was late last fall. Now this spring there is no volunteer buckwheat to bother the corn crop.

Last summer colony No. 1 gave me 70 full sections of honey, and 14 partly filled sections, besides about 25 pounds in the brood-chamber. The honey was fine and rich.

The two boys in the picture are my Damon and Loyal, who are not afraid of bees and never get a sting. They love to watch and study them. WM. W. MURPHY.

### Good Reports—National Convention

—General Manager France, writing us May 27, had this to say:

Nearly every State reports good honey prospects.

The Texas Committee on the next National convention at San Antonio, has planned a free banquet for all members who attend, the food to be composed wholly of Mexican dishes; also a 4-hour trolley ride is arranged. There will be a big Fair in San Antonio, Oct. 21 to Nov. 1, so they have asked that our meeting be held between those dates. One day at the Fair will be "Bee-Keepers' Day," Texas certainly will do her part.

N. E. FRANCE.

We don't know about those red-peppery "Mexican dishes." They will likely be pretty "hot stuff," and so A. I. Root and Dr. Miller will have to go "tenderfootedly" down there even when eating "with their fingers." But perhaps they will have their rubber bee-gloves on to protect them when

handling the fiery viands. But what about the linings of their stomachs?

May be those two "boys" would better stay at home, or else take their "best girls" along to look after them, and help defend

them from the internal as well as external dangers that those lively Texans seem to be preparing for their guests!

The rest of us can take along a supply of "Dr. Gandy's Famous Catnip Honey."

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Honey-Paste for Chapped Hands

Honey-paste for chapped hands is made by combining the white of an egg, one teaspoonful of glycerin, one ounce of honey and ground barley.—MME. QUI VIVE, in Chicago Record-Herald.

### Honey-Muffins

Sift together 2 cupfuls of flour,  $\frac{1}{2}$  a teaspoonful of salt, and 2 teaspoonfuls baking powder. Beat the yolks of 2 eggs very light, add 2 level tablespoonfuls butter (melted), and  $\frac{3}{4}$  of a cup of milk and same of extracted honey. Stir the liquid into the flour, beating to a smooth batter. Beat the whites of the eggs to a stiff froth and fold them in. Bake in muffin-rings placed on a griddle.—Grand Rapids (Mich.) Post.

### Hive-Making at Home Explained

As to whether or not it will pay to manufacture one's own hives depends altogether upon how one is situated and upon what kind of machinery he has at hand. Certainly it will not pay to put them up without some kind of special machinery, for not only is labor worth too much, but the average bee-keeper, unless an accomplished workman besides, would be unable to make corners, frames, and other parts to compare with those cut out in factories equipped for the purpose. But such apparatus as is needed in hive-making is not expensive nor difficult to run, and where a bee-keeper has the necessary time to spare, with upwards of 30 colonies to provide for, it would probably pay him well to invest a little in hive-cutting machinery.

Although we have kept bees for a number of years, averaging 50 colonies to twice that number, we have never had a factory-made hive on the premises. Nor would I exchange the ones we are using for any offered by the best bee-supply house in existence.

Our first start of bees was bought from an old man who made his own hives much as we make ours now. With the 3 colonies bought

we also bought a half-dozen hives in the flat. These were sufficient for the first season, and by the time the next came around we were prepared to put up hives for ourselves and our neighbor bee-keepers. The machinery I will endeavor to describe, also give first cost as far as money invested is concerned.

Some kind of power was of course the first essential. My husband fortunately owned a small-sized horse-power, which he used for sawing stove-wood, and other kinds of light work on the farm. These, at that time, could be secured quite cheaply of thresher-men, who had discarded them for the more popular steam outfit. This one has been re-framed, I believe; but this did not represent any considerable expense.

Having the power and a jack with belt, the only thing necessary to buy was the cutting machinery. Two 7-inch circular saws, one a cut-off and the other a rip-saw, were ordered through a local hardware merchant. These cost in the neighborhood of \$3, the exact amount I have forgotten now. Although 7-inch saws will do quite nicely, 8-inch we have since found would be much better. A little framing material and suitable lumber for table and carriage was all that was bought besides.

Carpenter tools abound here, the master being what may well be called a "handy man." During the winter, when farm work was not pressing, the wood parts were made and put together. An ingenious contrivance, which may be adjusted instantly to any measurements, insures square ends and perfect-fitting joints. Square and saws (other than those belonging to the machine) are never needed. Any kind, size, and make of hive, with any style of frame, can be cut accurately, rapidly, and with comparative ease. Two horses are generally used, though, perhaps, one would be sufficient; at any rate for a short run.

This machine does not cut dovetailed corners, of course, but instead we make what are called "halved corners." These are nailed from both sides, and are really all that could be desired. We have never had one spread or warp away from the joint. For our own hives we use the V-shaped top-bar and self-spacing frames. These the machine cuts as readily as the old-fashioned thick top-bars.

Even hand-holes are cut out when so wanted. Supers of all kinds are as easily made as hives. There is, in fact, no wood article except sections, which we buy from bee-supply houses.

One man with two horses can easily cut out and pack 20 to 30 hives, with frames and supers, in an ordinary working day, while two men—one at the machine and one to move and pack away the parts as cut—could turn out nearly twice that number.

Shipping-cases, poultry-crates, and numerous other such things are cut out and made at home. Our neighbors never think of buying hives from bee-supply houses, as we can furnish them as needed, and at even lower prices. This trade, however, we do not solicit, furnishing them only as an accommodation.

As to the cost of hives made thus, it is evident that this is represented altogether by cost of lumber. For hive-bodies and covers it is usually necessary to buy high-priced lumber, costing perhaps from \$40 to \$50 per thousand. For bottom-boards, made with inclined alighting-board, narrower and cheaper lumber can be used. Supers can also be made of narrower lumber, though of quality equal to the hive-bodies. Frames are largely cut from short pieces and waste strips left from other parts of the hives. Only best quality lumber is used for them, whether waste pieces or not. Common  $1\frac{1}{2}$ -story 8-frame Langstroth hives will usually cost from 65 to 75 cents each for material, covers and bottoms included, of course. But this is for best quality of lumber at ordinary retail prices. Nailing and painting costs perhaps 10 cents more per hive. Whether or not it pays, any one can decide for himself, but we shall continue to make what hives are required for use in our own apiary, at any rate.

To any one desiring to put in such machinery as that described above, I would say that many practical hints may be obtained from the "A B C of Bee Culture." With this book at hand any man handy with carpenter tools should be able to build a very satisfactory hive-cutting apparatus. I would say, however, that ours is somewhat more complicated and of greater capacity than the small machines described there.

Perhaps some may like to know where this machine is used and kept when not in use. Like all other farmers in this vicinity, we have tobacco-curing sheds on the farm, and the saw parts are both used and stored in one of these. The power is set up outside for use there, and the rod driving the belt is run through or under one of the small side doors provided for in curing the tobacco. Any good-sized work-shop would accommodate the saws and frame parts without difficulty.

(MRS.) MILLIE HONAKER.

Vernon Co., Wis.

[The "A B C of Bee Culture" can be had for \$1.20, postpaid, or for \$2.00 the book will be sent with the American Bee Journal one year. Address all orders to the American Bee Journal, 334 Dearborn St., Chicago, Ill.—EDITOR.]

## Contributed Special Articles

### "The Cloistering Hive and the Cloistral Method"

BY C. P. DADANT

THE above is the title of a book which is just now attracting the attention of the bee-keepers in France. The authors, J. M. and J. B. Gouttefangeas, here describe their method with a number of cuts. The book is in the French language.

Cloisters, convents, monasteries, hermitages, belong mainly to the Old World. Here they are. It is therefore not astonishing that the ideas emitted originate in the Old World, and

that this title sounds strange to our ears. One of the authors describes his home, where he has practiced the method which his book recommends:

"The Hermitage is an antique monastery perched at 1100 meters of altitude [3600 feet], in the midst of a large forest of beautiful pine trees. The summers are charming here, but the winters are long and rigorous, nothing can be heard but the noise of the wind among the trees and sometimes the shrill piping of the titmouse, but during the night there are powerful screams, well harmonized with the savage nature of this rustic spot, the piercing voice of the owls which seek for one another or hunt for their prey. They have their nest just above my room in the mansard of a spacious attic, and I have given them full permission to establish there their graceful family. They are my friends; they are also the friends of my bees; they destroy more rodents than all the cats of the canton, and the rodents are the enemies of the bees; the enemies of my enemies are my friends."

The cloistering hive is provided with an apparatus for closing it up while at the same time letting a current of air pass freely through without admitting light. This apparatus is composed of pipes in the shape of chimneys or flues pierced with holes and placed in an ante-chamber or portico, where the bees congregate when there is any desire on their part of taking wing.

In Auvergne, the home of the authors, it is customary

among the old-style bee-keepers to close up the hives with cow-dung in the fall, leaving for air only three or four hollow hemp-stalks. The bees then remain cloistered four or five months. But when a warm day comes they are restless, and it is to avoid this restlessness, by excluding light, that the authors have devised the method in question. Evidently the temperature of those regions differs from that of our climate, for in the United States we would expect a large loss of bees confined out-of-doors, even with air and darkness during the warm days of winter. The writer quotes Preuss, a German, who closes his hives within a portico with wire-cloth, when he wishes the bees to be confined, and he criticises this method because of the heavy loss of bees that worry themselves to death in trying to get out when the weather is suitable.

The Gouttefangeas method is described at length in the book. It is evidently good in some instances, and would per-

The Cloistering Hive with Two Air-Tubes. A Dadant-Blatt Hive. The Alighting Board is hinged to close the Portico when wanted.

haps prove quite profitable here in backward springs to prevent spring dwindling when the bees go out, in spite of the cold, after pollen or water. In connection with this, they recommend a watering-trough to be used with the hive at the time when the bees need water for breeding.

They advise the use of this implement mainly during winter to prevent the bees from flying out when there is snow on the ground. It may do very well in a country where the cold of winter is not very severe and does not compel the bees to consume much stores, and where the warm days are not sufficiently warm to make it advisable for the bees to be allowed out. But in our extremely cold climate, with an occasional day when the sun shines warm enough to disturb the bees through the walls of their hive, we have always found it better to allow them to take a flight, even at the risk of losing many bees outside, than to keep the colony confined to the hive in the dark.

They use this cloister in the fall, when the bees go out without purpose, or only to seek for flowers which can not be found. They hold, with some reason, that a colony often becomes depopulated by numerous late flights in cool, fall days. They even close the hives in summer when there is nothing in the field. But their summer is not like ours, for the hottest temperature upon which they reckon is 77 degrees, and they even hesitate as to the advisability of closing the hives when the temperature exceeds 18 degrees Centigrade, which is equivalent to 66 Fahrenheit. There are many winter days in this latitude when the temperature rises above that point.

They use the cloister method when a hive is robbed, or when they want to feed the bees, especially weak colonies. They also recommend it in making artificial swarms by the addition of bees to combs of brood for strengthening colonies, for making nuclei, for transporting colonies and holding them a few days captive that they may the better remember their new location and forget the old one, when released.

On the whole, the book has many good ideas, and is to be considered as the exponent of a system which would be practical at high altitudes or in very cool climates when the heat of

the sun is never so intense that it may make the bees uncomfortable in confinement. Of course, the closing in of these active insects is contrary to their nature, but this is only another instance of the change of conditions brought about by man. If it proves necessary to put the bees into the cellar, or to confine them, we need not be held back by anything but the actual results after trial.

Hancock Co., Ill.

## Mortality Among Bees—Tree-Planting

BY PROF. A. J. COOK

MR. G. F. MERRIAM, of San Diego Co., Calif., sends me a letter from J. M. March, wherein is described an apparently new bee disease. Both Mr. Merriam and Mr. March are very much interested in the matter, and desire my opinion regarding the cause of this rapid taking off of the bees. The mortality was in February, and seemed to be among the old bees. These would die in the hive, would tumble over just outside, and often would fly to the field never to return. The result was the loss of many colonies. Mr. March inclines to the opinion that this is caused by collecting poisonous nectar, and Mr. Merriam wishes my opinion regarding this explanation.

I very much doubt if bees ever gather poisonous nectar from the flowers. True, I remember the old account of Herodotus and the soldier, and I am aware of the reputation of jasmine and some other honey even in modern times. Is it not true that these accounts of poisonous honey, like witchcraft and ghosts, grow beautifully less as we know more? I have studied the matter a good deal, and I greatly question if there is any such thing as poisonous honey gathered from flowers. I have so often given the arguments in the American Bee Journal that I will not repeat them here. Suffice it to say that if poisonous honey were gathered it would be more common, and more a matter of observation. As honey often makes people sick, it is easy to explain the origin of such stories without recourse to any theory of poison.

I should the rather think that poison had been sprayed on trees when in blossom, an inexcusable and indefensible trick in this day of better knowledge, except that at so early a date (February) we can hardly see why such spraying would be done, except with malicious intent, which is not at all supposable in this case. I am sure of cases where spraying fruit-trees with Paris-green while in blossom has not only brought on great mortality among the mature or imago bees, but has also resulted in great mortality among the brood or larvae.

There is still another explanation which I think is the correct one in regard to Mr. March's bees. Last year was one of exceeding drouth in Southern California. As a result the bees gathered little and often no honey at all in many localities. Where Mr. Merriam lives, in San Diego County, is one of the driest in this section. It is easy to believe that last season Mr. March's bees went the season through without gathering any honey at all. We all know what occurs in the hive when bees get no honey for long periods of time. The queen ceases laying and brood-rearing ceases. Thus it is easy to believe that there were no young bees produced in these hives in all the long months of 1904. Yet the old bees would go right on dying, as bees live not over long, even at the best. We thus understand how it would be that these bees should disappear simply by natural law. They simply die of old age.

In case my explanation is the correct one, the remedy is not far to seek. Stimulative feeding at times of honey-dearth would not only give sufficient supplies to the bees, which they are quite likely to need at such times, but will also incite to brood-rearing, and thus this mortality would be avoided. What makes me more inclined to believe that this explanation is the correct one, is the fact that with the rains, the bloom, the nectar, and the honey of this spring, the mortality has ceased, and the bees, which a short time back were rapidly disappearing, are now decidedly on the up grade, and the colonies promise rich returns for the coming season.

THE ACACIAS.

Among the many rich treasures that California has received from Australia and the contiguous islands, are the beautiful acacias. These are now (April 24) in full bloom on our college campus and in the private yards of our beautiful village. As I have collected sprigs for purposes of identification, I have been interested in the loud hum of countless bees visiting the trees not only for nectar but for pollen. While the bees very likely get some nectar from the flowers themselves, which surely furnish great quantities of pollen, I think they get far more from extra-floral glands. Would any

one say that this is not floral honey? We thus see the absurdity of giving any definition of honey other than "sweets stored by bees," not specifying the source.

I wish in this article to commend acacias for general planting. Southern California is already one of the most beautiful parts of the world. There is a general feeling at present prompting to general roadside planting. Claremont, Pomona, and San Dimas, all neighboring towns with a common telephone, have recently engaged in very extensive roadside tree-planting. It is worthy of remark that each of these places has a vigorous farmers' club. Communities with such clubs are not usually asleep to their own best interests. One of the trees that these communities have planted quite extensively is the black acacia. The following are some of the reasons why it pays to plant acacias, not only along the roadside but in our private grounds:

In the first place let me say, these trees come from an arid region. Thus they are used to drouth, reach far down into the ground for water, and so are fortified against neglect. If we plant acacia then we may be quite sure that our trees will live, and with a dry season or neglect to irrigate we will not be disappointed with a lot of dead or sickly trees throwing reproaches at us.

Another gain in planting these trees comes from the fact of their exceeding beauty. I don't know of any trees that are more attractive. With many of them the foliage is as delicate and graceful as that of the fern or that of the sensitive-plant; and when there is mingled with this wondrously elegant foliage the rich profusion of bloom that these trees fling out for us, we have before us truly objects that are a joy forever. We often desire in our yards shrubs or small trees that are beautiful.

To any who may be wishing for such, I would recommend *Acacia cultriformis*, *A. pulchella* and *A. pendula*. The first of these is as beautiful in foliage as in flower, and when the two are combined people coming suddenly upon the plants are forced to pause in admiration. *Pulchella* is true to its name, while the nodding habit of *pendula* adds another feature to its grace and elegance.

If one wishes larger trees, then I would recommend the willow like *A. nereifolia*, usually known as *A. floribunda*; or, most beautiful of all, *A. baileyana*, which is incomparable in its foliage among the acacias, and when in bloom becomes simply unparalleled in its beauty. I really think this is "the noblest Roman of them all." For roadside planting, probably the Australian blackwood, or black acacia, *A. melanoxylon*, is to be preferred, as it is a very rapid grower, fine in form, and gives a beautiful avenue effect. The blossom, however, is white instead of yellow, rather small, and so quite inconspicuous.

Before closing let me suggest that in roadside tree-planting we do not mix trees, but plant all of one kind. This gives a much finer effect, and is recommended by all our best landscape gardeners.

#### CALIFORNIA HONEY-TREES.

From what I have written above it needs hardly be said that the acacias are worthy a place in our planting because of their value as honey-trees. The eucalypts are also to be selected for this same reason. Indeed, the eucalypts have all the virtues that belong to the acacias. Like the acacias, they have been brought from the southern hemisphere to the northern, hence there is a tendency to change their time of bloom. Consequently, we have in these, as in the acacias, trees blossoming at every season of the year.

Another tree worthy of consideration both for its elegance and as a honey-tree, is the incomparable pepper. I know of no tree the world over which has more to recommend it.

Los Angeles Co., Calif.

## State Inspection of Apiaries in Illinois

[Read at the Illinois State Convention Nov. 15, 16, 1904]

No more interesting occupation can be imagined than that of an inspector of apiaries. Early in the summer of 1904 the writer got his commission from Hon. J. Q. Smith, Inspector of Apiaries for Illinois. Soon after he started on his rounds among the Cook County bee-keepers.

Quite a number were visited who kept bees in box-hives, and never saw the interior of a brood-nest from one year's end to another. Some of these said their bees had nearly all died out, that they had not done well, etc. Of course in such cases it might be necessary to break up a colony or two

of the weakest live ones, to make a thorough examination, transferring the bees and combs to another hive. In the cases that I have in mind the parties were somewhat ignorant of our language and customs, and were entirely unwilling to have the hives touched, almost refusing to let me go into the back yard to have a look at the outside of the hives. Of course the colonies might be diseased, and the losses might have been caused by disease, but under the law as it stands, an inspector has no power to touch a hive for any purpose, without the consent of the owner, and the disease continues to spread in all directions from an infected apiary. By all means should the legislature be asked to give a drastic law, similar to the Wisconsin act. Otherwise it seems like wasting the money.

In my work of inspection I pass the home and apiary of a near neighbor and friend. He is an old-timer, having kept from 100 colonies up and down for 20 years or so. I never supposed his bees had the disease until one day I made him a formal call, asking him how his bees were. His answer, "They have got it," expressed the situation. We spent some time that day, and another day I returned and we examined nearly the whole apiary, and found 4 out of 5 colonies had foul brood. His loss will be over \$100.00 this season, by the disease. I questioned him as to where they could have gotten the infection. He named a party a mile away as the likely one. He said further that he had allowed the bees to clean out a honey-barrel that had been shipped in from Wisconsin. I visited the party named and found only the lady of the house at home. I told my errand. We went out to the colonies, and found 3 dead and only 1 alive. The live one I opened without smoke, and found a few bees on three frames and brood on two frames. They were in the last stage of foul brood. Now, I should have had the power to burn up the whole outfit, except the hives, on the spot. I urgently requested the lady of the house to have them burned up at once, and she promised to have it done. My time was too short, and the ground too large to get over it the second time, so I don't know whether it was done or not.

Now here is the condition that confronts us: The big State of Illinois has 102 counties, with about 350 apiaries to the county. Suppose an inspector can reach 5 apiaries in a day, it would take 70 days to cover one county effectually. This does not seem far out of the way when you remember that second and third calls must be made on a certain number of them. Seventy days to a county, 102 counties—7140 days' time to inspect the State. Suppose each deputy could put in 6 months—May, June, July, August, September, October, and put in 25 days in each month, which would make 150 days for each inspector. It would take about 48 inspectors to cover the ground. Allow \$5.50 a day for each inspector—\$4.00 and \$1.50 expenses. That makes \$39,270 as the sum needed to cover Illinois properly in one season. The moral of this is that we must ask the legislature for \$5,000 at the very least.

In order to get the money we must show them what was done with the money already given us the past two years. We must *make a report* of work done and money expended. We must show why we need a new law, and why we need more money. This report must be in proper form and addressed to the Governor and the legislative bodies. It must not be too voluminous, for they will not read and understand it if too many words are used. It seems fairly certain that we can get the largely-increased appropriation if the proper means are used. The Hon. H. W. Austin has consented to introduce our bill. You may remember that we would have had no law in 1903 without his aid. He recognizes the fact that even \$5,000 is an insignificant sum to cover the great State of Illinois.

It seems to be a fact that the aid of the Chicago-Northwestern Bee-Keepers' Association is necessary to the success of this plan. Let us suggest that a clause be incorporated in the new law to give the control of the fund to a joint board composed of the executive committees of both associations equally. It seems as if under such an administration the largest constituency could be reached, and the greatest good done to the greatest number. The Chicago-Northwestern is looking forward to great things. Two thousand invitations have been mailed for the coming convention at Chicago, Nov. 30 and Dec. 1, 1904. If these two of the best associations in America join hands, there will be no limit to their usefulness.

HERMAN F. MOORE,

Secretary of Chicago-Northwestern and Member of Illinois State.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### NO ADULTERATED COMB FOUNDATION AMONG AMERICANS.

It is not that all Europeans are rogues and all Americans honest, that we don't have adulterated foundation in this country. Climate and Conscience trot in double harness for us as they do not elsewhere. In our extreme climate impure foundation is nearly sure to break down; while in cool climates the break-down is only occasional—not frequent enough to stop the use of the article. We have rogues, and they can simulate honesty and innocence *ad libitum*; but they can't keep people from abandoning the use of an article that absolutely won't work. Page 324.

### WISCONSIN APIARY INSPECTOR'S BLANK.

Did you suitably thank N. E. France for that "Subscriber for" in the inspection blank? It appears to be suggestive enough to do lots of good without being quite iterative or impertinent enough to be insulting. This latter contingency is sometimes sadly forgotten in human affairs. I'm well acquainted with the superintendent of a little country Sunday-school who feels insulted by the blanks he is required to make out—with iterative "none—no—no—no." A closing-up line reading, "Nothing but heathen, moss-backs and savages out here" would almost be appropriate. Page 324.

### FREIGHT-RATE ON HONEY IN JACKETED CANS.

The importance of getting juster freight-rates for extracted honey in jacketed cans is considerable, even if it applies to but one classification region. Easier to make other regions follow suit than. Something more than six lines of fine print might very properly be given to this success of Mr. N. E. France. Very plain that Mr. F. does not make the incubating hen his sole model of performance. Let us remember that a few appreciative words now and then are excellent to make a servant who does well keep on doing well. For costing little and accomplishing much they take first prize. And they bless him who gives them almost as much as him who receives them—keep him from growing to be a bear in this zoological world. Page 324.

### TARIFF ON CUBAN HONEY.

With all allowances made, the present actual tariff on Cuban comb honey is a cent and a quarter a pound, it seems. Not heavy enough to be prohibitive or seriously repressive. By common repute there's going to be some time a general readjustment of the tariff; but our folks want a rise, and the popular

idea is a general reduction. Driving from Derby to London when London drives out to Derby to see the great race is said to be a trifle trying. Page 324.

### KNOWING THE PURPOSE OF ONE'S EXISTENCE.

So you concluded the Root Company know what they are there for without being told! Well, if the bell knows what it's there for without being told, it should still be tolled at proper times. Won't hurt us perhaps to say that on the whole they are there because they best deserve to be there. And in this world of God's, *continuing* to deserve leadership is an immensely important item—seeing that we have Scripture to inform us that the crown does not endure to all generations. Page 324.

### POLLEN OF VARIOUS HUES.

The pollen pellets which bees bear on their legs take a wide range of color; yet they rather rarely verge on the greens, and still more rarely on the blues. Some of the California gillias, according to Prof. Cook, yield a blue pollen. Page 325.

### BEEES DON'T STING FRUIT.

Lots of us have been living with bees for a good share of our lives, and I venture the assertion that none of us has ever seen anything in their behavior that would lead one to expect them to sting a grape or peach. Not like them. And that sort of consideration counts heavily. The dog might make faces at the looking-glass, but he is not going to do it. The captured rabbit might defend himself by biting (and we greatly wonder why he does not), but somehow he never does. The great carnivora of the cat tribe might, when tamed, hunt under a master like the dog, but they just *won't*. Domestic pussy pretty nearly ditto—she must boss her own hunting or there'll be none. Similarly it's not in the nature of bees to sting things for mechanical purposes. Dander must be up or no sting. Or let us get at the slander from a different direction. Suppose bees did sting grapes. Those who charge this do not consider what an exceedingly fine shaft the sting is. No insect would notice so infinitesimal a puncture, and no juice would exude—unless I am very greatly mistaken. In fact, we may offer our own hides in evidence. An ordinary sting does not let out the blood. But when it causes a spasm of the tissues, making the spot to assume a different color, and to draw into an entirely new shape, then a visible dot or color of blood is forced out. But fruits do not have the kind of life that can get up a spasm. Page 328.

effect. But you will hardly find it proof against ants and moths.

2. To give all the remedies that have been offered for bee-stings would occupy pages. Perhaps as good as any other remedy is a plaster of mud. Most bee-keepers of experience seem to think that no remedy does much good; the only thing they do being to get the sting out as soon as possible. Don't pull out the sting by grasping it between thumb and finger, for that helps to squeeze more poison into the wound; but scrape it out with the finger-nail, or else, if it is in the hand, by striking the hand hard on the thigh with a sort of sliding motion which wipes out the sting. A sting will swell on a healthy person in nearly every case if the person is not used to it, and perhaps a little worse on an unhealthy person; but after being stung often one generally becomes to an extent immune, so there is little or no swelling.

## Putting on Supers

Is it better to put on supers before swarming-time or at once? MICHIGAN.

ANSWER.—In most localities it is better to put on supers before swarming begins. As you are probably in a white-clover region, you will do well to put on supers a week or 10 days after the *very first* clover blossom is seen. Better put on supers too early than too late.

## Clipping Off Queens' Legs

In clipping queens, do you not sometimes clip off a foot? If you should accidentally do so, what effect would it have on the queen? Would she die, stop laying, or be superseded by the bees? IOWA.

ANSWER.—I think I was never more than once so careless as to cut off a leg. A queen with 5 legs will do good work laying, as I have had several born lacking one leg.

## Management for Increase

I bought a 3-frame nucleus May 12, and put it in an 8-frame hive with 5 frames of empty combs. It has been said that properly managed this could be increased to 4 or 5 full colonies by fall. How ought it to be managed in order to accomplish this result? I have been feeding syrup, and the bees have taken considerable of it into the combs. MISSOURI.

ANSWER.—If any one tells you that you can increase that 3-frame nucleus to 4 or 5 colonies by fall, tell him you don't believe it. That's a feat for a veteran of long experience under the most favorable circumstances. I wouldn't dare to promise I would do it. To make the greatest increase, you need familiarity with basic principles which you will get from a book of instructions on bee-keeping. This department is intended to supplement such a book, not to take its place, for which enough room could not be allowed. After studying up the book, if anything is not clear, I shall be glad to help clear up all I can in this department.

## Bees Gnawing Foundation in Sections

What is the cause of bees cutting foundation out of the sections?

I am a beginner, having started with a swarm which came to me July 6, 1903. I hived it in a box, and put it in an orchard, where I keep it. In the spring of 1904 a neighbor helped me to put the bees in a hive, and I secured one swarm and 30 sections of honey from them that season. I caught 3 runaway swarms, but lost 2 of them in the winter.

I used inch starters in the sections, but this spring I thought I would use full sheets, and I notice that the bees are cutting out some of them. I can not imagine what makes them do it, unless I did not fasten them in right. I fastened the foundation at both ends. Did I

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to Dr. C. C. MILLER, Marengo, Ill.  
Dr. Miller does not answer Questions by mail.

### California Redwood—Bee-Sting Remedies

1. I have a chance to get some hives made of California redwood. It is used for making incubators in this town. They say it will not take water, ants or moths will not work in it, and it will stand painting. Would the honey taste of it, or would the bees want to live in hives with that odor? Some say to wash with salt water or peach leaves. I can get hives made from this very cheap, although

redwood is high-priced. Have you had any experience in this matter?

2. What is the best remedy for a bee-sting, either for a person on whom the sting swells or one that it doesn't? It does not swell on me. I have heard that a sting will always swell up on a healthy person. Is that true? NEBRASKA.

ANSWERS.—1. California redwood has been successfully used for bee-hives, and you need not fear its effect on the honey, even without salt or peach leaves, which probably have no

do right, or ought the bottom to have been left loose? IOWA.

ANSWER.—The foundation should not be fastened at the bottom, but should be about 1/4 inch short of reaching the bottom (unless you use also a small bottom-starter), otherwise it is likely to sag and buckle. But that was not the reason the bees gnawed it. They probably gnawed the foundation because you gave it to them entirely too early, when they have no use for it. In your locality sections should not be given till after clover is in bloom. A book of instruction would be a paying investment.

**Colony With a Poor Queen**

I have a colony of bees, hived about July 1 last year, which is not doing very well. I found a queen in the hive to-day, but there were hardly any eggs and only a small quantity of brood in 4 or 5 frames. The queen is very small compared to other queens in the bee-yard. What ought I to do with this colony? IOWA.

ANSWER.—If you had said the small amount of brood and eggs was all in one frame, there might be reason for believing that the queen was all right in a very weak colony; but when you say there is brood scattered in 5 frames, that condemns the queen. The only thing to do is to destroy the queen and give the colony another queen or a sealed queen-cell, or else allow the bees to rear a queen, giving them unsealed brood from other colonies. All this on the supposition that the colony is strong enough to be worth saving, which is indicated by the brood scattered in 5 frames.

**Corn Honey**

I am sending you a sample of corn honey—a thing not often to be had. Three colonies brought in about 100 pounds last season, but the other bees did not get beyond the pollen contained in the tassels. Everything must be just so for corn honey—plenty of rain during the night, and temperature from about 70 to 80 degrees during the day. PENNSYLVANIA.

ANSWER.—Thanks for the sample. It is granulated extracted, of not very heavy body, rather light amber in color, and of rather pleasant flavor.

**Space Between Bottom-Board and Brood-Frames**

How much space can be left from the bottom-board to the bottom of the brood-frames in summer or during the honey-flow, without danger of the space being filled with comb? MISSOURI.

ANSWER.—I don't know just how much. Probably as much as 3/4 of an inch with narrow bottom-bars, and perhaps a full inch with bottom-bars 1 1/8 wide.

**Wintering Bees—Early Drones—Swarming**

My success in wintering bees in a cellar for the first time the past winter prompts me to relate it briefly, so you may form your own conclusions as to whether it was ventilation or what that gave me my success.

About Nov. 10, 1904, I was passing through the bee-yard and found a colony with plenty of bees, but almost destitute of stores. I put an empty super on, filled a pan with very thick syrup from granulated sugar, and hoped for warmer days, but was disappointed. There were only a few days from then till I moved them into the cellar that were warm enough for the bees to go up and get the syrup. I think they emptied the pan twice. Nov. 30 real winter seemed to be on us, and I carried the bees to the cellar. There was a pan on this hive nearly full of syrup which I removed and marked the hive "Very poor." I made no preparation, but left the covers

**STAR DYES**

Pure, Brilliant, Fast Colors. Quickest, Safest surest dyes made. Same package Star Dye colors cotton, wool, silk or mixed goods. All other dyes require different dyes for different goods. Star Dyes do the work in one hour. No chemicals required. Cheapest and best for successful home use — no failures if instructions are followed. Ninety shades. Sold by mail—any color—10 cents per package.

on without any cushion or top ventilation, and no ventilation below except the summer entrance. The thermometer registered from 38 to 45 degrees almost all of the time, and the bees were constantly humming. Some weeks after they were put in a few dead bees began showing on the floor, and I suppose during the winter I swept up a quart of dead bees from the 10 colonies—the number I put in. They were let severely alone till March 5, 1905. It being a warm sunny day I carried out one colony. This was a colony of yellow Italians that I had developed last summer from a 3-frame nucleus. My reason for selecting this colony was that I noticed there was some dripping at the entrance, while the others were perfectly dry. I should state that this hive stood only 6 inches from the bottom of the cellar, while the others were a foot from the bottom and tiered up on each other. I found the bottom-board covered with a black muck and smelling ugly. I cleaned this all off. The bees had a fine flight and I returned them to the cellar that evening. There was a hive full of beea and some honey and abundance of brood in all stages. This, remember, was March 5.

March 17 being very warm in the morning, I went into the cellar, and although it was very dark it was full of bees, flying in every direction. I immediately opened the outside entrance and without coat, hat, or gloves carried out the 10 colonies. I got several doses of anti-rheumatic for my temerity. I put them on the summer stands and they have been there since. I found them nearly all very populous, but not a great supply of honey. There was one with only a few bees and every comb full of honey. It is building up rapidly now. It seemed to me that I took out more bees than I put in. In 2 colonies I am sure I did. The hives in these two instances would hardly hold the bees, and one of them sent off a swarm May 12, covering every frame in an 8-frame hive. It was a tremendously big swarm. Did they rear brood all winter?

Now the colony that swarmed is poor in honey. In fact, they are all getting skimped, as there were 4 big freezes here after fruit was in bloom, and I think these destroyed the saccharine in the blossoms. Then it is raining so much it is impossible to gather any nectar. I am going to have to feed some if it does not soon warm up and bring out white clover.

Now as to the colony fed syrup in November and marked "Very poor." It came through in fine condition and is now threatening to swarm, though it is almost destitute of honey. The colony of yellow Italians that I put out March 5 and then returned till March 17 (the day I took all of them out) and which was full of bees March 5, dwindled and died till they did not cover more than 3 frames. Was this because of the flight March 5, or was it because the bees were not healthy? I am unable to account for the early appearance of so many drones. Can you? Remember I am only a novice.

I reported No. 1 as sending out a very large swarm May 12. I put the new colony on the old stand, and moved the parent colony the width of itself west, expecting to carry it to some distant part of the yard when the 8 days were up. This morning (May 18) was cloudy and windy, the thermometer registering 58 degrees. The parent colony sent out another good swarm. I caught one queen, and saw another with the swarm, which I put back in the parent colony. May 19 I carried it to another part of the yard. Lying in front of this parent colony this morning is a dead queen, and a cap off of a queen-cell. Did the queen I returned kill another, or get killed? If it were not so cold I would examine the hive and see how many more queens are there.

ILLINOIS.  
ANSWER.—As you are south of latitude 40 degrees, it would generally be supposed that outdoor wintering would be best for you; but your success in cellaring seems a pretty good warrant for its continuance.

One factor in your favor, judging from the sketch you send, is that there is abundant provision for ventilation without letting light into the cellar.

It is not at all likely that brood was reared all winter in any colony; but the rearing of so much brood at an unusually early date

## A Standard-Bred Italian Queen-Bee Free!

For Sending One New Subscriber.

As has been our custom heretofore we offer to mail a fine, Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year

2. Sending your own name with the \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a

new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

We will book the orders as they come in and the Queens will be mailed

Will you have one or more?

If you cannot get a new subscriber, and want one of these Queens, we will send the American Bee Journal a year and the Queen—both for only \$1.50. Address,

**GEORGE W. YORK & CO.,**

**CHICAGO, ILL.**

may have had something to do with the dwindling of the one colony. It probably suffered also for want of ventilation, as shown by the dampness while other colonies were dry. Possibly its being nearer the ground had also some effect. The flight March 5 was hardly to blame.

The early appearance of drones is no more than a mark of prosperity, and also a result of the fact that the season was earlier than usual, notwithstanding the fact that there has been so much backward weather since the opening of spring that the season is now no earlier than usual.

You should not wait 8 days till after the issue of the prime swarm before moving the old colony to a new location, for usually the second swarm issues at about that time. About a week is long enough, and that's too long if the prime swarm has been delayed as to issuing by bad weather.

I don't know whether the virgin queen you returned was killer or killed. There was a fight to the finish among all the queens present, and the strongest remained victor.

### HONEY-CANS AND FOUNDATION.

# Reports and Experiences

## Bees Doing Well

Bees wintered well on the summer stands. No losses. One swarm came off yesterday, a good, large one. Hived nicely. Is this the first swarm reported this season in this region? One colony is working in the super. We hope for a good honey season. A. B. METTLER, Will Co., Ill., May 24.

[We have published all the very early swarms that have been reported to us.—EDITOR.]

## Heavy Winter Losses—Good Prospects

Apple-trees are in bloom now and bees are doing very well, but we still have some frost at nights. Some of my colonies in 12-frame hives have 9 frames of brood. The winter loss seemed very heavy just in this immediate locality, but mostly from lack of feed. There were also a great many queenless colonies this spring, and some spring dwindling.

Clover never looked more promising, and if nothing happens to prevent it we will have another 1903. I have found some queen-cells in my best colonies. HARVEY SMITH, Ontario, Canada, May 22.

## Shaken Swarms Without Shaking

On pages 411, 459, 493, 520, (1904) will be found references to a plan which I stated on page 411 under the head of "Shaken Swarms Without Shaking." I do not remember to have seen any other mention of it. I would like to call the attention of the readers to it,

**BLACK BREASTED RED GAMES—The KING of Poultry.** Large size, good layers of finest eggs. Hardy and fearless, the best all purpose fowl. Willow legs and Bay eyes. Illustrated circular. 25th year. H. H. FLICK, MANCHESTER, MD.

The most attractive eastern excursion during the coming summer will be to Asbury Park, N. J., on occasion of the annual meeting of National Educational Association, July 3 to 7, inclusive, via the Nickel Plate Road and its connections, either the West Shore or Lackawanna Road, with privilege of stop-over at Chautauqua Lake points, Niagara Falls and New York City. Rate, \$21.35 for the round-trip. Dates of sale, June 29 and 30 and July 1 and 2, with extreme return limit of Aug. 31, by depositing ticket. Patrons of this route may have the choice of a ride over the most interesting mountain scenery in New York and Pennsylvania, and through the celebrated Delaware Water Gap, or through the beautiful Mohawk Valley and down the Hudson River, which also includes the privilege of a ride on day line boat on Hudson River, between Albany and New York City, in either direction, if desired. No excess fare charged on any train on Nickel Plate Road. Meals served in Nickel Plate dining cars, on American Club Meal Plan, ranging in price from 35c to \$1.00; also a la carte. Chicago Depot, La Salle St. Station, corner Van Buren and La Salle Sts. City ticket offices, 111 Adams St. and Auditorium Annex.

For further particulars, address John Y. Calahan, General Agent, 113 Adams St., Room 298, Chicago. 7—23A4t

to see if any one has tried it. I have used it 3 seasons now and it works well with me. It saves lots of work, and, with variations that will occur to any one, does the job of shook swarming without shaking. The essential of the plan is using the bee-escape board to get all the field-bees into the old colony, and as many young ones as may be desired.

TURNER BUSWELL.

Somerset Co., Maine, May 22.

### Bees Working in Decoy Hives

That afterthought on page 376 has made me do quite a bit of thinking. At first blush I was inclined to think that the chance to do something at cleaning out a decoy hive would make the bees more willing to accept it; but the more I think about it the less inclination I have in that direction. The sentimental fancy that bees are attached to a place because of their remembrance of hard work done there is somewhat attractive, Mr. Hasty, but it haso't good wearing qualities. Of course they can't "go and work day after day in a hive where there is no work to do," but that doesn't prove that they prefer a place where there is much work to do. If they were after work, they would prefer an empty hive to one filled with combs, and I have had evidence that they have no such preference.

I have had abundant opportunity to see scouts at work, and if you will drop in almost any day throughout the season I'll show you scouts working at hives containing empty

**Beeswax Wanted at all Times.**

**DADANT & SONS, Hamilton, Ill.**

combs. They're by no means always at work, but seem to get a lot of enjoyment out of simply flying in and out of the empty hive, which exercise they keep up day after day till something happens in their native place to make them give up the scout business. As nearly as I can interpret their utterances, they say, "We like this place ever so much better for having combs already built; our business is to spend most of our daylight time here till the swarm is ready to come, and in the meantime if there is any cleaning up to do we may as well be at it."

Now, Mr. Hasty, don't you go and say I'm not a good interpreter. C. C. MILLER.  
McHenry Co., Ill.

### White Bush Clover

I send a new flower which appeared in this (Atascosa) County 2 years ago. It is a fine honey-plant and produces the finest honey we have. It blooms in May and lasts until August. What is its name? W. T. BRITE.  
Atascosa Co., Tex., May 10.

[The plant is the white bush clover (*Petalostemon candidus*), and is pretty well spread over the prairie States. Being a clover it would be sadly out of place if it did not give the bees something fine.—C. L. WALTON.]

### The Cotton Controllable Hive

I notice on page 359 "The Wonderful (?) Cotton 'Controllable' Hive." I will give my experience with it. In June, 1885, I purchased one of the Cotton Controllable hives for \$4 and put a swarm of hybrid bees into it. I never saw bees work better. Not being a very good honey season I fed them 50 cents worth of syrup to give them a start. Aug 10 following I took off 60 pounds of nice white honey in glass honey boxes, and sold it at 15 cents a pound. But the hive was so expensive that I abandoned it, and am now using the

## The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the Knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$2.00.

H. M. ARND, Manager.

Danzonbaker and Langstroth-Simplicity hives exclusively.  
At that time, in 1885, the hive and system of management was all right, but the price of the hive and bees—\$20—was an outrage. There being no patent on the Cotton hive, they can be furnished complete with a full set of glass honey boxes, holding about 2 pounds of honey each, with a full colony of Italian bees, for \$10. I have full and complete plans for the hive and outfit. **SUBSCRIBER.**  
Boone Co., Mo., May 26.

### Wintering — Discouraging Outlook

Last season I lost 184 colonies out of 185. Then I bought, requeened, and put into the cellar 70 strong colonies, and carried from the cellar 40 live colonies, 25 of them very strong. Yesterday I took an inventory, and I found 8 colonies with about 8 pints of bees, and I am having no worse luck than my neighbors. I will give, as nearly as I can, the number of colonies of bees in this and 5 adjoining towns 20 years ago, and contrast them with the number at the present time:

Rupert, 1885	.....	2100	Same, 1905	..	20
Pawlet, "	.....	700	"	"	4
Dasset, "	.....	400	"	"	.60
Sandgate, "	.....	300	"	"	2
Hebron, N. Y., 1885	..	350	"	"	.40
Salem, 1885	.....	450	"	"	.70

I have had letters from other towns in the county, and the decrease is about the same. I had a letter from a man in Sunderland, Vt., saying that he had only 3 colonies left out of 80 which he had 3 years ago.

I have tried every way that I could read or think of to keep the bees. I have not lost 20 colonies because of their not having stores enough, and in 55 years I have never had a swarm winter in any kind of double-walled hive left out-doors, never had them in S-frame dovetailed hives but 2 winters, and have built 2 new houses at a cost of \$5000, my aim in building both these houses being to have a cellar that would winter bees. They are dry and well-ventilated, and the temperature is from 42 to 46 degrees, but after the bees have been in the cellar about 4 weeks they will begin to roar and come out, and they keep this up all winter, and if I leave them out they do the same. I will give any one \$100 who will give me a successful plan that will winter and spring 90 percent of the strong colonies put into winter quarters. The time will soon come when the hum of the honey-bee on the willow or apple tree, will not be heard in this vicinity.  
**C. M. LINCOLN.**  
Bennington Co., Vt., May 24.

## GRIGGS & BROS.

521 Monroe Street,  
**TOLEDO, OHIO.**

CHICAGO, May 8.—With April about all the trade in comb honey ceases so far as this market is concerned; occasionally a case sells, but no lots, so that prices now are practically without change, pending the new crop. Extracted is exceedingly slow of sale; white ranges from 5½@7c, and amber 5¼@6c, according to flavor, quality and package. Beeswax in active demand at 30c.  
R. A. BURNETT & CO.

CINCINNATI, June 2.—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4¼@6c, according to quality. White clover extracted at 6¼@8c. The comb honey market is practically closed for the summer. Beeswax, 29c.  
THE FRED W. MUTH CO.

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12¼@13c. Extracted, from 6@8c, according to quality.  
BLAKE, SCOTT & LEE.

PHILADELPHIA, May 19.—The season is about over for the sale of comb honey, with so few sales that the market is not established enough to quote price. Extracted honey has met with some demand, and we quote as follows: White, 6@7c; amber, 5½@6c. Beeswax, 28c.  
We are producers of honey and do not handle on commission.  
WM. A. SELSER.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.  
HILDRETH & SEBELKEN.

KANSAS CITY, May 12.—The honey situation is a little stronger, and there is but little honey left in the hand of the dealers. Best honey bringing from \$2.25 to \$2.50 a case; amber at from 25@30c a case lower. Extracted, 4¼@6c. Beeswax, 28c.  
C. C. CLEMONS & CO.

CINCINNATI, O., May 18.—The large stock of comb honey yet offered with hardly any demand causes lower prices. I quote fancy water-white at 12c; other grades lower, in proportion. Extracted is in usual demand for this season of the year. We quote white clover 7@8c; amber in barrels at 5¼@5½c; in cans, 5¼@6c. Beeswax, 28c.  
C. H. W. WEBER.

ALBANY, N. Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; huckwheat, 10@11c. Extracted, better demand: Buckwheat, 6@6½c; white, 6@6½c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c.  
H. R. WRIGHT.

SAN FRANCISCO, May 3.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted-white, 5¼@6 cents; light amber, 4@5c; amber, 3@3½c; dark amber, 2¼@3c. Beeswax-good to choice, light, 29@30c; dark, 27@28c.  
The steamer City of Peking, sailing Saturday last, took 85 cases for Belgium. Movement on local account is light. Buyers are holding off, anticipating arrivals of new crop at an early day.

# Bees Hold Up a Passenger Train

This is only one of the many remarkable incidents related in our little book, "Bee Pranks." The cut to the left is a reproduction of the front page of this little pamphlet which is compiled from newspaper clippings. It will amuse and instruct you.

This book we will give Free for the names  
and addresses of 5 bee-keepers,

The offer holds good only while they last. They are going fast, so if you desire a copy  
act at once. Published only by G. B. Lewis Co.

# GLEANINGS

## IN BEE-CULTURE

It is most possible that every reader of the American Bee Journal is familiar with Gleanings. But how many are numbered among its subscribers? They all should be, for a bee-keeper that finds one bee-paper profitable can afford another and still increase his profits. Gleanings has many points of excellence. We outline a few of them below. But we would prefer to have you read our new "Gleanings Prospectus." This is a 24-page booklet telling all about Gleanings. A postal will bring it!

### Contributors

Gleanings has a splendid array of departments and contributors. Every issue should be worth the price of a year's subscription to any bee-keeper. We can't give a complete list here, but if you read the list below you will see how valuable a paper we are publishing.

### Stray Straws

By Dr. C. C. Miller. In this department you will find him at his best.

### Bee-Keeping Among the Rockies

By J. A. Green. The bee-keepers of this region will find their interests well taken care of; indeed, Mr. Green's articles are read with pleasure everywhere.

### Gleanings from the Pacific Coast

By Prof. A. J. Cook. The Coast bee-keepers have problems of their own, and Prof. Cook is perhaps the best authority. His department is always timely and of great interest.

### Bee-Keeping in the Southwest

By Louis H. Scholl. The Southwest is a great bee-keeping country. Mr. Scholl is a practical bee-keeper and a writer of note.

### Conversations with Doolittle

Perhaps no one writer has contributed so much information to modern bee-keeping. In this department appear his best articles, and no bee-keeper can afford to miss a single one.

### Pickings

By Stenog. A review of all apicultural literature.

### Heads of Grain

A gold mine of valuable ideals for the bee-keeper. Every issue contains 20 to 30 short articles by bee-keepers, telling of their favorite way of doing things. Illustrated by an expert.

### General Correspondence

Should have been entitled, "Golden Correspondence." In every number the most successful bee-keepers of the world tell their experiences. No bee-keeper can afford to miss a word from such men as these: Hoffman, Burnett, Hershiser, Hyde, Alexander, Bingham, West, Phillips, etc., etc.

### Illustrations

Every number of Gleanings contains such a wealth of illustrations that it is exceeded by no other bee-paper in the world. Full-page and less of the best half-tones printed on special paper as well as numerous line cuts. This item alone doubles the value of Gleanings.

### Special Offers

To induce every reader of the American Bee Journal to read Gleanings also, we make the following special offers: Pick out the one that suits you, and then send **TO-DAY**. You cannot regret this move.

1. Gleanings and the American Bee Journal one year.....\$1.75
2. Six months' Trial..... .25
3. Gleanings 1 year, and Red Clover Italian Queen (April, May, or June)..... 1.50
4. Gleanings 1 year and A B C of Bee-Culture, postpaid ..... 2.00
5. Gleanings 1 year and Langstroth revised, postpaid..... 2.00
6. Gleanings 1 year and Doolittle's Queen-Rearing, postpaid..... 1.75
7. Gleanings 1 year and Standard Cornell Smoker, postpaid ..... 1.85

### Our Second Prize Photo Competition

Is open to all subscribers of the American Bee Journal. Read the conditions over and try to win one of our prizes:

We offer the following prizes for different kinds of photos: Class A, photo of apiary. Class B, photo of comb honey. Class C, photo of any object of interest to bee-keepers, not included in first two classes.

### REWARDS

Each class will be awarded a first, second, and third prize. First prize, winner will be allowed to select goods from our catalog to the amount of \$5; second prize, same as first, except amount is \$3; third prize, same as first, except amount is \$2.

### CONDITIONS

Contest closes Sept. 1, 1905. Contest is open to all ages, and limited to United States and Canada, as the foreign contest is still on. We suggest that photos of honey should show the product of one colony, and be arranged so as to expose the entire face of each section, similar to the photos often shown by Mr. Danzenbaker. If preferred, a select 10 sections could be photographed, or any other idea may be used.

Photos should not be marked in any way, but your full name and address should be put on a separate sheet, and enclosed with photo, marked "For prize competition." Do not neglect this. Photos not winning a prize will be paid for according to the value to us, if we can use them. The prizes will be awarded with special reference to clearness of photo and artistic beauty and the instructive and interest-drawing power. No photo returned unless stamp is enclosed for return. Prize-winning photos are to become our property.

## Editorial Notes and Comments

### Honey Definition and Standards

Prof. E. N. Eaton, analyst of the Illinois State Food Commission, has sent us the following, with the request that we submit it to bee-keepers for their opinions, the same to be sent to this office, when we will refer them to him:

#### Suggested Definition and Standards for Honey

##### ANIMAL PRODUCTS

###### Sugars

##### COMMERCIAL HONEY—

Commercial honey is nectar of flowers or similar saccharine secretions or exudations gathered from natural sources by the honey-bee, transformed and stored in a comb composed exclusively of bee's wax.

*Comb Honey* is honey in the comb.

*Extracted Honey* is honey removed from the comb.

##### COMMON STANDARD—

Should be ripe, unfermented, free from objectionable odor and flavor, and, if extracted honey, should weigh at least  $1\frac{1}{2}$  pounds per gallon.

##### CHEMICAL STANDARD—

Percent

Water—maximum.....20  
 Sucrose (cane-sugar)—max..... 7

Prof. Eaton is endeavoring to assist in establishing a code of definitions and standards of food products for the guidance of the various State Food Commissions, and will appreciate any aid that bee-keepers can give him on the subject of honey.

### Keeping Qualities of Honey

Extracted honey is sometimes spoken of as a thing that may be kept an indefinite number of years without deterioration—unless granulation be considered deterioration. But those who have tried keeping it a number of years are well aware that it undergoes changes easily recognizable—changes that are not for the better—it is reasonable to suppose that some deterioration takes place in a much shorter time, even if that change be not so easily recognized.

The change that takes place is both in color and in body. At the Colorado State convention, as reported in *Irrigation*, H. Rauchfuss showed a sample of comb honey 3 years old that was in a fine state of preservation, but "it was getting darker in color with each season, that is, the honey itself within the

comb was darkening." He also showed a 14 year old sample of extracted honey gathered from cleome "which was almost wholly liquid, but was very much darkened with age. The samples of extracted had all candied promptly after being extracted, but after a time would again liquefy wholly or in part, about once in a year or two years passing from one to the other condition and back again.

"The later granulations are never so firm as the first, and usually the liquefying are not complete either, it gradually changes to a semi-liquid condition seldom all becoming liquid, and as it candies again it is more truly a granulation, the granules being mixed with liquid parts. All samples of aged honeys show a decided tendency to become darker with age."

Mr. R. C. Aikin said: "I have a sample of white clover extracted honey 30 years old. It has showed the same peculiarities as that by Mr. Rauchfuss. It remained liquid the better part of a year, but gradually candied. I do not remember how long it was candied, but think it was about the second year that it began to liquefy standing on a shelf in a comparatively warm place not far from a stove, until it was almost entirely liquid except some granules. After this it candied as described by Mr. Rauchfuss, not a true condition, but a liquid full of granules. It has since become almost entirely liquid, remaining for the past 15 or 20 years a liquid with a cake of crystallized honey in it together with some granules throughout the mass. It is now about as dark as dark sorghum molasses, such as we used to make 20 or 30 years ago."

### Stewart's Foul-Brood Treatment

The Bee-Keepers' Review gives a plan of treatment obtained from W. H. H. Stewart, as follows:

Mr. Stewart's plan is simply that of giving the colony a new location, and allowing the returning bees to enter any colonies that they choose—probably those standing near the old stand. The diseased colony is moved in the evening, after the bees have stopped flying. Even if the moving does disturb the bees, or cause them to fill themselves with honey, none fly from the hive, and by morning all has become quiet, and all bees leaving the hive will be empty and in a normal condition. When such bees return with a load, they go back to the old location, and join some neighboring colony. They are not lost. Other things be-

ing equal, a bee is worth as much in one colony as in another.

In 8 or 10 days the hive is again moved to a new location, and left there several days, when it is picked up and carried into the shop. As the bees hatch out, and become old enough to fly, they leave the hive, fly to the window, go out through an escape, and probably join some colony in the apiary.

The combs eventually become free of bees or healthy brood, when they may be rendered into wax after extracting the honey. All this has been accomplished without any risky shaking off of the bees, or even so much as the opening of a hive. Can anything be more simple or easy of accomplishment?

This is somewhat after the Baldrige plan, which allows the bees of a diseased colony to escape in front of a neighboring colony through an escape. In the Baldrige plan of curing foul brood the trouble of putting on the escape stands against the two removals in the Stewart plan, but the Baldrige plan has the advantage that no robbers can enter the infected hive, while with the Stewart plan the colony, weakened by removal, and especially by the second removal, would most surely be at times attacked by robbers. To be sure, an escape could be used with the Stewart plan, but then it would have no advantage over the other.

### Celluloid for Queen-Excluders

In the British Bee Journal Mr. Reid is reported as saying that he had used nothing else but celluloid for queen-excluders, and that they continued sound and could be depended upon.

### Disinfecting Combs With Formalin

At the Ontario convention, as reported in the Canadian Bee Journal, Mr. Sibbald said:

"A year ago I thought of curing by the formalin method, and went to considerable trouble to get everything in good shape, according to the directions as I understood them. I fumigated a number of combs, and I think I turned on the formalin gas for about two hours, and I used it pretty strong, because I could hardly take out the combs the next day, but the disease developed after I gave the combs back to the bees. I thought perhaps I didn't give them enough formalin, and so I kept the lamp going all night; not only was the box full of gas, but the room also. I left them for two weeks in that box, covered up tight, and when I came to take them out I could hardly bear to reach down into the box, the formalin was so strong. I gave the comb again to the bees, and the disease developed again."

Prof. Harrison, while admitting that Mr. Sibbald had been very thorough in his work,

still felt that if used correctly formalin might be depended upon. He told about its use in disinfecting rooms from diphtheria, tuberculosis and small-pox, and said:

"I am convinced of its efficiency for the 'bacillus alvei' if it is properly done. In all these cases, in the application of formalin vapor, there is one point to be remembered, that the gas generated is more potent, that is to say, more germ-killing if the temperature is low, and if there is lots of moisture in the air—a low temperature—because it is easy to hold the moisture in the air when the temperature is low rather than high. In all these cases one has either to hang wet sheets in the room or else get moisture in the room by turning on the steam jet, allowing it to cool a little. When the air is well saturated with moisture, and if there is bedding or anything of that sort to disinfect, we very frequently sprinkle it with water in order to get more moisture present, then the gas is much more potent and more effective. That is also true of disinfecting any combs you may have. I would strongly advise either the spraying or sprinkling of them. I suppose it would not hurt to dip them in water. Then, having generated the gas, they should be left in this tight box for at least 12 hours.

**New South Wales Association Rules**

Besides having Christmas in hot weather, our Australian friends have some other things different from what they are on this side of the globe. Among the "Rules and Objects" of the New South Wales Bee-Farmers' Association are the following:

3. To advise members as to suitable localities for establishing apiaries.
4. Any bee-keeper can become a member on approval of committee, subscription 2-6 per annum.
5. That every member with more than 50 colonies shall be allowed an extra vote for every additional 50 effective colonies.
6. No member be eligible for office who has less than 50 effective colonies, or his subscription is in arrear.
11. Supply dealers or commission agents can not become members.
12. Members unable to attend meetings or conventions can authorize or nominate any member they know will be present to vote for them on any subject brought forward. Such vote or votes to be in addition to the member's present own vote.

It would be a good bit of innovation to have our National Association adopt such rules. It would be something of an undertaking to follow rule No. 3, advising members in what part of Canada or the United States to establish apiaries. The smaller territory in the case of our antipodal friends under consideration makes such advising more feasible, New South Wales forming but little more than a tenth of Australia; yet New South Wales is, after all, somewhat larger in size than a calf-pasture, for our New England States might be cut out of it four times, leaving still enough stuff to make the State of Pennsylvania.

In some respects it might be a good thing to measure a member's power by the number of his colonies, in other respects it would not.

In this country it has seemed rather the policy to court the co-operation of "supply dealers or commission agents," and where there is such a manifest community of interest that policy is likely to remain undisturbed. Possibly conditions in New South Wales may make it advisable to bar them out of membership.

**Miscellaneous News Items**

Mr. Wm. Russell, 4810 38th Ave., South, Minneapolis, Minn., has just recently been appointed inspector of apiaries for Minnesota, his commission taking effect Aug. 1, 1905, and being good for two years. We congratulate the bee-keepers of Minnesota on this appointment, and we trust they will patronize Mr. Russell should their bees become diseased.

**Bees and Honey at Illinois Fair.**

We have received a copy of the Premium List issued by the State Board of Agriculture for the 1905 Illinois State Fair, to be held at Springfield, Sept. 30 to Oct. 7. The premiums offered on apiarian displays are as follows:

	1st	2d	3d
Display of comb honey.....	\$20	\$15	\$10
Collection of labeled cases containing 12 or more pounds of white honey from different flowers....	8	5	3
Collection of labeled cases containing 12 or more pounds of amber or dark honey from different flowers.....	8	5	3
Case of white clover comb honey, 12 to 24 pounds.....	4	3	2
Case of sweet clover comb honey, 12 to 24 pounds.....	4	3	2
Case of basswood comb honey, 12 to 24 pounds.....	4	3	2
Display of extracted honey.....	20	15	10
Honey extracted on the grounds..	5	3	2
Frame of comb honey for extracting.....	5	3	2
Display of candied honey.....	20	15	10
Display of beeswax.....	15	10	5
One frame of observatory hive dark Italian bees.....	4	3	2
One frame of observatory hive golden Italian bees.....	4	3	2
One frame of observatory hive Carniolan bees.....	4	3	2
Honey-vinegar, 1/2 gallon, with recipe for making.....	4	3	2
Display of designs in honey.....	10	7	5
Display of designs in beeswax ..	10	7	5

OPEN TO THE WORLD.

The judges in this lot will be governed by the code of rules adopted by the Illinois State Bee-Keepers' Association.

Five hundred pounds only will receive full score for quantity in displays of comb and extracted honey, and 300 pounds only in displays of candied honey; 50 pounds will receive full score for quantity in display of beeswax.

Only one entry will be allowed by each exhibitor for any one premium.

We trust that there may be a proper interest shown by bee-keepers in the foregoing, as the Illinois State Fair managers are treating them well in their premium awards. A copy of the full Premium List can be had by addressing Mr. H. J. Cater, Libertyville, Ill., who is the able superintendent of the department known as "Dairy and Apiary."

**West Michigan Fair and Bee-Keeping.**

We have received the following from Mr. A. G. Woodman, superintendent of the apiarian department of the West Michigan State Fair, which should interest bee-keepers in Michigan, at least:

EDITOR AMERICAN BEE JOURNAL:—It might be of interest to bee-keepers, especially those in Michigan, to know that we have just secured an addition of \$50 to the Premium List in the Apiarian Department of the West Michigan State Fair, to be held in Grand Rapids, Sept. 18 to 22, 1905. We also have a

promise of more the coming year should we make a showing. What additions we get in the future will depend upon the show those interested put up. We want to urge bee-keepers to come and advertise the business—their business—create an interest in and a demand for their product, and at the same time, if they win the prizes, they will be paid for advertising their own goods—free advertising.

The Premium List will be issued as follows, with competition open to the world:

	1st	2d	3d
Nuclei of hybrid bees.....	\$ 3	\$ 2	\$ 1
Nuclei of Italian bees.....	3	2	1
Nuclei of Carniolan bees.....	3	2	1
Queen-rearing nuclei.....	5	3	2
Three different strains of bees....	3	2	1
Specimens of comb honey—not less than 10 pounds.....	5	3	2
Display of comb honey—most attractive.....	25	15	10
Specimen of extracted honey—not less than 10 pounds.....	4	3	2
Display of extracted honey—most attractive.....	20	10	5
Beeswax—not less than 10 pounds	3	2	1
Most attractive display of honey-producing plants, pressed and mounted.....	3	2	1
Largest number of specimens of different kinds of honey, each named.....	2	1	
Largest, best, most interesting and instructive exhibit in this department.....	15	10	6
Diploma to best exhibit.			

The bee-keepers of West Michigan are to be congratulated on their success, doubtless through the efforts of Mr. Woodman. It is hoped bee-keeping at the next Fair may be so well represented that another year even a larger Premium List may be offered.

Mr. and Mrs. H. H. Hyde, of Bexar Co., Tex., are rejoicing over a fine 9-pound boy, born June 2. Both mother and child are doing well. Our congratulations are hereby extended. "Papa" Hyde says this "adds one more name to the bee-keeping fraternity in Texas." But he doesn't give the lad's name. It's perhaps a case of "Hyde and seek." The "Hyde" is there, and now they'll "seek"—a name. As Texas is a big State it may take quite a while to find one that is suitable.

**Biographical**

ROBT. A. HOLEKAMP

On the first page appears the portrait of Robt. A. Holekamp, of St. Louis Co., Mo., one of the members of the Executive Board of The Honey-Producers' League.

In the early part of 1870 he arrived in this country, being 22 years of age, from the Province of Hanover, Germany, where he had received a good business education, and had just finished a year as volunteer in the Prussian Army. He soon found employment as book-keeper and salesman in an agricultural implement and hardware business in St. Louis, which business he left a few years later to fill a position as bank teller.

In these positions Mr. Holekamp had an opportunity to become well acquainted with the business methods of this country, and they prepared him for his later business

career. He had become acquainted with a firm which started a sash and door business, but which dissolved a few years later by dividing the assets of the business.

One of the former members of this firm, living in Wisconsin, and running a sash and door factory there, made him business manager in St. Louis, to assist his young son whom he made his partner. The business went on for a few years when the senior member of the firm died, and the son and Mr. H. bought the business and continued it under the firm name of Gray & Holekamp.

Their business grew rapidly, and soon became one of the largest of its kind in the country, their customers being all over the South and West, and every new railroad in their territory brought new trade.

A few years later the former partner of his old employer lost his health. They bought him out and moved into his just finished, new and commodious quarters. After a few years more Mr. H. bought out his partner, and continued the business in his own name.

The continuous strain of managing a large business, and at the same time doing a good deal of traveling to work up new territory, gradually told on his health, and finding that rest was necessary, he sold his business.

After he was through winding up his old business affairs, he looked around for some business where he could spend his time out in the open air, and soon bought an interest in a sawmill and timber-lands in southeast Missouri, and incorporated the business.

He and his family lived there for a number of years, right in the wilderness, away from civilization, and surrounded only by about 50 little houses, the dwellings of his milkbands and teamsters. Mr. Holekamp says those years in the wilderness were the happiest of his life. He was busy from early till late, but enjoyed splendid health, and soon built up a nice business, but the necessity of giving their children a better education than it was possible to give them in the backwoods, compelled him to give up business again and to return to St. Louis. There he bought an in-

terest in a surgical instrument business, which he sold several years ago.

Mr. H. kept his old sawmill home for a number of years, running a farm and spending the summers there during the time of the children's school vacation, but sold it a few years ago, it being rather unbandy to run a farm so far away. He has no business now except looking after his rented property and attending to his bees, which keeps him as busy as he cares to be. He has kept bees for the last 15 years, and considers the work with them the most interesting outdoor employment he can find.

It will be seen from the foregoing sketch that Mr. Holekamp has had a very extensive as well as successful business experience aside from his 15 years of bee-keeping. It would seem that he will prove to be a very valuable member of the Executive Board of The Honey-Producers' League. He is right in his prime, and should be quite an addition to the ranks of those who are endeavoring to improve the keeping of bees as a business.

## Securing Large Increase—Keeping Queens

BY G. M. DOOLITTLE

**I**N a late number of the American Bee Journal I closed what I had to say with the remark that "I was open to any further question on the subject." This has brought me a lot of questions, and in this I will try to answer briefly those from a man in West Virginia.

He first wishes to know how I would work to secure a large increase, something like that which I wrote about as given in the April 27 issue of the American Bee Journal, only that he wishes to use comb foundation instead of frames filled with combs. Bees can not be increased as fast where foundation is to be used as with plenty of drawn combs; but they can be increased faster where comb foundation is provided than is possible where the combs are to be built in frames having only starters in them. In using foundation, proceed the same as I gave in that article until quite a few young bees have emerged in the spring, and the colonies you have are beginning to get fairly prosperous, when a frame of foundation is to be put in each colony between two frames containing brood, and left one, two or three days, as is necessary for the bees to draw out the side-walls to the cells from  $\frac{1}{8}$  to  $\frac{1}{4}$  of an inch, but not long enough for the queen to lay many eggs in these drawn-out cells. If honey is not coming in from the fields in sufficient quantities for the bees to think they can work on the foundation, then the colonies must be fed in sufficient quantities for them to do so. In this way keep on till you have sufficient frames of this drawn foundation to proceed as I gave in that April 27 issue of the American Bee Journal.

Having these frames of drawn foundation, go to making your colonies as there given, and if you can not procure enough frames so fixed from the few colonies you have in the spring, those which you will make will work foundation as soon as their queens get well to laying, and thus these new colonies will help along with the work. But always remember that it is useless to try to make any very weak colonies contribute to any part of this work. Far better wait a little for all to get strong enough to do this work to advantage.

If you do not have foundation enough to use full sheets in all of your frames, then use the larger part of it as above, when the rest can be cut into strips of four rows of cells each and fastened to the top-bars of the frames, when, in due time, they are to be placed in between the combs of the colonies you have made (those having young queens), when the bees will build them down with comb of the worker size of cells. Remember you *must* feed at all times when nectar is not coming in from the fields, if you would have foundation drawn out, or combs built from starters, as the bees will do nothing at this work in times of a famine of nectar.

### KEEPING QUEENS UNTIL NEEDED—QUEEN-NURSERY.

The writer next wants to know how he can keep queens when he buys them, till he is ready to use them, and also what a queen-nursery is. I will answer the last question first.

A queen-nursery is a frame having cages in it, each cage of which is fixed for the accommodation of one queen. The cages are generally made out of a piece of inch lumber, the same being cut about 3 inches square. In the center of this piece a 2-inch hole is bored, and then two  $\frac{5}{8}$  holes are bored through the edge of the piece till they open into the large hole. Now the large hole is covered on both sides with wire-cloth, and one of the small holes filled with "queen candy," or a sponge filled with honey for food for the queen, while the other is left for a doorway to be used in putting the queen in and letting her out. Both holes are to be closed with a proper sized cork, so that the bees from any colony into which it is put can not get to either the queen or her food.

When you have enough of these cages made to fill an empty frame, and they are put in place so that the frame is full, that frame of cages is called a "queen-nursery."

And to use it, provision the food apartment, run in the queen or queens, and hang the nursery in place of a brood-frame in any colony. Some think it best to hang this nursery, when the queens are in it, in a queenless colony, and others are equally sure that it is best to keep it in a colony having a laying queen, as the bees in a queenless colony will cluster on the most of the cages, and try as much as they can to torment the queens in these blocks or cages of the nursery. But, with me, the bees will cluster on the blocks to a greater or less extent, no matter into what colony they are placed, and, as a rule, I do not like to keep queens thus longer than can be helped, as it is against "queen nature" to be thus confined, which is often shown by the queens dying after being so confined for from a week to a month.

I use these nurseries most largely where I have more "ripe" queen-cells than I can use just at the time they are ripe. Just put the ripe cell into the hole that is used as a doorway for the queen, and when the virgin emerges she is in the cage, ready to be used just as soon after she has emerged as possible, for I consider that the shorter time she is in this or any other cage, the better queen she will make.

Next, and last, the questioner wishes to know more about slipping the queen-excluding zinc down into a hive so that queen-cells will be built in the side not having the queen, which I mentioned in the other article, this plan being used in early spring, or at any other time when colonies are not strong enough to rear queen-cells in an upper story.

Take one of your hives and nail on a tight bottom-board. Now, if you have a 10-frame hive, put in a sheet of the perforated metal just where the fourth frame would stand when the hive has the whole 10 frames in it. This is best done by making a saw-kerf, just there, in each end of the hive on the inside, so that this sheet of zinc can be slipped in and out at pleasure.

Now slip in the sheet of queen-excluding metal or zinc, and make sure that there are no places where the queen can get above it, around it, or under it, when you are ready to take it out to the apiary and place one of your strongest colonies in it. To do this, look over the combs of the strong colony till you find the queen, when the comb she is on is to be set out of the hive till you have things arranged. Having found the queen, you will set in the smaller side of your pre-

pared hive two frames of the youngest brood you can find, and one where you can see the bees just gnawing from the cells, all of which combs should have more or less honey along the tops of the combs and at the upper corners. Having these combs in place, set in a frame which is the most full of brood of any, next the zinc in the larger side of the hive. Now set in the frame having the queen on it, and then fill out that side of the hive, which will contain six combs, leaving out the one which would go in where the sheet of perforated metal is used. The comb to be left out is one having no brood in it, which you generally can find. If not, give this comb of brood to some other colony, after having shaken the bees off it into their own colony.

The next day after having the colony so fixed, start your queen-cells as given in "Scientific Queen-Rearing," take out the frame of hatching brood of the three put in the smaller side of the hive, draw the next to the side of the hive and put in the frame of prepared queen-cups in the open place. If there is a frame in the larger side of the hive which does not have brood in it, take that out so as to give place to this frame of brood; otherwise shake off the bees and give it to some other colony. Now close the hive, and in three days, if you look, you will find nearly every one of the queen-cell cups on their way toward completed queen-cells, if you are anywhere near as successful as I am.

I can see no difference as regards the good qualities of queens reared in this way and those reared in upper stories, as given in "Scientific Queen-Rearing;" but the work is less with the upper stories after the colonies have become strong enough to do good work above. Onondaga Co., N. Y.

## California Bee-Keeping—Past and Future

BY C. W. DAYTON

OUR long season of anxiety is ended. The bees began to make their own living the first of April. We began to feed them on the first day of last July, making it a nine months' dearth of honey. Still, all along through July and August they continued to get a small amount of honey from sumac and wild buckwheat. Some of the most industrious colonies got enough, perhaps, to keep them alive, but the general class of colonies went right down to starvation condition. At the start there were about 210 colonies. Now there are probably 160 left, about 50 having dwindled out from having too old queens or none at all. Some did not rear enough young bees last September, and the old bees continued to fly out of their hives all the fall and winter, of course causing the hives to become depopulated from old age of working bees.

During this time we fed about 3000 pounds of honey, nearly all in the open air. The next apiary north fed \$35 worth of sugar to 220 colonies. There are 90 alive now. The next apiary south, of 250 colonies, fed 600 pounds of honey. There are 80 colonies alive now. The mortality among the colonies has been greater than usual for dry years. I do not know whether it is because the bee-men are losing courage, or because it was a worse case than usual. One thing, last season the sage utterly failed to bloom—something I never heard of before. It has always yielded somewhat. But the sumac and buckwheat held out exceedingly well. Sumac continued for something like six weeks, while I have known it in good years to dry up and fail in 10 days of hot weather. But last season held out cool and favorable. I have known buckthorn to yield honey early in the winter so as to fill the supers pretty well, but this time it almost failed to blossom and gave no honey at all, notwithstanding the abundance of moisture. Three years ago there came two inches of rain the second day of November, and in December the bees roared on the buckthorn bloom nearly equal to basswood. Neither did the eucalyptus yield anything in the valleys. In 1898, from eucalyptus, they completely filled their supers in January. Still there has been very mild weather all winter. Sometimes we have frosts and freezes often, and I have known a pretty heavy frost as late as May 5.

While this fine weather has failed to help us out with a yield of bee-fed from some source, it has permitted the colonies which have been fed liberally, to make the greater strides in the way of brood-rearing. Since the middle of December we fed, every pleasant day, all they could carry to their hives. This caused them to rear brood during January and February to their utmost, so that the first of April finds the hives full of bees and all the combs full of brood. Usually the sages are ahead of the bees, but at the present time the bees are waiting for sage, which is just beginning to blossom, and every corolla-tube contains a small drop of nectar.

If the price of \$10 a colony were offered it would be no

temptation to us to sell bees. They have never failed to yield 200 pounds to the colony in such seasons as the present. We count 200 pounds of honey worth \$16, and sometimes it brings \$18 for the first quality, according to how it is marketed.

The 50 colonies which have died I think might have been saved had they had better attention. That is, by feeding them in the hives, specially last August, to make them rear the required amount of young bees, and then to keep them supplied with stores in the early part of the winter. Colonies having old or poor queens do not seem to have energy to carry feed. Yet if they are kept until spring they would build up into good working colonies, and could be requeened for the season with queen-cells from some of the most forward colonies.

The 50 colonies at 200 pounds each would gather five tons of honey, which, at 8 cents per pound, would amount to \$800. I do not think it would have cost more than \$50 in labor to have saved that amount. But we tried one of the "short cuts" by open-air feeding. It required only to heat up a can of honey, mix with water and put it out in pans, where the bees could take it.

In 1896 I had 225 colonies to take through a dry year just like this, and not one was lost. But they were fed in the hives. In the spring I sold 75 colonies for \$250. I gave the purchasers their choice out of the apiary and they took the strongest, of course. The apiary averaged 225 pounds to the colony that season. But we sold honey at 5 cents per pound then. Since then we have made a market, and there is no question but that we shall get 8 cents for all of the first grade and 7 cents for amber. This is not a high price, nor yet a low price. It is a price that we as producers and the consumers can afford. If extracted honey is held at 10 or 12 cents a pound it becomes a luxury—to look at, for company, or for some special occasion. Then it comes in competition with candies and other fancy, nonsensical trash which is only calculated to tempt the sight and palate. Then if it is sold at 3 to 5 cents per pound there is not much remaining above the cost of production. It has often been stated that it costs about 4 cents per pound to produce extracted honey. By an unusually good harvest, by buying the colonies at a low price of some one who does not know what they ought to be worth, or by the employment of cheap help, or by taking all the bees gather and allowing them to starve, the cost-price of honey may sometimes be cut down a cent or two per pound lower than that; but to the one who is keeping bees from year to year such methods do not pay. A person will have to wait and watch for such opportunities. And then they may not appear, and he is compelled to maintain himself two or three years without an income, or until his means are all used up. The only sure way is to get into "the game" and stay in it. Those that stay in it are always in practice, or, as we may say, "in training." These are the ones who are best prepared to endure the hard "tugs." And the bee-man who brought his bees through such seasons as the one just passed does not need to look for employment or await an opportunity.

It is simply a matter of "keeping the shoulder at the wheel." The main force that enables one to stay at the "wheel" is love for the business. With the more "ups and downs" and "hard knocks" there come, and success at last, unwavering confidence is established or increased; and we should then set out to contrive methods to be conveyed over such times easily, or by the least amount of interruption when they occur in the future.

One fault of our management a year ago, just previous to the scarcity of honey, was allowing the colonies to breed up so as to contain a large force of bees which could be of no use. This was done at the expense of their abundant supply of winter stores, which was left in the hives from the previous good season. If the queens could have been restricted to two or three brood-combs there would have been enough young bees reared for all needs, and besides would have saved the laying capacities of the queens. If the queens had been prevented from exhausting their egg-laying disposition in the spring, they might have kept up more brood-rearing in September and October, and produced more late-reared bees, which were so much needed to go through the past winter and spring. The queens would have possessed better vitality, also, which exerts a corresponding influence on the worker-bees, resulting in the colonies being more tenacious of existence and the appropriation of feed. The useless bees reared a year ago would be of high value now, but our hives were not so constructed as to permit of such transposition, at least, "on short notice." It was known that there could be no honey for them to gather. Some persons suggested that bees know when, and when not, to rear their brood. So we allowed them to follow their natural instincts. Another time we intend to inject some intelligence into their methods.

In the eastern and northern States, when colonies are

taken from the cellar there are often hives full of bees. The cold, backward weather during the last of April and in May, and the first half of June, often reduces the strong colonies to mere handfuls of bees through spring dwindling. Often in a couple of weeks after the bees are put out they will have three or four combs of brood, and with pleasant, warm weather, with maples and fruit and dandelions yielding pollen and honey, the bee-keeper will be led to think that they will soon be swarming and the colonies increased and his business fairly boom.

But there comes a day with a bright, sunny morn. Clouds by 11 or 12 o'clock. Rain, sleet, or possibly snow, by 4 o'clock in the afternoon, and during the night perhaps the formation of half an inch of ice by the next morning. Our balmy, sunny May weather seems to catch a cold that it can not throw off. All the spring flowers receive a set-back which often "puts them out of business" for the remainder of the season. The weather continues more or less cloudy or chilly, and what becomes of the tender brood in the hives? In a week or 10 days we examine and find, in place of the broad sheets of brood with eggs and all-sized larvæ strewn in strips several inches wide clear to the outer margins, a few patches of sealed brood the size of a hand or smaller. The eggs and larvæ have disappeared from the outside, and there may be only now and then an egg placed in the occasional empty cells among the sealed brood. Indeed, the prospects look slim, or "blue."

If such colonies as were taken from the cellar were set down here in California in any of the winter months, I believe there would be 6 or 7 combs full of brood in 3 or 4 weeks, and the weather would not prevent it from hatching. But our colonies in January are weak—notable to maintain more than 2 or 3 combs of brood. Thus through January, February and March they go through the process of "building up" to attain strength sufficient to swarm. The cause of their becoming weak is that they continue to fly about during September, October, November and December, and get to be old bees, or get lost. Then the weather is unpropitious enough to hold a weak colony in check, when, if the colony was strong in bees, it could make rapid advance from the start. Such colonies would be too early for sage or any other harvest, but the number could be increased, young queens reared, etc., in short, about double the gathering force of the apiary, or reduce one-half the number of colonies to be carried through a dry season.

Los Angeles Co., Calif., April 10.

By request, I offer the above suggestions, and hope action along the line indicated will be taken.

Kanabec Co., Minn.

C. H. HARLAN.

### BEE-KEEPING AS AN OCCUPATION

The occupation of the bee-keeper is a most interesting and unique one. There is no other business like it. The skillful manipulation of bees, whether for the production of honey or for the rearing of queens is an art of which the general public know but little. Surprisingly strange questions are asked us by people refined and educated, as well as by the unlettered.

The progress of the industry in this country has placed the occupation among the trades or professions, and like them must be learned by careful study and practice in order to pursue the business intelligently and successfully.

It is certainly more of an *art* than a trade, and must be classed among the skilled avocations of men and women. In many of the *trades* the hands may become so skillfully trained as to work automatically, and by the use of patterns sometimes the mind is used very little.

Not so with the pursuit of the bee-keeper. To be successful he must not only acquire a knowledge of bees, he must also acquire skill by practice, and with something of an inventive mind be on the alert for the different emergencies that are sure to confront him, and especially during the swarming season.

Here I am reminded that one season when I had been too busy to clip the wings of many of my queens, and the swarming season in all its commotion came on, I found some comfort in reading in Gleanings that at the "*Home of the Honey Bees*" they had also been too busy to clip the queens' wings. And while they had to climb tall trees in order to capture some of their swarms, I had only to pull up an evergreen tree on which most of my swarms clustered and carry it to the hive prepared for them and shake them down into it, then return the tree to the socket in the ground in time for the next swarm that would come out.

During a recent visit to New England I found but few bee-keepers even among the farmers. The old-style hive was generally still in use and the black bees, infested with millers, still predominated. I wondered that Langstroth's movable frames and the "A B C of Bee Culture" were not well enough known to be appreciated. I noticed the absence of white clover from the fields and pastures and roadsides. These conditions doubtless accounted for the fact that No. 2 and No. 3 comb honey was sold in the city at 25 cents per pound.

They are fortunate indeed who can learn the theory and practice of bee-keeping in some State Agricultural College, under such instruction as Prof. A. J. Cook gave in the State of Michigan, and perhaps is now giving in California. It seems to me that the Agricultural Colleges in the different States should consider bee-keeping important enough to be included in their course of study. When such instruction cannot be had it would be undoubtedly much to the advantage of the student or beginner to spend one or more seasons with some veteran in the business.

Yet most of us bee-keepers are probably self-made, and are still learning our lessons by experience, striving to know and do the important things essential to the highest success, eliminating the non-essential and trying to create or adopt the best system for use in our apiary.

But what a debt the student of to-day owes to those of the past who, like Huber, Langstroth, and others, have patiently observed the honey-bees at work in the field and in the hive, at various times and seasons, and experimented with them until they had found ways and means of managing these industrious and wise little servants.

If the Hebrew writer of the proverb "Go to the ant, thou sluggard" had been as well acquainted with the honey-bee as the ant, he would doubtless have said, "Go to the honey-bee, consider her ways, and be wise."

The most excellent periodicals published in the interests of bee-keeping are not only exceedingly helpful but are indispensable to all "up-to-date" bee-keepers. Those of us who are beginners in this industry owe our success thus far chiefly to the benefits we have received from the veterans of experience who have acquired their knowledge through the slow and sometimes costly course of years of experience, and who have freely furnished it to be printed for the benefit of others. The debt we owe them should be acknowledged, and our praise and honor bestowed upon them.

I have been interested to notice that the art of bee-keeping to most persons, as they learn it, becomes fascinating, and they grow enthusiastic in it. A common bond of sympathy is

#### INSURING BEES

The principal upon which insurance of all forms is based is not a subject for debate. It has been accepted after years of trial to be one of the best and cheapest known means of protection against accident, and nearly all possible kinds of losses are susceptible of protection through the agency of insurance. Prominent among the exceptions to this general rule is loss of capital invested in stock and fixtures of an apiary.

We know of no insurance company at the present time that will consider for a moment the proposition of issuing a policy on property of this kind. Why insurance companies assume this attitude towards this species of profitable investment of capital I shall not try to explain, but such is the present condition, and the proposition that confronts the owners of large apiaries, who wish to protect themselves against loss of their property by accident, is, How can we obtain insurance?

From the standpoint from which I view the subject I can see only one method that would be cheap, safe and desirable, viz.: Form a bee-keepers' mutual insurance company and put it in the hands of good, practical business men, who would be interested in the success of the company and the business it was created to protect.

This subject should be brought before the bee-keepers at their annual convention, and proper measures taken to organize a company and commence business.

created extending even to strangers. One perhaps unusual illustration is furnished by a prominent bee-keeper whom you doubtless know by reputation, Mr. Henry Alley, of Massachusetts.

When at his home last summer he stated that the season before he sold a queen to a lady keeping bees in New York State. At the end of the season she wrote him that she was very well pleased with the queen; it had proved to be the best one she had. This started a correspondence between them so agreeable to both parties of threescore and more years of age, that a few days previous to my visit they were married, and I found them enjoying their honeymoon!

The Creator gave man dominion over all the creatures he had made, that they might serve mankind, and the man wh

is able to acquire that dominion, and use it in harmony with the law of their being, is served and benefited thereby.

We bee-keepers who understand much about the honey-bee, so wonderfully made and endowed with ability to draw for us such supreme sweetness from the tiny store-houses in which the delicious nectar is found, are able to understand more of the Divine thought and wisdom because it is beautifully shown in the life and mechanism of the honey-bees and their queen.

Our occupation, then, while being a means of sustenance, unlike some others which dwarf the mind and degrade man, tends to elevate manhood and womanhood to a higher plane of thought and life.

J. KIMBALL.

### A New Book: "How to Keep Bees"

Such is the title of a new book by Anna Botsford Comstock, B. S. In the preface she says:

"When we began bee-keeping we found the wide range of information and varying methods given in the manuals confusing. . . . For the sake of simplicity this volume is restricted to knowledge gained in practical experience in a small apiary."

That gives one the expectation of instruction, based mainly on practical experience, of just such character as one needs to begin the business, especially as the sub-title of the book reads, "A Handbook for the Use of Beginners," and the first word of the preface is, "This book has been prepared especially to meet the needs of the beginner in bee-keeping."

A somewhat careful reading of the first 40 pages, and a hasty glance through the rest of the book, hardly fulfill this expectation, rather giving one the impression that the knowledge of the author has been gained mainly through the writings of others, some of those writings being perhaps not as reliable as they might be. For example, on page 29: "In developing a queen the bees usually proceed as follows: They select the important egg, which differs in no wise from any other worker-egg, and destroying the partitions between its cell and two adjoining cells, give it more room." Bees do not "usually" select an egg from which to rear a queen, "the important egg" being found in a cell which needs no enlarging—a queen-cell, and not a worker-cell. Even in the exceptional case, when in a queenless colony the bees do make a selection, it is a larva, and not an egg, that is selected. Neither would any one who has actually watched the work of the bees say that there was any "destroying the partitions between its cell and two adjoining cells," for no such thing happens.

The work is written in charming style, its 228 pages being printed from beautifully clear type on paper of excellent quality, and it contains 31 full-page illustrations that are very beautiful. The general reader will find it interesting; but as a guide for the beginner it is not to be commended without reservation.

### Capturing Swarms of Bees

In a recent number of the American Bee Journal I noted an inquiry in regard to the best way to capture swarms of bees, and the answer to same. I am tempted to give a little history of a "method" that was used with apparent success in this vicinity last season.

My husband is a bee-keeper, and we live on a hill. I say this that you may understand the story which follows:

A man came to the house of a near neighbor and asked the boy, "Does that fellow up on the hill keep bees?" Being told that he does, he said, "Well, I want to put up a box

in one of your trees. I am going to get a swarm off of him, and I will give you half of the honey they make."

He put up the box with cross-pieces in it, and smeared it inside with a mixture of honey and sweet anise-oil, assuring the interested youth that he had known bees to desert their hives for a box with this oil in it.

Well, he got the bees, and, as we had good reason to believe, "off of" my husband. Also, he took good care to come in the night and replace the full box with an empty one, which also caught its swarm. I have heard, from reliable source, that this man had over 100 colonies last fall, which he destroyed to get the honey, which he sold, as of course he could afford to do, at a reduced price, thus further injuring honest bee-keepers.

I should like to have an opinion as to his theory that anise-oil will draw bees.

Also, have honest bee-keepers no redress in such a case?

I should add that the bee-keeping industry in our State has not yet reached the stage where apiarists do not consider the swarms of value. We had an extra-good season last year for both increase and honey. Our 17 colonies yielded an average of 80 sections of honey each, and increased to 36 colonies, only 5 of which proved too weak to winter successfully on the summer stands. NEBRASKA.

Saline Co., Nebr., May 11.

It is a popular belief that bees are attracted by odors, and especially the odor of anise.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glassea.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### PLACING SECTIONS IN THE SUPER.

I'm all torn up in mind again, Dr. Miller. On page 329 you say sections look better when so given to the bees that the lock corner is the bottom corner. Wish you had been a little more explicit as to the *why* of that. In setting starters in sections I take a little pains to have the locked corner at the top. Sections filled in that position are much less liable to be pulled apart in handling—a consideration which weighs quite a bit with me. Both in pile and in case I want a section to stand the other side up from what it did while being built. I wish this because along the top-bar the honey is pretty sure to be plumped out fuller than along the bottom-bar; and finger bruises would start little leaks else. Also there are sections that will jar loose from the wood unless bottom side up. And when the honey-yield is poor (a common state of things with me) some sections are not attached to the bottom at all, and lots of

There is very likely some ground for this belief, although bees are certainly attracted by sight as well as smell; for a bee may sometimes be seen making a hasty visit to a flower which has just been rifled of its sweets, a still stronger proof lying in the fact that if an artificial flower closely resembling the flowers upon which bees are working be placed among the real flowers, the bees will also call upon the artificial flower. Admitting that the odor of anise attracts bees, it does not follow that it would make any difference as to deciding upon a place for the lodgment of a swarm, for the search of food is one thing and the search of a home quite another thing.

The placing of a comfortable hive or box in a convenient location is, however, no small temptation, it being not so very rare an occurrence for a fugitive swarm to locate in an empty hive, even when that hive has not been placed with any view of its offering attractions to prospective house-hunters.

There is no law against putting empty hives or boxes where swarms may find them; but our Nebraska sister may without great difficulty make her bees proof against the blandishments of all and sundry empty hives and boxes. One way is to keep close watch for swarms and hive them when they issue. For a swarm will not issue and immediately go to its new abode. It will settle and remain clustered for some time on some tree or other object, apparently with the distinct purpose of allowing the owner time to house it before it sails away to parts unknown.

A better way is to have all laying queens clipped. Then when a swarm issues it will return, and the owner will have a second, or even a third opportunity to see the swarm when it issues. An afterswarm will be prevented by the well-known plan of putting the prime swarm on the old stand with the old hive close beside it, and moving the old hive to a new location a week later.

them only attached an inch or so at one side of bottom. These last would keep me in an exasperated frame of mind while handling honey did I follow Dr. Miller's way. My Hasty jerk tears 'em loose—starts a big leak instead of a finger-bruise leak. The beea (just to pester me, and set a trap for me) won't propolize a lock in a way to improve the holding of it much. The only safety is to have well-attached comb both sides of the lock; and if the lock is placed at the top I can be tolerably sure of this.

### CLIPPING QUEENS AND HUMAN SCENT.

R. L. McColley is all right to clip his queens so as to keep them from getting the scent of his fingers. That sometimes is quite an important little item. But he still exposes them to the scent of his thumb. Can't he improve his machinery and obviate that also? Or has he discovered that the human thumb is non-odorous? There, now! I've always

wondered why little Jack Horner inserted thumb instead of finger in the pie! Page 330.

SOWING ALSIKE CLOVER SEED.

I think R. A. Morgan is right that alsike clover is the best honey-plant to push. Farmers can be induced to sow it—but it's no use to ask them to sow white clover. Page 331.

A NEW FORM OF BEE-HAT.

Shouldn't wonder if A. L. Oliver's form of bee-hat would be liked by many—especially by those who have not become habituated yet to any other kind. (Tobacco-pail cover with screen tacked all around it; and then the head, hat and all, butted into a suitable hole in said cover.) Be a great success if all the "butting in" folks adopt it. Page 334.

EVOLUTION OF BEES.

Great is evolution! And how the bee of the newspapers does evolve! Talk of three genera for the bee—here comes a fourth genus already! Room for *Sanctumapis meli-phobia*! And the leading characteristic of the new bee is great aversion to, and terror at, the sight of flowers and the smell of nectar. Page 339.

EDITING A BEE-PAPER AT LONG RANGE.

For an editor to conduct a leading magazine in England and live in California at the same time seems quite curious. The Yankee proverb, "Some things can be done as well as others," hath British followers as well as American. Page 340.

CONSTITUTIONAL VIGOR OF BEES.

So Arthur C. Miller thinks there has been a decline in the constitutional vigor of our bees as a lot—to take them as they run. Some things do look a little like it. And he thinks transferring larvæ, and too constant feeding of candy to nursery queens responsible in part. His proof of this is not altogether convincing (to breeders, at least), but it is worth thinking of. I fear some seeming evidences of decline might be picked up in regions where never an artificially reared queen has been introduced since Samson took the honey from his "frame hive." Also I incline to say that Mr. M. and others exaggerate somewhat the depressing effects of old-style bee-keeping. The light colonies that were spared to continue the apiary were largely second swarms with excellent young queens, not decadents. And some at least of the heavy ones chosen to take up were heavy because the queen had recently begun to lose her fecundity from age. Page 241.

EZERA THRASHER AND HIS BEE-FEVER.

And Ezera Thrasher, who mourned the post-office which the rural route wiped out, and looked to the big bee-association to protect him against stings, some of us will regret that his bee-fever got well so soon. If Manda had only been a B.-K. Sister, now, he would have seen some chance to rest up. Watching for swarms may be made a good rest-up job, if one doesn't have to do something else while watching—vile scheme to distract the watcher's attention, and let the swarm get away. Page 342.

# QUEENS

We have secured the services of one of the best Queen specialists in the U. S. Over 20 years' experience rearing Queens. Our Yard is stocked with select breeders from the best yards in America, and can send Queens by return mail.

### Prices to Sept. 1, 1905:

Untested Queens .....	\$ .75
Select Untested Queens .....	1.00
Tested Queens .....	1.50

## WANTED

Young man, single, experienced with bees, possessing large stock of bee-appliances, etc., desires interest in established apiary in first-class Eastern locality, New York State preferred. Correspondence solicited from all parts. Address, M, Care AMERICAN BEE JOURNAL, 24A1t 334 Dearborn St., CHICAGO, ILL.

BEE-KEEPERS' SUPPLIES. We are now able to quote lower prices than ever before. Highest quality guaranteed. We handle the G. B. Lewis Co's goods. Italian Bees for sale in dovetailed hives. Send for my 88-page Catalog, and leaflet for beginners. They are free. 44Etf W. J. McCARTY, Emmetsburg, Iowa.

# Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to DR. G. C. MILLER, Marengo, Ill. Dr. Miller does not answer Questions by mail.

## Prevention of Swarming—Transferring Bees

1. I have 2 colonies of bees in common box-hives which have already sent forth one swarm apiece to the present date (May 15). I would like to let them swarm again, and then stop them from swarming any more. As they are strong colonies I fear that they may swarm as often as 3 or 4 times. Advise me how to use them to the best advantage.

2. I would like to get them out of the old box if such a thing can be done.

WASHINGTON.

ANSWERS.—1. As I understand it, a colony has sent out a prime swarm, and you desire to prevent its sending out more than one after-swarm. When the second swarm (which is the first after-swarm) issues, hive the swarm and put it on the stand of the mother colony, setting the latter in a new place. That will prevent further swarming.

2. Twenty-one days after the issue of the prime swarm, drum out all the bees, put them in a new hive with frames filled with foundation, or with starters, then break up the old hive and get what honey and wax you can from the old combs.

## Best Hive-Entrance—Bees Dying

1. Regarding the quotation from Swarthmore (page 336) as to the auger-hole being the best hive-entrance, I wish to say I bored a 2-inch hole in the front end of several hives, put a button over each, and opened them during the honey-flow, but my bees did not use them much. It might work better if I turned the hole to the back end, which I now intend to do.

2. Some of my colonies died mysteriously last winter, with plenty of honey and a large number of young bees. I should like to know the cause. So far my theory seems to indicate that they were clustered over combs of

bee-bread when the long cold spell caught them. Is there anything in it? In a divisible brood-chamber I think the bees would not have died. We are in Southern Nebraska.

NEBRASKA.

ANSWERS.—1. Bees are creatures of habit, and it is not easy to get them to change their place of entrance. If you had given the auger-hole first, and opened the other entrance later, they would have stuck to the auger-hole. You'll probably not do any better with the auger-hole at the back—I think not so well. For several years I gave my bees an opening at the back for the sake of ventilation at the time of putting on supers, and they didn't use it as an entrance.

2. The presence of pollen probably did no harm; the harm came from the lack of honey. They ate all the honey in reach; then the cold held on so long that before they could get to the honey in the other frames they starved. I doubt that a divisible brood-chamber would have saved them; although under certain conditions it might.

## Canadians and Americans

On page 329 you say that Mr. McEvoy is a Canadian, but not an American. It may have been the custom in the States to give the name to no one but a United Stateser, but it is only the custom among the lower classes, and is purely an expression of provincial egotism. We Canadians are proud of our name, and have no desire to steal the name of another country. Can you say the same? By styling yourselves as "Americans" you take credit for the good works of all America. Look out and see that some day we will be refusing to annex the States. CANADA.

ANSWER.—As already said on page 329, "There may be a certain inconsistency... in saying that a Canadian is not an American, but established custom controls." The feeling "in this locality" is one of such brotherly kindness toward the bee-keepers of Can-

## A Standard-Bred Italian Queen-Bee Free!

For Sending One New Subscriber.

As has been our custom heretofore we offer to mail a fine, Un-detailed Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own sub-scription paid in advance at least to the end of this year

2. Sending your own name with the \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a

new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

We will book the orders as they come in and the Queens will be mailed

Will you have one or more?

If you cannot get a new subscriber, and want one of these Queens, we will send the American Bee Journal a year and the Queen—both for only \$1.50. Address,

**GEORGE W. YORK & CO.,**

ada that it would be a real pleasure to apologize for having used the word "American" as applying only to the inhabitants of the United States, with the promise never to offend in like manner again, if thereby "established custom" could be changed.

You say, "It may have been the custom in the States...but it is only the custom among the lower classes." I do not know just what opportunity you may have had for observation in the States, but I may be allowed to say that with the exception of a very few delightful days spent in Canada, my whole life—not a very short one—has been spent in the States, and I have been privileged to meet some of the best and most intelligent in the land as well as those of the lower classes, and I have not found that the use of the word "American" as applied to people of the United States was confined to the latter.

In any case I suppose that you will agree with me that we shall not go astray if we follow the lead of a good dictionary. The Standard dictionary is a work in good repute—among the upper classes of the States—between you and me I'm not sure I know just what upper classes are—it also stands well in England, and I suppose in Canada. It gives 3 definitions for the noun "American." The second is, "Any native or inhabitant of the American continent, whether aboriginal or descended from European settlers." In that sense Mr. McEvoy is an American. The third definition is: "One of the aborigines of the American continent." Mr. McEvoy doesn't look like an American of that kind. But the first definition, which in that dictionary gives the most common meaning of the word, reads thus: "A native or legally constituted citizen of the United States." Surely Mr. McEvoy is not an American in that sense, the common sense of the word.

While feeling obliged to defend my use of the word "American," I may be allowed to say that if I had known it would give you offense I should have chosen some other word for illustration on page 329, and shall have a reckoning with "A Reader" for having drawn me so near the vortex. But I make no apology to Mr. McEvoy. I think he so thoroughly understands my kindly feelings toward him that if I should call him a thief he would shake himself and laugh in that funny way of his, and say, "Well, they must have some new meaning over in the States for the word 'thief,' for I'm sure that so good a friend of mine as Dr. Miller would never apply it to me in any other than a complimentary way."

### Extracting-Combs—Cover for Sections—Using Combs in which Bees Died—Bi-Sulphide of Carbon

1. Can good extracting-combs be built in Hoffman wired brood-frames, from 2-inch starters of medium brood foundation?
2. Will they stand extracting as well as combs built from full sheets?
3. In running for comb honey do you use an oil-cloth or the underside of the cover next to the sections?
4. What can be done with combs in which bees have died during the winter, and crawled into the cells?
5. In using bi-sulphide of carbon for killing moths in brood-combs, how much should be used to the cubic foot of space?

ILLINOIS.

ANSWERS.—1. Yes.

2. No; and for two reasons. Most of the comb will be built without any foundation, and the septum of natural comb is more tender and thinner than that in foundation. Also, the wires in this natural comb will not be all in the septum as will be the wires in full sheets of foundation.

3. The cover is directly over the sections, with a bee-space of air between the cover and the tops of sections.

4. Give them to the bees as soon as convenient.

5. Perhaps an ounce.

Please mention Bee Journal when writing Advertisers.

## Reports and Experiences

### Bees Wintered Well in the Cellar

Bees are doing well. No swarms yet. I had no winter loss at all. I tried cellar wintering for the first time, and those wintered in the cellar are in better condition than those wintered outdoors, although I had the strongest colonies outside. HERMAN HEURKENS. Brown Co., Wis., May 30.

### Hans Bloomenstine Und Bees

I see by de American Bee Shournal dat our colored brudder (Jeems Schmidt) vas done wrote somedings for de Bee Shournal. Now I dinks perhaps maybe I can do dot too. I made my first acquaintance mit de honey-bee about 30 years ago alreatty, und diak I know whereof I am shpeaking about, don't id, you know? If you don't know den I dells you. You see id come about dis way. I vas vonce a leetle dutch poy, und like all poy's I had a grandfadder, und he vas dutch also, und he had some bees. I don't know odder if dey vas dutch or Idalian or plack bees like our brudder Schmidt, but I do know

a vay as dis? Und I also read about a kind of Root dat grows in Ohio, dat is good for bees.

I would like if Dr. Miller would answer all dese questions und make all dese dings clear to me, und maybe me und mein frow Katrina might join de National Sociation in a body. If dey is no color line maybe dere is no nationality line. If dese questions are all answered maybe I vill write again some dime und dell you all I know.

HANS BLOOMENSTINE.

### Too Dry for Clover

Bees are doing poorly. It is very dry here—but little rain for two months. There will be no clover unless rain comes soon, nor will there be any hay.

HENRY ALLEY.

Essex Co., Mass., June 6.

### Getting Combs Cleaned of Pollen

Of the 180 colonies of bees packed for winter on the summer stands I have 140 left at this date, May 30. In overhauling the combs left by the 40 colonies of dead bees, I found many that were so full of pollen as to make them useless for brood-rearing or storing honey. When this discovery was made I searched the old files of bee-papers to find what Mr. Doolittle does with such combs. Since reading what he says on the subject I have found, by accident, a wholesale way of getting the combs cleared of pollen with but very little trouble.

Last summer a colony of bees became queenless, but I did not know it until I began packing them for winter. Then I found a good-sized colony with combs almost wholly filled with pollen, and was puzzled to know what disposition to make of the bees and combs. I finally concluded to place a strong colony with plenty of honey and a laying queen on top of the hive containing the queenless bees. They wintered well together and now make a strong colony for summer

### LOSS BY LICE

on poultry amounts to many times the cost of Lambert's Death to Lice—the sure preventive. Loss can be saved and profit made by its use. Frees sitting hens from lice without harming eggs or chicks. A trial 10c box will prove it. 100 cz., by express, \$1.30.

O. K. STOCK FOOD CO.,  
D. J. Lambert, Vice-Pres.  
406 Monon Bldg., Chicago, Ill.

\$21.35 to Asbury Park, N. J., \$21.35 and return, via Nickel Plate Road. Tickets good via New York City. Dates of sale, June 29 and 30 and July 1 and 2, with extreme return limit of Aug. 31, by depositing ticket. Chicago City Ticket Offices, 111 Adams St. and Auditorium Annex. Depot, La Salle and Van Buren Sts., on Elevated Loop. 8—23A4t

work. A few days ago I looked at those pollen-laden combs (9 of them) and I could not find a particle of pollen in any one of them. They were all as light and clean as new-made combs.  
EDWIN BEVINS.

Decatur Co., Iowa.

### Poor Prospects for This Season

I have taken up bee-keeping for a living. So far I have had good success, but this spring is a failure. All over Texas bee-keepers seem to be having a hard time of it. I took an average of 133 pounds to the colony from 41 colonies, spring count, last year, but from present prospects I fear I will not get half that amount this year.

We had very cool weather 3 or 4 times in April. That stopped the flow of nectar. Bees don't find enough to build combs with.

OTTO SUELTFENFUSS.  
Bexar Co., Tex., May 30.

### Too Much Swarming

I wintered 8 colonies of bees. They commenced swarming the last Sunday in April, and I have to date saved 12 swarms, but lost 3. I think they will swarm themselves to death.  
MARION CO., ILL., May 29. J. A. HOYT.

### Honey Famine in Tennessee

We have had a famine here among the bees for the past year. I have lost 40 or 50 colonies. I have had no surplus honey since 1903. Honey is light here this year, and I fear our honey crop will be a failure again. Bees are nearly all dead where they have had no attention.  
G. D. HAWK.  
Sullivan Co., Tenn., May 29.

### Bees Wintered Well—Building Up Fast

Bees wintered well here with no loss that I have heard of. It has been a good spring. Bees are building up fast, and will be in fine condition for white clover.

C. W. HOPSEGER.  
Skagit Co., Wash., May 24.

## For Queens

SEND TO

# BEE=BOOKS

SENT POSTPAID BY

GEORGE W. YORK & CO.,

CHICAGO, ILL.

**Forty Years Among the Bees**, by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. Seventeen years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**Bee-Keeper's Guide**, or Manual of the Apiary, by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee**, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**ABC of Bee-Culture**, by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing**, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

**Bees and Honey**, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages. Price, in cloth, 75 cents; in paper, 50 cents.

**Advanced Bee-Culture**, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages; bound in paper, and illustrated. Price, 50 cents.

**Bienen-Kultur**, by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

**Apiary Register**, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

**Dr. Howard's Book on Foul Brood**.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

**Winter Problem in Bee-Keeping**, by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

## Honey and Beeswax

CHICAGO, June 7.—The volume of sales is infinitesimal; hence prices are not considered important at this season. Comb brings 12@12½c per pound for best grades, off lots 7@10c. Extracted, 5@7c, according to what it is. Beeswax sells upon arrival at 30c per pound.

R. A. BURNETT & CO.

CINCINNATI, June 2.—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4½@6c, according to quality. White clover extracted at 6½@8c. The comb honey market is practically closed for the summer. Beeswax, 29c.

THE FRED W. MUTH CO.

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12½@13c. Extracted, from 6@8c, according to quality.

BLAKE, SCOTT & LEE.

PHILADELPHIA, May 19.—The season is about over for the sale of comb honey, with so few sales that the market is not established enough to quote price. Extracted honey has met with some demand, and we quote as follows: White, 6@7c; amber, 5½@6c. Beeswax, 28c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.

HILDRETH & SEGELKEN.

KANSAS CITY, May 12.—The honey situation is a little stronger, and there is but little honey left in the hand of the dealers. Best honey bringing from \$2.25 to \$2.50 a case; amber at from 25@50c a case lower. Extracted, 4½@6c. Beeswax, 28c.

C. C. CLEMONS & CO.

CINCINNATI, O., June 9.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5½@5¾c; in cans, 5½@6c. Beeswax, 28c.

C. H. W. WEBER.

ALBANY, N. Y., Feb. 8.—Honey market dull this extreme cold weather, especially comb, which candies or granulates and cracks easily. We quote: Fancy white, 13@14c; No. 1, 12@13c; mixed, 10@11c; buckwheat, 10@11c. Extracted,

better demand: Buckwheat, 6@6½c; white, 6@6½c. Buckwheat most in demand, as the Jewish people will have no other. Beeswax, 30@32c. H. R. WRIGHT.

SAN FRANCISCO, May 31.—White comb, 1-lb sections, 11@12 cents; amber, 8@10c. Extracted, white, 5½@6 cents; light amber, 4@5c; amber, 3@3½c; dark amber, 2½@3c. Beeswax—good to choice, light, 27@29c; dark, 25@26c.

The ship Atlas, sailing Saturday last for New York, carried 236 cases extracted, reported to be Hawaiian Island product. Offerings of this year's California honey so far have not been large, and mainly by sample. The movement on local account is light.

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

# EVERY BEE-KEEPER

Should subscribe to Gleanings in Bee Culture. No progressive bee-keeper can afford to miss a single number. You subscribe to one paper already? Now, isn't it entirely logical that if you find one bee-paper profitable two papers would be doubly so? Providing the second paper was right, and Gleanings is right. Every reader of the American Bee Journal is familiar in a way with Gleanings, so it is not necessary to go into details regarding its merits. Every number is entirely original matter. Every number contains a wealth of beautiful illustrations. In fact Gleanings is par excellence in many ways. We have just published a little booklet devoted to Gleanings. It is a perfect miniature of Gleanings, going into details describing every department, and showing just how Gleanings meets the needs of every bee-keeper everywhere. We will gladly send this booklet with a sample copy of Gleanings on receipt of a postal card.

THE OLDEST BEE-PAPER IN AMERICA

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., JUNE 22, 1905

Vol XLV—No. 25

PUBLISHED WEEKLY BY  
**GEORGE W. YORK & COMPANY**  
 334 Dearborn Street, Chicago, Ill.

**IMPORTANT NOTICES**

THE SUBSCRIPTION PRICE of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

THE WRAPPER-LABEL DATE indicates the end of the month to which your subscription is paid. For instance, "dec 15" on your label shows that it is paid to the end of December, 1904.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

ADVERTISING RATES will be given upon application.

**National Bee-Keepers' Association**  
 Objects of the Association

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00  
 General Manager and Treasurer—  
 N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**The Honey-Producers' League**  
 (INCORPORATED)

**OBJECTS:**

1. To create a larger demand for honey through advertising.
2. To publish facts about honey, and counteract misrepresentations of the same.

**MEMBERSHIP DUES**

1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.
2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-spacer publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.

GEORGE W. YORK, Manager,  
 334 Dearborn St., CHICAGO, ILL.

**Queen-Bee Free as a Premium**

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is a good time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

THE AMERICAN BEE JOURNAL is absolutely an independent publication, and not connected with any bee-supply business whatsoever. It stands entirely upon its merits as an educative force in the field of bee-keeping, and as a medium for legitimate advertisers in apicultural or other lines. It is the oldest, and only weekly, journal of its kind in America. Its publishers believe that it deserves to be in the hands of every would-be progressive successful bee-keeper in the land. It is in its 45th year, and to-day is acknowledged to be better in every way than at any time during its long and honorable history.

**Editorial Notes and Comments**

**Hive-Ventilation During Harvest**

A good many bee-keepers probably fail to get the benefit they might have from a sufficient amount of hive-ventilation during the time bees are storing. In many cases the hive-entrance is the same in July as it was in March. In March a strong colony may do with not more than one square inch for its entrance; but ten times that amount will be better when the harvest comes, partly because of the greater strength of the colony, and partly because of the greater heat of the surrounding atmosphere.

Those who run their bees for comb honey have perhaps no successful plan for giving ventilation except at the bottom of the hive, either by a large entrance or by raising the hive on blocks at each corner. But in running for extracted honey one need not be so careful where the cool air strikes, and can have an opening at the roof, perhaps by having the cover shoved forward so as to leave a space of  $\frac{1}{4}$  inch or more. That allows a passage of air clear through the hive. No need to worry if rain should beat into such an opening. This abundant ventilation will make the bees more comfortable, and in some cases—indeed, in many cases—may be the means of preventing swarming.

Probably not a few who read these lines would be the gainers to go at once and give the air a better chance to get into their hives. If fearful of the effect of too much fresh air, try it on a few colonies at least.

**Foul Brood and Extracted Honey**

In an article in the Bee-Keepers' Review, Elmer Todd says:

The principal causes why foul brood spreads faster in an extracting apiary, is due to extracting from combs containing brood, some of which is, occasionally, diseased, and then

transferring such combs to healthy colonies. With such management, the extractor also becomes a source of contagion, and might disease a whole apiary if it were not cleaned after extracting, even one set of combs containing brood taken from a diseased colony.

But he has learned from experience that by using proper precautions, even in a badly infected district, one may work just as safely for extracted as for comb honey; and he gives the following instructions:

Use a queen-excluding zinc between the upper and lower stories, thus confining the queen below, and extract from no comb from the lower story, or from any comb containing brood; also be careful, when filling the upper story for extracting, to use no combs taken from diseased or dead colonies, such as may contain the dried-down scales of the diseased. Do this, and foul brood can be as easily controlled as though the apiary were managed for comb honey.

Commenting on the article, Editor Hutchinson quotes Wm. McEvoy as saying repeatedly that clean, white combs from the super-combs that had never contained brood—were perfectly safe to use when emptied of honey and cleaned by the bees, and concludes by saying:

Once we thought it necessary to burn up hives, bees, combs and honey—then, gradually, we began to learn to save first one thing, then another, and that honey in the supers is not contaminated may be the next thing we will learn.

**Doolittle and Pratt on Queen-Rearing**

At a meeting of the British Bee-Keepers' Association, reported in the British Bee Journal, Mr. F. W. L. Sladen, after giving an outline of the "Swarthmore" process of queen-rearing, and giving Mr. Pratt credit for doing a good service to queen-rearing by introducing queen-cells mounted in wooden cups, related a comparison he had made, as follows:

In July and August last year I carefully compared Pratt's method of rearing the

queens in a small cage in the top of a brood-comb, with the latest form of Doolittle's method of rearing them 4 or 5 inches from the top between combs of brood separated from the compartment containing the queen by a partition of queen-excluding zinc, by rearing queens by both methods at the same time in the same hive during a honey-flow, in my apiary. In both experiments Pratt's cage was placed in the top of the central comb of the brood-nest. I found that the pupæ in it were smaller, and weighed less than those reared by the Doolittle method. The queen-cells by the Doolittle method were large, broad, and pitted all over like good specimens of queen-cells produced naturally under the swarming impulse, while those in Pratt's cage were smaller and narrower, and their walls and cappings were thin and comparatively smooth. The amount of food left in the cells after feeding ceased was less in Pratt's cage, and as the pupæ developed into queens it did not grow hard so quickly.

I believe that these results were chiefly caused by the excluding-zinc, by which the queen-cells were closely surrounded, preventing the nurse-bees attending to the queen-cells and feeding the larvæ sufficiently, and also to some extent by the queen-cells being placed in the top of the brood-combs, the whole of the upper halves of which were outside the brood-nest (as they always are during the middle and latter part of the queen-rearing season, especially when there is no super on the hive), and were filled with honey, so that a large proportion of field-bees, and a smaller one of nurse-bees, were probably surrounding the queen-cells than if they had been in the brood-nest, and in cool weather the queen-cells, being separated from the brood-nest, would be liable to be chilled.

As the production of well-developed queens is of the first importance, I prefer the form of Doolittle's method above mentioned, and it is not more laborious; on the contrary, it is less so, for giving the queen-cups first to specially-obtained queenless and broodless bees is unnecessary. I find they can be given direct to the queen-rearing compartment of the colony in which they are to be finished, and, if this compartment contains only old brood, they will be accepted satisfactorily here by confining the bees in the compartment for a few hours through the insertion of a wire-cloth partition as by specially-obtained bees. Queens should always be reared inside the brood-nest between combs of brood, and the nurse-bees should have free access to the queen-cells.

### Storing Extracted Honey in Tanks

In the Thirtieth Annual Report of the Ontario Agricultural College and Experimental Farm at Guelph, the Lecturer on Apiculture, H. R. Rowson, gives the following on storing extracted honey:

During the last two years I have been trying to discover the very cheapest and most profitable method of storing extracted honey. When a large amount of honey is to be stored it is found that the 60-pound cans generally used represent a large outlay, and unless sold quickly generally become dilapidated. Large tanks, such as are used for water, vinegar or pickles are expensive, and very much more so when they leak. Oak barrels are costly, and if granulated sugar is taken out of them it costs nearly as much to cooper a barrel together again as to buy a new one. I have been using rectangular tanks made of flooring, the ends and sides of which could be removed after the contents had granulated. Although they were well waxed they sometimes leaked at the corners.

This year [1904] I tried, with entire success, lining these tanks with manilla paper painted with hot paraffin wax. I experimented with dry goods packing cases lined with waxed manilla paper, and found these boxes absolutely proof against leaking.

To store honey in this way a box must be used, the interior of which is free from any projections which would cut the paper when pressed against the sides of the box. Then a full sheet of manilla paper is laid on the bottom of the box (completely covering it), and

another sheet around the interior sides. Where the two ends of this sheet meet in one corner is nailed a carpet strip so as to cover both ends of the paper, and other pieces of carpet strip join the edges of the sheet on the interior sides to the one on the bottom. Manilla paper can be bought in sheets of any length, and 36 or 42 inches wide. Then the paper and carpet strips are painted over with hot wax, and wherever the paper is accidentally torn a small piece of shingle is nailed over the break and then covered with wax. This box makes the very cheapest means for storing extracted honey, and one that is perfectly safe.

Nearly all bee-keepers strain their extracted honey through cheese-cloth. This is a very slow process. The honey runs slowly, especially if it is not very warm, the cloths be-

come clogged with minute particles of wax, and more or less honey is spilled in changing cloths. Others run their honey into tanks; and after the impurities have risen to the surface, they run the clear honey out of the bottom of the tanks. But this can not be done unless the honey is thin, either from heat or from not being sufficiently ripened. I have made this method very reliable by using a large tin storage-can placed out in the sun. The can is painted black so as to absorb heat more readily from the sun. The cover of the can is a wooden frame with glass top, sloping after the manner of a hot-bed sash or solar wax-extractor, and this glass is kept turned towards the sun. When the sun is strong, the honey becomes very warm, and the small particles of wax and other impurities come to the surface.

## Miscellaneous News Items

**The Washington Bee-Keepers' Association** asked the Lewis & Clark Exposition managers for an appropriation of \$7000 for collecting and preparing an apiarian exhibit at Portland, Oreg., this summer. We do not know whether or not they got it, but it showed that the State of Washington did not intend to be left behind in the bee-keeping line.

**Apiary of James McNeill.**—Mr. McNeill says this about his apiary:

I send a picture of my home apiary with honey-house in the background. In 1880 I began my bee-keeping on this spot with 3 colonies bought from a neighbor. I have produced extracted honey almost exclusively. I have been fairly and uniformly successful, never having had a failure, nor can I record any large yields of honey.

I winter my bees on the summer stands packed with leaves. I started this spring with 170 colonies at this yard.

JAMES MCNEILL.

**The San Antonio Convention of the National Bee-Keepers' Association** is to be held Tuesday, Wednesday and Thursday, Oct. 31 and Nov. 1 and 2. Texas bee-keepers are planning great things for the convention. Their hospitality and entertainment of convention members promises to be as large and generous in extent as are the bounds of their big State. It will be their opportunity to set the pace for future conventions of bee-keepers. We hope the bee-keepers from all over the country will just "swarm" down on those Texas bee-rangers, and give them the "time of their lives" to "hive" the visitors.

### Honey Adulteration in Illinois.

—We are indebted to Prof. E. N. Eaton, State Analyst of the Food Commission of Illinois, for a copy of their Fifth Annual Report for 1904. Referring to honey, we find this paragraph:

"The percentage of adulteration recorded in honey, 33 percent, hardly conveys a true idea of the condition of the market. The samples were few, and most of them suspected of adulteration. As a matter of fact, adulteration of honey with glucose, once so prevalent, has been practically driven from the markets."

Surely, the State Food Commission is a good thing, not only for honey-producers, but for all other honest producers of food products. But what the State Food Commission

need is "more power to their elbows" through the enactment of stringent laws against the adulteration of foods of all kinds. The importance of such laws, and the great need of the work the State Food Commissions are doing, are becoming more and more apparent to the public.

**Apiary of L. W. Elmore.**—Mr. Elmore wrote us as follows when sending the picture:

I send a snap-shot of part of my apiary of 50 colonies, taken Feb. 4, 1905, after one of our heavy snow-storms. I winter my bees on the summer stands altogether, and have been very successful in wintering, although this spring I have lost several queens. Our fall honey didn't show up at all last fall, consequently a great many colonies, especially late ones, were short on winter rations, and have come up minus this spring. Some bee-keepers have had a heavy loss. My bees are doing well now (May 5). White clover is in abundance. We expect some honey in the near future.

L. W. ELMORE.

**Clover and Basswood Prospects** are good in Wisconsin. So reports Inspector France, who generally knows all that's going on in that State along the apiarian line. He says there has been some delay in re-issuing his new commission as Inspector of Apiaries, and until he gets it he will be unable to answer the calls for him to go on with the work. So if there are any delays, those who have requested him to come and inspect their bees will now know the reason why. At least those who read the American Bee Journal will know. And, of course, we think every bee-keeper in Wisconsin, as well as elsewhere, should read the old American Bee Journal every week.

**Apiary of J. M. Mosteller.**—Mr. Mosteller writes as follows:

I am sending a photograph of my apiary and family, so that others may see what North Carolina can do in bee-culture.

I started with the movable-frame hives just last year. The bees wintered well, and I have had 3 swarms so far (May 22). June is the principal swarming month here. Basswood, sourwood, and chestnut are the main honey-plants.

I have 60 colonies of bees, 4 of them Italians, and the rest blacks. I secured an Italian queen in May of last year, and now have the 4 Italian colonies.

North Carolina and northeastern Georgia are about as good a country as can be found for bees.

J. M. MOSTELLER.

## Contributed Special Articles

### Making a Bee-Hat—Hiving Swarms

BY C. E. MEAD

EVERY one likes his own fixings. A hot bee-veil is as bad as being stung, for some folks.

Take a strip of *black* wire-cloth 6 or 7 inches wide, depending upon the length of your neck. Make a hoop of it that will just go around the outer rim of a straw hat. Sew the top edge of the wire-cloth to the edge of the brim of the hat. Sew a cylinder of mosquito-bar on the lower edge of the wire, and cut it out so it will fit over the shoulders. Bind the lower edge with cloth having some B B shot or gravel stones in the lower edge. Put it on and button your vest, and your face is safe and cool. Air will go through wire-cloth and not through veiling. You can see through black better than any other shade. To those who do not wear vests in hot weather, sew two pieces of tape to the back flap just where it will come under the arms, and tie over the front or breast-flap.

#### HIVING INACCESSIBLE SWARMS.

The first swarm I ever hived was in as bad a place as I ever saw. It was on the trunk of an apple-tree that had the top broken off by the wind, and the sprouts had grown on the trunk from 2½ inches thick and less. An old bee-keeper told me mashed burdock leaves wet were offensive to bees. So I took a butter firkin, holding about 5 gallons, and sprung sticks in, which were cut a little larger than the diameter. My companion sprung two of the largest of the sprouts apart and outward, and we put the firkin in against the trunk, then packed burdock leaves right behind the firkin and next to the trunk, so that the bees could not get in there. Then we made an oblique circle of burdock leaves around the trunk, the highest point meeting the packing between the firkin and the trunk. A few bees were put up in the firkin on a sprout, and then by the use of a burning rag on the opposite side from the firkin they were soon stampeded into it.

We carefully spread the sprouts and took the firkin, with a board under it, to the bee-house where we turned it head down, put two sticks on top, and set the hive on them, and let the bees run up into the hive.

You can put a light box or basket, open end down, on top of a limb that is too big to shake, and let the bees run up into that. Then hive to suit. With a branch that you can shake or jar the bees off by bumping, just hold a light box under it and then shake them into it, place the hive over the box, covering the surplus space with a board, and let them run up.

A good way is to put two empty hive-bodies where you wish to have the bees stay. Dump the bees into them and set the hive, with frames, on top of the two bodies, and put on the cover. Remove the two lower bodies in from 5 to 7 days afterward, and put on surplus room, if the season demands it. If the bees are the least bit cross, sprinkle them well with sweetened water. They do not care to sting with honey-sacs full.

Cook Co., Ill.

### What Is Honey?—Definitions Reviewed

BY DAVE S. DUNLOP

THE question, What is honey? is one with which chemists as chemists have no concern, and can have no authority.

The question, What is honey? can be answered only by—1st, the naturalist or student of bee-life from a scientific standpoint; 2d, the man who deals in honey as a commercial product—bee-keeper, honey commission merchant; and 3d, the purchaser or consumer of honey—the average mortal.

Prof. Eaton, at the Chicago-Northwestern convention last December, said the Department of Agriculture had asked its chemists for a definition of honey. If this statement is exact, it is very surprising, and the Department of Agriculture is on entirely a wrong track. A chemist, as a chemist, has no more authority to define honey than he has to define water or to define milk. The chemist's work begins just after the definition of a thing has been made. His work is to discover constituent elements, component parts, their proportion and man-

ner of combination. Water is not defined as H<sub>2</sub>O, but H<sub>2</sub>O is said to form water. The definition of water is settled by long usage, and the chemist merely says that in this thing defined as or called water he finds the constituent elements are hydrogen and oxygen in certain proportions combined in a certain manner. Where the water comes from, be it from clouds, the physical geographer and weather bureau are asked about the matter; if from artesian wells, then geologists are consulted about the earth's hidden strata. If it is to be used for manufacturing purposes, the manufacturer is consulted; if to be used as a beverage the physician is consulted. But the chemist is concerned, as a chemist, neither in the place nor manner of the origin of water except as it affects his calculations or instruments, nor is he concerned with its subsequent use at the time he analyzes it.

What is true of water is true of milk and everything else. The naturalist defines a mammal and its food secretion which he terms milk. This fluid having been defined by the naturalist, then, and not till then, does the chemist's work begin. He analyzes to see what this substance called milk consists of. What is true of water and milk and everything else is equally true of honey. The chemist has nothing to do with bees as a chemist. He has nothing to do with a honey-comb as a comb, for a comb is a physical not a chemical fact. He has nothing to do with flowers, nor with nectar of flowers, nor with sweet-leaf excretions, nor with plant-lice excretions, nor with a bee's manner of collecting nor manner of storing its food. These things are all in the biologists sphere of labor. The naturalists—the students of bee-life—deal with these matters. He, as a chemist, deals only with substances. Of course, the facts he discovers are very valuable, and aid our practical conduct of life, but this practical application of his knowledge is not to be confused with his laboratory analyses.

On page 13, are four definitions of honey. The first three, "Honey," "Comb Honey," "Extracted Honey," are all definitions with which a chemist as a chemist has no connection whatever. The naturalist, bee-keeper, honey dealer and consumer are the only persons with authority to define these three things. The fourth definition, entitled "Standard Honey," is apparently not honey as a whole, but only a certain kind of honey. Honey would be honey, and be "pure honey," even though it were or were not "standard honey." For their own laboratory use chemists can make as many different standards or chemical statements of differing grades of pure honey as their convenience may demand, and bee-keepers, nor honey consumers, nor naturalists, would be concerned in the least. But the first three definitions can not be allowed for one moment to be within the province of any analytical chemist. Therefore, are we to assail chemists for these definitions—errors? Is it not more likely that the first three definitions were given the Government Chemists, and they deduced therefrom the fourth statement, which is not a definition, and does not profess to be, but is merely a chemical description of a certain grade of honey?

The avicultural bureau, or the customs officials, or the food commissioners, must have made the original definitions of honey, and it is to these authorities rather than the Government Chemists, that criticism of errors should be made. Who gave the Bureau of Chemistry the definitions which they sent out? Let us learn this, then we will know to whom to write. A chemist, as a chemist, has no knowledge whatever of the fact that bees gather nectar from flowers. That fact is outside his scientific province, and he would have no authority whatever to use that fact in any statement as printed below the three definitions given.

As to the three definitions of honey, the third, which defines extracted honey, is the nearest to accuracy, but could be made to include more than its originator probably intended, or bee-keepers would allow under the term. The second, which defines comb honey, would include section honey, bulk honey, extracting-frame honey, and brood-frame honey, though usually only section honey is meant when the term "comb honey" is used. But the first definition of honey in general, which is supposed to include everything entitled to be called honey, is undoubtedly incorrect from the standpoint of the biological scientist, the honey consumer, the honey-dealer, or anybody else.

It is popularly understood, and has been from prehistoric times to the present day, that honey is the stored natural food of adult bees, whether its flavor were sweet or spoiled, whether it was wholesome or poisonous, whether it was white or yellow, or purple. It has always been understood that there were various grades of honey, good, fair, and bad. But so long as it was a natural product uninterfered with by man or other disturbing factor; so long as it was just as the bees stored it, it was pure honey even though only fit to be made into honey-vinegar. Milk is pure milk no matter if in

spring the cows do eat wild garlic. The quality of the milk may vary with the cow's food and health. But it is still pure milk so long as some other secretion of the cow, such as blood, etc., is not mixed with the milk; and the bee's secretion (chemically changed nectar from any source) is still pure honey no matter whether gathered from fruit-juices, a neighboring farmer's kitchen, or elsewhere.

A natural product may have many grades of various qualities, but a natural product so long as it is left in its natural state can never be called adulterated. Adulteration, for which a man can be punished, is a condition which the man produced, not a condition which a bee produced. A man may be forbidden by food commissioners (on the advice of boards of health) to sell certain grades of honey, not because they are not pure honey, but because they are unhealthy grades of honey, just as a milkman can be forbidden to sell milk of a cow just delivered of a calf, because of its undesirable effects, but not because it is not pure milk. Milk with germs in it is also bad, but that is not a chemical impurity, originally at least. It must have the germs added after leaving the cow. Germs added to honey after the bee stored it would also be an impurity. But in its pristine condition, after being ejected from the bee's sacs into the cell, the honey is pure honey no matter where the bee got her supply of liquid sweet which in her foraging she collected. Any definition of honey must be this broad to be true natural history; and any definition of adulterated honey must include some addition or unnatural modification of this natural product.

The stored natural food of adult bees is undoubtedly honey, no matter where the bee secured its food. If the health boards deem honey-dew an unhealthful source of honey, they may recommend that food commissioners forbid the sale of honey-dew honey, but this is because it is unwholesome honey, not because it is not honey, just as the sale of a badly sprouted potato should not be allowed, not because it is not a potato, but because it is an unwholesome potato.

Honey is the natural, viscid, sweet substance stored by bees for food. It has varying flavors, colors, and qualities, and if the writer understands aright, not always exactly the same chemical make-up. But so long as it is the latter, uninterfered with natural substance, taken by the bee out of her honey-sac, and by her stored in a cell of a bee-comb for the future food of adult bees, or to be later mixed with pollen for young bees, then it is, in the bee's estimation, honey—pure honey. What the bee classes as pure honey, it has heretofore been the custom from Jonathan's day and before down till now, for all mankind to call honey. To make a new definition would be arbitrary. Neither naturalist, consumer, bee, nor bee-keeper is calling for a new definition of honey. Let us keep the old one.

## Saving Weak Colonies—A Cheering Experiment

BY ALLEN LATHAM

**I**N writing our opinions for publication, too many of us I fear write from too narrow a point of view, failing to put ourselves in the other fellow's shoes while offering advice. The veterans, in particular, are writing from the point of view of the specialist, and have all too little sympathy for the tender feelings of the man with two colonies.

For instance, a beginner asks what he shall do with a weak colony, and is told to double it up. Now a man with 100 colonies can not pamper a weak colony, for it will be a waste of his time, for has he not the ninety and nine left? But the man with two colonies does not feel like cutting down his apiary 50 percent at one slash.

I sometimes wonder whether even the old vets don't once in a while recall the time when they would do almost anything to save the individuality of a weakling colony, a time when the loss of a colony carried with it a pang akin to the loss of a child, though the feeling be ever so far removed in degree.

I have not yet reached the time when I can with complacency see the destruction of an individual colony, and I still put myself to great inconvenience to save the life of such. It is the purpose of this article to describe the saving of a little colony last year.

Some seven years ago I fell into possession of a stray swarm which had been living on the branch of an apple-tree two or three weeks. I cut off the branch and fastened it in a common box about which I put many thicknesses of paper with roofing-paper outside. This colony built up and has furnished me with one or two swarms nearly every season since. Naturally it has acquired an individuality of its own.

Last winter nearly proved its death. When the bees flew

in-March last there were but a mere handful compared with the pile of dead bees on the bottom-board and the thousands which clogged the spaces between the combs. It was a most disheartened and wretched weakling, and I felt assured that, unless I bore a helping hand, it would be numbered with the dead.

Understand that I am writing to the man with one or two colonies, and you who own your hundreds will only scoff at what I have to say, so you would better not read further.

I made a box much larger than the hive, and in the box arranged a shelf of thin board about 10 inches from the bottom. Flush with this shelf in front was a daring entrance, while under the shelf was built a chamber which opened by a double door to the outside in the rear. The hive was set in without its bottom-board on the shelf, and all about it was packed ground-cork. Thus the hive was amply protected from cold. Over all was put a tight cover. It required less than one afternoon to put the whole thing together in good shape.

An old gallon can was hunted up, filled with boiling water, and put in the lower chamber. Over the entrance, which I have said was flaring, the outside size being about 10 by 3 inches, was nailed a wire-cloth screen, lightly nailed so that it could be easily stuck on and pulled off.

In less than 3 hours the bees began to feel the warmth from the water and began to appear at the entrance. The next morning I removed nearly a cupful of fragments of bees from the wired-in porch of the hive, and for about 3 days nearly the same amount of refuse was piled out next to the wire-cloth. The colony was extremely weak and made little effort to leave the hive, bending all its energies to house-cleaning. I had, of course, brushed out all the dead bees I conveniently could before setting the hive in place, but the bees found hundreds dead in the cells, and to get them out they had to pull them to pieces.

The can of water was renewed daily, or else brought to the boiling point by setting on the stove. By the way, always remove the stopper when the can is set on the stove. I did not do this one day, and when it blew out later on there was a good exhibition of a spouting geyser.

In a few days this little colony was carrying in more flour and meal than any other colony, and seemed to be getting into prosperous shape. For 3 weeks they carried flour and afforded an opportunity to compare flour with pollen. Flour is a poor substitute, though better than none. Bees brought up on flour appear to be short-lived and less energetic, unless the experiment for some other reason cut down the length of life and energy of the bees. The nurse-bees are rendered costive by flour, and find difficulty in ridding their systems of the pasty mass which, as it is ejected about the hives, has the appearance after drying of vermicelli.

The can of water was furnished the colony for 4 weeks and more, till the colony had gained a strength that warranted letting it shift for itself. By early June it compared very favorably with my average colonies.

I drove a swarm from it late in June, and to-day I have the swarm and the parent colony both in excellent condition, and in every way equal to my best.

I got much pleasure out of the experiment, for the work came at a season when bees required little attention, and there was solid comfort in seeing the colony grow from a hopeless wreck into a self-supporting colony.

So I say to all little bee-keepers: Do not double up your colonies from necessity, for if you wish to save a weak colony so that your apiary may hold its own in numbers, you can do so by doing as I did.

Does it pay to double up? Even if your colonies number hundreds does it pay? Evidently it does or so many successful apiarists would not recommend it. Yet my own experience in doubling up has never been satisfactory in the results obtained.

It has always been my experience that the double swarm seemed to have at the end of a few days only as many bees as the single one which occupied the stand had before doubling. Possibly I do not understand doubling, but it is my opinion that after doubling many bees are stung, many do not like new quarters and leave, and many die from failing to mark the new location. For a day or two the double colony appears to have received new life, but there follows a rapid decline into a state no better than existed before doubling up.

The fact is that in the weak colonies, as a rule, there are only old bees, and old bees are not worth doubling. But if there are a few hundred new-season bees the results will be very different. I have seen amazing results follow the introduction of a pint of young bees into a weak colony—new life and rapid building up quickly follow.

## Convention Proceedings

### Papers Read at the Minnesota Convention

Held at Minneapolis Dec. 7 and 8, 1904

#### SOME THINGS I HAVE LEARNED ABOUT BEE-KEEPING

My first interest in bees dates back to the early fifties, when as a small child I observed an old man hiving new swarms in hives that were up to date at that time. They were boxes 12 or 15 inches square and two feet or more high, hung upon flat posts by cleats nailed to their sides, the posts having similar cleats for the hives to rest upon, and when the hive was in position the bottom was about 15 inches from the ground. The bottom-board slanted enough so that anything dropping down inside the hive was easily carried out by the bees. The bottom-board projected about three inches for an alighting board. Two sticks were fastened crosswise near the center of the hive to help support the comb. Two or three holes were bored through the top of the hive which were closed with stoppers, the same being removed when supers were placed in the hives for the surplus honey. These supers consisted of square boxes and round ones about the size of one peck measure. When this man thought there was surplus honey to take off he would take a broom straw and remove a stopper inside of the super, run the broom-straw in, and upon drawing it out would look for honey on it, and by the amount of honey on the straw he would judge as to whether it was best to take off surplus honey!

It was observing this man handling his bees, and the bits of honey he gave me from time to time, that caused me to try to keep bees later on.

Upon taking my homestead rights in Renville county, in 1877, I still had a desire to try to keep bees, but I was told I could not keep them on the prairie, so I did not undertake it until after some years when I found a swarm of bees had taken possession of a martin house on top of the barn. I tried transferring these bees into a box, but they soon died.

The spring following I bought two colonies and from that time until now I have not been without bees and honey. First I used the Langstroth portico 10-frame hive with wide-frame section-holders in the supers. My bees would swarm before they would work in the supers.

With these I had better success in obtaining honey in sections; but even with the 8-frame dovetail hive and the latest improved section-holder I found only one or two hives in an apiary of 15 or 20 would store much section honey. My opportunity to study and observe the bees was limited, as farm work took my attention, so I learned but slowly from the school of experience.

Now after fifteen years of keeping bees I have decided upon what I believe to be the best method to adopt, to obtain the best results in getting surplus honey, both extracted and comb.

On all good, strong colonies I place full extracting supers with full-comb frames, or full foundation frames. If any of the colonies get the swarming fever and a large swarm comes off I hive it either on full-comb frames or full foundation frames, and place a section super with foundation starter in the sections. In this way I find the bees almost always go to work at once, filling the sections. Sometimes I take the frames from the extracting supers to hive the bees upon, substituting comb foundation frames for the extracting supers.

Now it occurs to me after these years of handling bees, since I have taken more time to observe them, that I have hardly begun to learn anything about them. They do things sometimes that are so unexpected that I have decided it would take much longer time, were I able to do so, to tell what I have yet to learn about bees than what I have learned.

The past summer, on two occasions, I observed a swarm come out of one hive and enter another, the hive of another colony that had just swarmed, and owing to the queen failing to fly, they came back and all entered the same hive peaceably, and each time they swarmed in about 3 days, and I hived them. Both swarms seemed to be double ones and stored a good quantity of surplus comb honey.

Another surprise for me was when I was shaking a plum-

tree I observed what I first thought to be a hornet's nest, but upon closer examination I found was a swarm of bees. This struck me as very strange, as it was Oct. 1, and I had seen no signs for two months or more of the bees swarming. Upon getting the bees down and shaking them in front of a hive I found they had built a good-sized comb on the limb.

In conclusion I will say in behalf of the great State of Minnesota, when one can do as I have done, take many pounds of the finest honey from the cornices of houses, and obtain plums and honey from the same tree, it is a good State to live in. I believe it will be in the lead of all States in all lines of advancement and progress.

Renville Co., Minn.

II. V. POORE.

#### BEE-KEEPING FROM A WOMAN'S STANDPOINT

Anything that tends to outdoor life has always appealed very strongly to me, so when I began, some three or four years ago, to read a series of articles in one of our farm papers on "Bee-Keeping for Women," my interest in the subject was aroused.

I had always said that there was *one* thing that should not come on our place, and that was a hive of bees, but when I read of the wonderful things that a woman could do, and how alone and unaided, even by her husband, she could supply her own table, and that of all her relatives and friends, and still have enough to sell so that her pocket-book would be full and running over at Christmas time, I was a firm believer in the bee as a money-maker. I at once sent for the "A B C of Bee-Culture," also subscribed for "Gleanings" and later on for the American Bee Journal. Every spare moment was spent in reading, until at last I decided I *must* have a colony of bees.

One April morning I found, among other birthday presents at my plate an envelope containing some money, whereupon the children exclaimed, "Now mamma will have her bees!"

A few days more and I had called upon Mr. Acklin, and made my first investment in one colony of Italian bees, veil, smoker, etc. As that was the first time I had ever seen a bee-hive, and stood in mortal fear of the bees themselves, I felt when I started home that I had thrown my money away.

The next day a telephone message announced the arrival of the bees at the express office, and suggested that I call for them at once. This only increased the "sinky" feeling, but smothering it as best I could I started out although with many misgivings.

My husband came home with me, and suggested that we stop at prayer-meeting on the way home! We did so, but a longer hour I never spent. The possibilities of unctio*n* *not* *divine* in case one of the small boys hanging around outside should take a notion to see the inside of that hive were anything but pleasant to contemplate.

The bees were finally safely landed at home and the number of cakes of honey that were promised to friends from that colony were beyond count.

Imagine my feelings when fall came and I had nothing to show for the summer's work but an empty super and one swarm—a good, strong one, however, which came out July 18.

The next spring the fever ran higher than ever, and when a man drove in one day and offered me three colonies of bees for a pair of fine geese, the trade was quickly made.

I was now fairly started in the business, and in a position to put to the test the theoretical knowledge I had absorbed during my year's reading.

Right here let me say to those who sneer at "book farming," that in my case at least theory and practice have fitted together very nicely. In addition to reading everything I could find on the subject, I have driven miles to talk with other bee-keepers. I have always found them willing and glad to aid a beginner, and many thanks are due them all, for much timely advice and help.

Every year since then I have added to my small beginning, both by natural increase and purchase, until I now have about 35 colonies, and the yield last season, of both comb and extracted honey, far exceeded my expectations.

Living on one of the principal thoroughfares out of Minneapolis, there is a constant demand for honey by people who see the hives in the yard, and I have no trouble in selling my crop at a good price.

A few months ago the question was asked in the Rural New Yorker, how a young woman of 20 could stay on the farm to assist her mother, and at the same time earn a little pin-money for herself. A large number of answers were sent in, advising her to try everything from sewing to small fruit, poultry-raising being the favorite, but not one mentioned bee-

keeping. Just which one the young lady decided to try we shall probably never know, but, if she is like most women, she is experimenting with them all.

It seems to me there is no comparison, both from a financial standpoint and the labor involved, between caring for a flock of poultry large enough to yield an income, and 30 or 40 colonies of bees. I know whereof I speak, for I've tried both.

How much pleasanter it is on a cold, rainy spring day to think that your bees are safely housed than to don waterproof and rubbers—if they're handy, and if not to wade out without them—to chase some poor half-drowned chickens or turkeys that have been foolish enough to leave their mother's wing.

Then, too, during our long, cold winters we know that our bees are safe and sound in the cellar without further care from us until the warm April days call them forth.

So far I have taken care of my 35 or 40 colonies without

any help except at swarming time. Occasionally an obstinate swarm would take to the top of a tall tree, but I have generally been able to control them with a small spray-pump.

I have been surprised to find how few women are engaged in this most interesting of all outdoor occupations. How much better to spend our spare time in the sunshine and fresh air, studying and caring for these tireless little workers, than to strain our eyes over the embroidery frame or intricate lace stitches.

To me there is nothing more fascinating than to watch the bees as they come in with their loads of golden pollen, or to open a hive and study the combs as they are filled with the tiny eggs or the young bees just hatching, and to hunt out the beautiful queen as she moves around among her subjects. Truly we may say, "Marvelous are thy works, O Lord."

Hennepin Co., Minn.

MRS. W. S. WINGATE.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### What to Combine With Bees

From time to time the question arises, "What business combines best with bee-keeping?" However it may be with the brothers, most of the sisters have no need to cogitate long about it; for them perforce house-keeping in the fullest acceptance of the term is with bee-keeping the combination. And the combination is not a bad one. A rainy day is not a good time to work with bees; but just the time to put up fruit. House-keeping keeps one too closely in the house; the work at the bees gives the chance for the needed sun and air. The sisters who enjoy bee-keeping, if they do not live the longer for it—and many of them do—have at least more of life for their work with the busy little insects.

See what Mrs. Honaker has to say about it in her article on this page.

### Bar-le-Duc Preserves—Currants and Honey

Inserted is this recipe, which never before appeared in print to my knowledge. Up-to-date cooks know that this imported delicacy is becoming more and more popular, as it is better known, though its price made it prohibitive where economy was essential. Where time is no object, and is more plentiful than money, one can now make this at home in the currant season, and nothing surpasses it as a company or holiday dainty.

Take selected red (or white) currants of large size, one by one, carefully make an incision in the skin  $\frac{1}{4}$  of an inch in size, with tiny embroidery scissors. Through this slit, with a sharp needle, remove the seeds, separately, preserving the shape of the fruit. Take the weight of the currants in extracted honey, and, when hot, add the currants. Let simmer a minute or two, then seal as jelly. The currants retain their shape, are of a beautiful color, and melt in the mouth. Should the currants liquefy the honey too much, carefully skim them out, reduce the syrup at a gentle simmer to desired consistency, and store as before after adding the fruit.—Boston Cooking School Magazine.

### Bee-Keeping for Women—A Desirable Occupation

In almost every rural community there are a number of women with considerable spare time on their hands and with a laudable ambition to engage in some small business which will insure them an individual income. To such, when favorably located, I would say, "Try bee-keeping." There is nothing about or connected with the work repulsive to the most fastidious, nor is there with the possible

exception of cellaring, anything about it beyond the strength of the ordinary woman. Any woman who is able to do the work of the average household, is able to take care of a small apiary. The returns from even a few colonies should, if bees are well managed, be sufficient to insure financial independence; while as experience is gained and the colonies increase, a larger income may be expected.

I do not mean to infer by this that women should endeavor to support themselves by any kind of special effort, but only to encourage those who are able and anxious to "do something," by pointing out to them the advantages of this most desirable occupation for the ambitious woman. For indeed it is a desirable occupation in more respects than one. Profitable, and moreover strengthening and uplifting to body, mind and soul, it is well able to supply the needs of many classes of women. There is possibly no occupation open to women capable of inspiring so much interest, enthusiasm and spiritual contemplation as that of apiculture. Even a woman's natural repugnance to "crawling things" is forgotten, and the wonder and admiration excited by a closer acquaintance with the busy little workers leads her to a greater appreciation of the provision of an all-wise Creator for the "children of men."

Then because of this same uplifting and ennobling influence, I would say to those women who are bowed down with mental care and worry, and who feel that life has brought to them too little of its sweets and too much of its bitter dregs, "Try bee-keeping." Oftentimes this would prove more diverting, more effective than a change of scene and habit which physicians are so prone

to advise. For most country women, especially those whose interests are centered in a farm home, there is small opportunity, and, only too often, small means for travel, in consequence of which the soul-sick and sorrow-burdened woman struggles on in suffering and despair until roused in some chance way, or until death ends the scene. If such a one could or would be induced to undertake the care of a few colonies of bees, untold good would probably result, and life would soon take on a new and broader meaning.

Not only is bee-keeping conducive to mental and moral health, but to physical as well. There is nothing which calls into play all the muscles of the body more effectually, and that, too, in the open air, than the various changes of work called for in bee-keeping. To those, then, who are in declining health, and who feel the need of wholesome outdoor exercise during the pleasant days of summer, I would say, "Try bee-keeping." Many a consumptive and rheumatic sufferer might have been relieved, and possibly cured, if bee-keeping had been engaged in at an early stage in the progress of the disease. Many another might be saved now, by engaging in it before it is too late for any means to avail.

Of course a certain amount of time must be available for the purpose before bee-keeping should be engaged in by any one, whether man or woman, whatever the object. For this reason it should not be undertaken by women whose hands are already full to overflowing with other work. But otherwise, other things being favorable, it is an occupation suitable in every way for women—that is, for those classes and under the circumstances named above.

MRS. MILLIE HONAKER.

Vernon Co., Wis.

### Bees Working Well

My bees are getting lots of honey now. They are working well on a good flow. I have 12 strong colonies, all mixed bees. I had all Italians last year, but now all are mixed, I believe.

MRS. D. MAYER.

Cherokee Co., Tex., June 5.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### BUYING QUEENS AND FOUL BROOD.

I wish to call attention to the fact that the Illinois Inspector thinks buying queens to be a leading cause of the spread of foul brood into clean territory. The Wisconsin Inspector is on record in the same direction, I believe. Let's have a National Inspector of the queen-breeding yards—bound to publish just what conditions he finds in every apiary that advertises queens for sale. Page 342.

### CUT LOAF SUGAR FOR BEE-FEEDING.

Cut loaf sugar as a substitute for candy to put over a colony for wintering seems to have, at least one excellent testimonial from the

sister on page 343. Bees can work at but one side of a candy-cake, while Old Zero works at the other side. The cubes of loaf sugar will be more nearly enveloped by warm bees during the process of slow liquefaction. This sister seems to find that they eat the most of it even in hives where they do not absolutely need it. And that's a good recommend for the form of feeding.

This lady seems to think it remarkable that it took her all last year to learn the different bee-traits. If she actually did all that we shall have to part with her—for the good of the human race. She must enter one of the great astronomical observatories, and in two

years she will discover all the secrets of the universe.

**BOSNIAN HIVES SHOULD BE POPULAR.**

Bosnia seems to be the place for those who howl about the high price of hives—the government furnishes free lumber to make bee-hives. "Wish the kickers were all in Bosnia!" (Hive-trust man.)

**FERDING SUGAR AND FEEDING BACK HONEY.**

So Hutchinson thinks that feeding sugar and feeding back honey are much alike in that almost any results can be secured. That phrase, "Almost any results can be secured," sounds like a stand-patter, worth memorizing. I suppose a good few of us experimented a little at feeding for sugar-honey—and our sections cost us much more than market price—and nevertheless we knew pretty well that we could make a success of it if it were worth while. Telling outsiders that sugar can not be profitably fed for surplus is not to be recommended—foolish, because they won't believe it—and immoral, because most likely it isn't true. Page 344.

**HIVING SWARMS ON DRY COMBS.**

Bees do swarm sometimes when they are in a very hungry condition; and it's not good practice to hive such on combs of honey. Results in excitement much like a robbing scrape, with more or less of actual robbing mixed in. Hive them on dry combs, and exchange for the combs of honey at nightfall.

When the honey-flow is on, the practice referred to is not so bad; but even then bees like dry combs best, and will be a little more likely to stay. Page 345.

**EXTRACTED VS. COMB HONEY.**

I would lift my voice in behalf of that fool on page 345. He is not damaging the honey market probably, while his wise (?) brother may be doing just that thing.

**QUEENS AND BABY NUCLEI.**

If a queen is put in a baby nucleus only in warm weather, and only when ready to mate, the harm the new device does would seem to be reduced to a minimum. Quite curious if queenless bees are less tolerant of supernumerary young virgins than bees of a colony with a laying queen are. According to John W. Pharr, page 346, the latter will feed them through the wires—presumably by the amount of sting-poison which they evaporate. Yet possibly this last may be wrong. All queens soon die from nerve causes if entirely bereft of company. Perhaps with only enemies for company death would be about as speedy, and the cause about the same.

**SOUTHERN CANE SYRUP VS. HONEY.**

So, according to the average Southern palate home-made cane-syrup is better than honey. We can thank Mr. Ashley for that item—even if we quarrel with the item itself. Page 348.

with them. I didn't know how to separate them, and as they seemed to agree I put 2 hives together, one on top of the other, making a double-decker of it. They did well. This was a new thing to me. In a few days another swarm came off, and while getting them into the hive a swarm from another colony came pouring into the hive. There was nothing else for me to do but to make another double-decker. This thing was repeated the third time.

This spring one of those double-deckers has swarmed. There seemed to be a half barrel of bees. They couldn't all get in a single hive any way I could fix it, so another double-decker was made.

What should I have done with them, and what am I to do in the future. If they keep this up I will have to get some 10-bushel boxes. IOWA.

ANSWER.—Some throw a sheet over the hive to prevent another swarm uniting with it. If they persist in spite of the sheet, you can help matters by having a smoker in full blast and playing lively upon them. A better way is to have your queens clipped; then when a swarm issues, move the old hive away, set a new hive in its place for the swarm to enter on its return. Pick the queen up when she comes out, and let her run into the new hive with the swarm. With this management swarms will seldom offer to unite.

**A Queenless Colony**

1. My bees are doing very well now. I wintered 7, but have lost 2, and one other is very weak. What shall I do with it? I think the queen is lost, so I have thought that I would put in with them the first swarm that comes along.

2. Would you advise putting another super on the hive before they swarm? They seem to be rather lazy. WISCONSIN.

ANSWERS.—1. Yes, you can put a swarm with them if they are queenless, or you can unite them with the weakest of the others.

2. Giving more room is not a cure for laziness unless they actually need the room. But be sure to give them all the room they need, and the best way to be sure of that is to give it a little before it is needed.

**Asking Questions—Hive-Ventilation—Feeding Honey—Ants in Supers**

1. Can one ask as many questions as he wishes, if they are not answered in his bee-books and are about bees?

2. Does a hive need ventilation if in the shade, and, if so, would it need it when the temperature gets up to 90 degrees in the shade or below that? How low can the temperature get before it needs shutting down?

3. Is it all right to feed honey in the comb from a colony that has died during the winter, if it smells all right, and would it be if it did not?

4. Would it do to put a little chunk of comb honey at the entrance at night to stimulate brood-rearing?

5. Do black ants harm anything in the upper stories? IOWA.

ANSWERS.—1. Yes, provided he does not ask more than 52 times in a year.

2. Yes, I once had combs melt down in a hive so thoroughly shaded that the sun did not shine on it all day long; but there was a thicket on one side and a corn-field on the other, so that there was little chance for the air to stir. A colony must have ventilation to some extent always; and, of course, it will have some ventilation with a very small entrance. At any time when bees are busy gathering there should be sufficient ventilation so the bees will hang out. An entrance equivalent to 9 square inches is as little as should be allowed, and if that can not be had otherwise the hive should be blocked up. But 20 square inches of ventilating space is better than 9. There is no need to make any change when the temperature runs up to 90 degrees, nor when it runs down on cold nights.

3. Yes, it is all right to feed honey from a

**Doctor Miller's Question-Box**

Send Questions either to the office of the American Bee Journal, or to Dr. C. C. MILLER, Marengo, Ill. Dr. Miller does not answer Questions by mail.

**Stachelhausen's Practice With Shaken Swarms**

On page 246 Mr. Stachelhausen says: "I put the shaken or natural swarm on the old stand, and the parent colony close by its side; 10 days afterward the most of the bees of the old hive were shaken in front of the swarm and the queen-cells cut out."

I am in the dark as to why he waits 10 days in the case of a natural swarm. Is there not danger that, in case the old colony was not too much weakened by the loss of its field-bees, a second swarm may issue 8 days or so after the first one issued? IOWA.

ANSWER.—Although both shaken and natural swarms are mentioned, I suspect that when Mr. Stachelhausen spoke of "10 days" he had shaken swarms particularly in mind; for surely, in the case of a natural swarm, as you say, there would be danger of a second swarm before the expiration of the 10 days. With a shaken swarm there would be no such danger, provided queen-cells had not been started before the shaking. If I am wrong in any way about it, will Mr. Stachelhausen kindly correct, if this should happen to catch his eye?

**Introducing Queen-Cells or Queens**

Suppose an apiarist has a number of choice, ripe queen-cells in protectors, or just-hatched virgin queens in cages, and they are of superior strain. How can he introduce them to full colonies, remove the old queen at the time of introduction, and know that they will be accepted, and that the bees will not rear queens from their inferior brood, take the swarming notion, and do other things objectionable? KENTUCKY.

ANSWER.—I don't know. That is, I don't know how he can be entirely sure, for bees are somewhat given to cutting up all sorts of didoes. But by doing as you say he can be as reasonably sure as he can of most things in bee-keeping. Sometimes a queen-cell that looks all right contains nothing but a dead

larva. In that case the colony would start cells of its own, and if strong enough would be likely to swarm as soon as the first virgin was ready to fly. So it would be a little safer to give a virgin queen. If not more than a day old, and caged, its acceptance would be practically certain. Indeed, if you take a virgin not more than 6 hours old—possibly it would be all the same if not more than 24 hours old—go to the hive and give to it the virgin queen without any caging, and then kill the old queen, there would be no question as to acceptance. There are still two "ifs" in the case: if there were no cells in the hive previously, and if the virgin is not lost on her wedding-trip. To provide against the first, you must make sure to kill all queen-cells in the hive at the time of giving the virgin or queen-cell; otherwise you will be pretty sure of swarming; and as to loss on the wedding-trip, you must take your chances and be ready to make good any chance loss.

**Best Kind of Bees**

Which kind of bees would you advise a beginner to get, the German or black bees, the Italians, or the Carniolans? Which are the best for comb honey? MAINE.

ANSWERS.—1. It doesn't make such a great deal of difference what kind of bees a beginner starts with, as it is so easy to change stock by the purchase of queens. So if he can get no other than black bees handily, let him start with them, and then get an Italian queen. Of course, if he can get Italian stock that will be better.

2. Italians are more gentle than black. Carniolans are reported to be still more gentle; but some report them cross. Carniolans may not all be alike, or not all pure.

**Swarms Uniting**

Last year a large swarm of bees came off, and while I was preparing to hive them a swarm issued from another hive and settled

colony that died in the winter, unless the colony died of a contagious disease such as foul brood, pickled brood, or black brood.

4. Yes, provided you do not leave it to start robbing in the morning.

5. No, except to annoy the operator by crawling over his hands and biting. There are, however, ants in the South that ruin whole colonies; and even where you live there is a very large kind that honey-combs bottom-boards.

### Starting With Bees

I am a novice in the bee-business, having just started this year.

I began by buying one colony of a bee-keeper close by, and the combs are so built that I can not get the frames out to examine them, so I can not tell whether they have started any queen-cells or not, and do not know whether they will swarm in a day or two or a month.

This has been a very cool spring, but we have had a few nice days, and it has not been so cool but that the bees could fly nearly every day. But when we would have a nice day the bees would come out and fly around the front of the hive so one could hardly see it. It has been nice for nearly a week, and the bees are not flying around the hive now, but seem to be working. Do you think they have swarmed and left, or that the last few warm days have brought the flowers out and they are in the field working? White clover is nicely in bloom (June 3), and also a good many wild-flowers. **KANSAS.**

**ANSWER.**—It is hard to be positive about it. It may be that the bees tried to swarm on the days when they were so thick on the hive, and some defect prevented the queen flying with them; and it is possible that they were out for a play-spell. If the bees were so thick on the front of the hive that they actually covered it from sight, they were probably swarming—that is, they had swarmed out, and you saw them when they had returned.

## A Standard-Bred Italian Queen-Bee Free!

For Sending One New Subscriber.

As has been our custom heretofore we offer to mail a fine, Un- tested Italian Queen to the person who complies with the follow- ing conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year

2. Sending your own name with the \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a

new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

We will book the orders as they come in and the Queens will be mailed

Will you have one or more?

If you cannot get a new subscriber, and want one of these Queens, we will send the American Bee Journal a year and the Queen—both for only \$1.50.

Address,

combs on top of them, then pour in water till nearly full. Having put on the cover, put a smooth, clean stone on it. The cover is made of heavy galvanized or tinned sheet-iron, with holes made about the center, and nailed to a cross made of boards 3 inches wide, notched to fit each other, or like paste-board in egg-cases, and just the length of the width of the can, so as to keep the cover from tipping as it is forced down.

Boil slowly till all the wax is on top. Let it cool on a slow fire. The combs will render better if exposed to the sun for awhile.

Jamaica, W. I.

ROBT. WEST.

### Backward Season—Bees Dying

The season has been backward. Bees did nothing on apple-bloom, and white clover had no honey till the past few days. The bees are booming on it now.

Some 10 days ago as I was looking over the bees I noticed a number crawling on the ground as though they were drunk. Later they seemed to be all coming out of the hive, and the next day all were dead. It was one of the strongest colonies. I can give no reason for their death. No other colonies seem affected any way. I imagine they found poison somewhere. I don't think it could be from spraying.

S. N. BLACK.

Adams Co., Ill., June 2.

### Marketing Unripe Honey

The unripe-honey talk in the May 18 issue is right, and if the advice were followed by all producers the demand for honey would surely be greater than it is now. Last year I was particular to extract all the unsealed honey beforehand from every comb, and this was kept warm in a tank over an oil-stove for several days, until it was good and thick.

Of course this did not have quite as good a flavor as the all-sealed honey, but perhaps was better than the whole lot would have been if extracted together.

Ashtabula Co., Ohio. H. E. CROWTHER.

### Treatment of Robber-Bees

I had a little experience with robber-bees which might help some one some time. I had a weak colony which I thought to strengthen a little by giving them a frame of brood from a strong colony. I had no sooner done so than another colony of rather black bees commenced robbing this weak one. I covered them up with a horse blanket, but they would crawl under. Then I piled grass before the hive, but to no purpose. I closed the entrance to one bee-way on the start; but they bothered 2 or 3 days. I tried putting the weak colony where the robber-colony was, and vice

with lice on poultry. Schild's Lightning Lice Killing Machine instantly removes them from tiniest chick or fat gobbler. 3 sizes. Also Poultry Bits, Lice Murder, Lightning Lice Killing Powder, etc. Catalog free. CHARLES SCHILD CO., 801 Detroit St. Cleveland, O.

versa, to see what they would do. It worked all right as far as I can see. The robber-bees were pretty quiet for a few days, but are now working nicely. The weak colony, of course, got the field-bees, and peace once more reigns in our midst. I don't know much about bees, but I had to do something, so tried the best thing I could think of. I put away 5 colonies last fall, and brought them through the winter, but lost one after putting them out this spring.

H. E. BARTHOLOMEW.

Du Page Co., Ill., June 4.

## Home-Made Hives—Honey on Coast

It is hard to say what is best for others, but as I am a carpenter and have a saw-table and tools I can make hives cheaper than I can buy them. Hive-bodies that cost 50 cents at the supply dealer's in Portland cost me 30 cents or less to make them, reckoning \$3 per day for the work, and I use better lumber. In the apiary no one could tell the difference between them and the factory-made hive. If there is a bee-supply trust I don't know it, but nearly all have the same prices. How would it do for the bee-keepers to form a trust or a union?

On page 199 it says, "Oregon was represented by a small quantity of inferior honey," at St. Louis last year. Perhaps that is true, but it also says, "It is said that the honey gathered near the Coast is inferior in quality to that obtained further inland." I am in Wahkiakum county, on the Coast, and have

In one of the best locations in the United States, both as to honey and market. No one need write me about it unless they mean business, and have at least \$700 cash to put in the business. Address, **W. S. MITCHELL,** 22A4t MUSKOGEE, IND. TER.

## Queens! ITALIAN Queens! By Return Mail

Queens from Root's Red Clover Stock and Golden Italian Queens, the best honey-gatherers in America. Untested, 50c each, or \$6.00 per dozen. I guarantee safe delivery. Send your orders to

**E. A. SIMMONS,**  
FORT DEPOSIT, ALA.

22A4t Please mention Bee Journal when writing

considered the honey the very best, if well ripened. I think it far superior to any California honey, and the public are my judges. When I first sold honey here it was always said, "Well, that is honey. It is not like the California honey." That was years ago, and those people are my customers still.

The bees are doing well. They were all strong in the spring, and have 25 and 30 pounds of honey in the supers. O. K. RICE. Wahkiakum Co., Wash., May 22.

[It must not be inferred from the above that California honey is inferior to any honey in the world. Every State produces the "best honey," we have learned. It is all according to one's taste as to which is the "best honey."—EDITOR.]

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

CHICAGO, June 7.—The volume of sales is infinitesimal; hence prices are not considered important at this season. Comb brings 12@12 $\frac{1}{2}$ c per pound for best grades, off lots 7@10c. Extracted, 5@7c, according to what it is. Beeswax sells upon arrival at 30c per pound.

R. A. BURNETT & Co.

CINCINNATI, June 2.—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4 $\frac{1}{2}$ @6c according to quality. White clover extracted at 6 $\frac{1}{2}$ @8c. The comb honey market is practically closed for the summer. Beeswax, 29c.  
THE FRBD W. MUTH CO.

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12 $\frac{1}{2}$ @13c. Extracted, from 6@8c, according to quality.  
BLAKE, SCOTT & LEE.

PHILADELPHIA, June 17.—As the season advances, there is very little call for comb honey. In fact, no sales, and we make no quotations. Commission men are accepting any offer they can get for what little stock they have on hand. Extracted honey is in some demand. Possibilities of a big crop are holding prospective buyers back. We quote: Fancy white, 7@7 $\frac{1}{2}$ c; amber, 6@7c; dark, 5 $\frac{1}{2}$ @6c. Beeswax in good demand, 29@30c.  
We are producers of honey and do not handle on commission. WM. A. SELSER.

NEW YORK, April 19.—There is no change in the condition of the honey market. Very little comb honey selling and prices ruling about the same as our last quotations. Extracted in fair demand only. Beeswax firm at 30c.  
HILDRETH & SEBELKEN.

KANSAS CITY, May 12.—The honey situation is a little stronger, and there is but little honey left in the hand of the dealers. Best honey bringing from \$2.25 to \$2.50 a case; amber at from 25@50c a case lower. Extracted, 4 $\frac{1}{2}$ @6c. Beeswax, 28c.  
C. C. CLEMONS & Co.

CINCINNATI, O., June 9.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5 $\frac{1}{2}$ @5 $\frac{1}{2}$ c; in cans, 5 $\frac{1}{2}$ @6c. Beeswax, 28c.  
C. H. W. WEBER.

ALBANY, N. Y., June 10.—Our honey market is practically over for this season and won't begin again to any amount until August or September. We have carried over very little stock

of either comb or extracted. We quote nominal quotations for honey in good condition. White comb, 12@14c; mixed, 10@12c; dark, 10@12c. White extracted, 5@6c; dark, 5@6c. Beeswax, 23@32c.  
H. R. WRIGHT.

SAN FRANCISCO, May 31.—White comb, 1-lb sections, 11@12 cents; amber, 8@10c. Extracted, white, 5 $\frac{1}{2}$ @6 cents; light amber, 4@5c; amber, 3@3 $\frac{1}{2}$ c; dark amber, 2 $\frac{1}{2}$ @3c. Beeswax—good to choice, light, 27@29c; dark, 25@26c.

The ship Atlas, sailing Saturday last for New York, carried 236 cases extracted, reported to be Hawaiian Island product. Offerings of this year's California honey so far have not been large, and mainly by sample. The movement on local account is light.

The most attractive eastern excursion during the coming summer will be to Asbury Park, N. J., on occasion of the annual meeting of National Educational Association, July 3 to 7, inclusive, via the Nickel Plate Road and its connections, either the West Shore or Lackawanna Road, with privilege of stop-over at Chautauqua Lake points, Niagara Falls and New York City. Rate, \$21.35 for the round-trip. Dates of sale, June 29 and 30 and July 1 and 2, with extreme return limit of Aug. 31, by depositing ticket. Patrons of this route may have the choice of a ride over the most interesting mountain scenery in New York and Pennsylvania, and through the celebrated Delaware Water Gap, or through the beautiful Mohawk Valley and down the Hudson River, which also includes the privilege of a ride on day line boat on Hudson River, between Albany and New York City, in either direction, if desired. No excess fare charged on any train on Nickel Plate Road. Meals served in Nickel Plate dining cars, on American Club Meal Plan, ranging in price from 35c to \$1.00; also a la carte. Chicago Depot, La Salle St. Station, corner Van Buren and La Salle Sts. City ticket offices, 111 Adams St. and Auditorium Annex.

For further particulars, address John Y. Calahan, General Agent, 113 Adams St., Room 298, Chicago. 7-23A4t

# Bee Journal

WEEKLY—\$1.00 A YEAR

Published by GEORGE W. YORK & CO., 334 Dearborn Street

45th Year

CHICAGO, ILL., JUNE 29, 1905

No. 26

Home Apiary of F. J. Miller, of Ontario, Canada

# EVERY BEE-KEEPER

Should subscribe to Gleanings in Bee Culture. No progressive bee-keeper can afford to miss a single number. You subscribe to one paper already? Now, isn't it entirely logical that if you find one bee-paper profitable two papers would be doubly so? Providing the second paper was right, and Gleanings is right. Every reader of the American Bee Journal is familiar in a way with Gleanings, so it is not necessary to go into details regarding its merits. Every number is entirely original matter. Every number contains a wealth of beautiful illustrations. In fact Gleanings is *par excellence* in many ways. We have just published a little booklet devoted to Gleanings. It is a perfect miniature of Gleanings, going into details describing every department, and showing just how Gleanings meets the needs of every bee-keeper everywhere. We will gladly send this booklet with a sample copy of Gleanings on receipt of a postal card.

# THE A. I. ROOT COMPANY

MEDINA, OHIO

BRANCHES : Chicago, 144 E. Erie St. Philadelphia, 10 Vine St. New York, 44 Vesey St.

# ESTABLISHED IN 1861

# AMERICAN BEE JOURNAL

## THE OLDEST BEE-PAPER IN AMERICA

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., JUNE 29, 1905

Vol. XLV—No. 26

THE AMERICAN BEE JOURNAL is absolutely an independent publication, and not connected with any bee-supply business whatsoever. It stands entirely upon its merits as an educative force in the field of bee-keeping, and as a medium for legitimate advertisers in apicultural or other lines. It is the oldest, and only weekly, journal of its kind in America. Its publishers believe that it deserves to be in the hands of every would-be progressive successful bee-keeper in the land. It is in its 45th year, and to-day is acknowledged to be better in every way than at any time during its long and honorable history.

## Editorial Notes and Comments

### Scarcity of Section-Timber

Some alarm is expressed occasionally lest basswood timber become so scarce that it can no longer be used for sections, and the suggestion has lately been made that we may as well face the problem in advance, and turn our attention to deciding whether bulk honey or what else shall take the place of section honey.

There is no cause for alarm; there is plenty of timber left for sections, even if every basswood tree were wiped out of existence. To be sure, the change must be made from one-piece to the four-piece, but there are some now who prefer the four-piece, and there is no denying that the four-piece sections are in some respects better than the one-piece. The loss of basswood is not likely to make much difference to producers of section honey.

But basswood lumber is not going to run out entirely for some years yet, though it may, of course, continue to rise in price. Until basswood sections get to be \$7.00 per thousand we believe they can be profitably used by the great majority of comb-honey producers, and possibly a few could afford to use them even at a higher price than that.

### Is Foul-Brood Legislation Effective?

In Ontario there were visited by the foul-brood inspector—

In 1900, 100 apiaries, among which 30 were foul-broody.

In 1901, 77 apiaries, among which 29 were foul-broody.

In 1902, 81 apiaries, among which 30 were foul-broody.

In 1903, 96 apiaries, among which 28 were foul-broody.

It will be seen that after the efforts of the three previous years there appear to be still left in 1903 nearly as many affected apiaries as at the first; and this is used by those across the water who oppose foul-brood legislation

as proof that the efforts of Mr. McEvoy were of no avail. But does it so prove? What with the ignorance of bee-keepers regarding the disease, and the insidiousness of its approach, it might well be that in many places it would not be discovered until the third year of its existence. In the meantime, through the ignorance or culpability of those having infected colonies, it is possible that the seed might be sown widely and in unsuspected quarters.

Before pronouncing final verdict, some questions might be asked and answered. Were all infected apiaries discovered the first year, or were fresh discoveries made each year where the disease, not previously discovered, had previously existed? Were all the apiaries of Ontario, whether infected or not, visited prior to 1903? And without enumerating others, this final question: How much worse would the disease have been in 1903 if there had been no inspector in the three previous years?

### A Tack-Puller as a Hive-Tool

A common tack-puller, such as is used for pulling tacks out of carpet, and costing about 10 cents, is recommended in *Gleanings in Bee Culture* as an excellent hive-tool.

### Smoking Robber-Bees

Beginners need cautioning as to the use of smoke when working at bees, and when robber-bees begin to be troublesome. The first impulse seems to be to deluge the robbers with smoke to drive them away. So a good lot of smoke is blown all over the frames where the robbers are trying to get in. But that has its effect also on the bees of the colony, making them less fit to defend their home. The beginner will do well to avoid, so far as possible, having hives open when

robber-bees trouble. Sometimes the robbers will not trouble at all if work be begun two or three hours later. If work be done in the evening, there is the advantage that night will soon stop the attempts of robbers. Yet evening is not generally the best time to work with bees. Especially when buckwheat is yielding, the gathering is done chiefly in the forenoon, when the bees will be good-natured, but cross in the afternoon.

### Invention of the Honey-Extractor

Here's a bit of history that may interest the younger readers:

Major Von Hruschka, a Hungarian, took from a hive a piece of unsealed honey and gave it to his boy to take to the house—some say in a tin pail, some say in a plate in the bottom of a basket. Boy-like, the youngster attached a string and whirled the basket about his head, and when the father looked at it he found the cells on one side of the honey-comb emptied. That set him to thinking, the result of which thinking was the centrifugal honey-extractor.

### Much Chilled Brood Reported

There seem to be an unusual number of complaints of chilled brood. It is easy to account for it by saying that it is due to the unusual amount of wet and cool weather, but it may not be out of order to ask whether this alone would have resulted in chilled brood if there had been no meddling with the brood-nest on the part of the bee-keeper. Indeed, it may not be an unfair question to ask whether chilled brood ever occurs in colonies left entirely undisturbed. When brood is spread, it may turn out all right if the weather favors, and it may be all wrong if the weather is adverse.

### Wintering a Queen With Few Bees

Many a bee-keeper has sighed for a plan by which he could winter over a queen without having her in a full colony. E. L. Pratt thinks he has solved the problem, and says in the *American Bee-Keeper*:

I have successfully wintered queens in Swarthmore mating-boxes with less than a pint of bees to each queen, and have, I believe, solved the problem of early queen-traffic for the Northern breeder.

It is surprising how well these little clusters of bees withstand the cold and blow of our severe Northern latitude—the rate of death seems much less in proportion to the strong standard colony—but being in compact clus-

ter directly on full combs of select honey, I suppose they have every chance. Where the full colony may become separated, these little clusters are closely confined in a given space.

I have not found it necessary even to cellar them. I, of course, provide shelter from the wind and the storm, either by placing the boxes inside a standard hive-body with a tight roof (four to a hive) and a flight-hole on each side, or inside a shed or small house, with flight-holes bored through the boarding.

In making up these wintering boxes I take up two or three cupfuls of young bees, as explained in my book, "Baby Nuclei," and just before winter actually arrives I give each box two fat combs of good honey; do this on a warm day to give the bees chance to settle as they like upon the combs. Do not disturb them again until spring, when they should be examined and supplied with more honey if needed, by changing the comb containing the least brood for one of honey.

To prevent any possibility of the queens wandering away from the cluster, place a piece of queen-excluding metal over the flight-hole on the inside. A  $\frac{3}{4}$ -inch flight-hole is none too large for wintering queens in Swarthmore mating-boxes.

### Precaution in Handling Bees

Dr. J. D. Reynolds, of Cobb Co., Ga., sends us the following clipping taken from the Atlanta Constitution:

CHARLOTTE, N. C., May 25.—(Special).—Mrs. Mattie Beard, a prominent lady of this

county, was seriously if not fatally stung by honey-bees to-day. Mrs. Beard, while attempting to save her cow from the bees, was stung 50 times on the face and neck. Her condition has been critical since 10 o'clock this morning, the attending physician holding out little hope for her recovery.

Dr. Reynold says, referring to the above, "though not very encouraging to the would-be bee-keeper, it might lead to more precaution in handling these irascible little insects."

There are some bee-keepers who do not approve publishing such items, but we fail to see the unwisdom of it. Surely, such items should be a warning not to go among bees without a good face and head protection. To do otherwise is dangerous, to say the least. But why run any risk when a good bee-veil can be bought for 50 cents?

Some bee-keepers seem to pride themselves on being able to handle bees without head protection. We think it is a false pride, and some day they may rue their presumption. It is better to be on the safe side always. Of course there may be emergencies that arise where a bee-keeper is away from home, and no veil at hand; in that case we would not take the risk—would prefer to let the cow take the stings.

for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The Fair Association has designated Saturday, Oct. 28, as bee-keepers' day, and will so advertise it, and especial pains will be taken to have on exhibition hives, honey, wax, bees, and other apianian products. At this fair will be on exhibition all of the agricultural and other products of the South and Mexico, and a visit to it will really be worth all the trip will cost to give one an idea of the South and her products.

Then the Texas members propose to give a genuine Mexican supper, which will be free to all outside members. There will be a Mexican band and toast-making—in short, it might be called a banquet. On Sunday the members can attend church or go on a trolley ride around the city. Side-trips to Uvalde and other places are planned for all who wish to see the country after the convention is over, bee-keepers at the various honey centers having promised to take bee-keepers around free of charge. Texas is one of the greatest, if not the greatest, of honey-producing States in the Union, and bee-keepers will now have an opportunity to see her wonderful resources, enjoy the hospitalities of her people, and profit by meeting in convention, all at a very small cost.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Everything is now all arranged except the program, and I wish that every one would write and make suggestions in regard to topics and men to discuss them. If you have no special topic that you wish put into the program, you must surely have some question that you would like brought before the convention. Pour in the suggestions and queries, and let me get up one of the best programs that we have ever had.

Flint, Mich. W. Z. HUTCHINSON, Sec.

Mr. E. A. Morgan, who conducts the Apiary Department of The Farmer, published in St. Paul, Minn., speaks very highly of The Honey-Producers' League and its objects in the issue of that paper for June 15.

## Miscellaneous News Items

Mr. R. A. Holekamp, of St. Louis, Mo., we notice by the printed letter-heads of the National Bee-Keepers' Association, has been selected as a director in place of Mr. W. F. Marks, who recently resigned.

The State of Washington bee-keepers have succeeded in having passed at the last session of their Legislature a foul brood law. In substance it is similar to the New York law. "Among other things it provides that on petition of 10 apiarists in any county the Board of County Commissioners shall appoint an inspector of apiaries, whose pay shall be

\$3 per day while in active service. This inspector is authorized to inspect all apiaries and take steps to eradicate diseases to which bees are subject."

Washingtonians are to be commended for their alertness and pushing qualities.

The San Antonio National Convention.—Secretary Hutchinson sends us the following notice for publication:

The International Fair holds its annual exhibition in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out

Besides the two hives overflowing with bees at a time when an immense number must have been in the fields, there were five frames of brood in the upper hive. These I gave to other colonies, put two supers full of drawn combs in sections on the lower hive, and kind o' thought there would be no early swarming from that hive. Supers with starters in sections would likely delay the swarming some more, but I did not have them ready.

There was less honey in the hives of this yard than I have ever known at the date I mention, June 2. From March 1 to June 1 I fed all the colonies—140, more or less—with perhaps a dozen exceptions. I had to feed or let the yard be practically annihilated. The honey-flow did not begin till the afternoon of June 2. There was a thunder shower the night before, and that day was hot. In the afternoon the bees stopped worrying me and went for the white clover—the first time they have seemed to be in good nature this spring.

### HONEY MARKET QUOTATIONS.

Have my brother bee-keepers read carefully the honey quotations as they have appeared in bee-papers for the last six months or more? What cheerful reading they make! Then glance, my dear brothers, over the quotations you have received for some other things which you think you must have, and ask yourselves how you are going to pay for them out of the net returns for your honey. Perhaps some of you have a home market for all, or most, of your product. Happy

### Putting Weak Colonies Over Strong Ones

BY EDWIN BEVINS

OWING to the success reported by Mr. Alexander and some others, in getting weak colonies in spring strengthened by placing them over strong ones with queen-excluders between, I tried it with two colonies this spring. In one instance there was no fighting; in the other there was some. Ten days after the unions were made there were no queens in the upper stories. I took away the zinc and let the queens of the strong colonies have the range of both stories until June 2, when I took off the upper stories and put supers on the lower ones. The colonies were very strong at that time, one of them much stronger than the other. This one was the yellowest and strongest in the yard. I call them "Yellow Devils." The bees seem to be of the strenuous, Rooseveltian type—always ready to work or fight.

is the man who is in such a case. Cultivate the home market, but—and let the cities “go to grass.”

#### “THINGS NOT SOLD FOR CASH!”

I must ask Mr. Davenport and others not to fire any more old chestnuts at me. I am not keeping bees now for the things I would not sell for cash if I could. I got enough of those things in the early days of my bee-keeping, but I will not deny that there is still a charm in the hum of the bees in the apple-tree bloom. I am keeping bees now mainly for revenue. But just as I have gotten the business up where there ought to be considerable revenue in it, the revenue has fallen out of the business. The bee-supply makers and dealers, the commission men and the railroads, get the revenue. I work for nothing and board myself. What am I going to do about it? I think I'll join The Honey-Producers' League.

#### UNITING AND WINTERING WEAK COLONIES.

In Coleman's “Rural World” a writer on bee-keeping says:

“Uniting two or more colonies in spring to make a good, strong one looks very plausible, but it does not work out in practice.”

No? My way of uniting weak colonies in spring works out very well in practice.

When the honey-flow begins, and I find I have some weak colonies and some of moderate strength, I rob as many as needful of their brood, and fill those of moderate strength with combs of brood. Sometimes I take away all of the brood of the weak colony, and sometimes I leave the comb on which the queen has done her latest laying. Supers are immediately put on the strengthened colonies. Work goes on in the hives of the robbed ones, and I have some colonies for the fall harvest.

To winter weak colonies in the way and at the time which the writer above-mentioned probably had in mind is worse than useless. One must necessarily deprive himself of the work of one queen if 2 colonies are united, and of more than one queen if more than 2 colonies are merged into one. Then the bees thus added are so old they will not be likely to live long enough to be of much use as honey-gatherers. By the method I use we have the work of all the queens all the time. The frames of brood can be put in other hives at the beginning of the honey-flow, and utilized for a time as dummies, and then the bees from them will add to the working force of the colony right in the midst of the honey-flow.

## Distinctive or Individual Odors of Bees

BY ARTHUR C. MILLER

**D**OES or does not a colony of bees possess a distinctive, individual odor, one differing from that of another colony? So many happenings in the regular course of the daily work with bees can be explained by an affirmative answer that it is currently given, but is it correct?

When honey is being stored freely it is an easy matter to unite bees of different colonies or introduce alien queens, but the instant the flow stops difficulties are experienced. Under such circumstances, when all bees and combs are in a sense saturated with the odor of flowers of some sort, we should not meet with any hindrances, if the theory is correct. It will not do to affirm that the individual odor—or body odor, if you prefer—is more potent than the honey odor, because we know that when the flow was on, we met with no trouble, and if such odor existed at all, it must be as potent during the flow as the day after.

If the odor of a bee announces to the guards of a colony that she is an alien, why do they pounce upon her in one case and not in another? If the alien odor is an excitant to the guards, why do they permit a laden alien to enter? If the odor of bees from an alien colony stirs the guards to attack, why do they permit alien drones to enter freely, for surely drones must possess the home odor (if it exists) as much as do their sisters? And it should be noted that the presence of an abundance of alien drones does not help their sisters to a friendly reception. Why are very young aliens accepted anywhere at any time? Has their youth prevented their acquiring any home odor?

If home odor guarantees a bee full freedom of her own hive, why do the bees ball their own queen when they chance to be overhauled at some inopportune time? In the excitement does she drop that gauzy-tissued garment, odor? If odor is a vital, or even an important, factor in the introduction of alien queens, why is a queen introduced by caging

sometimes killed despite the supposedly acquired odor? Or why is a queen run in free, under one of several conditions, not killed? The first is supposed to have acquired the odor of the receiving colony and the second has not. If the bees recognize an alien queen by her odor why will they, with their own queen free in their midst, accept any number of queens we choose to give? Or why will they sometimes ball their own queen when she returns to them after a few minutes chance-separation?

It may be asked why the bees of different colonies do not intermingle more frequently if odor is a slight factor. Chiefly, I believe, on account of their wonderful sense of location. They will “home” if it is possible to do so. When conditions interfere with this, they readily gain access to some other colony. I recently saw an excellent illustration of this. A colony of “golden” bees stood near the windward end of a row of colonies of dark bees, and the bees of the former had distributed themselves all through the leeward colonies, the colony next to the goldens containing a lot of them, the next not quite so many, and so on down the row. The prevailing southwest winds did the distributing, and the other colonies freely received the aliens. Perhaps golden bees have no odor, or mayhap the dark bees had colds.

Many of these things occur too frequently to be logically called exceptions, and others can be so regularly and uniformly produced by the apiarist as to make the odor theory untenable. It is one of those beliefs accepted almost without question because our grand-daddies said so. It may be right, but, if so, how will we explain the multitude of exceptions? I believe the explanation is to be found in the attitude of the individual bee, the so-called “alien.” I have satisfied myself that the queen's attitude governs her reception, and it is logical to assume that the same law applies to the workers. If a worker possesses senses so keen as to guide her from the fields to her home and direct her in so many, to us, intricate and obscure labors, it is quite reasonable to assume that these same acute senses quickly acquaint her with the presence of strange or unfamiliar surroundings, whereupon she is instantly on her guard. Her actions then govern her reception.

## Seasonable Manipulation of Colonies

BY G. M. DOOLITTLE

**I**T was with great interest that I read the questions by “Pennsylvania,” and Dr. Miller's answers thereto, found on pages 210 and 211, for they touched on something that has very much to do with the successful ending of the honey season for the apiarist.

In Dr. Miller's answer to question 5, he tells us regarding the number of times the hive containing the colony which gave him 300 sections of honey—the largest yield he has ever obtained from one colony—was opened, and what he did at each time he opened said hive. My method of working for comb honey has been condemned very many times, as being one requiring much “fussing” and manipulation, but if I ever opened any hive having a colony in it which was worked for section honey as many times during one season as the good Doctor says he did that hive, I do not recollect the same. Certainly, Dr. Miller does not train with the Hutchinson, Townsend, Alexander, etc., class, who believe in working bees with only two or three visits to an apiary each year, claiming that an extra number of colonies with little attention is better than a less number with manipulation. And, of course, I am on the Doctor's side. And why should I not be? None of these “many colonies with little manipulation” recommenders ever reported a yield of 300 sections of honey from a colony in a single season, nor anything like it, as far as I can remember; nor is their average yield of section honey anywhere near up to those who “look after the best interests of the bees and themselves.”

But I note in Dr. Miller's answer to question 3, that he thinks I may enlighten the readers of the American Bee Journal regarding how I manipulated the colony which gave me 309 pounds of section honey in one season, the same being 30 pounds greater (in pounds) than that secured by the Doctor.

Like him, I opened the hive in April to see if the queen was clipped, and to know that there was honey enough to last them till the flowers bloomed. Then, about May 10, the hive was opened and the brood reversed. That was done by putting the frames at the outside of the brood-nest in the center, and those in the center on the outside, so that in a few days all frames having brood in them would be very nearly literally full of brood. As I used 9 frames to the hive, this caused 6 of them to become full of brood by May 17, when a frame of

honey was taken from the outside, next the side of the hive, and the cappings of the honey broken by passing a knife over them flatwise, and bearing down on it quite strongly while doing so. This prepared frame was set in the center of the brood-nest, giving the bees great stimulus in removing the honey and storing it around about the brood.

On May 24 there was brood in the whole 9 frames, 7 of them being full all except the upper corners, the brood coming clear out to the wood of the frames on all four sides. At that time the brood-nest was reversed again, which practically filled the 9 frames with brood 5 days later. Also at this time of reversing the brood-nest, 2 frames having some honey in them were set in the space for the side sections, as this hive was calculated for sections at the side as well as on top. These frames of honey insured the colony against running short of stores to feed the brood, as well as to give room for bees, so that the hive should not become overcrowded so as to bring on the swarming fever. A week later 2 frames of the oldest brood were taken from the brood-nest and 2 frames with some honey in them, with the cappings broken, were set in their places, while the place for side sections, opposite from that having the 2 combs of honey put in the week before, was opened so it could be used. One of the frames of brood was placed in one side next the brood-chamber, and the other on the other side, while the 2 frames of honey were used by placing one on each side of these, so that I now had 13 frames in that hive, 11 of which would soon be solid with brood, or very nearly so.

At this time the sections were put over the brood-chamber, so that the bees had all the room that was necessary to spread out in to ward off the swarming fever.

When the colony was well at work in the sections the 4 frames in the side-section apartments were taken out and their places filled with sections. And this was all the manipulation used for the brood-chamber, or for the brood-frames in the hive. The rest of the work consisted in taking off the filled sections and putting empty sections in as needed.

From the above it will be seen that this colony giving the 309 pounds of section honey had its frames of brood-comb manipulated only 6 times, as against Dr. Miller's 9 times with his colony. This colony did not swarm, no increase was made from it, nor was it helped in any way, except as given above. That same year, two other colonies worked in the same way, gave each 306 and 295 pounds of section honey, while very many gave from 200 pounds up to the three above given. That same year a colony worked for extracted honey gave 566 pounds. This colony was worked very similar to the above, till it got its brood-chamber full of bees and brood, when it was set over into a hive 4 feet long, and holding 32 frames. This colony gave the remarkable yield of 22 pounds of honey a day. Or, to tell it just as it was, the yield was 66 pounds in 3 days, or an average of 22 pounds a day. This colony was not manipulated at all after it was in the long hive, only to extract the honey. In fact, after any colony has gone into the active storing of honey, I have never been able to see where any manipulation can help any.

As I look at it, only that manipulation which has an "eye" toward the securing of the maximum number of bees on hand just in time for the main honey harvest, counts any thing toward the successful production of honey. And, as Dr. Miller says, "There's a big lot in that." Let me repeat it again like this, "THERE'S A BIG LOT IN THAT." And this I would say right face to face with Mr. Hutchinson, Townsend, and others, were I where I had the opportunity to talk to them thus.

Onondaga Co., N. Y.

PS.—Lest I be misunderstood, allow me to say that I consider the "shook" method of preventing swarming far ahead of the cutting off of queen-cells. And as the larger part of Dr. Miller's manipulation was used to prevent swarming, I own that, outside of this, he used less manipulation than I did.

G. M. D.

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food", written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey". It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy.

PRICES, prepaid—Sample copy for a two-cent stamp; 50 copies for 70 cts.; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

### Papers Read at the Minnesota Convention

Held at Minneapolis Dec. 7 and 8, 1904

#### LATE FEEDING OF BEES

At our annual meetings there is some person who wants some light on the subject of feeding. It is to be inferred here when such person comes to put his bees into winter quarters, or brings them in from the out-yards, that, to his astonishment, some colonies are light in winter stores. How to supply them is what he wants to know.

The year that W. Z. Hutchinson was with us feeding was discussed. Mr. Hutchinson told how he did late feeding.

The fall of 1902 I made my first attempt at late feeding, using the Miller feeder. I had 4 "nukes" that contained late-reared queens, and were light in feed. Being desirous of saving the queens, I tried Mr. Hutchinson's plan. I prepared the feeders as follows:

Place the feeder upon a separate bottom-board, with a comb-honey super rim for the hive to rest on. If you haven't the rims you can make them; have them 5 inches deep. Heat the honey hot, 140 or 150 degrees; pour into the feeder what you need, and place a float in each compartment of the feeder; take the hive off the bottom-board it stands on and place it on the prepared board. Be careful not to disturb the bees before transferring, so that they will remain clustered and not be on the bottom-board. After placing them on the feeder, I usually raise one end of the hive a little and let it drop, so as to rouse them up and get them to work at once.

These "nukes" came through the winter in good shape, and 2 of them were in an out-yard of 50 colonies that gave me a crop of 8000 pounds of extracted honey last season.

The fall of 1903 I fed some 25 colonies the last of November and the forepart of December. They did well, with two or three exceptions. The past fall I have fed quite a number. This point I noticed, that unless the honey was hot—140 or 150 degrees—the bees did not take up the feed readily.

I usually wait about a day and a half, then I raise the hive up from the feeder by placing under each end strips about 2 inches square, and leave them for another day. Usually by that time the bees will be clustered on the frames, leaving the feeder clear of bees. Then transfer them to the bottom-boards.

I do the feeding in the cellar, as the weather is too cold to do feeding outside.

A. D. SHEPARD.

Pierce Co., Wis.

#### SIZE OF HIVE RELATIVE TO THE HONEY-FLOW

During the time in which I have kept bees (about 10 years) I have been trying to figure out the size of hive best adapted to my locality. In doing this I have naturally come to some conclusions which might hold good in localities where the honey-flow is entirely different from that in my locality.

In the first place, this is the flow as I get it year after year: Dandelion and fruit-bloom just enough to keep up a fair amount of brood-rearing, but not enough to boom the colonies. White clover enough to boom the whole apiary, but not enough for surplus. Basswood in unlimited quantities; nothing afterward, not even enough to lay up stores to winter on.

Now, what kind of a hive would a bee-keeper of experience choose to fit into these conditions if he knew of them to begin with (which I did not)? Would he use the same appliances as he did in a clover country, or buckwheat country, or an alfalfa country? If he did, he would not be conducting his business intelligently. Good business men do not go into new ventures or new localities to start industries of any kind without figuring out the last detail. No more should the bee-keeper!

Now I think there are a few general principles which should govern a man choosing a size of hive, two of which I shall now mention.

First, you can not produce comb honey with a short but profuse flow, as in my locality.

Second, the shorter and more profuse the flow of honey

the larger the hive-body, and, *vice versa*, the longer and steadier the flow of honey the smaller the hive-body.

Now try a small hive with a short, profuse flow for comb honey, as I did at first, not knowing any better, and the result will be that without a profuse flow from clover the bees will not work in the sections until the basswood begins to produce, then immediately they will swarm, and before they settle down to work the season is over, with sections about half filled. Such a result is a waste of time; even with large hives the result for comb honey with such a flow is no better, for the reason that while the swarming can be kept down to some extent, the bees will not work in the sections as long as there is room in the large hive, and the result will be half-filled sections in the end. Thus such a flow is impossible for comb honey under any circumstances.

Now having settled on extracted honey as the only successful form of production for our locality, which shall we use, large or small hives? I say large hives, by all means. With small hives the swarming will begin at the beginning of the main flow, and the settling process, if you try to keep them together, will consume half the period of flow. I say, keep them together, for what could you do with them divided at such a time? You have two almost worthless colonies for the work in hand.

Another thing, with this combination, should you be able to keep the swarm together, the hive-body will be so packed with brood that there will be little or no honey, which will make extensive feeding necessary every fall, which adds greatly to the cost of keeping the bees; besides, if sugar syrup is fed, the bees will not winter as well as upon good white honey that they have put in and themselves arranged.

Now these reasons I think sufficient to militate against the small hive for a short flow of honey. For the large hive,

under the same conditions, there is to be said, first, there is plenty of room for brood and stores for winter, and no overcrowding just before or just at the beginning of the main flow. If up to this time they have not acquired the swarming fever, it is easy to keep them together until the end. Such a condition is ideal; they are ready to put into the field every available bee to gather honey during the short period of flow. After such a flow, when the honey is sufficiently ripened, the supers can be removed and the bees will still have room enough in a large hive if you do not wish to increase; should you wish to increase you can remove two frames of brood and stores from each hive and make one booming colony with stores enough for winter, from every four hives, and still leave a plenty in each of the hives so depleted.

I will say at this point that I consider a large hive one that has a capacity of 12 frames of the common dovetailed hive; anything less is a small hive.

Now, for a long, steady flow of honey, I can see why the whole system must be changed, and that small hives would be altogether the best to use. First, because you want the bees to swarm as early as possible, thereby getting two working colonies with two laying queens, and double the working force. The smaller the hive the quicker each (the parent colony and the swarm) will recover from the division of forces, and reach the surplus-storage period. With such a flow comb honey can be produced, because the crowding process, which is necessary for its production, will not cause a second period of swarming.

With a fall flow of honey, even with small hives, the bees are likely to have stores for winter, because the surplus arrangements for light honey having been removed, and brood-rearing falling off, plenty of storage-room is obtained.

Hennepin Co., Minn.

D. D. LEONARD.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Discouraged Sister

I went into last winter with 7 colonies and came through with 6, losing my observatory colony. For the past 4 years our bees have profited us nothing (but experience). Last year I fed all fall and got them into winter and through in nice shape, but just when the fruit-bloom was opening we had a hard freeze, and since the clover came out, and there are acres almost white, we have had such cold, drenching rains that the bees have done nothing, so I have had to feed 2 colonies right when there was plenty of clover and poplar bloom. Do you wonder at me feeling discouraged? But I do not mean to give up. We will sit about the fires in June and buy sugar to feed the bees, and hope to catch buckwheat and fall bloom.

MRS. J. C. PARKER.  
Monroe Co., W. Va., June 3.

Don't feel too discouraged; the season is not over yet. I distinctly remember just such a season a number of years ago. Plenty of white clover, weather cold and wet, bees starving in June, dragging out their brood ere we discovered their condition. Had to hustle with the feeding in order to save them. Things looked blue, and yet in spite of all we had a very good crop at the end of the season. So you see you may have a good crop after all. Let's hope.

### Only Pollen—Finding Queens—Starters for Sections

I do not know as a subscriber is allowed to ask questions twice in one season, but as I am much puzzled and not a little worried, I am taking the liberty to impose on your kindness once more.

On May 8 I transferred a swarm of bees to a new hive to get the frames in such shape that they could be removed. In the new hive

I put full sheets of comb foundation. Everything, apparently, was all right and in good shape when the transfer was made.

Last week one day I was examining the frames and looking for the queen-cells in the above-mentioned hive, when I noticed perhaps 12 or 15 cells among the brood that looked a blackish gray. It looked like a mixture of honey and pollen that had grown—well, not like milkdewed, but yet like milkdewed. Some were hard when I ran a toothpick down, and others were about the consistency of muck or dirt.

I was at once alarmed, and thought of foul brood, but upon consulting my "ABC of Bee Culture," I found foul brood was entirely different, and could not find anything like it described. Then I came to the conclusion that it was honey and pollen mixed and stored for future use. But the color was so dark, and they all appeared the same but one, which was red. This fact bothered me. I thought of inquiring about it, but thought I would wait a little and see if I could discover for myself what it was.

Yesterday, upon opening this same hive, I discovered about three times as much as there was the other day, and I am very much worried as one other hive contains a few of these cells.

Was the brood or eggs chilled in taking out the frames, or could the comb foundation have been manufactured from wax from a diseased colony? I must mention that some of the cells were about half full of the substance, and others would only have a little, but they all seemed a little sticky when a toothpick was run down. All cells were uncapped containing this substance. Have I any cause to be alarmed for fear of spreading among the other colonies?

I read a short time ago in the American Bee Journal how to divide the colonies so I would not have to bother catching swarms if busy. This struck me as an excellent idea, as I work during the day. But the thing that bothers me is how to find the queen moderately quick.

All but one of my colonies are very large and strong, and yesterday—and only then by mere chance—was the first and only time I have succeeded in finding one of my queens. They are not clipped. I don't like to do it. Is there a way to find her quickly other than taking out each frame—center frames first—and hunting for her among the other bees? I have looked repeatedly in each hive I open to see her, and I do not seem to be able to find her. I know she is there as there are brood and eggs.

In my sections last year I put a square piece of starter. This year I put in a three-cornered piece, letting the point hang down. The bees seem to take to it much better. I make the piece about  $1\frac{1}{2}$  inches, or  $1\frac{3}{4}$  inches on each edge. Is that a large enough piece of starter? I had only one comb crooked last year, and the starters were about 1 inch by  $1\frac{1}{2}$  inches last year, with the long end hanging. This may seem a simple question to "one who knows," but a beginner has to learn all these simple things.

I would like an answer as soon as convenient in my turn, as I am desirous of checking the mischief if it is one to be checked, and I should also like to know how to stop it.

June 13.

MISS MICHIGAN.

Don't be worried about asking questions. You are at liberty to ask as many as you wish. We are always glad if we can be of service in helping to overcome your difficulties.

Now as to the cells you speak of. I think there is no reason for you to be alarmed, for, judging from your description, I should say it was pollen, and a very good thing it is for the bees, too, large quantities being used in brood-rearing. You will find that the quantity will steadily increase, and instead of being two colors there may be as many as half a dozen different colors. If you will notice closely I think you will find that there is much more of this substance in the outside frame, on one or both sides of the brood-nest; as the season is well advanced you will find these frames almost solid pollen.

With regard to finding queens, I can speak from much experience, that particular part of the work generally falling to my lot, and sometimes I find from 25 to 100 queens in a day, doing more or less of it through the entire season. Practice is what you need; however, I might mention a few things that will help you.

First, give your bees just as little smoke as possible to keep them quiet. In opening

your hive do it as quietly as you can, avoiding any sudden jar—anything that will alarm the bees and set them to running. This caution is more applicable to black bees than to Italians.

Remove the first frame, the one nearest you, and glance at each side of the frame for the queen. She is not very likely to be on the first frame, although you will sometimes find

wait an hour or so or till another day. Even if the bees remain quiet, if you do not find her upon the first or second time going over, it may be economy to wait till another time, when she may be found very promptly. There are special ways of proceeding when a queen must be found at once, as by sifting the bees through an excluder, putting the combs in pairs, etc., but I have given you just the

TOP AND BOTTOM STARTERS IN A SECTION

her there. Set this frame down outside the hive; this will give you room to handle the rest of the frames easily. Lift out the next frame and examine it, first looking over the farther side of the frame, as the queen naturally inclines to get away from the light. Continue thus with all the frames, moving them towards you as you return them. You will most likely find her the first time going over the frames, but if you miss her repeat the process, unless you have been so unfortunate as to start the bees running, in which case you will do best to close the hive and

every-day plan by which I find queens by the hundreds.

The bees will fill a section with almost any kind of a starter, but after more experience you will probably prefer to have the section as full as possible of foundation.

If comb honey is to be shipped to market it is very desirable to have the comb well fastened at the bottom of the section. In order to secure this we use a bottom starter  $\frac{5}{8}$ -inch deep and  $3\frac{1}{8}$  wide. The top starter is  $3\frac{3}{4}$  inches deep and  $3\frac{3}{4}$  wide. The picture of a section thus filled is shown herewith.

mostly capped; if slowly, it may be good honey before much capping is done. Something depends, too, upon the condition of the nectar, owing to the degree of moisture in the atmosphere.

O. O. POPPLETON (Fla.)—This depends. Some honey never get properly ripened even if all sealed and left in the hive for months. Other kinds are well ripened as soon as any is sealed. As a usual thing, however, except in extreme cases, at least  $\frac{3}{4}$  of the comb should be sealed. More is better.

P. H. ELWOOD (N. Y.)—The more the better. You get the best quality for table use by leaving it on until the end of the flow. When it is not possible to do this extract when fairly well ripened—it may be when bees have just nicely commenced to seal, depending largely upon the weather.

E. D. TOWNSEND (Mich.)—Our practice is to keep adding upper stories as they are needed clear through the season, then extract 10 days or 2 weeks after the season closes. In this way we get say 80 percent sealed before extracting. Even with this late extracting the sealed honey is very much superior to the unsealed.

J. M. HAMBAUGH (Calif.)—This depends upon the kind of honey. Linden or basswood honey should be sealed almost entire, while clover, Spanish-needle and many other kinds will not require so thorough sealing. The sages here in California, and alfalfa in Nevada, require but little sealing, at least that is my experience. The condition of the atmosphere plays an important part.

E. S. LOVESY (Utah)—If it is very thin it is best to leave it on till it is capped and ripened, but there are times when it is thick and ripe when the bee-keeper doesn't need to wait for it to be capped; while it will improve any and all honey to settle it in an open tank before canning. Thin honey, which may otherwise turn sour, will, as a rule, ripen all right if left in an open tank for a month, then the scum and all foreign matter should be skimmed off before canning.

G. W. DEMAREE (Ky.)—It depends upon the condition of the nectar when gathered by the bees. If the weather conditions are such as to favor the bees with good, "thick" nectar, a strip unsealed at the bottom of a part of the combs does not injure the quality of the honey. A good judge of the quality of honey need not make any mistake along this line. In the past few days I opened a jar of honey that was produced in the famous honey year, 1883—over 21 years ago—and it is as fine honey as was ever spread on bread.

E. E. HASTY (Ohio)—As a matter of choice it would be advisable to have it all sealed. If we extract mainly at the close of the season—and also in mid-season if we use combs enough, properly arranged—it is often possible to make a cheerful approximation to this ideal. Under some circumstances honey much less than half sealed may be nearly or quite as good as any. Something must be conceded to the impossibility of doing just what we desire; but a proper system and proper forethought would for the most part keep us out of such impossibilities. One of the worst things in connection with our craft is the wide-spread disposition to stretch terms and provisos and extract honey in a dreadfully unfit condition.

### An Impromptu Sermon on Bees

The Rev. Dr. Linklater, of Stroud Green, who was the special preacher at Chaldron Church on Sunday, was driven from the pulpit by a swarm of bees which had taken possession of the nearest window.

From the lectern Dr. Linklater addressed the congregation on the subject of the intrusion of the bees, instead of preaching from the text he had selected.

Let them preach the sermon, he said, pointing to the bees. Watch them. They want to escape to the fields and flowers, to their home and honey, and the way is open, and manifest to all who look on. There is the aperture—the window wide and open, and nothing to prevent them escaping to the

## Some Expert Opinion

### What Proportion of Comb Sealed Before Extracting?

**Ques. 27—** What proportion of an extracting comb is it advisable to have sealed before extracting?

Mrs. J. M. NULL (Mo.)—Fully three-fourths.

S. T. PETTIT (Ont.)—All, or very nearly so.

EUGENE SECOR (Iowa)—Practically all of it.

R. C. AIKIN (Colo.)—Three-fourths to all.

MORGAN BROS. (S. Dak.)—At least three-fourths.

L. STACHELHAUSEN (Tex.)—At least three-fourths.

DR. J. P. H. BROWN (Ga.)—I prefer to have the combs sealed fully one-half.

DR. C. C. MILLER (Ill.)—It probably pays to have 95 percent of the surface sealed.

REV. M. MAHIN (Ind.)—I prefer to have it all sealed, or nearly all. The more the better.

WM. McEVOY (Ont.)—Three-fourths to all from clover. All if from basswood or buckwheat.

E. WHITCOMB (Nebr.)—If you desire good, well-ripened honey at least two-thirds of the comb should be sealed.

C. P. DADANT (Ill.)—Sealing has but little to do with ripening. See whether the honey is thick or thin, and act accordingly.

N. E. FRANCE (Wis.)—That depends upon the weather. As a rule, the more sealed the

better is the honey. Unripe honey is one of the causes of low prices.

ARTHUR C. MILLER (R. I.)—Seven-eighths, at least. But honeys and climates make a great difference.

JAS. A. STONE (Ill.)—About all, or the honey will be thin and not keep well unless ripened by ventilation in a warm, dry place.

G. M. DOOLITTLE (N. Y.)—The whole unless artificial evaporation is practiced. If left on the hive 2 weeks after sealing the honey is all the better.

PROF. A. J. COOK (Calif.)—It is better that it be pretty well capped over. That is always safe. To market any but fully ripe honey is always a mistake.

C. DAVENPORT (Minn.)—Two-thirds or more, as a rule. But I have known combs to be nearly all sealed when the honey was thin and unfit to extract.

ADRIAN GETAZ (Tenn.)—Enough to make sure that the whole is sufficiently ripe. I should guess not less than one-third under ordinary circumstances.

C. H. DIBBERN (Ill.)—In a warm, dry time, when the honey is quite thick, I should not care much if it was capped or not; while in a wet time I should want it all capped.

J. A. GREEN (Colo.)—I prefer to have it all sealed. In a dry climate like that of Colorado, good honey may be secured without waiting for it to be sealed, but I doubt if much is gained by extracting sooner.

R. L. TAYLOR (Mich.)—That depends. If nectar is coming in rapidly it ought to be

free breath of heaven. But, no, They will go their own way! They mean to escape through the glass. For any length of time they have been attacking the window, and defeat only lends energy to the renewed attack. They will not learn from experience. Within easy reach, a few inches above, there is the open window, and the free breath of heaven. But they have set their obstinate minds to go their way, and they will go no other. They will perish in the attempt. Already there are multitudes of their companions on the window-sill, who struggled and were defeated. These living ones will not learn from the dead.

Poor buzzing bees, beating out your beautiful lives to no advantage, when the way to freedom is open, when you could be enjoying the life that God has given you! Is not this a pathetic picture of poor human bees who are thirsting for religious light, seeking that which is impossible in the way they seek it? The picture of the world of today, of so many splendid lives, is the picture of those imprisoned bees, seeking the right thing, but seeking it in the wrong way, and in their obstinacy preferring death rather than the life which is theirs through the open window—Jesus Christ.—British Bee-Journal.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,  
or to Dr. C. C. MILLER, Marengo, Ill.  
Dr. Miller does *not* answer Questions by mail.

### Selling Section Honey by Weight

In advertising honey would it not be wisdom as well as strict justice to both the honey-producer and the purchaser of honey, to require the members of the League to sell section honey by actual weight, instead of selling less than 16 ounces, and exacting full-pound price for the same? As far as I know the custom now is to sell section honey by the section at full-pound prices, when both the purchaser and salesman know that very many sections fall short of a pound. This is driving many people to the extremity of letting the purchaser of honey severely alone. A number of people buy both chunk and extracted honey from me because they say they get the amount they pay for.

KANSAS.

ANSWER.—It is far from the universal custom to sell sections by the piece. Much section honey is sold at its exact weight. To sell section honey by the piece, with a full understanding on the part of the purchaser that he is buying it by the piece with no reference to its weight, is all right. To sell a section of honey with the understanding on the part of the purchaser that he is getting a pound when he is really getting less, is all wrong, even if the seller does not say in so many words that the section does weigh a pound. An honest seller would not allow any such misunderstanding. It may be more convenient to sell by the piece, but there is more exact justice in selling by the pound.

### Putting on Supers—Bees Deserting the Hive

1. Several times in this Department you have said that you have several supers on at a time, and you thought that you would lose by not using 2 or more. When do you put the last ones on? I have tried using one at a time, and also several at a time, and I can see little difference.

2. In the spring I had a colony leave the hive when they had some honey and brood. The next day they came back and I clipped the queen's wing, but they left the following day regardless of this. I don't think the queen went with them, though I could not find her. Do you think they were "crazy," or what? There were no mice, moth, etc., to bother them.

3. I have been thinking of dividing some of my colonies equally, putting 4 frames of brood and bees with the queen on a new stand, and letting those on the old stand rear a new queen. Would the bees on the new stand be likely to return to the old one?

MISSOURI.

ANSWERS.—1. When the first super is about half filled, and the harvest continues, a second is placed under the first. Then I continue giving fresh supers throughout the season just as often as the one last given becomes half filled. The empty super is put at the bottom until toward the close of the season, when it is not certain whether an additional super is needed or not, and then the empty

super is put on top, where the bees can use it or not, as they like. The oldest super on the hive is always kept next over the one last given. Answering your question direct, you will see that the last super will be given toward the close of the harvest, which time varies in different years.

2. Bees sometimes have a craze for deserting their hives in spring, leaving plenty of brood and honey. I don't know why. Sometimes it looks as if the old bees had all died off rapidly, leaving so much brood on hand that the young bees remaining deserted on account of discouragement. Clipping the the queen has no effect in keeping bees in the hive; it only prevents her from going with them.

3. Yes, you may count on all the field-bees returning to the old location.

### Uniting Colonies

I have tried, in a limited way, the plan of temporarily uniting colonies with an excluder between, and it does not work satisfactorily for me. Inside of two weeks one or the other of the queens will disappear. In one case the lower colony was very strong, and the one put on top was weak, with brood in only 2 frames, and the queen in the lower strong colony was gone at the next examination. There was no fighting among the bees, but one queen seemed to be enough.

In uniting no smoke was used. They were simply set together and left to themselves. Have I omitted anything that should have been done to make the plan a success?

If it would work, colonies could be equalized very quickly by putting the lower one on a new stand when separating.

OHIO.

ANSWER.—There does not appear to be anything lacking in your practice. According to the descriptions given by those who have been successful, all that is to be done is to set one colony over the other, an excluder between. Have others made a trial of the plan? and, if so, will they please report?

### Putting on Supers—Swarming

When is the best time to put supers on hives? Do bees necessarily accumulate on the outside of the hive before swarming?

I have asked these questions before but received no answer.

MICHIGAN.

ANSWER.—The best time to put on supers depends a little upon what you may desire. If you are anxious for increase through natural swarming, it may be best to delay putting on supers till after the harvest is under way, for crowding the brood-chamber with honey will have its effect in starting the bees into the notion of swarming. Indeed, it would make a more sure thing of swarming if no super should be given until after the bees have actually swarmed.

Generally, however, the desire is for honey rather than swarms. In that case a super should be given before there is any danger of

crowding the brood-chamber with honey. A little too soon is better than a little too late. One way is to watch the flowers from which the harvest is expected, and put on supers as soon as they appear in quantity. In your region white clover is probably the thing for you to watch. Another way is to watch the condition of the brood-chamber, and put on supers when the brood-combs begin to be crowded with honey. The old rule was to give supers when white wax begins to be plastered on the upper parts of the comb; a good rule in most cases, but for those who prefer not to have any swarming (even though it may be a rare thing for the bees to respect their wishes) it is better to have supers on before the bees get so far as to secrete this extra wax.

I do not understand how it should be that your questions have not been answered, unless there has been some failure on Uncle Sam's part, and he is a very reliable old gentleman. All questions received are answered just as soon as possible. See "Send Questions on Time," page 404. See also "Putting on Supers," pages 297 and 393.

## Reports and Experiences

### Bees Doing Little Work

Bees are not doing much here just now. The first crop of alfalfa is out and the weather is dry. They are killing drones, but I keep mine stimulated to breed, so when alfalfa comes again I hope they will begin work in earnest.

G. BOHRER.

Rice Co., Kans., June 14.

### Bees Wintered Poorly—Prospects Good

Bees did not winter well in this locality, mostly because of lack of feed. We had very little surplus honey last year, but there is a fine prospect for this season. The pastures are fairly white with clover now, and things never looked more promising for a large honey yield. I had 2 very large swarms on June 6 and 14.

JOHN STOTTS.

Marion Co., Iowa, June 15.

### Progressive and Up-to-Date

"Progress" and "Up-to-Date" seem to be the watchwords of the "Old Reliable," ever looking after the best interests of all concerned. It must require considerable hustling to get so much bee-information together for each weekly edition, and as you have subscribers in all stages of development, from the beginner to the expert, so the information necessarily must be varied. Extended articles on one subject by the experts no doubt suit the older heads, while we in the student class require to learn from the ground up. Success in apiculture like any other business, does not depend entirely upon one idea but upon a combination of circumstances.

A. BURKHOLDER.

Wayne Co., Mich., June 6.

### An Old Bee-Keeper's Experience

It is my purpose to give an account of how I caught the bee-fever. If in your imagination you will go back with me to the year 1832, when I was 15 years old, living in Crawford Co., Pa., it was then my grandfather got me to work in the garden and watch his bees, while he attended court. He provided me with a ladder, a rope, a bell, and a straw skep, with orders to get the "king" in the skep should they swarm.

Well, one day while at dinner the boy called out "Bees swarming." I went to the yard, found them alighting on a pine tree some 15 or 20 feet high, and placed the skep on the ground under them, sawed off the limb, let them down by the skep, and by the time I got

Untested Queen.....\$ .75	Select Breeding Queen.....\$5.00
Select Untested Queen.....1.00	Best Imported Queen.....5.00
Tested Queen.....1.00	Fair Imported Queen.....3.00
Select Tested Queen.....2.00	

**WALTER S. POUDER,**

513-515 Massachusetts Ave., INDIANAPOLIS, IND.

down they were going in nicely. In the evening when grandfather came home the first inquiry was, "Did the bees swarm?" I was ready to say "Yes." He said: "Did you get them to alight?" I said: "Yes, they lit before I got the bell, and I lived them." "Well, you ought to be a bee-man," he then said.

That started the fever. When his friends came in he told the story and closed by saying, "Little John ought to be a bee-man." That was no antidote for the fever, so I asked him if he would sell me that swarm. He said he would if I would hoe corn for him. I asked him how long, and he said, "About 2 weeks, and I will teach you to make the skeps in the bargain."

It was the last week in May that we closed the bargain. I took the bees home, got my mother to take care of them when I was from home, and 5 years later I went to a home of my own. I started with 4 skeps. About this time a sawmill was started in the neighborhood, and I learned the carpenter and joiner trade, so I got to making box-hives, and quit the skeps.

About the year 1844 a man from Vermont came through Pennsylvania, selling "Week's Patent Hive"—a box-hive with a chamber for surplus honey. I got this hive and used it for 6 years, and increased to 30 colonies.

In the month of May, 1851, I sold my farm, made a sale of stock and bees, and left Pennsylvania, coming to Lafayette Co., Wis., June 6, and bought a farm. Then I started out to

\$14.00 to Chautauqua Lake, N.Y., and return, from Chicago, via Nickel Plate Road, July 7th, with extreme return limit of Aug. 8th, by depositing ticket. **Please Mention Bee Journal when writing advertisers.**

buy 2 or 3 milch cows, and while looking for them I ran across a man that had a number of colonies of bees in logs that he got in the woods. He said they were wild bees, but the honey was sweet. I gave him \$5 for one, got it home, and it swarmed in a few days. Then I started with 2 colonies, in about a month from the time I sold out. So you see I still had the fever.

About the year 1860, when I had 100 colonies in box-hives, I heard of the Langstroth frame hive. I got a sample, made hives of that style, and transferred 60. I keep the best Italians I can get, and change every third or fourth year. I have a mill, make my own foundation and some for the neighbors. I aim to keep about 50 colonies over winter.

To keep back swarming I give plenty of room and shade.

To avoid absconding I give each new swarm a frame of brood of all ages, with frames of drawn comb as starters.

To avoid after-swarms I pick out all queen-cells but one on the 6th day after swarming.

To avoid robbing I keep strong colonies, and don't leave honey lying around to tempt them to rob.

I have about all the books that treat on bees, and I take the American Bee Journal, Gleanings in Bee Culture, and the Bee-Keepers' Review.

I have owned and handled bees for 73 years and still have the fever. JOHN CLINE. Lafayette Co., Wis.

### Bee-Keeping in Uinta Co., Utah

Bees are doing first-rate this season. I have had 22 swarms, all prime, and expect a good increase and also a good crop of honey. June 2 a swarm issued with 3 queens.

## A Standard-Bred Italian Queen-Bee Free! For Sending One New Subscriber.

As has been our custom heretofore we offer to mail a fine, Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year

2. Sending your own name with the \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

We will book the orders as they come in and the Queens will be mailed. Will you have one or more?

If you cannot get a new subscriber, and want one of these Queens, we will send the American Bee Journal a year and the Queen—both for only \$1.50. Address,

**GEORGE W. YORK & CO.,**

**CHICAGO, ILL.**

county inspector at any time, when one is needed. We are not troubled with any kind of bee-diseases. We all guard against them by keeping our bees and our yards clean, and we also have the best bee-feeder there is made. There is no danger of robbers, and we can feed a yard of 200 colonies before breakfast any time. We don't have to open the hive, need no smoke, and drown no bees.

G. W. VANGUNDY.

Uinta Co., Utah, June 4.

### Aphides and Honey-Dew

I am sending a twig cut from the soft-maple tree with a shell-bug (?) of some kind on it. The maples are covered with it in some parts of the country, and the bees tumble over themselves in the early morning and late evening—sometimes nearly up to dark—gathering the exudation or honey-dew. I have seen it many times before, but not to so great an extent as this summer.

We have a number of the different aphides that work on the trees, and plants of various kinds which produce "honey-dew" of some kinds, and sometimes the trees are dripping with it. A small green kind is at this time working on box-elder, and does almost every year, the sidewalk at times being wet with it.

Bees are in tolerably good condition, though there are many weak colonies. F. W. HALL.  
Sioux Co., Iowa, June 12.

### Do You Need Queens? By Return Mail?

If so, we can fill your order with the best Queens that money can buy. Try our strain of 3-band Italians; they will not disappoint you with empty supers. Untested Queens, 75 cents; \$8 per doz. Tested Queens, \$1 each. Send for circular. **J. W. K. SHAW & CO.**  
134tf LOREAUVILLE, Iberia Par., LA.

### What Adel Bees Do

E. MILTON, MASS., May 27, 1905.  
Send me queen same strain as the one sent 1904. That queen proved the best queen I ever received. Her bees filled a super before May 15, 1905. **ROBT. FORBES.**

All Tested Queens are \$1 each.

**MONDENG MFG. CO.,**

147 and 149 Cedar Lake Road, MINNEAPOLIS, MINN.

Please mention Bee Journal when writing.

The most attractive eastern excursion during the coming summer will be to Asbury Park, N. J., on occasion of the annual meeting of National Educational Association, July 3 to 7, inclusive, via the Nickel Plate Road and its connections, either the West Shore or Lackawanna Road, with privilege of stop-over at Chautauqua Lake points, Niagara Falls and New York City. Rate, \$21.35 for the round-trip. Dates of sale, June 29 and 30 and July 1 and 2, with extreme return limit of Aug. 31, by depositing ticket. Patrons of this route may have the choice of a ride over the most interesting mountain scenery in New York and Pennsylvania, and through the celebrated Delaware Water Gap, or through the beautiful Mohawk Valley and down the Hudson River, which also includes the privilege of a ride on day line boat on Hudson River, between Albany and New York City, in either direction, if desired. No excess fare charged on any train on Nickel Plate Road. Meals served in Nickel Plate dining cars, on American Club Meal Plan, ranging in price from 35c to \$1.00; also a la carte. Chicago Depot, La Salle St. Station, corner Van Buren and La Salle Sts. City ticket offices, 111 Adams St. and Auditorium Annex.

For further particulars, address John Y. Calahan, General Agent, 113 Adams St., Room 298, Chicago. 7—23A4t

**Alfalfa's Merits — Best Mortgage-Lifter Ever Known**

Alfalfa is better than a bank account, for it never fails or goes into the hands of a receiver. It is weather-proof, for cold does not injure, and heat makes it grow all the better. A winter flood will not drown it and a fire will not kill it. As a borer it is equal to an artesian well; it loves water, and bores to reach it. When growing there is no stopping it. Begin cutting a 20-acre field; when your last load of hay is handled at one end of the field it is ready to cut again at the other end. For filling a milk-can, an alfalfa-fed cow is equal to a handy pump. Cattle love it, hogs fatten upon it, and a hungry horse wants nothing else. If your land will grow alfalfa you have the drop on dry weather. Once started on your land alfalfa will stay by you like Canada thistles or a first-class mortgage, but only to make you wealthier and happier. Evidences of the profitableness of alfalfa on irrigated land in the semi-arid regions multiply from year to year. Best results are obtained in

**NORRIS & ANSPACH, Kenton, Ohio.**

Montana, Utah, Wyoming, and Idaho, by sowing in May or June.

#### DIRECTIONS FOR SOWING.

For dry farms, for raising seed, 6 to 8 lbs.; for hay, 8 to 10 lbs. Irrigated land, 10 to 16 lbs.

Be very careful to have the land well worked and leveled. The leveler the land the closer you can cut the hay. If sown with drill, put seed in from one to two inches. If sown broadcast sow evenly over the land, then drag once with light harrow. Will grow best in gravelly or sandy land. Heavy clay or alkali land does produce good alfalfa.—Selected.

### The Wrong of Selling Unripe Honey

"Look out for number one." That's all well enough; but I tell you the man who wants all the happiness to be got out of this life needs to do a lot of looking out for others. The chauffeur who recklessly rides over people and frightens teams brings into disrepute the army of good people who ride in automobiles. The few evil-minded sluggers who are killing people in the Chicago strike are bringing into disrepute the whole scheme of organized labor. The man who puts on the market unripe extracted honey is doing a wrong to every honest man who produces honey.—[Just so. I am not sure but we ought to keep harping on this subject during the entire marketing season. The trouble is, the chaps who unload their bad stuff are just the ones who do not read the bee-papers. It would, perhaps, be well for bee-keepers to buy up some of these odd lots in order to prevent their getting on the market at all, either to depress prices, or, worse still, disgust the whole trade with any kind of honey.—Ed.]  
—Gleanings in Bee-Culture.

## Honey and Beeswax

CHICAGO, June 19.—The little that sells consists chiefly of extracted and the market is a small one. Comb ranges from 12@12 $\frac{1}{2}$ c for the best white with off grades 1@3c less. Extracted, white, 5 $\frac{1}{2}$ @7c; amber, 5@6c. Beeswax, ready sale at 30c.  
**R. A. BURNETT & Co.**

CINCINNATI, June 2.—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4 $\frac{1}{2}$ @6c. according to quality. White clover extracted at 6 $\frac{1}{2}$ @8c. The comb honey market is practically closed for the summer. Beeswax, 29c.  
**THE FRED W. MUTH Co.**

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12 $\frac{1}{2}$ @13c. Extracted, from 6@8c, according to quality.  
**BLAKE, SCOTT & LEE.**

PHILADELPHIA, June 21.—As the season advances, there is very little call for comb honey. In fact, no sales, and we make no quotations. Commission men are accepting any offer they can get for what little stock they have on hand. Extracted honey is in some demand. Possibilities of a big crop are holding prospective buyers back. We quote: Fancy white, 7@7 $\frac{1}{2}$ c; amber, 6@7c; dark, 5 $\frac{1}{2}$ @6c. Beeswax in good demand, 29@30c.  
We are producers of honey and do not handle on commission.  
**WM. A. SELSER.**

ALBANY, N. Y., June 17.—The honey market here is very dull now. It is between seasons. Receipts and demand very light. Very little old crop carried over, and will be in good shape for new crop, which begins in August. Quotations are nominal now. White comb, 12@14c; mixed, 10@12c; dark, 10@11c. Extracted, white, 6@6 $\frac{1}{2}$ c; mixed, 5 $\frac{1}{2}$ @6c; dark, 6@6 $\frac{1}{2}$ c. Beeswax, 28@30c.  
**H. R. WRIGHT.**

KANSAS CITY, June 21.—There is very little comb or extracted honey on the market at present, but what there is being quoted as follows: Fancy white comb, 24 section cases, \$2.25 to \$2.50; No. 1 white and amber, \$1.75 to \$2.00. Extracted, per pound, 4 $\frac{1}{2}$ @6c. Beeswax, 25@28c.  
**C. C. CLEMONS & Co.**

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Ex-

tracted honey in fairly good demand. New crop California honey selling at 6 $\frac{1}{2}$ @7c for water-white, 6@6 $\frac{1}{2}$ c for white, and 5@5 $\frac{1}{2}$ c for light amber. Southern at 50@60c per gallon, according to quality. Beeswax somewhat declining; choice average stock selling at 29c.  
**HILDRETH & SIBELKEN.**

CINCINNATI, O., June 9.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5 $\frac{1}{2}$ @5 $\frac{1}{2}$ c; in cans, 5 $\frac{1}{2}$ @6c. Beeswax, 28c.  
**C. H. W. WEBER.**

SAN FRANCISCO, May 31.—White comb, 1-lb. sections, 11@12 cents; amber, 8@10c. Extracted, white, 5 $\frac{1}{2}$ @6 cents; light amber, 4@5c; amber, 3@3 $\frac{1}{2}$ c; dark amber, 2 $\frac{1}{2}$ @3c. Beeswax—good to choice, light, 27@29c; dark, 25@26c.

The ship Atlas, sailing Saturday last for New York, carried 236 cases extracted, reported to be Hawaiian Island product. Offerings of this year's California honey so far have not been large, and mainly by sample. The movement on local account is light.

4 Largest Sizes Soot Burning

OTISVILLE, PA., Jan. 18, 1904.

Dear Sir:—I have tried almost everything in the smoker line; 3 in the last 3 years. In short if I want any more smokers your new style is good enough for me. I thank the editor of Review for what he said of it. Those remarks induced me to get mine.  
**FRED FODNER.**

# JUST ABOUT NOW

Is the time to be careful where you order your Bee-Supplies and what goods you order. Lewis' Goods will never disappoint you. They are standard and will go together rapidly and accurately. This means something

## WHEN YOUR BEES ARE SWARMING

### Bee-Keepers, Do Not Be Misled

By the so-called cheap prices. They mean poor goods, constant delays, trouble and dissatisfaction. A little more money expended on LEWIS' BEEWARE in the beginning will save you double the amount in the end.

## MILLIONS OF SECTIONS READY FOR YOU

As is customary with all large concerns we have agencies or jobbers in different parts of the United States, where our goods are carried in stock. If you are located near any of those named below it will save you time and freight charges to send your order to them. Where the distance is not so great from Watertown to the agency, these jobbers sell the goods at our regular list prices.

The following are distributing points for Lewis' Goods:

<b>ENGLAND</b> E. H. Taylor, Welwyn, Herts.	<b>ILLINOIS</b> Dadant & Sons, Hamilton York Honey and Bee Supply Co., 141 and 143 Ontario St., Chicago.	<b>MISSOURI</b> E. T. Abbott, St. Joseph.
<b>CUBA</b> C. B. Stevens & Co., Havana.	<b>INDIANA</b> C. M. Scott & Co., Indianapolis.	<b>OHIO</b> Fred W. Muth Co., Cincinnati. Norris & Anspach, Kenton.
<b>CALIFORNIA</b> Paul Bachert, Acton. California Lumber & Milling Co., San Francisco.	<b>IOWA</b> Adam A. Clarke, Le Mars. Louis Hanssen's Sons, Davenport.	<b>PENNSYLVANIA</b> Cleaver & Greene, Troy.
<b>COLORADO</b> R. C. Aikin, Loveland. Arkansas Valley Honey Producers' Association, Rocky Ford. Colorado Honey Producers' Associa- tion, Denver. Fruit Growers' Association, Grand Junction, Robert Halley, Montrose.	<b>MICHIGAN</b> A. G. Woodman, Grand Rapids.	<b>TEXAS</b> Southwestern Bee Co., 438 W. Hous- ton St., San Antonio.
	<b>MINNESOTA</b> Wisconsin Lumber Co., Faribault.	<b>UTAH</b> Fred Foulger & Sons, Ogden.
		<b>WASHINGTON</b> Lilly, Bogardus & Co., Seattle.

RESIDENCE OF E. KRETCHMER.

# HONEY CROP

Already the harvest has commenced. Now is the time to think of packages. Don't make the great mistake of neglecting this point. You may lose the entire profit of the year by shipping your honey in poor packages. Appearance counts in the market. When you buy **ROOT'S GOODS** you are sure of the best. Sections and Shipping-Cases; in fact, everything for the bee-keeper, can be promptly obtained at Root's Branches or Agencies everywhere.

### No-Drip Shipping-Cases

Don't allow your Comb Honey to be sold at low prices on account of poor Shipping-Cases. Put your crop into Root's No-Drip Cases and it will reach the market in perfect condition, thus bringing satisfactory returns. Our Cases are made of selected basswood, with 2 or 3 inch glass front, which shows off the honey to the very best advantage. Below is a condensed price-list. Complete prices and particulars are found in our general catalog.

Shipping-Cases. Name and Size of Case.	Nailed each.			Price complete including 3-in. glass one side, nails and paper, in flat.	With 2 in. glass instead of 3 — per 100.	Without the glass, per 100.

6 1/4-in. 3-row " " .....	25	20	1 40	11 50		10 00

### Porter Bee-Escape

The great labor-saver. No well-regulated apiary can afford to be without it more than a smoker. Price 20c each; \$2.25 per dozen, prepaid. Price with board, 35c; \$3.20 for 10, not postpaid.

### Aikin Honey-Bags

Don't fail to try this package. It is now an established success. No loss by breakage. Easy to fill. No package so cheap and attractive. Develop a home trade that will prove very profitable.

### PRICE-LIST OF AIKIN HONEY-BAGS.

Capacity	Size	Price of			Wt of 1000
		100	500	1000	
1-pound bags .....	3 1/2 x 5 1/2	\$ 65	\$3 00	\$ 5 50	10

Printing name and address extra.....		30	75	1 00	

May be sent by mail at 18c per pound extra for postage and packing.

### The Simplex Jar

The handsomest glass package on the market. It's a package you need not be ashamed of, and will find its way beside the finest of the grocery shelves. Create a demand for your honey.

This is a new jar with glass screw-top and rubber gasket fitted to the taper screw on jar, which seals absolutely air-tight. Put up in re-shipping cases of 2 dozen jars each, with corrugated protectors.

Price \$1.10 per case; 6 cases @ \$1.05; 20 cases or more @ \$1.00.

### Honey-Labels

We print them. Write for our sample book.

### 5-Gallon Square Cans

The above cut shows the favorite package for shipping extracted honey. There is no shrinkage and consequent leaking; no taint to the honey from wood, as is so frequently the case with barrels and kegs. The cans, being made square, economize space, and are easily boxed. They are used exclusively in the far West. Take 4th class freight-rate.

### PRICE LIST OF SQUARE CANS.

No. in a box.	Capacity of each can in gallons, in honey.	Price of		Wt. of 1 box.	
		1 box.	10 bxs.

**Queen-Bee Free as a Premium**

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an antested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year.

## Editorial Notes and Comments

**Prof. Benton Off for the Far East**

Twenty-five years ago, in company with D. A. Jones, of Canada, Prof. Frank Benton started to the Far East in search of new races of bees, not returning to his native land until 11 years later. The introduction into this country of the Cyprian, Syrian, Palestine, and Carniolan bees followed. Now with Uncle Sam at his back, and as the accredited head of the Apicultural Branch of the Department of Agriculture, he starts in the same direction for a two-year trip, seeking more worlds to conquer. Besides obtaining queens from the Caucasus, he has his eye on the big bee of India, *Apis dorsata*, and any other new bee that may fall in his way. Neither will he slight any chance for something new in the way of honey-plants. Bee-keepers will hope for substantial gains from his efforts.

of drouth the drouth has already begun its injurious effect on the growth of honey-plants, and although the immediate effect may be an increased storing of nectar condensed to a greater extent than usual, the after effects in the way of checking plant-growth may more than counterbalance all the gain.

Speaking of white clover alone, the desideratum seems to be weather so hot that one can not find any spot cool enough to sleep at night, with plenty of moisture in the ground from previous rains. Does the man who grumbles at the interruption of the gathering by timely rains, really know what is for his own good?

**Townsend's Mixed-Super Plan**

Editor Root is quite enthusiastic over O. H. Townsend's plan of having sections and extracting-combs in the same super. Dr. Miller, while not denying advantages in the plan, thinks it can be used successfully only when extracting-combs are new and white, because of the habit bees have of carrying bits of wax from the extracting-combs to finish sealing the sections.

**Studying the Wants of Beginners**

The province of a bee-paper is to supplement the information gained from books of instruction on bee-keeping, not to take the place of such books. Lack of understanding this sometimes causes disappointment, and occasionally a subscriber writes after the manner of one who lately wrote:

"I think a paper printed for beginners should state what should be done every month or less, and should not fill up its pages at this time of year telling how to winter bees. I don't receive much advice through the columns of the American Bee Journal in regard to each day's work, or each month's work."

It would certainly be a very desirable thing for a beginner to have explicit instruction given as to the work of each day in the season. It would, however, be a difficult thing to give such instruction. What would fit one locality would not fit another locality. What

**Don't Save the Uncapping-Knife**

If you extract before the bees have sealed the combs, you can save the time and labor of uncapping. But you will lose money by it. The honey will be of such quality that your customers will conclude they do not like honey, whereas if you leave it in care of the bees till all is sealed your customers will want more, and "children will cry for it." It is not, however, for the sake of avoiding the use of the uncapping-knife that most of the extracting of unsealed honey takes place, but for the supposed greater quantity of honey to be thus secured. To a large extent this is a delusion. If every bee-keeper should realize how little in weight he gains by extracting unripe honey, and how much more in proportion he loses in quality, he would hesitate thus to spoil the market not only for himself but for others.

**What is Good Honey Weather?**

Quinby said that the honey-flow was at its best when farmers were just beginning to complain of drouth. Admitting this to be true, it is just a bit doubtful whether in the long run there is a gain in having such weather. When farmers begin to complain

would be right for May 15 of a certain year in a given locality might be the right thing for June 1 of another year. Supposing, however, it could be easily done, it would have to be much the same for each year, and those who had been taking the Journal a year or more would object to having space thus occupied. It would be proper matter for publication in a book of instruction, which is expected to give general instructions. Even the books of instruction do not all count it feasible to give such plans of operation.

All this is said with no feeling of criticism against our correspondent. It is always desirable to know what our readers want, and just so far as practicable it is intended to gratify their desires.

**Gentleness of Caucasian Bees**

A correspondent, after a visit to Prof. Frank

Benton at Washington, writes with regard to a colony of Caucasian bees:

"It was simply wonderful the way he handled them. I do not think anything that has been written has been overrated. He first began by taking them out and handling them the same as we do the ordinary bee; he then blew on them; shook them; kicked the hive, and put them to all the tests that you or I could think of to make an ordinary bee get up and sting. After all these tests they still clung to the frame and did not show the slightest intention to sting."

While many bee-keepers prefer bees having sufficient resentment in their make-up to keep at a respectful distance any one inclined to be light-fingered, there are others who would be glad to have bees without any sting. Next to a stingless bee is a bee with a sting it will not use upon its owner. Let us hope that these very gentle bees may at the same time distinguish themselves as honey-storers.

bees, and in 1860 purchased an Italian queen of the first importation by S. B. Parsons, paying for her \$150. At \$8 a month it took quite a long time to pay for that queen. Italian queens are somewhat cheaper now, it seems.

Mr. Kretchmer is the oldest bee-supply manufacturer in America. He began to make hives by hand in 1864, on a carpenter's workbench under a tree. From that humble beginning his business has grown until now

CHARLES W. KRETCHMER.

there are 60 employes in the factory, divided into a day and night shift. We were surprised to learn that the Kretchmer Mfg. Co. now makes everything used by up-to-date bee-keepers excepting bee-hats, excluder zinc, and comb foundation. They used to make the last-named article, but now handle Dadant's brand. Their section-making capacity is about 25,000 per day. Their output last year of all kinds of bee-supplies was something like 60 car-loads. At the rate they were running when we were there we should think their total sales this year would exceed last year's.

An uncapping fork is one of the new things offered. Mr. Kretchmer imports them for his trade.

Mr. Kretchmer is founder and president of the Kretchmer Mfg. Co., his son, "Justus C.," is vice-president, and Geo. A. Smith, a brother of Mrs. Kretchmer, is the secretary. Another son, "Charles W.," is also in the business. There is still a third son, "Ray," who is expected to be a part of it a little later on.

The Kretchmer Mfg. Co. issues its full catalog also in the German language, the only one of its kind in the world.

Mr. and Mrs. Kretchmer have three sons and three daughters, all of whom are married, we believe, and also have nice homes. Mrs. K. is a motherly woman, a good, practical housekeeper, and takes a deep interest in the success of her husband and children.

We shall not soon forget the genuine cordiality with which we were received and entertained at the Kretchmer home and factory. May their success continue, and ever continue to be well-deserved.

Red Oak is an ideal city of 5000 inhabitants, and not a single saloon. It has 13 good church buildings, one of which, the Methodist—a new one—cost over \$60,000, with a seating capacity of about 2000 people. It is

Miscellaneous News Items

Rev. John Dooly, of Berkshire Co., Mass., wrote an interesting article on the honey-bees for beginners, which appeared in The Courier, of Chatham, N. Y. If every bee-keeper who can do so would follow Mr. Dooly's example, and write an article on bees and honey for his local newspaper, it would doubtless help to increase the demand for honey, and also would afford an opportunity to correct the comb-honey misrepresentation that has appeared so often in print. If all would help in this matter we believe the tide would soon be turned in the direction of honey as a daily food.

Kretchmer Mfg. Co.—For a long time we had been promising Mr. E. Kretchmer, of the Kretchmer Mfg. Co., Red Oak, Iowa, to visit him and their factory. Finally we found

enjoy a view of the rich farming country with which Iowa abounds. It seems to us we never before had seen such abundant fields of

GEO. A. SMITH.

white clover in full bloom. The tempting fragrance could be inhaled from the open car windows as we sped swiftly along.

Mr. Kretchmer kindly met us with horse and buggy at the train as it rolled in at the Red Oak station. We rode through the town and on beyond about a half mile to his residence, which adjoins the factory, and all of them being located quite a distance from neighboring buildings.

The factory is on the left side of the road, as we drove to the entrance, and some 10 rods back, with a nice apiary of about 80 colonies of bees between, right on a carpet of white clover. We never saw quite so thick a mat of white clover in any apiary before. The bees had begun to work on the endless fields of clover just two or three days preceding our arrival, and were doing a hustling business. In fact, it seemed that all through the State of Iowa there was promise of a rich harvest of white clover honey.

Mr. Kretchmer located his factory in Red Oak 15 years ago, coming from Coburg, a few miles away, where he had taken up his residence over 30 years before. He came from Germany, and began to work on a farm at \$8 a month. In 1857, we believe it was, he got his first

JUSTUS C. KRETCHMER.

the opportunity to make the trip, starting from Chicago the night of June 12, and arriving there about 1:30 p.m. the next day.

Red Oak is 450 miles west of Chicago, so we had a ride almost across both States of Illinois and Iowa. We arrived at Burlington, Iowa, about daylight, so from there on we could

said to have the largest number of \$10,000 residences of any city in the West. That seemed a large saying, but as Mr. Kretchmer drove us up and down its delightfully abaded hills adorned with beautiful homes, we could but believe it was very near the truth. The

UNCAPPING-FORK.

buildings are all kept well painted, with door-yards nicely mown and tidied up. Red Oak certainly is a model residence place. And its people appear to take much pride in keeping up a thrifty and home-like appearance, which indicatea prosperity and success.

By the way, Red Oak has a "curfew whistle" at 9 p. m., instead of ringing a bell at that time for the children to go home. It is the whistle connected with the electric power and lighting plant which runs day and night.

We hope to visit Red Oak again some time. It is in itself an inspiration, and makes one feel like wanting to go there again.

**Mr. W. P. Just**, editor of the Sauk County (Wis.) News, called at this office June 24. Mr. Just is also a bee-keeper, and takes great interest in everything relating to the busy bee.

**Colorado Fair Apiarian Exhibit.**—**Mr. Frank Rauchfuss**, 1440 Market St., Denver, Colo., superintendent of the Apiary Department of the Colorado State Fair, to be

held at Pueblo, Sept. 11 to 15 inclusive, sends us a copy of the list of apiarian premiums offered, which are as follows:

	1st	2d	3d
Italian bees and queen in single-comb observatory hives .....	\$ 8 00	\$ 5 00	\$ 3 00
Carniolan bees and queen in single-comb observatory hives .....	8 00	5 00	3 00
Caucasian bees and queen in single-comb observatory hives .....	8 00	5 00	3 00
Largest and best display of beea of various races in observatory hives .....	10 00	6 00	4 00
Largest display of queens of various races in mailing-cages .....	5 00	3 00	2 00
Best case of white comb honey .....	3 00	2 00	1 00
Best case of light amber comb honey .....	2 50	1 50	1 00
Best and largest display of comb honey .....	10 00	6 00	4 00
Best display of special designs .....	3 00	2 00	1 00
Best dozen jars of white extracted honey .....	2 50	1 50	1 00
Best dozen jars of light amber extracted honey ..	2 00	1 50	50
Best and largest display of extracted honey .....	8 00	5 00	3 00
Best display of extracted honey in granulated form ..	3 00	2 00	1 00
Best 10 pounds of yellow beeswax .....	2 00	1 00	50
Best and largest display of beeswax .....	5 00	3 00	2 00
Best display of special designs in beeswax .....	3 00	2 00	1 00
Best display of honey-producing plants, mounted ..	3 00	2 00	1 00
Best display of fruits preserved in honey .....	3 00	2 00	1 00
Most instructive display of apiarian products and of the various uses made of honey and beeswax .....	20 00	10 00	5 00

All honey and beeswax must be Colorado products.

Mr. J. A. Green is the assistant superintendent. Surely Messrs. Rauchfuss and Green should be able to get together a great apiarian exhibit if anybody could, for there are not two abler bee-keepers and general hustlers in all beedom.

Mr. Rauchfuss says: "We have now a larger list and better premium than formerly, and hope to have a larger display than ever."

The way to keep up a good and liberal premium list is for honey-producers to show their appreciation by making a big display. And Colorado bee-keepers know how to do it, too. Write Mr. Rauchfuss for any further desired information.

**Mr. Frank G. Odell**, of Lancaster Co., Nebr., was a caller at our office recently. He has about 20 colonies of bees, and intends to increase to perhaps 100, then make a specialty of queen-rearing. In fact, he has already begun the work. And he will succeed.

**Rev. A. R. Seaman**, of Fayette Co., Pa., dropped in to see us June 24. He has about 40 colonies of bees, and is located in the great iron manufacturing region where there is a good deal of smoke and dust that is not conducive to the growth of honey-plants.

**Mr. E. B. Gladish**, secretary of the Leahy Mfg. Co., of Lafayette Co., Mo., wrote us June 26: "The honey crop has been good here locally so far this season. We had a nice rain to-day."

## How to Treat Foul Brood by the Baldrige Plan

BY M. M. BALDRIDGE

**T**HE Baldrige plan of treating a foul-broody colony successfully is as follows:

1st. Open the hive of the diseased colony and cage the queen. The best time to do this is late in the afternoon or near sunset. Place the caged queen in the top of the foul-broody hive, and where the cage can be got at with as little trouble as possible.

2d. Bore a small hole—about one inch in diameter—in the front end of the foul-broody hive a few inches above the regular entrance, and fasten over it on the outside of the hive a Porter bee-escape. After the bees are through flying for the day turn the foul-broody hive half way around so the bee-entrance will face the opposite direction.

3d. Now go to some healthy colony and select one or two combs of brood well covered with bees, and place them in an empty hive and fill this hive with empty combs, frames of comb foundation, or empty frames, and set this hive on the stand of the diseased colony. The rear ends of both hives will now touch each other, or they may be a few inches apart. Now leave the hive thus say 2, 3 or 4 days, or long enough for the outdoor workers in the foul-broody colony to return to their old location. This they will do, of course, and they will then remain in the new hive having one or two combs of healthy brood.

4th. Near sunset of the second or third day take the caged

queen away from the diseased colony and simply let her run into the entrance of the new hive.

5th. Now close the regular entrance of the foul-broody hive and all other exits except the one through the bee-escape. Then gently place this hive by the side of the new hive and close to each other, the closer the better, with both fronts facing the same way. Thereafter the bees that hatch or fly out of the diseased colony must pass through or out of the bee-escape, and as they can not return they must and will go into the new hive. By this means the new hive, in the course of 3 or 4 weeks, will secure all, or nearly all, the bees and brood that were in the diseased colony, and during this time, or for any length of time thereafter, no robber bees can gain entrance thereto and carry away any diseased honey.

This plan of treating foul-broody colonies prevents all loss in bees, brood, honey, or the building of new combs, and is a simple and practical way of treating the disease. In some respects the plan is a far better one than any other I have seen described.

My plan may be carried out in divers ways, but it is not always best to describe such and thereby confuse the reader. The entire plan is based upon the well-known fact that foul brood is a *germ* disease, and that the germs may be taken into a new hive by the bees filling their bodies with the diseased honey deposited in the foul-broody hive. The disease may likewise be taken into the new hive by the *nurse-bees*. My plan does away with all such danger, for when the diseased colony is left undisturbed over night the bees re-deposit all their honey, and on going out to work the following day they go out with empty bodies and return with healthy honey. All the *nurse-bees* will remain in the diseased colony, and before they pass out of their hive through the bee-escape all germs in their bodies will have been disposed of in nursing the uncapped brood in the foul-broody colony.

My plan of treating foul brood is not exactly a new plan, as it was outlined by me in 1897, page 333, in the *Bee-Keepers' Review*. Since that date I have treated a number of foul-broody colonies by my plan, and always with good success. I am advised that others have done likewise.

Kane Co., Ills., June 20.

## Dodder or Love-Vine—Other Honey-Plants

BY PROF. A. J. COOK

I HAVE an interesting letter from Mr. B. S. Taylor, now of Riverside Co., Calif., but formerly of Michigan. Mr. Taylor has 400 colonies of bees, and has made quite a success in apiculture since coming to this State. He now calls attention to the fact that gold-thread, or dodder, is destroying much of the wild buckwheat—*Eriogonum fasciculatum*, which is one of our much-prized honey plants of Southern California. I have noticed ever since I came to this section that this dodder was seriously menacing the very life and existence of our wild buckwheat, yet I think that it will take many years before it exterminates the plant, if it ever is able to do so.

This dodder is a plant of many names. It is known as dodder all over the country; as gold-thread here in California, and we often hear it referred to as love-vine. These last names are quite appropriate, as it is thread-like in appearance, and it is golden-yellow in color. It twines about its victims in a very close, loving way, and though with no loving thought such would be suggested by its close embrace. It is known to science as *Cuscuta Californica*, and there are three other species (one *C. subinclusa*, which is very common), which are found in this county.

This dodder is a very interesting plant for three reasons: It is a parasite, which accounts for its color, as all plants that have not the green which comes from chlorophyl must depend upon other plants or organisms for their nutriment, and so sponge their living. This is the habit of dodder, and thus it is that Mr. Taylor rightly brings his plaint against this plant murderer.

This plant also interests us as it victimizes some of our best and most prized plants, notably alfalfa, which suffers greatly from its attack. Indeed, I know of no enemy that the alfalfa-grower more dreads. It is, on the whole, a worse enemy of this incomparable forage-plant than is the ubiquitous gopher or the destroying wire-worm.

The third peculiarity that attracts interest to this love-vine, is its life history, which is surely unique, and which may be truly "made to point a moral and to adorn a tale." Its tiny seed drops like other seeds to the earth, takes root after the manner of all proper seeds, and springs up with no peculiar feature except its exceptional color, which, in itself, is a threat and a promise of evil. It now stretches up its golden strands, entwines the luckless herb or shrub that promises companionship, and now loses connection with the earth, and draws all of its nourishment from the host that not only holds it up, but gives it its entire support. This is how the buckwheat suffers, and why Mr. Taylor is disturbed as he sees one of our best honey-plants sacrificed to support this grasping parasite.

In most of our works on botany, this plant is included in the morning-glory family—the convolvulaceae. Some of our recent authorities put it in a separate family—cuscutaceae.

We may describe dodder briefly as follows: Annual, leafless, parasitic herbs, with string-like twining golden stems that are entirely destitute of the green that comes of the presence of chlorophyl. The flowers are very small; in the present species hardly more than a line (1-12 of an inch) long, and are borne in clusters on the side of the slender stems. The calyx and the corolla are of the same color, the latter being deeply five-cleft. The corolla-lobes are slightly longer than the campanulate tube. There are five stamens inserted on the corolla-tube, but the scale-like appendages usually inserted below the stamens are absent in this species. The ovary is globular and two-celled, with two seeds in each cell. The seeds are small, irregularly rounded, and, as we see from the above, are very numerous.

As stated above, this plant is a great alfalficide, and the form and size of the seed make it possible to avoid it. The alfalfa seed is crescent shaped, and not a little larger than is the dodder seed. Every one interested in growing alfalfa should possess himself of a good hand lens, and learn to detect the presence of dodder seed in case it is present with the alfalfa seed that he plans to use. In case he finds the intruder present, he must take great pains to screen it out. From the smaller size of the seed this only requires a little pains, and with the free use of the lens may be done very perfectly.

The method of eradication in the alfalfa meadow is not difficult of application, and will succeed with a fair trial. We have only to put straw over the patch, which, from the bright color of the gold-thread, is easily seen, and then burn. This better be done as soon as the dodder is discovered, and thus seed will not be formed. As the dodder is rootless we will destroy it all in this eremation of its host. If all would practice this method, and exercise care to screen all seed that con-

tains the dodder seed, this pest might soon be banished from the alfalfa fields, and large amounts saved to the growers of this incomparable forage-plant.

In answer to Mr. Taylor regarding this pest in the bush, where it runs riot among the buckwheat, I can only suggest this same fire-and-torch method. If it will pay to take this pains we could soon very materially lessen the evil, and so keep this valuable honey-plant. It might pay well to do this, and surely it will be well to give the matter earnest consideration, as I have noticed, as Mr. Taylor has, the rapid increase of this pest along the roadsides about Claremont.

### HONEY AND THE WEATHER.

We have been having very exceptionally cold, wet, foggy weather for this region. A few days ago we had a few very warm days, and the way the honey came in was most encouraging to the bee-keeper. Now for days it has been so cold that we were more comfortable with a daily fire, and the fogs were very pronounced each day. It was so cold that the bees ventured out but little, and, of course, the amount of honey gathered was very light. Now we are having it warmer again, and the bees are at work at a more lively pace, and we may expect a good harvest as the abundance of bloom is phenomenal. The black sage is now in full bloom, and white sage is just opening.

### CALIFORNIA HONEY-PLANTS.

I have been noticing the bees at work the past few days, and marvel at the richness of our bee-forage. The peppers, both staminate and pistillate trees, are humming all the day through with the bees as they crowd the bloom with their presence. There are many mints that share with the sages the friendly, appreciative visits of the bees. The abundant horehound is now in full bloom, and I notice that it, as well as the black sage and the abundant salvias, is crowded all the day long with the honey-gatherers. *Phacelia tanacetifolia*, with several other species of the same genus, is swarming with the nectar-lovers. Several species of gillias are now in full bloom, one of which—*Gilia capitata*—has great heads of flowers, and bears beautiful blue pollen. I was greatly interested the first year I came here to see the novel sight of bees heavily laden with this blue pollen, and was not content till I had hunted out its source. I find that several of the gillias bear this, and I am glad to state that all of these gillias are good honey-plants.

### BARREN FRUIT-TREES.

J. C., of Geoeva, N. Y., asks my opinion why his pear-trees do not set any fruit. He adds that they blossom full, but fail to set almost entirely. I will soon give a full paper on this subject, but will only say that in such cases lack of pollination is usually the explanation. With pears, especially, and there are so many other fruits of which this is equally true, cross-pollination is often imperative to the production of a crop. It is always wise in setting orchards to mix varieties. Even granting it is better to grow just one kind of fruit, there should be a sparing admixture of other varieties, at least one tree in eight, if not in four. Care, too, should be exercised that the varieties blossom at the same time. It is true, however, that this cross-pollination is not always necessary. The Bartlett pear is often entirely sterile to its own pollen, yet I have known rare cases where it was wholly a success under such circumstances. Probably season and climate have much to do with this.

Los Angeles Co., Calif., May 29.

## A Few Apian Notes and Comments

BY G. M. DOOLITTLE

HOW do you pronounce s-t-i-n-g-y?" asked Prof. Comstock. The smart boy nearest the foot of the class stood up and said, "It depends a great deal whether the word is applied to a man or a bee."

"Go to the head, young fellow."

### WHERE TO KEEP COMB HONEY.

To keep comb honey perfectly the temperature should never go below 70 degrees F. From 80 to 95 degrees is what should be aimed at during the daytime, and the room in which it is kept should be dry and airy, if possible. A dark room keeps the capping to the combs of a lighter color. Keeping honey in a warm room makes the body of it thicker and heavier. When thus kept, if there are any unsealed cells, the honey will become so thick in them that it will not run out, even if the combs are turned down on their sides. If the room

is damp, and the temperature falls lower than 60 degrees, the honey takes on moisture, becomes thin, and eventually runs from the combs and sours. Therefore, always store honey in an upper dry room, and *never* in the cellar, as so many are prone to do.

#### STUDY YOUR LOCAL HONEY-FLORA.

There is no subject of more importance to the bee-keeper, nor is there one that gives him more pleasure than the study of the honey-producing flora of his locality. No matter whether they bloom in the garden, the field or forest, or perchance along the roadside; if bees gather nectar from them they at once become an object of interest and investigation. The question of bee-forage is one that every one engaged in bee-keeping should investigate, for upon the amount and duration of the honey-producing plants and trees in the vicinity of the apiary depends the success or failure of the enterprise.

In locating an apiary for honey-production, one should have an eye to the amount of bee-forage in reach of the location, for no amount of labor and skill in the manipulation of our bees will pay where it is wanting. Having the desired flora in our location, and then so manipulating our colonies that the maximum amount of bees comes on the stage of action just at the time when the flora producing the maximum amount of nectar is in bloom, our success is assured. And without the desired flora, we can not meet with the success we otherwise would, for planting and sowing for honey where Nature does not give the same in profusion, can not make up for what is lacking. It will help some, however, where our environments keep us in a place where Nature does not furnish flowers in profusion.

#### HOW BEES BUILD CELLS WITH EXACTNESS.

The question is asked, "How can so many insects occupied at once on the edge of combs where it is dark, as in a beehive, concur in giving them the common curvature from one extremity to the other, as is found in the comb of the honey-bee?" It is supposed that this direct mathematical work is done by actual measurement, as each bee has a square or rule to measure by, in the shape of the antennae. All who have observed the antennae of the honey-bee know that there is a joint in each, out toward its end. In building worker-comb, which is 5 cells to the inch, this joint is closed like a jack-knife, so that when the antennae thus closed is straightened out on each side of the head, the folded joints just touch the walls of the cell, and thus each bee is enabled to work in harmony with every other bee in the hive, and we have every cell of worker-comb as nearly exact as the average carpenter can make a duplicate of the work of another carpenter.

In building drone-comb the antennae are straightened out fully straight, so that they touch the walls of the cells when fully extended at the extreme outside points, and by so doing larger cells are made, or those numbering 4 cells to the inch, which is the size of cells in drone-comb; and these are as uniform as to size as are those of the worker pattern. In this we see the wisdom of a kind Providence, which placed within the bee an instinctive capacity as great, according to its wants, as is the reasoning capacity in man.

#### FINDING BLACK OR HYBRID QUEENS.

To find a black or hybrid queen often baffles an expert. To say nothing of the novice. Much care at the beginning is the great secret of success. If possible, let the work be done between the hours of 10 a.m. and 2 p.m., when the largest number of field-bees are generally out at work, so that the hive is not congested with bees.

Open the hive slowly without a jar, and use as little smoke as possible. Be very careful not to kill a single bee, for if bees are killed the colony is liable to resent it, this causing so much smoke to be used in quieting them that the whole mass is likely to be "stampeded," under which condition it is nearly impossible to find any queen of any race.

Having the hive opened, remove the comb next to the side of the hive nearest you first, and sit on the east side of the hive during the forenoon, and the west side during the afternoon, thus allowing the sunlight to strike the side of the combs next to the operator. As soon as the first comb is examined, set it in a box or empty hive, placing the same on the side farthest from you. On removing the second comb from the hive, glance down upon the side of the comb in the hive which was next to the one you have now raised before you look at the one you have in your hands. If the queen is on that side of the comb, she will immediately, upon the strong sunlight striking her, commence to run around the comb to get out of the light. If you do not see her at once (which you will be apt to do if she is there, as the strong light striking

against the side of the abdomen as she is running, will arrest your attention as nothing else would), then look on the side of the comb you hold in your hands that is the farthest from you, as the queen is sure to be on one of the dark sides of the combs. If she is not seen here, set this comb in the box up against the one that you put in first.

Proceed in this manner till all the frames are taken from the hive and placed in the box, unless you find the queen sooner. If not found, proceed to look in any corner of the hive wherever you see little clusters of bees, for if the queen is very shy she may leave the combs and run down into the corners of the hive. Not finding the queen in the hive proceed to take the combs from the box in the same order you took them from the hive, and glance the combs over in the same way, and in nine cases out of ten any one should find any queen before the combs are all back in the hive again, even if the colony is composed of black bees in their purity, and the operator is only a novice.

As noted at the beginning, care at the start so as not to stampede the bees, is the great secret of success, and this coupled with a strong light and a knowledge of how any queen behaves under such conditions, gives you the key to the whole matter. Onondaga Co., N. Y.

## Convention Proceedings

### Papers Read at the Minnesota Convention

Held at Minneapolis, Dec. 7 and 8, 1904

#### SELLING HONEY THROUGH GROCERS.

The methods of selling honey through the grocery trade, whether in cities or small towns, must be pretty much the same in all essential respects. It will hardly pay to attempt to sell honey from house to house, especially in cities. There is already too much of the peddling or canvassing business done there. It is becoming an unbearable nuisance to the house-keepers. So I take it that the best way for the honey-seller is to work through the grocers who are already established and are supplying families with other things for their tables.

At present honey is considered by consumers a luxury, or else is not bought on account of fear of its adulteration. In either case it will be necessary to do considerable educating. Honey should be used more, and will be when once the people come to know its value as a food, and also when they can be assured that they are getting the absolutely pure article every time they buy honey.

But one of the main questions is, How put up honey so that grocers will be induced to handle it? Of course it must be in suitable or convenient packages. Comb honey will always be retailed by the section, which usually weighs about one pound. And the price should be for the best grades, from 18 to 25 cents, depending upon the locality—or ability of the consumers to pay. People who think they can afford to pay 10 cents or more for a useless cigar certainly should not object to paying 25 cents a pound for honey.

Extracted honey, put up in neat labeled jars holding a pound each, should retail for at least as much as a section of honey.

It is very important that honey of always the same grade and flavor be bottled. If these characteristics are varied, the consumer's suspicions are at once aroused, and he thinks he is being swindled by an adulterated or mixed article. He does not know that different kinds of flowers produce different flavored honeys. Where a bee-keeper or honey-dealer has a mild-flavored honey, but of insufficient quantity to supply his demand year in and year out, he can buy a stronger-flavored honey to mix with the mild kind, and thus increase his supply, and with about the same flavor.

In order to do a bottling business of any magnitude, or where one bottles several tons of honey a year, it is necessary to be equipped to do it rapidly and well. A full equipment will cost about \$100, which includes hot-water heater, a metal melting-box for 60-pound tin cans, and a combined mixing and filling tank with jacket for holding hot

water. A firm with which I am familiar has such an outfit, and can bottle about a half-ton of honey a day.

This concern's melting-box holds 18 60-pound cans at one time, and the bottle-filling tank about 100 gallons. It also has a second filling tank holding about 50 gallons. This latter tank is used mainly for melting granulated honey that was in barrels. A barrel of honey is stood on end on a sheet of galvanized iron about 4 feet square laid on the floor. If the honey is not solidly grained, the edges of the metal sheet may be turned up, say two inches. After ending the barrel, it is all removed in pieces, except the bottom-end. The honey is then shoveled into the melting tank. This beats digging the honey out of the barrel. Emptied barrels are worth practically nothing, anyway, so they may as well be torn to pieces, and the honey shoveled, as mentioned. Perhaps the barrels could be sawed or broken up, so as to be burned in the heater, and thus be used as fuel for heating the water to melt the honey.

The heater and the melting tanks should be connected so that there can be a circulation of water through all of them at the same time, or arranged so that each can be disconnected at will.

The honey should be bottled and corked or capped hot, say as near 160 degrees as possible. But great care must be used not to let the honey stand long in the melting tanks at a high temperature. It should be bottled at *once*. If not, the flavor and color will be injured. If overheated, or allowed to stand too long at a high temperature, it becomes a dark amber, and somewhat bitter in taste. Of course such honey can be used for baking purposes or for making honey-vinegar, but even for baking I think that better honey would make better cakes and cookies.

Now, having the honey bottled, and nicely labeled, the next thing is to get it into the grocers' hands. Take a sample jar or bottle (several, if you have various sizes) and call on the grocer. Tell him your prices, and suggest at what prices the honey should be retailed. It is a good thing, also, to leave him a honey circular, giving directions as to the uses of honey and where to keep it properly. Tell him what day you will deliver whatever he orders, and try to have a fair-sized wagon-load *before* making any deliveries.

It is a good thing to make regular calls on the grocers, and see that they are kept supplied. Also, whenever you call leave a self-addressed card (authorized postal size) on which they can write their orders, affix a one-cent stamp, and then mail. Such cards are a convenience all around. If you have a telephone it is well to print your number on the card also.

Some honey-sellers have found it an advantage to have attractive honey show-cases which they *loan* to any grocer who will keep their honey for sale. Such case holds perhaps two or three dozen jars, and about as many sections of honey. The idea, then, is to load up a wagon with honey, call on the stores where the honey-cases are, and see that they are kept filled. This plan has worked well. It is rather expensive to start with, but as many grocers have no good place to put honey so that it can be seen by their customers, and also where it will be kept clean, a glass show-case is a good thing for all concerned.

An individual glass jar has been used with some success in the restaurant trade. It holds about two ounces of honey, and is also neatly labeled. The cost of the jar is about 2 cents. The jars can be returned after using, at one cent each. As many restaurants charge 10 cents for a serving of honey it will be seen that there is a profitable field for the individual honey-package for hotels and restaurants.

But what needs to be done *first* is to get into the heads of the consumers the fact that they can buy pure extracted honey; that comb honey is not made by machinery; that honey is the best sweet on earth; and that they ought to eat more of it, and cut out the glucose syrups and other questionable mixtures that are forever being palmed off on the public. These are matters in which every bee-keepers' association, as well as bee-keepers themselves, can help, and help mightily. We must all unite in *talking* honey, and also in getting newspapers to print items about honey. The National Bee-Keepers' Association should lead in this campaign, I think. It should prepare suitable matter for publication, and then its members and local organizations should see to it that every editor they know publishes it in his paper, even if it takes a little cash or several pounds of honey to induce him to do it.

I believe when the people of the United States once understand the honey question they will use our sweet in such quantities that bee-keepers will have to bestir themselves in order to supply the demand. Then the advice to "keep more bees" will be heeded more than it is now, for bee-keepers will see that there is a profitable outlet for their crops of honey, and that there is good money in the business.

I trust this convention will discuss this question fully. It means so much to every bee-keeper in the land. Just now there are bee-keepers who do not know how or where to dispose of their honey. In the good time coming such will not be the case. Honey-buyers will be hunting for honey—they will be calling on bee-keepers to send in their honey, and at a good price. May that happy day be hastened in its coming!

GEORGE W. YORK.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Some Sisters' Sayings and Doings

Over in England the sisters seem to have gotten the start of the brothers—at least their bees have—as appears from the following item in the British Bee Journal:

"Mrs. Wright would like to inform the editors of the British Bee Journal that she had a swarm of bees from one of her hives at noon on May 6."

This seems to have been the earliest swarm reported.

On the other hand, a sister in Australia seems to have come to grief from having been too slow, according to the following from the Australasian Bee-Keeper:

"Mrs. Amos Milford, wife of a fruit-grower, whose house and orchard are situated at Harcourt, Victoria, walked into the garden yesterday, and, as she did not return, her husband went in search of her. He was horrified to find his wife prostrate on the ground, her head and shoulders black with a swarm of bees, which had evidently attacked and settled on the unfortunate woman. The bees were driven off and medical assistance hastily summoned. Mrs. Milford, however, is suf-

fering so greatly from pain and shock that her condition is regarded as very critical."

Does any sister live in the vicinity of Mad. Cawein, who can coach her a little on the matter of bees and rotten peaches before she writes another book of poetry? The Literary Digest, which calls her a poet of Nature, gives the following as a specimen stanza:

Bee-bitten in the orchard hung  
The peach, or, fallen in the weeds,  
Lay rotting where still sucked and sung  
The wild bee, boring to the seeds  
That to the pulpy honey clung.

"Stenog," of Gleanings, seems to think it is not entirely according to Nature "when we are called to watch a bee making its way by boring into a rotting peach lying on the ground." But, then, "Stenog" is not "a poet of Nature," and is not up on poetic license. Indeed, it is generally understood that he is not a license man at all, either high or low. He should remember, too, that this was a "wild bee," that had never had the ways of Nature trained out of it in a Danzenbaker hive. Neither was it a common peach, but one of the poetic kind that turns into honey. What a beautiful thought is expressed in the words,

..... "the seeds  
That to the pulpy honey clung,"

How plainly that brings before us the picture of the clinging nature of peach-seeds, clinging to the honey, "pulpy" honey at that! No, "Stenog" is not "a poet of Nature."

### Bee Dress, Veil and Gloves

I do not know how other women bee-keepers dress, but after a number of years in the business I have settled down to pretty much one style of dress, and one kind of veil and gloves. In the first place, I tried wrappers—the usual kind with loose fronts—but for several reasons I found them unsuited to the work before me. First, they are too warm to admit of anything being worn over them, and not having the sleeves lined the bees would sting the arms and shoulders through the thin fabric of which summer wrappers are commonly made. Next, the loose front, even when belted down by girle or apron, would drag down when obliged to stoop for a length of time over the hives, so that it quite seriously interfered with the free use of the feet at such times. Again, when carrying heavy hives and supers, the weight pressed against the dress would pull down this loose portion enough to almost trip one down, especially if obliged to travel over rough ground or through high grass.

For the above reasons, also because of their unwieldiness in the wash-tub and on the ironing-board, the wrappers were discarded and loose, unlined, bloused-waist suits adopted instead.

These suits are made of calico or gingham,

with gored and neatly-fitted skirt which opens directly in front. If placket is properly made the closing will be practically invisible. The skirt is joined, by means of a narrow belt, to a carefully fitted bloused waist cut after the latest shirt-waist pattern. The waist is closed with buttons, the button-holes being placed close together. The neck is finished with a wide ruffle which falls well down over the shoulders. The sleeves, instead of being finished with cuffs, are simply hemmed and a rubber cord run into the hems. Over the dress I wear, when working in the apiary, a common dressing-sack made of flannelette or outing flannel. These suits are neat, easily made, and very easily laundered. They very closely resemble the two-piece shirt-waist suits so popular the past few seasons.

Veil and hat are made in one. The hat is usually a good quality of straw or cloth, such as the men wear in the fields. To the outside edge of the rim is sewed a wide, full veil of tulle or mosquito-netting, with face part of best grade of sewing-silk face-veiling. In the bottom of the veil is rubber cord or a round, smooth shoe-lace, put in "draw-string" fashion. The veil is drawn up close about the neck, under the ruffle of the neck of the dress, thus making a bee-proof combination here.

Gloves are of canvas or duck, such as are sold in country stores for 10 cents per pair. Sometimes old kid gloves are used, but these I do not like so well as the canvas. To the

top edges are sewed the tops of heavy ribbed black hose, which are drawn well up over the arms, thus preventing any bees from getting under the sleeves. Equipped in this way one may work among the bees for hours in comparative comfort. This rig I have found light, cool, and effective—in fact, all that could well be expected of a bee-dress.

Slippers were once a favorite summer footwear, but since working in the apiary I have learned to wear high shoes. In fact, I wore the slippers once too often, getting badly stung about the ankles as a consequence.

But while for my own use I sew veil and hat together, for the men folks I make veils separate with rubber cord in both top and bottom hems. I frequently notice, however, that they use the combination in preference to the separate articles. It is well to have a number of each kind on hand for the accommodation of visitors or extra help, as the case may be.

A thing which one should try to do is to make all these beforehand, for when the rushing season is fairly on there is very little time for extra work of any kind. This is more essential when women do the work in the apiary than where this falls to the men, since in the latter case the women are still free to make or mend gloves and veils, and do any other similar jobs, while, in the former, time even for the most trivial task often can not be found.

MRS. MILLIE HONAKER.

Vernon Co., Wis.

the flying force. As it was, you left the mother colony strong, and as soon as the first virgin queen was ready it sent out a swarm.

You will drive 3 weeks after the first drive, just the same as if there had been no swarming.

2. It is a more common thing than is generally supposed for bees to start queen-cells in a swarm soon after being hived, for the sake of superseding the queen.

### Ventilation of Hives

I use the Danzenbaker bottom-board, and have practiced, in a limited way, putting a piece of wire-cloth in the place of one-third or one-half of the bottom, sliding that much of the wooden bottom out. This is done for the purpose of giving ventilation across the bottom of the hive. Last year in no hive with such an arrangement did the bees cluster out evenings, while they did in the other hives. This wire-cloth produces about one inch more space beneath the frames, and sometimes comb is built below the bottom-bar. But the most serious drawback to the plan is that during hot days the bees cover the inside of the wire-cloth at the rear end of the hive, apparently frantically trying to get out, although the entrance at the front is wide open,  $\frac{1}{4}$  inch by width of hive.

It would seem as if the time and energy of several hundred bees was wholly wasted every day. Possibly a small outlet at the rear of the hive might relieve the situation.

Can you suggest any remedy? Is the ventilation worth the drawback? I suppose the light attracts the bees. I use this wire-cloth only between June 15 and Aug. 31.

MASSACHUSETTS.

ANSWER.—The ventilation is probably well worth the drawback. I don't know of anything better than your suggestion of a small outlet at rear of hive, unless it would be a large outlet. You perhaps think the proper place for the entrance is at the front, and that well-behaved bees should be satisfied with that. Well, now, you try giving a full entrance at the rear, and I prophesy that not a colony will use it as such, providing it is not given till June.

## Reports and Experiences

### Honey Crop a Failure

Honey is a complete failure in this locality. In some of my strong colonies the bees have not entered the supers, and some have starved since spring.

V. H. TUBB.

Walker Co., Ala., June 20.

### Worst Spring for Bees

This is the worst spring for bees I have seen. I have fed mine 500 pounds of honey since taking them out of the cellar, and have lost 7 colonies from being robbed, with entrances  $\frac{1}{2}$  closed.

LEWIS LAMKIN.

Woodbury Co., Iowa, June 19.

### Prices of Bee-Supplies

The first paragraph of that article, letter, or whatever it may be, by Mr. Hasty, on page 248, headed, "The Present Prices of Bee-Supplies," is a sort of puzzler to me. Why he doesn't want the price of sections any lower he doesn't explain. He gives us the impression that he believes it would be contrary to the spirit of Christ for bee-keepers to insist on getting them at lower prices than those given in the catalogs. I have read and believe the story of Jesus, from the immaculate conception to the resurrection and ascension, and find nothing in the wonderful record that requires me to love my neighbor better than myself. If it can be shown that the outside prices charged for sections afford the makers

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Probably Bee-Paralysis

What ails my bees? I have one Italian colony that has quite a lot of dead bees in front of the hive, and some are also crawling around in front of the hive. They seem not to be able to fly, and their intestines are full of a bad-smelling excrement. The brood is healthy and they are working well, but a good many on the entrance of the hive can not fly. Do you think that I would better burn it?

MICHIGAN.

ANSWER.—Don't think of burning. The trouble is probably paralysis, which is not likely to be very serious as far north as you are; although in the South it may be. You can try sprinkling thoroughly with sulphur, which O. O. Poppleton has found a cure. Dust the bees with it.

### Non-Swarming Bees—Increase—Comb Over Top-Bars

1. I have 6 colonies of bees, and none of them has swarmed yet. My neighbors' bees swarmed a long time ago. I have mine all in box-hives, and one colony began to cluster on the front of the hive the first day of June, and has been clustering more or less ever since, but has not swarmed yet. What do you think is the trouble?

2. Will it do to build up nuclei and divide colonies in July?

3. My bees build combs on the top of the brood-frames and between the super. Is it because there is too much room between the frames and the supers?

IOWA.

ANSWERS.—1. It is nothing strange; but without knowing particulars it is not easy to say just why one colony swarms and another does not. It is possible that your bees have more room, or younger queens, or that they are more shaded. Possibly your bees are of such disposition that they are not inclined to swarm; and, in that case, you are to be greatly congratulated. The one colony you mention may have been clustering out for want of room, yet with little disposition to swarm.

2. Yes, you can start new colonies in August, only the later you start them the less they can be left to themselves. For example, you might start a colony late in August by giving it rapidly frames of sealed brood with adhering bees, so as to fill up the hive.

3. You are likely to have at least a little building over top-bars no matter what you do. The more crowded a colony is, the more inclined to such work. If the space between top-bars and sections is more than  $\frac{1}{4}$  inch, the trouble will be aggravated.

### Transferring—Bees Starting Queen-Cells to Supersede

1. May 27 I tried to transfer a strong colony from a large box-hive, No. 1. I turned the hive up, then set hive No. 2 on it, and smoked and hammered a lot of bees out into the hive. I know I got the queen. After this I set the hive back, aiming to drive again in 21 days. After 4 or 5 days I took a peep at No. 2, which was on full sheets of foundation, and found one frame with cells about half built, and eggs in them. Another had queen-cells started. After 4 or 5 days I took another peep, and found another frame with eggs in, also the one that had the queen-cells on it. On taking a good look I find from 1 to 4 eggs in a cell; more of them had 4 than had 1, but there were generally 2 and 3. I took the frame out and put it in a nucleus to see what will become of the cells. No. 1 should have been ready to drive again June 18, but the 15th a very large swarm issued from it. Now I am at a loss to know just when to drive again, or just what to do, as I want them in a frame hive.

2. Why should No. 2 want to rear a queen when there is already a good queen in the colony?

ILLINOIS.

ANSWERS.—1. After making your drive you say you "set the hive back," by which I suppose you mean you set the old hive back on the old stand. That was a mistake. You ought to have put the driven swarm on the old stand and put the old hive on a new place. Then the driven swarm would have gotten all

# Tennessee Queens

Owing to the great demand for my TENNESSEE QUEENS for several seasons, and the quantity of standing orders from old customers, I decided not to advertise until my books were cleared of orders, and thus avoid disappointing customers.

I am now ready to fill orders by RETURN MAIL. Breeders used; Imported dark leather-colored Italian; my selections from light imported Italian; Moore's long-tongue; golden; Carniolan (mated to Carniolan drones in distant yard, and to Italian drones); imported Caucasian (lately received, mated for the present to Carniolan and Italian drones (after Aug. 1 to Caucasian drones).

Prices until Oct. 1.		After Oct. 1.		Tested—

I am able, and he claims something because of his necessities, but I believe that the spirit of "Live and let live," should be a part of the other fellow as well as of me.

When he comes to the matter of hives Mr. Hasty talks a little differently. He administers a very mild and harmless kick to the hinder parts of what seems to be taking shape in his mental vision as a bee-supply-makers' trust. Later, Mr. Hasty exhibits admirable fighting qualities when he sees this possible trust fastening a "yoke," which, of course, will be of no possible use till it has been adjusted to the necks of the bee-keeping world. He administers a most vigorous and well-deserved kick right in the stomach of the possible "octopus" in the presence and to the pleasure of applauding bystanders. These by-standers are saying for his encouragement, "Lay on, McDuff." I refrain from adding that part of the exclamation which follows the copula.

EDWIN BEVINS.

Decatur Co., Iowa.

### Poor Prospects for White Honey

June 6 Henry Alley reported, "Too dry for clover." I can report from western Pennsylvania, "Too wet for bees." The weather is very warm, with a thunder-storm every afternoon, and often another during the night. There will be but little white honey in west-

## Queens by Return Mail

The **Standard-Bred** kind, reared by some of the best queen-breeders in America, and warranted purely mated. Sent by **return mail** at these prices:  
One Untested Queen for 75 cents; 3 for \$2.10; or 6 for \$4.00.

## An Untested Italian Queen-Bee FREE as a Premium

For Sending One New Subscriber

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription **paid in advance** at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a **NEW** subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be **earned** in a legitimate way. They are worth working for.

If you can not get a new subscriber, and want one or more of these Queens, we will send the American Bee Journal a year and a Queen—both for only \$1.50.

Address all orders to

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL.

ern New York or Pennsylvania. There is no prospect for a change for the better. The grass crop is simply immense, but whether or not it can be made into hay remains to be seen. The cultivator and hoe are lying idle, while weeds flourish in all hoed crops.

Warren Co., Pa., June 20. W. J. DAVIS, 1st.

## You and Your Bees

—WILL LIKE—

### "THE ELGIN HIVE"

A proven success Not an experiment

"THE ELGIN" is comprised of fewer pieces than any other knocked-down hive. No nailing required to put it together. Any man, woman or child can assemble THE ELGIN in a few minutes. Saves labor, trouble and racked nerves. No pattern, diagram or book of instructions needed in order to set it up.

Simplicity of construction is such that mistakes are impossible. Standard size brood-frames, supers and other accessories perfectly fit "THE ELGIN."

Material and workmanship unexcelled. Patent corners of metal make it air and water tight, and prevent warping. Made in 8 and 10 frame sizes. Special sizes if desired.

Let us figure on your **Bee-Supplies—Hives, Sections, Frames, Foundation, etc. GOOD GOODS. SATISFACTORY PRICES.**

### CONVENTION NOTICES.

**Texas.**—The Texas State Bee-Keepers' Association will hold its next meeting at College Station, with the Farmers' Congress, July 25, 26 and 27, 1905. These annual meetings are usually largely attended and are pleasant and profitable occasions. Visiting bee-keepers from other States are cordially invited to be present with us. **W. H. LAWS, Pres.**  
**LOUIS H. SCHOLL, Sec.-Treas.**

**National.**—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will

begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Flint, Mich. **W. Z. HUTCHINSON, Sec.**

# SECTIONS

Millions of Sections. You want quick delivery. We have the facilities for executing orders promptly. Remember that

**Quality** is the first consideration about Sections. "Lewis Sections" means highest quality. Do not be misled by low prices. A clean-cut, brilliant, white section enhances the price of your honey.

## Shipping-Cases

Order your supply now. Pack your honey in cases before storing away; this keeps them in a bright, clean condition. We invite your inquiries. We can ship promptly.

## Honey and Beeswax

CHICAGO, June 19.—The little that sells consists chiefly of extracted and the market is a small one. Comb ranges from 12@12½c for the best white with off grades 10@10½c. Extracted, white, 5½@7c; amber, 5@6c. Beeswax, ready sale at 30c. R. A. BURNETT & CO.

CINCINNATI, June 2.—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4½@6c. according to quality. White clover extracted at 6½@8c. The comb honey market is practically closed for the summer. Beeswax, 26c. THE FRED W. MUTH CO.

BOSTON, May 23.—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12½@13c. Extracted, from 6@8c, according to quality. BLAKE, SCOTT & LEE.

PHILADELPHIA, June 21.—As the season advances, there is very little call for comb honey. In fact, no sales, and we make no quotations. Commission men are accepting any offer they can get for what little stock they have on hand. Extracted honey is in some demand. Possibilities of a big crop are holding prospective buyers back. We quote: Fancy white, 7@7½c; amber, 6@7c; dark, 5½@6c. Beeswax in good demand, 29@30c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

ALBANY, N.Y., June 17.—The honey market here is very dull now. It is between seasons. Receipts and demand very light. Very little old crop carried over, and will be in good shape for new crop, which begins in August. Quotations are nominal now. White comb, 12@14c; mixed, 10@12c; dark, 10@11c. Extracted, white, 6@6½c; mixed, 5½@6c; dark, 6@6½c. Beeswax, 28@30c. H. R. WRIGHT.

KANSAS CITY, June 21.—There is very little comb or extracted honey on the market at present, but what there is being quoted as follows: Fancy white comb, 24 section cases, \$2.25 to \$2.50; No. 1 white and amber, \$1.75 to \$2.00. Extracted, per pound, 4½@6c. Beeswax, 25@28c. C. C. CLEMONS & CO.

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Ex-

tracted honey in fairly good demand. New crop California honey selling at 6½@7c for water-white, 6@6½c for white, and 5@5½c for light amber. Southern at 50@60c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29c. HILDRETH & SGOELKEN

CINCINNATI, O., June 9.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5½@5¾c; in cans, 5¾@6c. Beeswax, 28c. C. H. W. WEBER.

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6½@7½c per pound. Beeswax, 26c. THE COLO. HONEY-PRODUCERS' ASSN.

SAN FRANCISCO, June 21.—White comb, 1-lb. sections, 11@—cents; amber, 8@10c. Extracted, white, 5½@—cents; light amber, 4@4½c; amber, 3@3½c; dark amber, 2½@—c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Samples of new crop are on the market, with asking prices mainly within range of 4@5½c per pound in carload lots at primary points for amber to water-white extracted. Some handlers estimated this year's yield of California honey at 250 carloads. This quantity has been materially exceeded in some previous years, but it is doubtful if the crop reaches the above mark this season.

# ONE-PIECE SECTIONS

JUNE BARGAIN—Stock C.

We have 300,000 No. 2—4 1-4 x 1 7-8 open-top Sections to move QUICK at the following prices :

1000—\$3.00	5000—\$13.75
3000— 8.50	10,000— 25.00

These Sections are extra good grade of No. 2, and we know will please you. Send your order quick.

**COLUMBIA MFG. CO.**

**ANTIGO, WIS.**

# HONEY CROP

Already the harvest has commenced. Now is the time to think of packages. Don't make the great mistake of neglecting this point. You may lose the entire profit of the year by shipping your honey in poor packages. Appearance counts in the market. When you buy **ROOT'S GOODS** you are sure of the best. Sections and Shipping-Cases; in fact, everything for the bee-keeper, can be promptly obtained at Root's Branches or Agencies everywhere.

### No-Drip Shipping-Cases

Don't allow your Comb Honey to be sold at low prices on account of poor Shipping-Cases. Put your crop into **Root's No-Drip Cases** and it will reach the market in perfect condition, thus bringing satisfactory returns. Our Cases are made of selected basswood, with 2 or 3 inch glass front, which shows off the honey to the very best advantage. Below is a condensed price-list. Complete prices and particulars are found in our general catalog.

Shipping-Cases. Name and Size of Case.	Nailed each			Price complete including 3-in. glass one side, nails and paper, in flat.	With 2 in. glass instead of 3— per 100.	Without the glass, per 100.

### Porter Bee-Escape

The great labor-saver. No well-regulated apiary can afford to be without it more than a smoker.  
 Price 20c each; \$2 25 per dozen, prepaid.  
 Price with board, 35c; \$3 20 for 10, not postpaid.

### Aikin Honey-Bags

Don't fail to try this package. It is now an established success. No loss by breakage. Easy to fill. No package so cheap and attractive. Develop a home trade that will prove very profitable.

### PRICE-LIST OF AIKIN HONEY BAGS.

Capacity	Size	Price of			Wt of 1000
		100	500	1000	
1-pound bags .....	3 1/2 x 5 1/2	\$ 65	\$3 00	\$ 5 50	10
2-pound bags .....	5 x 7 1/2	80	3 75	7 00	18
3 1/2-pound bags .....	6 x 9 1/2	1 00	4 75	8 75	28
5-pound bags .....	7 x 10	1 20	5 50	10 00	35
10-pound bags .....	10 x 10 1/2	1 50	7 00	13 50	45
Printing name and address extra.....		30	75	1 00	

May be sent by mail at 1Sc per pound extra for postage and packing.

### The Simplex Jar

The handsomest glass package on the market. It's a package you need not be ashamed of, and will find its way beside the finest of the grocery shelves. Create a demand for your honey.

This is a new jar with glass screw-top and rubber gasket fitted to the taper screw on jar, which seals absolutely air-tight. Put up in re-shipping cases of 2 dozen jars each, with corrugated protectors.

Price \$1.10 per case; 6 cases @ \$1.05; 20 cases or more @ \$1.00.

### Honey-Labels

We print them. Write for our sample book.

### 5-Gallon Square Cans

The above cut shows the favorite package for shipping extracted honey. There is no shrinkage and consequent leaking; no taint to the honey from wood, as is so frequently the case with barrels and kegs. The cans, being made square, economize space, and are easily boxed. They are used exclusively in the far West. Take 4th class freight-rate.

### PRICE LIST OF SQUARE CANS.

No. in a box.	Capacity of each can in gallons.	in honey.	Price of		Wt. of 1 box.
			1 box.	10 bxs.

## Editorial Notes and Comments

### Bottom-Starters in Sections

On another page in this number, Dr. Miller makes a strong plea for the value of starters of comb foundation at the bottom as well as the top of sections. But it must not be forgotten that bottom-starters are one of the Doctor's own inventions, and every one is partial to his own baby. Do others who have tried them find the same advantages? It certainly is more work to put double the number of starters in a section, and there should be no small gain to warrant so much trouble.

Another thing: By his own confession Dr. Miller is troubled with poor seasons; in a good season is there any advantage—or, rather, a sufficiently paying advantage—in having bottom-starters?

To those not familiar with the matter, it may be well to explain that a bottom-starter  $\frac{3}{8}$  of an inch deep is fastened in the bottom of the section, and the top starter comes down to within about a fourth of an inch of the bottom one. (See illustration on page 456.)

Some beginner is likely to say, "Why not make the top-starter deep enough to come clear down to the bottom-bar of the section?" Because if that is done the foundation will stretch enough to allow it to buckle and bend over to one side, making the section a bulger. If a very small space is left to allow for stretching, the bees are likely, especially in a slow yield, to keep a space between the starter and the bottom-bar. The space between the two starters allows for the stretching, and the bottom-starter prevents any space being left next to the bottom-bar of the section.

### Comb Honey and The League

In the Chicago Daily News for June 21 appeared the following, which, we believe, would be a good thing to have published in every newspaper in the land:

#### Comb Honey

In March, 1905, there was formed in Chicago, and incorporated the following month in Illinois, an organization called The Honey-Producers' League. One of its objects is "to

publish facts about honey and counteract misrepresentations of the same." It is hoped through the efforts of this League, with the co-operation of the leading newspapers and magazines of our country, to turn the tide in favor of the use of honey as a daily food, and also, as before stated, to endeavor to correct the popular delusion that comb honey is a man-made article.

Some 25 years ago a noted "professor," in order to work off a superabundance of "fun," as he termed it, published the statement that honey-comb was manufactured, then filled with glucose and sealed over, all with appropriate machinery. It seems that the press of those days was waiting to welcome such a yarn and forthwith scattered the news throughout the length and breadth of the land. It was so well done, and seemed to be so eagerly swallowed by the public, that its unfortunate repetition has been going on during all the years. The very best of metropolitan dailies of largest circulations, have been deceived by the comb-honey misrepresentations, and have unwittingly aided in its further dissemination.

Almost for the last 20 years there has been a standing offer of \$1000 made by a reputable firm for just one pound of the so-called manufactured comb honey. But if there is any such article in existence, strange to say no one has as yet proved his claim to the reward offered. The fact is, comb honey has never been made except by bees, as otherwise it is a mechanical impossibility.

It is true that the liquid honey—honey taken from the original honey-comb by centrifugal force—is sometimes adulterated with glucose and offered as a pure article, but the various State food laws are fast getting after such adulteration, and either compelling its true labeling or driving it from the open market. At least since the passage and enforcement of such laws in various States adulterated liquid honey is disappearing from the field of food products.

To sum up, then, any comb honey found upon the market in small wooden frames can be relied upon as being absolutely pure bees' honey. Of course, the flavor may not always be the same, as each nectar-yielding variety of flower produces honey of its own peculiar aroma, just as the pure maple sugar or syrup tastes of the maple and not of the beech or oak.

It may be said, further, that the prospects for a generous crop of honey to be harvested throughout the country the next two or three months seem to be excellent at this time. So, in all probability, there will be plenty of this most healthful sweet for every inhabitant in

in the land, and each should see to it that he gets his share. GEORGE W. YORK,  
Manager The Honey-Producers' League.

If any of our readers will try to have this published in their local newspapers, we will be pleased to furnish copies of it printed from type-writer type, on one side of the paper, which can simply be handed to the local editor with the request to publish.

If the above brief item could be gotten into several thousand newspapers within the next two or three months, we believe it would help the sale of honey tremendously, and would also go far toward overcoming the evil effect of the manufactured-comb-honey story that has been going the rounds of the newspaper press for so many years.

If any of our readers can use the article that appeared in the Daily News, as published herewith, let us know, and we will be pleased to furnish a type-written copy of it, on receipt of a 2-cent stamp.

Since the foregoing was written, we have received several marked copies of the Philadelphia Press, of which Hon. Chas. Emory Smith is the editor-in-chief. Mr. Wm. A. Selser, a member of The Honey-Producers' League, had an interview with him, and, as a result, Editor Smith published the following as an editorial in the Press for June 24:

#### Honey and Pure Food

Pure food has its myths as well as every other crusade for reform.

The ingenious story printed as a Sunday special in the supplement of a number of papers by a Newark correspondent, who made a business of furnishing ingenious hoaxes, that honey was made of glucose and forced into combs made of paraffin, has remained for 20 years the bane of the honey industry and the sport of the exchange editor.

The old story is still in circulation, passes through that devious orbit which begins with the syndicate, passes to the Sunday special, finds its way to the patent insert, is repeated by more reputable weeklies, taken up again by some ingenious writer and started again on its syndicate course.

The Honey-Producers' League, formed in Chicago last March, has enlisted itself in the effort to end this myth. For years it appears there has been a standing offer of \$1000 for any honey of this character. In the nature of things, neither paraffin combs nor glucose filling can be prepared and sold at the price at which actual honey can be furnished. Liquid honey, separated from the comb, is sometimes adulterated, but any bee-keeper is aware that it is impossible by artificial means

to counterfeit the disposition of honey in the comb as made by the ingenious and busy but non-adulterating bee.

Honey was the earliest of sweets. It undoubtedly began the human preference for sweets by its consumption in the days of the Lemur and the later Simian ancestor who succeeded the Lemur in the chain of human development. It produces none of the dietetic disturbances due to either beet or cane sugars. Its production steadily increases in this country. Its consumption grows, and, in time, if The Honey-Producers' League accomplishes all that it proposes, people will undoubtedly understand that no food is so free from adulteration as honey in the comb.

## Miscellaneous News Items

**Mr. J. T. Calvert**, of The A. I. Root Co., dropped in to see us last week when on a trip among some of the bee-supply manufacturers of the Northwest.

**Southern Bee-Keepers' Association.**—This Association is sending out a very neat little booklet containing the program of its second annual convention to be held at Savannah, Ga., July 5, with some beautiful illustrations. Wisely, the program is not so crowded with long papers as to prevent impromptu discussion. Those who can not attend the convention are asked to become members by sending 50 cents to the secretary-treasurer, Judson Heard, of Macon, Ga.

**Mr. H. G. Quirin**, of Ohio, according to a half-column write-up in the Cincinnati Enquirer, is making a small fortune from producing honey and rearing queens. It figures an annual output of queens at 3000, selling at \$1 to \$6, or an average of \$2 each, or \$6000. Then it also estimates \$1780 from the sale of honey and bees. We think Mr. Quirin, or any other queen-breeder and honey-producer, would like to see the man (or woman) who gets \$7780 annually from the sources mentioned. Truly, if such were the case, there would be a grand rush into the business.

**Mr. Jos. Nysewander**, of Des Moines, Iowa, is perhaps as large a dealer in bee-keepers' supplies as there is outside of the ranks of the manufacturers who also do a retail business. It was our good fortune to visit him on June 14, coming from the Kretschmer Mfg. Co., of whom we wrote last week in these columns. We walked into the office about 11 a.m., and found both Mr. and Mrs. Nysewander hard at work taking care of the correspondence which was just bordering on a "rush," as the bees of their many customers had begun to hustle on the thousands of acres of white clover bloom that was beginning to yield its nectar so bountifully.

For 22 years Mr. Nysewander has been in the bee-supply business in Des Moines. He's not an old man, either. He's just about the right age to be in his prime. So is his good wife. They certainly make a big team. They unfortunately have no children, so Mrs. N. helps in the office in the busy season. It is a fine sort of partnership. "All in the family," you see. And all the family in it, too.

We would hardly like to tell how much business Mr. Nysewander did last year, but

Surely, bee-keepers owe Editor Smith a big vote of thanks for the above utterance. We hope the honey-producing readers of the Philadelphia Press will write and thank him for it. We have already done so as Manager of The Honey-Producers' League.

Let us urge again that all of our readers who have any influence with the editors of their local newspapers, request them to publish the short article on "Comb Honey," which was published in the Chicago Daily News.

It was quite satisfactory to him. And he must have satisfied a good many customers else the total sales would not have been so large.

Mr. N. owns the building shown on the first page. The lower two floors in width and the basement are used for the bee-supply business, and the upper two floors are divided into four apartments, which are rented to families at a good price. So it is a profitable as well as a convenient building for its owner. Mr. and Mrs. Nysewander reside some distance from their office. They had just sold

They had not changed a bit, unless it be for the better. And the success they have achieved is all deserved. May their tall shadows ne'er grow shorter, nor less in width.

**Home Apiary of Stanley Bros.**—Arthur and William H. Stanley are old-time bee-keepers in Lee Co., Ill. And neither of them is yet an old man. We called on them when on our way back to Chicago from our Iowa trip, June 15. They own about 300 colonies of bees between them, located in several apiaries besides the home apiary, one of which is in Clark Co., Wis. We believe all are run for comb honey except the Wisconsin apiary, which is devoted to the production of extracted.

Mr. Arthur Stanley is the inventor of the Stanley Queen-Incubator, which is a success in the hands of the queen-breeder.

When we were there the white clover was just beginning to yield, and so the bees were getting busy. Up to that time feeding seemed to be the order of the day, and for many days, as there had been so much cold and rainy weather previous to that time.

Stanley Bros. were right in the midst of strawberry-time. They also furnished various vegetables for the local market, all of which kept all hands very busy. We arrived before breakfast, our train having reached their

HOME APIARY OF STANLEY BROS., OF LEE CO., ILL.

their nice residence, and expected to move in a month or two. They will perhaps build another one in a better part of the city, although nearly all parts seemed delightful. Mr. Nysewander gave us a carriage ride for several hours, and we were surprised to see so many miles of beautiful residences, and also lawns and parks.

We first met Mr. and Mrs. Nysewander at the Philadelphia convention of the National Bee-Keepers' Association some years ago. It was then that Mr. W. A. Selser gave us that never-to-be-forgotten 30-mile drive along the Wissahickon River. Mr. James McNeill and Mr. and Mrs. Nysewander were also in the two-seated carriage. We had not met them since then until we saw them in Des Moines.

station,  $2\frac{1}{2}$  miles away, at about 5 a.m. It was a hot morning, at least we thought so after walking out to the Stanleys and back to town again in the hot morning sun. And we think we are pretty good on the walk, too.

**Honey-Preferences**—A "Stray Straw" in Gleanings reads thus:

"Prof. Cook, after testing pretty much all the honeys, pronounces sage 'pre-eminently superior.' The editor of the Modern Farmer puts Missouri honey at the top, and the editor of the Rural Bee-Keeper calls Wisconsin honey the best, which is only another way of saying that these three men live respectively in the three regions mentioned."

## Contributed Special Articles

### Advantages of Bottom-Starters in Sections

BY DR. C. C. MILLER

ON page 424, our affable Afterthinker refers to my saying sections look better with lock corner down, and says, "Wish you had been a little more explicit as to the *why* of that." Well, Mr. Hasty, I'll try to be explicit, and as you make some strong points against having lock corners at the bottom, which show that it is a somewhat important matter to have them the right way, we may as well talk the whole matter over.

First, as to being more explicit as to the *why* of sections looking better with lock corners down. They look better that way because—because—why, because they look nicer so. The matter of looks is a matter of taste, and I don't know enough to tell *why* a peach tastes better to one man and an apple to another. One thing, however, might be said, and that is that there is more symmetry in the appearance of a section with both visible corners alike. If both upper corners were lock corners, then it would be a question as to whether a lock corner or a plain corner looks better, and upon that question there might be a division of opinion.

I don't dispute the truth of all you say. Been through it all years ago; but much that you say is not true in this locality at the present time. And the things you say would not be true with you *if—you—used—bottom-starters*. I'm not sure that I ever so fully realized the value of bottom-starters as I do since reading what you say.

You say that sections filled with lock corner up "are much less inclined to be pulled apart in handling." That was true with me before I used bottom-starters, because the bees did not build the comb down to the bottom. But it isn't true now. The comb is well built to the bottom, and you would often have to examine closely to tell by the comb which was bottom and which top.

"Both in pile and in case I want a section to stand the other side up from what it did while being built," you say further. Most emphatically that's what I don't want, and what you wouldn't want if both top and bottom of the comb were well fastened to the wood. I want the sections to stand always (unless for a very short time) exactly as the bees had them standing. The honey stays in the cells best that way. Sometimes there's quite a slant to the cells.

"If the honey is all sealed how can it make any difference which side is up?" Yes, but it isn't always sealed, every single cell. Sometimes there will be one or more cells next the wood unsealed; at least in this locality. To be sure, if that honey is thoroughly ripened, as it ought to be, it is not likely to run out of the cell when upside down. But it is a little more sure to stay all right in the cell if left just as the bees placed it. Even the honey that is sealed will stay in the cell without running down against the capping at the lower side, just a *little* better, if left just as the bees placed it.

"Along the top-bar the honey is pretty sure to be plumped out fuller than along the bottom-bar; and finger-bruises would start little leaks else." There's where you have the advantage over me. When you turn a section upside down, you have a place to take hold. I haven't, because the comb is plump full at the bottom as well as at the top. But although yours is safer to handle, it doesn't look nearly so well; and what is of more importance, it doesn't ship so well. (But, say, we don't put finger-bruises in our sections.)

"And when the honey-yield is poor some sections are not attached to the bottom at all, and lots of them only attached an inch or so at one side of the bottom." I know all about that; have had them so they'd almost swing like a pendulum when turned on the side—not fit to ship at all. I don't have that sort of thing now. When the bees attack a section, about the first thing they do is to fasten top and bottom starter together, and at any time during the progress of that section it could be taken out and shipped with perfect safety without the danger of breaking out.

I'll tell you another thing that puzzled me for some time: Like you, I'm addicted to poor seasons; and often when the bees were storing very slowly I've had them fill honey faster on the part of the starter toward the middle of the super than

on the outer side of the starter. The result was that the bottom of the starter would swing over toward one side, and then the bees would fasten it to the separator. All at once they ceased doing that sort of work, and I wondered why, till it occurred to me that it couldn't swing over, because I had begun using bottom starters, and as the bees fastened top and bottom together there was no chance for swinging over to one side.

Now don't you come back at me, Mr. Hasty, by saying that you *do* use bottom-starters and have the troubles mentioned in spite of them. In that case, I can only say they work all right "in this locality." McHenry Co., Ill.

### Simple and Safe Way to Get Increase

BY F. GREINER

IN practicing the so-called "shook swarm" method, or when following the Heddon plan to prevent afterswarms, the mother colony cuts no figure in the production of comb honey. It is this mother colony which can be utilized advantageously to swell the number of colonies without incurring any risk, providing we can depend upon a fall honey-flow, and we have combs enough at our command to fill the hives. With comb foundation alone we can not increase as fast, although we will succeed in a measure.

On the seventh day after a colony has swarmed, following the Heddon plan referred to, we move the hive to a new location, and after the bees which have marked their location have left it, which will be after a few hours, we proceed to divide the bees and brood-comb, forming two or three nuclei. We observe that each division has a queen-cell or a virgin queen. Queen-cells are plenty at this time, and if we have some cells from choice stock, all the better. It is not very difficult to obtain choice cells if we manage rightly. Almost any good colony will finish up stocked-up cells in an upper story over an excluder at swarming-time or during the honey-flow. It is not the purpose of this article, however, to show how it may be accomplished. So I only say, each nucleus colony must be provided with a ripe cell, and combs added from time to time. A nucleus thus formed seldom fails to get its queen, and it is surprising how quickly the colony builds up when honey is coming in.

A year ago last winter one of my out-yards was almost wiped out of existence, and I did not make much of an effort to populate the empty hives. This season I am increasing on the nucleus plan explained above. A number of young queens have already commenced laying, and I find these nuclei are just the place to dump the many brood-combs obtained by "shaking."

All these early made-up colonies will be brought up in this manner to a state of populousness, not only to enable them to gather their winter stores, but also to give a fair surplus from buckwheat. I am now viewing the many fields being put into buckwheat in the locality around this out-yard with some anticipation. In localities without a fall honey-flow perhaps as good results may be obtained by feeding. But I am not partial to this kind of work, and do not recommend it. Ontario Co., N. Y.

### The Season—Shooting Down High Swarms

BY WM. STOLLEY

LAST winter my bees wintered well without any loss, but I have united with others several (rather medium) colonies having very old queens, thus reducing the number of colonies from 42 to 36, all of which are in the very best working condition now.

In January we had 8 zero days, and on 3 days, during that month bees had flights.

February brought us, from the 1st to the 15th, 15 zero days, and the temperature dropped as low as 26 degrees below zero during that cold spell. During the remainder of February bees were out more or less on 12 days, and in March the zero mark was not reached again, while bees flew on 21 days in that month.

Our spring was anything but favorable for bees—it was too cold and wet. The valley of the Platte River has been flooded several times, and but yesterday we had another down-pour of 2½ inches, flooding all lowlands once more. Many fields on low land are water-soaked, and farmers are still at it, trying to plant corn—4 weeks late.

White and red clovers are in bloom now, and bees are busy at work on them.

Alfalfa and sweet clover will very soon follow, and with suitable weather conditions a fair honey crop may be expected, where bees are in proper condition.

Generally speaking, winter losses of bees were heavy here. It was not until May 26 that I removed the winter packing in my apiary. Yesterday I had my first swarm of the season, and this reminded me of the severe criticism I suffered at the hands of Mrs. L. Fees (page 38), and our Afterthinker, Mr. Hasty (page 38), upon my applied "shot-gun remedy," as reported by me in the American Bee Journal of 1904, page 838. However, Miss Emma M. Wilson, of "Our Bee-Keeping Sisters," in a very sensible and able way defended me against the slur of the "telescope" sister, and I can well afford to trust that other practical and sensible bee-keepers will judge similarly with Miss Wilson about it.

It is true that a person with a weak vision, cross-eyed, or lacking in good judgment, will most likely make a bungling job of bringing down a swarm of bees (when clustered out of reach) by a well-aimed shot or two, but I hope that my report, and this rejoinder to the comments made upon my veracity, will cause other apiarists, who will have to deal with "high-flyers" this season, to apply the shot-gun remedy, and thus be convinced of the entire practicability of "bringing them down."

I regret that the "inner consciousness" of Mr. Hasty was so seriously aroused as to cause him to say that swarms shot off of trees can not *always* be landed at a spot beforehand ascertained. If Mr. Hasty had read carefully what I say about it in my article, his conscious troubles would have been avoided entirely, because I have *not* claimed that the cluster of bees will *always*, and under all circumstances, fall where the operator desires it to fall; but I said, "*as it happened*," etc., it brought down the cluster of bees *in every instance* right in front of the hive, properly adjusted. *And it did.*

Mr. Hasty's voluntary counsel and advice to adjust the hive *after* the dropping of the swarm is not very good advice, whereas the adjusting of the hive can be done much better, in most cases, before the shooting takes place, for the simple reason that even most gentle bees, after they have struck the ground when shot down, are angered and infurled to such a degree that it is decidedly unpleasant to fool around them adjusting the hive. If Mr. Hasty will give it a practical trial he is almost sure of being convinced. I have tried it in former years, and have profited by experience.

It is also my opinion that even in cases when bees are clustered too far out of reach for hiving them, and so located that they can not be brought down in front of a properly adjusted hive, several shots of fine shot fired right into the cluster is a very practical way to prevent absconding of the swarm, in a majority of cases.

Should it happen that the queen is killed by the shooting, the bees will, on their own account, return to their old hive, and thus not be lost to the apiarist by absconding.

Hall Co., Nebr., June 10.

### Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904.

The 14th convention of the Chicago-Northwestern Bee-Keepers' Association was held in Chicago, Nov. 30 and Dec. 1, 1904. The first session was called to order by Pres. George W. York, at 10:30 o'clock a. m., Nov. 30, after which Rev. R. B. McCain offered the following invocation:

"Almighty God our Heavenly Father, we rejoice in the fellowship of thy servants in the world who, whatever their avocations and occupations may be, may come together in fraternal relations and speak to each other of the interests of their lives. We thank Thee for the goodly number that have come here to talk over their daily work; and we pray, Heavenly Father, that Thou wilt give us the Master who walks in the midst of the blooming fields and waving corn, and who speaks the words of eternal truth to those who listen to Him. Wilt Thou give His direction and the guidance of His spirit in all we have to do. We pray Thou wilt

bless those left at home, protect them and keep them and watch over the interests of all Thy people. Guide us to Thy praise and glory while we live, and afterwards may we have an eternity to spend in Thy presence with Christ, our blessed Redeemer. Amen."

Pres. York at this point took the opportunity of introducing those present to one another, after which the secretary read the minutes of the preceding convention, which, on motion, were confirmed.

Secretary Moore—A great many years ago there was an honest old gentleman by the name of Jimmie Griffin, when I was very small, and he says, "Francke, blow your own horn or you'll never get a wife." So we have to blow our own horn a little or people won't know we are doing anything. The Executive Committee about three months ago got together and decided they would try to have a big meeting here this fall. We decided to send out two thousand notices of this meeting. We sent it to everybody that would likely, as we thought, come to the Live Stock Show in Chicago in December. Mr. York thought we would get quite a few dollars in. We got \$23 in the mail as a result of that, and we are hoping we will get many more dollars at this meeting.

The President appointed Messrs. Fluegge and Jacob as ushers.

Dr. Miller—After hearing the report of the Secretary I feel, as an officer of the National Association, like thanking the officers of this Association for the action they have taken. It didn't occur to me before that a thing of that kind would mean so much to the National as it does; and that sort of thing I think will help to increase the membership of the National. It is an auxiliary to it in increasing its numbers. I believe the action in that respect is worthy of commendation.

Pres. York—There were some who did not get the notice we mailed, and the reason is this: We took the American Bee Journal list, commencing with the State of Wisconsin and stopped when we got to the end of the two thousand notices, which included Wisconsin, Iowa, Illinois and Indiana. There was no intention to slight anybody, but we thought we had better stop when we got to the end of the two thousand.

Sec. Moore—I thought we would get a lot of people in, but I didn't expect to get even \$23 in the mail, but I was sure we would have a very big meeting.

Mr. Abbott—I want to call attention to one fact, that because only \$23 came in is no argument against the circular. Publicity is the biggest part of advertising. We newspaper men find they are always trying to play that racket on us every time, but a man doesn't throw his money away when he does not get returns. He lets people know he is in the world, and that is the biggest part of advertising.

The treasurer's report was read and approved, after which an intermission of ten minutes was taken to allow those present to pay their annual dues.

#### THERMOMETER IN THE BEE-CELLAR.

"Where should a thermometer hang in a bee-cellar?"

Dr. Miller—I should say that it is not an easy matter to decide always where a thermometer should be hung in the cellar. Quite a number of degrees difference will be found in different parts of the cellar. At the top it will be warmer than down at the bottom, so I try to find where I think will be about an average temperature for the cellar, and it does not matter so much where it is as that you keep your thermometer in the same place all the time. If I have it in any one place and decide about what I think the temperature is at which the bees are quietest, then I try to keep it at that temperature. Another thing, you can not go by absolute degrees, because thermometers vary so much. As I said before, it doesn't matter so much, then, what temperature you have as that you find at what temperature the bees seem most quiet, and then try to hold it at that.

Mr. Dadant—I wish to emphasize what Dr. Miller says as to the temperature at which bees are quietest. The thermometer is always needed to tell you whether, when the bees are not quiet, the temperature is too high or too low. If you find your bees quiet at say 40 degrees and you come back again and find they are not quiet, and the temperature is 42 degrees, you know it is a little too high. If you did not have a thermometer you would not be able to tell whether it was too high or too low. I believe that is the only purpose of the thermometer. If you can get your bees quiet and

find out what the temperature is under those conditions, and you keep your bees quiet at that temperature, it does not make any difference where your thermometer is.

Dr. Miller—I am not sure but there is a way of telling. If I understand Mr. Dadant correctly you can't tell by the noise of the bees whether they are too cold or too warm. I wouldn't like to be too critical about it, but I think when they begin to get too cold there is a kind of rattling noise, if I may so call it, of their wings, that you hear, and I don't think I could tell you what the other is, but there is a little difference in the noise, Mr. Dadant, between being too cold and too warm.

Mr. Colburn—In relation to this noise that you speak about, that is the noise bees make in the cellar, I have never had much experience in cellar-wintering—only two winters—and I found my bees making some sort of a noise all the time, and yet they came through last winter very nicely. The question is, how much or how little noise would a greenhorn want to observe in order to know what the temperature should be?

Mr. Stewart—Is there any temperature where bees always keep quiet in the cellar, or do they always keep quiet at any temperature in the cellar?

Dr. Miller—I think there are some who claim they can secure perfect quiet. I never could. I think you will find this: If you have one colony in the cellar and watch it closely you will find part of the time that colony will be perfectly quiet, and then it will have a spell of stirring up and it will be noisy, and then quiet for a long time. If you have a number of colonies in the cellar you will find that there will be a noise there all the time. At least that is the way I find it. At times there will be very little noise; it will suggest to you the blowing of a gentle breeze through the dead trees in winter time. That you will find at all times if your cellar is like mine; and that I think comes from the different colonies, here and there, making an unusual amount of noise. I don't believe there is any one colony that is all the time the same way. I think they have their spells of "turning over in bed," when they make a little more noise than usual. But as to trying to get them so that they are entirely quiet all the time, you might as well give that up. But, find the temperature at which they make the least noise. That is the point.

Mr. Kimmey—Do bees make more noise as they become too cold?

Dr. Miller—Yes.

Mr. Kimmey—Suppose I should find my thermometer at 28 degrees, would you advise me to leave it that way? Do you think it is possible to find it that way?

Dr. Miller—No. I think you might possibly find, the way you have it in your cellar, that they were most quiet at 40 degrees. I might find them most quiet at 47 degrees. That is, your place and my place may be different. But your question?

Mr. Kimmey—My point is, is it possible that the bees would be so cold that they would make less noise than they ought to?

Dr. Miller—No, sir, unless they are dead. When they are dead they make hardly any noise! (Laughter.)

Mr. Kimmey—I don't want that then. I have tried to keep mine between 45 and 50 degrees, and have succeeded very well and have not lost any. I would like to do better than that if I could!

Mr. Abbott—I would like to ask a question, to bring out a point. Dr. Miller says that they will make some noise unless they are so cold that they are dead. I should like to know if Dr. Miller thinks that bees ever get so cold in the cellar or out-of-doors that they die from cold when they have plenty to eat? I don't think they do.

Dr. Miller—There are some things I don't know. One of the things I do know is that Mr. Abbott doesn't think as I do about that. My bees will freeze. I take a bee in my hand and if I hold it out in the cold long enough, that bee is going to freeze.

Mr. Abbott—That is not the question. Don't confine it to a single bee. If two lie together they make heat. You can't make heat with one. If a lot of bees lie together they make heat. Do they ever freeze when they all lie together in that way?

Mr. Dadant—How big a bunch of bees?

Mr. Abbott—The ordinary size?

Dr. Miller—If there is a stove in a room and it is hot enough people are not going to freeze, and as long as there is plenty of food there to keep the furnace going the bees will

keep up that heat; they are not going to freeze. When they fail of that they are going to freeze, Mr. Abbott to the contrary notwithstanding. He says they starve. I say they freeze. You can pay your money and take your choice.

Ernest R. Root—I would like to answer both Mr. Abbott's and Dr. Miller's questions. Last summer in queen-rearing operations we conducted a series of experiments to get some drone-layers. We had read in some of the old works that if you freeze a queen for awhile she will become a drone-layer. So I took about a dozen of our young, nice vigorous laying queens, caged them with the bees, put them on a cake of ice in a refrigerator and left them, varying all the way from two hours up to 48. I expected some of them to be dead. The bees were perfectly stiff at the end of two hours. I took them out and examined them and put them back, and some of them we put into nuclei to see what they would do, to see whether the queens would refuse to lay regular worker eggs. I don't know whether you believe me or not—I don't know whether Dr. Miller or Mr. Abbott would; I don't know exactly how they disagree, but we found in every case that when taken off the ice, chilled, cold—I won't say they were frozen to death; they couldn't have been—in a few hours they would "come to;" the queens would begin in three or four days afterwards to lay, and lay normally, and not one of them laid drone-layer eggs. The question was, if bees can be put in a position where they are perfectly stiff with cold for 48 hours, can they be kept in that condition longer, and, if so, how long? I omitted to carry on that experiment. It has been said bees do not die of cold. What kills them we do not know.

Another question, I should say the question of the temperature of the cellar and the buzzing and noise depends somewhat on the time of year. When the bees are first put, in they are apt to be quiet in our cellar, with a high or low temperature, but after they have been there for three or four months they begin to get uneasy. Then the latter must be accounted for. If the temperature is too high or too low it must be brought to the proper degree. Giving bees a midwinter flight stops the buzzing and roaring in our case. I would describe this noise, when it is normal, as like a harp. Once in a while you will get a noise something like the sound of telephone wires, not that high note, but a sort of low, distant hum. When you get something of the effect of that contented, quiet noise amongst the bees that seems to indicate everything is normal and right, that is the condition we call perfect; and yet there is a little noise there, and that noise might, to the beginner, seem to be the wrong thing.

Mr. Abbott—We don't get the point exactly yet. I think this is a vital point, and I have been trying to get the bee-books and bee-papers, to say something about it for a long time and they have persisted in not doing it, and that is the reason I am calling it out. I hold that bees are wintered successfully where the mercury runs down to 40 degrees below zero, out-of-doors, on the summer stands; and that that can be done in any place in the United States, provided there is food accessible; and that no normal cluster of bees ever dies from cold when there is food accessible; and to be accessible it must be directly above the cluster; and that the bees in that condition will winter safely any place in any temperature that ever existed in the United States or ever may exist—if the food is accessible—if the "stove" is there, as Dr. Miller says. He brings the point out clearly. If the food is on another frame or where they can't get at it without breaking cluster or following up the line of heat they will die from starvation, but if they can get at the "stove" they will not die. Now if anybody has any evidence to prove to the contrary I should like to know it, for I have been talking this thing for 15 or 20 years, and I don't want to talk it any longer if it is not right. But I do, if it is right, longer and louder.

Mr. Wilcox—What I was going to say was bearing rather upon the discussion between Dr. Miller and Mr. Root, but since Mr. Abbott has spoken I want to say I have conducted one experiment that substantiates his claim very much. I once took a bee-tree about four feet long and set it up in the front yard, full of honey and bees, and with a temperature of 40 degrees below zero. It froze and burst open the whole length; and those bees wintered well and came out right in the spring. I could put my hands right through a crack anywhere in that tree. That goes to confirm somewhat Mr. Abbott's theory. The other matter about which I wish to speak is not very important or profitable, but may perhaps be interesting as an experiment. Before I commenced keeping bees in movable-comb hives I inverted a half sugar barrel filled with bees and honey; poured cold water clear to the brim to drown the bees; left

it 24 hours with a temperature of 25 or 30 degrees below zero; then went to carry my bees in and get my honey. I was surprised on moving it into the house to find that the water was not entirely frozen over at that very cold temperature and 24 hours out-doors, but I rolled it up under the stove just the same and melted the ice out and went away from home. In a few hours more the bees drove my wife out. They were all alive and happy as ever. The query is, Why didn't they drown? Every bee was under water; they were completely covered. Then, again, why didn't that water cool off and freeze over? I suppose perhaps the warmth of the bees prevented that, but I would have expected them to drown if they breathed. Can they live that long without breathing?

Mr. Becker—As to the question, do bees freeze out-doors, I want to say this, that I have had bees that were out-doors all winter with broken hives that you could almost run your fist into, and they appeared to have wintered all right. Last winter when the thermometer went down to 25 degrees below zero in our latitude, I had 10 colonies in new hives, with plenty of honey, and every one of them died, with the exception of one, before spring came. It lived until spring and then dwindled away and finally died, and in the hive there was as much as 50 pounds of honey. The other hives, many of them full of holes, stood on the summer stands. I couldn't take care of them in the fall because I was too busy. I put in a piece of gunnysack to fill up the opening and they wintered through in good shape, and produced virtually the honey I got this year. I believe it is not so much the cold as it is the condition that the bees go to winter quarters in. I don't believe in outdoor wintering. I don't want to risk it if I can possibly help it. I believe what will do one year won't do another year. The conditions as to bees are different one year from another in one locality; and they may be all right in one locality and not in another. I also believe that if we can keep our bees dry, or from getting too much moisture around the cluster, that the cold will not affect them so much as the dampness does. The honey will freeze around when there is much honey in the comb, and there will be great chunks of ice hanging around the bees all over the comb, and that is one effect of out-door wintering. When it is not warm enough so that they can come out and clean themselves they will begin to get damp, and the dampness will get through all the hives, and then the next little cold spell will catch every one of them and they die. Where we winter bees in the cellar, we aim to keep them dry and avoid the extreme cold. I believe that dampness has more to do with it than cold weather.

Dr. Miller—I don't believe that this is a matter of vital importance and I hope we will not take up time with it, but if you are going on with it I want to say what I think about it is, a single bee will freeze—I think no one disputes that; two bees put together will freeze if it is cold enough and the cold continued long enough; so will three or four; and there comes a point somewhere where Mr. Abbott will tell you they don't freeze, they starve. If you have a small cluster that small cluster will freeze, and before we get to the place where Mr. Abbott says they starve, they still will die, whether it is from freezing or from starvation, or whatever it may be. But here is the point. You put them down to 40 degrees below zero, or put them down to the point where they do not stir, and I think you will get a point, and I don't believe the bees will move at that even if there is honey above them. They will wait until it gets a little bit warmer before they will break cluster to get anything fresh. If you hold them there long enough, and if the cold is severe enough, they are going to stay there and they will freeze, and freeze to death. That is what I think. Now Mr. Abbott thinks they starve. Stop that cold at any time and let them warm up and start in afresh. But I say, put it down cold enough and hold it there and those bees are going to freeze. You don't call it starvation with a single bee, why should you call it that with the colony? I don't believe it makes a particle of difference which way you believe.

Mr. Abbott—They don't get 40 degrees below zero in the cluster.

Mr. Stuebing—I am an old bee-keeper—about 50 years in the business. When bees are given honey they will never freeze outdoors.

Mr. Root—I don't know whether I agree with Dr. Miller or Mr. Abbott. I am going to tell you something, and Mr. Abbott can clap his hands to show us whether it hits his way or not. We wintered bees for a good many years at Medina outdoors. We winter a good portion indoors now. I noticed that the bees that were dead on the comb would be circled around as near a sphere as they could be; that on each comb they would be in the form of a circle. If they were dead there would be about two inches without any honey around them at all. I never saw any bees that were dead that had access to honey, no matter how cold it was, but every time I found a cluster of bees dead I found they had eaten away all the honey around them to the extent of three or four inches. Seemingly they had got to the point where they couldn't move; whether they froze or starved Dr. Miller can settle.

(Continued next week.)

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Uniting Dwindled Colonies in Spring

No doubt some of the sisters will feel grateful to Bro. Latham, page 438, for arguing there is no necessity for ending the life of a colony, even if it has dwindled down to almost nothing. When one has only 3 colonies, it seems a serious matter to reduce the number to 2; and even when one has 100 colonies it goes against the grain to reduce the number to 99. One can not divest oneself entirely of sentiment, even in this dollar-and-cent age, and the sick chicken is likely to be nursed carefully up to the day of its death, even if one is sure that it has no chance for recovery. And colony No. 3 can not be remorselessly swept out of existence without leaving an aching void. So there will be those who will be glad to take Bro. Latham's plan of keeping the family circle of 3 colonies unbroken, even if it does cost more than it would to buy another full colony. What mother could be satisfied to give up the care of a sick child by being told that another child could be bought to take its place for less money than it would take to doctor the sick one?

But if it is merely a matter of dollars and cents, it must be admitted, albeit with a sigh, that tinkering up a weakling in early spring, especially if queenless, costs more than it

comes to, and it is hard to understand how it can be more profitable for one with only 2 colonies than for one with 200.

### Bees Troubled with Moths—Queenlessness—Transferring

DEAR MISS WILSON:—Will you please tell me how I can rid a hive of bees of the wax-moth. I notice the bees are at work most of the time carrying out stuff that looks like fine sawdust. I have killed quite a number of the moths on the outside of the hive. The colony of bees is hybrids, and not a very large one.

1. How does a colony appear if it has no queen?

2. If I should transfer them to a new hive with one-inch foundation starters in the frames, and starters in sections, would they stay there all right and go to work?

3. The hive they are now in is an old one—a chaff hive. Do you think I could lift out the frames and clean them, and get rid of the moths that way?

4. If I should transfer them to a new hive, and there was any young brood sealed, or just coming out, what could be done with them?

I bought the colony this spring, and the

man that I bought them of said they were all right, and I took his word for it. I think he does not know how to keep bees clean, or he would keep them in better shape. The bees have not swarmed yet.

I hope this is not too long for you, but I am very anxious about my bees, for I love them, and they have not offered to sting me. I think I will get along all right with them.

MRS. NEW HAMPSHIRE.

1. Bees that have been queenless some little time will carry in a noticeably less quantity of pollen than those that have a laying queen and are rearing much brood. But the best way is to lift out the frames and examine their contents. If a laying queen is present there will be eggs found in the cells, and if she has been present long enough there will be brood in all stages. There may, however, be a virgin queen in the hive, and in that case there will, of course, be no eggs or brood from her. On the other hand, there may be eggs and brood and no queen. That would be a case of laying workers. The laying of these pests is not as regular as that of queens. If drone-cells are present they will be used in preference to worker-cells, and two or more eggs may be found in each drone-cell. Often one of the first signs of laying workers is the finding of eggs in queen-cells, and if you find more than one egg in a cell you may find a dozen eggs in a single queen-cell.

One way to help decide whether any queen is present, either laying or virgin, is to give a frame of eggs and brood from another colony, always apposing you have another, and if queen-cells are started it is tolerably certain that no queen of any kind is present.

2. Yes, but it may be well to say that it is poor economy to put in starters of foundation in brood-frames. You will be pretty

sure to have a good deal more drone-comb built than you will like, and the loss from rearing and feeding a big crop of drones will more than counterbalance all you will save on the foundation.

3. Yes, you can help in that way, but it is the bees themselves that must be depended upon to keep out the moths. Don't lay the blame on the old hive. A weak colony, especially if the bees are of black blood, will allow the moths to get the start of them in a new as well as an old hive; and a strong, active colony of black bees, or even a weak colony of vigorous Italian blood will not suffer the presence of moths.

Lift out the frames one after another, shake or brush off the bees, and look for the silken galleries of the worms. They will be found more especially in the cappings of the sealed brood. Take a big pin, wire nail, or something of the kind, and tear open the gallery

at one end. Then begin at the other end, tearing it open as you go, and you will thus drive along Mr. Worm till he comes out at the hole you first made. Then when he is at your mercy you can end his existence in any way that suits your fancy.

4. The combs containing the brood can be cut out and fastened into the new frames in the regular way of transferring, filling the frame with combs and tying strings about it till the bees fasten it in. Perhaps an easier way will be to leave in the old hive all the frames with just enough bees to keep the brood from chilling, and then when all the brood is hatched out, which will be in 3 weeks from the time of transferring, drive or shake out all the rest of the bees. But it may be that your bees will do all right in the old hive.

Don't send any postage stamps when you write to this department, and write just as long letters as you like.

shken, when queen-cells are started without brood in them yet—after brood can be seen in them, or after they are capped over?

3. In removing the old hive to a new location, and putting a new hive on the old stand, is it essential that the old queen should remain or be shaken into the new hive on the old stand? or can she be put into the old hive on the new location?

4. Do afterswarms come out only when the old hive remains on the old stand?

5. Do they always fail to come out when the old hive is put in the new location?

6. If no afterswarm comes out when the old hive is changed to the new location, is there any need of cutting out queen-cells?

WISCONSIN.

ANSWERS.—1. Bees do not generally swarm until a number of queen-cells are started and the most advanced ones are sealed. Sometimes they do not wait till cells are so far advanced, and in rare instances they have been known to swarm without having even eggs in queen-cells. This refers to prime swarms. Afterswarms have sealed cells with quacking queens in them ready to emerge as soon as the swarm has issued.

2. Swarms may be shaken without paying any attention to queen-cells as soon as the season of swarming comes, or as soon as colonies are sufficiently strong. Some prefer to wait until a number of cells are found containing eggs or larvae. It would hardly do to wait till sealed cells are present, for at that time a swarm is likely to issue. The presence of queen-cell cups with neither egg nor larva in them need not be considered, for these may be found at any time, even in winter.

3. The queen is to remain on the old stand with the shaken swarm. The point is that the brood is to be taken away.

4 and 5. Afterswarms are likely to issue if the old hive is left on the old stand, and are less likely if the old hive at the time of swarming is removed to a new place; but may occur then. If the swarm is put on the old stand, the old hive close beside it, and then a week later the old hive removed to a new place, you may count quite safely on no afterswarm.

6. According to what has just been said, it will be seen that removal of the old hive to a new location will not prevent the necessity of cutting out cells, unless such removal occur some days after swarming.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal,

or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Uniting Bees—Some Difficulties

Why does a colony sometimes unite peaceably with a strange swarm, and at other times fight it off until apparently not a bee is left?

The case is this: Last Saturday I put out a few boxes with strips of foundation fastened to the top. On Wednesday I found a swarm of black bees in one of them, so I brought it home after dark and placed it at the side of the Italian colony with which I expected to unite it. I left them there until Thursday at about 6 p.m., when both were smoked some. The box was then turned upside down, the bottom removed, and the bees shaken on a board in front of the old colony. The black queen was found and disposed of. The black bees rushed in, and those that were slow about it were helped along with smoke.

They were at once attacked by the Italians inside the hive and on the alighting-board. I smoked them through the entrance, which seemingly stopped the fight, but only for a very short time. I smoked them again, this time sufficiently to take all fight out of them—so I thought. Results: Truce until the smoke had passed away, then wholesale exhibition of Jiu-Jitsu.

After dark I brushed all dead and dying bees from the alighting-board, and this morning I found not only the alighting-board covered with dead bees, but also the entrance ( $\frac{3}{8} \times 1\frac{1}{4}$ ) blocked so that hardly a bee could pass in or out, and they were under the frames as far in as I could well remove them with a stick.

Now I am quite sure that had I hived the swarm on regular size frames, hunted the queen out, and then placed the hive over the other, or the frames between the frames of brood in the Italian colony, they would have united peaceably. But last year I captured 12 strange swarms, and every time united them with other colonies that I had at home, and in the same way, not even hunting up the queen in every case, and of the 12 just one acted as the one did to-day. That one, however, was as bad as, if not worse than, this; for the day after I united them the colony was seemingly weaker than before, and the ground was just covered with dead bees.

While I do not intend to unite 2 colonies in this way again, yet I would like to have your opinion of the cause and the prevention of the trouble.

At present the bees are gathering well from white clover.

IOWA.

ANSWER.—It is difficult to say why bees unite at one time peaceably and at another time fight when conditions seem just the same. I don't know just what was the trouble in the case you mention, but it is just possible that the black swarm was an afterswarm, having a virgin queen. If the

weather was bad, and the bees were not gathering, that would make trouble about uniting. You would have had less trouble if you had killed the black queen 2 or 3 days before uniting. Also if you had united in a somewhat piecemeal manner. Bees seem to welcome the accession of a small number when they resent the entrance of a whole family. In hundreds of cases I have given to a colony a single frame of brood or honey with adhering bees, and never knew any fighting.

### Swarming

1. Will bees swarm before building any queen-cells? If so, are they likely to do so?

2. It is impractical for me to stay at home and watch for swarms, so I must resort to artificial swarming or dividing—probably the brush-swarm plan. At what stage of the erection of queen-cells should the swarm be

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### NATIONAL ASSOCIATION HONEY-LABEL.

If a sore spot has anything of the pathetic quality about it, surely we may say that the spot that's going to be sore is still more pathetic. Our Editor touches a spot that's going to be sore, on page 355—that prospective honey-label of the National Association. A label of this sort says to the public, "We produce better honey than do the common herd of our craft, because, you see, we are the progressive men." Is this going to be true? I am almost for conceding that our progressives exercise themselves to get more honey, to harvest honey easier, to have things look nicer, to test and adopt novelties, to have some specially desirable kind of bee—anything and everything except quality of product, secured in the only reliable way—ripeness.

Ripeness involves time (among other things), and our typical progressive is scandalized by the expenditure of that one thing. His words are, "Hurry!" "Push things!" Honey just barely ripe enough to keep without fermenting and changing flavor, is the mark many set before themselves to strive for. The true mark should be a great deal higher than that. I even fear that the gentleman exists who wants to lean on a label—and thereby sell honey more unripe than be-

fore. Also, a practical minimum of ripeness for Association enforcement is going to be very hard to set. Capped honey is not always ripe; and uncapped honey is not quite always unripe. Honey may be very ripe and yet not taste very good. And, otherwise, honey may (if right from the comb) be delicious to the taste and yet be very unripe—totally unfit for keeping. Yet if there is not some sort of enforcement from the start the label will become a stone around the neck instead of a benefit—like the name of an immensely advertised ginger snap that might be named—all will soon expect it to be below average quality instead of above, and persist in that expectation.

### AUGER-HOLE ABOVE USUAL ENTRANCE.

Somehow I don't believe bees prefer an auger-hole entrance to the usual form. I'll admit that it often looks that way. Many hives have an ordinary entrance at the bottom and an auger-hole 2 or 3 inches above. We see the latter popular and the former unpopular—and jump to wrong conclusions. The auger-hole is the nearest road to where the bees want to go. Also every inch away from the ground (up to a certain limit—10 feet or so) adds a little to the desirability of an alighting-place, from the bee's point of

# You and Your Bees

—WILL LIKE—

## “THE ELGIN HIVE”

A proven success Not an experiment

“THE ELGIN” is comprised of fewer pieces than any other knocked-down hive. No nailing required to put it together. Any man, woman or child can assemble THE ELGIN in a few minutes. Saves labor, trouble and racked nerves. No pattern, diagram or book of instructions needed in order to set it up.

Simplicity of construction is such that mistakes are impossible. Standard size brood frames, supers and other accessories perfectly fit “THE ELGIN.”

Material and workmanship unexcelled. Patent corners of metal make it air and water tight, and prevent warping. Made in 8 and 10 frame sizes. Special sizes if desired.

Let us figure on your Bee-Supplies—Hives, Sections, Frames, Foundation, etc. **GOOD GOODS. SATISFACTORY PRICES.**

Send to-day for illustrated circular and prices of “THE ELGIN.” It will pay you.

## Queens by Return Mail

The **Standard-Bred** kind, reared by some of the best queen-breeders in America, and warranted purely mated. Sent by return mail at these prices:

One Untested Queen for 75 cents; 3 for \$2.10; or 6 for \$4.00.

## An Untested Italian Queen-Bee FREE as a Premium

### For Sending One New Subscriber

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.

2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a **NEW** subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

If you can not get a new subscriber, and want one or more of these Queens, we will send the American Bee Journal a year and a Queen—both for only \$1.50.

Address all orders to

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL.

view. At a small round hole the professional guards have less chance to get in their moneymaking with each incoming bee. So far as that may cause popularity it would be a genuine popularity. Page 356.

**NEW VS. OLD COMB FOUNDATION.**

As to new foundation being better than old, a majority of the experts (15 out of 29) say it is not. Three more join the same rank with an "if"—if you'll steam it, or temper it, or dip it in warm water. Then 9 more, inclining more or less to think there is some difference, think the difference is quite small. That leaves only 2 unaccounted for, neither of whom thinks the difference large. Seldom we get so near absolute unanimity. Page 356.

**HONEY VS. SOAP FOR WASHING.**

I haven't gotten around yet to the experiment of washing a pair of big, rough, dirty, masculine hands in honey used instead of soap. Of course we are interested to see that a competent judge finds it to work tolerably with feminine hands. Lack of penetrative power is the off-hand suspicion one would feel toward honey for this purpose; may be we suspect wrongly. The soap we quite commonly meet imparts a bad smell, and honey wouldn't do that. Also, soap often carries in itself a fearful nastiness, only partly eliminated by strong alkali; and honey is innocent on that score. Say, Sister Wilson, try a batch of handkerchiefs and napkins, and similar small hardware, with honey and not a particle of soap. Using as little water as practicable, soak over night and wash out in hot water. May be there's something to be found out yet, who knows? Speaks nothing but decidedly white honey should be used on delicate goods, lest it stain them. Page 360.

**VIRGINIA QUEENS** Italian Queens secured by a cross, and years of careful selection from red-clover queens and superior stock obtained from W. Z Hutchinson. # C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

**CHICAGO, June 19.**—The little that sells consists chiefly of extracted and the market is a small one. Comb ranges from 12@12 $\frac{1}{2}$ c for the best white with off grades 1@3c less. Extracted, white, 5 $\frac{1}{2}$ @7c; amber, 5@6c. Beeswax, ready sale at 30c. **R. A. BURNETT & CO.**

**CINCINNATI, June 2.**—There is only a fair demand for honey at the present time. We quote amber extracted honey in barrels at 4 $\frac{1}{4}$ @6c. according to quality. White clover extracted at 6 $\frac{1}{2}$ @8c. The comb honey market is practically closed for the summer. Beeswax, 29c. **THE FRED W. MUTH CO.**

**BOSTON, May 23.**—Our honey market continues very dull, with very little movement to be noted. We quote fancy white at 14c; No. 1, 12 $\frac{1}{2}$ @13c. Extracted, from 6@8c, according to quality. **BLAKE, SCOTT & LEE.**

**PHILADELPHIA, June 21.**—As the season advances, there is very little call for comb honey. In fact, no sales, and we make no quotations. Commission men are accepting any offer they can get for what little stock they have on hand. Extracted honey is in some demand. Possibilities of a big crop are holding prospective buyers back. We quote Fancy white, 7@7 $\frac{1}{2}$ c; amber, 6@7c; dark, 5 $\frac{1}{2}$ @6c. Beeswax in good demand, 29@30c. We are producers of honey and do not handle on commission. **WM. A. SELSER.**

**ALBANY, N.Y., June 17.**—The honey market here is very dull and demand very light. Very little old crop carried over, and will be in good shape for new crop, which begins in August. Quotations are nominal now. White comb, 12@14c; mixed, 10@12c; dark, 10@11c. Extracted, white, 6@6 $\frac{1}{2}$ c; mixed, 5 $\frac{1}{2}$ @6c; dark, 6@6 $\frac{1}{2}$ c. Beeswax, 28@30c. **H. R. WRIGHT.**

**KANSAS CITY, June 21.**—There is very little comb or extracted honey on the market at present, but what there is being quoted as follows: Fancy white comb, 24 section cases, \$2.25 to \$2.50; No. 1 white and amber, \$1.75 to \$2.00. Extracted, per pound, 4 $\frac{1}{4}$ @6c. Beeswax, 25@28c. **C. C. CLEMONS & CO.**

**NEW YORK, June 19.**—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Ex-

tracted honey in fairly good demand. New crop California honey selling at 6 $\frac{1}{2}$ @7c for water-white, 6@6 $\frac{1}{2}$ c for white, and 5@5 $\frac{1}{2}$ c for light amber. Southern at 50@60c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29c. **HILDRETH & SROELKEN**

**CINCINNATI, O., June 9.**—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5 $\frac{1}{4}$ @5 $\frac{1}{2}$ c; in cans, 5 $\frac{1}{2}$ @6c. Beeswax, 28c. **C. H. W. WEBER.**

**DENVER, June 26.**—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6 $\frac{1}{2}$ @7 $\frac{1}{2}$ c per pound. Beeswax, 26c. **THE COLO. HONEY-PRODUCERS' ASSN.**

**SAN FRANCISCO, June 28.**—White comb, 1-lb sections, 11@—cents; amber, 8@10c. Extracted, white, 5 $\frac{1}{2}$ @—cents; light amber, 4@4 $\frac{1}{2}$ c; amber, 3@3 $\frac{1}{2}$ c; dark amber, 2 $\frac{1}{2}$ @—c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

Market is quiet and presents in the main an easy tone, especially for other than choice to select water-white. In a limited way on local account the latter sort is salable to fair advantage. Common amber grades are not readily placed, even at low figures, either for shipment or on local account.

## CROP 1905

We have a party wanting the first car of new comb honey. It would probably pay those having such goods to write us.

Ready for You.

### Read What Has Been Said by Those Who Know

OAKLAND, MO., May 22, 1905.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—Your sections are simply superb.  
Yours respectfully, ROBERT WILSON.

ROME, PA., Route 16, May 22, 1905.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—I think the sections the best I ever saw.  
Yours truly, W. J. HILL.

SMITHVILLE, GA., May 9, 1905.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—Am anxious to use your sections, for I consider them  
the best made. Yours truly, R. P. JOHNSON.

DEERFIELD, IOWA.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—I want to say that I consider your make of sections  
the nearest perfect of any I have ever had. I have folded packages of  
500 without breaking one, and I can not say that of others I have used.  
Yours truly, GEORGE BROWN.

GRAND VIEW, IOWA, June 3, 1904.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—I received those sections in good shape, and am well  
pleased with the same. They are all right in every way. I shall recom-  
mend your bee-supplies to other bee-keepers. I think you make  
better goods than any other firm in the world. Accept my thanks.  
Yours truly, GEORGE B. MCDANIELS.

KENTON, OHIO, May 4, 1904.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—The goods are simply fine in every respect. We have  
compared a few of the No. 1 sections bought of another firm which we  
carried over from last season with your No. 2, and find that the No. 2  
are superior. Yours truly, NORRIS & ANSPACH.

CENTRALIA, KANS.

G. B. Lewis Co., Watertown, Wis.  
*Gentlemen:*—Everybody wants Lewis sections.  
Yours truly, A. W. SWAN.

45th Year

CHICAGO, ILL., JULY 20, 1905

No. 29

LOUIS C. DADANT

C. P. DADANT

HENRY C. DADANT

New Home of Mr. C. P. Dadant, with Mississippi River Shown in the Rear at the Left.  
(See page 502)

PUBLISHED WEEKLY BY
GEORGE W. YORK & COMPANY
334 Dearborn Street, Chicago, Ill.

IMPORTANT NOTICES

THE SUBSCRIPTION PRICE of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

THE WRAPPER-LABEL DATE indicates the end of the month to which your subscription is paid. For instance, "decs" on your label shows that it is paid to the end of December, 1904.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

ADVERTISING RATES will be given upon application.

National Bee-Keepers' Association
Objects of the Association

- 1st.—To promote the interests of its members.
2d.—To protect and defend its members in their lawful rights.
3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00
General Manager and Treasurer—
N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

The Honey-Producers' League
(INCORPORATED)

OBJECTS:

- 1. To create a larger demand for honey through advertising.
2. To publish facts about honey, and counteract misrepresentations of the same.

MEMBERSHIP DUES

- 1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.
2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-paper publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.
GEORGE W. YORK, Manager,
334 Dearborn St., CHICAGO, ILL.

Queen-Bee Free as a Premium

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is the time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

HONEY-JARS.

For a limited time we offer No. 25 Honey-Jars, porcelain cover, metal screw cap, holding one pound of honey net, one gross in case complete, in 5-gross lots, \$4.00 per gross; less quantities, \$4.50 per gross, f.o.b. New York. If you want to secure some, let us know at once.

HILDRETH & SEGELKEN,
265 & 267 GREENWICH ST., NEW YORK, N. Y.

- Fulton & Ford, Garden City, Kansas.
- I. H. Myers, Lamar, Colo.

# IN SEASON

## Sections

We have a larger stock of sections than we ever had at this season, and are prepared to make prompt shipment of sections, foundation, and most other goods. There has been very little delay in orders all season except in a few cases where something special has held some orders longer than usual. Our agents generally are also in a position to make prompt shipment. If the bees get lots of honey, and you need more goods quickly, remember we are in a position to furnish them by first train.

"I desire to thank you for being so prompt in sending the sections I ordered from you. They came in less time than it takes to tell it."

L. G. REED.

Kent, Ohio, July 10, '05.

## Special Price on Tin Cans

We recently secured a special bargain in half-gallon square cans. They are choice bright stock; but as the pattern differed slightly from the regular one they are now making, they closed them out at a special price. We have also an overstock of quart oblong square cans. While this stock lasts we will make the following prices for shipment from Medina only:

1/2-gal. oblong square cans with 1 1/2-inch screw, \$5.00 per 100; \$45.00 per 1000.  
 1/2-gal. square cans with 1-inch screws, \$6.00 per 100.  
 1/2-gal. " " 1 1/4-in. " 6.50 "  
 1/2-gal. " " 1 1/2-in. " 7.00 "  
 In 500 lots, 50 cts. per 100 less.

We have also a good stock of one and five gallon cans at regular prices.

## Glass Honey-Packages

Anticipating a demand for honey jars and bottles we have put in two car-loads of stock before the summer shut-down of the glass-factories, so that we are prepared to furnish the various jars listed in our catalog. We have also a few odds and ends of stock, such as we formerly listed, which we offer, to close out, as follows. We can not duplicate these when present stock is sold:

1-lb. tin-top tumblers, No. 789, 5 bbls. of 200 each, at \$4.50 per bbl.  
 1 1/2-lb. tin-top glass pails, No. 778, 2 bbls. of 100 each, at \$5.00 per bbl.  
 Large lb. tin-top glass pail, No. 777, 1 bbl. of 150, \$5.00.  
 Small lb. tin-top glass pail, No. 776, 1 bbl. of 200, \$5.50.  
 1-lb. Oaken Bucket tin top, with wire bail, 1 bbl. of 150 for \$5.00.

These prices are all a dollar less than we used to sell these tumblers and pails at. We have also a little loose stock which we will pack and include at same rate.

## Wide-Mouth Mason Fruit-Jars

The car-load price on Mason fruit-jars is over a dollar a gross higher this year than last. We carried over quite a large stock, which we will sell at the same prices as heretofore—namely:

Pint.....doz., 52 cts.; 6 doz., \$3.00; 12 doz., \$5.75  
 Quart..... " 55 cts.; " 3.10; " 6.00  
 Half-gallon... " 75 cts.; " 4.10; " 8.00  
 Triumph wrench, 15 cts. each.

Ball's waxed rings, 5 cts. per dozen. These are far superior to rubber rings for fruit-jars, and cheaper.

In addition to the regular style of Mason jars we have a stock of wide-mouth special Masons, with 3-inch opening. These are especially desirable for canning large fruit whole, or for packing chunk comb honey. These jars are of extra quality, and cost \$1.65 per gross more than the regular pattern. As we do not list them, we offer our present stock at an advance of 10 cts. per dozen, \$1.20 per gross, on any size. They have zinc caps and rubber rings. We have no wax rings of the right size to fit these jars. They are a bargain at this price.

## Caucasian Queens

We can spare a limited number of imported Caucasian queens, received direct from the best breeders in Caucasus. Prices as follows:

Extra select Caucasian imported queens.....\$15.00  
 Select Caucasian imported queen..... 10.00  
 Extra select untested Caucasian-Italian queens,  
 from Caucasian mothers mated with Italian  
 drones..... 3.00  
 Select do..... 2.00  
 Orders filled in rotation. Delivery begins about July 15.

## "How to Keep Bees"

A charmingly written manual describing clearly, and in detail, the outfit, first steps, and methods. The author's well-known literary ability has combined with her enthusiasm for the subject to produce a very unusual volume.

Finally, with all due deference to the authors of excellent books on bee culture which we have already, my opinion is that this new book, "How to Keep Bees," is the best one for a beginner, or one who does not wish or expect to keep more than a dozen colonies, that has yet come before the world.—A. I. Root, in Gleanings, July 1.

Price, \$1.00. Postage 10 cts. extra.

## Gleanings' Contests

**Second-Prize Photo.**—Very liberal awards for best photos of apiary and other bee-keeping objects of interest. Full particulars on application.

**Fair Contest.**—Gleanings offers prizes of \$10, \$5, \$3 and \$2 for the largest list of subscribers taken by agents during Fairs throughout the country this fall. Here's a chance to make money on regular commissions and prizes. Write for entry blank and particulars.

Complete Catalog by Return Mail.

## Editorial Notes and Comments

### Locality in Bee-Keeping

A few years ago it became somewhat the fashion to make a joke of the matter of locality, possibly because some attributed to locality things not fairly due to it. But its real importance can not be pooh-poohed out of existence. The fact that in Australia bees are busily working at Christmas, and are in winter quarters July 4, is a mere matter of locality; as also the fact that in the southern part of the United States bees are at work weeks before they are out of winter quarters in the North.

But differences of locality are not alone shown by parallels of latitude. Differences of flora or other differences may be such that a plan of work in a certain place may be excellent, while not at all appropriate in another place only a little distance away. For example, a bee-keeper in a part of Illinois where clover is the chief, if not the sole, source of surplus, might be somewhat puzzled upon reading of P. H. Elwood's plan of management, and would be likely to say:

"I don't quite see how I could carry that out. I'm to dequeen no colony, if I understand correctly, until it is found making preparations for swarming. Then the cells are to be removed just before they would hatch, which would be in 10 days or more. Then a cell is given, and it will be another 10 days before the young queen will lay, or something like 3 weeks after the colony is dequeened. Then we are told, 'This operation should be timed so the young queen will begin to lay at the time of the opening of the main harvest.' That is, the dequeening must take place when the bees are found preparing to swarm, and it must be about 3 weeks before the opening of the main harvest. But bees don't prepare to swarm till the opening of the main harvest; so how can I dequeen when they are found preparing to swarm, and yet do it 3 weeks before the harvest? I don't understand it at all."

He will understand it better if he understands that Mr. Elwood's main harvest is probably basswood, which comes later than

the opening of the white clover harvest; so that it would be an impossibility for the said Illinois bee-keeper to carry out Mr. Elwood's plan, however good it might be in a basswood "locality" in New York State.

The moral of which is, that while one is to study plans and practices of bee-keepers in all localities, yet in applying the knowledge so gained one must keep clearly in view the difference in locality.

### Giving Brood to Shaken Swarms

In shaking swarms, some advise giving a frame of brood to hold the swarm, others say the frame of brood will make the swarm desert, and prefer no brood, while still others advise giving a frame of brood and then taking it away as soon as the swarm becomes sufficiently attached to the new home. Just how long it takes for them to become sufficiently attached may be an open question. J. A. Green, after saying that swarms deserted for him when given a frame of brood, was asked whether such desertion occurred on the day of shaking or several days after. He thus replies in *Gleanings in Bee Culture*:

I believe they all came out again the day after they were hived. Two years ago a large percentage, to many of which brood had been given, swarmed out the next day. Some of them, though, were hived in only one section of my hive, with supers above. This season, all swarms, artificial or natural, were hived in two sections of the brood-chamber, generally with only starters in the frames, and without brood, except in the case of two or three afterswarms. Two or three days thereafter the lower section was taken away, leaving them in a brood-chamber six inches in depth, having the capacity of about five Langstroth frames. So far as known not one of them swarmed out. Of course, supers were given them at the time they were hived.

### Preventing Swarming by Dequeening

Some years ago a good deal was said about management by making colonies queenless to prevent swarming. P. H. Elwood used the plan successfully, but others reported failure. Possibly they did not understand correctly

Mr. Elwood's plan, having an idea that the thing to do was to keep colonies queenless a longer time than was done by him. It seems, however, that Mr. Elwood's plan might be called requeening rather than dequeening, or, to be more exact, dequeening and requeening.

Here is Mr. Elwood's scheme of management, as given in the *Bee-Keepers' Review* by Irving Kinyon, who, with one other man, helped Mr. Elwood take care of 1200 colonies:

"We discouraged swarming until we were ready to remove the queens. Then, if any were found preparing to swarm, the queen was removed, also one frame of bees and brood. If the queen was an extra good one she was put in an empty hive with the frame of brood. The next 6 or 7 colonies dequeened had their queens killed and one frame of brood from each taken to put with the queen that was saved, which made the increase.

"The eggs that these queens would have laid, if they had been left in the hive, would hatch after the main honey-flow.

"After dequeening began, each yard was gone through and the cells removed just before they would hatch. Since there had been no eggs laid for several days when the cells were destroyed the second time, the bees had given up all idea of swarming, but were very anxious to have a queen. We now select a cell from some colony preparing to swarm, place it in a West cage and give it to the dequeened colony. This operation should be timed so the young queen will begin to lay at the time of the opening of the main harvest, and this colony will have its share of surplus honey, as this plan prevents the bees from dividing their working force at the beginning of the best harvest; and also gives them a vigorous young queen during the honey-flow. In destroying these cells we *must be sure* that we don't skip even a small one, or it may upset the whole plan."

### Freshly-Hived Swarms Deserting

A common question from beginners runs something like this:

"I hived a swarm, and the next day it sailed off to parts unknown. What shall I do to prevent such a thing in the future?"

The most frequent cause of such desertion is heat. A hive unshaded, standing out in the broiling sun with a very small entrance and all the rest closed tight, is a pretty warm place in which to set up housekeeping, and one can hardly blame the newly-settled family for moving out.

The remedy is not difficult to imagine. If possible, let the hive be in a cool, shady place. A temporary shade, and sprinkling with

water will serve a good turn. Give plenty of chance for air. Some practice leaving the hive partly uncovered for two or three days. Some give two stories to the swarm, taking away the lower story after two or three days. Either of these plans provides to some extent against an overheated dwelling. Some practice giving a frame of brood to the swarm, with the idea that the bees will feel they can

not afford to abandon so valuable a piece of property.

In any case, if all laying queens are clipped no prime swarm can abscond unless it joins, or is joined, by some other swarm having a queen with whole wings. The queen with clipped wings may be lost, but it is better to lose the queen alone than to lose both queen and swarm.

the milling of the foundation, which position he has held for 23 years, and he figures that if all the sheets of Dadant foundation he has made were put end to end, they would reach two-thirds of the way around the earth. In a few more years Dadant's foundation will encircle the globe.

The bulk of the foundation made by the Dadants is the "Weed process," which refers to the method of sheeting the wax before milling it. Mr. Leon Saugier, Mr. Dadant's son-in-law, and also brother of Joseph Saugier, is in charge of this part of the work.

They have a certain foreign trade that for some reason will have only the foundation made by the old or dipping process of sheeting the beeswax.

The Dadants have always been famous as bee-keepers also. For 40 years they have run several hundred colonies for extracted honey at the home as well as at out-apiaries. For 12 years—from 1872 to 1884—Mr. C. P. Dadant alone managed 550 colonies in 5 or 6 apiaries.

## Miscellaneous News Items

**Prof. A. J. Cook and Wife**, of Los Angeles Co., Calif., called at this office last week when on their way to spend a year of travel and study in Europe. Their daughter, Miss Bertha Eldredge, will accompany them, and devote herself to music while abroad. They expect to sail Aug. 19, in the meantime visiting relatives in the East. Prof. Cook holds his 63 years wonderfully well, scarcely looking a day older than when we first met him. California climate and other things seem to keep him young in looks and spirit even if they can not stay the passing years.

Prof. Cook will continue to write monthly for the *American Bee Journal* while he pokes around various places in Europe. So we can all anticipate some interesting articles from his kindly pen during the ensuing year. And, meantime, all will join us in wishing the three globe-trotters a safe journey across the Atlantic, and a pleasant and profitable year on the other side.

**A Visit to Dadant & Sons.**—For many years we have had a desire to visit the leading bee-supply manufacturers and dealers in the United States, who are also our leading advertisers, and finally the opportunity to begin doing so came last fall. We started out in October, and, as most of our readers know, we have had the pleasure of visiting quite a number of such firms, and also of telling something about them in the *American Bee Journal*. We believe that these personal and often somewhat minute introductions have been appreciated both by the firms visited and by those who read this paper regularly, who, very likely, are their patrons in a business way.

The last firm that it was our good fortune to see was that of Dadant & Sons. For more than a quarter of a century it was "Chas. Dadant & Son." (Doesn't that look and sound familiar?) But since the elder Dadant passed away, in 1902, his son "C. P." has taken into partnership with himself two of his sons—Louis C. and Henry C., the former being in his 26th year and the latter in his 23d.

The first home of the Dadants, and also their factory, are located right in the woods, about two miles from Hamilton, Ill., for they began by growing grapes and keeping bees, and their present business has developed slowly from these. There are so many trees around their factory and other buildings that it is impossible to take a good view of them from any side, however we succeeded in getting a snap-shot of the main factory, or at least the smoke-stack, as shown herewith.

One of the buildings, constructed of iron,

and then painted, contains only beeswax, and holds something like 20,000 pounds. It is usually kept full, for the Dadants believe in having on hand a large supply of beeswax so as not to run out of the only suitable material for making their excellent comb foundation.

The original firm of Chas. Dadant & Son was founded in 1863, and began the manufacture of comb foundation in 1878. When

THE LATE CHAS. DADANT.

MAIN FACTORY OF DADANT & SONS.

they began it was the intention to make only for their own use, as they were extensive bee-keepers. The first year they made 500 pounds, but they made it so good that others wanted some of it, so the second year they made 2000 pounds, the third year 6000, and so kept on, some years making more and some years less, until during the year from July 1, 1903, to July 1, 1904, they made and sold over 115,000 pounds, which put them away up at the head of the manufacturers of comb foundation. If this season should continue as did that of 1903, they may again reach their banner record.

One secret of the wonderful success of the Dadant foundation is that every inch must be equal in every way to sample. We saw how they make it, and were surprised at the extreme care with which every part of the process is conducted. The least defect is detected by the quick, clear eye of the young lady who lays each sheet on the paper put down by another young lady. Thus it is sorted and papered as it comes from the mill. These young ladies exchange places occasionally to relieve the monotony of the work.

Mr. Joseph Saugier is the man in charge of

One year (1884) they had 45,000 pounds of extracted honey. This was their largest crop, from which they realized \$2800 net of all expenses. They use a very large hive, taking 10 Quinby loose-hanging frames, size  $11\frac{1}{2} \times 18\frac{1}{2}$  inches, outside measure. Their hives face south, and on the west inside of the hive is a division-board or dummy, and the back end is made of two boards. On each of some of the best colonies (when we were there, June 21), there were 3 and 4 shallow extracting-supers nearly full of honey. And they had had only one swarm in their 4 apiaries of a total of 250 colonies, so far this season! They have practically no swarms. They run their apiaries for honey, and not for swarms! They believe in large hives—big colonies—and then they always get the honey—if it is to be had from the flowers. Their methods are successful, and they know it. When we enquired why they did not push the sale of their special or Dadant hive, Mr. D. replied, "Oh, bee-keepers think it is too expensive." We found it costs only about \$1.00 more than the ordinary hive. Surely, that should not prevent business bee-keepers from buying them, if by their use and following the Dadant eye

tem of management larger crops of honey can be secured.

Mr. Dadant has promised to write a series of articles on their hive and management for the readers of the American Bee Journal in good time for the season of 1906. To the bee-keeper who desires to make a financial success of producing honey, those articles will be worth hundreds of dollars. There will be no theory about them. The Dadants produce the honey, and can give a good reason for the faith that is in them regarding this matter.

It may not be known to all our readers, but Chas. Dadant & Son were among the very first to make successful the importation of Italian bees on a large scale. They received as high as 400 queens a year, and sold them at \$10 each, or \$20 for a colony of bees with an imported queen. Of course, this was long ago—in the early 70's. Mr. Chas. Dadant made a trip to Italy at a cost of \$400, in order, if possible, to discover a method whereby a large number of queens could be safely shipped to this country. Finally a plan was devised, each queen being put in a very small nucleus box, then 22 of the boxes were packed together and shipped. Often the whole 22 queens, or at least 20 of them, would arrive safely; then, again, all would arrive dead except 2 or 3 in a shipment. The business continued successful and profitable until com-

petition, and unfaithfulness on the part of their Italian shipper, put an end to it.

Mr. Dadant is fortunate in his family. Besides his good wife (who, by the way, is a most faithful and excellent mother, cook and housekeeper), he has three sons and four daughters. Louis and Louisa, the two oldest, are married, the son living on the old homestead which is located only two or three rods from the main factory, and the daughter about a half mile away. Henry and Maurice are the other two boys. Louis and Henry are graduates of the University of Illinois, and Maurice has still three years of work there. The daughters at home are Valentine, Clemence and Harrietta, the last being the "baby" of the family, about 10 years old. Miss Valentine, who has also attended the University, is president of the Hamilton Library, an organization formed three years ago through her efforts, and of which the town is justly proud. It is open to the donation of good books, and has now almost 1000 volumes.

Last year Mr. Dadant built a most beautiful and substantial brick house, from which at the rear the majestic Mississippi River can be seen for nearly 14 miles. It is just opposite Keokuk, Iowa, from which city it looks like a young college in the distance. He and his family moved into it last December.

Hamilton, the home of the Dadants, is just

across the river from Keokuk, a fine railroad and driving bridge, three-fourths of a mile long, spanning the Mississippi at that point. Hamilton is a city of 1300 inhabitants, and Keokuk about 15,000.

Mr. Dadant is vice-president and director of the State Bank of Hamilton. Louis C. is also a director. Mr. Dadant's property interests in and about Hamilton are extensive. He is the leading business man of the city, and one whom all respect and delight to honor.

We shall not soon forget our very enjoyable visit with the Dadants. We were royally entertained, Mr. Dadant devoting himself wholly to us from the time of our arrival until we departed. We understood how he could thus absent himself from the business when we saw how his sons, Louis and Henry, made things hum in the office and factory. They are taking right hold of the work, so that Mr. Dadant is required only occasionally during the day or week simply as counsellor, his advice and experience often being of inestimable value.

In next week's issue we will complete the account of this trip, telling of a visit to the old city of Nauvoo, and also of an 11-mile carriage drive to see Mr. E. J. Baxter, a brother-in-law of Mr. Dadant, who is another large and very successful bee-keeper.

## Contributed Special Articles

### Light-Weight vs. Full-Weight Sections

BY L. V. RICKETTS

**F**OLLOWING my article on light-weight sections being one cause of the small demand for section honey, on page 229, I will say that with the sections now in general use, a 24-section case of No. 1 separated honey will weigh not more than 22 pounds, on an average, which is  $14\frac{2}{3}$  ounces per section.

As stated by M. A. Gill (page 213), these sections were at first intended to hold one pound of comb honey, which they did, on an average, as they were used without separators, but since separators have come into general use, and as by their use the holding capacity of sections is reduced, we find that the original 16-ounce section of honey has been reduced to approximately  $14\frac{2}{3}$  ounces; yet it is being sold to the consumer as a pound of honey.

This reminds me that for many years, and until about a decade ago, a well-known soda company put up their soda in two different sizes of packages, one size contained 12 ounces, and the other 16 ounces. For many years the lighter weight package was the one generally sold, but finally some of the more enterprising of our grocers adopted the heavier package. For a long time both sizes were sold, one groceryman selling the 16-ounce, while his competitor across the street sold the 12-ounce size, yet the price was exactly the same—10 cents per package. But this state of affairs has changed by the light-weight packages being forced out of the market.

I predict that within 10 years from to-day the average weight for a 24-section case of No. 1 separated honey will be 24 pounds, or 16 ounces per section. This change will at first be made by a few bee-keepers adopting a section large enough to hold 16 ounces of No. 1 separated honey, thereby increasing the sale of their product and finally forcing others to follow in their foot-steps.

Imagine a butter manufacturing company producing bricks of butter weighing only  $14\frac{2}{3}$  ounces coming in direct competition with a company producing bricks weighing 16

ounces. Would they not soon be forced to increase the weight of their product, or be driven from the market? A "pound of comb honey" and a "section of honey" are synonymous terms in the minds of the average consumers of section honey, yet they are learning to their dissatisfaction that when buying a section of honey they seldom get a pound.

Leo F. Hanegan (page 268) says in his locality they have trouble in getting  $4\frac{1}{4} \times 1\frac{1}{8}$  sections to weigh 22 pounds to the case of 24 sections, on an average, when used with separators when being filled, while across the country 8 miles from his locality the bee-keepers must use sections of  $1\frac{3}{4}$  inch width in order to keep them from weighing over 23 pounds per case of 24 sections. He says: "Our market demands an average of 22 pounds per case of 24 sections of No. 1 honey," and asks me to name one size of section for those two localities. My answer is to use a section a little larger than the largest one mentioned by Mr. Hanegan—one that will average 16 ounces to the section of No. 1 separated honey. No one expects to have each and every section weigh exactly 16 ounces.

The idea is to have them average that amount as nearly as possible. I don't believe the old man, "Locality," will assert himself so forcibly as to make it necessary to use two different sizes of sections in order to have them average 16 ounces each.

As to Mr. Hanegan's market demanding 22 pounds per case, I think he meant the wholesale market or commission houses, and not the real market, which is the consumer. It is this market that we must endeavor to please with regard to the weight of sections, and not the large buyer, for if we have plenty of those who buy and consume our product, there will be no difficulty in finding the large buyer. There is where a great mistake is made by bee-keepers trying to please the large buyer instead of the consumer.

Perhaps the principal argument advantage by the advocates of light-weight sections is, that the consumer often prefers them, as they cost (when sold by weight) a cent or two less than one of full weight. With reference to this I will say that a customer who is too poor to buy 16 ounces of honey at one time is too poor to be reckoned as a purchaser and consumer of honey. And a family that can not use 16 ounces of honey before it goes to waste is not to be considered as a consumer of honey. The facts are that those light-weight sections are preferred by some for the purpose of some one to receive pay for something they never possessed. This "some one" may be either the producer, wholesaler, or retail merchant, but it is never to the best interest of the consumer or the bee-keeper at large, as it tends to decrease the demand for honey, and also its consumption.

Whitman Co., Wash.

## Knowing the Age of Bees Quite Necessary

BY G. M. DOOLITTLE

**M**ANY seem to suppose that a knowledge regarding the age of bees is of minor importance, and something which only scientists should be interested in. This I think is a very mistaken idea, for in all our manipulation of colonies we shall succeed only as we keep the right proportion of bees of all ages in each or any colony we may make.

Nothing in the bee-business has given me more pleasure in the past than experimenting to ascertain the different ages of bees, and the different offices they perform at certain ages when in a normal condition. When these conditions are not complied with the colony is thrown out of balance, and in that unbalanced condition we find that bees will feebly perform any office of the hive till they can arrange matters normally again. Then it is that we find very young bees going into the fields, when they will bring less than one-half the load that the bees over 16 days old will carry. Old bees will rear queens which are not of half the value of those reared by the younger or nurse-bees, and some workers will even lay eggs, while this office is usually restricted to the queen.

In these experiments I have found that queens reared under the most favorable circumstances attain the average of 4 years, and that, too, under the great stimulus which is brought to bear on them under our modern bee-keeping, wherein a queen is coaxed to lay more eggs each year than did the queens of our fathers. In this way queens are constrained to lay from 3000 to 4000 eggs daily, while in box-hive times, if a queen layed from 2000 to 2500 eggs in a day she was doing remarkably well.

On one occasion I had a queen that lived and did good work till she was nearly 6 years old, laying prolifically till within about 3 months of the time of her supersedure, while several have lived to be nearly or quite 5 years old.

Then I have had queens reared in little nucleus boxes, as was quite the general way 30 years ago, which would not live more than 5 to 9 months, and never keep more than 4 or 5 Langstroth frames full of brood while they lived. Those rearing queens in this way were generally the ones who did not think that there was anything worth looking after regarding the age of the bees, which bees were making the best they possibly could out of the bad plight into which their would-be bee-keeper placed them. In a state of Nature neither all old bees nor all very young bees rear queens, unless some accident happens to force them to do so; and I have found it a good plan not to adopt the "accident" policy if I wish to rear queens which will tend toward an improvement in the bees in the apiary.

The worker-bee rarely attains to a longer life than 45 days during the months of June, July, August and September, while those emerging from their cells in September may live, many of them, till the next May or June, if not injured by our winters, their life being prolonged above the 45 days just in proportion to the work that they do, or the amount of hardship they are required to undergo. Never have I known a worker-bee to survive a single year, and I do not believe it possible for such a thing to come to pass.

I find that, approximately, the bee is in the egg form 3 days; in the larva form  $5\frac{1}{2}$  to 6 days, and in the pupa form 12 days. After emerging it takes the bee from 6 to 12 hours to get fully straightened out, soon after which it begins preparing chyle for the larvae of the hive, doing this work very largely till it is 6 days old, when, if the weather is pleasant, it comes out of the hive for the first time to take an airing and mark its location, still continuing its work inside of the hive—feeding the brood, building comb, evaporating nectar, etc.—until it is 16 days old, when it goes out to labor as a field-bee, after which it does very little of the inside work of the hive, and dying of old age from 25 to 29 days later. While these bees that are over 16 days old can be forced, through being made queenless, to prepare chyle and rear queens, still queens so reared will work after about the same order as will the workers at field-work, when forced out after honey and pollen when only 5 or 6 days old. In all our artificial increase of colonies it is well so to form them that bees of all ages will remain in each part of any division made.

I find that the life of the drone is nearly the same as that of the worker under favorable conditions, but a very precarious life he lives; for at any time when a scarcity of honey prevails, and the bees are not fed by the apiarist, the drones are unmercifully driven from the hives or are killed by the workers. I have seen it stated that the drones do not live one-half the time the workers do, the proof of which was the writer's experiments made with a nucleus colony. All beekeepers should know that drones are "commoners;" that is,

they have the privilege of entering, unmolested, any hive that allows its own drones to remain, and that if they are driven from one hive they are allowed to enter another which is retaining its drones. Such is the experience with all close observers along this line.

A nucleus having a queen just fertilized has no more need of drones, and persecutes them till they leave, or, if they persist in staying, kills them. But with an isolated hive, and feeding when there is a scarcity in the fields, it is quite easy to prove that drones will live from 40 to 45 days.

It is a rare thing that any drones live over the winter, but in one or two cases when the hives were unusually full of stores, all during the late summer and fall months, I have had them live so as to be flying in February, but they seem to wear out faster during a state of inactivity than do the workers, for with the advent of pleasant days in the latter part of March and the first of April they are soon all gone, and that when they are not driven from the hives.

Onondaga Co., N. Y.

## Convention Proceedings

### Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904.

(Continued from page 490)

#### ABSCONDING OF SHOOK SWARMS.

"How to prevent absconding of shook swarms."

Mr. Smith—I find hiving them on a frame of brood as a rule would prevent that.

Dr. Miller—May I ask Mr. Smith whether he finds in hiving on a frame of brood they start cells on that brood?

Mr. Smith—Yes, I have found that also; not as a rule, though.

Dr. Miller—One of the writers says, Give them a frame of brood and within two or three days take it away again to prevent them starting queen-cells.

Mr. Becker—If I have two swarms that come out at the same time I hive them on a frame of brood, and I never had one yet that left if I did that; and I always do it if I have two swarms come together.

Dr. Miller—Are you talking about natural or shaken swarms?

Mr. Becker—Natural swarms.

Mr. Snell—I never practised that very much, but whenever I have done so I have given the colony a frame of brood, and as yet I have never had them desert.

Mr. Whitney—I have practised shaking swarms and I have never had the shaken swarm leave the hive. Sometimes if I shake them on comb I take the queen with them, and I never had them leave.

Mr. Hutchinson—I never have had any experience myself with shook swarming, but quite a number of those who have written articles on that subject have made one point quite clear, that the bees should be pounded and disturbed and jarred until they fill themselves thoroughly with honey. The natural swarm fills itself when it starts out, and when that point has been attended to there has been very little trouble with absconding. Whereas, if we simply take them off the combs without any of this previous disturbance there will quite frequently be absconding.

Mr. Abbott—I want to ask if the people who practise shaking swarms give them the queen at once? The question is asked if they start cells on the comb? Do they not have a queen given them at once?

Mr. Hutchinson—They have the old queen.

Mr. Abbott—Suppose you make two or three swarms out of a colony?

Dr. Miller—We don't.

Mr. Abbott—I thought if they would give them a queen, and they had brood, I couldn't see why they would start cells.

Dr. Miller—As a matter of fact they do start cells. There are two things you are getting a little mixed, the absconding and the starting of queen-cells. The point is, Do they start cells? They have started cells for me in more than one case,

and perhaps you who say they do not abscond, if you had examined carefully you might find that they had started cells. What they start cells for I don't know. Mr. Stachelhausen says they start cells and he gives them the sheet of brood, holding them there so that they won't abscond. Whether they would go on with that and rear a queen and swarm again I don't know, because I always stopped them and took them away. But it is, I think, a pretty common thing that they start cells when you give a frame of brood to a shaken swarm.

Mr. Whitney—Perhaps I don't understand. When I said they didn't abscond when I put them on frames of comb it is simply old combs with the queen. I don't understand that they would commence queen-cells under such circumstances as that. But when I give them uncapped brood and eggs I have never had them trouble me by attempting to abscond, but they do rear queen-cells, and they will rear a queen unless you introduce one, of course. I would think if they didn't commence making queen-cells you would have a very weak colony of bees very soon. When parts of mine leave the hive sometimes I have shut them in for 36 hours, and especially if I move that hive away from the old stand; and I have never had any trouble, and I have shaken swarms a great many times.

Mr. Abbott—I made shook swarms long before I ever heard tell of shook swarms, at least I suppose I was doing the same thing. I did this: I took a colony of bees and divided it up into two or three colonies sometimes and gave them all a laying queen. I had the queens, maybe a dozen, before I commenced my work, and with each colony went a queen, turned loose at once, and they had one frame of brood and the rest foundation, and under such circumstances I have never had any cells started or had any trouble. My idea was to bring out the point that the way to make shook swarms

is to keep a number of laying queens on the colonies you want to divide, and then turn the laying queens loose at once, and I don't think they will build any cells if you do that.

Mr. Hutchinson—If I understand the matter, they do not shake the bees from the colony until they have made preparations for swarming; and the bees are shaken off on the old stand and the brood given the bees on the new stand; and the old queen and all of the bees, or nearly all, go on the old stand, and the flying bees that come back join that, and that has a queen; and what we have been talking about is the giving of a new swarm a comb of brood to prevent them absconding, and sometimes they go to work and build cells on that. That is all the division they usually make; they do not divide them up into several parts; they just have the two; and the old combs of brood are usually given a queen-cell nearly ready to hatch, or else given a laying queen, preferably a laying queen. If it is given, then there is no use going to work and hunting up the queen-cells and destroying them, because that colony and laying queen will destroy them themselves.

Mr. Smith—I believe it is their instinct for their own preservation. You disturb a colony of bees, or alarm them, and they will immediately start queen-cells, but they will cut them out again after they find their old queen is secure, in a day or two. I think that is the reason; it is the fear of their queen being injured or taken from them that they start queen-cells.

Mr. Snell—I would like to ask any one who has given a shook swarm a queen, and then that colony started cells, if he has ever known them to be matured and a swarm made from such colonies? I would doubt their doing it very much.

(Continued next week.)

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Putting Weak Colonies Over Strong Ones

I see that you wish everybody to report results in putting a weak colony over a strong one. We tried 12 that way and we had no queens killed.

We were very well satisfied with the results. We have 8 pairs still together. May not the use of hybrid bees explain failure in other cases?  
MISSOURI.

ANSWER.—I don't know. It doesn't seem that there should be any difference between hybrids and others, but sometimes there is a difference where it is not suspected.

### Putting On Supers—Dividing for Increase

1. What is gained by putting the second super below the first one?

2. Why put on a second super until the first one is full?

3. Why not take the super off when full, before putting on another one?

4. How long is it after the egg is deposited in the cell until the cell is capped.

5. At what time and in what way are the young bees fed?

6. How long is it after the old queen leaves the hive with the first swarm until the new queen meets the drone and is ready to begin laying?

7. I live in southwestern Missouri. Would it be advisable to divide the bees in a hive now? My bees have failed to swarm any this season, and I should like to increase my stock. Can one not having experience divide them successfully?

How late would it be advisable to introduce new Italian queens into old colonies, in this

latitude? I have only one Italian colony in 11, which I got by introducing an Italian queen in September, 1904. I had no experience at that time, but met with the best of success, and now the colony is very strong and working nicely. I have had no swarm from it. Would it not be better to introduce new queens about Aug. 1, in this locality?

9. Would it be advisable to try to divide the colonies after the supers have been put on.  
MISSOURI.

ANSWERS.—1. The bees will begin to work sooner in the new super if it is put under than they will if it is put on top.

2. After the first one is full, so that there is no room for the bees to store, it will still take them some time to finish up the sealing so the sections are fit to take off, and the second super gives them room to work in during that time.

3. For the reason already given. Try two colonies side by side the two ways and see which you like best. At the present writing (July 10) very few of my colonies have only two supers on. Some of them have four, and a few five.

4. Eight or nine days.

5. They are fed by the nurse-bees for 5 days or more from the time the larva hatches out of the egg until it is sealed over.

6. The young queen will emerge from her cell about 7 or 8 days after the prime swarm issues. When 5 days old or older, she will mate. In 16 days or more from the issuing of the prime swarm she will begin laying.

7. Yes, by reading up well in your book of instruction so as to have general principles well in mind, you ought to be able to make increase successfully on first trial, and there is plenty of time for it yet.

8. You can introduce any time from now until bees stop work.

9. Yes, if increase is important, although

you must remember that you can't have your cake and eat it too, and if you turn the force of the bees toward increase it will interfere with the honey crop. There are localities, however, where the harvest is heavy late in the season, and in such a locality it is possible to get more honey by dividing early. In most places a colony that works straight through without having its forces divided will store more than the colony and its increase together would store.

### Catching the Drones—How Many Colonies to Keep

1. When should the drones be caught?  
2. Why are there so many when it is only necessary for them to meet the queen once?

3. I live in the south central part of the State. Is it a good bee-district?

4. How many colonies would it be advisable to keep?  
INDIANA.

ANSWERS.—1. Any time. Prevention, however, is better than cure. Allow very little drone-comb in your hives and you'll have few drones.

2. For greater safety to the queen. If there was only one drone for each queen, the queen might make many trips before mating.

3. Yea, but some parts are better than others.

4. Probably not more than 100, and perhaps less than that if other bees are within 2 or 3 miles.

### Transferring Bees from Box-Hives

I have a colony of bees in a box-hive. There are no frames in it. The comb is built every way in the brood-chamber. I would like to get them into a modern hive. I have a new 10-frame dovetailed hive. Can I put the new hive on the old stand and set the old hive on top of it, and have the bees go down and build comb in the new hive, getting the bees out of it in that way? How can I get them into the new hive? When would be the best time of year to do it? They swarmed June 11.  
MICHIGAN.

ANSWER.—It is not certain just how you will come out if you set the old hive over a new one. If the old hive is quite large, and

the colony weak, they may not build down into the new hive. If strong, and the season good, they may build down satisfactorily. If they do not build down, it is perhaps as well to leave them right where they are, so as to build up strong for winter; then next year you can transfer 3 weeks after swarming, when there will be no worker-brood in the hive, driving out the bees, and melting up the comb, unless you want to save some of the best of it. The probability is that the bees will winter better and be stronger next spring if you leave them in the old hive, as the colony was probably not so very strong after swarming.

### Bees That Never Swarmed

I bought 7 colonies 2 years ago, and they have never swarmed. Isn't that a very uncommon thing?  
ILLINOIS.

ANSWER.—Yes, it is a most decidedly unusual thing, and if you have bees that will do good work and not one of the whole 7 colonies offer to swarm in 2 years, you have something to be greatly thankful for.

### Fastening Foundation Starters in Sections

1. How do you fasten starters in the sections where you put them in say  $3\frac{1}{4}$  inches long? I can not keep them straight, as they are not fastened at the bottom.

2. I find that when I leave as much as  $\frac{3}{4}$  of an inch space between the bottom of the super and the frames, the bees invariably fill in the space with comb and honey. Is it not best to leave a space about  $\frac{3}{8}$ -inch?

MISSOURI.

ANSWERS.—1. At our house they are put in with a Daisy fastener. The best way to have the comb fastened well at the bottom is to use a bottom starter  $\frac{3}{4}$  inch.

2. Of course they will build in a space of  $\frac{3}{4}$  of an inch. And they'll build no little in a  $\frac{3}{8}$ -inch space. Don't have it more than  $\frac{1}{4}$  inch.

### Preventing Robbing—Using Queen-Cells—Italianizing—Starting Nuclei Late

1. How can I prevent robbing among bees?

2. I have a queenless colony with 6 queen-cells started. Can I use some of them to any advantage?

3. I have several colonies of goldens and two of blacks. Would I best get rid of the black queens?

4. Is it too late in the season to start a new colony with two frames and a queen?

KENTUCKY.

ANSWERS.—1. Robbing is likely to be started if honey is left exposed where bees can get at it, especially at a time when bees are not gathering. Avoid anything of that kind. When there is nothing to be had in the fields, sometimes robber-bees are so troublesome that even opening a hive and taking out

the comb will start robbing. At such times avoid opening hives, or if you already have a hive open and see by their darting into the top of the hive that robbers are getting the start, close up at once, and if for any reason you *must* handle the bees, do it under a tent, or wait till nearly dark before opening the hives. Weak, queenless colonies fall an easy prey to robbers. Either break them up or supply them with a queen. Keep all colonies strong and provided with good queens, and don't do anything to tempt the robbers, and you'll not be likely to have much trouble.

2. Yes, if you wish to have more queens, each cell may be given to a nucleus.

3. Yes, if you find them inferior to the others, as they probably are.

4. No, you can start in August, by giving enough help.

### Location for Keeping Bees

I am thinking of going to Arkansas, or western Kansas, to keep bees. The forage is sweet clover in both places. In which place will bees do the best?  
KANSAS.

ANSWER.—That isn't a question that can be answered in a single word. You will find good and poor locations in both States. The best way will be to make a personal visit and find out whether a certain location will suit you. The number of bees already on the ground must be taken into consideration. The best location in either of the States is not the best place for you if the ground is already occupied by others. If you find a place where there are no apiaries, only some one with a few colonies who has no intention of increasing the business, and whose bees are doing remarkably well, that's likely to be a good place for you. But remember that you can't count on as good results with 50 or 100 colonies as you can with only 2 or 3.

### Queen Laying Several Eggs in a Cell

I have a queen that I reared in a nucleus. She is of good size and pure Italian; very gentle. I have seen her lay while holding up the comb, but I have counted as many as 6 eggs in one cell. What do you think is the matter with her? She is in a hive, but the bees cover only 4 frames in it. Do you think there ought to be more bees in it so the queen could have more room?  
INDIANA.

ANSWER.—It is nothing unusual for a good queen to lay more than one egg in a cell when she has so small a force of bees that she hasn't room to spread herself; although it is unusual for her to lay so many as 6 in a cell. If she keeps supplied with eggs all the cells that the bees cover, you needn't worry about her throwing in a few for good measure. If, however, she lays duplicates in a few of the cells and leaves other available cells empty, there is something wrong, and if she persists in that line of conduct she should lose her head. But it happens sometimes that a queen will lay in an abnormal manner for a week or so, and then straighten up and lay as a good queen should.

handy for one to do any more. Just let them look around here. Here's original scientific work that will last as long as the coal-beds do. Let such a youth select one or more insects for close acquaintance, and put himself in communication with some institution or university that works at this branch of Nature work.

"How to Make a Cage for Your Canary Out of Old Umbrella Ribs," is it now? Fine specimen of Prof. Bigelow's scorn for the clap-trap arrangements of previous workers when they studied bees a little. It seems that they have been very inconsistent, in that they use costly and nice apparatus to study creatures of much less importance than bees. Still we must not forget that sometimes very costly and fine-looking apparatus works—not half so well as the clap-traps. I object decidedly to calling the one-frame observation hive a failure. Allen Latham has recently been making it a success to a remarkable degree. There is room for both the Bigelow Educational Hive and the one-frame kind. Let there be no fighting and calling names between them. The former is new; and a season's work with it is likely to result in considerable modifications—strange if it didn't. I notice Prof. Bigelow speaks of letting the bees run in, and letting the bees run out, instead of speaking of putting the bees in and taking them out. I infer, therefore, that he has not continued very long working with bees—in all weathers, and in all their moods and tempers—and hardly knows yet how contrary they can be about doing just what one wants them to do on mere asking. Students well inured to bees are likely to prefer in large measure free manipulations in the open to bee-tight ones indoors.

The feeder arranged with a powerful magnifying lens attached, to study the bee's members "on the critter," and especially the ligula and its way of taking in honey, I would commend in the highest terms. I sadly fear that most of our folks have never taken in the idea yet that bees *can not* suck honey through a straw as breathing creatures can. Just how far suction is got up some other way than by breathing, and just how far the fluid is paddled up, or chain-pumped up, or swallowed up, or by capillary attraction wheedled up, are fascinating propositions to study.

What we are after most greedily is the seeming impossibility of a hive in which any part can be seen at will *without disturbing a bee*. We especially need to see them "at home" with home feelings and quietness. We want also a prosperous colony and not an abnormal and woe-begone one. We can dispense with great populousness, but we don't want the colony *too* small. The Bigelow Educational Hive provides for a colony of maximum strength (which is very well so far); but some of the bigger desirabilities, one can hardly see how they are provided for.

### THE PUCKERING ALUM-WEED HONEY!

Alum-weed honey, eh? warranted to pucker a child's mouth so it can't bawl for seven hours! The demand for it should rise with the progress of the anti-race-suicide reform; but Brudder Smith will have to shell out advertising rates when he tells us his price for it. Page 376.

### SUMAC HONEY AND BLOOM.

The honey that I call sumac (still a possibility of mistake) is amber or yellowish in color, and in quality not bad—but still not as good as I wish it was. When raw nectar it has a tang, a sort of sour, reminding one of the taste of sumac fruit (the red bobs), if you ever tried to eat them. My locality is strong on sumac, especially *Rhus copallina*, which blooms far along in summer, much later than the other species. Page 361.

### COMB HONEY IN CONFECTIONERY.

All right to experiment with honey, using wax and all, for confectionery, but look a little out. So little wax as my experience goes, it is that honey always gets more or less of bad taste from contact with melted beeswax. Rather queer. Don't seem as though it ought to be so. Wonder if it is the detergent quality that makes the mischief—washes the wax and takes the impurities to itself. If that's really the case a little invention may come in here, too. Page 360.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### BEES AS A NATURE STUDY.

Prof. Bigelow, on pages 373-5, gives us a most delightful article. Hard work to handle it adequately in the limits of this department. It is well adapted to stir up some of that strangely large proportion of intelligent people who keep themselves oblivious to Nature's multiple and perennial miracles as shown in the transformation of insects—things are created before our eyes, not out of nothing, but out of incongruous previous things. And

what an enormous mass of world-work—world's scientific work—is yet to be done relating to insects! Of insect species 30,000 have been described (how little that is!), but of undescribed species there yet remain nine or ten times as many—say over 250,000! Most of the lesser host of 30,000 still need to have their life history and characteristics studied up. I suppose many ambitious young men and young women have mourned that there was nothing of world-embracing significance

# Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

## The Laying of Laying Workers

If you ever have much to do with laying workers, you'll find that one of their peculiarities is a preference for drone-cells in which to lay their eggs, and rather than to take up with worker-cells they will lay two or more eggs in each drone-cell, if drone-comb is present. It has been said that they prefer the larger cells because they can more comfortably reach to the bottoms of the larger cells to deposit their eggs there. If that be the case, a queen-cell ought to be still more to their liking on account of its great diameter. And in actual practice that seems to be the case, for it is not uncommon to find in a colony of laying workers a queen-cell with a plurality of eggs, sometimes as many as a dozen eggs in one cell.

So when a queen-cell has been found containing more than one egg, it has been counted a sure sign of laying workers. But it seems the rule can not be relied on as one without exceptions. About 10 days ago, in a prosperous colony whose queen was less than a year old and doing good work, I found a queen-cell containing three eggs! I called Dr. Miller's attention to it, and he said he had never seen or heard of such a thing before. Yet since then two other cases have occurred, one with three eggs in a queen-cell and one with two. Is there a conspiracy among the bees to unsettle our dependence upon a rule that has been heretofore considered without exception?

## Roger's Song

Who loves the rose without a thorn? Not I.  
No guardian darts around her close,  
For every passing hand she blows,  
With every touch her bloom is straw—  
I love no rose without a thorn. Not I.

Who loves the bee without a sting? Not I.  
'Tis but a stupid, idle drone  
May live a feeble life alone,  
And be so dull and poor a thing—  
I love no bee without a sting. Not I.

Who loves a maid without a will? Not I.  
A thornless rose, a stinging bee,  
A will-less maid, are not for me;  
Give me the sweet wild briar still—  
I love no maid without a will. Not I.  
—DOROTHEA GORE BROWNE, in Sweetbriar.

## Does it Pay to Double Up Colonies?

Mr. Allen Latham asks the above question, on page 433, and gives the following rather two-faced answer:

"Evidently it does or so many successful apiarists would not recommend it. Yet my own experience in doubling up has never been satisfactory in the results obtained."

Then he goes on to say that in a few days the doubled colony has apparently no more bees than the single one previously had on the same stand.

In the spring there are times when colonies dwindle away, and when they are taken with the "dwindles" it doesn't pay to double up, a half-dozen of them united will shortly appear no stronger than each single one did. Doubling such colonies has not been advised of late years. Indeed, it is not generally advised to unite two weak colonies in the spring if each has a good queen. In the fall it is advised, as both are likely to die if not united.

Doubling colonies in the spring is advised when a colony is queenless. Then is the time when the beginner finds it hard to believe that by reducing the number of colonies she will have more bees. She thinks that by

giving to the queenless weaking a frame or brood from time to time she can coax it along and have it rear a queen. But if she has only two colonies, and one of them queenless in early spring, experience will probably teach her that reducing the two colonies to one will result in more bees, and more colonies as well, by fall.

## Honey for the Toilet

Apart from the medicinal uses to which honey is and may be applied, are those connected with the toilet. A small jar containing honey should be kept on every washstand and in every nursery. Honey proves a panacea for most of the ills that flesh, or rather skin, is heir to, in the shape of cracked lips, roughness of the skin, blotchy patches around the mouth, which are most disfiguring to even the most beautiful, chilblained or chapped hands, sore and cracked heels, wind-caught ears, etc., which can all be prevented by this simple remedy.

The application is so easy, and no one can object to it, as they do to so many other remedies. After washing any part of the body suffering from any of the above unpleasantness, apply to the part affected, while still wet, a very little honey, by dipping the finger into the jar and smearing over. To those who suffer habitually in winter from any of these distressing complaints, the continued use of honey will prevent them from appearing. Begin to use as soon as the weather gets cold, or as soon as the wind begins to nip.—Irish Bee Journal.

# Reports and Experiences

## Light Honey-Flow So Far

This is the time when we should have our heaviest honey-flow, but up to 2 days ago the bees had barely made a living; now there is a light flow on and we hope the same will keep on getting better. Bees in general are in fine condition and we may have a fair crop yet.

F. RAUCHFUSS.

Arapahoe Co., Colo., June 26.

## Good Clover Crop—Unsettled Weather

There is an abundance of white clover, but the weather is very broken—so much so that the bees are handicapped, and can not put in over half time. I lost 15 colonies through spring dwindling, and had to feed a lot of them. What are left are in good condition.

W. IRVINE, SR.

Webster Co., Iowa, June 19.

## Season in North Central California

"One swallow does not make a summer," neither does a big rainfall make a respectable crop of honey. At least such is the observation I am led to record in regard to the output of the bee-hives in that portion of California about the Bay of San Francisco. For nigh some 40 years bees have been kept on our place in the foothill north of Oakland, and about 12 miles directly east of the Golden Gate. As near as I can recollect our bees heretofore stored a fair, or, in most cases, a good crop of honey, every year we had over an average rainfall. This year, however, there is an entire failure of a crop; in fact, I

have had some colonies make a fair storage of nectar in our dryest years.

The past winter and spring was above the average as to rainfall, in places it was much above the average, and extended over a long period. The nights, too, were cooler than usual. This state of affairs no doubt prevented the flowers from secreting nectar.

Such a long, wet season had a beneficial effect in producing a fine stand of vegetation; the flowers were plentiful and marvelously gorguous. But, as stated, the nectar was lacking, or could it be that the bees were lazy and thought that there would be an abundance of flowers the year through, and that it would be unnecessary to fill their larders with winter stores? I hardly believe so.

THE DRONES TO GO EARLY.

The indications were good for early swarming. Some colonies cast swarms in April and some in May, but by the end of May and early in June I noticed that many colonies began to drive out the drones; in fact, there was a great slaughter of them. I never saw the banishment of the male population of the hives begin before until toward the close of July, or in August. This convinces me, too, that the bees considered the honey season closed early. No honey, no drones; no drones, some winter stores, may be. Perhaps this is bee-logic. W. A. PRYAL.

Alameda Co., Calif., June 19.

## Gathering from Sweet Clover

I have 15 colonies of bees and they are doing very well. I have a small field of sweet clover in bloom and my bees gather lots of honey from it.

The American Bee Journal is worth its weight in gold to me. JAMES ULRICH.

Lebanon Co., Pa., June 26.

## Terrible Cyclone in Kansas

On May 8 a most terrible cyclone made its way through our little town, doing an immense damage to life and property. Twenty were killed, 45 families were made homeless, \$10,000 worth of damage was done to property, and a score or more who were seriously hurt were taken to the school-house. Aid came from all directions. Kansas City wired us \$1000 to-day.

My loss is \$1000, but my family escaped from injury, so we are thankful. I lost 22 colonies of bees out of 75. The hives and bees are entirely gone—no trace of them anywhere. CHAS. NORLIN.

McPherson Co., Kans., May 15.

## Waterleaf—A Honey-Plant

I enclose a specimen of honey-plant quite common here, but have never seen it described or named in any of the bee-papers. It grows on high land, in the edge of forests, and in the old slashings, and yields a light-colored honey of good quality. Coming as it does between dandelion and white clover it is a valuable addition to our honey-plants. Our bees often store quite a surplus from it, and it is rarely a failure. F. M. COTTRELL.

Shawano Co., Wis., June 10.

[The flower is the common waterleaf (Hydrophyllum Virginicum). The name is not a characteristic of the flower, as it does not grow in water. Damp woods and shady places suit it best, but it grows well in more open ground. The pale blue blossoms open slowly and bloom from June to August, thus giving the bees a lengthy harvest time.—C. L. WALTON].

## ITALIAN QUEENS

# SECTIONS

Millions of Sections. You want quick delivery. We have the facilities for executing orders promptly. Remember that

**Quality** is the first consideration about Sections. "Lewis' Sections" means highest quality. Do not be misled by low prices. A clean-cut, brilliant, white section enhances the price of your honey.

## Shipping-Cases

Order your supply now. Pack your honey in cases before storing away; this keeps them in a bright, clean condition. We invite your inquiries. We can ship promptly.

## Louis Hanssen's Sons

27A4t Davenport, Iowa.  
Please mention Bee Journal when writing.

## Three Requisites

### SECTIONS FOUNDATION SMOKERS

Every comb-honey producer knows how extremely necessary are these three articles to insure success in his apiary.

**We Have Them All in Guaranteed Quality**

**SECTIONS**—We have a quantity of No. 2 which are better than some we have seen classed No. 1. And to move quickly—\$1.75 for 500; \$3 per 1000.

**FOUNDATION**—Thin Surplus, every inch of it guaranteed to be right or money refunded: 1 lb., 65c; 5 lbs., 62c per lb.; 10 lbs., 60c per lb.; 25 lbs., 58c per lb.

**SMOKERS**—The best hot-blast, direct-draft Smoker made: 4-in., \$1.25; 3½-in., 85c; 3-in., 75c; 2½-in., 70c; 2-in., 50c.

Why not put those good bees in good hives? They will appreciate it. You'll feel better about it, too.

We sell the best made—**THE ELGIN**—patent corners. No nails—no dovetails.

Money and brains cannot make better. Maybe a circular will make you believe it. Write for one to-day.

## Queens by Return Mail

The **Standard-Bred** kind, reared by some of the best queen-breeders in America, and warranted purely mated. Sent by return mail at these prices:  
One Untested Queen for 75 cents; 3 for \$2.10; or 6 for \$4.00.

## An Untested Italian Queen-Bee FREE as a Premium

### For Sending One New Subscriber

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a **NEW** subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

If you can not get a new subscriber, and want one or more of these Queens, we will send the American Bee Journal a year and a Queen—both for only \$1.50.

## Honey and Beeswax

CHICAGO, June 19.—The little that sells counts chiefly of extracted and the market is a small one. Comb ranges from 12@12½c for the best white with off grades 10@3c less. Extracted, white, 5½@7c; amber, 5@6c. Beeswax, ready sale at 30c. **R. A. BURNETT & CO.**

ALBANY, N. Y., June 17.—The honey market here is very dull now. It is between seasons. Receipts and demand very light. Very little old crop carried over, and will be in good shape for new crop, which begins in August. Quotations are nominal now. White comb, 12@14c; mixed, 10@12c; dark, 10@11c. Extracted, white, 6@6½c; mixed, 5½@6c; dark, 6@6½c. Beeswax, 28@30c. **H. R. WRIGHT.**

KANSAS CITY, June 21.—There is very little comb or extracted honey on the market at present, but what there is being quoted as follows: Fancy white comb, 24 section cases, \$2.25 to \$2.50; No. 1 white and amber, \$1.75 to \$2.00. Extracted, per pound, 4½@6c. Beeswax, 25@28c. **C. C. CLEMONS & Co.**

PHILADELPHIA, July 15.—As the season advances, there is very little call for comb honey. In fact, no sales, and we make no quotations. Commission men are accepting any offer they can get for what little stock they have on hand. Extracted honey is in some demand. Possibilities of a big crop are holding prospective buyers back. We quote: Fancy white, 7@7½c; amber, 6@7c; dark, 5½@6c. Beeswax in good demand, 29@30c. We are producers of honey and do not handle on commission. **WM. A. SELSER.**

CINCINNATI, July 10.—We sold to-day at our store new crop of fancy comb honey at 13½c per pound. There is still a big stock of last season's honey on the market, that is going begging at any price. Extracted honey is moving quite lively now. We sell amber in barrels at 5½@6½c, according to quality. White clover at 7@8½c. Beeswax, 26c. **THE FRED W. MUTH CO.**

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Extracted honey in fairly good demand. New crop California honey selling at 6½@7c for water-white, 6@6½c for white, and 5@5½c for light amber. Southern at 50@60c per gallon

according to quality. Beeswax somewhat declining; choice average stock selling at 29c. **HILDRETH & SEGELKEN**

CINCINNATI, O., June 9.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5½@5c; in cauls, 5½@6c. Beeswax, 28c. **C. H. W. WEBER.**

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6½@7½c per pound. Beeswax, 26c. **THE COLO. HONEY-PRODUCERS' ASSN.**

SAN FRANCISCO, July 5.—White comb, 1-lb. sections, 11@—cents; amber, 8@10c. Extracted, white, 5½@—cents; light amber, 4@4½c; amber, 3@3½c; dark amber, 2½@—c. Beeswax, good to choice, light, 27@29c; dark, 25@26c. There has been no wholesale movement in honey this week and no new features have developed.

# IN SEASON

## Sections

We have a larger stock of sections than we ever had at this season, and are prepared to make prompt shipment of sections, foundation, and most other goods. There has been very little delay in orders all season except in a few cases where something special has held some orders longer than usual. Our agents generally are also in a position to make prompt shipment. If the bees get lots of honey, and you need more goods quickly, remember we are in a position to furnish them by first train.

"I desire to thank you for being so prompt in sending the sections I ordered from you. They came in less time than it takes to tell it."  
L. G. REED.  
Kent, Ohio, July 10, '05.

## Special Price on Tin Cans

We recently secured a special bargain in half-gallon square cans. They are choice bright stock; but as the pattern differed slightly from the regular one they are now making, they closed them out at a special price. We have also an overstock of quart oblong square cans. While this stock lasts we will make the following prices for shipment from Medina only:

- 1/4-gal. oblong square cans with 1 1/2-inch screw, \$5.00 per 100; \$45 00 per 1000.
  - 1/2-gal. square cans with 1-inch screws, \$6 00 per 100.
  - 1/2-gal. " " 1 1/2-in. " 6 50 "
  - 1/2-gal. " " 1 1/2-in. " 7.00 "
- In 500 lots, 50 cts. per 100 less.

We have also a good stock of one and five gallon cans at regular prices.

## Glass Honey-Packages

Anticipating a demand for honey jars and bottles we have put in two car-loads of stock before the summer shut-down of the glass-factories, so that we are prepared to furnish the various jars listed in our catalog. We have also a few odds and ends of stock, such as we formerly listed, which we offer, to close out, as follows. We can not duplicate these when present stock is sold:

- 1-lb. tin-top tumblers, No. 789, 5 bbls. of 200 each, at \$4.50 per bbl.
- 1 1/2-lb. tin-top glass pails, No. 778, 2 bbls. of 100 each, at \$5.00 per bbl.
- Large lb. tin-top glass pail, No. 777, 1 bbl. of 150, \$5 00.
- Small lb. tin-top glass pail, No. 776, 1 bbl. of 200, \$5 50.
- 1-lb. Oaken Bucket tin top, with wire bail, 1 bbl. of 150 for \$5.00.

These prices are all a dollar less than we used to sell these tumblers and pails at. We have also a little loose stock which we will pack and include at same rate.

## Wide-Mouth Mason Fruit-Jars

The car-load price on Mason fruit-jars is over a dollar a gross higher this year than last. We carried over quite a large stock, which we will sell at the same prices as heretofore—namely:

- Pint.....doz., 52 cts.; 6 doz., \$3.00; 12 doz., \$5 75
  - Quart..... " 55 cts.; " 3.10; " 6 00
  - Half-gallon... " 75 cts.; " 4.10; " 8 00
- Triumph wrench, 15 cts. each.

Ball's waxed rings, 5 cts. per dozen. These are far superior to rubber rings for fruit-jars, and cheaper.

In addition to the regular style of Mason jars we have a stock of wide-mouth special Masons, with 3-inch opening. These are especially desirable for canning large fruit whole, or for packing chunk comb honey. These jars are of extra quality, and cost \$1.65 per gross more than the regular pattern. As we do not list them, we offer our present stock at an advance of 10 cts. per dozen, \$1 20 per gross, on any size. They have zinc caps and rubber rings. We have no wax rings of the right size to fit these jars. They are a bargain at this price.

## Caucasian Queens

We can spare a limited number of imported Caucasian queens, received direct from the best breeders in Caucasus. Prices as follows:

- Extra select Caucasian imported queens.....\$15 00
  - Select Caucasian imported queen..... 10 00
  - Extra select untested Caucasian-Italian queens, from Caucasian mothers mated with Italian dronea..... 3 00
  - Select do..... 2 00
- Orders filled in rotation. Delivery begins about July 15.

## "How to Keep Bees"

A charmingly written manual describing clearly, and in detail, the outfit, first steps, and methods. The author's well-known literary ability has combined with her enthusiasm for the subject to produce a very unusual volume.

Finally, with all due deference to the authors of excellent books on bee culture which we have already, my opinion is that this new book, "How to Keep Bees," is the best one for a beginner, or one who does not wish or expect to keep more than a dozen colonies, that has yet come before the world.—A. I. Root, in Gleanings, July 1.

Price, \$1.00. Postage 10 cts. extra.

## Gleanings' Contests

**Second-Prize Photo.**—Very liberal awards for best photos of apiary and other bee-keeping objects of interest. Full particulars on application.

**Fair Contest.**—Gleanings offers prizes of \$10, \$5, \$3 and \$2 for the largest list of subscribers taken by agents during Fairs throughout the country this fall. Here's a chance to make money on regular commissions and prizes. Write for entry blank and particulars.

Complete Catalog by Return Mail.

## Editorial Notes and Comments

### Help Blow the "Honey-Horn"

Editor E. T. Abbott, of the Modern Farmer and Busy Bee, comments thus suggestively on the short article we had published in the Chicago Daily News:

George W. York, editor of the American Bee Journal, and Manager of The Honey-Producers' League, has an interesting article in the Chicago News on the importance of honey as a food and the folly of thinking that comb honey is manufactured. Such articles in a great city like Chicago must result in a world of good to the bee-keeping fraternity, and we hope the time may come when this subject will be discussed in all the large dailies of the land, as well as the country weeklies. The way to make a market for honey is to talk about honey, write about honey, and show people what honey really is, and what a healthy, delicious food it is for the human family. In other words, the way to boom your business is to blow your own horn, and get as many more people as possible to help you. The oftener the thing is repeated in print the sooner it will attract the attention of the public, and the sooner they will be ready to test the merits of the claims made in the articles written.

By the way, for a two-cent stamp we will mail a copy of the short article that appeared in the Chicago Daily News to any of our readers who may be able to get their local editors to publish it. We have it printed in typewriter type, on one side of the paper—just the nicest kind of "copy" for an editor to hand right to his printer. If it could be published in every newspaper in the land it would help both consumers and producers of honey. Not because we wrote it, but because it contains the truth about honey that should be read by everybody.

### Prevention of Swarming by Inversion

This is revived, after quietly slumbering for some years, by an article in the American Bee-Keeper from E. H. Dewey. He turned the combs of a hive upside down, and a week later he found that the bees had destroyed the cells that were started. Other cells, however, had been started, and these in their turn were a week later found destroyed as a result

of inversion. This weekly inversion was practiced upon 4 hives successfully. But the same success was obtained by others years ago, only to be followed by failures on further trial. This is mentioned so that no one may risk too much upon a plan that would be a boon to bee-keepers if it could always be depended upon.

### Ventilation of Hives in Cellars

At the Ontario convention, reported in the Canadian Bee Journal, discussion brought out a number of expressions to the effect that cushions were not of any special advantage in cellars, bees doing as well with sealed covers, only so there was large enough opening for change of air *somewhere*. The statement was also made that experiment had shown that colonies in hives placed close to the cellar-bottom did apparently as well as those higher up.

### Apis Dorsata to Be Investigated

A few years ago there was some talk about introducing into this country the giant bee of the far East, and fears were expressed that if introduced it might prove among bees what the English sparrow has proved to be among birds—an intolerable nuisance. There is little doubt that before Prof. Benton returns again to his native land we shall know something definite in the matter. Instead, however, of shipping these bees direct to this country, Prof. Benton proposes the very sensible plan of bringing them under test and observation on "their native heath" before making any shipments, and if such testing proves it advisable they can be shipped to California across the Pacific.

One of the points, no doubt, to be first settled, will be the mooted one as to whether these bees can be kept in hives, or whether they have the migratory habit so fully developed that they will desert their place of abode periodically so as to interfere entirely with their domestication. Northern bee-keepers, at least, need hardly have any anx-

iety on the score of similarity to the sparrow business, for it is not likely that they would survive a northern winter if they should attempt to occupy the land by spreading themselves about promiscuously on trees as they do in their present home. If, however, they can not be persuaded to stay hived in their native habitat, it is hardly worth while to take any further trouble about them. But many a thing that appears impossible proves possible if persevered in, and it's well worth while to know positively about those big bees.

### White and Yellow Sweet Clover

J. A. Green, of Colorado, says in Gleanings in Bee Culture, that both this year and last the yellow sweet clover bloomed 15 days in advance of the white, and he thinks an increase in the amount of yellow sweet clover would be a good thing for bee-keepers in that region. There would not, however, be the same advantage in yellow sweet clover in regions where white clover is the leading honey-plant. It would then come in direct competition with white clover, while the white sweet clover would give an additional amount of surplus, because, on account of its lateness, it continues to bloom after white clover is gone.

### Water for Bees

As the honey harvest begins to wane, the trouble of bees about pumps, watering-troughs, etc., will begin or increase. The great point is to get the bees started at the watering-place you provide for them before they get in the habit of going where you don't want them. If nothing else, provide a big crock with a few sticks of fire-wood in it and fill with water, and then see that it is never dry.

### Combs and Sections in Same Super

Speaking of this, which has been given as the Townsend plan, the editor of the American Bee-Keeper says:

"This method is so old that we supposed it was universally known. Mr. Samuel Cushman (then of Pawtucket, R. I.) and the writer, began using it about 1885, and the writer has used it ever since, having hives and supers specially made to facilitate such practice. It has been mentioned by many writers, if memory serves us correctly."

### An Appreciation from England

The following editorial paragraphs, taken from the British Bee Journal for June 22, and which we are pleased to reproduce here, are very appreciative of Mr. Frank Benton and his long journey after bees and honey-plants across the ocean:

We have been favored with a call and a pleasant interview with Mr. Frank Benton, Apicultural Investigator, United States Department of Agriculture, who, in his official capacity, has undertaken a journey extending more than half around the world in search of foreign bees and honey-producing plants. It came as an agreeable change from our ordinary editorial work to spend a few hours with so fully-informed and widely-traveled a bee-specialist as our visitor. Few men have had such a long and varied practical experience with foreign bees in their own habitats as Mr. Benton, who seems eminently fitted for the task entrusted to him. Fully impressed with the importance of his mission, he was frank and willing to a degree in conveying to us—and through us to our readers—what his journey really meant, and this will be realized when we say that, after a very few days' stay in England, he goes through France, Germany, Switzerland, Italy, Austria, and to

Turkey; then leaves Constantinople for the Caucasus, thence across the Caspian Sea and by rail on to Bokhara, and, if possible, through Afghanistan by caravan to Punjab, in India, and finally from Calcutta to the Philippine Islands.

The specific object of his errand is, among other things, to obtain a good supply of Caucasian queens of a particular strain, which has been tried in the experimental apiary of the Government apiary at Washington by Mr. Benton himself with gratifying results. He also hopes to be able to do something towards deciding the usefulness, or otherwise, of the giant bees of India, *Apis dorsata*, and other species of this genera, known as *Megapis dorsata*, *M. zonata*, etc.

With all this before him, we heartily wish for Mr. Benton's success, and if the desired object is secured, as we trust it will be, British bee-keepers will no doubt, in some degree at least, benefit from his labors, because, should the particular strain of Caucasian bees mentioned maintain the extremely docile and prolific character of those already tried at Washington, we shall hope to see them introduced into this country for the general good of the craft. In any case, we shall hope to hear from our good friend occasionally as time passes, and that he may return safely from his journey will be the wish of all readers along with ourselves.

## Miscellaneous News Items

**Crop Reports and Prospects.**—The California National Honey-Producers' Association sent a notice to its members July 6, signed by Secretary H. J. Mercer, from which we take the following information as to crop reports and prospects:

Southern California will have about  $\frac{1}{8}$  of a crop.

Central California, "prospects are for a fair crop."

The Colorado crop will be about 60 percent of a full crop. Worms are destroying honey-plants. Eastern slope cold and windy.

The Arizona honey crop to date is the lightest in many years.

In Texas a fair crop is expected.

They estimate the crop for Southern California to be 125 cars of 20 tons each. This estimate is not a guess, but is based on reports received and the number of cases and cans sold.

**A Visit to Mr. E. J. Baxter.**—The morning of the second day we were at the Dadants', Mr. D. hitched up a good horse to the carriage, and gave us an 11-mile ride along the east shore of the Father of Waters. It was a somewhat exciting drive, as nearly all the bridges along the road had been washed away during the recent unprecedented flood, so that we were compelled to ford streams often up to the box of the carriage. In one township 27 bridges were reported as having been thus swept away. But much of the way was very pleasant, as it was in the shade, and also early morning.

About a mile north of Hamilton the sweet clover is simply wonderful in its luxuriant growth along the roadsides. Mr. Dadant said it was right there where his father, some 40 years ago, first recognized melilot, or sweet clover, in this country. He had been familiar with it as a good honey-plant in his native France. So he began at once to gather the seed and scatter it until all over that region it grows in rich abundance, and is a source of much nectar for the bees.

We arrived at Mr. Baxter's about 11 a.m. He was just getting barrels ready for the first

extracting of the season. Besides a home apiary of about 100 colonies, he has several out-apiaries, in all some 250 colonies of bees. And he seldom has a failure in the honey crop. Like his brother-in-law, Mr. Dadant, Mr. Baxter believes in large hives, and runs for extracted honey exclusively, following the Dadant methods of management which are invariably successful.

Mr. Baxter has always made money at bee-keeping, his annual honey crop running up into the tons. He is a director in the State Bank of Nauvoo, which is one of the most prosperous institutions of the kind in all Illinois. Its capital is \$25,000, with a surplus fund of \$50,000. Its deposits of all kinds amount to nearly half a million dollars.

Nauvoo is a city of perhaps 2,000 population. It was founded by the Mormons who were compelled to leave it in 1847, going on to Salt Lake City. A few of the small brick houses built by the Mormons are still in use at Nauvoo. Some of the larger buildings were constructed out of the stone from the Mormon Tabernacle, which was taken down after they left Nauvoo.

But to return to Mr. Baxter. He has two sons and two daughters, the elder of the latter being a musician. Both sons are at the State University, as is also Maurice Dadant, mentioned last week.

Like Mr. Dadant, Mr. Baxter is just completing a brick mansion. It is a result of his bee-keeping—a substantial proof that he has succeeded. It is located at the side of the home apiary. (See first page). The picture of the apiary was taken before the house was built. It would be utterly impossible to get a good picture of it now, as it is located under so many large trees, some of which are basswoods. And how the bees were humming on the just-opening blossoms! It seemed we never saw much finer basswood trees than those in Mr. Baxter's apiary.

As the white clover had been yielding for a

week or two, on some hives there were 3 and 4 10-frame extracting-supers. Each had 9 frames, so there would be thick combs, thus requiring less work in uncapping.

Mr. Baxter seldom has any swarms. This condition would be expected as he uses hives and methods similar to the Dadants, as before mentioned.

Mr. B. has been a reader of the American Bee Journal for over 20 years.

Both Mr. Baxter and the Dadants are large growers of grapes, and have clearly proven that grapes and bees may be kept within close proximity to each other without one doing damage to the other. The Dadants were induced to plant grape-vines on a large scale in order to convince their neighbors that bees did not, and could not, damage sound grapes. Mr. Baxter has one of the largest vineyards in the country, and the Dadants have about 12 acres of vines, and grow as fine grapes as anybody, in spite of near-by apiaries. Nauvoo is noted for its vineyards.

Immediately after dinner Mr. Dadant drove us around the city of Nauvoo, then we started on the homeward trip by another route. The day's 22-mile ride afforded a good chance to visit with Mr. Dadant. And we improved the time.

We arrived just in time to partake of Mrs. Dadant's splendid supper, after which it was necessary for us to start for Keokuk to take the train for Fort Madison, and then back to Chicago again. It was a pleasant 2-day's trip—one that we will not soon forget.

**The Apiary and Residence of W. D. Soper,** of Jackson Co., Mich., appear on the front page. On July 3 there were 75 colonies of bees in the apiary, all booming, and part had 3 stories on, each 12 inches deep. It is Mr. Soper's farm residence, as the large grain-barn can be seen in the distance at the right. It is located 4 miles north of Jackson, on the Lansing road. Mr. Soper is also a dealer in bee-supplies, and is a general all-around hustler. We had the pleasure of meeting him at the Michigan State Convention, held at Grand Rapids, last February.

**Walter S. Hoss,** a new queen advertiser, located at Indianapolis, Ind., is sending out some very fine Italian queens. We think a trial order will convince any one that he has nice bees. See his advertisement on another page.

**Mr. and Mrs. E. E. Coveyou,** of Emmet Co., Mich., are rejoicing over the arrival of a fine baby boy, born July 13. They intend to make him the "Bee-King of the North." We hope they will succeed in so doing.

### "Unite," Not "Winter"

The word "winter" in first line of the last paragraph of my article on pages 452 and 453 should be "unite." I was writing solely with reference to the uniting of weak colonies in spring, and not about wintering at all. Whose was the mistake I am unable to say.

The season here so far has been a fairly good one for honey. The weather is very wet at present. I have had but 4 swarms. Cause, an abundance of storage-room in the shape of drawn combs.

EDWIN BEVINS.  
Decatur Co., Iowa, July 3.

## Convention Proceedings

### Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904

(Continued from page 490)

#### ADVANTAGES OF THE "WISCONSIN HIVE."

"What are the advantages of the so-called Wisconsin hive?"

Mr. Bacon—It seems to me that the Wisconsin hive has the combination of the good points of the Improved Langstroth-Simplicity and also the dove-tailed; it seems to me that is the main reason for its popularity. It has a portico front and it is now made so that the supers which are now used with the dove-tailed hive can also be used on the Wisconsin hive. Those I believe are the principal points.

Mr. Abbott—I want to say that the main advantage of the Wisconsin hive is that its makers took all they could of the "St. Joe" hive and put into the Wisconsin, and made a very good hive! [Laughter.]

Mr. Fluegge—I would like to ask these gentlemen what the slatting arrangement in their super is. If they got that from Mr. Abbott he didn't lose much. [Laughter.] I have several of them and I always took an axe to them to get the honey out. They may have improved them now. I hope they have. When I was a beginner I had six of them and the slats had no end-blocks; they fitted into a rabbet at the bottom of the super, and in order to get them out—one rabbet was a little deeper than the other—I had to lift them up a little ways and shove them over probably a quarter of an inch, and the other end would come out.

Mr. Wilcox—I have tried the Wisconsin hive somewhat. I bought one or two some years ago for trial and I found some disadvantages. The question calls for advantages.

Pres. York—We don't want to know the disadvantages—just the advantages!

Mr. Wilcox—One thing I disliked was that the end-bars of the brood-frames stuck right out.

Mr. Root—That is the Langstroth-Simplicity.

Mr. Wilcox—I think it was listed as the Wisconsin hive. I might specify another peculiarity of it which was that the frames were anywhere from one quarter to three-eighths of an inch shorter than the regular Langstroth or what would be the old frame Langstroth length and that was an odd feature of it because it didn't correspond with any other frames in the neighborhood. Another feature of it was that described by the last gentleman about the supers. The slats in the bottom of the super didn't trouble me very much but I didn't exactly like them. I may be mistaken. I don't know. But I have always called it the Wisconsin hive. I think it was.

Mr. Whitney—I want to back up what Mr. Wilcox said about what he supposed to be the Wisconsin hive. You know last winter didn't treat some of us very well, and we lost a good many bees. I wanted some last spring to build up my apiary, and I went out and bought four or five colonies. They happened to be in a queer sort of hive; the frames were a little shorter than the Langstroth; I couldn't use them in the Langstroth hive when I came to make a transfer; and they had supers on that had that rabbet arrangement that the gentleman here speaks about. I thought it was a Chinese puzzle. I couldn't use it at all. Now, I don't know whether that is the Wisconsin hive or not, but as they describe it I should conclude it might be. It had a portico.

Mr. Abbott—I want these gentlemen to get a clear idea about these hives, and it is a matter of some interest. While I represent the firm making the Wisconsin hive, I think an explanation is due them at least. They have made what was called the Langstroth-Simplicity hive which is, I admit, practically worthless. They have discussed taking it off the market for a long time. It has a shorter frame, and a groove all around, and the frames extend over. A great many people call that the Wisconsin hive. That is not the Wis-

consin hive at all. That is a Langstroth-Simplicity hive. They make at the same time what they call a Wisconsin hive, that is the trade name; that has Hoffman frames in it which fit inside the hive on a tin rabbet. The sliding arrangement of the hive is the same as the St. Joe hive, and if the gentlemen do not know how to handle that, why, we are ready to show them how to handle it so that they won't have any trouble about it. But don't get the two hives confused. The old Langstroth-Simplicity hive, in my opinion, is worthless because it hadn't a correct bee-space above it and the frames were not the same. So when you order hives don't say you want a Langstroth-Simplicity hive unless you want an odd frame, for you will get it. The other is the same as the dove-tailed hive; and in all of the hives that concern makes, the frames are the same except that old Langstroth-Simplicity, and that is not of any account.

Mr. Whitney—When you order hives don't order the Whitney hive. He has a hive of his own, and he doesn't want any better, and he has none to sell!

Mr. Stuebing—It depends mostly on the man, how he handles the bees and how he places and handles the frames.

(Concluded next week.)

### Report of the North Texas Convention

The North Texas Bee-Keepers' Association met at Blossom, Tex., and was called to order by the President, J. M. Hagood, at 1 p.m., April 5, 1905, the morning having been taken up in a general social time. In the absence of the chaplain, prayer was offered by W. H. White. The secretary being absent, Mr. White was elected temporary secretary.

The first business was the appointment of a committee on program, as follows: E. A. Ribble, Dr. R. P. Davies, J. R. Scott, and E. W. Cothran. While the committee was out the members were enrolled and membership fees taken up.

The Program Committee then reported the following, and was discharged:

1. Spring Management of Bees in North Texas.
2. Best Method of Increase.
3. Best Method of Suppressing Increase.
4. The Best Bee for North Texas.
5. Honey-Producing Plants of North Texas.
6. The Best Frame for North Texas Bee-Keepers.
7. Which is the More Profitable, Bulk Comb Honey or Section Honey?

The Program Committee suggested that a committee be appointed to select special subjects for discussion at the next annual convention, and certain members be assigned the special subjects.

The program was then taken up as follows:

#### SPRING MANAGEMENT.

Spring management of bees, as given by E. A. Ribble, is to see to it that all colonies are supplied with plenty of stores to carry them through to the first honey-flow, either by feeding them syrup or giving them honey kept over for that purpose. He keeps honey that is not in good marketable shape for spring feeding. His unfinished sections are used for this purpose by filling a super and setting it over the colony needing feeding. Thus he tides them over the dearth which usually comes in North Texas from May 15 to July 1.

Dr. Davies advocates feeding enough to keep colonies strong in bees and in good working condition for the honey-flow.

Mr. Hagood gave his plan of taking the combs out very early and then giving them back as they need the stores.

Mr. Scott prefers using the Doolittle feeder, and feeding as much as they need.

#### GETTING AND SUPPRESSING INCREASE.

Dr. Davies prefers natural swarming.

Mr. Cothran increases by dividing.

The best method of suppressing increase, as given by Mr. Ribble, is to run for extracted honey. Mr. Hagood prefers large hives for the purpose.

#### BEST BEE AND HONEY-PLANTS FOR NORTH TEXAS.

Mr. Ribble thinks the leather-colored Italian bees are the best.

R. C. Abernathy prefers dark Italian bees.

As to the best honey-plants for North Texas, Mr. Hagood thinks alfalfa is good; also cotton always produces more or less honey every season. Huckleberry and sumac were spoken of as being good by those who live in the timber part of the country.

## BULK COMB VS. SECTION HONEY.

As to which is the more profitable, bulk comb or section honey, Mr. Hagood says section honey.

Mr. Abernathy, bulk honey, every time, having produced last season 18,000 pounds from 280 colonies of bees, and sold the entire crop for 10 cents a pound. After disposing of his crop he had orders for 16,000 pounds more.

Dr. Davies prefers section honey. Messrs. Ribble, White and Scott also prefer section honey.

Quite a discussion took place on this subject, and much good was derived therefrom.

On motion the convention adjourned to meet at 8 o'clock the next morning.

## SECOND DAY.

The convention met promptly at 8 o'clock, and resumed work as laid down in the program.

A committee to draft a program for the next meeting was appointed as follows: E. A. Ribble, J. H. Barnes, Dr. R. P. Davies and W. H. White.

The election of officers for the ensuing year resulted thus: J. M. Hagood re-elected President; R. C. Abernathy, Vice-President; and W. H. White, Secretary.

A vote of thanks was tendered the people of Blossom for the cordial manner in which they entertained the members of the convention.

A motion was carried to tax the members 25 cents each as annual dues for the purpose of keeping up the stationery and other expenses that may occur.

Blossom was selected for the next place of meeting.

The convention adjourned until the first Wednesday and Thursday in April, 1906. W. H. WHITE, Sec.

## Contributed Special Articles

### Management of Bees for August

BY C. P. DADANT

THE second honey crop begins usually about the middle of this month wherever fall blossoms abound. It begins with the knotweed, and the ironweed, and ends with the Spanish-needles and the asters, in September. Sometimes the white clover lasts through the entire summer, and furnishes quite a little honey during August, especially if the summer has been moist. It is therefore necessary to give the hives additional space unless the supers have been removed and replaced by fresh ones. It is in fact not very good management to leave the supers on all through the summer, because the bees will put a great deal of propolis in the sections. It is better to remove them as soon as the clover crop is at an end, to put them on again as soon as the fall crop begins, except when the honey season is uninterrupted.

This applies especially to the production of comb honey. With the extracting supers it matters but little whether the bees put propolis in them, and they are safer over the brood-combs than stored away in the bee-house.

Just as soon as the bees are noticed whitening their combs, they should be given ample room. New swarms that have filled the lower story during the clover harvest are often known to fill supers during the second crop, so they must be supplied with supers. Sometimes, also, colonies that have swarmed and have become greatly weakened begin to recuperate and may prove among the best for the second crop.

It is well also to examine all the colonies for laying queens. After the swarming season is over some queens get lost in the field while out to mate, and the colonies to which they belong may not have had suitable brood at hand to replace their loss. So we often find, late in July or early in August, strong colonies dwindling down because of being queenless. It was formerly customary among the practical bee-keepers to rear a number of queens and to keep them in nuclei for such emergencies, but the queen-business has gone into the hands of specialists, and the price of a queen is now so low that it is hardly worth while to bother with queen-rearing. Most of our producers order their queens from well-known breeders at a less price than it would cost them to rear them.

But if we do not wish to buy our queens, a good way to replace the loss of a queen is to supply the colony with a sheet

of brood in all stages (especially young brood), with the adhering bees, from the best colony in the yard. A queenless colony helped in time will still rear a queen and gather enough honey for winter.

But we must bear in mind, at the August crop, that the condition of the colonies is changed since the swarming season has passed. Some colonies that were strong in June may be weak in August, and *vice versa*, so each hive must be examined just as at the beginning of the harvest, and either given more space or reduced according to its requirements.

If the colonies have been given extra ventilation during the hot weather by raising the hives from the bottom-boards, it will be well to lower them down again by the end of the month, as cool nights are coming and there will be loss of heat if too much space is left.

New colonies made by dividing on old combs should be reduced to the amount of space they can readily cover. In this way they will put their honey in more compact shape for winter, and will also protect themselves best against the moth. For it is at this season that the moths are most numerous. Strong colonies have nothing to fear from them, and every colony may be regarded as sufficiently strong if it does not have more combs than the bees can cover, and if it has a good laying queen.

Hancock Co., Ill.

### Is Old Foundation as Good as New?

BY J. A. GREEN

THE article by G. M. Doolittle, on page 54, would seem to the inexperienced to be a "settler" on the question of the comparative value of old and new foundation; yet, to my mind, it is as good an example as one could wish to find of the desirability of really proving a thing instead of either taking the word of some one else or accepting as conclusive the results of incomplete experiments.

The question of the comparative value of old and new foundation can not be settled entirely by the bee-keeper. In a matter like this, we should ask the bees. But, you will say, this is what has been done.

Doolittle and other bee-keepers have used old foundation, and have found that the bees used it all right. Does not that prove that old foundation is as good as new? By no means.

Take notice that Doolittle says that *all* the foundation used by him for 15 years has been put into the frames or sections during the months of December, January, February and March, then stored away until used. Will he tell us what he has had to compare this foundation with? All that his practice really proves is that bees will use old foundation, something that I think no one will question. But it would give scarcely a hint as to what was the preference of the bees.

Now let me tell you how I have tested this matter, in what I consider the only fair and convincing way. Although I fully believe that new foundation is best, and though I much dislike to have any sections filled with foundation carried over from one season to the next, I am obliged by the necessities of my position to anticipate the bees' needs, and consequently the close of the season usually finds me with quite a number of supers filled ready for the bees, but unused. These, Doolittle tells us, are just as good for use the next season as if they were filled with fresh foundation just before the honey-flow. Accordingly, no doubt, he would use them just as they are, and consider himself lucky in having them all ready for the bees.

Experience has made me a little cautious about this, though, and I never give a colony a full super of old sections. Instead, I divide the super, putting half the old sections into another super and then filling both with sections containing foundation as fresh as I can conveniently get it. They are always put in in a certain way, the new sections all on one side of the super, the old on the other, and I can always tell at any time not only which supers are prepared this way, but can always tell which of them are the old and which are the new sections. I have done this for many years, having each season from 20 to 100 supers prepared in this way. Now, as to results:

In nearly every case, except when the bees have been crowded into the supers by a heavy flow of honey, the bees will start on the new sections first. Occasionally they will make quite a start on them before they will touch the old ones, but usually, in an ordinarily good honey-flow, there will be only a little difference, just enough to show that they prefer the fresh foundation. Even this little difference will usually disappear before the super is finished, so unless you keep close watch of the work being done, you will not notice that the bees have any preference.

Perhaps you will say, if the difference is so slight that it can not be detected at the time the super comes to be finished, it does not amount to anything. It does amount to something, though, in just this way:

It is so exceedingly important that the bees make an early start in the supers; that they form as early as possible the habit of storing their honey there; that for the first super at least everything should be made as attractive as possible.

The man who has a large apiary must have his sections prepared in advance of the time they are needed, but if you have not many bees do not be in too great a hurry to get the sections filled. When they are ready for the bees, keep them closed up as tightly as possible, away from the air, and especially the light. The action of the light and air is to bleach and harden wax. In the early days of comb foundation, bleached wax was used for surplus foundation until it was found that it was not as good as the softer yellow wax. Foundation that is left closely packed, as it comes from the factory, will deteriorate but very little.

That there is a difference in quality between fresh foundation and that which has been exposed to the air is proved by the fact that the paper separating the sheets of foundation is often marked by an oily stain where it comes in contact with the wax, while foundation that has been exposed to the air

for any length of time can not be made to stain paper by contact.

No, Mr. Doolittle, this matter of old foundation not being as good as new, will not do. It will keep on its rounds through the papers and on mortal lips, bobbing up its head again and again until nearly all the bee-keeping world not only thinks but *knows* it to be a fact.

The foregoing applies to foundation that has never been put into the hives. If the foundation has been left in the hive some time, so that it has been propolized by the bees, the case is even stronger. I have frequently seen or heard the statement in regard to putting sections on late in the fall, that they were all the better for having been worked over a little by the bees, even if they had not been drawn out any. No greater mistake was ever made.

When foundation is left on the hive at a time when the bees are not inclined to draw it out, they are liable to cover it with a varnish of propolis, after which they are very loath to do anything with it. I have known such sections to go through two good honey seasons untouched, though several sets of other sections in the same super were promptly filled and finished. The most profitable thing to do with foundation in sections that the bees have begun to propolize is to cut it out and melt it up. Mesa Co., Colo.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### A Bereaved Sister—Motherwort

A few weeks ago I sent you a copy of the Crawford County Press, containing an account of the death of my husband, and forgot to mark it with my honey stamp, so that you would know that a bee-keeper had sent it.

In the care of my husband all winter and his recent death I had almost forgotten that I was a bee-keeper. After a very severe winter and long, cold spring I found on June 1 that I had lost 50 percent of my bees, and some of those that were left were in a very poor condition, but they are building up now. The weather, and especially at night, is very cool; to-day we are having a heavy rain. I have taken off no honey to date (June 29).

LATER.—To-day (July 5) I took off my first super of honey. It is very nice, but we need a little sunshine. It has been pleasant to-day, but I think it will rain before morning. Basswood trees are budded and almost ready to blossom. I hope for some honey from that source. There is an abundance of white clover, but there is a little too much rain for the bees, as we have a shower almost every afternoon.

What is the name of the enclosed plant? It begins to blossom in June and continues to blossom till frost comes, and the bees work on it incessantly.

I am all alone with my bees now, and feel too sad and lonely to write. I wish you a pleasant and prosperous summer.

MRS. PAUL BARRETTE.

Crawford Co., Wis.

Yes, I received the notice of your husband's death, and was considerably puzzled over it. Your letter makes all plain. I am sure the sisters will all join with me in extending our heartfelt sympathy in your affliction. That sentence, "I am all alone with my bees now, and feel too sad and lonely to write," made me feel that I would like in some way to let you know that the sisters *do care*, and feel, oh, so sorry for you.

I think the enclosed plant is motherwort, one of the mint family.

### Artificial Increase—Putting on a Second Super

1. In artificial swarming do you recommend forming one or two colonies from the original

one? A bee-keeper tells me his bees gather little or no surplus honey if only one new colony is formed.

2. Will you kindly explain how the second super of a Langstroth-Simplicity hive is fitted on the first? Regular size  $4\frac{1}{4} \times 4\frac{1}{4}$  sections are an inch or more higher than the top of super No. 1, and a groove  $\frac{3}{8}$  inch from bottom of super No. 2 admits tin supports for the section-holder.

Now, I am at a loss to know how proper spacing can be given. MISS WISCONSIN.

1. The bee-keeper is right that increase, either natural or artificial, is at the expense of the honey-crop, if that is his meaning. But your asking whether the increase should be one, or two, from each colony, and saying in close connection with that that little surplus is obtained "if only one" new colony is formed, sounds as though he meant that there would be more surplus if two new colonies were made. That can hardly be correct anywhere in Wisconsin. It could be true only where a long, heavy flow came late in

the season. In your State, and with your harvests, you will probably find that a colony will give its greatest yield if it happens to be one of that accommodating sort that directs all its energies to the amassing of stores, not bothering its head about sending out any emigrants to populate some other hive or hollow tree. In actual practice most bee-keepers try to limit increase to a single new colony formed from each old one, while some limit the increase to one from each two old ones. In this locality we try to limit to less than that, but we have a time of it. You may be assured that making an increase of two from each colony will not give you more surplus than an increase of one.

2. Ignorance of the exact construction of the supers of the Improved Langstroth-Simplicity hive makes it difficult to answer. It looks just a little as though your second super were made different from the first, and it can hardly be that such is the proper thing. If the tops of sections are an inch higher than top of super No. 1, and bottoms of sections only  $\frac{3}{8}$  of an inch higher than bottom of super in No. 2, there's plainly a misfit. It looks as if by some means there should be more than  $\frac{3}{8}$  of an inch, and you should raise the supports up more than an inch from the bottom, so that the bottom of super No. 2 should telescope down over the sections in No. 1, and still leave a space of  $\frac{1}{4}$  inch between the two sets of sections. In any case, all supers should be perfectly interchangeable, and so should all be alike.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### MENDING A LEAKY WOODEN TANK.

That a wooden tank otherwise leaky can be made perfectly tight by covering it internally first with manila paper and then with hot paraffin (as per page 436) is a good thing to remember. I do not feel like praising the arrangement very highly, however. I fear the first time it gets empty more or less of the paper will get knocked off. Have a tank that is permanently tight, even if it does cost quite a bit more.

### CHEMISTS AND HONEY DEFINITIONS.

Quite willing am I to see Mr. Dunlop go for the chemists—when they get outside their province and try to upset definitions which have stood for ages. Still, perhaps he may be getting on this ice at one point. If man should put oil of garlic in milk it would be an adulteration, and a bad one. If the cow puts it in it is not an adulteration—perhaps. If

man puts filthy water in milk it is an abominable adulteration; but if he puts it in *first running it through the cow*, how then? The practical distinction is getting pretty slender. Poisonous, disgusting and uneatable honeys are to be avoided, and proceeded against all the same whether we put them in the same class with adulterated honeys or in a class by themselves. Shifting the skunk from one classification to another—we need not resist that with any idea that it is going to deodorize him. Page 437.

### DOUBLING WEAK COLONIES IN SPRING.

I have an apiary that often ranges above a hundred colonies, and yet I want to thank Allen Latham for his article on the weak colony in spring—from the small apiary's point of view. Most of us, I reckon, do not find doubling up in spring a very satisfactory operation. But shaking the little forlorn remnant into a hole in the ground and cover-

ing them up, there's no particular profit in that; and in addition it's unpleasant to one's feelings. Doubling up saves the unpleasantness, and gets the problem off one's hands. I also will plead guilty to the soft impeachment of being willing often to save a colony by doing for them much more than they are worth. We are not, I trust, mere two-legged bears with certain mental improvements. But if he had asked me I should have guessed that four weeks with a hot-water can every day would have netted more harm than good—forgotten once in awhile, and also making cold mornings worse by contrast. All's well that ends well. I suspect that particular colony was a little abnormal in devoting so large a share of its energies to house-cleaning. With me the *somewhat weak* colony is apt to be provokingly remiss about cleaning up, except just as far as it needs the combs. That nurse-bees using much flour instead of pollen are apt to find defecation difficult, is a rather important item, strong reason for waiting till natural pollen comes. Page 438.

#### THINGS WE DON'T KNOW—AND DO KNOW.

So H. V. Poore thinks it would make a longer article to tell what he has yet to learn. Alas, we can not tell what we have not found out yet! And there is one circumstance still worse than that. We tell what we have learned wrongly with much greater facility than we do what we have learned rightly. The latter seems so commonplace and uninspiring that we give it the go-by. Page 439.

#### A WOMAN'S BEES AND POULTRY.

Prayer-meeting. Small boys intent on fun ranging around outside. Colony of bees in buggy waiting to be driven home after devotions are over. These are not collocations to be recommended—too much like pin-wheel in powder magazine. But never mind; Mrs. Wingate has tried both a flock of poultry and

an apiary of bees as home money-getters, and finds the latter to succeed much the better. Her testimony is valuable; testimony on such points being much more valuable than theory. Of course it goes without saying that poultry is confining in its every day demands, while bees allow lots of vacation time. Page 439.

#### THE MISTAKES OF THE PRINTER.

For champion idiocy the printer's "out" is quite in the habit of taking the cake. For example see in the next to the last caption of my department on page 441. According to that bees feed young queens through gauze presumably with sting poison. I can only hope that the reader may conjecture that the doings of two different sets of bees have got condensed into one. Still I do much prefer to say things myself rather than burden the reader with slinging his own English—and, eke, untangling mine if possible.

[The following is the paragraph referred to in the above, with the omitted part in italics:—EDITOR.

#### QUEENS AND BABY NUCLEI.

If a queen is put in a baby nucleus only in warm weather, and only when ready to mate, the harm the new device does would seem to be reduced to a minimum. Quite curious if queenless bees are less tolerant of supernumerary young virgins than bees of a colony with a laying queen are. According to John W. Pharr, page 346, the latter will feed them through the wires, *while the former succeed in killing them through the wires*—presumably by the amount of sting-poison which they evaporate. Yet possibly this last may be wrong. All queens soon die from nerve causes if entirely bereft of company. Perhaps with only enemies for company death would be about as speedy, and the cause about the same.

detect, and that may make some difference as to the bees stinging.

2. Some time ago it was claimed that a bee could not sting one so long as one held his breath. It's all bosh, as any one can easily prove. Quiet deportment is probably the secret of immunity from stings of wasps.

3. Often bees will sting one more readily at a little distance from the hive than when close up; I hardly know why. I work among bees with bare hands, and there are thousands upon thousands of them that never sting me; others, however, don't seem to have the proper respect for me, so I get a good many stings. As already said, difference in the quickness of motion, and difference in the odor of the body, may make bees sting one person more than another. Clothing may also make a difference. Woolen or soft cotton goods are not so good for bee-keepers as cotton or other goods with a hard surface. Dark clothing is also more offensive to the bees than light colored.

4 and 5. Clipping the wings of a queen before she is fertilized would ruin her. When a prime swarm issues, the queen is a laying one, and does not need fertilization. In after-swarms the queen may or may not be fertilized during the act of swarming; but no queen should ever be clipped till it is known that she is laying.

6. I do not know that any one ever clips all four of a queen's wings. Some clip the larger wing on one side; others clip the two wings on one side. Clipping only one wing leaves the looks of a queen less impaired; but some, myself among the number, prefer to clip both wings on one side because it makes it a little easier to see at a glance, when a queen is moving over the combs, whether she is clipped or not.

7. Any time at the convenience of the operator after she begins to lay. A common custom is to look through the hives as soon as convenient after the bees get to work in the spring, so as to clip any new queens that have come upon the stage through supersede the preceding fall.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to Dr. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Use of the Drone-Trap—Second Swarms

1. Is there not danger of suffocating the bees with a drone-trap?
2. After the first swarm issues, how soon can I look for another? MISSOURI.

ANSWERS.—1. There is little danger of doing any harm with the trap, although it seems to annoy the bees somewhat, and there is a bare possibility of an extreme case with such a multitude of drones that the trap would become entirely filled and suffocate the bees. But such a case has never been reported yet that I know of.

2. A second swarm usually issues about 8 days after the first, but the time may be less, and it may be more. The 2 swarms you mention in your letter were three days apart. If the first one was a prime swarm, then the first one had been delayed about five days. The issuing of a prime swarm is sometimes delayed by bad weather, and it may be delayed by the queen failing for some reason to go with the swarm. It is quite possible, however, that both your swarms were after-swarms. You may have failed to see the prime swarm, or it may have issued and the queen may have been lost or killed, the swarm returning. Then the 2 swarms would each have virgin queens, and it is nothing unusual for 2 after-swarms to be three days apart.

### Handling Bees Without Being Stung—Clipping Queens

1. We occasionally have men pointed out to us who, it is said, "can do anything with bees;" that bees will not sting them as they

do other people. Is it because they are cool and self-possessed, ignoring a sting or two and by avoiding quick, rapid movements bees are less likely to sting them? or is there really a class of people protected by electrical influence, or otherwise, against bee-stings?

2. A young man in this vicinity handles wasps freely. He claims that by holding his breath they do not sting him. Others who tried it were promptly stung before they could catch their breath. Can you explain the trick?

3. I had a man manipulate my hives, which he did with bare hands, and yet the bees did not sting him, while they persisted in trying to sting me, although I stood 10 feet distant in the rear. Why was this?

4. How do those queens that have their wings clipped, and are unable to fly, become fertilized, as I understand that this occurs during the flight of swarming?

5. Is there not danger or rendering queens sterile by clipping their wings so they can not fly?

6. Is it customary to clip both wings, or one only?

7. When is the proper time to do it? NEW YORK.

ANSWERS.—1. It is doubtful that there is any one whom bees will not sting when they are in the right mood for stinging. But it must be remembered that comparatively few bees ever sting, or try to sting. If 50 bees should be flying about you at one time, trying to sting you, it would be a big lot, but there are thousands of other bees flying about that show no hostility. The person who is nervous and makes quick movements is likely to find it resented by the few irascible bees, while one who is slow and deliberates in movement will be unharmed. There may be a difference in the odor of different persons that the bees

### Methods of Increase Other Than Swarming

I have 8 strong colonies of bees, and I also have 4 Danzenbaker hives with full sheets of foundation, desiring to have them drawn out in worker-comb. Being a beginner I don't know how to proceed to increase to 4 more colonies in the Danzenbaker hives, but here is my plan:

To order 4 queens, and on their arrival—before going any further I wish to say that 7 of my colonies are in Langstroth hives, and the remaining one is in a 2-story Danzenbaker, with 10 frames of honey above and quite a little in the brood-chamber—take two frames, or one frame, of honey, placing same in a Danzenbaker hive with 8 or 9 frames with full sheets of foundation, and then go to another strong colony and shake half of the bees in this hive, placing a piece of screen over the entrance, then place the caged queen over the frames to be released by the bees. Then set all in a new place. After 4 days take the screen off the entrance. Look at them about September, and if in poor condition feed them.

My point is to increase to 4 more colonies, using the Danzenbaker hive, taking frames of honey from another Danzenbaker hive, so the bees would not starve until they get started.

I bought 6 queens, and not receiving any instructions with them, I introduced them to the best of my knowledge, after reading in the "A B C of Bee Culture" how to introduce. With the first 2 colonies I was successful in finding the queen, and after killing her I looked for queen-cells; not finding any I placed the caged queen over the frames, and after about 5 days I noticed them carrying in pollen and working.

In colony No. 3 I found no queen, but about 8 queen-cells, so I placed an empty hive-body on the ground, and after putting a piece of perforated zinc over the entrance, I brushed all of the bees in front of the hive and let them run in, then placed the frames back in the hive again. I put a queen-excluder over

the hive-body, and left the zinc over the entrance for nearly a week, and found them gathering pollen and working.

Hive No. 4, not having time on Monday, when I removed the other queens, to remove the queens in the other 3 hives, I just placed the caged queens over the frames, and it being bad weather I couldn't do anything with them until the following Monday, when I went to hive No. 4, and finding the queen I killed her and removed the stopper in the end of the cage.

No. 5, not finding any queen I took an empty hive-body, placed a piece of perforated zinc over the entrance, shook all the bees in front, and let them run in, placing the frames in the empty hive-body. I put a queen-excluder over the hive-body containing the bees, and placed them on their stand. I did likewise with No. 6. I noticed that they are all working and gathering pollen. Do you think I was successful? After introducing a queen, and the bees gather pollen and go to work, doesn't this signify that everything is satisfactory? DELAWARE.

ANSWER.—Your plan of making the 4 new colonies will work, although there are objections to it. The loss of time while the bees are imprisoned 4 days is quite an item. The bees will fret no little at the confinement, and you will find an unpleasant number of them dead when you open the entrance, especially if the weather is very hot. Better keep them in the cellar during their time of imprisonment.

Here is another plan that is not open to the same objections: From the colony in the Danzenbaker hive, take one frame of brood without any bees. Put it in one of the empty Danzenbaker hives, the rest of the hive being filled with frames of foundation. Set this new hive on the stand of one of the Langstroth hives; shake into the new hive the bees from half the frames in the Langstroth hive, after first finding the queen, which you will also put in the new hive, and set the Langstroth hive in a new place, putting into it your new queen caged. Do this with each of the four hives, and the bees will work right along with no interruption.

After introducing a queen, if the colony is working vigorously and carrying in big loads of pollen, it is pretty good evidence that the queen is all right; but the safe plan is to look and see whether eggs are in the frames. You were certainly successful in introducing, if the whole 6 are laying well.

I thank you very much for your kind words in appreciation of this department.

### Self-Requeening—Hiving Wild Bees in Trees—Where to Fasten Section Foundation—Ants in Hives

1. A week ago I transferred a frame of brood from an 8-frame hive to a Danzenbaker hive, cutting the comb of course to fit the Danzenbaker frames, but I did not transfer the queen, and I gave them the  $\frac{1}{2}$ -inch entrance. Do you think that was right, or should I have given them the small entrance? How long will it take them to rear a new queen? I put the new hive on the old stand.

2. I would like to know some good method of getting a colony of bees out of a hollow tree into a frame hive.

3. When one receives a queen from a queen-breeder, does the cage always have the name of the kind of a queen on it?

4. In putting foundation in sections on which end or side of the section should the foundation be put, the one that has the dovetailed end, or the other?

5. Why not use full sheets of foundation in every other frame instead of every one, to insure straight combs in the brood-chamber?

6. A neighbor of mine has one colony of bees whose hive is fairly alive inside with little black ants, although the bees seem to be working well, but the ants are on the bees, in the combs, and everywhere else. What can he do to get them out? I thought mine might get that way, and I would better find out what to do. KANSAS.

ANSWERS.—1. Unless they build down into it the larger entrance is better. Probably

they will not build down. If no queen-cells were already started when the queen was taken away, it would be about three weeks before they would have a laying queen. It is a severe drawback to leave a colony so long without a laying queen at the beginning of the season.

2. Something depends upon the tree and the height from the ground to the swarm. If the bees are low down, the side of the tree can be chopped away, leaving the brood-nest exposed, when the combs can be cut out and fastened in frames. If the bees are too high for that, it will depend upon circumstances whether to cut off the tree above the bees and below, letting down with a rope the section containing the bees, or to fell the tree and run the risk of some smashing.

3. Generally not, I think, although I do not know.

4. I prefer to put in the foundation so that the dovetailed corner shall be at the bottom, but a certain gentleman who does some very interesting afterthinking for these pages, and for whom I have very great respect, prefers the dovetailed corner at the top. But I think he does not use bottom starters, and I do.

5. It will not make as even combs as to have all frames filled alike. Rather than have every alternate frame filled and the rest empty, I would have all the frames filled half full. In either case you are likely to have more drone-comb than is profitable.

6. I have known ants to be troublesome at the hives on account of getting on the hands of the bee-keeper, and apparently annoying the bees, but the bees always kept them driven out, and I never knew them to be allowed on the bees as you say. (Down South it is different.) Trace the ants to their nest, and destroy them with gasoline or bisulphide of carbon.

### Taking Off the Hive-Cover—Sowing Buckwheat—Perhaps Milkweed Pollen

1. Is there any danger of the brood getting chilled if the hive-cover is taken off when it is warm, and if off for any length of time?

2. What do you think is the best to sow as a honey-plant? Is not buckwheat about as good as there is? About what time should it be sowed?

3. What is the cause of bees coming out of the hive with their legs fastened together?

IOWA.

ANSWERS.—1. On a warm day a frame of brood well covered with bees may be left out a long time without any harm, perhaps all day if the bees do not leave it. Without bees the larger larvæ will begin to crawl out of the cells if left out too long—starving, probably, rather than chilling. If the weather is too cool for bees to fly freely, avoid taking out brood, or at least keep it out as short a time as possible.

2. Buckwheat is good, and probably there is no better time to sow than the usual time farmers sow for a crop in your locality. Sweet clover is also good, and perhaps rape or mustard.

3. The pollen from milkweed sometimes adheres to the feet of the bees, and thus gives them the appearance of clinging together.

### Perhaps Motherwort—Red Clover Bees—Don't Swarm or Work

1. I am sending the top of a plant that grows on our farm in great abundance, when not restricted. There is none of it on adjoining farms, and no one seems to know what it is. It grows from 2 to 3 feet tall, and the blossoms extend up and down the stalk for 8 or 10 inches. It seems to be a great honey-plant, for I have seen the stalk black with bees when in blossom. What is it?

2. What kind of bees is the sample enclosed?

3. Can red clover Italians get honey from red clover? There are great amounts of red clover here, but my bees can not get it. I know this, for the other day while looking over my bees I found a red clover blossom which had grown right in the entrance of one

hive; I pulled it up and found in it a large amount of nectar.

4. I have some bees in box-hives, and 2 colonies of them have been covering the fronts of the hives for three weeks and haven't swarmed yet. They will not work, either. What is the matter with them, and what can I do for them? MISSOURI.

ANSWERS.—1. It looks like motherwort.

2. It is hard to tell anything about bees that are mashed in the mail; but the sample looks like blacks.

3. There is difference in the length of the tongues of bees, and there would consequently be a difference in the depth to which bees can reach in red clover; so there is no reason why there should not be obtained a strain of bees able to do a good deal more than other bees on red clover. There is also a difference in clover. Sometimes, either because the blossom tubes are shorter, or because they are more fully filled with nectar, even black bees may be seen working on red clover.

4. I don't know. I'm afraid there's lazy blood in them. It is possible that they have young queens, and don't care to swarm, and are crowded out of the hive for want of room. If you drum them out, and put them in frame hives, it might stir them up to work; at any rate you could then see more about their condition. Likely, however, they will shortly swarm, and the swarms may then show better industry.

### How Much to Smoke Bees—Requeening to Change Stock

1. How much smoke should I give a colony of bees?

2. When and what is the best way to requeen some of these warrior colonies? I expect to try some of those gentle long-tongued yellow queens. O, no, they don't "bite!" Well, just come to my apiary and I will show you some of those "yellow jackets." But they store lots of honey. WISCONSIN.

ANSWERS.—1. As in other cases, use as little as possible, but enough to subdue them. That isn't very definite, is it? Perhaps I might say, keep on smoking so long as the bees keep darting out at you, and stop as soon as they beat a retreat. With most bees a very little smoke is necessary, and if you keep on smoking they will boil out and run over the sides of the hive at the top. That's too much. Some have reported bees of such disposition that smoke seemed to have little or no effect on them, if indeed it did not make them fiercer, and the only thing to do was to manipulate very carefully. Yours are hardly of that kind.

2. Right away, or as soon as you can give a queen of gentler nature, put her in the hive caged so the bees can not free her. In two or three days open the hive, kill the old queen, and leave the new one in the cage, but with candy which the bees can eat out to liberate her.

## Reports and Experiences

### Uniting Weak Colonies with Strong

Dr. Miller asks for reports from those who have had experience with uniting a weak colony with a strong one in the spring with the use of the excluder, to save both queens.

The past spring I had a strong hybrid colony in two extracting-supers for a brood-chamber—call it No. 6. About 4 rods to the southeast was a colony in a 10-frame Langstroth hive with a fine queen and about one pint of bees—call it No. 7. About 8 rods to the northeast was a colony in a Jumbo 10-frame hive which had lost its queen but had a fair-sized cluster of bees—call it No. 8.

I put 2 wood-zinc honey-boards on No. 6 so the queens could not get their heads together. I then placed No. 7 on No. 6. Of course a few fielders were lost from No. 7, but

as best I could tell they seemed to become welcomed at their next-door neighbor's, which was a strong colony.

Now, No. 7 staid on No. 6 about 10 days, by which time it had drawn up a strong force of young bees and developed a fine lot of brood, and by this time No. 8 had developed laying workers. I then placed No. 7 on top of No. 8, the field-bees returning to No. 6. In a few days the laying-worker nuisance was done with, and the queen, brood and bees of all ages were all together in the upper story, and most of the honey. I then removed the empty combs from the lower (Jumbo) hive, spread those which had a little honey, and as soon as they carried up the balance of the honey I removed the Jumbo hive and had a fine force ready for business.

I could not see that No. 6 was hurt a particle. The queen was there all right and laying profusely, and bees in great enough abundance. I had calculated that it would dampen the swarming propensity in No. 6, but afterward concluded to break up that colony into nuclei, and did not wait to see results on swarming.

W. T. CARY.

Carroll Co., Mo.

### Bees Doing Well Now

Bees are doing well now. I have had only one swarm so far, and it was a fine one. I had only 2 colonies to begin with in the spring, but I found a big one in a hollow log, which with the new one makes 4 colonies.

DAVID HAYNES.

Dallas Co., Tex., June 26.

### Bees Doing Well

I have now about 25 colonies. I began with 25, and they seem to be doing quite well considering the weather, for it rains a great deal this season. There is plenty of forage for honey. Basswood is just beginning to flow. The weather is clear this morning, so look for a lot of honey now. Some of my colonies have stored nearly 50 pounds of surplus honey. We have plenty of alsike clover, also white and red.

N. H. KEIZER.

La Crosse Co., Wis., July 5.

### A Swarming Time

We are completely outdone, out-generated, and non-pleased. Adjectives and swear words are useless. Our woe is caused by the busy bee that is supposed to gather honey all day long, and later be robbed of its stores by wanton man. If any veteran bee-man has any bee-lore that fits a tenderfoot, let him exhale it, or forever after hold his peace.

Hear our troubles and weep.

As the Editor of the American Bee Journal knows, my brother and myself have been dallying with the supposedly useful bee for 10, these 3 summers. Last fall we put into winter quarters 9 colonies. Five survived the rigors of our Harveyized-steel winter, and this spring we doped them liberally with granulated sugar at \$6.25 per barrel.

May 20 the first swarm came out. This was very kind of them, and we hived the industrious insects promptly. But listen: Those bees haven't done a thing since that date but swarm and—sting. Twenty-three swarms have emanated from those 5 since May 20. That is the truth, the whole truth, and nothing but the truth, so help us John Rogers, and we refer you to Stoughton Cooley, of Cook County, as to our veracity and other desirable qualities. He was out here and saw the bees. We changed hives and tried other anti-swarming devices, but the misguided insects went on doing business at the old stand. It is a fact that one colony sent out a swarm, and three days later sent out another swarm. How is that for industry?

A short time ago we noted a wail from somebody that his bees didn't swarm. Shades of the gentle Huber! If he lived near us we could strike up a bee-trade in short order. However, we must bear our burden of bees alone. They haven't swarmed now for two days, and we are resting easier.

By the way, we noted in the Bee Journal that some gentleman tried shooting swarms from high limbs successfully. A little later

we noted that some one in Ohio, who seems grievously afflicted with afterthoughts, criticised the aforementioned shotgun method caustically.

Now we 'fess up. A swarm clustered on a high limb shortly after we read of this unique method. My brother said he would try it. The shotgun was brought out and two shells slipped in. He aimed at the limb, about 6 inches from the clustered bees, on the tree side, and let go both barrels. It worked beautifully. The shock knocked the bees down, and they fell in a cluster at his feet. (He had taken the precaution to don a bee-veil.) The jolting made them pretty mad at first, but they took the matter philosophically, and after circling a few moments, clustered on a low cherry-tree, and we had no more trouble with them. That's all.

If any one can beat the record of 23 swarms from 5 in less than two months, we would like to hear of it. Some of these hilarious swarms have begun work in the supers, so we have a faint hope that they may reform in time.

FRANK E. KELLOGG.

McHenry Co., Ill., July 14.

### Good Promise from Basswood

We have had a very good honey crop so far, with a good prospect for basswood and willow-herb. Basswood is 10 to 15 days later than it has been in years; it will not be in for nearly a week yet. But I never saw a better promise for a bloom.

ELIAS E. COVEYOR.

Emmet Co., Mich., July 17.

### Rain Spoiled the Basswood

Bees are doing fairly well, though it rained every day for two weeks. Basswood slipped by without the bees getting much more than a smell. White clover and catnip are now in bloom, and these rains will give us a good stand of red clover and fall flowers though it did spoil our basswood.

H. G. QUIRIN.

Huron Co., Ohio, July 14.

### Not a Large Honey Crop

The honey crop is of extra-good quality and lots of it. But nights are cold, and there have been many foggy days, and the bees failed to reach home, so many have perished with their loads. Many colonies failed to store last year, and those not fed starved, consequently the California honey crop will not be overly large this year.

DELÓS WOOD.

Santa Barbara Co., Calif., July 4.

### May Be a Short Crop

The bees are hardly holding their own. If they don't get some honey before long I am afraid our honey crop will be short for 1905.

R. R. PATTISON.

Otero Co., Colo., July 6.

### Getting a Fair Honey Crop

I think we are getting a fair honey crop in this State. The weather is spotted, the flow is not continuous, and there is too much swarming; things seem abnormal, but the clover is still fresh, and with good weather it should secrete nectar. The basswood is full of buds and will open very soon.

GEO. E. HILTON.

Newaygo Co., Mich., July 6.

### Honey Season in the East

Honey has been coming in quite freely in some parts of the eastern States, some bee-keepers having taken off some extracted and in sections. What the season will be as a whole I am unable to say. Bees have been building up quite well, though in some localities there was quite a winter loss.

H. S. FERRY.

Westchester Co., N. Y., July 5.

### CONVENTION NOTICES.

**National.**—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Flint, Mich. W. Z. HUTCHINSON, Sec.

**Missouri.**—The Missouri State Bee Keepers' Association will meet in Sedalia, Aug. 22 and 23, opening session to be at 2:30 p.m., Aug. 22. The room to meet in will be named later on. The State Fair meeting there at the same time will obtain low railroad rates from all parts of the State. The Livestock Association also meeting there on the 24th will give us some inspiration. Hon. Geo. B. Elliot, Secretary of the Agricultural department, will be there and give a talk and lend a helping hand. Louis A. Osborn, of that place, has kindly offered to act as host, and will direct to the place of meeting and to accommodation. Hotel accommodations can be had at \$1 to \$2 a day. Private boarding cheaper. Let us turn out en masse and have a glorious time as well as to effect some extraordinary progress.

W. T. CARY, Sec.

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

334 Dearborn Street, CHICAGO, ILL.

**JOHN M. DAVIS, Spring Hill, Tenn.**

You will have to hurry to get your **Shipping-Cases**

We are running overtime filling orders, but are willing to run day and night to insure prompt shipment. No extra charge for this service. Besides, our **SHIPPING-CASES** are sold for less money and are of better quality than you can buy elsewhere. This is no pipe dream, but a proven fact. Ask those who have bought from us.

All cases are made with one-piece covers in any width up to 13 inches. Send us your trial order **NOW**. Be sure to mention width desired.

## JOHN DOLL & SON,

Power Building, **MINNEAPOLIS, MINN.**

## Queens by Return Mail

The **Standard-Bred** kind, reared by some of the best queen-breeders in America, and warranted purely mated. Sent by return mail at these prices: One Untested Queen for 75 cents; 3 for \$2.10; or 6 for \$4.00.

## An Untested Italian Queen-Bee FREE as a Premium

For Sending One New Subscriber

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a **NEW** subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

If you can not get a new subscriber, and want one or more of these Queens, we will send the American Bee Journal a year and a Queen—both for only \$1.50.

Address all orders to

**GEORGE W. YORK & CO.**

334 Dearborn Street, CHICAGO, ILL.

## G. B. Lewis Co's Goods at Factory Prices

We carry a most complete line of **BEE-KEEPERS' SUPPLIES**. Send for catalog. It's free. Foundation Cutter free with each order, if you state where you saw this ad.

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

CHICAGO, July 18.—Market is at a standstill, partly because of the time of year when little comb honey is consumed and partly to await the outcome of the present harvest. The weather is at present ideal and the flow of nectar makes the bees hum, that hum that puts smiles on the face of the husbandman though he be weary. **R. A. BURNETT & CO.**

ALBANY, N. Y., June 17.—The honey market here is very dull now. It is between seasons. Receipts and demand very light. Very little old crop carried over, and will be in good shape for new crop, which begins in August. Quotations are nominal now. White comb, 12@14c; mixed, 10@12c; dark, 10@11c. Extracted, white, 6@6½c; mixed, 5½@6c; dark, 6@6½c. Beeswax, 28@30c. **H. R. WRIGHT.**

KANSAS CITY, July 20.—New comb honey has made its appearance; fancy white in 24-section cases selling at \$2.75 per case; No. 1 at \$2.50, and good demand. There is no new extracted in as yet, market on old stock being quotable at from 5@6c. Beeswax, 25@28c. **C. C. CLEMONS & Co.**

PHILADELPHIA, July 19.—The outlook for honey is very good. Some lots of new white honey have already arrived and are selling in a small way, according to grade, from 12@14c. New extracted honey is selling: Fancy white, 6½@7c; amber, 5½@6½c. Beeswax in good demand at 28c.

We are producers of honey and do not handle on commission. **WM. A. SELSER.**

CINCINNATI, July 10.—We sold to-day at our store new crop of fancy comb honey at 13½c per pound. There is still a big stock of last season's honey on the market, that is going begging at any price. Extracted honey is moving quite lively now. We sell amber in barrels at 5½@6½c, according to quality. White clover at 7@8½c. Beeswax, 26c. **THE FRED W. MUTH CO.**

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6½@7½c per pound. Beeswax, 26c. **THE COLO. HONEY-PRODUCERS' ASSN.**

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations, Some few lots are sold here and there at 13c for fancy, and 10@12c for lower

grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Extracted honey in fairly good demand. New crop California honey selling at 6½@7c for water-white, 6@6½c for white, and 5@5½c for light amber. Southern at 50@60c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29c. **HILDRETH & SROELKEN**

CINCINNATI, O., July 17.—There is no demand for comb honey on account of the w.a.n weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5½@5¾c; in cans, 5¼@6c. Beeswax, 28c. **C. H. W. WEBER.**

SAN FRANCISCO, July 5.—White comb, 1-lb-sections, 11@—cents; amber, 8@10c. Extracted, white, 5½@—cents; light amber, 4@4½c; amber, 3@3½c; dark amber, 2½@—c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There has been no wholesale movement in honey this week and no new features have developed.

# SECTIONS

Millions of Sections. You want quick delivery. We have the facilities for executing orders promptly. Remember that

**Quality** is the first consideration about Sections. "Lewis' Sections" means highest quality. Do not be misled by low prices. A clean-cut, brilliant, white section enhances the price of your honey.

## Shipping-Cases

Order your supply now. Pack your honey in cases before storing away; this keeps them in a bright, clean condition. We invite your inquiries. We can ship promptly.

Southwestern Bee Co., 438 W. Houston St., San Antonio, Tex.

# QUEENS

August is the time to requeen the apiary. It pays to have the best possible stock. Root's Red Clover Strain is famous the world over for its many points of excellence. A young, vigorous queen introduced now will bring the colony up to the best possible condition for wintering. Queens, too, now are the cheapest, and prompt delivery is made.

We are in an unequalled position to fill your queen orders. Having eleven apiaries, approximately 900 hives, with hundreds of Baby Nuclei, we are in condition to take care of all orders sent.

## Table of Prices

### Regular Italian Queens

Untested queens .....	75
Select untested queens .....	1 00
Tested queens .....	1 50

One colony of bees in 8-frame Dovetailed hive, no queen .....	7 50

"I received my bees and queen and I am well pleased with them. The queen is a beauty, and the bees easy to handle. They were to work in ten minutes after I put them in the hive."—E. T. MILLS, Ills., May 15, 1905.

"I beg to acknowledge receipt of five fine queens, and, as they got here in good shape, beg to thank you for prompt and successful delivery. Without further advice, I am yours truly,  
"FREDERICO SOMERFORD, Cuba, June 13, 1905."

"I am pleased to say that the bees are doing fine. I find eggs in every available cell. I also found the queen, and it is entirely satisfactory."—W. H. DURST, Ohio, July 20, 1905.

Send for complete price-list

# CASES

Don't allow your comb honey to be sold at low prices on account of poor Shipping-Cases. Put your crop into Root's No-Drip Cases, and it will reach the market in perfect condition and bring the highest prices. Our cases are made of selected basswood, with 2 or 3 inch glass front, which shows off the honey to the best possible advantage. Below is a condensed price-list. Complete prices and particulars are found in our General Catalog. Write for it.

Shipping-Cases. Name and Size of Case.	Price complete including 3-in. glass one side, nails and paper, in flat.			With 2 in. glass instead of 3—per 100.	Without the glass, per 100.

### 5-Gallon Square Cans

These are the favorite packages for shipping Extracted Honey to the market. There can be no shrinkage and consequent leaking; no taint to the honey from wood, as is so frequently the case with kegs and barrels. The cans being square economize space, and are easily handled. This package is almost exclusively used in the West. They take 4th class freight-rate.

"The consignment of bee-material received to-day. Your promptness in filling orders is remarkable, especially when the circumstances are considered. I am very well satisfied with the goods and your dealing. I take pleasure in having introduced Root's Goods into this neighborhood."—REV. WM. ENGELKE, Iowa, May 5, 1905.

"I do not want anything set up, as I would rather set the hives up myself, besides it is a pleasure to put Root's hives and fixtures together."—JOHN L. FUNK, Ohio, Jan. 11, 1905.

"I desire to thank you for being so prompt in sending the sections I ordered from you. They came in less time than it takes to tell it."—L. G. REED, Ohio, July 10, 1905.

## Editorial Notes and Comments

### The Fourth Double Number

It will be noticed that this is another double number—32 pages—making the fourth of the kind so far this year. It will take several minutes longer to read it all, but it will pay to do it. We hope it will be enjoyed also.

### Marketing Honey

This copy of the American Bee Journal might almost be called a special number on the very important topic of marketing honey. Results of actual experience are given, and if minutely followed by others similar successes should be attained. We bespeak a careful reading of all in this issue on marketing honey, as well as the other contents.

### Shipping Extracted Honey

Usually extracted honey is shipped with no loss whatever. Perhaps a large majority of the producers put it into the common 5-gallon or 60-pound tin can, two cans in a wooden box. Practically all the Western extracted honey is thus put up for market.

In some of the Middle States, notably Wisconsin and certain parts of Illinois, and even in New York State, much of the extracted honey is put into barrels. Where the right kind of barrels can be had, and if the producer understands the use of barrels for such purposes, they are all right. But please excuse us from handling honey in barrels, especially if it is to be held in storage many months before being sold to the consumer who will use it very soon.

### Grading Comb Honey for Market

Few bee-keepers agree as to the grading of comb honey. This doubtless is the result of every bee-keeper seeming to think that his own honey is always the fanciest kind of fancy honey. At least that was our experience when we were dealing somewhat extensively in honey. Nearly every shipper that we dealt with thought he should have the

top-of-the-market price for his honey, no matter in what grade it deserved to be placed.

We had some interesting experiences that we could give if it were necessary. But we remember several instances where half-filled and half-sealed sections were put in back of the row of nice ones next to the glass front. Also where dark and "measley" looking sections of honey were mixed in with the nice white ones that invariably venerated the case.

Let us say it in the kindest way possible, that we are certain it will pay even bee-keepers to be straight and honest. It never pays to be otherwise, in the long run. It may be possible to work off a gold-brick once, but hardly the second time—not on the same person, at least.

Were we to ship honey to a distant market we would send only the best grades, and either eat the poorer honey or sell it in the home market at a little lower price, perhaps, to people who would just as soon have it as the finer-looking honey.

We would not put our name and address on the sections or cases of honey unless we had the consent of the purchaser to do so. We might, however, put our initials on the outside of all the cases, so that the receiver should not get it mixed with some other shipment of honey.

### Shipping Comb Honey

Some time ago we promised to publish detailed directions for shipping comb honey safely. As the time to put such information into practical use is now here, we present not only the result of our own experience, but that of some others as well.

For a number of years we were in the honey business rather extensively, and every shipment of comb honey that was either sent out or received at our store, if packed according to our instructions, carried safely.

In the first place, the comb honey should be put in either 12-pound or 24-pound shipping-cases. Then say 9 of the 12-pound or 6 of the 24-pound cases packed in a shipping-

crate, first putting in the bottom of the crate a thick bed of straw or hay, or excelsior. This will act as a cushion under the cases of honey. The crate should then be enclosed on top by nailing on say two or three strips of boards, on which must be marked in large, plain letters—

COMB HONEY.  
HANDLE WITH CARE.

Also coming even with the upper edge of each side of the crate we would nail on a piece of board, say an inch thick by 3 or 4 inches wide, and extending beyond the ends of the crate about 5 inches. These will serve as handles for the freight men to take hold of when moving the crate either on or off the cars.

As said before, whenever the foregoing instructions as to preparing comb honey for shipment were implicitly followed, the honey arrived at its destination in perfect condition. It seems such a pity to have a lot of nice comb honey arrive in a broken or smashed-up condition, and all for the lack of proper packing before shipping. We trust that readers of the American Bee Journal will never be called upon to suffer any loss when sending their comb honey to a distant market.

### "Sell Your Honey Early"

Editor Root gives in Gleanings the following good advice as to selling honey:

"As we have said before in these columns we say again, sell your honey early. New honey, right off the hives, always has the advantage. Consumers learn to expect new honey just as they expect new maple molasses. It is generally poor policy to hold back, waiting for better prices. Anyhow, manage to get it sold before the holidays—the sooner the better, as a rule."

Usually, higher prices rule for a very few months after the first honey comes on the market; after that the tendency in prices has been to drop a little. So Mr. Root's advice is all right, taken one season with another. Occasionally it may be the case that prices of honey will go up in a few months after the new crop is put on the market, but such experience is quite exceptional, we believe.

### Lava Soap for Removing Propolis

This has been highly extolled, but J. A. Green, in Gleanings in Bee Culture, reported

it a failure with him. Editor Root, having previously used it successfully, finally struck a kind of propolis that was proof against lava soap. He says:

"To-day I got my hands pretty badly smeared up with a yellowish-brown propolis, 'and now,' said I, 'is a good time to test the lava soap.' It had absolutely no effect on the propolis. I rubbed and scrubbed; but the

more I lathered and soaped the more it seemed to stick. I then went to the benzine-can, sopped my hands in the liquid, and soon had the satisfaction of seeing the propolis roll off. A second application of the soap made my hands nice and clean."

He thinks this "gummy, yellowish-brown stuff" must first be treated with gasoline, alcohol, or the like.

## Miscellaneous News Items

**Fourth of July with Dr. Miller.**—Again it was the happy privilege of the editor and wife to spend Fourth of July with Dr. C. C. Miller and his family. Doubtless the great majority of our readers know that Dr. Miller's family usually comprises, besides himself, Mrs. Miller, her sister (Miss Emma M. Wilson), and their beloved mother, Mrs. Wilson. "Mother" Wilson will be 87 years of age her next birthday. The presence of this dear old saint would be a benediction in any home. Although the day was cloudy and rainy, we persuaded her to sit on the porch, holding a tray of four boxes of just-picked luscious strawberries, in order to "take her picture." The result is shown on the first page.

Dr. Miller has two apiaries this season—one at home, having 125 colonies and nuclei, and an out-apiary (3 miles away) with 100 colonies. All are run for comb honey. He began with 178 colonies in the spring.

In early spring he and his efficient assistant, Miss Wilson, had prepared 26,000 sections, each with a top and a bottom starter of comb foundation, and all put in supers ready to place on the hives when needed. The pros-

He is using what proves to be a very rapid method of having queen-cells completed for the queen-nursery. He removed the queen from the only Cyprian colony he has, and then gave that queenless colony two frames of eggs and young larvae from the banner colony. In due time the Cyprian colony had those two combs looking like the picture on the first page. There were 45 queen-cells on one of them, and 74 on the other. It was really laughable to see how the bees of that "Cyp" colony had humped themselves in order to provide a queen or two for themselves! Then at the proper time Dr. Miller simply cuts off the perfected cells and puts them in the queen-nursery, which is placed over another colony for hatching. As the virgin queens then emerge, they are introduced to nuclei previously formed, and awaiting the reception of the hybrid queens reared by the fiery-tempered Cyprian nurses. It is all a very successful procedure.

Dr. Miller keeps a book record of each colony of his apiaries. The home yard is numbered beginning with 1, while the out-yard begins with a higher number. One book contains the records of both apiaries for the sea-

very annoying, as it is located only a few rods from the home. And when starting for the out-apiary the record-book, of course, is about the first thing thought of as necessary to take along.

There is great advantage in this record-book. Dr. Miller can, before starting from the house in the morning, look over the colony records in his book, and see in a few minutes nearly all the work needed to be done that whole day. In fact, the condition of each colony in his apiaries is noted in the book. He can almost at once see just what should be done next—the most important thing that requires prompt attention—before going to the apiary for personal examination. And by referring to his record-books, he can tell just what he has done each year with bees during the past two score years or more. In the picture shown, the Doctor is sitting in a rocking-chair on the porch, with record-book open on his lap, ready to find out just what nuclei need virgin queens. After learning that, we proceeded to the apiary and introduced a number of them.

He is also making trial of the dual method of introducing queens. Suppose a nucleus contains a virgin queen. Three or more days before she is likely to be ready to lay, a second virgin is introduced. She is put in a cage something like the Miller introducing cage already on the market, but with no provision for the bees to release her by eating out the candy. Instead of that a little ball of candy is dropped right into the cage, and the virgin put in with it, then the stopper is put in. Just as soon as virgin No. 1 becomes a laying queen she is removed from the nucleus and used wherever needed. On the same visit when No. 1 is removed, No. 2 is let out of the cage, and at the same time virgin No. 3 is put caged into the nucleus. Then when No. 2 is

(From the Northwest)

(From the Southwest)

TWO VIEWS OF DR. MILLER'S HOME APIARY

pect was, July 4, that even more sections might be required, should white clover continue to yield as it had in previous best seasons.

Dr. Miller believes in rearing all the queens for requeening his apiary and for increase, from the queen whose bees produced the largest quantity of honey a previous season. As it happened, that queen this time was a hybrid. But he is requeening and queening the increase made by the nucleus method with queens reared from the one mentioned.

son. Each year requires a new book. Every detail of each colony, and also of everything connected with both apiaries, is carefully noted down. Then at the end of the season it is easy to total the results, not only of each colony, but of each apiary.

A lead-pencil is attached to the book with a string, and notations are made at each hive as the work proceeds. Of course, there is danger of forgetting to take the book along to the apiary when starting, but in the case of the home apiary such forgetfulness is not

laying she is taken out, No. 3 is released and No. 4 is caged, and so on. This plan has been successfully used by Editor Root, and saves the usual time of introducing a fresh virgin.

Dr. Miller likes horses also. He drives a spirited team of mares in a two-seated carriage. If he were a young man we should fear his taking to race-horses. But as he is now about 2 months past 74 years, he will not likely be "carried away" with anything faster in the horse-flesh line than he now owns. One of his mares had a colt a year ago

in May. On July 4 Dr. Miller haltered it and led it out on the lawn to have its picture taken. The result is seen. It is three-quarters Clydesdale stock, and promises to grow into a fine horse of a beautiful light bay color. The Doctor will soon be harnessing Roderick and likely be driving him a little by the time he is two years old.

We must not forget to mention the delicious strawberries that are found on Dr. Miller's place, which, with their "home grown" cream, make such a rich feast.

But one day is all too short with Dr. Miller and his happy family. It's almost a continuous bee-convention from morn till night, for aside from the time spent in the apiary it was mostly bee-talk.

Dr. Miller is probably the most prolific writer on bees in all the world. And his writing is so original and entertaining that it charms, entertains and instructs those who are privileged to read it. But his conversation is just as pleasing, and withal he is so cheerful and young-hearted that to be with him even a whole day seems all too brief a time. We count it a thing to be greatly

they will be announced with the dates as soon as known. We are hoping to get up a carload of bee-keepers to start from Chicago in time to take in the "Bee-Keepers' Day" at the Fair, and then the National Convention. As soon as we can get any definite information concerning transportation we will place it before our readers, and trust that as many as can do so will arrange to go together from Chicago.

**They Leave the "Wax."**—"Your government," said the foreigner, "is a failure. Everywhere your institutions are honey-combed with graft."

"Oh," replied the hopeful American, "it isn't as bad as you think. The grafters have been public-spirited enough in most cases to leave the wax."

**T. W. Bryan**, somewhere in Illinois, is running a small advertisement in farm papers offering, for \$1.00, "The Art of Attracting and Catching Swarms of Bees. Copyrighted June 6, 1904." We can hardly believe that any of our readers would be willing to pay

MISS WILSON READY FOR BEE-WORK

prized, that we have been permitted to know Dr. Miller so intimately, and to be able to present each week to our readers something from his ready pen, drawn from years of practical experience with bees. We are sure all will join with us in wishing him yet many, many years of health and happiness ere he shall be called to exchange his earthly home for the one "not made with hands, eternal in the Heavens."

The San Antonio Convention of the National Bee-Keepers' Association meets Oct. 30, 31, and Nov. 1. Oct. 28 will be "Bee-Keepers' Day" at the International Fair to be held at that time in San Antonio. We have consulted several leading railroad companies here in Chicago, and they tell us that no special rates have as yet been decided on that bee-keepers in the North can take advantage of. They think there will be low rates in force at the time of the convention, and that

\$1.00 for what they can easily find out in any one of the standard books on bee-keeping, besides a thousand and one other things of value. Mr. Lisle Schneider, of Iowa, has kindly sent us a copy of Mr. Bryan's advertisement, taken from some farm paper. We are always glad to have our readers send us anything apiarian that they may find in publications that we would likely not see otherwise.

**W. H. H. Stewart**, of Whiteside Co., Ill., gave us a brief call last week. He is a bee-keeper of many years' experience, and usually attends the annual meetings of the Chicago-Northwestern Association.

**Ira Barber**, of St. Lawrence Co., N. Y., writing us July 27, said:

"There is a large crop of white clover honey in this locality, and the honey season is over."

## Some Expert Opinion

### More Honey from Colony and One Swarm, or from Colony and No Swarm?

**Ques. 28**—Which will give you more honey, a colony with its one swarm, or the same colony without any swarming?

**Mrs. J. M. NULL** (Mo.)—Usually the former.

**G. M. DOOLITTLE** (N. Y.)—Without any swarming.

**MORGAN BROS.** (S. Dak.)—The colony with its one swarm.

**R. C. AIRIN** (Colo.)—One year with another, the non-swarmier.

**E. WHITCOMB** (Nebr.)—A colony without any swarming, every time.

**N. E. FRANCE** (Wis.)—Big colonies pay best. For comb honey, "shook" swarms.

**JAS. A. STONE** (Ill.)—My experience has usually been in favor of the one not swarming.

**ADRIAN GETAZ** (Tenn.)—The one that does not swarm, by a long way. At least in this locality.

**EUGENE SECOR** (Iowa)—I can't say positively, but I prefer the colony that has not swarmed.

**DR. J. P. H. BROWN** (Ga.)—Conditions being the same, such as the honey-flow, the colony without any swarming.

**R. L. TAYLOR** (Mich.)—I like to have my bees swarm once, and think I get more honey that way, besides having an extra colony.

**J. M. HAMBAUGH** (Calif.)—A great deal depends. With a prolonged honey-flow of two or three months, the colony "with its swarm."

**DR. C. C. MILLER** (Ill.)—In this locality the one colony without any swarming. With a flow sufficiently long the reverse might be the case.

**REV. M. MAHIN** (Ind.)—I can get more honey from a colony that I do not allow to swarm. Something depends, perhaps, upon the season.

**J. A. GREEN** (Colo.)—I have not been in this State long enough to feel sure. In Illinois, the one that did not swarm, other things being equal.

**PROF. A. J. COOK** (Calif.)—It depends. I think usually it is wisest to permit one swarm when the bees so desire. I would always stop with the one.

**ARTHUR C. MILLER** (R. I.)—It depends upon the man, and upon the time of swarm and honey-flow. Usually the non-swarming colony is the more profitable.

**S. T. PETTIT** (Ont.)—Where the flow is short and sharp, without swarming will give most. Where the flow runs over several months, the colony with its one swarm will win.

**C. P. DADANT** (Ill.)—The colony if it does not swarm, unless the crop happens to come six weeks or two months after swarming, when two colonies would, of course, do better than one.

**P. H. ELWOOD** (N. Y.)—With us the colony without swarming. Where there is a later honey-flow, *i. e.*, where the late honey-flow can be counted on, undoubtedly the two would give more.

**E. D. TOWNSEND** (Mich.)—I take the question to mean surplus honey after the one or two colonies are allowed their regular amount for winter stores. With our Kalkaska bees, where the season opens early in June, and lasts during five weeks, usually, with no later flow, the colony without any swarming. Here

in Mecosta County, where the early flow is about the same, followed with a buckwheat and aster flow, the difference is not as great. Still, I think even here the colony without any swarm.

C. H. DIEBERN (Ill.)—I would get more section honey, or extracted honey, as surplus from the colony that did not swarm. If the total amount gathered is meant, I will have to admit, *a la* Dr. Miller, "don't know."

WM. McEVoy (Ont.)—Where the season is short, and ends when the colony is done, then the colony without any swarming. In localities where the season is long, and much buckwheat is grown, then from the colony with its one swarm.

O. O. POPPLETON (Fla.)—If the honey-flow occurs early in the season, and is short and heavy, the one colony will probably give most honey; but if the flow comes late, or is long-drawn-out in time, the 2 colonies will probably do best.

G. W. DEMAREE (Ky.)—It depends upon the length of the summer honey season, and the time the prime swarm issues. If the swarm issues at the right time the parent colony and its issue—if properly managed—will beat any non-swarming colony.

E. S. LOVESY (Utah)—This is rather a hard question to answer. If the colony is weak it will not do much in either case, but with a strong colony, as a rule, it would swarm unless it was divided. Personally, I could produce more honey by the latter method.

C. DAVENPORT (Minn.)—This depends upon a number of things or conditions, as, for instance, length of flow, what time they swarm, and how the swarm and the parent colony are handled. I can "swarm" any colony artificially so as to get more honey, either comb or extracted, than if they swarmed naturally, or did not swarm.

E. E. HASTY (Ohio)—Sometimes and sometimes—very often one way and very often the other. With the early harvest a semi-failure,

and a good, late yield, the two would do much the better. With those two conditions put *vice versa*, the one would do much the better. Probably the last state of things is rather the more common of the two.

L. STACHELHAUSEN (Tex.)—In this locality in some years a colony with its one swarm gives nearly twice as much honey as the same colony without swarming. In dry years, with an early honey-flow, a colony without swarming may gather quite an amount of honey. If the same colony had swarmed during this honey-flow we would get no honey crop at all.

### Honey Circular for Shipping-Cases

The Honey-Producers' League has prepared, and succeeded in getting some of the leading bee-supply manufacturers to send out with their shipping-cases, a guarantee comb honey circular, intended to aid in dispelling the belief that comb honey is ever machine-made. Bee-keepers all know it is never so made, but on account of the general impression that it is, the League thought it would try to pass the truth along through the honey-dealers.

We trust that every bee-keeper who receives shipping-cases with the circulars will be sure to put one in every case just under the lid, so that whoever opens it will be compelled to sell it.

The G. B. Lewis Co. are putting the circulars in sealed envelopes with printed directions on the outside, then including them with their shipping-cases in the flat.

Should any of our readers desire a supply of these guarantee comb honey circulars, we can furnish them, postpaid, at 10 cents per 50.

That our readers may see just how the comb honey circular reads, we give it below.

## "Combed" and "Extracted"

DRY WEATHER AND COLOR OF HONEY.

I do not believe that dry weather affects the color of honey, except that in non-irrigated countries it is apt to lessen the yield, so that bees, in their search for honey, work on plants that ordinarily they would leave alone. The honey thus secured is apt to be darker and poorer in quality than what they get from ordinary sources. In the irrigated districts of Colorado and Utah, where alfalfa is grown, the air is extremely dry, though the ground may be well watered. When alfalfa honey is secured free from any admixture, it is water-white in color, and I have never seen anything to indicate that the weather had anything to do with the color. In this valley, though, it is but seldom that alfalfa honey is secured alone. An average of my honey, even excluding the fall honey, which is distinctly darker in color, is of a light golden tinge.—J. A. GREEN, in Gleanings

BANNER HONEY COUNTY OF NEW YORK.

Tompkins Co., so I understand, has the honor of being the banner honey county of New York. Its output was over 236,000 pounds, or, figured in cars, it would be between seven and eight. When it is remembered that that county is only about 20 miles across it either way, these figures are somewhat remarkable; but perhaps it will be better understood when it is known that the largest bee-keeper in the world, probably, at the present time, Mr. W. L. Coggs, has something over 20 apiaries within its borders. There are other counties in the United States that will show a larger output of honey, but these counties are as large as some whole States in the East. I refer to Los Angeles, San Bernardino, and San Diego, in California. All these central counties in New York yield immense amounts of honey. The territory is already overstocked, and it would be useless for an outsider to try to squeeze in.—Gleanings.

## To the Purchasers of this Honey

The producer of this Comb Honey, and also the undersigned, guarantee that the product in these sections or small frames was all made by honey-bees.

*There is no such thing as manufactured comb honey.* It never was made, and never can be, newspaper and magazine articles to the contrary. If any one says there is such a thing as manufactured comb honey on the market, just tell that person that the National Bee-Keepers' Association, an organization of over 2000 members, through its General Manager, N. E. France, of Platteville, Wis., will pay \$1000 for proof of such machine-made combs filled with glucose or any other cheap syrup, and capped over by means of machinery without the aid of bees. Also, a corporation capitalized at \$300,000, all paid in, has had for many years a standing offer of a like sum for the same so-called manufactured comb honey as described, and the offer is still good. In addition to this, the bee-expert, a life-long bee-keeper, now in the employ of the Department of Agriculture at Washington, has repeatedly, in government bulletins and in public addresses, denied the existence of any such product. For evidence of this fact, refer to the report of the Secretary of Agriculture for 1904, page 83; also to Farmers' Bulletin No. 59, for 1905, pages 32 and 34, also issued by the Department of Agriculture, entitled "Bee-Keeping," by Frank Benton.

It may be well to state that the basis for these comb-honey canards is possibly due to the fact that the flavor of honey in one locality may be very different from that of another; that when one tastes of a honey quite different in color and flavor from that which he used to eat on the old farm, he concludes it is adulterated or manufactured, especially if it be of poor quality. As a matter of fact, the comb

honey from California is just as different from the same article produced in the Central and Eastern States as the fruits of that State are different from those in New England. In the same way, the honey from Texas differs very widely from that produced in Ohio, or honey from Florida from that in Texas. Some honeys, like that from buckwheat, are very dark; others are not only dark but ill-flavored, and should never be sent to market, but be sold to the baker or fed back to the bees for rearing young bees.

Two-thirds of the States in the Union have pure-food laws; and one may rest assured that, in all the States where such laws are in force, both honey in the comb and in the liquid condition, generally called "extracted," is and must be the genuine product of the hive.

The oft-repeated misstatements about adulterated honey and manufactured comb honey in the newspapers and magazines has made it necessary for The Honey-Producers' League to put out this statement, for the reason that the general public has come to believe that a large part of the honey on the market is adulterated or manufactured. If the dealer will join with the bee-keepers in helping to correct these monstrous lies, it will materially increase his sales of both comb and liquid honey.

## The Honey Producers' League

GEORGE W. YORK, Manager  
CHICAGO, ILL.

DR. C. C. MILLER, President, Marengo, Ill.  
GEO. C. LEWIS, Vice-President, Watertown, Wis.  
W. Z. HUTCHINSON, Secretary, Flint, Mich.  
A. L. BOYDEN, Treasurer, Medina, Ohio.

N. B.—Do not store comb honey in a refrigerator, cold storage, or cellar. These are the very worst places you can put it. It should *always* be kept in the warmest and driest room you have. It is advisable to keep liquid or extracted honey in the same warm, dry place.

## Contributed Special Articles

### Comb Honey in the Home Market

BY "ILLINOIS"

Twenty-five years ago a man with 10 colonies of bees, kept in the old-fashioned way, could supply our little town with honey; now we need about a ton to each thousand people to supply the home market.

Then honey was sold by the pound, and in a small way; now we sell to consumers by the case, and if bee-keepers in their home markets would put up their comb honey in small cases of not more than 10 or 12 pounds each, and quote and sell it that way, their market would be improved.

We have told people all about honey as a medicine, and so the general public buys honey about as freely as bee-keepers buy pills.

Sell a woman a section of honey and tell her how good it is for the croup, mixed with lemon-juice, and she is likely to put it away somewhere until the baby has the croup, and by that time the honey may be in a condition either to kill or cure—to kill the baby, or cure it of its love of honey for good and all.

What we want is, people to use honey as an article of food, so sell to them by the case, and they will eat it by the case, and want more.

Put the retail price per case so that you can sell to grocermen at market rates, and so that they can make a fair profit if they sell by the case, and a larger one when they sell by the section, and let them supply the demand for less than a case. You and your grocer will then be good friends, and can work together.

It is an advantage to put your name on your honey in your home market, and also use a stamp with "Keep Comb Honey Where it Will Be Dry and Warm," or something to that effect.

One thing I must say, and that is, that people become educated in regard to the quality of honey very fast, and so first, last, and all the time, *quality* must not be lost sight of. Keep all unfinished, leaky and broken sections out; and don't try to convince people that what they don't like is all right.

Good salesmen, and much talk, will not sell poor and off grades of honey a second time; and if I and my location can not produce honey that will sell itself the second time, I would better quit, for I will have to do so in the end.

My experience in city markets is small, and I know that ignorance in regard to honey prevails, yet it would seem as if methods which are successful among a few thousand people ought to be so among many, and I fully believe that what we most need is men who will get honey of the right quality to the eaters of it, in a clean and attractive condition, and then The Honey-Producers' League, which is a long step in the right direction, and other means of education, can do the rest.

I sometimes wonder if a "Honey-Eaters' League" should not be organized to educate a large proportion of our bee-keepers in the handling and care of their bees and honey.

The marketing of extracted honey is quite different from that of comb, but the same principles apply to both—small quantities used as a luxury, large quantities as food.

### Selling and Shipping Honey

BY F. GREINER

If every lover of honey had a fair opportunity to obtain all he wanted at a reasonable price it would not be necessary to hold over a part of our crop. We bee-keepers do not reach consumers—there lies the trouble. We must aim to distribute the honey we produce over a larger territory, *each one of us*.

If we find it necessary to place our crop in the hands of commission men, it is not advisable to ship it all to one firm. It may work all right, and it may not. The practice is, altogether too hazardous. One friend writes me from a neighboring county, saying he saw my honey at a certain house in Boston, and went home and shipped his 7000 pounds to the same firm last fall to be sold on commission, but it seems he has not yet received his money for it; the honey is not yet sold.

Another friend in my own town shipped the larger portion of his crop—all the white honey—to the same firm, and has not yet had his pay. My own honey was sold to the firm before it went, at a fair price. The honey the two friends shipped would have netted more than what I had received, had it been sold at that time. But it seems to me the firm could not handle so large an amount of honey, and made no effort to find an outlet somewhere else. They allowed the time when it might have been sold at a good price to pass by, and now it is on their hands and the producers have no money to use. The chances are they will have to wait till next fall, and then take a small price.

It always has seemed to me a poor policy to ship a large quantity of honey to one firm at one time, when it is to be handled on commission. I have always sent small lots—not over 400 or 500 pounds at one shipment. When that was sold I shipped more. I also tried different markets. In this way I received some cash right away, and I selected those markets for further consignments which gave me the quickest returns and best net prices. I never have been caught with comb honey on my hands when winter came on, following the plan as outlined.

I want to sell for cash if possible, but I am never at a loss to know what to do with my honey if the cash buyer does not come around.

The firm to whom my two friends shipped their honey is all right. I have dealt with them for years, sold to them a number of times, but last fall they had too much on their hands, and should have so informed their shippers.

#### HOW BEE-KEEPERS OBTAIN LOW FREIGHT RATES BY COMBINING WITH FRUIT GROWERS IN NEW YORK STATE.

The fruit-growers of this vicinity formed an association some years ago, having for its objects obtaining low rates from the railroad companies, and to oversee the shipping of the fruit, particularly grapes. The association hires a man to see to the loading, and another one is sent to Boston, where all the fruit is sent, to oversee the unloading. A great many dollars have thus been saved to the fruit-men yearly.

While originally the association was formed for the benefit of fruit-growers, concessions have been made to peach, plum and even apple growers. I have also shipped butter, eggs, chestnuts and honey in the same cars with the grapes without objections being raised by the railroads. The rate on all these products to Boston is but 35 cents per 1000 pounds, which I consider a low rate. The transit is quick and safe. Our own men and we ourselves handle the products. There is seldom any smashing. When our honey can be corded

METHOD OF PACKING COMB HONEY FOR SHIPPING.

right in with the grapes (the grapes being in five-pound baskets) no better way can be devised; but I aim always to get my honey into the center of the car, the grape baskets thus forming a cushion on each end.

When honey must be shipped by way freight in small lots, to insure safety it should be put up in specially constructed crates, as shown in the picture herewith. They may be constructed on a different plan, but this, it seems to me, is the simplest. It is doubtful that any straw put under the honey, as is recommended, increases the safety or is a further guarantee against breakage.

Ontario Co., N. Y.

## Honey Results Not All in Management

BY DR. C. C. MILLER

I have read with much interest the article by my good friend, G. M. Doolittle, page 453. Just a little bit hard not to feel envious because he can do 30 pounds better with a colony than I can, but I've concluded to be good and congratulate him. I want, however, to warn beginners not to conclude too hastily that the difference in the plan of management is solely responsible for the difference in yields.

Remember, I'm not discussing the point as to which management is better. I'm only saying that Mr. Doolittle's greater yield does not *prove* that he has the better plan. A number of things might play a part. With the same management, Mr. Doolittle might be more skilled and more careful in carrying out details. He might have better bees. He might have a better season; for seasons differ, and it may be that next year I shall have a better season than I've ever had before. (But I'm hardly expecting it.)

There's another item that probably makes more difference than all other things combined. Mr. Doolittle got one colony to store 66 pounds in three days. I can't do that. I never did it. I don't expect ever to do it. I haven't the basswood trees. I haven't some of the other things Mr. Doolittle has. I am in what is called a poor honey region, with white clover as the only source of surplus, although of late years cucumbers or something else seem to help out in the fall. So far as I know, Mr. Doolittle has as much white clover as I, but I think the greater part of his surplus comes from other things, basswood looming up as the greatest producer. Without basswood I don't think he could get 22 pounds a day. I think that's at least 12 pounds a day more than any colony ever stored for me, or could store from white clover.

It may do no harm to dream a little about what I might do if I could turn my bees loose on Mr. Doolittle's pasturage during the basswood harvest. It would be hardly reasonable to count on 12 pounds a day extra throughout the basswood season, but I suspect that if the bees of that best colony of mine had had the chance upon that basswood that gave Mr. Doolittle 22 pounds a day, they would not have ruptured any blood-vessels in storing 6 pounds a day more than they could on clover. If they had done that for a week it would have made a difference of 42 pounds, distancing Mr. Doolittle's best by 12 pounds.

Aside from advising beginners not to draw hasty conclusions, a moral of the lesson is not to be too hasty about settling in a place of poor pasturage, especially not to settle in a place with only one honey-plant for surplus, where the bottom falls out a good many years because of the failure of that one plant.

Most likely some one would like to ask why I settled in such a place. I didn't know any better. For years bee-keeping was an avocation, and by the time I decided to make it a vocation so many ties had bound me to the place that I couldn't break loose. Even now I sometimes dream that if an earthquake or something else should tear me loose from this "locality," so I could be free to form new ties elsewhere, I should begin to look for a bee-keeper's paradise just as soon as I could wipe away the tears enough to see clearly where I was alighting.

McHenry Co., Ill.

## The Honey-Producers' League and Section Honey

BY DR. G. BOHRER

On page 596 of *Gleanings*, Mr. Virgil Weaver states a truth which, in my opinion, should not be overlooked or ignored by The Honey-Producers' League. He says, "The section has done more harm to the comb honey market than all other agencies combined." He claims that the comb-honey lie was caused by section honey. I do not know just how nearly correct this statement is, but I do know that all who believe the artificial-honey and artificial-comb falsehood invariably point to the section as the chief support of their position.

If this embraced all the harm the section has done, we might hope that, in time, the masses would learn that there never was, in all time past, is not now, and probably never will be, such a thing as artificial comb honey. But the so-called pound sections, which seldom ever contain a pound of honey, cause many persons to let them severely alone, for the reason, as they very truthfully say, they do not weigh a pound, but are sold at pound prices, and that they do not pro-

pose to pay for a pound and accept from 1 to 4 ounces less than a pound.

If the section were consigned to eternal infamy, and comb honey in shallow-super frames substituted, and sold strictly by weight, very much more honey in the comb would meet with ready sale than is sold as matters are now.

I have made it a rule to sell section honey by the pound, and get 14 cents per pound for it, and I sell comb honey stored in shallow super or extracting frames at the same price, the honey being cut out of the frames, which makes of it what is known as "chunk honey." In this shape I am free to admit that it is short of much "cosmetic ornament," which is all that the section does for honey, by keeping the cell-cappings intact, as a rule, so that the honey does not escape from the cells and run over the comb surface and muss the section or shipping package. That is, in case the shipping package is not so roughly handled while in transit as to break the honey-combs. In such an event the dealer can not stand the loss, and must sell what does reach him in safety at a higher price, in order to save himself. Thus it will be seen that the consumer pays dearly for the useless ornament furnished by the section.

I suggest that The Honey-Producers' League advertise the so-called pound section as not a pound, and urge both honey-producer and honey-dealer to sell section honey by actual weight, and not by the piece and under the name of a pound at pound prices, when it is not a pound by perhaps several ounces.

In a brief period of time the masses will let the section honey severely alone, for they will soon learn it to be an expensive luxury, and will call it "dude honey," leaving out the term "pound section."

I am fully aware of the fact that it is claimed by our newspapers that there is no such thing as a measurement for an exact pound section, which is true, but the term "pound" sticks to the section tighter than propolis, and serves the purpose of causing the public very largely to denounce it as a deception and a fraud. Lighter sales of honey are the natural and legitimate result. Most of the counters of our honey-dealers bear computing scales. Let them buy and sell honey by weight. If they refuse, let The Honey-Producers' League not only advertise to do so, but actually buy and sell by weight, and other dealers will be glad to follow suit.

In addition to this, advertise extensively the fact that bee-comb or beeswax is not at all digestible, and that in the extracted form honey is the most wholesome as food.

Also, labor incessantly for a national pure food law which will impose a severe penalty for adulterating honey with glucose, keep on nailing the artificial comb honey lie, and educate the masses to the extent of knowing that comb honey has never been manufactured by man. Rice Co., Kans.

## Selling Honey in the Home Market

BY J. M. HOBBS

I will explain how I dispose of my honey in the home market. I sell nothing but comb honey, and have sold all I could produce for the last 14 years right in this city and vicinity. I get 12½ to 15 cents a pound, or a section.

I sell about 1,200 pounds or sections a year, and it is all sold by Dec. 1st. When the last pound is sold I have received the cash for every pound sold, each year, so far, and we keep some 150 to 200 colonies right in the city.

This is how I have done it: In the first place, I don't use any separators in the supers. I use the standard sections, which will weigh a pound, and I always make them clean and attractive. I never sell a case of honey that does not weigh 24 pounds net. My customers know this, and they know that they get from 4 to 6 pounds more from me than they do from those who use separators; and they know that no other man in this state sells a better grade of honey in the comb. They also know that I always give 16 ounces, or more, to the section, and that when they buy of those who use separators they seldom get over 14 ounces for a pound.

The most of the bee-keepers who use separators do not use them always for the reason they say, that is, to make the honey of a uniform appearance, but, as I have said before, it saves them 4 to 6 pounds to the case. Those who use separators for short weights also want as many supers as they can get in one season, therefore they cannot see a super remain on the hive a moment after it is capped. They want it off so another can be put on.

My customers have learned that unless honey is left on

the bees until well ripened it is little better than sweetened water and will never be good honey no matter how white and fine it may look. This fad about looks does not deceive them into buying short weights and an inferior quality.

I always have been honest with my customers on all of these points, and they know it. They can tell my honey anywhere they see it, as my name is on every section and once I get a customer he gets for me his neighbor, and I sell most of them one-half case or 12 pounds at a time.

I also make light cases that hold 12 sections, and deliver the honey in them. The customer leaves the honey in them until spring, or till the honey is used up. I have a book in which I keep the names of the customers where I left the cases. I request them to save the cases for me, and I go around in the spring and gather them up.

Once you get a customer in this way, and deal honestly, you will gain others without any soliciting. This has been my experience, and I cannot supply my present demands, last season I made 12 pounds a wholesale rate, and less 15 cents a pound.

To get a customer, and instead of losing him the next season have him come and bring one or two more with him, is the way to sell your honey in the home market. If one is honest this will work nicely, but if you must use separators in supers, you will have to order sections large enough to hold 16 ounces to the pound, for the 14-ounce pound is as dishonest as the grocer's 3-quart gallon of molasses, or 12-ounce sugar done up in a nice, little, dainty package, as M. A. Gill says on page 213.

The way to dispose of anything is to make it attractive, but in doing so do not use deception assisted by dishonesty. One can use care without dishonesty. One can put up a full pound as tastily as he can a 12-ounce pound, or a full quart can of honey as showy as one that is a little less.

If any one will follow out what I have said, and does not dispose of his honey in his home market it will be because he has a good deal more honey to sell than I do, or has less customers to supply. But once you get the confidence of the public for honest dealing, the rest is easy. Your last sale is always good seed sown.

Yankton Co., S. Dak.

## Honey Education for the Public

BY C. A. STARK

The widespread belief in the adulteration of comb honey is, to my mind, the cause of the low price and small demand for it.

To illustrate: I live in a small village and have an apiary. There are two groceries here that handle section honey bought from commission men in the city, yet in this small place I have never been able to supply the demand for my honey at 5 cents per pound advance over prices at grocers. Even the grocer pays me, when I let him have honey, my regular retail price in order to be able to furnish pure bees' honey to his best customers.

Last fall one of these grocers sent to my house to know if I had honey to sell. I sent word that I had sold all I cared to sell, wanting what I had left for family use. He sent back to say that his little son was sick, and wanted honey. Couldn't I spare him a pound? Of course that appeal could not be denied, so selecting a choice section of honey I carried it down to the store myself.

Almost the first thing that attracted my attention on entering the store was a case of fine looking honey. I was astonished; thought that perhaps there was some mistake. But on accepting the honey he remarked that he was particular what his children ate, and that the honey in the case was from the city, and for all he knew was made there in some factory! Right there I did some missionary work along the line of comb honey.

I have had persons try to buy honey of me right in those stores where nice section honey was on sale, and not getting it of me they would walk out without buying, because they doubted its being pure bees' honey.

Another time, one grocer bought a small stock of extracted honey put up in quart Mason fruit-jars. After keeping it until he was tired of looking at it he closed it out at 20 cents per jar—good honey, too—while I was selling my extracted at 30 cents per quart, the customer furnishing his own jar.

The remedy for this condition I think, is in publicity. Educate people to know pure honey by sight, in case of comb

honey, and by taste in extracted. Carry samples. Show them that no two sections are exactly alike, while they would be exactly alike if made by machinery.

In selling extracted, if possible secure a sample in the original package, of the glucose mixture sold for honey. Compare it with your own pure honey. Let customers sample it. You will not find it difficult to sell your honey, I think.

It has been my experience that the only thing necessary to make sales is to convince your prospective customers that you have pure honey of fine quality, and of course that is the only kind you should ever attempt to sell for table use, if you care to continue in the business.

Putnam Co., Ill.

## Keeping Comb Honey in Good Condition

BY G. M. DOOLITTLE

A subscriber to the American Bee Journal wishes me to tell how to keep honey when off from the hive so it will be as good when he gets ready to market it, as it was when he took it from the hive. He says that his honey almost always sweats and in some cases becomes nearly sour before he is able to prepare it for shipping to market. This being especially the case when the season happens to be damp and rainy after he takes it off.

It is barely possible that the correspondent removes his honey from the hives before it is fully sealed. This should never be done, unless it is at the close of the white honey harvest, so that the dark honey shall not be mixed with the white, or at the end of the season in the fall, when, of course, we are compelled to take off all sections.

Fully capped honey is not as likely to become watery and sour as is that which is unsealed, and as unsealed honey in any part of the section makes that section more or less unsalable, it is always best, if possible, to leave all sections on the hive until they are fully sealed.

But I mistrust the trouble with the honey has been in its being kept in a room not sufficiently warm, or lacking in ventilation. Any room, or article in such room, will draw or take on moisture rapidly if allowed to become much cooler than the surrounding air at any time, and this room might have been colder than the surrounding rooms, hence attracted moisture to it. If the room had been well ventilated it would have helped much; and had it been thus, coupled with suitable warmth, I cannot see what hindered the honey from evaporating and keeping all right. I have found that a high temperature in a room is of very little service if said room is so tight and close that no draft of air can carry off the moisture. Consequently honey should not only be kept in a dry, warm room, but there should be enough ventilation in and about the room to carry off all moisture which evaporates from the honey; and the larger the pile of honey stored in any room the greater should be the draft or ventilation. Where such a room can be had, even honey that has begun to sweat can be brought back to fairly good honey again; but honey that has been kept in a poor room until it has begun to sour can hardly be made salable again; for honey which has once soured will never become fit to put on the market, and no one who cares anything for his reputation or the good of the market will ever do such a thing.

The warm, dry, airy room will help much to thicken even the worst sweating, souring honey, but it will never bring back its original flavor. I have even returned such honey to the bees, and let them try their hand at making it marketable again; and while they will dry and clean it up even if they have to remove it from the cells and redeposit it again, still it is an unpleasant job all the way around, and at best the honey never looks as nice as when first removed from the hive, and in taste it is very far from good honey from the kind of flowers from which it was gathered.

The best thing that can be done with any honey which has soured is either to extract it and keep it for feeding purposes, after scalding it, or cooking till sufficiently thickened, allowing the bees to clean out the combs; or feed the honey to strong colonies right from the combs, when in either case the combs can be preserved for bait-sections the next season after the bees have thoroughly cleaned them.

Then it is not well to store any comb honey directly on the floor, for where so stored the air cannot go under the bottom of the pile, and through lack of circulation of air under the bottom, honey will become watery in the most dry and well-ventilated room at the bottom-back side of the pile.

Some kind of a platform should be fixed on which to pile the honey, and this platform should be made of open-work so that the honey resting on it can not only have a current of air going up through it, but all about the bottom of the pile.

When I first commenced keeping bees, I stored my comb honey in a room on the north side of the house, and piled it directly on the floor, thinking I was doing the proper thing, as the most of those having bees near here stored their honey in the cellar at that time. But when I came to casing that honey I found that the honey next the wall of the room and the floor had soured and the honey was bursting from the cells, while that higher up in the room, and out from the wall, was still in good shape, as was considered at that time. I took the hint at once, and the very next year found me with a temporary platform fixed of slats, spread apart enough so that the edges of the sections would just catch on them, the platform being raised up a foot from the floor. When another tier of sections was to go on top, strips were placed between, and so on clear to the top of the pile, and in this way there was no hindrance to the air from circulating all round the sections from below, from above, and from between, and around the wood holding the honey. I now had the problem solved, and the same has proven good for more than a score of years.

All these things are little matters, but the *whole* of such little matters applicable to every phase or part of bee-keeping life, when put together to make *one great whole*, makes all the difference between success and failure in our beloved pursuit, according as we understand and use them.

Onondaga Co., N. Y.

## Re-queening Colonies During the Summer

BY C. P. DADANT

The re-queening of colonies, or replacing of queens by younger ones has been much discussed. Some of our large producers have advocated the replacing of queens every two years. One of our Western leading bee-keepers has even advised and practiced re-queening, that is, removing the queen to compel the bees to rear another, and thus making an interruption in the breeding. When this method was recommended, I wondered whether it was possible to follow such a method and succeed. My view is that the bees need their queen at all seasons. It is true that they need her less in the summer, after the crop is over, than in the Spring before the crop begins, but the depletion of bees by colonies in the summer is so prompt that there is need of constant refilling of the ranks by new additions, though they need not be so numerous. So I felt that this was a move in the wrong direction.

Later, I had occasion to meet the person in question and to inquire as to the success of his idea, and he acknowledged that it was not satisfactory, though in his opinion this lack of success was due to the conditions of the crop and dates of the harvest of honey. But I doubt very much if any conditions can be found that will justify a killing of queens to compel the bees to rear others, thereby losing some 20 odd days of breeding. In addition to this loss there is also a risk of the loss of some of the young queens. In fact we can safely calculate on losing about 10 percent, that will either be lost in their wedding-flight or that will prove worthless. To eliminate good queens that may prove still good for another year, and run the risk of having a part of them, at least, replaced by worthless ones, is a mistake.

It is also a mistake to re-queen hives that have good, prolific queens, just because they are two years old. If the bees did not usually change their queen by rearing another as soon as they notice that she is failing in her laying, there would be good excuse for such an action, but there is no doubt that the bees do change their queens whenever they lessen their breeding, and it is only in exceptional cases that a colony allows itself to run down because its queen has entirely lost her fecundity. Those who clip their queens' wings have noticed how often these queens are replaced without the knowledge of the apiarist. If this were not the case, an apiary in which no queens were replaced artificially would soon dwindle down to nothing.

But it is advisable and even necessary to replace queens when there are evident signs of lack of prolificness. In my experience, extending over nearly 40 years, with several apiaries, I have noticed that the bees are less likely to replace a queen that is only of very moderate prolificness, but whose

capacity is unchanged; that is, a queen that from the first has been of but little value, than to change a queen which has been all her life vigorous and begins to fail. Our attention must therefore be directed to the naturally inferior queens—to those colonies that have given but little crop. It matters but little whether the queen looks bright, if she has not filled her combs with eggs she should be condemned, and looks should not be considered. Not only must those queens be changed, but the bees must not be allowed to rear others of the same blood. Too often our bee-keepers have paid attention to the looks of the bees rather than to their working qualities. That is why so many of our bright Italians are sluggish and slow, though beautiful to look at.

The months of August and September are good months in which to change queens, because queens are plentiful and cheap at that time. We have also been able to discover the poorest and the best colonies.

Those who have produced neither honey nor swarms can probably be made to give a good harvest the following year by changing the queen.

If we expect to rear our queens ourselves, we must be sure and have the queen-cells from the most prolific, and at the same time the gentlest colonies in the apiary, if these two qualities can be found united in the same colony. If we breed from the best honey-producers we will be sure to make no mistakes. But let the queens be reared and laying before we attempt to change our breeders. Better have a queen of mediocre value in a hive than an interrogation point.

As a matter of course if we buy we must know the man of whom we buy our queens, and we must get young queens from an apiary where foul-brood is unknown, for there is but little doubt that this disease may be transmitted by the queens, though it is probably only in exceptional cases. Honey, being used in the larval food is much more likely to spread the contagion than any other thing. But there is too much danger in foul-brood for us to risk anything from a foul-broody apiary. There are plenty of good, reliable breeders, and the business of queen-rearing has become so much of a specialty that it is hardly worth our while to rear queens. I never realized the truth of this as vividly as I did when at the St. Louis Convention. Mr. Gill, of Colorado, one of the most practical honey-producers in the United States, said that it did not pay him to rear his queens; that he preferred buying them, although he needs several hundred every year. Scientific queen-rearing requires a special outfit, and daily care, and is better conducted as a specialty.

Let us bear in mind that the best time to introduce a queen is during a flow of honey; that robbing is the greatest incentive to the killing of strange queens by the bees, and that after we introduce the queen it is best to let the colony alone for several days. Queen-introducing is always more or less risky. Some apiarists will tell you that there is nothing difficult about it, that they have always succeeded. You can just rest assured that the man who has always succeeded is the one who has done the least of it. We practiced introducing in former days when we imported some 40 queens from Italy every season. The best method, in my opinion is the one now generally used by breeders: Cage the queen in the hive, just after removing the old one, and let the bees liberate her by eating their way to her.

Hancock Co., Ill.

## Brood-Frames and Frame-Spacing

BY C. W. DAYTON

I wish to answer Mr. Latham, on page 154, that if a bottom-bar is sawed out  $1\frac{1}{8}$ -inches wide, in six months it will have shrunk to about one inch. A top-bar which is  $1\frac{1}{8}$  at first will be 1-16 less in six months, regardless of how dry the lumber is when it is sawed.

I use what I call full width bottom-bars. That is, a bottom-bar the same width as the top-bar, and on account of shrinkage it makes them finally about 7-16 inch apart when in use, with  $1\frac{3}{8}$ -inch spacing. With side-bars no wider than the top-bar, when any certain frame is to be taken out we can move the frame on both sides away probably about  $\frac{1}{4}$  inch, though there may be honey along the upper edges of the combs. This gives somewhat less than one inch "play" when the bottom-bar comes up past the top-bars.

The ends of the top-bars rest in notches  $1\frac{1}{8}$  inches wide in strips of galvanized iron. These are used instead of the

usual tin rabbit—like the spacer in the "St. Joe" hive, put out by Mr. Abbott, only his notches are twice as deep as those I use. But I employ another contrivance that makes up for the difference in depth of the notches. My bottom spacer is of wire, soldered solidly to a strip of galvanized iron, which is nailed fast to the bottom-board. This wire projects upward between the bottom-bars  $1\frac{1}{4}$  inches and is shaped like the rounded or closed end of a wire hairpin. Quinby advised a wire spacer, in the appendix of his "Mysteries," published in 1860, but he fastened it to a strip of wood. Soldered to iron is better. In fact, by soldering it in a permanent position is the only way wire can be used at all. But when so used it becomes the best spacer.

If it were not for these bottom-spacers, the full width bottom-bars would crush bees when their edges pass one another in the bottom of the hive, but before they come together by about  $\frac{1}{2}$  inch they are caught between the spacers and guided into their positions.

On page 38 mention is made of frames which were 10 to 12 inches. Dzierzon favored a hive which was only 10 inches wide. Langstroth adopted a hive having a 14-inch frame, the same as your present adoption. And he probably never would have used any other length had not Quinby told him of long hives being good winterers. Then Mr. L. went to work and made his hive with frames 24 inches long.

It is pretty certain that Quinby adopted the length of frame on account of wintering while the death was all right for the production of comb honey by side-storage. But for extracting, so large and deep frames are unwieldy. But extractors were unknown at that time. If I am not mistaken, the British Association adopted the 14-inch frame as the standard. Cowan and Cheshire both use the 14-inch length. And Mr. Root also used and preferred the 14-inch length; so all evidence goes to show that that was the best length.

As to those closed ends I have no love for them. It seems to be a cheap way of providing an outer casing. Americans are getting to keeping bees entirely too cheaply. I expect they would have their colonies camp out under a little piece of canvas if they could get the honey that way. If one bee gets smashed between two side-bars their purpose is spoiled. Bee-gine will begin to accumulate so as to need scraping every time they are handled—*a la* Hyde. I haven't scraped a frame in 20 years.

Gallup's plan of an outer protection was to make the super or cover 12 inches deep. Then tack the strip which the cover rested upon, and which extended all around the brood chambers some 8 inches below the upper edge of the brood hive, so as to telescope. Then put a good chaff cushion in the cover over the bees. I saw these in his apiary at Osage, Iowa, in 1881. I would think a colony would be about as cozy in that fix as in the old straw hive.

#### MARKET CHANGING FROM COMB TO EXTRACTED.

I find it easy to shape a market according to what can be produced for it. When I came to Southeast Los Angeles, ten years ago, all the stores were selling comb honey and no extracted. Now since we have been pounding away in the same spot and manner with extracted honey, there is not one case of comb honey sold there in a year. And the five stores there know better than to get any comb honey in stock. They all have a good trade on extracted. A pound of comb honey could not be found within three miles of Florence. Yet in all other stores about the city comb honey takes the lead. Now, while a hive arranged for the production of extracted honey costs about the same as for comb honey, I think a hive built for the production of extracted especially, can be run with one-third the labor.

Los Angeles Co., Cal.

## Our Country's Undeveloped Apiarian Resources

BY PROF. A. J. COOK

I have just made the entire transit of our great country and I have been greatly impressed with the apparent magnitude of unused bee-forage. I made a brief stop on the Sacramento river, and while there visited my friend, Thomas W. Stevenson, who today owns an apiary which as he informs me rarely fails to give a crop, in precisely the same locality that his father used for bees years ago. Indeed I bought honey from his father from this same apiary over 40 years ago.

The reason that Mr. Stevenson is so uniformly successful is not far to seek. He runs a large and successful dairy,

and owns great fields of alfalfa. Indeed, he is in one of the best alfalfa regions of the Coast. Here, as in the San Joaquin Valley, unlike the alfalfa bloom of Los Angeles County, the alfalfa flowers secrete richly of nectar.

While in this region, I visited the Lisbon Reclamation Tract, on the Yolo side of the river. It was never my pleasure to look upon finer fields of alfalfa. Hundreds of acres of this magnificent plant could be seen at a glance of the eye, and much bloom was in evidence. Yet there were very few bees so far as I could see. As the conditions here are so similar to those on the Stevenson ranch, it seems almost certain that this would be a good region for the apiarist.

As we came north along the beautiful Shasta Route, through the Sacramento and Klamath Valleys, and thence on into Oregon and Washington, it came to me over and over that here, as on the Sacramento, much nectar was going to waste because no apiarist was there to utilize the rich floral resources of the region.

As we came east over the Northern Pacific, through Montana, North Dakota, and Minnesota, the same condition was apparent. Surely, we have a wonderful country. The man's soul must be very dead, indeed, if he does not exclaim proudly, "This is my own, my native land." Probably the bee-keeper of no other land has greater reason to boast. Yet I doubt if we have even more than touched the apiarian possibilities of our great country.

Since making this trip across our continent, I have asked one who is in position to know, if there are not successful honey-producers in all these regions. He answered, "Yes, but very few of them." This makes me more certain of the two positions which I take in this article: Excellent bee territory, very much of which is not occupied.

#### IMPORTANT WORK FOR THE DEPARTMENT OF AGRICULTURE.

The fact of flowers does not necessarily argue a honey region. The flowers may bloom when bees are few in the hive, as in case of most fruit-bloom, and thus, while these are valuable, unless they are supplemented by later flowers, such regions are worthless for bees.

Again, climatic conditions may stay nectar-secretion. I have often referred to the fact that while alfalfa is a great honey-plant in several States and regions, in parts of California it seems almost worthless for such purpose. For this reason, it would not be wise to embark in the bee-business in any of the promising valleys mentioned in the above paragraph, until an actual trial had proved the regions. This kind of knowledge is of great general importance, and it ought not to devolve upon the individual to gain it. What better work could the Agricultural Division of the Department of Entomology at Washington do, than to determine just this point?

Which of the great valleys of the West are really valuable for bees? Surely such knowledge is most desirable. It is to be feared that it will be long delayed, greatly to the detriment of our people, if left to individual enterprise. Great economy could be practiced if the Government should undertake in scientific fashion to determine these facts.

#### AGRICULTURAL WORK AT WASHINGTON.

Without doubt all our bee-keepers have read with more than passing interest, the important article in one of our leading bee-papers, by Mr. Frank Benton, regarding his trip to the Orient in search of new varieties or species of bees that we may possibly improve our apicultural possibilities. I have long thought that such work might well be undertaken, by the Government, and urged it upon the Department of Agriculture several years ago. Yet I am asked the very pertinent question, Why did not Mr. Benton give the article to all our bee-papers? He, as an officer of the Government, is working for the whole people, and surely he, and Dr. Howard as well, would be glad to have the work of the Department receive the greatest publicity possible. It would have been very easy for Mr. Benton to have furnished all the bee-papers with duplicate copies of the article. It is equally certain that all the papers would have been glad to have published it. Of course, they are not so eager, if the publication is of necessity delayed and so seems to indicate a lack of enterprise on the part of the editor.

I am sure that this matter has only to be brought to the attention of Dr. Howard and Mr. Benton to secure the desired change.

#### HONEY CROP IN MICHIGAN.

I think I have called the attention of our readers to the fact that the present season has been disappointing to the

bee-keepers in California. The abundant rains gave great promise, but the exceptional cold of the early part of the year interfered greatly with success. In the East, the season has been one of excessive rains—indeed, one of the wettest seasons ever known. If I am correct, such a season in the East is favorable to a generous honey crop. Of course, if the rains preclude the flight of the bees so that they cannot work, or if the season is too cold for the secretion of nectar in the plants, there may be a dearth of honey even in these wet years.

I think the present season has been wet and cold throughout the East, and I believe, until quite recently, the weather has been so cold that the honey promise has been disappointing. This seems not to have been true in this part of Michigan. At Owosso, where my brother has a large apiary, he informs me that he has already secured a large amount of honey, and the bees at the present time (July 19) are gathering very rapidly. I believe it is generally conceded that the honey crop of Michigan this year will be well to the front.

#### SAGE HONEY.

Mr. Milo Smith, one of our readers from California, writes me that in his section, black sage produces much more honey than does the white sage. I think a good many beekeepers in California have the same feeling. I think the honey from all the sages is so much alike that it would be indistinguishable. The fact that the black or ball sage pushes farther up into the canyons would certainly give it a wider range of bloom. It often blossoms much before the white, and the flowers continue for a long period. Its locality is usually also more moist, and thus adds to its certainty as a honey-producer. I think that very likely the preference of either plant would be more due to surrounding conditions than to the plants themselves.

I did not wish to give the impression in my articles that sage honey is superior to clover, linden or mesquite. The honey from all these sources is so excellent that it would be invidious to make comparisons.

## Doctor Miller's Question Box

### Putting on Supers—Winter Stores

1. If one should give a super to a colony of bees when the brood-frames were about half full of brood and honey, would the bees leave the frames below and work in the super, or would they fill up below first?

2. If one should take only what honey is stored in the supers at the close of the season, would there be any danger of taking too much away from them so they would not have enough to winter on, or would they provide for that in the frames below before they filled the supers?

3. Is there any danger of giving a super too soon?

MAINE.

ANSWERS.—1. If strong enough they might work in both places. If they had only strength enough to work in one place, it would be below; and in general they prefer to work as near the brood-nest as possible.

2. Generally not, but sometimes, especially with a small hive, there would be danger of a sudden close of the harvest with so much of the brood-chamber occupied with brood that there would not be enough winter stores.

3. Yes, if you should give a super a month before the harvest it would be making the bees keep up the heat unnecessarily in just so much more room.

### Cutting Out Queen-Cells—Honey-Sections vs. Strawberry Boxes—Yellow Bees

1. Do you think it is all right to cut out all the queen-cells in a hive when the second swarm goes out? I cut them all out and hive or catch the second swarm in a living-box, then put them right back.

2. At swarming time I have some hives with full-size combs, and most of them with space of ½ inch not attached to the bottom-bar. When hiving a swarm I tip the hive

over till they will work up on the top-bar. Has this plan been tried already?

3. Are there more honey-sections or more strawberry boxes used? I mean in the United States, on an average, right through?

4. Which kind of queen do you think is the better? I have seen some very yellow and some pretty black ones in my apiary.

5. Do you call the yellow ones Italians?

6. When does basswood blossom here in Marathon Co., Wis.?

7. How often is the average time to go through the hives and cut out queen-cells?

WISCONSIN.

ANSWERS.—1. Yes, that will work all right, providing you don't miss any cells. If you miss any the swarm will come out again, but of course you can return it again. The plan is a good one where you wish to keep up the strength of the mother colony, but many prefer to have the force mostly in the swarm, setting the swarm on the old stand, the mother colony close beside it, then moving the mother colony to a new place a week later.

2. Yes, many have tried it, and some hives have been constructed with especial reference to turning somersaults.

3. I don't know. My guess would be that the strawberries have the majority.

4. It isn't a matter of color. Some black queens are better than some yellow ones, and some yellow ones are better than some black ones. And there will be two young queens from the same mother, one light and the other dark, one good as the other.

5. Yes, but Cyprians and others are also yellow.

6. The time varies in different years. This year it was probably not far from July 1.

7. That depends on the management. The majority of bee-keepers do not kill cells at all. If you mean to destroy cells with the object of hindering swarming, it should be about once in 10 days. But in the majority of cases that will not prevent swarming, only defer it for a time.

### Itching from Bee-Stings

Is there any danger from bee-stings that cause intense itching all over? I got a lot of stings on my right hand the other day. I put my hand into a tub of pond-lilies, bees and all, and kept it in about a minute, then took it out. There were lots of stings in my hand, and I pulled them out. In about 5 minutes I was itching all over. It was something terrible. I knew that something must be done right away, so took a big drink of whiskey. In a short time I was better. I have handled bees for 10 years, and never had anything like that before. I did not mind one sting, nor half a dozen. Possibly my blood was poor, but I am in fine health, all the same. I hope it will not happen again, for once in 10 years is often enough to take a drink of whiskey.

MAINE.

ANSWER.—I suspect you would have done just as well without the whiskey, and I'm sure you would have been better off without that minute in the pond-lily tub, for during that time the stings were busy pumping in poison. The stings should have been scraped out immediately. Possibly a wet pack would have been a good thing. It is not likely that there is danger of anything more severe another time, although one can not always tell.

### Superseding Queens—Introducing—Building Comb—Danzon Baker Hive—Drone-Brood in Sections—Foul-Brood Law in Illinois

1. What time of the year is the best to supersede old queens?

2. Should they be superseded while the bees are working in the sections?

3. If I want to introduce a queen to a colony that is working in a super where can I place the introducing cage?

4. The directions on the cage say to place the cage over the brood, but as there is only ¼-inch space between the frames and the super, I can't put the cage there, and if I space the brood-combs wide enough apart to put the cage between them, won't the bees build comb between the two frames?

5. When I receive a queen from the mail, should I take out the escort bees before introducing the queen?

6. If I take a queen from a colony and replace her with a caged queen will they build queen-cells while the queen is caged?

7. Have you ever tried Doolittle's plan of getting worker-comb and section honey built at the same time, as described in "Gleanings," pages 723 and 724? If so, what is your opinion of the plan?

8. Will bees build comb behind the division-board of a hive if there is more than a bee-space behind it, say  $\frac{3}{4}$  of an inch, if they have room to work in the sections?

9. What are your objections to the Danzenbaker hive?

10. I have one colony of bees in a 10 frame dovetailed hive that has all the frames filled with brood, and one of the supers has drone-brood in the bottom of the sections. What shall I do with it?

11. Has Illinois any foul-brood law? ILLINOIS.

ANSWERS.—1. Most of the superseding by the bees occurs toward the close of the honey harvest, and there is probably no better time.

2. There would be no objection to a change of queens during the latter part of the honey flow; no bee is living in the time of the harvest that hatches from an egg as late as three weeks before the close of the harvest.

3. Anywhere where the bees "do congregate"; there being no better place than right between the combs in the brood-nest.

4. You will find that you will not need very wide spacing if the brood-combs, right where there is brood, are shoved together till the cage is crowded into the brood, and the bees are not likely to trouble by building comb there. If they do build a little it can easily be cut away.

5. Generally they are not taken out.

6. Yes, unless you follow Mr. Abbott's plan—a good plan, too—of caging the queen for 2 or 3 days, leaving her so the bees can free her, at the same time you remove the old queen.

7. No, for I have combs built on full sheets of foundation; but I think Mr. Doolittle's teachings, as usual, are sound.

8. I think not.

9. Difficulty of handling rapidly without killing bees, and trouble with pollen in the sections, are two of the reasons. Another reason is that I don't know of advantages enough to make them preferred to the dovetailed.

10. There is nothing but to cut the brood out of the sections, using the rest of the section as chunk honey. To avoid the same thing again, use a queen-excluder under the super, or, what is perhaps better still, fill the sections full of worker foundation.

11. Strictly speaking, no; a sum is appropriated to help toward keeping down the disease, but there is no law compelling me to do anything about it if I have foul-broody colonies. It is hoped, however, that what has been done so far may help toward getting a satisfactory law.

### Alfalfa—Bee-Sting Remedies

1. I have an abundance of white clover, and I have read about alfalfa being such a good honey-plant. Would you advise me to plant some, or would the white clover be plenty?

2. What is a good remedy to keep bee-stings from poisoning me so? This must seem a silly question to you, but it is an important one to me.

3. What is the latest in the season one can start a nucleus and be safe?

I read the American Bee Journal and can not recommend it too highly. MINNESOTA.

ANSWERS.—1. I doubt your gaining much by alfalfa so long as the bees have more white clover than they can take care of.

2. A great many remedies for bee-stings have been given, and what is commended by one seems to fail with others. The important thing is to get the sting out instantly. Among remedies offered are ammonia, saleratus or soda, juice of onion or plantain leaves, kerosene, cloths wet in cold water, etc. A homely remedy, perhaps as good as any, is to lay on the place moistened clay or mud. *Don't rub or scratch.*

3. That depends upon the kind of season, the strength of the nucleus, and the amount of help you give it. Two

Langstroth frames well filled with brood and well covered with bees the 1st of August, with the right kind of a season, may build up to a fair colony without help. Usually however, commencing as late as that, they would need help in the way of bees or sealed brood, or both.

### Wine Barrels for Extracted Honey

How would wine barrels do for holding extracted honey? I have a number of them, and they are clean and almost new. IOWA.

ANSWER.—I have an indistinct recollection that some one has objected that honey was inclined to ferment in such barrels.

### Mosquito-Hawks Catching Bees

I have 5 colonies of bees, and the mosquito-hawks are catching them very rapidly. Do you know any way to stop it? They come only early in the morning and late in the evening. I am about two blocks from the woods or swamps. LOUISIANA.

ANSWER.—In an early volume of Gleanings a writer said they were easily scared away by boys or brought down by whips.

### Best Bees for Super Work

Which is the best bee for super work, the black, the Italian, or the golden? I have all three kinds and the goldens are in the lead so far, but some people tell me they are no good for super work. KANSAS.

ANSWER.—The way to decide is by their work, and as you have the three side by side you can tell better than any one else which does the best work for you. You will find bees of either of the three kinds that are good for super work, as well as some that are poor. You can't always tell by the color of a man's hair how big a day's work he can do.

### Transferred Bees Rearing No Brood

I have a colony that I transferred from one hive to another, and they seem to have the hive about half full or better. I made the transfer about 3 weeks ago, and there is no sign of any brood yet that I can see. I also took one out of a tree about 2 weeks ago, and they haven't any sign of brood. The one I transferred first had no queen, and I put in another queen, but I think they killed her. How long after they are transferred do bees begin to rear brood, and what shall I do with them? I can never find a queen. IOWA.

ANSWER.—The queen should go right on laying with scarcely any interruption, and in 3 days after an egg is laid a larva will hatch from it. You are probably correct in your supposition that the queen was killed, and another should be given. A queen should also be given in the other case, as well.

### Uniting Weak Colonies

Last fall I attended a sale near here where a bee-keeper was selling out to remove to California. As the bees were put up and bid off colony after colony, I thought it would be a fine thing to own a colony or two to provide honey for family use, so I bought a couple of colonies in Langstroth hives.

Afterwards I bought a colony in a box-hive. Then I brought them home and packed them for winter. They came through in good condition. This was only the beginning. Soon after I bought them I discovered I had an "elephant on my hands." I knew about as much about bees as a hog does about Sunday.

So I subscribed for the American Bee Journal, bought a text-book, and straightway became almost inextricably mixed up in a maze of queen-cells, brood-frames, supers, etc. I persevered in my studies all winter, and this spring I laid in a stock of bee-supplies and began puttering with the bees. When those in the Langstroth hives prepared to

swarm I divided them, letting the queenless part rear its own queen. I also found a couple of bee-trees in the woods. These I cut down and transferred, so now I have 8 colonies, some strong and some weak. They all have laying queens now (July 10), and if we have seasonable weather from now on I am in hopes will all be in good shape for wintering.

There is quite a lot of big timber here yet, and a good many bee-trees are cut every fall. I have often seen colonies starving to death where the tree had been robbed. I always felt sorry for the bees and wished I could do something to keep them from perishing.

1. If I should have some weak colonies this fall, say covering 4 or 5 Langstroth frames, could I unite with one of these "naked" colonies?

2. Would it be an advantage to me, or otherwise?

3. How much more stores would it take to winter the united colonies than the weak colony by itself?

MISSOURI.

ANSWERS.—1. Yes, you could thus have a strong colony instead of a weak one, but you must take more pains as to uniting in fall than during a flow, and of course you must look out to have stores enough.

2. It would be an advantage to have a strong colony rather than a weak one.

3. I don't know just how much, but at a guess I would say that if you unite two weak colonies of equal strength, the united colony would not need more than 50 per cent more than either of the colonies separately. If that be a correct guess, you will see that it would be a saving of one-fourth of the stores. More important than that, it would, in many cases, be a saving of one or both of the colonies.

### Sweet Mixture for Winter Stores

Would a mixture of sugar, "sugarall" and corn-starch do to feed bees for winter stores? Of course most of the starch will settle to the bottom so the syrup could be poured off. I can get any amount of this mixture for nothing, as I handle the syrup after it is mixed, and at noon and night the tanks are emptied, and it is thrown away. It is very sweet. We will all agree that the sugar is all right, but what about the starch and "sugarall"?

MAINE.

ANSWER.—I don't know. It would seem a little doubtful that anything of so little value as to be thrown away would be good feed for bees in winter. You could easily experiment on one or more colonies. Even if not safe for winter food, it might be good to feed for brood-rearing in spring.

### Greatest Honey State

What State has made the greatest success with bees and honey during the last 10 years, and what is the best location in the State? I want to go into the bee-business quite heavily.

KANSAS.

ANSWER.—Put in short, your question asks for the best location in the United States. I don't know just what that is, but there are a number of excellent locations. Take the names of the leading producers of large crops of honey, and each one of them is likely to have a good location. But that doesn't interest you particularly, for such locations are fully occupied already. Answering more directly your question, Texas contends with California for the highest place in honey-production, but I don't know what available locality in either is best.

### Motherwort—A Good Honey-Plant

In my back yard grows this weed. It is a very hardy one, as I have tried to exterminate it and failed. It comes early and grows to be 3 feet high. I never happened to notice till this spring how especially fond the bees are of it. Now I am interested and want to grow it in waste places. Very early in spring it begins to bloom, probably when 8 or 9 inches high. As the stems grow it continues to bloom, while the first bloom matures into seed. You will notice this on the enclosed stalk. The bees prefer it to catnip, white clover, basswood, or anything else. What is it? And is the yield such as to pay growing it? When

must one plant the seed and how? We would have had an immense honey-flow here but for the rains. I should have added that as these flowers mature into seeds the pod is a burr.

ILLINOIS.

ANSWER.—It is motherwort. It is counted a good honey-plant, and is good for waste places, but it would hardly pay to occupy with it cultivated ground. I know nothing about its cultivation—never heard of its being cultivated—but you would be pretty safe to sow at any time when seed matures.

### Swarms Uniting

What is the reason my bees act as they do? Monday morning, July 10, I noticed one colony of bees swarming, and they settled on a small plum-tree. About the time I was ready to put them in the hive another colony swarmed, and settled on them. I was about to put them in when another swarm settled on them, making 3 swarms in one from 3 different hives. I put them in a hive and they seem to agree all right. If any one doubts it he can bring 2 hives and have the pleasure of separating them.

WISCONSIN.

ANSWER.—Unfortunately the behavior of your bees is nothing very exceptional. If two or more swarms are out at the same time, they are very likely to go together, and some have reported five or more swarms in one huge mass. The consolidation of your three swarms will do good work, only by next spring the colony will be no larger than each of the three would have been if they had been separated. You could have divided them into two or three parts, dipping up the bees with a tin dipper, and giving each a queen. The finding the queens is not so very difficult, as in case of such uniting the queens are likely to be found balled.

## Convention Proceedings

### Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904

(Continued from page 490.)

#### FIRST DAY—AFTERNOON SESSION.

Pres. York called for the report of the Foul Brood Committee which had been appointed two years ago.

#### REPORT OF THE COMMITTEE ON FOUL BROOD.

Mr. Moore—The Foul Brood Committee, of which I have the honor to be chairman, really has nothing to report. We reported in full to date at the last meeting, and from then till now there was no work that could be done except inspecting apiaries. I don't suppose that comes under the scope of this report. There is a heading in the program that does refer to such matters as that. We might make our recommendations; we might tell you a lot of things; we might say this fall the Legislature meets again and we have to get the law over again, or fail to get it. Mr. Kannenberg is with me on this committee, and I believe there is a vacancy to fill. As the committee having charge of this matter, we have to urge upon each one of you individually to do what you can to get a law through the Legislature this fall. If you know some member of the Legislature, communicate with him by all means. If you do not know any member take the pains to find the names and addresses of the nearest member to you and communicate with him. If every one of us would do that it would have a material effect. When I was there two years ago and appeared before committees of the Legislature to get the laws we did get, they said, "For goodness sake, stop writing us letters; we will give you anything if you will only quit writing to us."

Advertising is what we want, and the members of the Legislature must know we are alive. How are they going to find it out unless by individuals writing and saying, Give us the laws we need? But hundreds have to do that. We

want to ask this fall for either five or ten thousand dollars. In this State there are 102 counties. The State, in its census, has formally said that there are 35,000 bee-keepers in Illinois. If there were inspectors enough to cover that ground it would take 50 to 60 working six months. You can see how far five or ten thousand dollars would go. I had a conversation with the Hon. Mr. Austin, who got our last Bill for us, and he saw the point; he saw a thousand dollars wasn't a beginning for this great State of 102 counties with that number of bee-keepers. So that we want this fall \$5,000 from the Legislature to spend in the interests of the bee-keepers in this State, and it is a question of judgment whether to ask for \$10,000 and give them a chance to cut it in two, or ask outright for the \$5,000 we want. If you don't ask for anything you won't get anything, and in order to get anything we must have the help of all the bee-keepers in the State. I would like to hear from Mr. Kannenberg, who is a member of this committee, and has some things to say.

Mr. Kannenberg—I am one of the committee and we did pretty good work last year. I do not know whether we can do it this year or not. But one thing I think I must say, if we want to strive for that law we must have a compulsory clause in it or else it is no good to us whatever.

Dr. Miller—Hear, hear.

Mr. Kannenberg—That is right, Doctor. We want about \$10,000, that is about the only thing; and they will give us only half, the same as in damage suits, if the bee-keepers don't join in with us; I think we won't get much out of it if they don't help us the way they did last year. Last year I wrote hundreds of letters to all the Senators; I hope it did some good. As far as I know, the Hon. Mr. Austin is again elected to the Legislature with a large majority. I have not spoken to him this year, personally, because he is on his honey-moon trip. As soon as he comes back I am going to speak to him.

Mr. Wheeler—I would like to ask who the other Committee man is?

Pres. York—Mr. Clarke, I think was the other member of the Committee, but he has not served on the committee at all.

Mr. Wheeler—I would like to ask how many colonies of bees Mr. Kannenberg has?

Mr. Kannenberg—82.

Mr. Wheeler—How many has Mr. Moore?

Mr. Moore—I have never kept a large number; I have less than 35 now. My family keeps about 400.

Mr. Wheeler—What I was getting at was, we want representative bee-keepers on this committee; we want people interested, and that have thousands of dollars invested.

Dr. Miller—I have more bees than Mr. Moore and I don't believe that I could influence Mr. Austin as much as he has done. A man may represent a body of people without himself being one of those people. Possibly it would have its weight; at the same time if he can present the thing the right way that is more than to say he has the bees.

Mr. Colburn—A man has a thousand colonies of bees and he goes to our Legislature and he says, I want this and that, and the fellows say, you are selfish. If I have but very few bees and I go there for somebody else it will be two to one I will get what I ask.

Mr. Whitney—My experience with politicians is that the man who has some influence in the community is the man who will get some help from the Legislature, not the man who may possess perhaps a thousand colonies of bees, or any other interest that he may represent. I know individuals who haven't a single colony of bees that I think would make good committeemen for that very purpose. It seems to me the point is well taken.

Mr. Becker—On behalf of Mr. Moore I will say that he is the right man in the right place. I have had some experience with Mr. Moore in the Legislature. Mr. Smith and I were before the Legislature when they tried to get our law passed and I know what efforts Mr. Moore made in that direction, and we never left until we had the guarantee that the law would be passed, as far as the Committee on Appropriations goes. We couldn't wait until the House debated on it and the Senate, but we had the promise of the Committee; and they passed it in the House and in the Senate before they left.

Mr. Wheeler—I don't like to be misunderstood. It wasn't in regard to getting that appropriation I was speaking, and getting the Bill through; it was in regard to the

committee's work afterwards. You must not lose sight of the fact that people are interested that have money invested, and it must be looked into a little and we must see that we do not take men who are not interested financially in bee-keeping and who are not interested in the welfare of bee-keeping.

Pres. York—As I understand it, it does not make any difference after the law is secured. This committee has nothing further to do. The inspector is then appointed on the recommendation of the State Association, and the money is turned over to the State Association.

Dr. Miller—I move that the report be accepted and the committee continued.

Mr. Smith—Has that vacancy been filled on that committee?

Pres. York—Not yet.

Mr. Smith moved, which motion was duly seconded, that the chair fill the vacancy.

Pres. York—I think we might as well consider it a vacancy because Mr. Clarke has never served on the committee.

Mr. Wheeler—I object to that. I don't believe that is fair.

Pres. York—Then we had better have a motion to declare the vacancy.

Mr. Moore moved, which motion was duly seconded, that a vacancy be declared in the office of third committeeman of the Foul Brood Committee. [Carried.]

Pres. York then put a motion to fill the vacancy which on a vote having been taken was declared, carried. Mr. Horstmann was then appointed as third committeeman on the Foul Brood Committee.

Pres. York then put the motion to accept the report and continue the committee, which, on a vote having been taken, was declared carried.

Pres. York—Before we take up some of the questions which have been handed in we will have a talk by Mr. Ernest R. Root, of Ohio, on

#### BABY NUCLEI AND MATING QUEENS—BRICK HONEY

(Mr. Root exhibited before the convention a baby-nucleus box, illustrating his remarks as he went on by pointing out various features of the little outfit. We have since obtained a series of illustrations, and think the reader will have no difficulty in understanding Mr. Root's explanations if he will keep before him the illustrations.—Editor's Note.)

Perhaps those of you who devote your *whole* attention to the production of honey, may think that what I am now about to say on this subject will be of no particular interest to you for the reason that you can better afford to buy your queens than to rear them yourselves. This, I believe, is a mistake, as the honey-producer should properly inform himself as to the latest method of rearing queens so that he can rear his own stock as a matter of economy. I hope to show you, therefore, that you can afford to rear your own queens to a very great extent after having purchased one or more breeding queens, or having selected something from your own stock which shows an unquestioned superiority over other stock in the yard.

The business has been developed to a very pretty science. Indeed I know of nothing in all the realm of bee-culture that is more interesting or more fascinating than watching the baby queens develop into full-fledged mothers.

It will not be necessary for me to explain how queen-cells may be reared in wooden cell-cups in quantity, nor how the eggs of one or two breeding queens may be used for all the cell-building work. This part of the operation has been usually regarded as simple and easy; but the problem of getting the young hatched virgins *mated*—aye, there has been the rub. I desire to show you a method whereby even this part of the work can be accomplished simply and easily, and at a trifling expense in bees and brood.

Until within the last year or so, full-sized two and three frame nuclei using standard Langstroth frames have been employed for mating the virgins. To make such, it has been necessary to break up a good many otherwise strong colonies for honey-production. As a general rule, only three or four nuclei could be made out of one colony. This made the question of mating somewhat expensive. Mr. Pratt, Mr. Laws, and others who have worked at this problem, have now demonstrated that a small teacupful of bees and one or two sections of comb will serve as good a purpose as a large

nucleus, with the added advantage that the queens can be found instantly.

I hold in my hand here one of Mr. Pratt's "baby" nucleus-boxes. As you will see, it is a miniature hive made of quarter-inch stuff with a small flight-hole in front. This has a tin slide on the outside so that the hole can be closed, and a

perforated zinc slide on the inside. This latter can be revolved around, holding the queen after she is mated. The little frames, as you will note, are secured to the cover, having no ears nor projections. They are not made permanently fast, but are secured by a staple bent at right angles, folded over against the top-bar. When these little frames are filled with comb and bees, the cover is turned bottom up, leaving the frames standing upright. If the queens or the eggs are not discovered on the two outside surfaces of the combs, a sliding twist will remove one of the frames so that its inside surface, as well as the inside surface of the other comb, can be readily seen. If the queen is laying, the fact can be noted at a glance. If she is to be caged and sent out through the mails she can be located without hunting. We have gone so far as to take every bee in the box and put it in the mailing-cage with the queen. In cases of this kind we supply the box with fresh bees in the manner I shall presently explain.

To get these little "baby" frames filled with comb, we make them of just the right size so that six of them will fit in a standard Langstroth frame, a good deal as eight sections used to be inserted in the old-style wide-frame. Each of these little frames is supplied with foundation, and the whole six in one frame is set down in the center of a strong colony. In a few hours the comb will be drawn out, and will contain some honey if honey is coming in, as well as, possibly, a few eggs.

We have a good many of these frames, each containing six small frames, scattered through the yard so that we can get freshly sealed combs whenever we need them for the "babies," for that is what we call these miniature nuclei

Now, then, how do we supply these little boxes with bees? We prepare a lot of them, say a dozen or so, with combs all ready for the bees. We next go to some good

colony and shake all the bees into a box, having previously smoked them in order to make them quiet, and to get them to gorge themselves with honey. This box of combless bees, after giving the brood to other colonies, is then carried to a shady place where we have the prepared miniature nuclei. The box of bees before scooping up is given a bump in order

to get them into a heap. The cover is removed, and with a tea-cup we scoop up one or two hundred bees and dump the teacupful into one of the baby boxes, when the cover with its combs is set down in place, thus confining them. In a like manner the other babies are supplied. Of course, the entrances are kept closed. Having supplied all the bees, we

can now give each through the hole in the cover a queen-cell built on one of these wooden cell-cups; or in 24 hours after the bees have come to know their utter queenlessness we may run in a young virgin.

We can now distribute these baby boxes around in different parts of the yard; but it is usually advisable to carry

HOW PRATT FEEDS SYRUP TO THE BABY NUCLEI.

them to an outyard or to some isolated locality where there may be one or two hives with a large predominance of selected drones. The queens are allowed to fly at this yard and become mated, when they are brought home and kept for supplying queenless colonies or to fill any orders that one may have; for these little boxes of bees will hold their queens for a considerable length of time. It may be neces-

sary to "repeople" these boxes, for Mr. Laws says these clusters sometimes get uneasy; but we have kept these same little clusters going all summer, rearing their own brood, and working a good deal on the same plan as the ordinary strong colonies.

I wish to call attention to the fact that one can almost control the male parentage of his bees by selecting some locality where there are no bees, and keeping there a few hives of select drones.

BRICK HONEY.

"I show here a sample of "brick honey," or what has been appropriately called "honey butter." It is nothing more nor less than an oblong cake of candied honey hard enough to hold its shape. It is wrapped in paraffin paper and then given other wrappings, or, better still, putting into a carton and properly labeling it on the outside. These bricks of candied honey are secured from the cans of alfalfa honey—the honey, of course, being granulated solid. The tin can is stripped off from the cake with a pair of tinner's snips. The block of honey is now put into a regular machine for cutting up butter into bricks. This consists of a cast-iron plate with four upright standards on which slides up and down a frame having two or more wires stretched tightly across it. These wires are forced *perpendicularly* down through the block of honey by a steady, even pressure. Another frame swung on one of the standards as an axis, carries another set of wires which cut the honey on a *horizontal* plane. When cut up, these bricks can then be taken off with a thin-bladed knife, placed on a piece of paraffin paper of suitable size, and wrapped.

We have developed quite a business in putting up brick honey at Medina and vicinity. It is now offered in some of the largest retail stores in Cleveland. Of late we have been calling it "honey butter;" and under that appropriate title it seems to take well with the general public. Our labels show how to liquefy, if preferred in that form, and also explain that pure honey, or nearly all of it, will turn to this solid state at the approach of, or during cool weather.

I believe this brick honey has a bright future, and that many of our honey-producers will find it a field well worth developing in their own localities. ERNEST R. ROOT.

Mr. Wheeler—Do you have any absconding?

Mr. Root—Very little. I expected that, but we had very little. Our early experiments indicated there would be more or less absconding but I do not think that will be the case.

Mr. Kimmey—I understand the advantage of taking that to an out-yard is to control the drones?

Mr. Root—That is all.

Mr. Meredith—Do you expect to put them on the market? If so, about what would the complete expense be?

Mr. Root—We are going to put them on the market. What the price will be I don't know. I am glad I don't. I don't think it would be proper for me to mention prices at this time.

Mr. Meredith—Will they be in your catalogue?

Mr. Root—In 1905.

Mr. Colburn—The queen-cell is sealed?

Mr. Root—Yes, what we call a "wrapped queen-cell."

Mr. Colburn—Would that be warm enough in severely cold nights?

Mr. Root—I couldn't say as to that. In our locality we had no difficulty from that. We had those cells hatch along in November. This cage is what we call the Titoff case. It is quite convenient for holding the cell.

Dr. Miller—With your indulgence, I would like to say if you want to try the plan of having queens fertilized with baby nuclei, that you can do it without any arrangement of this kind at all, only just what you have at home. I reared a number of queens last year and had them fertilized. I followed Boston Smith's rule, "Do the best you can with what you have." I didn't have anything of that kind. I had an ordinary hive that I use every day, a dove-tailed hive. In that I put a wide frame that will hold four sections. In that I put one section of honey filled solid full of honey. Another frame beside it with a section of comb, no honey in it at all. It doesn't matter whether there is or not. I put those two in the hive. Had the hive closed up in front so that it would have only an entrance of one-quarter of an inch. Then I go to a hive, take out a frame of brood with the adhering bees and bring it to that hive. Then I tell my assistant to take that and pound off the bees and at the same time I drop a virgin queen in the bottom of the hive, quickly shut the

thing up, and leave them fastened there for three days. Then open the entrance, and that is all. The bees do the rest.

Mr. McCain—After forming the little colony—the nucleus—how long does Mr. Root keep that closed before liberating the bees or the queen?

Mr. Root—That all depends upon whether you carry them to an out-apiary.

Mr. McCain—In the yard.

Mr. Root—Not less than three days. They will have to be shut up at least three days to get them so that they will get used to a new location. At the end of that time they will do very well. In the out-yard you can use them immediately.

Mr. Wheeler—Mr. Stanley is here. He rears queens and I have bought hundreds of them in the last year and he has a very unique and fine way of rearing them, and he will exhibit for you any time you want him to in the back room. He does not care to come before the assembly and speak; but there is one thing I can assure you he rears good, lively queens, and the bees take them, and they lay, and they are a good color. He is one of the largest bee-keepers in the State, I understand; he represents about 700 colonies. Such men as that are men that work as well as talk.

Pres. York—Has Mr. Stanley anything to say on this?

Mr. Stanley—No, not unless anyone wishes me to talk.

(Mr. Stanley was requested to explain his method of rearing queens.)

Pres. York—While Mr. Stanley is getting ready I think we may take up a question or two.

SHOOK-SWARMING.

"How many present think shook-swarming a preferable and practical method of management?"

Mr. Whitney—That would depend largely upon circumstances.

(Pres. York called for a show of hands on the question. The request was complied with.)

Pres. York—It would be preferable, I think. There were four I think who raised their hands.

Mr. Wilcox—How many have an opinion concerning the subject and know anything about it?

Pres. York—Do you mean how many have tried it?

Mr. Wilcox—Yes.

Pres. York—How many have tried shook-swarming? Raise your hands. (About 10 responded.)

Pres. York—How many think it is preferable to all other methods? Raise your hand. (One responded.)

LAWS ON BEE-KEEPING.

"In what respect does the law of Cook County differ from the State laws relative to bee-keeping?"

Pres. York—Does anybody know of any different law in this county from any other county in the State?

Mr. Moore—There are no laws in Illinois except State laws which are applicable to every county in the State. There are no County laws.

Pres. York—Are there any ordinances in the City of Chicago relating to bees or bee-keeping?

Mr. Moore—There have been ordinances made in certain places in the State against keeping bees within certain limits.

Mr. Pease—We have in the ordinances of the City of Chicago, an ordinance that bee-keepers do not care to discuss very much, as a rule. It is still one of the ordinances. It is to this effect, prohibiting the keeping of bees within 200 feet of a public highway or alley. That ordinance is still in effect although it has never been enforced. There has been no litigation on the subject whatever. There has been considerable controversy among some of the bee-keepers of Cook County to have that ordinance repealed. As to the legality of it, it is a question as to whether it would be sustained or not. It is in a measure conflicting with the State Laws as being rather class legislation, and there has been a strong inclination on the part of many of the bee-keepers of Cook County to have that ordinance repealed. Philadelphia had a similar ordinance which was taken into Court and contested and carried to the Supreme Court of the State and there found unconstitutional. I suppose that is what is referred to by this question.

Mr. Moore—I am certainly instructed by the gentleman's authority, which I take for granted is correct, that there is an ordinance in Chicago on keeping bees within certain limits, but it has given us so little trouble that we didn't know there was such a thing. It would take \$500 or \$1,000 to wipe it off the statute book. No legislation of that sort is going to give us any trouble either now or in the future, judging by

the amount of bother it has been in the past; it might as well stay there, as there has been no attempt made to enforce it.

Mr. Abbott—I am not a lawyer, but whenever there is any specification regarding keeping bees a certain distance from any place I pay no attention to it whatever. It cannot be enforced in any State in this Union. That belongs to the common principles of law that underlie all law. Every law must be specific and must apply specifically to all the people engaged in that industry.

Mr. Kimmey—Suppose you lived next door to a church and should insist on keeping a row of bee-hives right along side of the church, don't you think there is power in the municipal power of a city to control that matter?

Mr. Moore—This matter has been threshed over at very great length. The law of nuisances covers a great many of these things. There is such a thing as a public and a private nuisance. No man would claim that keeping a cow was a nuisance, but in a city where people live close together you can keep a horse or a cow in such a way as to become a nuisance. It may be a private nuisance, it may be a public nuisance. The whole neighborhood is interested in having it abated, in which case there is appropriate remedy. Keeping bees or chickens is not a nuisance, but they may be kept in such a way as to become an awful nuisance. Then there is a remedy for the people aggrieved, at law.

Mr. Kimmey—Don't you think there is a remedy with the authorities. Has the pastor of a church got to go to law? Why can't he ask that there shall be a reasonable ordinance passed to control those things?

Mr. Moore—It is not necessary to pass an ordinance. If the church authorities are agreed, the church authorities as a corporation can maintain an action for specific nuisance.

Mr. Kimmey—Your argument would abolish all law. I don't believe that we should take the high and lofty position that we can keep bees wherever we please, regardless of everybody and anybody. When we do I believe we will find ourselves subject to municipal legislation under the police power granted by the State of all municipal corporations.

Mr. Moore—If the Legislature or if municipal corporations attempted to make laws to govern everything, pretty soon they would be making laws telling you to have your picket fence so high, to keep your next neighbor's chickens out.

Mr. Kimmey—They do that very thing right here in the city of Chicago.

Mr. Moore—There are a whole lot of things that must be governed by common sense, and they have attempted to make general laws to remedy specific cases of grievance. There is always a law for specific grievance.

Mr. Stanley being now ready to explain his method of queen-rearing, the subject was taken up.

#### STANLEY METHOD OF QUEEN-REARING.

Mr. Stanley—I have a frame of queen-cells here.

Dr. Miller—How do you get those queen-cells started?

Mr. Stanley—Started as they are now? Do you mean grafted?

Dr. Miller—Yes.

Mr. Stanley—They are started with royal jelly and then the larva is grafted in. I made these myself.

Mr. McCain—Are those the ordinary Doolittle cups?

Mr. Stanley—No. This is a frame showing complete cells, some of them hatched and some of them not. At this stage that should be removed (indicating).

Mr. Kimmey—What would I do with those if I had them?

Mr. Stanley—If you wanted to save the queen I suppose you would put it in a cage until she hatched and then you could make use of it by putting it in a nucleus, the full colony.

Mr. Moore—Before these hatch you cover them with some kind of a metal cover.

Mr. Stanley—Yes. In introducing the cage it is supplied with a candy to liberate the queen at any time. They are kept warm with the heat of the colony in full colonies or nucleus.

Dr. Miller—Right down in the colonies?

Mr. Stanley—Yes; they are put right between brood-combs, one, two, three or four colonies.

Dr. Miller—I wish you could all see closely the beautiful workmanship of all of this. Mr. Stanley is a wonder as a mechanic. His work is beautiful.

Mr. Whitney—Do you mean to say that you can intro-

duce a queen to a colony in one of those protectors—that is, a laying queen, and the bees not kill the queen?

Mr. Stanley—Yes, I can introduce a virgin queen into a colony and have the laying queen caged.

Mr. Whitney—With room for the bees to go in and out at pleasure?

Mr. Stanley—Yes, the bees can go in and out and feed their laying queen. Have your laying queen caged, and the virgin queen at liberty on the combs.

Dr. Miller—Would it do if there were a laying queen at liberty in the hive?

Mr. Stanley—You couldn't liberate the virgins. You might lose your virgin and you might lose your life.

Mr. McCain—In regard to fertilizing. You have quite a number of cells there. What is your method of getting the queens fertilized?

Mr. Stanley—I use a three-frame nucleus, standard size frame. I have tried the small one. I have had some failure and some success.

Mr. McCain—Do you introduce the virgins one at a time?

Mr. Stanley—One at a time.

Mr. Kannenberg—How long can you keep the queens after they are hatched in those cells you have there?

Mr. Stanley—I have kept one 34 days to see how long I could keep them.

Mr. Kannenberg—Without any honey? The bees will feed them?

Mr. Stanley—Yes.

Mr. Wheeler—Could you introduce them after that time?

Mr. Stanley—Yes.

Mr. Whitney—Could you introduce that virgin queen into the center of the hive where there is a laying queen, and not have any of these virgin queens killed?

Mr. Stanley—Yes; they can be cared for in the colony with the laying queen.

Mr. Moore—They simply can't get at them.

Mr. Stanley—Certainly.

Mr. Moore—They are protected by the zinc.

Mr. Whitney—The question is about the bees killing them.

Mr. Stanley—I haven't had any trouble with the bees killing them.

Mr. Wheeler—Do they ever attempt to ball them?

Mr. Stanley—No, I have never had any trouble with balling.

Mr. Wilcox—Would it not be better, in introducing them into a hive, to put them in an upper story with a queen-excluding honey-board?

Mr. Stanley—If there are bees enough it would be just as well; all they require is to be kept warm.

Mr. Wilcox—You supply them with food?

Mr. Stanley—You don't need to supply them; the bees feed them.

Mr. Wilcox—The bees will not feed the virgin queen?

Mr. Stanley—Yes, the bees feed the virgin queens while they have a laying queen in the hive. There probably are cases where they will not, but it can be brought about so that they will.

Mr. Wilcox—I have very often slipped a virgin queen in the hive with a laying queen, and found her dead afterwards. I thought they killed her or starved her to death.

#### RE-INTRODUCING A BALLED QUEEN.

“When a laying queen is balled in introducing, what method should be adopted to introduce her again to the same colony?”

Mr. Whitney—That comes directly in line with some practice I had a year ago, although I didn't ask that question. I introduced the queen to a queenless colony for a young lady who bought a colony of bees from me, and the next day or two afterwards she wanted to see whether that queen was accepted or not. She found they had eaten out the candy and the queen was liberated. I told her there was a little danger in opening that hive so soon, but if she cared to have me do it I would try to do so. I opened the hive and I didn't find the queen—I gave them a little smoke—I was afraid perhaps they had killed her. The young lady looked down into the hive at the bottom and she said, “Mr. Whitney, what is the matter?” I looked in and I said, “There they are balling that queen as sure as you are alive.” I put my hand down and took that ball of bees out and shook them and there that queen was and they hadn't hurt her. I re-caged her and put her back and left it till the next morning,

when I pulled the plug out and in three or four days the queen was all right.

Dr. Miller—There is just one part that might be added to what Mr. Whitney has said. He says that he introduced that queen the second time in the morning.

Mr. Whitney—No; I introduced her immediately.

Dr. Miller—About what time was it?

Mr. Whitney—About the middle of the day it was that we looked, and I introduced her again, but plugged up the cage so that she couldn't get out, and left her there over the frame till the next morning, and then carefully removed the frame and didn't disturb the bees at all.

Dr. Miller—That is the point—if you free her at a time when the bees are likely to be troublesome, in the morning. Any other time in the day you will not be quite so safe as if you free her just at night when there will be no chance for robbers or foreign bees to get in. In this case it is the queen with which you have had trouble, and you want to take more than ordinary care. So take the additional precaution to liberate her at night and you will be safe.

Mr. Wilcox—I thought perhaps there might be a word more said in regard to the manner of picking up that queen in the ball. He said he picked it up with his fingers and put it in the cage.

Mr. Whitney—No; I scooped the whole ball of bees up from the bottom of the hive with my hand and shook them out and the bees were very much surprised.

Mr. Wilcox—Sometimes a bee-keeper is, too! I could recommend those that are very timid to use a little table spoon and pick up the ball and throw it into some water.

Mr. McCain—In regard to the ball of bees, I would like to ask if it is a dangerous or unwise thing to smoke the ball.

Dr. Miller—Yes, and no. I take the smoke and I will warrant that one way I use it they will kill the queen, and another way I use it they will not hurt the queen. Hold the smoker off far enough so that the cold smoke comes upon them, and they will leave it about the same as they will when you throw them into the water. Get some bees in your fingers and hold the smoker up so that the smoke will be hot and see if you don't get stung. You will be sure to kill the queen if you blow hot smoke on it.

Mr. Kimmey—I don't know anything about these matters, but I have had just a little experience. I got a queen, and found after she was liberated the bees had balled the queen in the bottom of the hive, and I picked it up and laid it on top of the frames and moved it a little, and it never occurred to me that they would sting me; and the queen flew away and I thought, "Well, surely she has gone." But I waited about an hour, or something like that, and I looked again and I found the queen back, balled in the bottom of the hive. I simply picked it up, from my previous experience, and carried it into a little building in my hands and then caged it there. I had a caged queen and the colony without any queen which I wanted to get that queen into. I didn't know what to do. I went back and hunted up all the old bee-papers I could find to get some information on the question. I don't know just what paper it was in, but it said to smear the bee with a honey and water mixture and throw it in the hive and it would be all right. I thought, "Here is a desperate case and I don't know what to do." I tried it and it succeeded, and that is all I know about it. I simply smeared the queen with that mixture and poured a teacupful right down between two frames and let the bees in, and it went on and made a good colony.

Dr. Miller—It may succeed next time, but maybe it won't.

Mr. Dadant—I think there is a great deal less danger than some people would think of bees stinging when they have balled a queen. I have never had patience to go after a pail of water to throw the bees into. We have found the bees ball and I was in too much of a hurry to release her to do anything like that and I never got stung. They are rubbing against one another and expect to be rubbed, and their stings will not hurt one another; they will hardly hurt your fingers. Our way to do it is to do it promptly.

Mr. Abbott—I would like to ask these gentlemen what they have queens balled for? I wouldn't think anything more about putting a queen into a hive and not having her balled than I would about picking a frame out. I think a bee-keeper hasn't learned his business that has them balled.

Mr. Whitney—If she were balled what would you do?

Mr. Abbott—She won't be. You might just as well ask me if my wife left me what would I do. She won't leave.

Mr. Kimmey—I would like to know what I did wrong. I simply put the cage in the hive and left it there, I believe, about 42 hours and found her balled in the bottom of the hive.

Dr. Miller—May I be allowed to interrupt and cut this matter short by asking that Mr. Abbott shall tell us what he can do so that there are never any balled queens or queens balled.

Mr. Whitney—Perhaps I can answer the question for Mr. Abbott. I don't believe he keeps any bees! [Laughter.]

Mr. Abbott—I used to have about 200 colonies when I was handling queens, but the question with me was, How your colony came to be queenless?

Dr. Miller—That is not the question. The question is, How does he do that he never has any queens balled?

Mr. Abbott—In the first place I don't have queenless colonies to begin with, when I want to introduce a queen.

Mr. Kannenberg—I had a colony of bees I wanted to Italianize. I got the queen out about two days before, and I left it queenless for two or three days. Then I looked to see when I put the queen in if there was—

Mr. Abbott—You followed the instructions of the bee-books and journals; you shouldn't have done anything of the kind. The way to introduce a queen is not to kill the old queen to start with. The way to do is to leave the old queen in the hive; don't interfere with her at all. When you get your cage with the new queen, uncover the wire so that the bees in the cage can get at the bees inside of it, and get at the queen if they want to. Leave it there at least 48 hours, then catch the old queen and kill it, and uncover the candy and cover up your hive as quick as you can. Just as soon as you find the queen and kill it don't spend another moment's time but get the frames back in as quickly as possible; uncover the candy, cover up the hive and go about your business, and pay no attention to them for two or three days; and when you go back you will find the queen laying every time, and never have one balled. If you kill the old queen according to the instructions in all the books, in nine cases out of ten you will have trouble and have them balled.

Dr. Miller—I have had queens balled a good many times when there was but one queen in the hive and none other had ever been in; they balled their own queen.

Mr. Dadant—There are many cases in which we have balled queens. I have seen hundreds of instances. I have had two swarms come out and each of the two queens balled because some of the bees of the other swarm were with that queen. I have had queens that I was about to introduce, balled before I had any time to do anything with them. I have seen young queens balled in the hive. Those things are accidents that happen in the bee-business, and the best of us cannot avoid them.

Mr. Root—I would like to agree with both gentlemen, but I think Mr. Dadant is exactly right. I also agree with Mr. Abbott on his method of introducing queens. We have been trying that all the past summer and the plan is all right. Leave the old queen in the hive until you are ready to release the new queen. We have been doing it with our virgin and laying queens and it works better than it worked the other way. But the "A B C of Bee Culture" has been changed, Mr. Abbott, and our directions are changed to cover that. We introduce our virgins; we have three or four in a hive at a time, and we also have a laying queen. As those virgin queens begin to lay we take out the laying queen and leave the other in the hive, and when the other begins to lay we take her out. I think there is one point that has been dropped, and that is this question of scent of the bees. At the University of Pennsylvania I spent some three months a year ago last summer, and after working a long time at this problem the intention was to consider some problem of introducing. I remember Mr. Abbott had been trying to pound that thing into us, and we didn't believe it—

Mr. Abbott—For twenty years. [Laughter.]

Mr. Root—And Dr. Phillips takes the ground—and he has been studying this question very carefully—that this question of introduction depends almost entirely on the scent of the bees. If the bees are balled, and you handle that ball in your hand and get that queen in your fingers, the chances are that they will ball up again because that scent has been changed. The bee's sense of smell is very acute. If the scent is changed a little bit the conditions are different. They recognize her somewhat as a stranger. I have had queens balled in our yard. By picking up the queen and showing her to visitors and dropping her back, they will ball her. Sometimes a disturbance in the hive will cause them to ball her. But

this question of scent plays a more important part in it than we bee-keepers have been in the habit of thinking. If she has the same scent as the rest of the bees she will be accepted. A little while ago Mr. Stanley spoke about putting virgin queens in a hive where there is a laying queen. If they have the scent of the rest of the bees the bees won't tackle them, but if the laying mother can get at those then there will be war.

Mr. Smith—Why do bees ball their queens? In my experience I find that there are two motives, one is to protect them and another is to kill them. I will illustrate: I had an Italian second swarm and a black swarm go together, and both queens were balled. The yellow queen was balled with her own bees; the blacks also balled their own queen. I liberated them and neither one was hurt. I introduced the black queen and she flew away. I introduced the yellow queen and shook the bees all out on the ground, and dropped her in among the bees as they went to the hive. She was introduced that way perfectly safe. The black queen came back and lit on the outside, and the yellow bees killed her. In the first place they had balled their own queen, which I think was for protection.

Mr. Abbott—I want to say I didn't mean my remarks to apply to these abnormal conditions of two swarms going together or anything of that kind. I want to be rightly understood. I just let them go together and let them fight it out. I don't fool with them.

Mr. Smith—If you alarm a colony they will sometimes ball their queen. That is to protect the queen.

Mr. Root—Shut the hive up and they will be all right.

#### DISPENSING WITH THE BEE-VEIL.

"Generally speaking, can the bee-veil be dispensed with? How many think it can?"

Mr. Smith—I would like to see a man go through 40 or 50 colonies in the honey season without a bee-veil.

Mr. Dadant—There are a few gentlemen here that get along without bee-veils but if they wanted to follow some of us all day among the bees and not flinch, stay right with it, they will wish they had a bee-veil, unless they are absolutely proof against the sting, and there are very few that are. When you have a bee-veil you don't have to wear it all the time, but you have it at hand so that you can wear it if you have to.

Dr. Miller—I may say in regard to that, that there are men who do not use a bee-veil at all. There was one of them went in one of my apiaries; he went around with me with a smoker and he said, "They will never sting me; there is no need for me to wear a veil." And he kept that smoke going all the while, so I couldn't have any use of the smoker. I won't give you the man's name because I am afraid it might hurt the feelings of his son Ernest. [Laughter.]

Mr. Whitney—There was a friend of mine who said he didn't need a veil. He was extracting a great deal of honey. He sold the honey around through the community. I didn't know anything about bees then, and he invited me into the yard where he was taking off some frames; and he said, "They never sting an honest man." I went in and stood around the hive and pretty soon a bee struck him right over the mouth. I said, "I guess you're right." [Laughter.]

Mr. Moore—If any one really wants to handle bees without a veil he can do it. I have been engaged in marketing honey in Chicago, and for the sake of advertising I have done a great many outlandish things. I have attempted to go into my own hives and other peoples' without the bee-veil. The past summer I didn't carry a veil with me except on one or two days. I opened the hive without smoke. But I want to tell you right now, I got stung on one occasion twelve or fifteen times because not wearing a veil. If you are so patriotic, all right; but as a rule it pays to have a veil.

Mr. Whitney—A friend of mine in Ohio has been able to handle his bees without a veil for years. At one time he thought he would look into one hive and he took off the cover, and they came out. He backed up and held up his hands and they still came. He turned around and ran down the outside cellar-way and shut the trap-door, and he was stung so badly he fainted away and was sick for three weeks. Since then he hasn't been able to handle bees at all. A lady friend said, "I always use a veil; never go into the yard without one."

#### "SHOOK" OR "SHAKEN" SWARM.

"Is it better to say 'shook swarm' or 'shaken swarm'?"

Mr. Root—If Dr. Miller wasn't here I would say "shaken swarms," but in his presence I always say, "shook swarms."

Pres. York—I think we would better refer that to Mr. Hutchinson.

Mr. Hutchinson—I agree with Mr. Root on that question.

Dr. Miller—If that thing is entirely to spite me, I am going to say a word about it. I am very glad of an opportunity to say a word in favor of having people at large understand that bee-keepers are not a lot of ignoramuses. I have felt mortified at the use of that word as a violation of common English, that a teacher in any one of our public schools would know better than to countenance. If either of these good brethren who have such a vicious feeling towards me can give me any possible reason why the word "shook" is any better than the word "shaken," they can give me something I have never had yet. The word "shook" expresses something to me a little stronger than the word "shaken." When Mr. Root told me that, I knew that there was something that had shaken loose in his brain. If they have a seat reserved in one of these places, say in a concert, there will be laid down a little slip and on it marked, "Taken." Do you think I would feel any more secure of that seat if it was marked "Took?" [Laughter]. Now, I consider this, without any joking, of enough consequence that we should spend a little time upon it. If there is any reason why "shook" is better than "shaken" I would like to hear it. One is good English, the other is bad, and it seems to me that is enough to settle the question, unless you can give some other very strong reason.

Mr. Dadant—In regard to this matter I think there is a great deal in locality! [Laughter.] I am foreign born, but when some of our Western Americans took a trip to Europe I was with them, and I had occasion to say to an Englishman, "Hurry up," and he said, "I suppose you mean 'make haste.'"

Mr. Whitney—When I saw the words "shook swarm" I thought the whole thing was wrong. What is a swarm? It is bees in the air or in cluster. Then you can't make a shook swarm or a shaken swarm. It is simply a colony of bees. You can't shake them or have them swarm in the air or cluster, so that it is not a swarm at all.

Mr. Wheeler—I would like to know of how much money value this is to us. We are here to learn something. I didn't leave my work to come here to listen to sport. I came here to learn something about bee-keeping. Now what does this have to do with bee-keeping?

Mr. Abbott—I used to teach school and they paid me \$50 a month for teaching their children the correct use of the English language. It must have had some value to me. But I disagree with Dr. Miller that the use of the word shook is not as correct as shaken. This is simply the invention of a new condition of things, and new conditions of things are creating words and phrases every day in America. I suppose I could mention 50 that have been created within the last few years. It is just as proper to apply "shook" to a new condition of things as "shaken," and the words got into Dr. Miller's dictionary that way.

Pres. York—This is one of the questions for diversion. Now we will go on to something more solid.

Mr. Wheeler—We have editors, such as Mr. Hutchinson; leave such things to him. We don't want to spend our time here to-day on that. He will put that word in just as he pleases when he gets home, anyway.

#### ADVANTAGE OF SHOOK SWARMING.

"What is the advantage of shook swarming?"

Mr. Hutchinson—I suppose primarily that the principal advantage of this shook swarming is that we are able to have the work gone on with without being there to see to it. We forestall swarming. We make preparations for the bees to swarm and we are not there to take care of them, so instead of that we go at it and shake them off and make the swarms while we are there to see to it.

Pres. York—What about joining the National in a body this year?

Dr. Miller—Moved, duly seconded, that this Association join the National in a body, at the rate of 50 cents a member.

Pres. York put the motion which, on a vote having been taken, was declared carried.

Dr. Miller—Right in connection with the point which is before us is the question of uniting with the State. If it is a proper thing to bring that up now I move that this Association, as a body, unite with the Illinois State Association, paying into its treasury 25 cents per member.

The motion was seconded.

Mr. Colburn—What is the present membership of the Illinois Society?

Mr. Smith—The present membership of the Illinois State Association is over 150.

Mr. Wilcox—How many bee-keepers' societies are there in the State of Illinois?

Mr. York—I think there are two besides this, outside of the State organization, that is, the Northern Illinois and the Western Illinois.

Mr. Whitney—I want to ask the Treasurer as to what effect taking 25 cents for each member joining the State would have upon our balance in the Treasury?

Mr. Moore—There would not be enough money left in the Treasury to support our Association if we paid out 75 cents on each dollar, that is, 50 cents to the National and 25 cents to the Illinois State. The actual expenditure for membership if this motion is passed, under our Constitution, will be about \$20 out of our treasury.

After a long discussion Pres. York put the motion that this Association join the Illinois State Association in a body by paying 25 cents a member, which, on a vote having been taken, was declared carried. The necessary amount to pay same was secured by passing the hat.

#### ELECTION OF OFFICERS.

The President appointed as tellers Messrs. Fluegge, Jacob and Dadant. Ballots were taken and the officers were all re-elected as follows: President, George W. York; Vice-President, Mrs. N. L. Stow; and Secretary-Treasurer, Herman F. Moore.

#### QUEEN'S WING AND LEG GROWING.

"Does a queen's wing ever grow again after being clipped?"

Dr. Miller—No.

Mr. Criggs—Does a queen's leg ever grow where a leg has been pulled out?

Dr. Miller—No.

Mr. Criggs—I was clipping a queen's wing one time with gloves on, and I didn't have a very steady hand, and in some way pulled off one of the large legs right to the bottom. I was sorry at the time, but I thought they had so much brood and eggs they could rear another queen. However, I kept close watch and they didn't rear another queen to take her place, but this queen in the course of another two weeks had another leg.

Mr. Wilcox—Did her progeny have a missing leg, too? [Laughter.]

Mr. Criggs—I didn't find any that did.

Dr. Miller—I would rather believe a clipped queen got into that hive from another hive than to believe the wings or leg would grow on again. That has sometimes happened. A clipped queen has gone from one hive into another.

Mr. Criggs—I should say not. This was a pure Italian queen and all the other queens within two rods were dark. I had only half a dozen Italian queens in the whole apiary of about 60 or 80 colonies; the rest were all dark bees.

Mr. Whitney—Was that a queen of your own rearing?

Mr. Criggs—No.

#### OUTDOOR WINTERING OF BEES.

"In outdoor wintering is water running out of the entrance of the hive an indication of poor wintering?"

Mr. Wilcox—I should say not, but it indicates poor preparation for wintering. There ought to be absorption enough so that it wouldn't condense and accumulate.

Mr. Snell—That has been my experience. If the ventilation is proper, and the preparation is proper for wintering, there will be no water running out from the entrance.

#### STARTING WITH BEES.

"Tell a few good ways for beginners to get a start in bees and a first-class experience at one and the same time."

Dr. Miller—Buy a colony of bees, buy a bee-book, or several of them, and subscribe for a bee-paper, or several of them, and then go on and get your experience.

Pres. York—I noticed that the Doctor didn't say he could buy his experience, too.

Dr. Miller—He will buy it and pay for it.

#### EFFECT OF MARKET REPORTS ON HONEY PRICES.

"What effect has market reports on the price of honey?"

Mr. Burnett—I don't know that I ought to answer or endeavor to answer that question. I make some market reports.

What effect it has, has to be problematic. I think, however, it is in general alignment with all other reports on prices. People are guided by what they find to be a price in a certain market. It gives you an idea of what goods can be obtained for there. It is also a guide for those seeking a market. I should think it had a good deal to do as a matter of fact with the general business of the country.

Mr. Colburn—I am a resident of Chicago and I asked that question because I wanted to find out if there is any difference, or if it had any appreciable effect; and the reason I asked it is, I have been on South Water Street a good many times and I always found on enquiring there that the prices of honey were invariably greater than these market reports give us to understand. Why that is so I don't just know. I think I know the South Water Street houses pretty well. I was a grocer here in Chicago for a number of years and went all around the streets with my market wagon on every day in the summer, and every other day in the winter, and I found things down there were quite peculiar. This fall I examined up and down the street on one or two days and I found at that time five different firms reported honey as selling at 15 cents a pound in one-pound sections. At that time our market quotations—the nearest was within seven days—gave us prices at 12 to 14 cents. This is what I don't understand, and I want to understand it. Every bee-keeper within 300 miles of Chicago who sends his honey here, if he takes these papers, naturally is enquiring and looking at these reports, and these reports ought to be reasonably accurate. At the stock yards, with which I was familiar for a number of years, the market reports give the actual sales as they are. They don't say, "We quote so and so." They say, "Armour bought so and so, such and such a kind of stock, and it sold for so much." I think our market reports ought to be under the control of this Association, on account of the fact that there is such an apparent discrepancy between the reports in the papers and the actual condition on the street. We as individuals who are bee-keepers are interested in having prices at a reasonable figure, and we don't want any market reports which show the prices of honey to be less than it is generally sold at. Whether they are, or not, I can't say, but I think they are. In every investigation I have made I have invariably found a difference of one or two cents in the reported price of the honey from the price on the street. In the quotation from Milwaukee it is from one to two cents higher than the Chicago market, and yet Milwaukee is 200 miles nearer the great center of honey-production than we are. I brought this up because I think the bee-keepers will lose two cents a pound on every pound they send to Chicago unless they get straight market reports.

Mr. Wilcox—The question is, What effect do market reports have on the honey market? If they be timely and truthful they tend to steady the market, to prevent fluctuations, and are highly profitable to all.

Mr. Moore—There isn't any use in allowing any prejudice to enter into the discussion of these questions. I know a good many people think that all lawyers are thieves, and all commission men in the same class. They are very much like the rest of us; they are all honest and all dishonest. But according to Mr. Colburn's own statement there is no discrepancy. He said the market report gave 12 to 14 cents. Twelve meant the lower grade, 14 meant the highest grade. Understand that those quotations mean some considerable sale. You go along and ask a man what is the price and he says 15 cents. He thinks, to look at you at first, you are a suburbanite, come to carry honey home under your arm. If you say, "Here, I want five or ten cases," he gives it at 14 cents, according to the quotation that you say was quoted. There are different circumstances. Quantity and quality of purchase make a difference as to quotations, as you state it, and are fair.

Mr. Burnett—As to difference, I would like to have him change the word invariable to variable. It seems to me it is hardly fair that it should be invariably higher than the quotations. As a matter of fact we all know that is not the fact. That buying honey, as he buys it—perhaps he met a man who buys from the receivers. The majority of the houses on South Water Street that sell honey in a small way or keep a few cases, buy it from some of the receivers, and they need to get a cent a pound as a margin over and above what they pay. The purpose, as I have understood for many years, of market reports, is to give as nearly as may be the actual value of honey sold as received. A lot of honey sold consisting of 25 or 100 or 1,000 cases is the price that the purchaser must be guided by. Allow him to send the honey here and get a cent a pound less than the quotations are for that grade of

honey, he feels that he has not had the market value for it. So that it is not fair to any one to say that it is invariably so, but that it does vary is a fact.

Mr. Fluegge—I find the market quotations in Chicago given out as nearly correct as they possibly can be. I visited a number of grocerymen and they informed me that the prices they paid for first-class honey were 14 cents a pound, and that is comb honey. That is what the quotations are now. I have been watching it for several years and there is very little difference between what the grocerymen say and what the quotations are, so I think they are as nearly correct as we can get them from that standpoint.

#### HORIZONTAL WIRING OF COMB-FOUNDATION.

"Can brood-frames filled with full sheets of foundation be wired horizontally in a manner that will prevent buckling?"

Mr. Dadant—If we wire foundation at all, I believe as a general thing those who do wire put their first wire too low. The weight is at the top—the pull is on the top story; the cells are nearest to the top of the frame and the first wire should be put very close to the top, within an inch. When you come to the bottom of the frame, those who have handled foundation for years, know that those cells are hardly ever stretched, and there is no need of wiring below the middle of the frame. If you put one wire at the middle and the other two above, you will have better success than if you put the wires within your space in the frame.

Dr. Miller—I would like to ask Mr. Dadant a question I think germane to the subject. In those, do you suppose that the wires are taut or slack?

Mr. Dadant—It would be better for the wires to be taut if they are pressed into the foundation. A slack wire is only supposed to follow the wax if it settles. The great trouble is giving it to swarms. When full sheets of foundation are given they sag at once before it is finished; that is the time when it is really more of a strain upon it than is natural with the comb, because bees build their combs entirely at the top before they lengthen them, but when you give them a full sheet they will load it from the bottom, and the top has a greater strain upon it, and I think nearly all the strain takes place from that. I think the wire ought to be taut, but in a great many cases it is not necessary at all if it is carefully done to wire.

#### SIZE OF COLONIES OF BEES IN SPRING.

"How much brood, honey and bees should there be in a hive in the time of fruit-bloom before putting on supers?"

Mr. Wilcox—I am confident that the answer to that will vary according to the locality somewhat. For my part I never put supers on during fruit-bloom. Then, the quantity of bees cuts no figure. If there is not surplus enough coming in our locality at that time to make a decent start, I always divide them, if they are strong enough to bear dividing without being weak colonies, when clover opens in the middle of June. Fruit-bloom is in the middle of May, and if there are two bushels of bees I would divide them; if there was one bushel I would divide them; if there were 10 pounds of live bees I would divide them and give the other half a young queen, but I would build them both up for the honey harvest the first of July or the latter part of June. Our best honey-yield comes in August, from wild flowers. Consequently I would be sure, anyway, to have more bees to gather more honey later in the season.

#### PREVENTION OF ROBBING DURING A HONEY-FLOW.

"What can be done to prevent bees from robbing in the honey-flow season?"

Mr. Hutchinson—You couldn't make them rob then.

Dr. Miller—They can rob. The way to stop them is to take away the fool bee-keeper that gets them to rob.

Pres. York—He ought to be clipped!

#### EXTRACTING FROM COMBS HAVING BROOD.

"Will extracting from combs containing unsealed brood injure the quality of the honey provided no brood is thrown out?"

Mr. Wilcox—No.

Mr. Burnett—A gentleman here has the idea with regard to that brood, that it has a tendency to sour the honey. If there is any such thing it is important. It may be one of those things that is an unknown quantity to us. We often find in a consignment of honey, there are one or two packages that will ferment, and the rest show no tendency to do so. As dealers, and finding so many instances of that kind, we are quite at a loss to know what is the cause of it.

Dr. Miller—I should say yes to that question; if you had obliged me to say yes or no just at first blush I should have said no, but thinking more carefully over it I should say yes, because if you put brood-frames—and by that we generally understand combs containing brood—into an extractor you most surely will have unripe honey in that, and when you throw unripe honey out you are likely to injure the quality of your honey, and that may account for the kind of honey that Mr. Burnett is talking about.

Mr. Wilcox—I think it is terrible to throw out unripe honey, but it does not follow just as he expressed it, surely.

Dr. Miller—Almost surely.

Mr. Dadant—I have had considerable experience in the matter of extracting honey. I must say, in the first place, it is not advisable to extract honey from combs containing young brood; and in the second place I believe Dr. Miller is right; if you do that you are extracting in the beginning of the season and you will have thin honey. If you extract at the end of the season from brood-combs that contain brood and sealed honey the brood will likely be sealed also. Therefore it is unlikely that the bee-keeper who wants good honey will extract from brood-combs containing unsealed honey. If it contains any he can throw it out without throwing any brood out. Those who are expert enough can make it in such a manner that it moved the larvæ a little forward when it was extracted and this larvæ could work back after the comb was taken back to the hive, or the bees would take them back, and yet none of them were thrown out. But you don't want a careless boy to turn the extractor, because a little too fast whirling will throw the brood out, and then you have a chance for fermentation. Although, I believe very ripe honey will not ferment even if it has brood in it. The ancients tell us they used to preserve bodies in honey, showing that honey will keep things from rotting. I believe that bees and larvæ will be preserved in the honey if the honey is ripe, but if the honey is unripe it will be sure to ferment, whether you have dead larvæ in it or not.

Mr. Wheeler—I have had a suspicion of that thing for quite a number of years, and the more I have watched it and studied it, the more I have made up my mind there is a great deal in it. You not only throw out the honey, but the food that is given to the bees, that sours the larvæ. One has to be very careful in extracting. Another point Mr. Dadant makes about the honey season being at a close; we don't have such a thing around Chicago where there is sweet clover; honey is gathered so that they can continue to breed and have young bees at all times. If you extract from those combs that have brood in you must have young larvæ. And then those young bees have a liquid; they are floating in a liquid. If that liquid is thrown out it is my impression it floats on top of the honey and it sours and gives the smell of sourness to the whole dish of honey. Yet I believe the honey down underneath is just as sweet as it ever was.

Mr. Wilcox—You don't believe that is thrown out without throwing out some brood?

Mr. Wheeler—That is immaterial. We do throw out the brood. I think you throw out some of that liquid when you don't throw out the brood.

(Continued next week.)

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food", written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey". It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy.

PRICES, prepaid—Sample copy for a two-cent stamp; 50 copies for 70 cts.; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Amerikanische Blenzucht**, by Hans Buschbauer, is a bee-keeper's handbook of 138 pages, which is just what our German friends will want. It is fully illustrated, and neatly bound in cloth. Price, postpaid, \$1.00; or with the American Bee Journal one year—both for \$1.75. Address all orders to this office.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Outdoor Suitable Work for Women

DEAR MISS WILSON:—As each week I read the interesting chats our "Sisters" give us, I most energetically want to "talk back," but, like Helen Keller, my hands being my only mode of communication, and they being otherwise pretty fully employed, I have been unable to do so. However, this special corner of June 22 is too attractive to let pass, so "here goes it."

In "Convention Proceedings" (page 439), Mrs. Wingate speaks of the Rural New Yorker's request for suggestions in regard to pin money for a "home-tied farm-girl 20 years old." I noticed that paragraph, and thought of suggesting bees, but it seemed foolish to do so, as any country girl should not need to be told the money-making abilities of either bees or poultry. A girl without sufficient observation, or "get there" resources, to carve out a lucrative line for herself in rural occupations, will not usually succeed in carrying out others' suggestions. In fact, I looked on the inquiry as manufactured to draw out unique, interesting and useful "pin money" opportunities.

Our country and farm girls are too bright and resourceful to need outside suggestions. But, of course, there are many ways to help "make the wheels go 'round" that a timely hint opens our eyes to, and which such answers as the Rural New Yorker's inquiry opened the flood-gates for, are most timely and helpful.

Again, Mrs. Wingate's comparison between our comfort in knowing our bees are safely housed, and to "don waterproof and rubbers, if they're handy, and if not march out without them, to chase some half-drowned chickens or turkeys that have been foolish enough to leave their mother's wing," is most killingly true. There is simply no comparison between the work of the two occupations, or the expense.

A friend of mine has made a careful estimate that it takes 1000 White Leghorns to support modestly two people. The initial expense of housing, feeding, etc., such a flock is a serious one. And the care! The same party says—and I think with truth—that there is no branch of farming, developed as a specialty, that so employs, at its utmost tension, every faculty the human body possesses, mental and physical.

As a rule, I think it's best not to put "all our eggs in one basket," or to depend for our income upon just one branch of "home industry;" but to keep some bees, and some poultry, and some small fruit, and make each the best of its kind possible. This gives a variety of interests, breaks the routine and drudgery, and insures every year a fair return and income.

Now concerning women managing bees alone, "I hae me doots" as to its being practicable for the "average American woman." And this because housekeeping, (which includes "Bar le Duc Preserves," and such like, I suppose, which seems to me a simply *awful* undertaking!), serving, social and church duties pretty well "tuckers them out," and they haven't much energy to lug around honey and manipulate bees. Of course, 5 or 10 colonies is a quite different matter, but take 20 to 40 colonies and there is considerable manipulating to be done, take the season 'round.

While I can manage 80 colonies for extracted honey with a helper, my hands are too weak to do really any very efficient work among the bees alone; so perhaps I am not a fair judge of the situation. At the same time it should be encouraging to invalid sisters to know that with the help of a small boy our returns are some years over \$800 from our bees, and this in a rather poor sec-

tion for flora, and where prices are low for honey—5 to 9 cents being our best.

Well, "We've got a swarm!" so good by all, and best wishes for "a big harvest for us all this summer."

FRANCES E. WHEELER.

PS.—Figuratively speaking (of course), I would like to "pat that brother on the back" who, on page 438, talks so sympathetically of the saving of weak colonies, and gives such useful, helpful advice.

F. E. W.

Misa Wheeler knows what she is talking about, as she keeps both bees and poultry, and her interesting way of talking about them makes one wish one could be clad in a cloak of invisibility and tag her around at her work to watch her for a day.

While bee-keeping has its rosy side, the darker side must not be supposed to go altogether with the chickens. If you keep enough bees there is many and many a time those same "rubbers and waterproof, if you have them handy," will be called into service; if not, you will have to get along without them. Even worse than working in rubbers, with the bees in no amiable temper, and crawling over you where you'd rather not have them—still worse, it is to have the weather so bad for a day or more at a time that you can't go near the bees, and yet you feel there's work that *must* be done, or things will get into such a snarl that you'll be swamped.

Fortunately, all tastes are not alike, and enough will be found of varying tastes to fill the different occupations. It would be bad if all the sisters should take to bees, and leave the biddies to take care of themselves.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### EXTRACTING SMALL QUANTITIES OF WAX.

I can bear witness that for neat and convenient extracting of small charges of wax a kink in the plan given by Robert West is excellent. Press all the refuse down with a perforated follower, and let the whole establishment get cold before removing the wax. Mine was a much smaller arrangement than his, and I used it very diligently and often. Not been used lately. Page 443.

### SAWING OFF THINGS WITH SWARMS.

Comrade J. Kimball, it seems, felt compelled to pull up an evergreen-tree to get the swarm clustered upon it. If he keeps on he'll yet be compelled to saw off the leg of a sleeping man for the same reason. Page 423.

### FEEDING BEES—SAGE FAILED TO BLOOM.

It appears that in famine time, in a mild climate, careful feeding of each colony individually saves practically all the colonies, while open-air feeding, much less work, still lets quite a percent of them perish—looking in fact like a case of not energy enough to get out and appropriate the feed. The demise of a thoroughly worthless colony may be considered as some gain as well as some loss; but a salve of that kind is hardly strong enough to cure the sore when the loss is 50 colonies out of 200. Think I should want to try a compromise system. Of course, the colonies that need least will get most; but with perfectly and easily movable frames all around it ought not to be a hard job to exchange a few frames between the feeble folk and the

### "Essence Honey"—Another Fraud

Karo Corn Syrup is not without a competitor as being better than honey. The writer received a circular laying before the public the discovery of "3 flavors that will gain you fame;" "their equals unknown to science." One of them attracted attention at once, being thus described:

"Far Ahead and Cheaper than Fresh Honey. ESSENCE HONEY. \$10 per gallon. Nothing like it in the world for candies, artificial honey, liquors, etc."

With visions of "fame" to be gained by the use of this wonderful discovery, as well as a fortune to be acquired by supplying the market with a superior article of honey, inquiry was made for full particulars as to how this "far ahead" honey was to be made. The reply was as follows:

"DEAR MADAM:—Take 80 percent glucose and 20 percent rock candy syrup; after mixing this then mix 2 ozs. Ess. Honey to every 100 lbs. Color with yellow to suit yourself."

There you have it, sisters. No longer any need to endure stings and hot suns. Make honey winter as well as summer. No failure of seasons. No danger of overstocking. No one who has ever had a good taste of glucose, with its lingering taste reminding one of an old brass spoon, would be willing to go back to the behind-the-times article got together by the bees!

In one respect the directions are a trifle vague: "Color with yellow to suit yourself." But that gives room for original experiment, and you can only tell what "suits yourself" by trying successively carrots, chrome yellow, aniline dyes, etc. There is a possibility of improvement also by varying the proportions of the ingredients. So large a portion of rock candy syrup (of course granulated sugar would not do at all) must have a weakening effect upon the delicious flavor of the glucose. Why not make it 99 percent glucose and 1 percent rock candy syrup?

bloated bondholders. Then, after a time (in the style of the Irish communist), "faith, and we'll divide agin."

And Mr. Dayton furnishes us another case of the ever-occurring unexpected, in that sage (never known to do so before) entirely failed to bloom last year. Queer. And yet a well-marked member of the numerous family that Mr. Queer, the cousin of Adam, has sent down to us. Page 422.

### QUEENLESS BEES PERSECUTING VIRGINS.

Doolittle also accuses queenless bees with persecuting caged young virgins. And bees with a queen he finds much inclined to the same trick. Avoid the whole thing as much as you well can. Page 421.

### PROF. EATON'S HONEY DEFINITIONS.

I think Prof. Eaton's honey definitions to be exceedingly good ones, and hardly have any suggestions to make. Page 419.

### KEEPING QUALITIES OF HONEY.

Glad to see we are getting to the truth about the behavior of honey when kept for considerable periods. The tiresome falsehood usually told in the past about honey "just as good as ever," shows signs of playing out. "Good riddance" to it! Page 419.

### RULES FOR BEE-ASSOCIATIONS.

I am not sure it would be advisable for us to adopt the Australian rules for our association; but I'm quite sure it will do us good to *consider* that men of the same race and

general objects as ourselves have found such rules advisable. Those whose interest in us is mainly in shearing us are sometimes favored too much—and also they might be proscribed too severely. Page 420.

#### THE "CLOISTERING HIVE" IN WINTER.

Mr. Dadant is right, that in our climate it is better to let winter bees fly when they can (and suffer real losses from chilling and snow-shine) rather than to try to restrain them of their liberty. Nevertheless the Cloistering Hive is interesting. It should do us some good to study up the ingenious devices of our fellow craftsmen of other lands. Giving bees air through perforated tubes darkened at the ends is a nice way. I'm not sure but some of our manipulations might borrow it. A lot of hollow weed-stems not quite large enough for bees to crawl through is also an ingenious air-supply when hives are to be closed in with cow-dung. Why cow-dung instead of mud? Mud, when perfectly dry, is a tolerably good bee-wall; but it reabsorbs water too easily. Every rain makes it wet. Cow-dung, when it does get dry once, resists water nearly as well as a board, and being lighter than a board, it holds more air, and is probably warmer.

Having such a nice arrangement for shutting bees in might very easily make the bee-keeper a hobbyist on that subject—be shutting them in at odd times all summer. And here's a question possibly profitable for our experts to butt their heads against: Would frequent shutting in through the summer get them so habituated to confinement that the winter's shutting in would do little or no harm? I'll venture the guess that most colonies (not all) could have their restlessness greatly mitigated that way—but not entirely cured probably. Page 405.

## Reports and Experiences

### Prospects Poor in Colorado

The first crop of alfalfa has been cut, and although bees are very strong not a pound of comb honey has been produced. Many bees are starving, and many are trying to rob those that are weak. It looks now as if the price of honey would solve itself, though I am sorry to see things in their present condition.

The weather has not been favorable for the secretion of nectar. It has been cool and quite windy, with very cold nights. Grass-hoppers are playing havoc with the sweet clover. I have but little hope now of a honey crop. W. S. BEVERLIN.

Delta Co., Colo., July 7.

### Good Yield from One Colony

I have 80 colonies of bees, 40 at one yard and 40 at another. I took 46 pounds in 13 days from one hive while it was rainy weather. I have doubled up my colonies now.

JOHN GERTHOFFER.

Onondaga Co., N. Y., July 21.

### A Peculiar Honey Season

The present honey season is in more than one respect a peculiar one. The copious rains during the first 3 months of the year produced an extraordinary growth of shrubs and bushes, at the same time causing great hopes for an unusually large honey-crop to spring up in the hearts of our bee-keepers. The honey-flow from black sage started in with full force, and in years there had not been seen such a glorious bloom of this wonderful honey-producing plant. Those bees that were in good condition (having been fed as late as March) profited well and carried in considerable honey, which, it must be said, was of rather thin quality. Unfortunately the weather was not very favorable—too cold, and dry fogs prevailing, and preventing the bees from making wax. Soon reports came, that in general the hives were honey-bound, that the bees were loafing, and it was rather

difficult to start them to working in the supers for comb honey. This state of things lasted all through the months of May and June, and thus it happened that not so much extracted honey, and still far less comb honey, was produced than might have been the case. The swarming-fever started in rather late, but when they began to swarm rather large swarms were cast off, and many an apiarist has more than doubled his number of colonies.

This month, up to date, we have had only 6 bright mornings; also a few rather hot days, the temperature running up as high as 100° F. When the black sage stopped blooming—which was sooner than expected—there was a lull for over 14 days, when the bees became rather cross and difficult to handle. White sage bloomed all right, though not so well as desirable. At present the bees are working hard on sumac.

We therefore might say that the present honey-crop, though by no means as large as anticipated, will still be above a medium average; that is, as far as extracted honey is concerned, while it will be far below half in comb honey. MAX BOELTE.

San Diego Co., Calif., July 17.

### Clover Crop Cut Short

I have 40 colonies of brown bees. It was so dry here during June that the white clover crop was cut short. Bees are at a standstill now. E. G. GUTHREY.

Saline Co., Mo., July 3.

### Splendid Work of One Colony

I started last spring with one colony of bees, it having wintered well, and in April I bought one colony of 3-banded Italian bees, which did well. It cast a swarm the forepart of May, and the swarm filled 10 Danzenbaker brood-frames and 28 sections, and the old colony filled 36, making 64 in all. This they did in about 4 weeks, when the honey-flow was cut short on account of dry weather. But the recent rains have brought white clover into bloom again, and bees are going to work on it once more. I use the Danzenbaker hive and sections. FRED W. MANEKE.

Madison Co., Ill., July 20.

### Rocky Mountain Bee-Plants and a Mint

I send samples of Rocky Mountain Bee-Plant (white and purple), also what I think is a species of mint. I would like to know what the name is. W. O. DARNELL.

Weld Co., Colo., July 8.

[We are glad to get samples of the Rocky Mountain Bee-Plant from its native home. The plant grows as far east as Illinois, but Prof. Cook, in "The Bee-Keepers' Guide," says it does not promise much for bee-keepers in the East. The other sample belongs to the Mint family, but has no common name except the ciliated *Blephilia*, which comes from the scientific name *Blephilia ciliata*. The whole mint family is famous for the fine-flavored honey which the bees get from it.—C. L. WALTON.]

### Odors of Queens

I think any one with experience will agree with A. C. Miller, page 453, in regard to the reception of an alien, whether a queen or not, but will not agree with him on the odor theory. Why will the bees cluster on a cage that a laying queen has been in, if there is no odor? Why will they sometimes ball her when she has been handled? Two different odors—one pleases, the other makes them angry. I think there are two sure indications that odor is one of the principal factors in introducing. Where hives set close together bees will intermingle, and I think nearly every one laden with honey, or a very young bee, will mix with other colonies unmolested.

If you walk into a strange boarding-house and put down \$10 for a week's board in ad-

vance, I think you would meet with as warm a reception as the little bee does with her pockets full, or the little infant that strays to the wrong door. They may have a full house, but will try to accommodate you somehow; it is so with the bee.

Give the queen plenty of time to acquire the scent of the hive, then let her in with as little disturbance as possible, is about the safest way. A. W. YATES.

Hartford Co., Conn., July 3.

### Short Season for Bees

Bees are doing fairly well now on white clover. The season will be short on account of excessive cold and rain.

C. R. BRIDGMAN.

Lafayette Co., Wis., July 15.

### Rains Injure the Honey Crop

We had an unusual amount of rain all winter and spring, and a good crop of blasted hopes in lieu of the big crop of mesquite and catclaw honey we were looking for. We generally get a second bloom of both in July, and hope to have it this season.

S. N. SALSBUURY.

Cochise Co., Ariz., July 15.

### Poor Weather for Honey Crop

We have had 5 days of good weather for bees to work (the last 5 days), and another good day to-day. Most of my colonies have 2 supers on. I have not taken off any honey to amount to anything yet. Cold nights and rainy weather have lost us 3 weeks of time. Our white clover has been a wonderful crop.

LISLE SCHNEIDER.

Delaware Co., Iowa, July 18.

### Prospects for a Good Honey Crop

Basswood is budding out nicely, and the fields and pastures are entirely covered with white clover bloom, so if the weather keeps favorable we will have a good honey crop. Heretofore it has been very unfavorable. It has been raining more or less nearly every day for the last 4 weeks.

C. O. BEROSTRAND.

Polk Co., Wis., July 3.

### Scarlet Sumac

What is the tree, a sample of which I enclose? It has clusters of blossoms from 3 to 6 inches across, and the berries are red and bitter when ripe. Is it a honey-tree?

NATHAN PULSIFER.

Aroostook Co., Maine, July 17.

[The tree or shrub is the Scarlet Sumac, *Rhus glabra*, the common name coming from the cluster of scarlet berries appearing in the late summer. All the sumacs are classed with the honey-producing plants.—C. L. WALTON.]

### Poor Yield from White Clover—Foul Brood

A good many bee-keepers are located along the Mississippi River bottoms. The principal sources of honey are clover, heartsease, and Spanish-needle. White clover has been very plentiful, but the weather has been too cold and wet for a good honey-flow, and the yield will hardly average 25 pounds of surplus comb honey per colony.

Foul brood has secured a good foothold here, many yards being badly affected before the owners were aware of its presence. It took about 125 colonies from me in 2 years—nearly all—but I have now built up to 116 colonies, all clean and doing nicely, thanks to State Inspector Smith, who visited us last year. Mr. Smith also called July 1. He found a great change for the better in my yard.

The next day I accompanied him, as pilot, and we visited nearly all the bee-keepers about Fulton and Albany. We found foul brood in every apiary but one. Some yards were in pretty bad condition, but their owners will try hard to head off the disease following Mr.

Smith's directions, and we hope to make this section of country once more a prosperous place to keep bees.

I have tried to do some work among the bee-keepers here, and while I find nearly all of them willing to try to stamp out the disease, I also find a few old-timers who don't believe there is any such disease, or they say, "It will all disappear when a good honey-flow comes; I don't believe it is contagious," and make no effort to prevent its spread. In fact, they leave old, diseased combs exposed, for the other bees to clean out. I found one old bee-keeper who would not let me look into a hive in his yard of 60 colonies; he said they were working all right, and that was all he cared for.

How I would like to see a law passed that would bring such men to time—teach them that this is not a country in which each one lives for himself alone.

The progressive bee-keepers must keep up the fight for a good law, and some time Illinois will be classed among the States having a good compulsory law.

Our outlook for a crop of fall honey is good.  
W. G. LAWRENCE.  
Whiteside Co., Ill., July 13.

### Light Honey Crop

The honey crop in this locality is only about half of what it was last year. The weather was too cold, and the clover season is about over. It is possible, but not probable, that we will get a light fall crop.

HENRY A. WYMAN.  
Kewaunee Co., Wis., July 17.

### White Honey Almost a Failure

I think the bee-keepers of this part of the State at least are suitable subjects for the "blasted hopes" column, as our white honey crop is nearly an entire failure, owing to the almost continuous rains and cloudy weather during the period of clover bloom.

Clover never promised better. There was a very rank, thick growth of it, and between showers it smelled very sweet, and bees worked lively on it, but for only a few hours or a day at a time, when they would be shut in by another rain, and consume a good part, no doubt, of what little they had just gathered. The result is that our supers are from partly-filled to empty. Those run for extracted honey did a little better, but not much.

There was a little basswood bloom, and bees got merely a taste from that. Now we hope our bees will get enough fall honey for winter stores, at least. We have had but little surplus from this source for several years, whereas usually we used to get much more dark than white honey.

In answer to Dr. Miller's request, I will say that several times I have set one colony over another with an excluder between, with good success.

In one of my upper extracting stories with an excluder below, we found an egg in a queen-cell at two different times, and there had been no brood reared from below where the queen was for a week or more. The eggs must have been brought up from below. Is this a common occurrence or very rare?

I have been wanting to get a crop of honey that would warrant me in attending the National Bee-keepers' Association, and thought when San Antonio was selected as the place for the next meeting, I must attend if possible, and meet face to face some of the veterans and larger honey-producers, most of whom I know only by their writings in the bee-papers. Also to look over some of the great State of Texas, which I hurriedly passed through 22 years ago.  
B. T. DAVENPORT.  
Green Lake Co., Wis., July 22.

### CONVENTION NOTICES.

National.—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these

facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Flint, Mich. W. Z. HUTCHINSON, Sec.

Missouri.—The Missouri State Bee Keepers' Association will meet in Sedalia, Aug. 22 and 23, opening session to be at 2:30 p.m., Aug. 22. The room to meet in will be named later on. The State Fair meeting there at the same time will obtain low railroad rates from all parts of the State. The Livestock Association also meeting there on the 24th will give us some inspiration. Hon. Geo. B. Ellis, Secretary of the Agricultural department, will be there and give a talk and lend a helping hand. Louis A. Osborn, of that place, has kindly offered to act as host, and will direct to the place of meeting and to accommodation. Hotel accommodations can be had at \$1 to \$2 a day. Private boarding cheaper. Let us turn out en masse and have a glorious time as well as to effect some extraordinary progress.  
W. T. CARY, Sec.

## Italian Queens by Return Mail

The STANDARD-BRED kind. Untested, 75 cents each; 3 for \$2.10; or 6 for \$4.00. They give satisfaction. Or the American Bee Journal for a year and a Queen for \$1.50. Here are some unsolicited testimonials from those who have had our Queens:

### What They Say of Our Queens

GEORGE W. YORK & Co

After importing queens for 15 years, you have sent me the best. She keeps 9 1/2 Langstroth frames fully occupied to date, and although I kept the hive well contracted, to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week.  
Ontario, Canada, July 22, 1905.

CHAS. MITCHELL.

GEORGE W. YORK & Co.

The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now and are doing good work.  
Nemaha Co., Kans., July 15, 1905.

A. W. SWAN.

GEORGE W. YORK & Co.

The queen I bought of you has proven a good one, and has given me some of my best colonies.  
Washington Co., Va., July 22, 1905.

N. P. COLESBY.

GEORGE W. YORK & Co.

The queen received of you a few days ago came through O. K., and I want to say she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee line.

E. E. McCORM.

Marion Co., Ill., July 13, 1905.

## An Untested Italian Queen-Bee FREE as a Premium

For Sending One New Subscriber

for the American Bee Journal for a year with \$1.00.

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

Address all orders to

GEORGE W. YORK & CO.

# Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

**GEORGE W. YORK & CO.**

# BEE=BOOKS

SENT POSTPAID BY

**GEORGE W. YORK & CO.,**  
CHICAGO, ILL

**Forty Years Among the Bees,** by Dr. C. C. Miller.—This book contains 328 pages, is bound in handsome cloth, with gold letters and design; it is printed on best book-paper, and illustrated with 112 beautiful original half-tone pictures, taken by Dr. Miller himself. It is unique in this regard. The first few pages are devoted to an interesting biographical sketch of Dr. Miller, telling how he happened to get into bee-keeping. Seventeen years ago he wrote a small book, called "A Year Among the Bees," but that little work has been out of print for a number of years. While some of the matter used in the former book is found in the new one, it all reads like a good new story of successful, bee-keeping by one of the masters, and shows in minutest detail just how Dr. Miller does things with bees. Price, \$1.00.

**Bee-Keeper's Guide, or Manual of the Apiary,** by Prof. A. J. Cook, of Pomona College, California. This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 544 pages. 295 illustrations. Bound in cloth. 19th thousand. Price, \$1.20.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.20.

**ABC of Bee-Culture,** by A. I. & E. R. Root.—A cyclopedia of over 500 pages, describing everything pertaining to the care of the honey-bees. Contains about 400 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

**Scientific Queen-Rearing, as Practically Applied,** by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00; in leatherette binding, 60 cents.

**Bees and Honey, or Management of an Apiary for Pleasure and Profit,** by Thomas G. Newman.—It is nicely illustrated, contains 160 pages. Price, in cloth, 75 cents; in paper, 50 cents.

**Advanced Bee-Culture, Its Methods and Management,** by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages; bound in paper, and illustrated. Price, 50 cents.

**Bienen-Kultur,** by Thomas G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

**Apiary Register,** by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00.

**Dr. Howard's Book on Foul Brood.**—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

**Winter Problem in Bee-Keeping,** by G. R. Pierce.—Result of 25 years' experience. Price, 30 cents.

## WANTED

500 Colonies of Bees to run on shares in Southwest Texas—that great honey country. Personal attention. **H. H. HYDE**  
3122 111 Fourth St., SAN ANTONIO, TEX.

# The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a long-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00.) We will club the Novelty Knife and the Bee Journal for one year, both for \$2.00.

**GEORGE W. YORK & CO.**

Chicago, Ill

Please allow about two weeks for your knife order to be filled.

## THE DEMAND FOR Moore's Strain of Italians

Is greater this season than ever. Why? Because his **FAMOUS LONG-TONGUED RED-CLOVER STOCK** has won a world-wide reputation for honey-gathering, hardiness, and gentleness. They were working so thick on a field of red clover at haying-time that the man who cut it was afraid to drive his horses into it to mow it. Their long tongues enable them to secure nectar beyond the reach of short-tongued bees.

Untested Queens, 75c each; six, \$4; dozen, \$7.50. Select Untested, \$1 each; six, \$5; dozen, \$9. Safe arrival and satisfaction guaranteed. Descriptive circular free.

Address, **J. P. MOORE,** Rt. 1, Morgan, Pendleton Co., Ky.

P. S.—I am now filling orders BY RETURN MAIL.

## Tennessee Queens

Owing to the great demand for my TENNESSEE QUEENS for several seasons, and the quantity of standing orders from old customers, I decided not to advertise until my books were cleared of orders, and thus avoid disappointing customers.

I am now ready to fill orders by RETURN MAIL. Breeders used: Imported dark leather-colored Italian; my selections from light imported Italian; Moore's long-tongue; golden; Carniolan (mated to Carniolan drones in distant yard, and to Italian drones); imported Caucasian (lately received, mated for the present to Carniolan and Italian drones).

Prices until Oct. 1.	After Oct. 1.	Tested—

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

**CHICAGO, July 18.**—Market is at a standstill, partly because of the time of year when little comb honey is consumed and partly to await the outcome of the present harvest. The weather is at present ideal and the flow of nectar makes the bees hum, that hum that puts smiles on the face of the husbandman though he be weary.  
**R. A. BURNETT & Co.**

**ALBANY, N.Y., July 26.**—There is some call for honey, new crop, and if here would probably sell for best prices of season, as the general impression is there will be a large crop. White comb honey will start off at 15c to early buyers.  
**H. R. WRIGHT.**

**KANSAS CITY, July 20.**—New comb honey has made its appearance; fancy white in 24-section cases selling at \$2.75 per case; No. 1 at \$2.50, and good demand. There is no new extracted in as yet, market on old stock being quotable at from 5¢ to 6¢. Beeswax, 25¢ to 28¢. **C. C. CLEMONS & Co.**

**PHILADELPHIA, July 19.**—The outlook for honey is very good. Some lots of new white honey have already arrived and are selling in a small way, according to grade, from 12¢ to 14¢. New extracted honey is selling: Fancy white, 6½¢ to 7¢; amber, 5½¢ to 6¢. Beeswax in good demand at 28¢.

We are producers of honey and do not handle on commission. **WM. A. SELSER.**

**CINCINNATI, July 10.**—We sold to-day at our store new crop of fancy comb honey at 13½¢ per pound. There is still a big stock of last season's honey on the market, that is going begging at any price. Extracted honey is moving quite lively now. We sell amber in barrels at 5½¢ to 6¢, according to quality. White clover at 7¢ to 8¢. Beeswax, 26¢.  
**THE FRED W. MUTH Co.**

**DENVER, June 26.**—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2 to \$2.20; No. 2, \$1.75 to \$2. White extracted, 6½¢ to 7½¢ per pound. Beeswax, 26¢.  
**THE COLO. HONEY-PRODUCERS' ASSN.**

**NEW YORK, June 19.**—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10¢ to 12c for lower

grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Extracted honey in fairly good demand. New crop California honey selling at 6½¢ to 7c for water-white, 6¢ to 6½c for white, and 5¢ to 5½c for light amber. Southern at 5¢ to 6c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29¢.  
**HILDRETH & SEBELKEN**

**CINCINNATI, O., July 17.**—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7¢ to 8c; amber, in barrels, at 5½¢ to 5¾c; in cans, 5¾¢ to 6c. Beeswax, 28c. **C. H. W. WEBER.**

**SAN FRANCISCO, July 19.**—White comb, 1-lb. sections, 11¢—cents; amber, 8¢ to 10c. Extracted, water-white, 5¢—cents; white, 4½¢—; light amber, 4¢—cents; amber, 3¢ to 3½c; dark amber, 2½¢—c. Beeswax, good to choice, light, 27¢ to 29c; dark, 25¢ to 26c.

There is now plenty of new honey of good quality on the market, but it is moving slowly and prices continue weak. Prices for all grades of both extracted and comb honey are ruling lower than last year, and even at the low prices there is a tendency for stock to accumulate.

## PURE BASSWOOD HONEY

IN 60-POUND CANS

We have a good supply of **Pure Basswood Honey** in 60-lb. cans that we can ship by return freight at these prices: 1 can in a box, at 8 cents a pound; 2 or more cans, boxed, at 7½ cents—all f.o.b. Chicago. Cash with order. Sample, by mail, 8 cents in stamps, to cover package and postage.

Address,  
**YORK HONEY AND BEE SUPPLY CO.**

141-143 Ontario St., CHICAGO, ILL.

## Do You Need Queens? By Return Mail?

It so, we can fill your order with the best Queens that money can buy. Try our strain of 3-band Italians; they will not disappoint you with empty supers. Untested Queens, 75 cents; \$8 per doz. Tested Queens, \$1 each. Send for circular. **J. W. K. SHAW & CO.**  
 13A4f LOREAUVILLE, Iberia Par., LA.

 Southwestern Bee Co., 438 W. Houston St., San Antonio, Tex.

# QUEENS

August is the time to requeen the apiary. It pays to have the best possible stock. Root's Red Clover Strain is famous the world over for its many points of excellence. A young, vigorous queen introduced now will bring the colony up to the best possible condition for wintering. Queens, too, now are the cheapest, and prompt delivery is made.

We are in an unequalled position to fill your queen orders. Having eleven apiaries, approximately 900 hives, with hundreds of Baby Nuclei, we are in condition to take care of all orders sent.

## Table of Prices

### Regular Italian Queens

Untested queens	75
Select untested queens	1 00
Tested queens	1 50
Select tested queens	2 50

### Red-Clover and Other Strains of Italian Queens Reared in the Root Co's Apiaries

Untested queen	\$1 00
Select untested queen	1 25
Tested queen	2 00
Select tested queen	3 00
Breeding queen	5 00
Select breeding queens	7 50
Extra select breeding queens, 1 year old	10 00

### Imported Queens

Fair imported queens	\$3 00
Best imported queens	5 00

### Caucasian Queens

We can spare a limited number of imported Caucasian queens, received direct from the best breeders in Caucasus. Prices as follows:

Extra select Caucasian imported queens	\$15 00
Select Caucasian imported queen	10 00
Extra select untested Caucasian-Italian queens, from Caucasian mothers mated with Italian drones	3 00
Select do	2 00

Orders filled in rotation. Delivery begins about July 15.

### Prices of Nuclei

One frame nucleus, without queen	\$2 00
Two-frame nucleus, without queen	3 00
Three-frame nucleus, without queen	3 50
One colony of bees in 8-frame Dovetailed hive, no queen	7 50

"I received my bees and queen and I am well pleased with them. The queen is a beauty, and the bees easy to handle. They were to work in ten minutes after I put them in the hive."—E. T. MILLS, Ills., May 15, 1905.

"I beg to acknowledge receipt of five fine queens, and, as they got here in good shape, beg to thank you for prompt and successful delivery. Without further advice, I am yours truly,  
"FREDERICO SOMERFORD, Cuba, June 13, 1905."

"I am pleased to say that the bees are doing fine. I find eggs in every available cell. I also found the queen, and it is entirely satisfactory."—W. H. DURST, Ohio, July 20, 1905.

Send for complete price-list

# CASES

Don't allow your comb honey to be sold at low prices on account of poor Shipping-Cases. Put your crop into Root's No-Drip Cases, and it will reach the market in perfect condition and bring the highest prices. Our cases are made of selected basswood, with 2 or 3 inch glass front, which shows off the honey to the best possible advantage. Below is a condensed price-list. Complete prices and particulars are found in our General Catalog. Write for it.

Shipping-Cases. Name and Size of Case.	Nailed each.			Price complete including 3-in. glass one side, nails and paper, in flat.	With 2 in glass instead of 3—per 100.	Without the glass, per 100.

### 5-Gallon Square Cans

These are the favorite packages for shipping Extracted Honey to the market. There can be no shrinkage and consequent leaking; no taint to the honey from wood, as is so frequently the case with kegs and barrels. The cans being square economize space, and are easily handled. This package is almost exclusively used in the West. They take 4th class freight-rate.

#### PRICE LIST OF SQUARE CANS.

"The consignment of bee-material received to-day. Your promptness in filling orders is remarkable, especially when the circumstances are considered. I am very well satisfied with the goods and your dealing. I take pleasure in having introduced Root's Goods into this neighborhood."—REV. WM. ENGELKE, Iowa, May 5, 1905.

"I do not want anything set up, as I would rather set the hives up myself, besides it is a pleasure to put Root's hives and fixtures together."—JOHN L. FUNK, Ohio, Jan. 11, 1905.

"I desire to thank you for being so prompt in sending the sections I ordered from you. They came in less time than it takes to tell it."—L. G. REED, Ohio, July 10, 1905.

## Editorial Notes and Comments

### A "Post" that Needs Posting

In the Denver Post the first week in July there appeared the following questions:

1. Is there such a thing as manufactured honey? If so, is it comb or extracted, and where can it be obtained?
2. Can eggs be manufactured?

The Post gave the following answers:

1. Yes. It is, both the comb and the extracted, and can be obtained from almost any grocer. A great percentage of the honey marketed now is of this class.
2. They can be and are.

Mr. R. R. Patterson, of Otero Co., Colo., sent us the newspaper clipping from the Denver Post, showing the above questions and answers.

As Manager of The Honey-Producers' League we wrote the editor of the Post, calling his attention to the honey misrepresentation, and requesting a correction, adding that we would be pleased to enroll the Denver Post in the list of newspapers that were helping to undo the wrong perpetrated on an honest industry by the starting of the manufactured-comb-honey libel some 25 years ago.

We have not had any reply to our letter to the Post's editor. If any Colorado bee-keepers have seen a correction of the quoted misrepresentations in the Post, we would be pleased to know it. Perhaps some Denver bee-keeper can enlighten us.

By the way, the poultry people ought to look after their "manufactured eggs" question and answer. We quoted it just to show what a lot of valuable information (?) the Post was giving its readers!

### Future of One-Piece Sections

Editor Root and Dr. Miller are at it again. This time it's a scrap as to the outcome of the growing scarcity of basswood lumber. Editor Root entertains the idea that as a result of that scarcity producers of section-honey will soon be driven to make a change to bulk honey or something else. The Doctor obstinately refuses to yield to such pessimistic views, and insists that he is not going to give up the production of section-honey, no matter how far skyward the price of basswood may soar. The following "stray straw" gives

the situation at latest accounts from the seat of war:

"At last we have the whole dread truth. After basswood lumber disappears it will cost 75 cents a thousand extra for 4-piece sections, page 701. Pshaw! If that's all, I'm not going to lie awake nights fearing that I'll have to give up the production of section honey."

To which Editor Root makes this comment:

"But, hold on, Doctor! When lumber advances labor will also advance somewhat. It is the experience of the Root Co. that our own labor has increased, and is still increasing in cost. Well, suppose we put the price \$1.00 per 1000 extra, you will have to add to that cost your own labor in putting the 4-piece sections together."

Clearly, Editor Root thinks 4-piece sections do not count. It's either 1-piece or no section honey. On the other hand, Dr. Miller will take "aid and comfort" from the fact that there are bee-keepers who used 4-piece sections before the 1-piece were known, and have never been willing to give up the 4-piece for the 1-piece. C. E. Woodward says in the last Bee-Keepers' Review:

"I have never yet seen a 1-piece section that I considered worth putting the foundation into. The 4-piece section, made from white poplar, is the only first-class section on the market."

### Injury to Queens in the Mails

Most of the queens sent by mail, fortunately, are untested queens that have only been laying a short time. These generally, not always, may be expected to do as good work as if they had taken no postal journey. On the other hand, there is much complaint that tested queens turn out poorly under the same circumstances, the purchase sometimes feeling that he has not been fairly dealt with to have a queen prove a poor layer after having paid an extra price. The following paragraph from the Bee-Keepers' Review emphasizes the matter. Recounting a visit to J. P. Moore, the Kentucky queen-breeder, the editor says:

"Among the things mentioned by Mr. Moore, one worth repeating is the injury that comes to tested queens from shipping them, or, to be more exact, perhaps, from checking their egg-laying so suddenly by taking them from full colonies when they are at the height of their egg-laying. He says that a young queen, that has just commenced to lay, stands shipment much better, and usually proves to

be of value as an egg-layer after shipment, while a tested queen often turns out very poorly. He says that a tested queen ought to be shipped in a full colony or a nucleus, to say the least. I have noticed the same thing myself. This year I have bought several tested queens of various breeders, and very few of them have turned out well. One laid worker-eggs for awhile, and then turned drone-layer. Another laid a little while, and then turned up missing. None of them have proved good, prolific layers. Young queens, of this year's rearing, sent as soon as they had commenced laying, turned out all right. Still further, I bought nearly a dozen full colonies having tested queens at least one year old, and some are probably older, and these queens, never having been out of their hives, are splendid layers. As Mr. Moore says, a choice tested queen ought to be shipped in a full colony or a nucleus."

It is no new suggestion that a sufficient reason for the different results in mailing tested and untested queens lies in the fact that a tested queen taken right in the midst of heavy laying carries a burden of eggs nearly equal to the weight of her own body, while an untested queen carries a lighter weight. Let a man with a bag on his shoulder, nearly equaling his own weight, attempt to stand in the middle of a moving, swaying railroad car, and he may judge something of the difficulty to be met by the heavily laden queen. If sent in a nucleus or a full colony, she has a more secure footing upon her native heath.

It is a question, however, whether, with the proper precautions, the tested queen may not be sent just as safely by mail as any other. If she be taken from the hive and kept in a cage for 24 hours or more before being shipped, her burden of eggs will be greatly reduced in weight. Surely she ought to travel more safely for the lightening. Most likely any queen would be a little better off to go in a nucleus or full colony, but in cases of long distance express charges are high, perhaps amounting to more than the damage accruing to the queen when sent by mail. Safe advice to the beginner would be to say:

When buying a tested queen, either have her sent in a full colony or nucleus, or else stipulate that she be kept out of the hive a day or more before being mailed.

### Size of Cells

It may be convenient to remember the figures 3, 4, and 5 as applying to the size of cells, that is, their diameters. The diameter of a queen-cell at the time when the egg is placed in it is such that 3 of them placed side by side measure an inch; 4 drone-cells measure an inch, and 5 worker-cells.

### A Queen Experience

We sent a very fine yellow, selected untested Italian queen to a bee-keeper in Woodbury Co., Iowa, on June 21, as a premium. Tuesday, the 25th, we received the following letter from him, dated June 24, and also the queen still alive:

GEORGE W. YORK & Co.

Dear Sirs:—The Italian queen you sent me arrived Saturday eve, but the wire was mashed in, and in bad shape, and the bees feeble, so I return you the queen by to-day's mail. You can send me another one; but I want a good one, and yellow one.

Yours truly,

We at once wrote him that he should have introduced the queen, and not have returned her, as she doubtless would have turned out all right. The wire on the cage was bent in just a little, but that was nothing worth mentioning. If the bees accompanying the queen seemed to be a little weak, that was no detriment, as some bee-keepers destroy the bees and cage that come with a queen, and introduce the queen in another cage. This is done

to prevent the possibility of also introducing a contagious bee-disease.

No queen-buyer is ever justified in returning a queen that is received *alive*, as queen-dealers only guarantee *safe delivery*, and then *satisfaction*, provided the purchaser does his part. Had the Iowa bee-keeper done his best to use the fine queen we sent him, and she had died in a day or two, or had not given promise of being all right, we would gladly have sent him another queen *free*. But to return a queen that arrived safely, just because the cage-wire was bent in a little, and the accompanying bees seemed to be weak (all as a result of going through the mails), is not the way to treat a queen-dealer or breeder. We have had sufficient experience in the queen-selling business to know that many of the complaints against queen dealers are wholly unwarranted. Of course, some complaints are entirely justifiable. But we know of a number of queen-dealers who would much rather give a customer a half dozen queens than not to treat him fairly. Queen-dealers have rights as well as do those who buy queens, and when both parties to a deal will act fairly there will be no occasion for complaints.

## Miscellaneous News Items

**Baron H. De Blonay**, a noted Swiss bee-keeper who was also a civil engineer, died June 9. He was the owner of the castle of which Mr. C. P. Dadant gave a description in the American Bee Journal on his return from Europe. De Blonay was a very democratic man, and did not boast of his ancestry, which dated back nearly 10 centuries. He always signed his name "H. De Blonay, Eng." He was quite a lover of the bees, and a member of the Societe Romande d'Apiculture.

**California Apiarian Experiment Station.**—We take the following item from the Kingsburg (Calif.) Recorder:

The United States Department of Agriculture has established a sub-station in the plant-introduction garden at Chico, for investigations in apiculture. An apiary has been established, and a specialty will be made of the testing of honey-plants to be secured by Frank Beaton, of the Department, who is now in India. Bee-diseases on the Pacific Coast will be investigated, and experiments will be made with the different varieties of bees, among them the giant bees of India, and the various specimens of the Philippines. The apiary and sub-station at Chico is in charge of John M. Raakin.

**Buy Your Own Paper.**—B. F. Schmidt, of Clayton Co., Iowa, sends us the following, and suggests that it might interest our readers. But we feel quite sure that very few, if any, of the readers of the American Bee Journal borrow it from their neighbors:

A man who was too economical to subscribe for his home paper, sent his little boy to borrow the copy taken by his neighbor. In his haste the boy ran over a \$4.00 colony of bees, and in 10 minutes looked like a warty summer squash. His cries reached his father, who ran to his assistance, and failing to notice a barbed-wire fence, ran into it, breaking it down, cutting a handful of flesh from his anatomy, and ruining a \$5.00 pair of pants. The cow took advantage of the gap in the fence, and got into the cornfield and killed herself eating green corn. Hearing the racket the wife ran and upset a 4-gallon churn of rich cream into a basket of kittens, drowning

the whole flock. In her hurry she dropped a \$25 set of false teeth. The baby, left alone, crawled through the spilled cream and into the parlor, ruining a \$20 carpet. During the excitement the oldest daughter ran away with the hired man, the dog broke up 11 sitting hens, and the calves got out and chewed the tails off of 4 fine shirts.—Corfu "Enterprise."

**J. H. Fitch**, of Taylor Co., Iowa, made this office a pleasant call last week. He is 72 years of age, and still takes a deep interest in bees.

**Wm. Duncan**, of Dupage Co., Ill., dropped in to see us last week. He is a banker, and says he has lots of fun with his bees, as well as considerable profit from their honey.

The Michigan Bee-Keepers' Association is advertising the honey crop of its members through the medium of a booklet. This booklet has a crop report, which gives the name and address of each member having honey for sale, how much he has (comb and extracted), and how put up. The booklet also contains information regarding honey as a food, care of honey, etc. They are to be distributed among the honey consumers, and large honey-buyers of the State and elsewhere. If funds will permit, other advertising will also be done outside of the booklet. The plan has been tried one year, and was successful enough to warrant a second attempt this season. The Association extends a hearty invitation to Michigan bee-keepers to join the Association, and also asks them to send their names and reports of their honey crop, and the way it is put up, before Aug. 12, with \$1.00, and they will then get the benefit of this year's advertising. The \$1.00 will also make each a member of the National Bee-Keepers' Association with its benefits. Every Michigan bee-keeper should *at once* send his (or her) name and address with \$1.00 to the acting secretary, Elmore M. Hunt, Bell Branch, Mich.

## "Combed" and "Extracted"

HONEY IN ANCIENT IRELAND.

There was no sugar, and honey was greatly valued; bee-hives were kept everywhere; and the management of bees was considered such an important industry that a special section of the Brehon Laws is devoted to it. The people used honey in a great many different ways. They basted roasted meat with it; it was used with salmon while cooking, and as a seasoning with all sorts of dishes. Often at meals each person had a little dish sometimes of silver, filled with honey, beside his plate and each morsel, whether meat, fish, or bread, was dipped into it before being conveyed to the mouth. The people often mixed honey with milk, either sweet or sour, for drinking. From honey also was made a kind of liquor called mead, very sweet and slightly intoxicating. This was considered a delicacy; and a visitor was often treated to a drink of mead immediately on arrival. As bees were so abundant, beeswax, as might be expected, was turned to account for lighting purposes. In some of our old records we find wax candles mentioned as being used in the houses of the richer classes (in Dinree for instance) long before the fifth century.—From Joyce's Child's History of Ireland, in the Irish Bee-Journal.

ACREAGE OF ALFALFA NECESSARY FOR 50 COLONIES.

How many acres of honey-plant are necessary to take care of 100 colonies of bees?"

This being an alfalfa district, I thought it would perhaps interest my fellow bee-keepers to state my experience this summer, as the above question has often put me to thinking regarding pasturage.

In partnership with my brother we had 79 colonies, spring count. The season was at least three or four weeks late, having cold nights accompanied with drizzling rains at intervals throughout May until the middle of June. By this time the alfalfa was starting to bloom, "scattering." There were very few stores in the hives, no brood-rearing to speak of, as we have no blossoms to mention until alfalfa comes on. On the 26th of June we had two swarms come out which we had to feed for a few days on account of a cold rain. After then we had fine weather, and the bees went to work with a will on the thousands of acres of alfalfa surrounding us, which had a purple cast by this time. By the middle of July all the alfalfa was cut except a little around ditches, etc., our own fields included, and everything seemed to be at a standstill in the apiary. Up to this time we had hived 48 swarms, making a total of 128 colonies. There being very little sweet clover in bloom we decided that the only surplus honey we should get would be gathered on our own farm; and having 30 acres or more of alfalfa, we knew we could control that amount of pasture, as other fields are generally cut when coming in bloom, making better hay. When the first cutting of alfalfa was all done we had only 19 colonies working in the supers. On the 5th of August we were putting on another round of supers, honey coming in galore. That 30-acre field was a sight to behold. From morning till night it was a constant uproar. We stood there many times and listened to the buzz overhead as they passed to and fro, it doing us more good to know that they had at last struck a land of plenty, and we the satisfaction of knowing that we can control to a certain extent our own pasture. That alone amounts to us to more than the loss in hay.

Though only a novice of a few years' experience in bee-keeping, my idea of success in that line, "to be master of the situation," is to control as much as possible our own pasture, and not depend on our neighbors being delayed in cutting their fields of bloom. We are not so fortunate as some bee-keepers where nature provides with plenty of moisture and a constant honey-flow throughout the season. A scarcity of water for irrigation means a scant honey crop; therefore, profiting by this year's experience with alfalfa we will try next year to regulate the bloom so as to have a paradise for the bees throughout the season.

I am satisfied that 1,000 acres of honey-plant isn't necessary to take care of 100 colonies of bees. We had 50 colonies that stored from three to six supers of honey, while the others fell below three supers.—Geo. J. Smith, of Colorado, in Gleanings in Bee-Culture.

## Contributed Special Articles

### Not More Colonies, But More from Each

BY GRANT STANLEY

THE question uppermost in the mind of many a bee-keeper is likely to be, How many colonies can I handle and make each colony turn out a good profit to the owner? There is scarcely any doubt, however, but that many bee-keepers are keeping more colonies than they can successfully handle, laboring under the impression that it is hives of bees rather than bees in a hive that is to bring ultimate success.

This article has no reference to the specialist or to the experienced bee-keeper who counts his colonies by the hundred, but rather to the majority of bee-keepers as we find them the country over.

Let us look at the farmer for instance. We know very well that there is scarcely a farmer that is large enough for his farm—he has so much land that he is “land poor,” so to speak; and if every farmer would put the manure and labor on 50 acres he now puts on 100 he would produce as much, while the reduction in taxes would be no small concern. If I mistake not, there are few farmers in Holland with more than 40 acres of land, and yet the best butter and cheese in the world is produced there. We can see from this that it is not so much in numbers as it is in making each number turn out the highest possible percentage of profit.

I am afraid too many bee-keepers are trying to over-reach in the increase of colonies instead of working to obtain the maximum result from the minimum number. It is not so much the number of colonies as it is in making each colony do its utmost in storing surplus. Any colony that does not store a high percentage after careful manipulation should be broken up, or change the queen. It surely does not pay to furnish hives, fixtures, and possibly labor, to run an apiary of 75 colonies when 50 can be made to secure the same profit. The “not how much but how well” principle will apply fully as well to bee-keeping as to any other line of business.

The queen may be from the most prolific strain in the world, and the hive simply a *ne plus ultra*, and yet without the constant attention on the part of the bee-keeper the highest results will not be reached. It must be the harmonious working of both bees and bee-keeper all along the line in order to bring all this about.

At present we hear a great deal about keeping more bees. If it refers to more bees in a hive, all right; but if it means more hives of bees, my views are somewhat different, and they are in tune with the highest principle of science—to obtain the best possible results from a minimum investment of capital.

Bee-keepers, above all others, have no time to sit at the corner grocery or post-office. If a few moments of leisure time manifest themselves he has perplexing questions which have so presented themselves that he needs to sit down and think them out. Remember, no business will run itself, and if we do not get behind it and shove it along it will not go. The more effort is put into any business the greater will be the success.

Lycoming Co., Pa.

### The Sense of Smell Among Bees—Some Experiments

Translated from “The Bulletin de la Societe Romande D’Apiculture”

BY C. P. DADANT

IN July, 1902, while sojourning a few weeks in the Cevennes, I was perusing some old journals found in the sitting-room of an inn, while I was seeking to kill time in a long, rainy day, and the following lines fell under my eyes. I found them in the “France Agricole and Horticole” for April, 1900, and the title was, “Ants Recognize One Another by the Smell.”

“The ants,” said this article, “recognize one another very readily. When an ant enters a colony which is not its own, it is almost immediately put to death. A German naturalist, Mr. Albrecht Bethe, of Strasburg, has sought to recog-

nize by which sense could be exercised so subtle a recognition, and has ascertained that it was a question of smell. Mr. Cook had already observed that if an ant touched water, it was infallibly attacked by its sisters at its return home, and he had concluded that the washing causes the ants to lose a special property enabling them to be recognized by one another. Then Mr. Forel (“The Ants of Switzerland,” page 263 and following) had confirmed this hypothesis, by showing that ants from different nests may be put together if previously their antennae, which are the olfactory organs, have been cut off.

“Adding to these considerations a new proof, Mr. Bethe crushed a few ants, and with the juice thus obtained he painted an ant which he then introduced into an ant’s nest. When the ant was perfumed with juice of ants from this same nest, it was well received; in the contrary case it was at once attacked.

“A larva, washed in alcohol at 35 degrees, then put back in its nest, was similarly attacked as a stranger. Put aside 24 hours before being returned to the nest it was on the contrary well received, that lapse of time having been sufficient to allow it to reproduce its family smell. It seems, therefore, most likely that in the phenomenon of recognition it is the sense of smell which is in action.”

These lines have impressed others besides myself, for I have found them reproduced in *L’Apiculteur*, of June, 1900, as well as in divers other agricultural or apicultural publications.

The thought has come to me, while reading them, that that which applies to ants is applicable to bees whose customs and instincts differ but little from those of the former. I therefore resolved to repeat with bees the experiments of Mr. Bethe as soon as I would return home. But time failed me, and the entire year passed before I could make the projected experiments.

Last year, in April, as I was classifying some notes, the above quoted lines came back to daylight and reminded me of my projects. I happened to have a few days of quietude, the season was propitious, and I decided at once to make a few trials.

All the experiments made upon ants by Messrs. Bethe and Forel, with the exception of that on cutting the antennae, repeated by myself upon bees, ended in the same results: they no longer recognized their sister taken away half a minute before, when she had been washed in diluted alcohol. They accepted without difficulty the drones and the workers of another hive than their own when they had been previously painted with juice from crushed drones from their own hive. A few larvae daubed with diluted alcohol were found thrown out a few minutes later. Returned the next day with their sisters, those bees that had been washed with diluted alcohol and had been held long enough away from the hive to permit this odor to evaporate, were again well received in their home.

In the presence of these facts of which several experiments giving constantly identical results evidenced the value, I was led to enquire whether bee-keepers could not take advantage of this to open their hives and handle their bees, by giving to their hands the odor of the hive which they want to examine. I conducted my experiments in this direction, and will give you further the obtained results which I copy almost literally from what I pompously call “My Apiary Journal.”

L. FORESTIER.

[To be continued.]

### Retailing Honey—Glucose, Etc.

BY F. STROHSCHNEIN

CONSIDERABLE has been said and written about educating retailers to care for honey properly, and there is some ground for it, too, as I shall presently show.

Some time after the early honey harvest two summers ago I entered a small country store, and at once spied a case of comb honey upon the counter. This, of course, interested me, so while the merchant was doing up the articles which I had ordered, I tried to raise the cover of the case. This was not an easy thing to do, for it was covered with other things, among which was a cigar-box full of tobacco. When I did raise the cover enough to get a peep inside I saw quite a good deal of tobacco among the sections. I saw that case for weeks with only a few of the sections removed, and it was no great wonder that the honey did not sell, for if consumers purchase honey with a tobacco flavor they haven’t much desire for more. If they did not see the tobacco they possibly had an

idea that the bees had gathered the honey from tobacco-plants.

I also saw in a store in a small city a case of honey which reminded me of a rugged, rolling country. It seemed to be up hill and down hill. The comb-surface was so uneven that it was very clear that the bee-keeper had used neither comb foundation starters nor separators. This honey retailed at 14 cents a pound, whether the price was higher or lower in the general market.

#### EATING GLUCOSE.

I have had some experience with glucose (Karo Corn Syrup). I have a delicate stomach, and certain articles of food produce a bad, slimy taste in my mouth the next morning after eating them. Glucose is among these articles, and up to the time of reading what Prof. Eaton has to say (page 710—1904) I supposed it was the acid, about which so much has been written, that produced these results. Now comes Prof. Eaton and upsets it all, saying that it is perfectly wholesome and contains no acid that is harmful. I have always supposed that pure glucose would be as easy to digest as honey. Yet if the commercial article is pure there is quite a difference, for honey has a beneficial influence on my stomach, while glucose produces opposite results.

#### HOFFMAN FRAMES WITH SQUARE EDGED END-BARS.

Several bee-keepers have expressed a preference for the Hoffman frames with a square instead of a V-shaped end-bar, and I must say that I agree with them, and the bees, too, for they will fill with propolis in the open space on each side caused by the V-shaped end-bar, making it square. In this way 10 times as much propolis holds the frames together as is possible with a square edge, and in separating these frames, and again in pushing them together, propolis gets between the edges and the spacing is increased to a certain extent, for frames need not be handled much, and they can not be gotten into a 10-frame hive unless the propolis is scraped off.

#### FASTENING FOUNDATION IN BROOD-FRAMES.

The method of fastening foundation with saw-kerf and wedge works beautifully with Dr. Miller, and yet after having tried both ways I find I can fasten starters or full sheets much quicker and more securely with melted wax. I say "more securely," for sometimes the saw-kerfs are not deep enough (or the wedges are too deep), when the wedges can not be driven in far enough, which leaves the foundation too loose, giving a lot of trouble by falling down.

My method is as follows: I get a piece of board  $\frac{1}{4}$  inch thick, 3 inches wide, and long enough to fit between the end-bars. One inch from one edge nail a strip one inch wide, and in thickness half of the top-bar less half of the thickness of the foundation. Hold this against the top-bar so that the strip will reach half across the underside of the top-bar, lay the starter against it, and fasten with melted wax. Thus fastened the starters will not fall down.

#### VALUE OF PROPOLIS AS A REMEDY.

L'Apiculteur advises bee-keepers to burn propolis on a stove to fill the room with a pleasant odor. I have often done this. But I know of a better use for propolis. For a swollen face, toothache, or other ailment, drop some propolis on a shovelful of hot coals, allowing the fumes to pass over the face, and its curative powers will soon be noticed. In Germany it was even used in this way to cure caked udders of cows.

The products of the hive are used far more as remedial agents in Germany than in the States. Little seems to be known as to where bees get their supply of propolis. In this locality they get their main supply from a sort of poplar-tree, or at least that is what I think it to be. The buds and short stems are full of this sticky glue, and propolis freshly gathered by the bees has the same odor as the glue on these trees, but after it has been for some time in the hive there is some difference in the odor.

#### IS CEDAR-WOOD MOTH-PROOF?

The honey-bees love the red-cedar trees because they know they are moth-proof. If one can afford to make cedar hives for his bees he will never be troubled with moths. So said Mr. C. S. Key before the Minnesota Horticulturists, when lecturing on the red cedar. I wonder if moths really will avoid cedar-wood. I do not think much would be gained by making hives of cedar-lumber, yet it might be of value for keeping brood and extracting combs secure from the moths. If any bee-keeper knows more about it I wish we might hear of it. I have also seen it stated that lice will not infest poultry if they roost on poles of cedar-wood.

#### WHY DO BEES IGNORE SOME FLOWERS AT TIMES?

Mr. D. W. Working (page 98—1904) tells of the prolificness of the Rocky Mountain bee-plant—*Cleome integrifolia*. One spring I got a package of its near relative, *Cleome pungens*, but none of the seed came up. Having some seed left it was again sown the next spring with the same results. To my surprise a single plant grew there last summer. It began to blossom the latter part of June and continued into September, and such a mass of bloom I never saw before. The discouraging part of it was that I never saw a honey-bee upon the blossoms, although a dozen or more bumble-bees were constantly swarming over it. I have also noticed this condition of affairs with golden-rod. Can any one give a reason why honey-bees will at certain times ignore the flowers of some plants though they are visited by bumble-bees, wasps, and other insects?

## Convention Proceedings

### Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904

(Continued from page 552.)

#### QUEENS KILLED WHEN INTRODUCING.

"I introduced a queen into a queenless colony and they killed her; four days afterwards I introduced another queen and they killed her. What should I have done?"

Mr. Wheeler—I would say, put healthy young bees into the hive to kill any drone-layers. They would prepare the way for the queen every time.

Mr. Swift—I had the crossset lot of bees I ever ran across in my life; I couldn't get the queen into that hive; I tried three different queens. I gave it up. I kept them supplied with young bees all the time.

Mr. Snell—The best way is to introduce two frames of young bees into the parent colony, and at the same time put their queen in with them, or introduce a queen at that time. Those bees seem to destroy the laying worker so that the queen is never molested. I have never yet had a failure in that way.

#### DETECTING ADULTERATION IN BEESWAX.

"How can we detect foreign substance in beeswax?"

Mr. Dittmer—I don't know that I can give any rule. It is force of habit with me. I get wax sometimes, and it looks suspicious, and there is generally something the matter with it. The most common thing that occurs with me is receiving wax that contains tallow. In fact, some people have shipped wax to me and were rather rash about it, so that I think almost anybody could have detected it; but as to giving any chemical process, I can't say anything about it.

Mr. Abbott—I see Dr. Wiley has written another letter to explain the matter with regard to what is called the "Wiley lie," published in the Rural New Yorker. I was writing an editorial note on it before I left, for the Modern Farmer, and I used a sentence at the last of it that these comb-foundation people will be interested in, and these bee-keepers. Dr. Wiley says that paraffin is used wholly or in part in comb-foundation in the United States. This statement came from Canada a short time ago, and now it is repeated by the chief chemist of the United States, and I say in my editorial there are only a few manufacturers of comb foundation in the United States. If they put paraffin in wax they know it, and we want to know it. If they don't do it, it will not be a very hard thing for them to prove it. If they do it, it will be a very easy thing for the United States chemists to prove. Now this subject of foundation is up, I think it would be a good time to hear from the comb-foundation makers right now as to what they have to say in answer to Dr. Wiley. I have had my say in the paper, and it will appear in the next issue, and I want to know if they put paraffin in foundation.

Mr. Dadant—I will give you three methods by which

you can all detect, without chemical analysis, whether comb foundation is pure or not, and you can test it with your own beeswax, comparatively. The first test we have is the **HEAT TEST**. It is the most delicate because you have to get the exact heat at the exact spot. Foundation is a little more brittle, a little more in pieces than solid beeswax. Therefore you will heat the foundation more readily than beeswax. A lump of beeswax that is round or large will not heat so readily through as sheet foundation full of holes. Therefore you must expect your foundation to melt a little more readily. Between 135 and 150 is the temperature, but your thermometers may vary a little. You take a piece of beeswax, tie it to the thermometer, take it to the right spot, put it in a pint bottle, put the stopper in it, put it on the stove, and see at what degree that thin beeswax melts. Do the same with the sheet foundation, and see whether it melts at the same or about the same temperature. Another test is the **SAAPONIFICATION TEST**. That is the changing of beeswax into soap; it will change to soap as grease will. It is no longer beeswax. Take lye and heat it, and take beeswax and melt it, and pour the two together and it will no longer be beeswax; if it is paraffin it will be paraffin. The paraffin will pour out just the same as before. The paraffin is a mineral substance which is not at all touched by lye, while beeswax is absolutely dissolved by lye.

The third test is **SPECIFIC GRAVITY**. Beeswax is heavier or lighter than other substances of the same kind. That is another very fine test, because if there is a little bulb of air in your specimen, whether beeswax or foundation, you will change the specific gravity. It is very difficult to make that test, but you can. A specimen that has a great deal of paraffin of one kind will flow where beeswax would go with the foundation. The way to do is this: Take water and put pure beeswax into it. Pour in alcohol until the beeswax goes to the bottom. The beeswax is then heavier than the solution which you have of water and alcohol. Then you are ready to test any samples that may come to you. In this particular it is the same thing as before. If your foundation is full of holes, when you put it under, the air will be in those and hold it up. You have to be very particular to have the wax from your foundation the same as your beeswax, if you want to make a proper test. If you have a sample of paraffin it will float, while the beeswax will go to the bottom.

Mr. Dittmer—It seems to me that the statement that Mr. Abbott has made, as to what Prof. Wiley said, puts the comb-foundation manufacturers in the position of being guilty unless they are proved innocent. It seems to me that is rather a poor predicament to find one's self in. Personally, I am perfectly satisfied that neither the Da-

dants nor the Roots use anything but what they know to be pure beeswax. So far as I am concerned, I think that my reputation with those who have used my foundation will carry me through. I think that the foundation manufacturers of this country have always had the reputation of using nothing but what they honestly knew to be pure beeswax; and as to taking the position of proving ourselves innocent, it seems to me that is the wrong position. We should be first proved guilty, and then give us a chance of saying something. But this idea of considering a man guilty until he proves himself innocent is wrong.

Dr. Miller—In Europe there are perhaps some 17,000 or more of the Rietsche presses in use; a large number of the bee-keepers making their own foundation. In this country I think there are not nearly so many bee-keepers making their own foundation as there were 25 years ago. I think the reason that so many of those Rietsche presses are used in Europe, and that the making of foundation has been simmered down to a small number of manufacturers, is that in Europe, they cannot buy pure foundation as we can here. I don't have any thought at all about the quality of foundation when I buy it; I know it is pure almost as absolutely as if I had given it all three of the tests mentioned by Mr. Dadant. I think Mr. Dittmer is entirely right in saying every man should be supposed to be innocent until proven guilty, and the burden of proof should not lie upon the manufacturer to prove that he is innocent. I think in the same way Wiley, if he has made that mistake again, should be taught to believe that he should not, after having made such a sad mistake before—that he should certainly not make the third mistake, or the bee-keepers of the country will resent it.

Mr. Abbott—Of course, you are just taking this on my say so, but I have the article and I suppose it is set up in type now and will be in the Modern Farmer in the next issue, and I cut it from the Rural New Yorker. This letter is addressed to the editor of that paper, and signed by Dr. Wiley. It seems the editor of the Rural New Yorker asked for an article with regard to the matter of adulterated honey, and Dr. Wiley is endeavoring to set himself right. It is in connection with the Ladies' Home Journal statement, and there is a whole column in it and the article closes up with the statement I refer to. Of course it was news to me. I thought I had been handling tons and tons of foundation that was pure, or, at least, I had been telling my customers it was pure, and I was standing behind it myself, and I had my reputation at stake and I wanted you people to know it as soon as possible. I thought I would send it to the American Bee Journal, but we like to get "a scoop," and I thought I would copy it first.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Marketing Comb Honey—Getting Bees Out of Supers

I started with 2 colonies of bees one year ago in nailed-up boxes. They stored a little honey and sent out 2 swarms. But this spring we sent for new hives and transferred them, making 7 colonies out of the 4. They are just doing fine; 6 have nearly filled the first supers. We will put on the second supers to-day. I am working for comb honey.

Where is a good place to ship such honey, and how should I prepare it for shipping? There are a good many bees kept around here, so our home market is more than supplied.

What is the best way to get bees out of full supers when taking them off the hive?

I will write again when we take off the full crop this fall. Mrs. ETTA BUTLER.

Iowa Co., Iowa.

Even if your home market is pretty well supplied there is a always a chance for competition, and if you put a superior article attractively prepared before the people you

may find a pretty good market for it at home, after all.

Still, if you wish to ship it, study the honey quotations in the American Bee Journal, and select from those nearest you. But remember there is a good deal of risk and trouble in shipping, and you will do well to take a lower price at home, making at least a difference of 2 cents a pound between home and distant market.

You can use the Porter escape, in the evening, placing the escape under the super you wish to remove, and by morning most of the bees will be down out of the super, which can then be removed. Or, you can place the supers in a room with screen-doors or windows, allowing the bees to collect on the screens, occasionally moving the screens to let the bees out.

At our house we like a quicker method, and

use the Miller tent-escape. We smoke the bees so they will run down somewhat before the supers are removed from the hive, then remove the supers, piling them up 10 or 12 high. If the piles are not so high of course the bees will come out quicker. Now we put on a Miller tent-escape and let the bees come out at their pleasure.

That you may know how to make a Miller tent-escape, the following is copied from Dr. Miller's "Forty Years Among the Bees:"

#### ROBBER-CLOTH.

I take a piece of stout cotton cloth (sheeting) large enough to cover a hive and hang down 4 inches or more at both sides and at each end. This must be weighted down at the side with lath, and for this purpose I take four pieces of lath about as long as the hive. I lay down one piece of lath with another piece on it, and one edge of the cloth between the two pieces of lath. I then nail the two together and clinch the nails. I use the other two pieces of lath for the opposite edge of the cloth. This makes a good robber-cloth just as it is, but it is better to have the ends also weighted down, especially on a windy day. For this purpose I make a hem in each end, and put in it shot, nails, pebbles, or something of the kind, stitching across the hem here and there so the weighting material will not all run together at one side or the other.

## QUICK COVERING WITH ROBBER-CLOTH.

In any case where one wants to cover up a hive quickly against robbers, as when opening and closing the same hive frequently for the sake of putting in or taking out combs, this robber cloth will be found a great convenience. No careful adjustment is needed, as in putting on a regular hive-cover, but one

away the three flaps of cloth all but about  $1\frac{1}{4}$  inches, and turn this  $1\frac{1}{4}$ -inch margin into the inside of the tent and sew there with heavy thread.

Another way is a little easier to do, and it is a little better, although a little harder to describe. Take a piece of wire-cloth  $22 \times 9\frac{1}{2}$  inches. Mark a point at the middle of one of the longer sides, and on the other side mark

this, also, that the queen was not lost. Queenless bees abandoning a hive which they do not consider home, would not cluster in a natural way, if I am right—might begin a cluster, but unlikely to form a complete and quiet one—most likely to throw themselves upon some other hive and try to enter, or, in case no other colony was by, to roam off in search of one. If any remains of their former home were to be found, they might go there and devote themselves to crawling helplessly around.

I should incline to say that the case in hand was a case of "swarming out," so-called. Queen stopped laying when the old colony was broken up. Probably had nearly stopped before by reason of short supplies. Hungry and discontented they felt still more discontented when the last brood was sealed. When there is little to eat, and nothing to do, a "hungry swarm," as they call it over in Europe, is quite in order. When put back they might be expected to stay for awhile. (Roosting in a tree-top did not strike them, on trying it, as improving the situation much.) And it transpired directly after that the honey-supply improved; and on that account they gratified their owner by flying out and in more. After all is said, however, I will grant the possibility of bees *long time* queenless forming a quiet cluster in a tree.

## TIME REQUIRED FOR SWARM-CLUSTERING.

When I first read Mr. Doolittle's article on how bees find their future home, I was taken a-back by the statement that a swarm clusters in from two to five minutes after coming out. Had it been some of our rank and file I should have smiled and said, He never actually timed bees with a watch, and his guess was quite a bit too small. But Mr. Doolittle rarely, if ever, lets things go with a mere wild guess. My first query was with myself. Does time seem longer to me just because a swarm is out? and have I been greatly overestimating? Well, swarms galore have been out this season, and (when not too much rushed) I have been timing them by the watch. I was not mistaken, so far as the strain of bees in my yard is concerned. They spend from 7 to 15 minutes on the wing.

Now the much more important question recurs, Do different strains of bees, and different yards, have different habits in this regard? If that's the case, it would explain some differences of opinion about certain other matters. Presumption favorable to the affirmative, to begin with. It's too late to ask for observations this season, but will not those who have the actual time of their bees please report? It's possible we shall find that different years differ. Quite possibly I *have had*, some time, a swarm come out and cluster in two minutes, but it is very, very rare if ever. The behavior of swarms in nearly all respects certainly takes a great range of variation. I think I wrote long ago that bees have forty different ways of swarming. Page 390.

## PUTTING WEAK COLONIES OVER STRONG ONES.

Edwin Bevis gives us, on page 452, a timely though small experiment—two weak colonies put over two strong ones without intending to unite. Total failure, so far as the object in view was concerned. Both queens of the weak colonies disappeared in ten days. The scheme is important enough to justify many more reports, small and large.

## BEE ODORS AND SENSE OF SMELL.

And so Arthur C. Miller must be getting after the bee's sense of smell as one of the old superstitions. All right. I'll hold his "bunnit" if somebody else doesn't get the job ahead of me. But until he *proves* something (as his first onslaught does not seem to), he must let us keep on using the familiar language about the bee's keenness of scent. Time enough to "go ahead" with new phrases when we are sure they are right. The dog (to an absolute certainty) recognizes his master by smell—and it's also certain that he has other means of recognizing him besides smell. Probability pretty strong that the same is the case with bees recognizing each other—also, that they are sometimes quite hateful to hivesmates when they do recognize

MILLER TENT-ESCAPE

can take hold of the lath with one hand, and with a single throw the hive is covered securely, with no killing of bees if any should happen to be in the way.

## MILLER TENT-ESCAPE.

Having made the robber-cloth, an escape, not in the shape of a cone, but in the shape of a pyramid, is fastened centrally upon it. Take three equilateral pieces of wire-cloth,

a point  $5\frac{1}{2}$  inches from each end, as shown in the figure. Make a fold at each of the dotted lines. The wire-cloth may be cut away at the two outside dotted lines, or, what is better, the end pieces may be folded over and sewed down. Now bring the two parts of the upper margin together and sew with wire, and then proceed to fasten the tent in place as before. In this latter case, of course, a hole must be cut at the top of the tent.

each of the three sides measuring 11 inches. Put them together in the form of a tent, sewing the edges together at the three sides by weaving fine wire through. At the top, however, let each of the pieces be folded out, so that a hole large enough to push your finger in will be left. Lay the tent centrally on the robber-cloth, and mark where the three corners of the tent come. Now starting at each of these points, cut the cloth to the center. Cut

When one of these tent-escapes is placed on a pile of supers, or on a hive containing bees, the bees will pass out freely at the top, but the bees that try to get in attempt to make the entrance farther down. Once in a great while there will gather a bunch of the outgoing bees at the top so as to clog the exit, and then the robbers will settle on this bunch of bees and work their way in, but a little smoke will scatter the bunch of bees.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

## PERHAPS A CASE OF SWARMING-OUT.

On page 377, a friend interested in bees, but quite uninformed about them, asks a long string of questions. The answer to the 10th one struck me as decidedly wrong—and being an appointed meddler, I meddle. The fact that the bees clustered and allowed themselves to be hived, although not *positive* evidence that they had a queen, seems to me a strong indication that they had. Bees in a hive which they consider home if they lose their queen just stray helplessly and hopelessly till they dwindle out by death, or by the inroads of moths and robbers. They do not swarm.

In a hive which they have not accepted as home yet, they are not likely to stay if the queen is lost—unless there is young brood to nurse, and rear a young queen from. With young brood and a strange hive I think it is a matter of some uncertainty whether they stay or not. If they choose to leave they can abandon the hive without doing it in exact swarming style. "Indiana's" bees had brood, and if indeed they were queenless they chose to stay.

Another thing. Bees eight days after losing their queen would have queen-cells, which they are unlikely to leave. I would infer from

them as such—and sometimes quite peaceful toward aliens when they recognize them to be aliens. To cite human parallels, the smell of the Negro is different from the smell of the Caucasian (for the Caucasian race has a dis-

tinctive smell); and the smell of the Chinaman differs from both. This shows that there is no ingrained absurdity about one little nation of bees differing slightly from another little nation. Page 453.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### A Swarm in a Chimney—Shade for Bees—Queenless Colony—Bee-Birds—Swarming—Taking Off Honey

1. How can I get a swarm of bees out of a chimney into a hive? Can I do so after they have started to build comb?
2. I have been told that all new swarms should be put in the shade and the old ones in the sun. Is this true?
3. If a colony is queenless will the bees rear a queen if given some brood?
4. How can I capture bee-killing birds?
5. When a swarm clusters and separates in two bunches upon the same limb, are there two or more queens?
6. How long before all the bees have left the super should a bee-escape be used?

IOWA.

ANSWERS.—1. It depends upon the particular conditions. Possibly all is within easy reach, so that you can easily get at the swarm and treat it just as if it was in a hive. If not, you can go at it in another way. Place a Porter bee-escape over the chimney, and over that a hive containing at least one frame of brood, the rest of the hive being filled with combs, frames of full foundation, or starters. The bees that come out, not being able to get back any farther, will settle in this hive, and at the end of 3 weeks you will have about all the bees, even if they have had comb and brood.

2. There is good reason for putting a newly-hived swarm in the shade, but I don't know why it isn't just as well to have an old colony also in the shade.

3. Yea, but it is much better to give them with the brood a sealed queen-cell.

4. Shoot them, then you can easily catch them. Perhaps, however, you might trap them, if you knew the kind of bait that would attract them.

5. Maybe, and maybe not.

6. The time varies. Sometimes the bees will be all out if the bee-escape is left on over night, and sometimes not. They are a help, but if you are in a big hurry they are too slow. That means escapes that allow bees to go down into the brood-chamber. The Miller escape, which is put on a pile of supers when they are taken from the hive, will be likely to leave the supers clear of bees if left on for half a day. For my own use I like these very much, but a man is likely to think well of his own baby. (See page 570.)

### White Flakes in Front of the Hive—Smoker Open at Both Ends

1. Last evening we had a telephone call to "bring a hive and take these pesky bees out of my grove." We did as we were told, and soon had the swarm transferred from the limb of a tree to a hive. I hived them on 2 drawn combs and 6 frames with full sheets of foundation, then set them in the apiary. Today noon we notice the ground is strewn with little particles of white flakes, and is fairly white in front of the hive. Of course I know they claim this is wax from the bees. I could fill three or four thimbles from what is on the ground, and there was a lot of it on the limb from which I took the bees. This has a tendency to cause me to believe wax is spittle. The bees certainly have a place to use it in those 6 frames of foundation, if it is wax.

Had the bees been put on a full set of drawn combs I should have thought nothing of it. This is the first time I ever saw so much of it.

2. Is there a smoker made that can be opened at each end? If we could open the breech end to relight when the fire goes out it would be lots handier than pulling out all the wadding from the top just to get a light into it.

IOWA.

ANSWERS.—1. You are right as to the similarity between wax and spittle, at least to that extent that both are secretions. But if you are hinting that the little white scales that you could pick up by the thimbleful are any other than beeswax, you will have trouble to establish your point. Even if that colony was wasteful, and didn't use all the wax that was secreted, that doesn't prove that it was not the genuine article. Haven't you seen a good many pellets of pollen dropped and wasted? But you didn't conclude from that that it was not good usable pollen. If you will make good use of Joe's eyes when bees are busy building comb, you can satisfy yourself pretty thoroughly that the little pear-shaped scales are nothing but pure wax, fresh from the bee-factory, when you see the bees bringing them into use, a scale sometimes being plainly seen stuck onto the progressing work.

2. So far as I know there is no smoker made that opens at both ends. I have had breech-loaders, but I don't believe you would like them. In general we want to pile fuel on the fire, not under it. But it would be an easy thing to have a smoker constructed so as to load at each end, and I've no doubt you could get one by paying a little extra. But it's so seldom that a smoker needs relighting, that it would be only a nuisance to have it open at the bottom. There's something wrong with the fuel, the smoker, or with Joe, that allows the fire to die out till it burns out, and I don't believe a double-ender is the proper solution of the difficulty.

### Bees Filling a Super—A Play Spell—Straight Combs—Storing for Winter

1. How long does it take a strong colony of bees to fill one super? I put one on July 6, and they started to work in it right away. It holds 24 sections.

2. What makes the bees gather and waste time by flying in front of the hive about a half hour every day? About a week ago I raised the hives an inch in front, but they still do it.

3. I used full foundation sheets in all my hives, and still the bees have not made straight combs, but have bound them together here and there. What causes this? How can I separate them so I can pull them out one by one? If done once, will they connect them again, or how can I hinder this?

3. Will the bees stop working in the supers of themselves in time to fill their frames below for winter? If not, what shall I do?

5. Some time ago I bought a large prime swarm and had to haul them 4 miles, but I did not give them air enough, and when I came home I had only one pint of bees left. I cleaned out 13 quarts of dead bees, and then introduced a queen to them July 4, which they accepted. Will they build up before winter, and get enough honey to take them through till next spring? WISCONSIN.

ANSWERS.—1. It may take all summer, and it may take 3 or 4 days. Either of these would be an extreme case. Perhaps 10 days to 2 weeks would be something like an average for filling and finishing; for it takes some time after being filled for the sealing to be finished. If the bees have abundance of room 2 weeks will be a pretty short time.

2. Bless your heart, you wouldn't grumble because children waste time playing, would you? Those bees are having a play spell, and raising the hive a foot wouldn't stop them. Don't worry, it's good for them.

3. Without seeing the case it's hard to answer; but if the work is properly done nothing of the kind should happen. I suspect just a little that you have put in the foundation without foundation splints or wiring, and that the foundation, being loose, has flopped about so as to touch in places. The foundation should be fastened securely in the middle of the frame, and then there would be no trouble. Carefully pull the frames apart, if necessary cutting apart the places that are fastened together; gently push toward the center of the frame any parts that are to one side, and when returning the frames don't have them just as they were, but turn every other one end for end. Then the same places will not come together as before; and after 4 days or more repeat the process if they are not yet all straight.

4. Yes, generally; but it is always well to have on hand some extra combs of sealed honey to give to any needy colony.

5. I don't know; they may if the season is remarkably good. The probability is that you will need to give them combs of honey or feed them otherwise.

### A Reporter and "The King Bee"

You will see the "king bee" mentioned in the accompanying clipping taken from the thrice-a-week World, of New York. I have been a bee-keeper since 1868, and as yet I can't say that I ever saw a "king bee," unless it is a drone; and if Mr. Fry was stung to death by a drone, don't you think they should have allowed him more space than a mere 1½-inch item in a newspaper?

Is it through my ignorance that I ask what is a "king-bee?"

I have been located here in Cuba with apiaries since 1899, and now have 4 apiaries.

CUBA.

ANSWER.—No, you never saw the king bee mentioned, for you never looked in the right place. This king bee had a ating that worked telescope fashion, and when opened out to its full extent was 1½ inches long. If you want to see him, don't go to looking through hives, but take a 2-inch auger and bore a hole through the skull of the reporter that wrote that item, and when you reach his brain there you will find that king bee in all his glory.

The newspaper item referred to reads as follows:

STUNG TO DEATH BY A KING BEE.

LOCKPORT, N. Y., June 19.—James T. Fry, a farmer, aged 83 years, succumbed this morning to injuries received in an encounter with a honey-bee. Fry was moving the bee-hives on his farm near this city last evening, and in so doing angered the honey-makers. A king bee attacked Fry and stung him several times in the face before Fry succeeded in killing it. He was chased to the house by a swarm of the indignant insects. Blood poisoning quickly developed in the wounds made by the king bee, and affected the heart, causing Fry's death within 12 hours.

### Swarming in Black Hives—Loaf Sugar for Bees—Starters in Sections

1. At the last bee-keepers' convention held in this city, a gentleman stated that if hives are painted black and set in shady places, the bees will not swarm. Have you tried this method with success?

2. Loaf sugar as a food for bees has been mentioned recently in the American Bee Journal, and was I think, tacitly commended by

Mr. Hasty. What are your objections, if any, to using it in winter in place of candy?

3. If one uses inch starters at the top of sections, do you think it advisable to place starters at the bottom of sections also?

CONNECTICUT.

ANSWERS.—1. No, I never tried it. If he meant that when a colony is set in the shade, the hive being painted black it will not make it swarm any more than being painted white, he was right; for when a hive is kept in the shade the black can not absorb the direct rays of the sun. If he meant that if you paint a hive black and set it in the shade, the colony in such a hive will never swarm, he was as wrong as wrong can be. A colony in the shade will not be as sure to swarm as if in the sun, but so far as black paint makes any difference, that difference will be in favor of swarming.

2. I never tried it, and don't know whether it would be as good or not. If there is any objection, it would be the danger that there might not be enough moisture for the bees to use the dry sugar. In most places that might not be an objection at all. But the safe thing would be to try it at first on a small scale.

3. The size of the top starter has nothing to do with the need of a bottom starter. The object of the bottom starter is to get the comb well fastened to the bottom-bar of the section, and this is needed just as much with a small as with a large top starter: if any difference, it is more needed.

## Reports and Experiences

### Bees Doing First-Rate

I bought 2 colonies, giving \$4 a colony for them last spring. I brought them home May 20, and have had 2 swarms which are doing well. The first swarm is filling the second super. If I can do as well for the bees when they need my help as they are doing for me now, I can talk to N. E. France.

W. M. MATTHEWS.

Grant Co., Wis., July 3.

### Good Price for Honey—Wintering Bees

I am the first one who kept bees in this county, and when I first began to talk about them some people thought I had a screw loose somewhere. I sent for 20 hives this spring for different people. I spent over \$100 before I got a live bee, but since we have a railroad here I am all right. I get as high as 50 cents per pound for my honey.

My first swarm issued May 21, and the bees are still swarming.

I winter the bees outdoors in winter-cases, and I can keep my bees out when the thermometer is 30 degrees below zero. I will write about my experiment later on.

Last week we had company who took my bee-hives for tombstones. They said they did not know that I had been living in a graveyard!

FRED HOFFMAN.

Fergus Co., Mont., June 28.

### Weather Hard on the Honey Crop

I had 6 colonies of bees, spring count, and increased to 16 this summer. All are in good condition, although the dry summer has killed all the white clover, and bees are doing nothing. They did very well in the fore part of the summer, but from all appearances I will have to feed if we should not have a fall honey-flow.

I have supers on all except 4 hives, and the bees have started to work in all of them. Some were very nearly full when the flow ended like magic. I took off about 100 pounds of pure white honey the beginning of June, and everybody says it was the nicest they ever saw. I retail my honey from the house at 15 and 20 cents a section, and have 2 grades by weight. We have had no rain of

any account all summer, or this would have been a bumper for honey.

I can not be without the American Bee Journal because I get all my information out of it, and it is a welcome visitor every week.

GEO. M. SEIFERT.

Northampton Co., Pa., July 28.

### Bees Not Doing Well

My bees are not doing very well this season. There seems to be no nectar in the white clover. One colony I have had for 4 years, from which a swarm has never yet issued, but it does the work.

W. H. HOBERT.

DeKalb Co., Mo., July 28.

### Discouraging Time with Bees

This year I have had the hardest fight I've had since I went into the bee-business. When the white clover came into bloom the rain during May destroyed the entire crop. Then came on the crimson clover, and met a similar fate, and dry weather in June got what little buckwheat there was. My bees seem to live "from hand to mouth" with nothing in the brood-chamber.

Time and again I've attempted feeding the weak colonies, placing the Boardman feeder inside and contracting the entrance to barely a bee-space, but robbers come "to beat the band."

My only salvation now is our fall flow of honey, though from my 50 colonies I do not expect to get a pound of surplus honey, because they are so awfully short of supplies. I hope no one else is having these things to contend with.

GEO. M. PHIFER.

Mecklenburg Co., N. C., July 10.

### White Honey Harvest a Failure

The white honey harvest is a failure here. There was much white clover bloom which yielded quite freely early, but failed to yield later. The weather was too cold, especially at night. To-day it is rainy and cool. I have taken only 20 or 25 supers of finished honey from about 70 colonies run for comb honey. Most of the hives now have on 2 supers each, and there are but very few finished sections to be found.

EDWARD BEVINS.

Decatur Co., Iowa, July 25.

### Doing Well With the Bees

I bought a 2-frame nucleus last year, which built up into a strong colony. In the spring of this year I put another hive on top of the one they are in, and now both hives are full of comb, with some honey at the top of each frame and the rest filled with brood. I expect to take 3 or 4 frames of brood from them to put into other hives. This is my first experience in such work, but I have "A B C of Bee Culture," and I think I will get along.

The bees have not swarmed this year. The king-birds are here every day. I often see them catch drones, and I think they have caught queens.

JOEL F. LEE.

McLean Co., Ill., July 5.

### Finding Queens

I seem to have made a little discovery in the matter of finding queens, that is worth reporting, as it enables us to find the queen in any old hive, whether combs can be lifted out or not, and in properly constructed hives it is much abbreviated.

If a box-hive is used make a hole, or two,

if preferred, say an inch auger-hole, (if there isn't one already) in the top and near the back part of the hive; then pour a good volume of smoke in at the entrance, keeping it up until the hive is pretty well filled. Very soon the bees begin pouring out at the hole, and in every instance that I have witnessed the queen was among the first.

In using the simplicity hive I slipped the enamel cloth forward so that about an inch at the back was uncovered. They poured out here and she was soon picked up with very little trouble and no harm whatever was done to the bees.

It might be a good plan to set the hive on an oilcloth, sheet, or the floor, if one is afraid the plan may not work successfully at first, then they would spread out over the back of the hive and on the cloth where she could be looked for. But with a little experience such precaution will be unnecessary. Remember, a good volume of smoke must be used, enough to start the bees at once on a stampede to get out.

DAVIS R. EMMONS.

Champaign Co., Ohio, Aug. 1.

### CONVENTION NOTICES.

**National.**—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Flint, Mich. W. Z. HUTCHINSON, Sec.

**Missouri.**—The Missouri State Bee-keepers' Association will meet in Sedalia, Aug. 22 and 23, opening session to be at 2:30 p.m., Aug. 22. The room to meet in will be named later on. The State Fair meeting there at the same time will obtain low railroad rates from all parts of the State. The Livestock Association also meeting there on the 24th will give us some inspiration. Hon. Geo. B. Ellis, Secretary of the Agricultural department, will be there and give a talk and lend a helping hand. Louis A. Osborn, of that place, has kindly offered to act as host, and will direct to the place of meeting and to accommodation. Hotel accommodations can be had at \$1 to \$2 a day. Private boarding cheaper. Let us turn out en masse and have a glorious time as well as to effect some extraordinary progress.

W. T. CARY, Sec.

### FOR SALE

My apiary, consisting of 98 colonies, 250 extra hives, 200 extra supers, and small supplies. Worth \$1,100; price, \$800. Good location.

# Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

## Italian Queens by Return Mail

The STANDARD-BRED kind. Untested, 75 cents each; 3 for \$2.10; or 6 for \$4.00. They give satisfaction. Or the American Bee Journal for a year and a Queen for \$1.50. Here are some unsolicited testimonials from those who have had our Queens:

### What They Say of Our Queens

GEORGE W. YORK & Co.

After importing queens for 15 years, you have sent me the best. She keeps 9 1/2 Langstroth frames fully occupied to date, and although I kept the hive well contracted, to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week.  
Ontario, Canada, July 22, 1905.

CHAS. MITCHELL.

GEORGE W. YORK & Co.

The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now and are doing good work.  
Nemaha Co., Kans., July 15, 1905.

A. W. SWAN.

GEORGE W. YORK & Co.

The queen I bought of you has proven a good one, and has given me some of my best colonies.  
Washington Co., Va., July 22, 1905.

N. P. OGLESBY.

GEORGE W. YORK & Co.

The queen received of you a few days ago came through O. K., and I want to say she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee line.  
Marion Co., Ill., July 13, 1905.

E. E. MCCOLM.

## An Untested Italian Queen-Bee FREE as a Premium

For Sending One New Subscriber

for the American Bee Journal for a year with \$1.00.

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

Address all orders to

GEORGE W. YORK & CO.

334 Dearborn Street, CHICAGO, ILL.

## ITALIAN QUEENS

EITHER GOLDEN OR HONEY QUEENS AFTER JULY 1.

Our Golden will come up with any other Golden strain. Our Honey-Queens are what some breeders call "Red Clover Queens."

# C. H. W. WEBER CINCINNATI OHIO

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

CHICAGO, Aug. 4.—Fancy white, 14c; No. 1, white, 13@13½c; fancy amber, 11@12c; No. 1, amber, 9@10c; fancy dark, 10c; No. 1, dark, 9c. White extracted, 6@7c; amber, 5@6c; dark, 5@5½c. Beeswax, 28c.

The new crop is appearing and selling in a fair way considering that this is midsummer time.

R. A. BURNETT & Co.

ALBANY, N. Y., July 26.—There is some call for honey, new crop, and if here would probably sell for best prices of season, as the general impression is there will be a large crop. White comb honey will start off at 15c to early buyers.

H. R. WRIGHT.

KANSAS CITY, July 20.—New comb honey has made its appearance; fancy white in 24-section cases selling at \$2.75 per case; No. 1 at \$2.50, and good demand. There is no new extracted in as yet, market on old stock being quotable at from 5@6c. Beeswax, 25@28c. C. C. LEMONS & Co.

PHILADELPHIA, July 19.—The outlook for honey is very good. Some lots of new white honey have already arrived and are selling in a small way, according to grade, from 12@14c. New extracted honey is selling: Fancy white, 6½@7c; amber, 5¼@6¼c. Beeswax in good demand at 28c.

We are producers of honey and do not handle on commission.

WM. A. SELSER.

CINCINNATI, Aug. 2.—At this writing there is a good demand for extracted honey; shipments are arriving daily. New comb honey is coming in quite freely, although the demand is only fair, a condition which may be expected early in the season. We quote amber extracted in barrels and cans at 5¼@6½ cents respectively. White clover extracted at 7@8½c. Fancy white comb at 12@15c. Beeswax, 26c.

THE FRED W. MUTH Co.

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2.20; No. 2, \$1.75@2. White extracted, 6½@7½c per pound. Beeswax, 26c.

THE COLO. HONEY-PRODUCERS' ASSN.

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower

grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Extracted honey in fairly good demand. New crop California honey selling at 6¼@7c for water-white, 6@6½c for white, and 5@5½c for light amber. Southern at 50@60c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29c.

HILDRETH & SROELKEN

CINCINNATI, O., July 17.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5¼@5½c; in cans, 5¼@6c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, July 19.—White comb, 1-lb. sections, 11@—cents; amber, 8@10c. Extracted, water-white, 5@—cents; white, 4¾@—; light amber, 4@—cents; amber, 3@3½c; dark amber, 2¾@—c. Beeswax, good to choice, light, 27@29c; dark, 25@26c.

There is now plenty of new honey of good quality on the market, but it is moving slowly and prices continue weak. Prices for all grades of both extracted and comb honey are ruling lower than last year, and even at the low prices there is a tendency for stock to accumulate.

## PURE BASSWOOD HONEY

IN 60-POUND CANS

We have a good supply of Pure Basswood Honey in 60-lb. cans that we can ship by return freight at these prices: 1 can in a box, at 8 cents a pound; 2 or more cans, boxed, at 7½ cents—all f.o.b. Chicago. Cash with order. Sample, by mail, 8 cents in stamps, to cover package and postage.

Address,

## YORK HONEY AND BEE CO.

141-143 Ontario St., CHICAGO, ILL.

## Do You Need Queens? By Return Mail?

If so, we can fill your order with the best Queens that money can buy. Try our strain of 3-band Italians; they will not disappoint you with empty supers. Untested Queens, 75 cents; 88 per doz. Tested Queens, \$1 each. Send for circular.

**J. W. K. SHAW & CO.**

13Atf LOREAUVILLE, Iberia Par., LA.

# WHEN YOU SEND FOR A DOCTOR

**Y**OU get the best you can find, don't you? You would rather spend a thousand dollars this side of the grave than a hundred in funeral expenses. You do not stop to consider the cost. The finest physician, the one best adapted to your needs, is the one you are going to have. So it is with **BEE-SUPPLIES**. A little more money expended on **LEWIS' GOODS** in the beginning will save you double the amount in the end.

**LEWIS' GOODS** are worth every cent they cost, and whether you receive them in

the dead of winter or at the height of the honey-flow, or when your bees are swarming, they will fit accurately, admit of being put together quickly, and will be found to be made of the finest material. This saves you time; this saves you trouble; this saves you honey, and time, trouble and honey mean money to you. Your honey put up in good shape will bring higher prices, and the demand for it will be increased from year to year. This factory's reliable goods have started many a man on the road to success.

ESTABLISHED IN 1861 THE AMERICAN OLDEST BEE-PAPER IN AMERICA

# BEE JOURNAL

WEEKLY—\$1.00 A YEAR

Published by GEORGE W. YORK & CO., 334 Dearborn Street

45th Year

CHICAGO, ILL., AUGUST 17, 1905

No. 33

APIARIAN EXHIBIT AT THE WEST MICHIGAN STATE FAIR, HELD AT GRAND RAPIDS, IN 1904  
(See page 582)

PUBLISHED WEEKLY BY  
**GEORGE W. YORK & COMPANY**  
 334 Dearborn Street, Chicago, Ill.

**IMPORTANT NOTICES**

THE SUBSCRIPTION PRICE of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

THE WRAPPER-LABEL DATE indicates the end of the month to which your subscription is paid. For instance, "dec 15" on your label shows that it is paid to the end of December, 1904.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows that the money has been received and credited.

ADVERTISING RATES will be given upon application.

**National Bee-Keepers' Association**  
 Objects of the Association

- 1st.—To promote the interests of its members.
- 2d.—To protect and defend its members in their lawful rights.
- 3d.—To enforce laws against the adulteration of honey.

Annual Membership Dues, \$1.00  
 General Manager and Treasurer—  
 N. E. FRANCE, Platteville, Wis.

If more convenient, Dues may be sent to the publishers of the American Bee Journal.

**The Honey-Producers' League**  
 (INCORPORATED)

**OBJECTS:**

- 1. To create a larger demand for honey through advertising.
- 2. To publish facts about honey, and counteract misrepresentations of the same.

**MEMBERSHIP DUES**

- 1. Any bee-keeper may become a member by paying to the Manager an annual fee of \$1.00 for each 20 (or fraction of 20) colonies of bees (spring count) he owns or operates.
  - 2. Any honey-dealer, bee-supply dealer, bee-supply manufacturer, bee-paper publisher, or any other firm or individual, may become a member on the annual payment of a fee of \$10, increased by one-fifth of one (1) percent of his or its capital used in the allied interests of bee-keeping.
- GEORGE W. YORK, Manager,  
 334 Dearborn St., CHICAGO, ILL.

**Italian Queen-Bee Free as a Premium**

To a subscriber whose own subscription to the American Bee Journal is paid at least to the end of 1905, we will give an untested Italian queen for sending us ONE NEW subscription with \$1.00 for the Bee Journal a year. Now is the time to get new subscribers. If you wish extra copies of the Bee Journal for use as samples, let us know how many you want and we will mail them to you. Address all orders to the office of the American Bee Journal.

**HONEY-JARS.**

For a limited time we offer No. 25 Honey-Jars, porcelain cover, metal screw cap, holding one pound of honey net, one gross in case complete in 5-gross lots, \$4.00 per gross; less quantities, \$4.50 per gross, f.o.b. New York. If you want to secure some, let us know at once.

**HILDRETH & SEGELKEN,**

# What is the United States Government Doing for the Bee-Keeper?

A Corner of the Government Apiary where the Caucasian and Carniolan Colonies Stand.  
Photographed by D. E. Lyon.

## Do You Know?

Do you realize to just what extent Uncle Sam has the interest of his bee-keepers at heart? Few do. To get the whole truth we have sent Mr. D. E. Lyon to Washington with instructions to place before the readers of *Gleanings* just what is being and what intends to be done by the Division of Apiculture of our great National Department of Agriculture at Washington. Mr. Lyon gives the results of his journey in the August 15th number of *Gleanings*. What he tells is intensely interesting, and every bee-keeper should know the facts. Mr. Lyon has also obtained some splendid photos, which are reproduced in this number.

Mr. Frank Benton, head of the Division of Apiculture, is now on a journey around the world in search of new Bees and Honey-Plants. *Gleanings* keeps in close touch with him, and its readers are always sure of obtaining news first hand of this most remarkable trip.

### Grading Rules

In the August 15th issue of *Gleanings* is found another article of greatest practical value to bee-keepers. It is headed, "Comb Honey Grading Rules." Hardly one bee-keeper in ten understands grading, which is of such importance in marketing comb honey. For this reason there is much confusion and loss. *Gleanings* has written to the most prominent Honey Dealers all over the United States, and gives their replies in this number. It's an important thing to know how to grade your honey, and *Gleanings* tells you.

### Superb Illustrations

The illustrations in the August 15th issue of *Gleanings* are typical of what its readers receive every number. Three full-page halftones, some smaller ones, and many line draw-

ings illustrating the numerous short articles. The halftones are the work of the finest engravers in the United States, and are printed on the best paper, giving results that are hardly equaled in many high-class magazines. This item alone doubles the value.

### Bee-Keepers Everywhere

*Gleanings* aims to make itself indispensable to every bee-keeper everywhere. It has succeeded. No progressive bee-keeper can afford to be without it. In every issue are departments that cover the peculiar conditions that are met in different parts of the country. The editors of these departments are the best practical bee-keepers in their respective localities. The best of bee-keepers everywhere contribute. A list of them would be a list of the most successful bee-keepers in the United States. What bee-keeper can not profit by reading the experiences of such men?

## Editorial Notes and Comments

### The Honey Crop of 1905

Editor Root gives the following paragraphs on the honey crop conditions, in Gleanings in Bee Culture for Aug. 1:

Although the reports have not come in as freely as I could desire, yet, taking all sources of information, including such reports as we have received, I am not far from the truth when I say the crop has been a light one, taking the United States as a whole, and an entire failure in many localities. The conditions in California and Texas are not materially different from those already reported. In the southeastern part of the United States, particularly in North Carolina, the season has been almost a failure. Apparently Michigan, Wisconsin, possibly Minnesota, northern Illinois, and Ontario, Canada, will have a fair crop of honey. The prospects were dubious two or three weeks ago, when there was a change for the better. New York and Pennsylvania report all the way from a fair to a poor season. New England seems to be in the doubtful list yet. Colorado will be very much behind its general average; and this is particularly so for the Western Slope.

.....Those who are located in the clover belt, where there is still considerable white clover in bloom, as well as pea-vine and common red, will do well to look to their bees and see what they are doing. Do not give up yet. You may get a fair crop of honey. The recent rains, which appear to be general, came just as it was beginning to get a little dry. Queer season this.

An old and experienced honey-dealer once said, "There is always enough honey somewhere to supply the demand." If you can get a fair price for your honey better not hold it, but sell, as later on it may turn out to be like last season—many held their honey, and then a lot was dumped on the market all at once, which caused the price to drop away down.

### Mating and Swarming of Virgins

Do bees sometimes swarm out with the only queen they have, leaving the colony hopelessly queenless? Does the colony, or part of it, generally, or sometimes, go out with the virgin queen when she goes out to mate? Not a few have answered both these questions in the affirmative. Mr. Muth-Rasmussen is quoted by Mr. Doolittle, in Gleanings, as saying that when a queen is lost in any way, and the bees rear a successor from her brood,

"when the virgin queen flies out to mate, the bees will swarm out with her and will settle on a tree or bush, like a normal swarm." Mr. Doolittle never knew of any swarm going with a virgin queen without a rival queen being left in the hive, said rival being generally confined in a queen-cell, and says:

"So far as my experience goes, a swarm goes out with a virgin queen only when there are rival queens left in the hive in the shape of other virgin queens in queen-cells, and when all but the last virgin have gone out with swarms, or been disposed of by the bees or by the queen that is at liberty in the hive; then, a few days later, this remaining queen goes out to meet the drone alone, with none of her bees accompanying her, is fertilized, and soon becomes mother of the colony."

Opinions on both sides are likely to be forthcoming, and it will be interesting to note the outcome. It will be a good thing if there can be a positive decision, unless, indeed, it happens that bees in California are not governed by the same laws in such cases as are those in New York.

### Sainfoin as a Honey-Plant

This plant, *Onobrychis sativa*, continues to loom large in Canada. The question arises, Why is so little said about it further south? "A York County Bee-Keeper," in the Canadian Bee Journal, makes a point in its favor which gives it distinct value; it differs from other clovers in that it appears to yield nectar early in the morning, the bees working on it fully an hour before they do on alsike and white clover. Also, that the first bloom comes between fruit-bloom and white clover, and the second crop when there is a dearth from other sources.

John Fixter, apiarist of Central Experimental Farm, who has done much to bring this plant into prominence, sends the following to the Canadian Bee Journal:

I am so pleased with the results of our sainfoin test that I feel it a duty to bring it again to the notice of our friends. The small field sown in the spring of 1904 was sown on poor, sandy soil, and therefore did not do very well the first season, it did not even bloom. Not being discouraged, we allowed it to stand over. Since spring it has made fairly good growth, coming into bloom June 9—white

clover bloomed June 14, and very little out at that date. Bees are working so well on the sainfoin that a bee-keeper standing in the center of the field would be looking where the swarm was—every plant has a bee on it. We can not do too much by way of bringing this wonderful plant before the notice of our friends. It is not only a honey-producer, but makes such excellent fodder, and will produce honey each time it blooms.

### Colonizing Bumble-Bees

Speaking of the relentless war that has been waged on most farms against bumble-bees up to a few years ago, because of the difficulty of harvesting hay with several bumble-bees' nests in the field, a writer in the Farmers' Review says:

"Now, we are coming to see that we have done a foolish thing in exterminating these insects, upon which depends the entire crop of red clover seed. Doubtless they can be colonized, and their habitations fixed at a distance from the fields that have to be cut over."

So far as reported, all attempts in the past to colonize bumble-bees have been unsuccessful, and it is doubtful that much can be done in that direction in the future. Their habits are quite unlike those of the hive-bee. A single female or queen starts out in business in the spring, all by herself. Some of her progeny come to her aid, but a nest of bumble-bees remains always a diminutive affair compared with the thousands in a hive of our honey-bees. There are no combs made of wax, larvae and honey alike being contained in cups formed in the pollen-mass, so movable combs are not likely to be viewed by them with favor. The same writer says:

"At this time of year they would be hard to get, as the broods hatch out later, but it is the second crop of clover that produces the seed and not the first, and that is the crop that is fertilized by the new broods of bees."

That's a little like saying that the moon is more useful than the sun, for the moon shines at night when it is dark, and the sun shines only in the daylight. To be sure, the bumble-bee is needed to fertilize the blossoms of the second crop of red clover, but many farmers seem to think there is something in the nature of the plant that makes it willing or able to produce seed only on the second crop. If bumble-bees were present in sufficient number to fertilize the blossoms of the first crop, why should it not produce seed as well as the second?

## Miscellaneous News Items

Pres. Jas. U. Harris, of the National Bee-Keepers' Association, surprised us with a call last week, when on the way to his Colorado home from eastern Pennsylvania, where he had been attending the funeral of his aged mother. Mr. Harris was looking very well. He has an apiary of nearly 100 colonies in Mesa Co., Colo., but reports the honey crop almost a failure in his locality, and exceedingly small for all of Colorado.

N. E. France, State Inspector of Apiaries for Wisconsin, reports that he has the bee-diseases nearly wiped out of that State. He says that a few bee-keepers have been careless, and so have not cured every case. Of course, it is necessary that bee-keepers cooperate fully with the inspector, else no disease can be completely eradicated. Mr. France certainly has done a good work in Wisconsin, and deserves the thanks of all its bee-keepers.

A Bee-Keepers' Field-Meeting will be held at The A. I. Root Co.'s exhibition apiary at Jenkintown, Pa., Thursday, Sept. 7, 1905, in which will unite the Pennsylvania State Bee-Keepers' Association, New Jersey State Bee-Keepers' Association, Philadelphia Bee-Keepers' Association, New York bee-keepers, and all bee-keepers and others interested in bees, from the surrounding territory. Jenkintown is a suburb of Philadelphia. If bee-keepers in that locality desire further information, they can address Wm. A. Selser, Jenkintown, Pa.

The West Michigan Fair Apiarian Exhibit of 1904 is shown on the first page. Beginning at the left of the picture the exhibits belong to: Mrs. C. I. Smith, of Grand Traverse Co.; Oscar Smith, of Kent Co.; W. D. Soper, of Jackson Co.; and A. G. Woodman Co., of Kent Co.

In order to get a picture of all the exhibits the plan of the exhibit of A. G. Woodman Co. is not fully shown. Comb honey was piled up in the form of a house, with comb foundation for the roof, pyramids of beeswax for spires, full sheets of foundation in sections for window-sashes and window-panes, etc. A neat little sign over the door bore the words: "Home, Sweet Home."

All the exhibits were very nicely arranged, as can plainly be seen.

The premium awards were well distributed, all exhibitors winning some of the money, so doubtless all were well satisfied. W. Z. Hutchinson acted as judge, and also took the photograph of all the exhibits.

The apiarian department commanded as much attention as any other on the grounds, and the bees were especially interesting to the school children and the school teachers. It is hoped that a great many more exhibitors will participate at the coming Fair, which is to be held at Grand Rapids, Sept. 18 to 22, inclusive. Mr. A. G. Woodman is the superintendent of the apiarian department. It is his desire that enough more exhibitors will take part this year so as to fill one entire wing of

the 8-winged octagon Cross building—Art Hall. The premium list has been increased by \$50 for the coming Fair, and no doubt if a due appreciation of the generous premium list is shown by bee-keepers, more money will be offered in premiums in the future.

For further information, address Superintendent A. G. Woodman, Grand Rapids, Mich.

John P. Coburn, of Middlesex Co., Mass., is a bee-keeper 72 years old, and has some 50 colonies. In the Boston Globe, for July 23, he is pictured as handling a frame of bees, with a veil on, etc. There is quite a nice write-up of his apiary and bee-keeping experience. Last year he had one colony that produced 104 pounds of honey, and another 102 pounds.

Such illustrated articles in the daily newspapers can hardly fail to be helpful in increasing the use of honey, as they call attention to it in the best way possible. Wherever it can be done, it would be a good thing to invite newspaper editors to visit your apiary, and show them the inside workings of the hive. Then, as they leave, be sure to give them a sample of nice honey, so that they can write intelligently and from personal experience. Of course, when possible, it is safer if the visited bee-keeper can have the privilege of reading the proof of what is written before it is printed.

The "Farm Journal" Apologizes.—In the Farm Journal for July, "Aunt Harriet," who had something to say about manufactured comb honey several months before, has the following paragraph:

Just one more reference to the statement about adulterated honey and artificial comb. As I neither eat nor buy honey, I based my opinion on newspaper reports, magazine articles, and the complaints of those who try to buy good honey. Wm. A. Selser's article, "The Honey-Bee," in the May number, will enlighten the consumers; the producers know the truth; and to all who read my mistake, I offer my sincere apologies.

That is a splendid utterance. "The producers know the truth"—yes, that is the best source of information to go to when wanting facts about any special business. It is not safe to attempt to write for publication on any unfamiliar subject. Even when fairly well acquainted one sometimes gets things twisted.

## "Combed" and "Extracted"

### A Plan for Increase

The method of increase given here secures queens for the new colonies reared under the swarming impulse, and the workers also which bear her company are fully developed, and have not been half starved in the larval state as so many young bees are apt to be where the apiarist interferes.

It will usually happen during the swarming season that several swarms will come off

on the same day, or within one day of each other. Hive each of the swarms on the old stand and place the old colony containing the young bees and queen-cells beside the new hive with its entrance facing in the opposite direction. Take the half-filled supers and put them on the new swarm in the way most bee-keepers are familiar with.

Just a word of caution here: When handling any hives or frames containing queen-cells use the utmost care to see that they are not jarred in any way as such treatment will destroy a large percentage of the unbatched queens.

The queen-cells in the old colony if the swarm has been a normal one, will be just about ready to cap over when the swarm issues, and in a day or two at the most the best of them (which are the oldest) will have been capped over.

Now we will suppose that this same procedure has been followed with two swarms that issued at the same time. If there is any choice in the stock, that is if one has proven superior to the other in honey-gathering qualities, or in other desirable traits, then arrange to preserve the queen-cells in it.

Two or three days after the swarms have issued, or when most of the cells are capped over, and when quite a number of young bees have come out of the hatching brood, shake the colony containing the cells, which you don't wish to keep, down at the entrance of its swarm, pinch off all the queen-cells from the frames, put the frames back in the super and set the super on top of the other hive containing queen-cells and young bees. There will be enough young bees in this hive to look after both lots of brood.

In 5 or 6 days from the time the swarms issued you will have a lot of ripe queen-cells just about ready to hatch; most of the brood will be capped over and the 2-storied hive will be crowded with young bees, the majority of which have never been outside.

Now is the time to make the division—place 8 or 9 hives where you want the new colonies to stand; see that the same number of frames contain a queen-cell each; put 2 frames (one with queen-cell attached) and all adhering bees into each new hive, give each new hive an extra frame of honey if you can spare it, if not never mind, but look out later when the queen starts laying, and see that they all have plenty to keep them going. Shut the little hives up tight until the evening of the following day if the sun is not too hot; if it is, then leave them open.

Avoid setting the new hives in a row so that their entrances all face in one direction; scatter them about in odd corners of the yard, or if you have an eye for symmetry in your arrangements you can put them in groups of four with the entrance of each hive in the group facing in a different direction from the rest.

It will thus be seen that from 8 to 10 colonies can be secured with the best of queens from the brood of 2 old colonies and the young bees of one. Nothing is taken from the swarm, and in fact one swarm is increased by its young bees.—FRANK P. ADAMS in the Canadian Bee Journal.

### Making Rock Candy for Feeding

The ordinary pulverized sugar in honey mixed into a stiff dough makes a very excellent bee-candy for cold-weather or spring feeding. But one objection to this kind of feed is that the granules will sometimes rattle down on the bottom-board, and be carried out and wasted. The candy that we prefer is made by mixing sugar and a little water and a little honey, and boiling long enough so when cold it will form a translucent block of rock candy. Do not stir, as that makes it somewhat mealy or grainy, and the result is the bees will cause the granules to drop down and so be wasted. The honey is necessary to prevent graining. It may be a little sticky, but it should be wrapped in paraffin paper, and then when ready for use the paper should be peeled off on one side and the candy placed on top of the brood-frames. Our experience in giving liquid feed in cold weather is not favorable. We always use combs of sealed stores first; then, if we have not the combs, candy.—Gleanings in Bee Culture.

### Kettle for Rendering Beeswax from Old Combs

BY C. P. DADANT

I FIND the following in L'Apiculteur for July, and as it appears to me to be very practical, I have concluded to translate it for the American Bee Journal:

At the last meeting of the Comtoise Association, one of the members, Mr. Beaux, of Chailluz, presented in the name of Mr. Kuhn, manufacturer at Chaille, a kettle intended to extract entirely the beeswax from the old combs of the apiary.

The slumgum obtained by the melting in an ordinary kettle contains still a large enough proportion of beeswax to enable the apiarists to sell it to the beeswax bleachers, who, with the help of powerful methods which are impracticable to ordinary bee-keepers, manage still to extract quite a quantity of beeswax from the slumgum in question. The rendering of

a—Removable crank. b—Level of the water. c—Screen for straining the liquid wax. d—Level of the combs. e—Wings of the wheel. f—Shoulders for supporting kettle on stove.

the wax in these cases has therefore not been thorough. The kettle of Messrs. Kuhn and Beaux washes entirely the remnants of broken combs, leaving in them no perceptible quantity of beeswax. The residue, after treatment by this method, may be considered as entirely cleaned out.

A mechanical disposition, simple and ingenious, and the use of a melting liquid of high temperature (water saturated with salt), permit reaching this much desired result. Let us examine the kettle.

1st. It is a receptacle of galvanized iron or tin, the shape of a circular wash-boiler, and supplied near its base with a projecting edge or collar which allows it to stand upright on any ordinary stove. Its capacity is about 5 gallons, which permits a woman to handle it easily.

2d. In this body is fitted a screened hoop, the center of which is perforated, and through which a shaft is placed, the latter at its bottom supplied with a winged wheel similar to those on windmills. The upper end of the shaft carries a crank which is removable at will.

We fill the kettle with old combs up to the level of the screen, and put on the inside the screen and the shaft with its winged wheel; then fit the crank on and fill the kettle to within 2 inches of the top with water. When heat is applied the wax melts and seeks to rise. But at the same time the

pellicles, cocoons and cast-skins of the brood-combs ascend also, and close the holes of the screen. Then comes the work of the winged wheel by the use of the crank. At the time when the water begins to boil, we turn this crank every half minute at the rate of 40 to 60 revolutions per minute. The fan-shaped wings stir the mass of cocoons, beat it, break it to pieces, and, thanks to the windmill shape of the wings, push towards the bottom all the obstructing residue, thus permitting the lighter beeswax to come up through the screen and rise to the surface.

This process is entirely new, and has much pleased the members.

Another "trick" still improves the result. We all know that the hotter a body gets the more fluid it becomes, and the easier it becomes separated from the solid particles. Beeswax is subject to this rule. Although it is fusible at less than the temperature of boiling water, it becomes very fluid at 212 degrees, and is still more so at a higher temperature. It appears that a much higher temperature may be reached by using for rendering wax a solution of salt in water. Take a certain quantity of water and add salt until it can melt no more; that is, until undissolved salt remains at the bottom of the vessel in spite of all the stirring you may do. In this condition the solution has its boiling degree raised to 230 degrees, and this is a first advantage which permits the beeswax to become more fluid and to pass through more readily to reach the top. On the other hand, the salted water has become more dense. It is heavier than pure water, and this helps to raise the beeswax to the top more readily. This use of salt was mentioned by Dr. Miller, in February Gleanings, as mentioned in L'Apiculteur for April.

Thus stirring with the screw-shaped wheel, and use of a salt solution, are the two new and ingenious points of the invention of Messrs Kuhn and Beaux. This was not found at first trial, but has been the result of a series of experiments. The trials have been numerous, and at the beginning success was doubtful. After a quarter of an hour of stirring every half-minute, the work is done. We remove the kettle from the fire, remove the crank which would otherwise be caught in the cooling wax, and we cover the kettle to let it settle slowly. After 30 hours the cake of wax will come out readily. We take it out and wash it with clean water. All that will not brush off readily still contains some beeswax, and should be put aside to be remelted with the next batch. The residue remaining in the kettle contains no longer any beeswax. The separation of the wax from the residue has been complete, and the maximum of economical rendering of wax has been reached by a simple method which is within the reach of all.

The presentation of this kettle has been a prompt success. It is certain that with this rustic implement, easy to manage, and enabling one to remove all the wax from the combs, the average bee-keeper has great advantage in being able himself to render all his old combs. The kettle is also suitable for any kitchen stove, and the cost of fuel is practically eliminated.

Several orders were given at once by members of the Association. The price is within the reach of all, 15 francs at the factory. I have had the curiosity of inquiring into the prices of similar implements, and I was astonished to find that this small implement is exceedingly cheap when compared with others, and its acquisition will complete the outfit of many a small bee-keeper. No other system gives the advantages mentioned in connection with this.

The Association complimented Messrs Kuhn and Beaux on their discovery, and hoped that the "Comtoise Wax-Kettle" may become as popular as several other implements invented by some of its members.

DR. SEXE,

President of the Comtoise Association.

I believe that the ideas expressed above are practical. The salt-in-water idea for rendering wax is developed here with a very good argument. I expect to try this implement myself, and report later.

Hancock Co., Ill.

### Hive for Producing Extracted Honey

BY W. W. M'NEAL

I WANT to tell the readers of the American Bee Journal about a hive I have been using for the production of extracted honey. I have done a good deal of experimenting in hives in my own apiary, and, besides, I have had the advantages of comparing the different styles of hives in actual practice in large apiaries in other places. The one I have chosen as being the most suitable for the purpose here, and I dare say in many other sections of the country it will work just as well, I will describe as follows:

The hive is double walled, and takes 10 crosswise self-spacing frames in the brood-chamber. The inner bottom slopes to the front, which permits of the hive being set level on its stand, and keeps the floor dry, too. There is no packing of any kind between the walls, the hive merely being lined inside with lighter material. The frames are 11x16 $\frac{1}{4}$  inches, outside measure, and there is room for a follower at the back. This gives an entrance space fully 17 inches long, and as I make it  $\frac{3}{4}$  of an inch high, it will readily be seen that there is abundant room or means for ventilation. I regulate the entrance in the ordinary way, by the use of entrance blocks.

Now, with this large entrance there is no need of prying the hive off the bottom-board, as is often done with hives having detachable bottoms. Bees need lots of air when they are storing honey, but to give it in this way is so much easier, so much more practical, that tall, narrow hives are not "in it" at all.

When you pry or wedge up a hive, such work must all be undone again at the close of the season. The bees fly out more or less along the sides, and often cluster there also. This makes it worse about bees getting into one's shoes while standing at the side of the hive. This is especially so if low-top shoes are worn. Then, when swarms issue the queen is liable to leave the hive by the side entrance, and get lost in the grass, if she is clipped. Give me the permanently large entrance, regulated with the blocks, every time.

Now this hive has a large base; it does not blow over easily, and, besides, affords large super accommodations.

I forgot to mention that it has a portico similar to the Langstroth hive.

The super takes 13 frames if ordinarily spaced, or 12 with a follower. I have used both a 6-inch and a 7-inch frame in the super for extracting, and both work admirably. For my own convenience I want nothing larger than a 7-inch frame for extracting purposes, but on 8 and 10 frame hives of the ordinary make it is better to use a deeper frame. There will be more honey harvested at less expense by using one deep super, taking the same size frame as those used in the brood-chamber, than in two shallow supers. A narrow, shallow super costs nearly as much as a standard-depth brood-chamber, and two of them require just double the amount of manipulation.

If one doesn't mind extracting from large frames, then there is no question about their superiority over shallow ones, in most places, for the production of extracted honey. When I say this I have in mind the Langstroth hive and frame. In my hive I get nearly as much super-room as there is in a 10-frame Langstroth brood-chamber, and have the pleasure of using a 7-inch frame.

There is a large telescope cover, ventilated, that fits down all over the super and rests on a rim about an inch below the top edge of the brood-chamber. This affords a good deal of shade in summer, and keeps out all rain during the winter. When I wish to prepare the colony for winter, all that is necessary to do is to remove the frames from the super, spread a cloth over the honey-board which is left in place, fill the super full of dry forest leaves, and the job is done. I always leave the flat super-cover off during the winter, otherwise the packing would become wet in the super and destroy the colony.

This hive costs a little more at the start, but if you produce extracted honey, and live in a place where bees need a good, substantial hive, make some on that order and compare their utility with other makes of hives. Scioto Co., Ohio.

the manufacture of foundation. Those are not exactly the words but that is the substance of it.

Dr. Miller—That leaves it, he might say if he knew of a single case in which some fool who was making experiments might have used only half a pound of it. Perhaps it will be wise for us to be careful in what we say, and rather ask the question whether Prof. Wiley has any proof; and perhaps it would be wise to let the journals ask him. I think that would be better.

Mr. Dadant—I think you are doing Mr. Wiley a great deal too much honor by paying so much attention to what he says. In regard to this accusation, it only strikes one or two firms. I am perfectly willing to stand on my own responsibility, and my respectability, without any attention being paid to it.

Mr. Dittmer—Mr. Dadant is wholly right. Prof. Wiley's reputation in the past has been such that he deserves no attention on our part, and the best way to get rid of an obnoxious person is to ignore him.

Mr. Abbott—Mr. Wiley is chief chemist of the United States; his word is authority not only in the United States but all over the world. He is quoted as the representative of the United States by the chemical men of the world and we cannot ignore Mr. Wiley. We have to face the fact that he represents the United States among the scholars of the world so far as chemistry is concerned, and he represents the United States so far as the people in command are concerned. We cannot ignore those things. It is all right enough to say we are giving him too much advertising. We are not giving him too much. The chief chemist of the United States, who speaks by authority of the United States, ought to tell the truth.

Mr. Dadant—But he doesn't. It will serve no purpose whatever to demand anything. A man who will state a thing which he knows to be false will stick to the falsehood. He will make an untruthful statement again, and it will simply make matters worse by having anything to do with him.

Mr. Hutchinson—Not only Mr. Dadant but all other comb-foundation manufacturers are affected if these statements go out in the Rural New Yorker all over to the reading community that buy honey; it prejudices them against our product.

Mr. Dadant—In that case, don't ask him to prove it but simply state that it is not so. If you ask him to prove it when he has made the statement he will prove it in some way if he has to manufacture something in order to prove it in one single instance. That will be sufficient for him, and sufficient to hurt your business that much more.

Mr. Colburn—I wanted to ask if anybody here knows whether bees will work on foundation that is made partially of paraffin?

Dr. Miller—Yes, they will.

Mr. Colburn—What proportion?

Dr. Miller—I don't know.

Mr. Wilcox—What causes the difference in foundation with regard to some being very hard and others very soft at the same temperature?

Mr. Dadant—Beeswax is a little like iron; you can cast iron and make it malleable, and it is the same way with beeswax. Pour beeswax into a mould and the cake will be brittle. It will break readily and you can't stretch it. But put that cake of beeswax under the roller and it will become malleable; that is, warm it to a certain temperature. There are a good many points concerning beeswax that it is impossible for the general public to know. In regard to the adulteration of beeswax with tallow, it may be well to inform you as to the way of detecting tallow. It is very easily detected; it makes the beeswax softer, and when you have a cake which you suspect of having tallow at the ordinary temperature, run your fingernail over the cake. If it is pure beeswax it will make ripples in the cake; if it is tallow it will make a dull-looking streak in the cake.

#### INCREASING THE CIRCULATION OF BEE-PAPERS.

Pres. York—Here is a question that I didn't ask myself, but I would like to know the answer. "What can be done to increase the circulation of bee-papers?"

Mr. Moore—Advertise.

Mr. Abbott—I do not think that that ought to be passed by. I am not saying that because I am interested in papers; I don't publish a bee-paper; I publish a farm paper. But it does seem to me that there is not enough pride among beekeepers in our industry. I asked that question and I asked

## Convention Proceedings

Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904

(Continued from page 569)

#### DETECTING ADULTERATION IN BEESWAX.

Pres. York—Have you the entire letter?

Mr. Abbott—I have the entire copy, my comment and the editor's upon it.

Dr. Miller—Just what is the statement he did make?

Mr. Abbott—The sentence states that honey is not adulterated, but that paraffin is used wholly or in part in

it because I wanted to say something. You take the poultry people, and there are in the United States something like 15 or 20 poultry papers that have a circulation ranging from 25,000 to 75,000. They all have good circulation, and every poultry keeper swears by his poultry paper. Every poultry keeper has a pride in his industry and therefore he reads carefully his poultry paper. They do not all take the same paper, of course, but they swear by some poultry paper, and they go out and talk it up amongst their friends, and they get subscribers for the different papers; they are talking it up at institutes and poultry meetings, and all the time interested in pushing the circulation of their papers. But it seems to be a crime to mention a bee-paper at any bee-convention. The editors are so modest they will hardly distribute sample copies for fear some one will say they are trying to drum up trade. If they are, they are drumming up trade that helps us. Take the American Bee Journal, the only weekly bee-paper that is published on this continent and it has a paltry circulation say of less than 10,000 copies, and perhaps there are less than 30,000, all told, that read bee-papers, and we are told, and we tell the world, that there are over 300,000 bee-keepers in the United States. Are there less than 30,000 out of 300,000 who have enough pride in the industry to spend one dollar a year to learn what is going on in the industry? It seems they must think it a very small business if it is not worth investing a dollar in. There is no other kind of an industry but what the people who belong to it are willing to take three or four different papers. The hog people, the sheep people, and the poultry people, take three or four papers. A man came into my place the other day who is just an ordinary poultry fancier in the city, and before he went out he had subscribed for four poultry papers in addition to mine. I said to my wife, "That fellow has some pride in his industry." If a man happens to take two or three bee-papers, and spends two or three dollars a year for bee-literature, he seems to think he is making a bank account for some fellow, that lives in the city. I can't understand how it is we have so little industrial pride in our papers. If the American Bee Journal, instead of having less than 10,000 had 100,000 subscribers, what a power it would be. Then when Mr. York opened his mouth in the American Bee Journal in regard to such a thing as we have just been discussing it would mean something, because he would have a constituency behind him, and he could make himself heard all over this land. I say, the way to do it is for the bee-keepers of the United States to take an interest in the circulation of our bee-papers. Mr. York, Mr. Root and Mr. Hutchinson will all be gone soon, their hair will soon be as grey as mine—mine is not very grey yet, but I am getting old, and I know it—and Dr. Miller there, and somebody must come into their places, and this industry is to be perpetuated and the bee-papers are what perpetuate it, and I say we ought to take more interest in it than we do, as individuals and bodies.

Dr. Miller—I must say a word in defence after such a lambasting as that. I very much doubt whether there is a larger percentage of poultry men take the poultry papers than the percentage of bee-men that take bee-papers. Did you tell us how many poultry subscribers there are and how many poultry keepers? Please remember this, that there are more people that keep hens than keep bees, very many more; there are more than five times as many.

Mr. Abbott—I am talking of the poultry fancier.

Dr. Miller—If you count the poultry fanciers and the bee-fanciers I think they will rate very fairly. I think the bee-fanciers take just as many papers as the poultry fanciers take poultry papers. But you must remember that the subscription list of these papers is not made up of fanciers so much as of those who keep a few hens or a few bees. My wife keeps hens and several other wives keep hens, and they don't keep bees at all. When you take the number, I do believe Mr. Abbott will find out he is a little hard on us. We are keeping up to the mark just as well as the chicken people are. The thing in a nutshell is, there are not so many bee-keepers as there are of the others, and I don't believe we are as "worse" as we might be.

Mr. Whitney—I agree somewhat with Mr. Abbott and with the Doctor. I think the Doctor's position is about correct when he makes a comparison between the chicken men and bee-keepers. But the fact is, we don't take the bee-papers as we ought to. I don't care how many chicken men take chicken papers, every mother's son of us ought to take a bee-paper. There is not a farmer in the country but ought to take an agricultural paper and a bee-paper and a fruit

journal. They all raise fruit, they all raise poultry, and nearly all of them ought to keep a few colonies of bees; that is, keep them right, keep them as they should be kept. I have tried my best in the last year to increase the subscription list of the different bee-papers; I have succeeded in getting four or five individuals to subscribe, and they are delighted with what they get in the bee-papers. I think if we would all take that interest in it, that we go to somebody who is our neighbor—and some clever fellow would just as soon give a dollar for something he doesn't know anything about, may be he will learn something about it, and in that way we have increased the circulation of these different journals may be one hundred percent. I think we can do it next year, and if we do that, we will increase the membership of the National Association, too.

Mr. Dadant—I wish to take issue with Mr. Abbott in the statement that there is a greater percentage of poultry raisers who take poultry papers than there are bee-keepers who take bee-papers. I believe it is the other way. I think you all know everybody keeps poultry, except a few people in the big cities. Every farmer keeps chickens. We see the chickens when we pass by the farm-house; and lots of city people keep poultry. Now, what per cent are there of those people who keep bees? How many are there of the people who keep poultry who read a poultry paper? Only here and there. But of those who keep bees the great majority, who have an interest at all I believe, take a bee-paper. There are plenty who raise two hundred chickens a year and who make money out of them who do not take a poultry paper. But there are very few farmers that we find who make any money at all out of bees that do not take a bee-paper. Therefore, I believe, generally, the bee-keepers take a journal where the poultry men do not take a poultry paper.

Mr. Whitney—I know a bee-supply man who has a large sign out by the side of the railroad advertising bee-keeper's supplies and honey, and he doesn't take a journal, and I have talked to him more than a little to get him to subscribe for some of the journals.

Dr. Miller—I would like to ask those bee-keepers who take only one bee-paper to rise. (7 rose.) How many take only two? (2.) How many take only three? (16.) How many take only four? (5.) How many take more than four? (6.) I am very glad to have the opportunity of asking those questions. I want to follow the advice of Mr. Abbott, and urge that those who do not take a bee-paper, that did not rise, to take a bee-paper. You will like it; it will do you good.

Pres. York—I would like to ask Mr. France to say what he found in Wisconsin, where he had made a pretty thorough canvass of bee-keepers, as to the proportion of them that take a bee-paper.

Mr. France—A few years ago, I don't remember the year, I was going to make a very thorough report while inspecting bees over the State. I believe Wisconsin will average up to any other State as a honey-producing State; it will average as well in its proportion of those who are readers of bee-papers. When I had finished that season, I am sorry to say I found only one in twenty who was a reader of the bee-papers. That looks pretty tough for my own State, but I believe if you take the subscription lists you will find it will average up with the other States. It is just the same with the farmers' institute. Wherever the farmers' institutes were frequently held we found better farmers; and invariably wherever I find a home that takes a bee-paper I find a better bee-keeper.

Mr. Abbott—I want to say further, I know scores of people who have from 10 to 15, 20 to 100 colonies, who do not take any bee-paper at all. I have a way of finding out because I am taking subscriptions on the basis of new subscribers only for the American Bee Journal, and you would be surprised to know the information that comes to me along that line. People come to me and say, "I want to take that club offer of yours;" and I say, "Why, you can't take that; you get the American Bee Journal right along; that is for new subscribers." They say, "No, I don't. I don't take it at all." Some of them say they never have taken it; and some of them say, "I never have heard of it; what kind of a paper is it?" And they don't all live in Missouri, either. [Laughter.]

(Continued next week.)

Why Not send in some new subscriptions for the American Bee Journal? Samples free for the asking.

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### White Clover and Cool, Wet Weather

In this locality, as in many others, white clover is doing a wholesale business at growing and blooming. Plenty of nectar in the bloom, too. But cool and wet weather has not allowed the bees full chance at it. Yet there may not be so much loss in that, for cool, wet days may prolong the growth and the blooming enough to make up all loss. Good weather or bad, the bees have done a lot of storing. Yet July 20, while the fields are still white, and apparently the bees are hard at work, robber-bees are beginning to trouble. There doesn't seem to be any plain reason for it. Most likely, however, it is only temporary. Other years there have been days when the harvest seemed about to close, and then the bees would take fresh hold again and do good work. Their finished work would show evidences of these breaks in the harvest. A section would show that they had begun rounding it off, sealing up without drawing out to their fullest extent the outer cells, some of the outermost cells still remaining unsealed, then, as if by an afterthought, these outermost cells would be drawn out to their fullest extent, the afterthought showing very plainly in the finished section.

### Honey in the Heart of London

Over 50 pounds of comb honey of excellent quality have recently been gathered in the very heart of London. The bees belonged to a woman apiarist.—Farmers' Review.

### So-Called Poisonous Honey

DEAR MISS WILSON:—I would like to ask a question which bothers me. Can honey be poisonous without poisoning the bees? The reason I ask is this: While I was uncapping some honey some was so green in the comb that when taken out there was a slight tint of green.  
NEW JERSEY.

Yes, there is such a thing as bees gathering honey that does not injure them, and yet is poisonous to the human family—at least the honey sickens the people that eat it. Such cases, however, are rare, and it is not likely you will ever be troubled in that way. There is the well-known story of soldiers—was it Xenophon's army?—being thrown out of action by eating honey gathered perhaps from mountain laurel. Some say honey from laurel is poisonous, while others who live where laurel is abundant say they never have any poisonous honey. Down South honey from yellow jasmine has a bad name.

Don't be alarmed at the slight tint of green in honey. Some very good honey has that; doesn't alsike or sweet clover honey?

### How Many Supers to the Hive?

What a difference in practice there is as to the number of supers on a hive at the same time. Now and then some one—generally a beginner in the first year—talks as if only 1 super at a time were to be used. Indeed there is—at least there has been—such a thing as a closed-top section; and with closed tops how could more than one super at a time be used? I wish some one who uses these closed-top sections, or indeed uses only 1 super at a time, whether the tops be closed or open, would tell us all about how it works.

Then there are those—experienced beekeepers, too—who advocate having only 2 supers at a time. It must be that their supers

hold more than usual, or that their colonies are smaller than they are in this locality. Some of our colonies would certainly be crowded out of the hives if the attempt were made to confine them to an 8-frame hive and 2 supers of 24 sections each. The bees simply couldn't all get in.

Some of the 2-super folks would probably raise their hands in horror if this third week in July they should see the supers piled up on our hives. Possibly 2 or 3 colonies have only 1 super each. That's because something has gone wrong with the colony, and it isn't counted as amounting to anything. A very few have only 2, and these are counted little more than failures. The season, however, is

good, or these might not have even the 1 or 2. Most colonies, however, have more than 3 supers each. Quite a number have 5, and a few have 6 supers each.

Of course it is possible some colonies have more super-room than they need, but it does less harm to give too much than too little room.

### Very Small Honey Crop

Our honey crop here so far is very small. It was too wet while the clover bloomed, and when the basswood opened we had 3 or 4 days of hot weather, and then 3 days of cold winds, so that bees could not fly, or could not fly enough to do anything. They work on sweet clover now, but there is not plenty of it. Goldenrod will soon bloom so they still have a show, although there has been no show for honey all summer—except a few hours at a time. I received a card from Faribault, Minn., and it says that the honey crop so far is short there.  
(MISS) MARY THEILMANN.

Wabasha Co., Minn., Aug. 3.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Plan for Wintering Bees

1. I am making some boxes to put over the hives to winter the bees, and want them water-tight. Would it be all right to cover the boxes with tar-paper, or would the tar odor be offensive to the bees?

2. Shall I close the entrance entirely during winter, or only part? What size opening should I leave?  
ILLINOIS.

ANSWERS.—1. The tar-paper on the outside will not trouble the bees.

2. By no means close the entrance entirely. Leave an opening equivalent to 1 to 3 square inches, according to the strength of the colony.

### "Lining" Bees in the Woods

How can I line bees out in the woods?

WISCONSIN.

ANSWER.—Set your bait and watch the direction the bees go when they leave it. Then move your bait in that direction, and try again. Keep on till you find that the bees go back in the opposite direction, and then you'll know you've passed the right place, and you can bait back nearer to it, all the while keeping a close watch on the trees to see or hear the bees flying in or out. Another way is to cross-line. After watching the direction the bees take, instead of moving directly in that line, move at right angles to it and watch the line the bees make. Now guess about where the point would be where these two lines cross, and try accordingly.

### Meaning of Queen Terms

1. In queen-bee advertisements what is the meaning of untested, warranted tested, tested, select tested, and breeders?

2. Have the untested queens sent as premiums been mated?  
WASHINGTON.

ANSWERS.—1. As used with regard to Italian queens, these terms have been in use as follows: An "untested" queen is one reared from an Italian mother, and has begun to lay, but it has not yet been determined what her progeny will be, so it is not known whether she has mated with an Italian or a black drone.

A "tested" queen is one which has been laying more than 3 weeks, and whose worker progeny show the 3 yellow bands.

A "warranted" queen is one whose progeny has not yet been seen, but is sent out with the agreement that if such progeny does not show the 3 yellow bands it will be replaced with another queen purely mated.

A "select tested" queen is one which in some respects seems better than the average.

A "breeder" is one supposed to be of such good stock and good characteristics as to be superior to others to breed from.

It may be added that these things refer largely to color, and a good many care less for color than performance.

2. When a queen is sent out by any one, it is always understood that she has been mated, unless it is specially stipulated that she is to be a virgin.

### Miller Frame—Split Sections—Foundation Splints—Spacing in Hives

1. In the Miller frame, what objections would there be, if any, to halving all bars as well as the bottom-bar, placing foundation over one-half, then nailing together?

2. Could sections be made in the half form, vertically, and a full sheet of foundation laid between the halves, then fastened some way?

3. Why do your splints not extend from top-bar to bottom-bar? On page 88 of "Forty Years Among the Bees," you say "1/4 inch shorter than the inside depth of frame."

4. Such light sticks as your splints are liable to twist or warp and make foundation wavy. Do you often find them not exactly straight just before using, and discard them? I suppose after being boiled in wax they would no longer warp.

5. It is complained that side-spacers, nails or staples are objectionable for several reasons, and that an indented rabbet is objectionable because the frames will not slide on it. Could the bottom spacing be accomplished by driving headless ("finishing") nails into the *hive-ends* so they would strike the bottom-bars in the middle, 1/8 inch from the bottom? To lift frames this small distance, several at once, and slide them on metal rabbets at the top would seem reasonably easy, a slight inclination of the frame being all that would be necessary. To secure top-spacing, why could not an indented metal spacer be used? One could be laid on each end of the frames, the two thus keeping the frames regular in distance. A notched strip of heavy tin, similar to the notched stick used for fastening frames for shipment (page 223, "A B C of Bee Culture"), would constitute the spacer. If the

hive is to remain on the stand, these 2 top-spacers could be removed before closing the hive, merely being used for a moment to see that the frames have been accurately spaced. If the hive is to be carried a few feet to another stand, the spacers could be left in until the hive is settled. The tin strip would simply be bent down, for the space between the frames and the intervening parts be at right angles so as to be flat and rest on the frame top-bars.

Of course, for out-apiaries and removals to the cellar, etc., different and more permanent fixtures would be necessary. What I am trying to get is a frame with all bars of identical width and no projections, automatically spaced, and with practically no propolis attachments. I am using closed-end frames, but I long for a hive where I can take out any particular frame without touching any other frame or springs, or other piece of hive furniture. Can my plan secure this? INDIANA.

ANSWERS.—1. I don't know that there would be any objection except the extra trouble and the difficulty of having all the parts accurately fitted together. But I don't think there would be any advantage in it. It is barely possible that you may be thinking that if all parts of the frame were halved there would be no need of any kind of support to keep foundation from sagging, but unless you use foundation expensively heavy there will certainly be need of splints or wires.

2. Yes, such sections have been used to a considerable extent in England. One objection is that the finished section does not present so good an appearance, the foundation showing through the upper surface of the top-bar, and also through the side-bars.

3. Merely for convenience in putting in the splints. If the splints filled the whole space from top-bar to bottom-bar, it would take a good deal more time to put them in. And it would make no better work.

4. No, I have no recollection of ever discarding a splint because it was not straight. Neither do I remember seeing a splint that was warped or twisted, either before or after being boiled in wax. I think that a splint no thicker than 1-16, even if warped or twisted, would be straightened out when pressed in the foundation.

5. Spacing, such as you mention at the top, has been in use, and bottom-spacing has also been used, but such spacing has not found very general acceptance. Without actually trying it, I should not expect your bottom-spacing with nails to work very easily. You would have to lift the frames at least an eighth of an inch, and that would take away all the slide at the top, and then it would be some trouble to settle them at the right place at the bottom. What is wanted often, is to have one frame, or all the frames in the hive, to slide as far as wanted with one shove. On the other hand, I am pretty sure that your spacing would not have to be changed in the least to move hives in or out of the cellar, or to haul to an out-apiary.

But remember that I don't know anything about the whole affair any more than you do, and the trial of one hive would settle the question for you more than a year's guessing on my part. You see I'm not as good a guesser as I might be, for I guessed you would try to coax along a queenless colony in the spring rather than to reduce the number of hives with bees in by uniting, and you went and did just the thing I guessed you wouldn't do. Nevertheless, I'm going to venture another guess. You say, "I long for a hive where I can take out any particular frame without touching any other frame, or springs, or other piece of hive furniture." You can easily have a hive that will allow that so long as no combs are built in the frames, but I venture the guess that when you get combs built in the frame, they'll never be so true and straight that you can take hold of any one of them and lift it straight up without interfering with one of its next neighbors. When you do I'm ready to apologize for my skeptical guess.

**Feeding Pollen-Gathering Bees—Producing Beeswax**

1. Do bees need to be fed if they are gathering pollen every day, and nearly all day some

days, although they have not the least sign of honey in the hives?

2. Will bees make nothing but wax if the combs are taken out every day during a honey-flow? I am so informed by a bee-keeper. If he is right, what becomes of the nectar which they are bound to gather? He says they convert that into wax also. I am much interested in this matter, for wax should be our main object here in Cuba, as our honey market is ruined. CUBA.

ANSWERS.—1. When bees are carrying in pollen they are generally, if not always, carrying in at least a little honey. They would hardly live without gathering any. If none can be seen in the hives, it is because they use it up for their daily needs, and although they may get along in that hand-to-mouth manner, it would be better to feed so that at least a small amount of stores should be in sight in the hives.

2. You will hardly make a brilliant success of wax-production by taking out the combs daily; that is, if you should take out all combs. There must be plenty of comb left at least for brood-rearing. Success in producing wax has been reported by taking out the combs every few days and feeding back the honey. Bees will construct comb only so fast as they have something to put in it, and your informant is not so far out of the way when he says that wax will be made of the nectar they gather if they have no comb in which to store it.

**Queen-Rearing—Is Natural Bee-Pasturage Diminishing?**

1. Can queen-rearing be made a profitable pursuit in a locality where the honey-yield is not sufficient to warrant one to run an apiary for surplus honey?

2. Is the inevitable diminishing of natural pasturage for bees, which is gradually taking place, calculated to affect seriously the industry in this country? I am told that localities which 20 years ago would abundantly support 100 colonies, will now barely support 20. GEORGIA.

ANSWERS.—1. I have some doubt about it. To be sure, feeding can take the place of nat-

ural harvests, but queen-breeders generally find it uphill business to get on when the flowers are not in good working order.

2. If there is an inevitable diminishing of natural pasturage, it must certainly have its effect upon the industry. But you will pardon me if I say that I am very skeptical about any such diminishing. There may be localities where only a fifth as many colonies can be supported as 20 years ago, but take the country at large, and I believe there's as much nectar secreted as there was 20 years ago.

**Queenless Colony—Swarming—Uniting a Swarm with a Colony**

1. I have one colony of bees which I think has lost its queen, but I am not sure of it. I looked all through the hive and could not find her. The bees worked hard after I first hived them, but are not working so well now. Do you suppose the queen is dead?

2. Will these bees construct queen-cells and rear another queen?

3. A colony cast a swarm 3 or 4 weeks ago and it has not swarmed since. What do you suppose is the trouble?

4. Would it be all right to put a new swarm in with a weak colony and thus make a strong one out of it? IOWA.

ANSWERS.—1. I'm afraid they have no queen.

2. Yes, if you give them a frame of eggs and young brood they will be pretty sure to rear a young queen. But it will expedite matters very much if you give them a frame from a colony that has swarmed, said frame having on it a sealed queen-cell. It will be likely, too, to be a better queen.

3. You probably have an idea that every colony that swarms should send out one or more afterswarms. That is by no means always the case. Many a colony is satisfied to send out a prime swarm without thinking of swarming again. And most bee-keepers would be thankful if there was no such thing as an afterswarm.

4. Yes; but in thus uniting, the 2 queens should be both laying queens, or both virgin queens. If one has a laying queen and the other a virgin, they are likely to fight.

**Mr. Hasty's Afterthoughts**

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

**SECTION WITH TOP AND BOTTOM STARTERS.**

On page 456, that picture of a section with the top pieces of foundation in it is very admirable in its distinctness. We can see that the two pieces of foundation are of two different kinds, one with side walls much better developed than the other. The picture is praiseworthy from two different directions—a beautiful example of distinctness as a picture, for one thing, also a most excellent way to show the uninitiated just how the thing is done.

**AMOUNT OF COMB SURFACE TO BE SEALED BEFORE EXTRACTING.**

As to what proportion of comb surface should be sealed before extracting, 6 of the 29 experts do not give direct answers. I am delighted to see that a majority of those who do (13 out of 23) say it should be all sealed, or nearly all—and Doolittle puts in the "tiger" by saying to let it ripen two weeks after it is all sealed. Good! If practice now could only be as excellent as precept! As to the minority, six name  $\frac{3}{4}$  to only two for  $\frac{3}{8}$ , one  $\frac{1}{2}$  and one  $\frac{1}{4}$ . One-third used to be the leading precept, and now it only gets one vote. Page 456.

**BALDRIDGE FOUL BROOD TREATMENT.**

The Baldrige foul of treating foul brood by depleting the old colony to nothing, and building up in its place a new and healthy

colony looks very well on paper. All it lacks is use sufficiently long and broad to show that it actually works according to program always. If it does fail you have increased not exactly the number of your diseased colonies, but the number of your diseased combs. The general success of this attractive method is greatly to be hoped for. Page 469.

**HOW BEES MEASURE ANGLES.**

Never thought of it before till Mr. Doolittle told me! Each bee carries antennae bevel-squares to measure distances and verify angles. Now, maybe that is the way they get their angles and diameters so nearly uniform. While making the first raise of the outer wall of a cell, they can gently keep touching the inner wall which is already up a bit. But those who have observatory hives and sharp eyesight must verify it that they actually do that—lest we be like that great professor (reputed the greatest in America), who gave it out that bees stood in their cells and built them up around them! Page 471.

**WOULD SAVE THE EMPTY HONEY-BARRELS.**

Our editor read a good paper to the Minnesota folks about keeping the grocers supplied—but I must get one arrow into it. Destroying a tight barrel to get the honey out of it is one of the barbarisms of the past which it is a reproach to our inventive good sense to have continue a minute longer. No patriotic per-

son, remembering how near exhaustion our country's wood-supplies are, can look at such crazy waste with placid feelings. I'll guess that the winning way will be a loop of slender steam pipe thrust through a big bunglehole—next shake it a good plenty—next turn out into a tank and finish the process there. The value of such a barrel as honey ought to be trusted in, would more than pay a laborer for a day's work getting the honey out. Page 472.

#### THE HIGH PRICE OF SECTIONS.

Mr. Bevins is puzzled at my seeming so indifferent to the high price of sections. I wrote (in a private letter) just as I felt. Presumably I felt that way partly from willingness to see good people make a good profit—as long as they refrain from making hogs of themselves altogether. Moreover, I felt that the cost of suitable wood would soon be up to the five-dollar-a-thousand mark, if it isn't now. Not wise to do kicking (mostly in vain) about so short a period of overcharge. I'll bend a little, however—can say that I don't at all admire selling No. 2 sections as No. 1. Perfectly white and clear material will have to be high while material that will make No. 2's holds out yet. Page 473.

## Reports and Experiences

### Bees Doing Well

I have 9 colonies. On June 15 they were all doing super work. On July 5 three of them began on their fourth super, having stored 72 pounds each. J. R. CHRISTIE.  
Miami Co., Kans., July 8.

### Hot Weather Burns the Clover

The bees in this locality stored several pounds of surplus honey as long as it lasted, which was about 2 weeks in June and the first part of July. Then hot weather set in and burned the white clover and basswood brown, leaving the bees in a condition to do nothing. They hang about the hives as if they were half asleep. To-day we had some rain, but it didn't last long, though it helps the bees. They were working on mustard right after the rain. The average will be about 75 pounds per colony.

B. F. SCHMIDT.

Clayton Co., Iowa, Aug. 2.

### Fine Crop of Honey

We had a fine crop of honey here. I have up to date about 2500 pounds of as fine honey as I ever produced, and have increased to 200 colonies of bees. There is prospect of a good fall flow. Everything seems to be favorable. Madison Co., Ill., July 17. L. WERNER.

### Bees Doing Fairly Well

The bees are doing fairly well, but it has been too wet in this locality. I am taking off some fine honey to-day. F. MCBRIDE.  
Hardin Co., Ohio, July 28.

### Inspecting Apiaries

The State Inspector of Apiaries, Mr. J. Q. Smith, visited some of us recently by invitation. He first called on Mr. J. E. Johnson, president of the Western Illinois Bee-Keepers' Association, who has an apiary of 56 colonies in the south part of Knox county. His bees were found in good condition. When he overhauled my apiary of 16 colonies he found 8 diseased. He pulled off his coat, slid into a pair of overalls, and went to work. We put foundation into nearly 100 brood-frames, the bees of the 8 colonies into new hives, and the hives which had contained the diseased bees aside for the rendering tank.

I spent 3 days with Mr. Smith, visiting and caring for apiaries in this vicinity, and would

recommend any of our members who have diseased bees to call upon him. He is thorough in his work, and has practical knowledge of the various diseases of bees.

ALVAH REYNOLDS.

Knox Co., Ill., July 17.

### "Culver's Physic" a Honey-Plant

I am sending a blossom of what I would call a weed, but I tell you it is a good one, and I find the bees working on every blossom. What is it?

I have just 100 colonies with my increase and they are doing very well.

C. M. LAURENCE.

Black Hawk Co., Iowa, July 20.

[The weed to which you refer is *Leptandra virginica*, or Culver's physic, but if you find it more useful than useless, it might be well to call it simply a plant rather than a weed. Of course, weeds are plants, but plants that keep their place, and are orderly and valuable directly or indirectly to man, should not be called weeds.—C. L. WALTON].

### Heavy Loss in Wintering

I put 35 colonies of bees into winter quarters last fall, and there was not one living bee in the 35 hives when I took them out, so I had to start anew, and was quite discouraged. I bought 3 colonies, which came on the train, and as they were being loaded on the car some of the bees got out, and the men who were handling them threw the hive down. I lost one colony in this way. I sent for 2 more to Ontario, and when they came both queens were dead. I hope I will have better luck another year. HENRY SWAIN.  
York Co., N. B., July 29.

### About Half a Honey Crop

There is about half a honey crop here in southern Iowa. Two weeks of rain did it. Bees ceased gathering June 27.

A. B. TACKABERRY.

Van Buren Co., Iowa, Aug. 2.

### The Great Value of Honey

I am very much interested in bees, having started with 11 colonies. I have discovered that honey is very healthful, so much nourishment is to be derived from eating it. In our home it is a remedy for all ills. To use it is to know its true value. A. MCCONKEY.  
Lyon Co., Iowa, July 31.

### Not a Good Honey-Flow

The honey season is over for the present. We have not had a very good flow. I have 3 bee-yards located in a valley running not quite north and south. The home bee-yard did the poorest; my next yard about 5 miles north did the best; the other one about 12 miles north comes next. It would seem that the latter has the best chance, as it has a more extended territory, while the other two yards are wedged in between the hills.

I may not have much more than a ton of white comb honey and 1000 pounds of extracted, from 160 colonies, spring count. I increased but little.

We expect some buckwheat honey, particularly in the yard that has already done the best. F. GREINER.

Ontario Co., N. Y., July 31.

### Good Bee Country—Hot Weather

I live 20 miles from a railroad, in the hills, and have about 10,000 acres of farming land, all in grain and cattle ranches. Our town has only two families, but we have a post-office. The Valley is stocked with heavy oak timber, and so are the hills, and one does not need to go very far to find a bee-tree in a 200-acre patch. I have found 11 of them.

Last spring I had 26 colonies of bees, but did not have enough extra hives on hand for swarms that might issue, so I made boxes and

sent to San Francisco for the fixtures. After 4 months the goods came. During that time I lost more than half of my bees. The very day the supplies came I lost a big swarm with the queen which I received from the American Bee Journal last year, and shortly afterward I lost the rest. I saved only 6 out of the whole apiary. By the first of April swarming was all over.

I increased to 45 colonies, and from one colony took 4 supers of the nicest and whitest honey I ever saw, and it has 2 supers on yet.

July 4th was exceedingly hot in this locality. The thermometer was 115 degrees in my house; at different places in the Valley 2 miles from my home it was 120 degrees, and 5 miles below it was 122 degrees. I heard that some places in the San Joaquin Valley it was as high as 138 degrees, dogs went mad and had to be killed, and men became insane and jumped out of windows. The combs in hives with brood and sections full of honey melted down to the bottom, drowning everything. I lost at least \$50 worth of bees and honey. I raised all the covers during this hot weather, and had shade-boards on all the hives.

This is a good bee-country, and I would like to make a business of bee-keeping. But I am alone, have poultry besides, and have to do my own cooking and housekeeping, so I am afraid I shall not make a success of it.

BERNHARD SCHNOCHEL.

Monterey Co., Calif., July 13.

### Different Races of Bees

In speaking of races of bees, the different authorities on bee-keeping do not give a description sufficiently definite to enable those unacquainted with the different races to distinguish one from the other, except perhaps the 3-banded light and dark, and the golden or 5-banded, Italians. I wish some one would describe the Caucasian, the Cyprian, the Carniolan and the Holy Land bees, giving size, color, and general appearance.

Just now all these different bees are being advertised for sale, and very many bee-keepers know nothing about them. I have been acquainted with the different colored Italians and the Egyptians, but the other varieties named I have never seen, nor read nor heard a clear description of, by any of the authorities on bees. DR. G. BOHRER.

Rice Co., Kans., July 31.

### Very Short Honey Crop

As far as I can learn the crop so far is short—very short. We had a very unusual cold and wet spring. May 29 bees were starving. They have been very slow to breed up since then, and were not in good condition for the first honey-flow, which is just past. We will hope the next crop will be a great deal better. I am running for extracted honey, although nearly all other bee-keepers are producing comb honey. J. T. HAMMERSMARK.

Washoe Co., Nev., July 31.

## Second Hand... Comb Foundation Mills

### Honey Glassware

We have for sale a 6-inch and a 10-inch Second-Hand Comb Foundation Mill. Used scarcely any; good as new. If interested write for prices.

$\frac{3}{4}$ -lb. and 1-lb. Octagon **Tip-Top Glass Honey-Jars**. Prices:  $\frac{3}{4}$ -pounds, \$4.50 a gross; 3 gross for \$13. 1-lb., 1 gross, \$5.25; 3 gross for \$14.50. Address,

## YORK HONEY AND BEE SUPPLY CO.

(Not incorporated)

141 Ontario Street, - CHICAGO, ILL.

## THE DEMAND FOR Moore's Strain of Italians

Is greater this season than ever. Why? Because his **FAMOUS LONG-TONGUED RED-CLOVER STOCK** has won a world-wide reputation for honey-gathering, hardiness, and gentleness. They were working so thick on a field of red clover at haying-time that the man who cut it was afraid to drive his horses into it to mow it. Their long tongues enable them to secure nectar beyond the reach of short-tongued bees.

Untested Queens, 75c each; six, \$4; dozen, \$7.50. Select Untested, \$1 each; six, \$5; dozen, \$9. Safe arrival and satisfaction guaranteed. Descriptive circular free.

Address, **J. P. MOORE, Rt. 1, Morgan, Pendleton Co., Ky.**

### CONVENTION NOTICES.

**National.**—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.

Flint, Mich. **W. Z. HUTCHINSON, Sec.**

**Missouri.**—The Missouri State Bee-Keepers' Association will meet in Sedalia, Aug. 22 and 23, opening session to be at 2:30 p.m., Aug. 22. The room to meet in will be named later on. The State Fair meeting there at the same time will obtain low railroad rates from all parts of the State. The Livestock Association also meeting there on the 24th will give us some inspiration. Hon. Geo. B. Ellis, Secretary of the Agricultural department, will be there and give a talk and lend a helping hand. Louis A. Osborn, of that place, has kindly offered to act as host, and will direct to the place of meeting and to accommodation. Hotel accommodations can be had at \$1 to \$2 a day. Private boarding cheaper. Let us turn out en masse and have a glorious time as well as to effect some extraordinary progress.

**W. T. CARY, Sec.**

### DON'T BE BOTHERED

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

CHICAGO, Aug. 4.—Fancy white, 14c; No. 1, white, 13@13½c; fancy amber, 11@12c; No. 1, amber, 9@10c; fancy dark, 10c; No. 1, dark, 9c. White extracted, 6@7c; amber, 5@6c; dark, 5@5½c. Beeswax, 28c.

The new crop is appearing and selling in a fair way considering that this is midsummer time. R. A. BURNETT & CO.

ALBANY, N.Y., July 26.—There is some call for honey, new crop, and if here would probably sell for best prices of season, as the general impression is there will be a large crop. White comb honey will start off at 15c to early buyers. H. R. WRIGHT.

KANSAS CITY, July 20.—New comb honey has made its appearance; fancy white in 24-section cases selling at \$2.75 per case; No. 1 at \$2.50, and good demand. There is no new extracted in as yet, market on old stock being quotable at from 5@6c. Beeswax, 25@28c. C. C. CLEMONS & CO.

CINCINNATI, Aug. 2.—At this writing there is a good demand for extracted honey; shipments are arriving daily. New comb honey is coming in quite freely, although the demand is only fair, a condition which may be expected early in the season. We quote amber extracted in barrels and cans at 5½@6½ cents respectively. White clover extracted at 7@8½c. Fancy white comb at 12@15c. Beeswax, 26c. THE FRED W. MUTH CO.

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6½@7½c per pound. Beeswax, 26c. THE COLO. HONEY-PRODUCERS' ASSN.

NEW YORK, June 19.—The comb honey market is very quiet and we are hardly justified in making quotations. Some few lots are sold here and there at 13c for fancy, and 10@12c for lower grades, but no large blocks could be moved at these figures. There is still considerable of last year's crop unsold, part of which, no doubt, will have to be carried over until the fall. Extracted honey in fairly good demand. New crop California honey selling at 6½@7c for water-white, 6@6½c for white, and 5@5½c for light amber. Southern at 50@60c per gallon according to quality. Beeswax somewhat declining; choice average stock selling at 29c. HILDRETH & SEGELKEN

PHILADELPHIA, Aug. 7.—Some honey arriving, with prospects of a good crop all through the East, but no call for comb honey during the hot weather, so that prices are not as yet established. Extracted honey arriving freely. We quote as follows: Fancy white, 7@8c; amber, 6@7c. Beeswax, 27c.

We are producers of honey and do not handle on commission. WM. A. SELSER.

CINCINNATI, O., Aug. 8.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5½@5¾c; in cans, 5½@6c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 2.—White comb, 1-lb. sections, 9@10 cents; amber, 7@8c. Extracted, water-white, 5@5½c; white, 4¾@5c; light amber, 4@4½ cents; amber, 3¾@4c; dark amber, 2¾@3c. Beeswax, good to choice, light, 25@29c.

There has been no noteworthy movement in honey during the current week. Prices remain steady as quoted. Receipts have been of fair size and show a very superior quality. Local jobbers complain that apiarists are holding above the ideas of local dealers and therefore little business is done.

## PURE BASSWOOD HONEY

IN 60-POUND CANS

We have a good supply of Pure Basswood Honey in 60-lb. cans that we can ship by return freight at these prices: 1 can in a box, at 8 cents a pound; 2 or more cans, boxed, at 7½ cents—all f.o.b. Chicago. Cash with order. Sample, by mail, 8 cents in stamps, to cover package and postage.

Please mention Bee Journal when writing.

# "Experience Teaches a Hard School"

**I**T is a bad plan to give your order for Sections and Shipping-Cases, or in fact anything in the bee-supply line, to the man who quotes you the lowest price. There's as much difference in bee-goods as there is in people. Last spring a bee-keeper in Michigan wrote to firms throughout the country for prices on a large bill of goods. Some of the quotations he received were delightfully low and inviting, much lower than "Lewis" offered them at. The man took all his catalogs and correspondence to an old bee-keeper of long experience and asked his advice. **Result:** WE GOT THE ORDER.

**LEWIS' GOODS** are worth every cent they cost, and whether you receive them in the dead of winter or at the height of the honey-flow, or when your bees are swarming, they will fit accurately, admit of being put together quickly, and will be found to be made of the finest material. This saves you time; this saves you trouble; this saves you honey, and time, trouble and honey mean money to you. Your honey put up in goodshape will bring higher prices, and the demand for it will be increased from year to year. This factory's reliable goods have started many a man on the road to success.

# What is the United States Government Doing for the Bee-keeper?

A general view of the Experimental Apiary of the U. S. Government, at Washington, D. C., in charge of Frank Benton. Photographed by D. E. Lyon.

## Do You Know?

Do you realize to just what extent Uncle Sam has the interest of his bee-keepers at heart? Few do. To get the whole truth we have sent Mr. D. E. Lyon to Washington with instructions to place before the readers of *Gleanings* just what is being and what intends to be done by the Division of Apiculture of our great National Department of Agriculture at Washington. Mr. Lyon gives the results of his journey in the August 15th number of *Gleanings*. What he tells is intensely interesting, and every bee-keeper should know the facts. Mr. Lyon has also obtained some splendid photos, which are reproduced in this number.

Mr. Frank Benton, head of the Division of Apiculture, is now on a journey around the world in search of new Bees and Honey-Plants. *Gleanings* keeps in close touch with him, and its readers are always sure of obtaining news first hand of this most remarkable trip.

### Grading Rules

In the August 15th issue of *Gleanings* is found another article of greatest practical value to bee-keepers. It is headed, "Comb Honey Grading Rules." Hardly one bee-keeper in ten understands grading, which is of such importance in marketing comb honey. For this reason there is much confusion and loss. *Gleanings* has written to the most prominent Honey Dealers all over the United States, and gives their replies in this number. It's an important thing to know how to grade your honey, and *Gleanings* tells you.

### Superb Illustrations

The illustrations in the August 15th issue of *Gleanings* are typical of what its readers receive every number. Three full-page halftones, some smaller ones, and many fine draw-

ings illustrating the numerous short articles. The halftones are the work of the finest engravers in the United States, and are printed on the best paper, giving results that are hardly equaled in many high-class magazines. This item alone doubles the value.

### Bee-Keepers Everywhere

*Gleanings* aims to make itself indispensable to *every* bee-keeper *everywhere*. It has succeeded. No progressive bee-keeper can afford to be without it. In every issue are departments that cover the peculiar conditions that are met in different parts of the country. The editors of these departments are the best practical bee-keepers in their respective localities. The best of bee-keepers everywhere contribute. A list of them would be a list of the most successful bee-keepers in the United States. What bee-keeper can not profit by reading the experiences of such men?

# AMERICAN BEE JOURNAL

Entered at the Post-Office at Chicago as Second-Class Mail-Matter)

Published Weekly at \$1.00 a Year by George W. York & Co., 334 Dearborn St.

GEORGE W. YORK, Editor

CHICAGO, ILL., AUGUST 24, 1905

Vol XLV—No. 34

THE AMERICAN BEE JOURNAL is absolutely an independent publication, and not connected with any bee-supply business whatsoever. It stands entirely upon its merits as an educative force in the field of bee-keeping, and as a medium for legitimate advertisers in apicultural or other lines. It is the oldest, and only weekly, journal of its kind in America. Its publishers believe that it deserves to be in the hands of every would-be progressive successful bee-keeper in the land. It is in its 45th year, and to-day is acknowledged to be better in every way than at any time during its long and honorable history.

## Editorial Notes and Comments

### Contradictions in the Bee-Papers

Occasionally the view is expressed that there are so many conflicting views in the bee-papers that it is discouraging; so discouraging that one would do better to give up such reading altogether. There is no disputing the fact. Just so long as you read bee-books and bee-papers you will find contradictions. If you never read a word about bees you would find contradictions in your own experience.

The contradictions you find in print sometimes are due to the fact that wrong views are entertained, and sometimes to the fact that what is true in one locality is not true in another, and often to the fact that some little difference in management is not recognized, but that same unrecognized difference in management makes a wide difference in results.

Often, too, the reader gets two opposite views from two different writers because said reader does not fully understand what one or both said. But if you keep on reading and studying, you will gradually get more and more of the tangles straightened out. It would be the height of folly to give up trying to obtain the advantage of the experience of others just because the experience of different writers is not always the same.

### Big Purchase of Honey

Gleanings in Bee Culture chronicles the purchase in one consignment, by the National Biscuit Co., of 70 carloads of honey. That is not because honey is the cheapest sweet. It is not because the National Biscuit Co. lacks business capacity, and recklessly spends money for a higher-priced article when something else as good could be bought for less money. It is because honey gives to the goods in whose manufacture it is used a keep-

ing quality that can be had in no other way. If it is a profitable thing for this money-making company thus to use honey, why is it not just as profitable in the home of every bee-keeper? Instead of making a fresh cake "when company comes," said cake to be kept till thrown away when dry and stale, why not make that which will keep the year around?

In all cooking, honey may be used in place of sugar, only keeping in mind that less moisture must be used with honey than with sugar.

### Selling Comb Honey in Frames

For some this may be an advisable thing. Here's the way L. L. Grass does it, as reported in Gleanings in Bee Culture:

I produce comb honey by using extracting-supers and shallow extracting-frames with starters. These weigh from 3½ to 5 pounds when filled out, according to thickness of comb in a frame. This I sell at 15 cents a pound by the frame or frames. I weigh it before starting, and put the weight of each frame on the top-bar. Customers seem to appreciate that style of package, and I very seldom fail to make a sale to those who need honey, after I have held it up to the light to let them see the clearness.

I carry it to market in the supers by tacking a strip of wood half way down the ends of the supers with slots sawed out to hold 8 frames to a 10-frame super. That keeps them from rubbing and breaking the cappings when some combs are thicker than others after grading. It also keeps them from sliding, which they would do after the first frame is taken out.

### Slow Introduction of Queens

There are conditions in which a queen will be promptly and kindly received, no preliminary caution being necessary. The queen is simply dropped into the hive or run in at the entrance, and all is well. But there is

always some risk, and, as a general rule, the element of time is an important factor. The queen is sometimes caged in the hive for a certain length of time, then set free upon the combs by the bee-keeper, but generally it is planned to have her liberated by the bees. To make them longer in liberating her, the candy may be made quite hard, or pieces of card-board may be nailed over the opening so that the bees must take time to gnaw away the card-board to get at the candy.

One of the American Bee Journal family thinks he has made an improvement over these plans. It is the very simple one of making as small as practicable the tube containing the plug of candy. Instead of having the diameter a half inch or so, it is only a quarter of an inch, allowing only one bee at a time to work at the candy. It will be readily seen that this will make slow work, but work that is pretty sure to go steadily forward, because the candy is fully exposed. With a small diameter, the time taken to liberate a queen in an introducing cage may be varied directly in proportion to the length of the tube.

### Cleaning a Bee-Smoker

When a thick coating forms inside the smoker pour in a little kerosene and set fire to it, leaving the smoker open. The deposit can then be easily scraped off while hot and soft, or peeled off when cold. This from J. A. Green, in Gleanings in Bee Culture.

### Sawdust for Smoker-Fuel

The question as to the best fuel for smokers is one largely of convenience. Each one is likely to have a preference for that which is most easily obtainable. To those who have unlimited quantities of sawdust at disposal, the very minute instructions of S. E. Miller, in the Progressive Bee-Keeper, may be of use. He says:

I used sawdust from under my buzz-saw table, which is mostly from pine or other soft wood, and the smoker is of the upright boiler (fire-pot) pattern, the kind now in general use.

Directions: First, put down on the grate a small wad of excelsior or fine shavings. In the absence of both of these use grass. Put on just enough to keep the sawdust from sifting down through the grate into the space beneath it. Next fill the fire-pot to within about three-fourths of an inch of the top with sawdust soaked and packed down until it is packed somewhat firm, but not too solid. Then with a pointed stick bore a hole down

## \* Some Expert Opinion \*

in the center by running the stick down nearly to the grate and giving the upper end a rotary motion so as to form a funnel-shaped hole in the sawdust. Into this hole drop about a teaspoonful of kerosene. I keep a 10-cent oiler with kerosene (coal oil) in it where it is handy, and find it useful in firing up, even when I do not use sawdust.

Now light a match and drop it into the hole and set the smoker outside with the cover thrown back, and leave it so for 15 or 20 minutes. Do not close it too soon or it will smother out in short order. After it is well started put some green grass on top of the sawdust to act as a spark arrester and close it up. Give several puffs to make sure that it is well started, and if you have done everything just right, you will be ready for 3 or 4 hours' work without replenishing of fuel.

When it gets too hot and begins to throw sparks it will be necessary to grab up a bunch of green grass and put it on top to keep down the sparks.

### Destroying Queen-Cells

Nearly every beginner, at some time in his career, conceives the idea that if he persistently destroys all queen-cells that are started, there will be no swarming. But he finds in time that bees will swarm in spite of such efforts, and concludes that the destruction of queen-cells has no effect whatever. Yet some experienced bee-keepers declare that in many cases destroying queen-cells one or more times is sufficient to prevent all swarming. Under such efforts some colonies will be prevented from swarming, others will not. The seasons may make a difference—undoubtedly do. Some seasons bees seem to have a mania for swarming; other seasons a good many colonies will make no attempt at it. Whether there is profit in destroying queen-cells is an open question.

### Drone-Brood for Fish-Bait

Some years ago this was mentioned, and now it comes up again in gleanings, more particulars being given. The knights of the rod "specify that the age of the brood shall be just before hatching, when the young drones are white. A young white drone is removed from the cell and strung on the hook. Its color and shape at once suggest to the fish a big, fat grub, and anglers say that fish will bite this bait as they will bite almost nothing else. It is especially adapted to all fish with large mouths like bass, bluegills, and the like."

### More Honey from the Basswood Leaves or the Blossoms?

**Ques. 29**—*Is it true that the bees gather more from basswood leaves than from basswood blossoms?*

S. T. PETTIT (Ont.)—No.

O. O. POPPLETON (Fla.)—I don't know.

J. M. HAMBAUGH (Calif.)—I think not.

JAS. A. STONE (Ill.)—I do not think it is.

E. D. TOWNSEND (Mich.)—No, not in this locality.

L. STACHELHAUSEN (Tex.)—No basswood in this locality.

ADRIAN GETAZ (Tenn.)—No, unless in exceptional circumstances.

N. E. FRANCE (Wis.)—No. I did not know that basswood leaves yield honey.

G. M. DOOLITTLE (N. Y.)—Bees gather nothing from basswood leaves in this locality.

C. P. DADANT (Ill.)—I think not. I have never seen much from either, in this locality.

DR. J. P. H. BROWN (Ga.)—I can not answer, as I do not live in a basswood location.

EUGENE SECOR (Iowa)—Not in this locality. I never saw bees gather anything from basswood leaves.

E. WHITCOMB (Nebr.)—I do not know. It is at least 75 miles from my apiary to the nearest basswood tree.

J. A. GREEN (Colo.)—I think not. They may get honey sometimes from the leaves, but ordinarily, at least, not in any quantity.

DR. C. C. MILLER (Ill.)—I shouldn't suppose so. I've seen many a bee working on the blossoms, but never one on the leaves.

REV. M. MAHIN (Ind.)—I think not. I have never seen them gathering from leaves, and in my locality I am pretty sure they do not.

R. C. AIKIN (Colo.)—I never lived in a regular basswood region, and don't think leaves yield any except in cases of insect honey-dew.

P. H. ELWOOD (N. Y.)—I never saw our bees work on basswood leaves. I never suspected that they gathered an ounce from that source.

E. S. LOVESY (Utah)—As to quantity, I have had no experience on this question, but as to quality I would say that no real, pure nectar is collected by the bees from leaves such as they collect from the flowers. The product on the leaves is produced by a small

insect of the aphid family; the dew softens it, and hence it is called "honey-dew," and bees and other insects gather it.

PROF. A. J. COOK (Calif.)—No, by no means. They gather wholly from flowers, except there are aphids or scale insects in the trees working on them.

MORGAN BROS. (S. Dak.)—Basswood leaves yield very little. Basswood honey is secreted in the calyx of the flower, and may be seen sparkling in the sunlight.

ARTHUR C. MILLER (R. I.)—Bees do not work on basswood leaves here. But basswoods are few and far between, the European linden taking their place, and the bees go only to the blossoms of that.

C. DAVENPORT (Minn.)—This is something I never heard of until lately. I never saw the bees work on the leaves, and I do not believe they ever do here. I will watch this matter closely in the future.

R. L. TAYLOR (Mich.)—Sometimes I have seen the bees apparently working a little on basswood before the blossoms are open, but not when they are open. But a trifle if any nectar is gathered from the leaves here.

MRS. J. M. NULL (Mo.)—I would like to know. I don't relish the notion of basswood honey-dew. We don't have it in this neck of the woods. All honey-dew, or at least most of it, is derived from hickory leaves here.

C. H. DIBBERN (Ill.)—I never knew that bees gathered any honey from basswood leaves. It is not true that they gather more from that source than from the blossoms, otherwise why do many bees visit the basswoods when not in bloom?

E. E. HASTY (Ohio)—I don't think it is a common state of things, although it may have happened sometimes, especially in recent years when the crop was small. Specks the old-fashioned 10-pounds-a-day basswood honey never came from the leaves.

WM. McEVOY (Ont.)—No. Some seasons the bees gather honey-dew from the leaves, but this condition of affairs happens so rarely that it's not worth counting, and although it is really honey-dew it gets spoiled by the countless millions of "stuff" that feast upon and soil this class of honey.

G. W. DEMAREE (Ky.)—No, not in my locality. In fact, bees do not gather "honey" from the leaves of basswood, or any other kind of leaves. But under certain conditions, not very well understood, bees gather a dark, sweet substance (condensed sap) called "honey-dew." But in my locality honey-dew does not show up more than once in 5 years.

### Bee-Paralysis and Pickled Brood

BY ADRIAN GETAZ

**D**URING the years from 1894 to 1896 quite a discussion on bee-paralysis occupied the bee-papers. Many articles and reports were written, and a number of remedies tried and the results reported. It must be remembered that at that time bee-paralysis seemed to have been much worse than usual. In fact, whole apiaries had been wiped out entirely.

It is in the early spring that the malady is the worst. It is shown by a large majority of the bees being hairless and

shiny, as if they had been polished. At the same time they are stiff and sluggish in their movements, as if half-paralyzed. Those in which the disease is less advanced show it by uneasiness and frequent scratching and twisting of the wings and abdomen. As the season advances the old, shiny bees gradually die out, young bees emerge in large numbers and take their place. It is possible—even probable—that some at least of the young bees contract the disease when in the larval state, but as bee-paralysis is a slowly developing disease, they do not show the signs of it until some time after having emerged, more or less, according to how bad the case is.

When the number of healthy, or comparatively healthy, young bees has sufficiently increased so that the management of the colony (if I may use that term) falls into their hands, they soon realize that something is wrong with the old, shiny bees, and proceed at once to throw them out of the hive. This is sometimes done gradually, but usually all at once. That is, when the old bees have not already died out from old age and sickness.

During the summer the bees do not live long enough to reach the shiny stage, unless it be in exceptionally bad cases, but plenty of them can be seen shaking and quivering.

## CAUSE OF BEE-PARALYSIS.

Microscopic and bacteriological investigations have shown that bee-paralysis is due to the presence of a bacillus. The expression "a bacillus" does not mean that there is only a single one in each diseased bee, but it means that all are of the same kind. That kind is called *Bacillus Gaytoni*.

What is bacillus, or what are the *bacilli* of different kinds? Bacilli are classified as "plants," though they are not at all like flowers, trees, grass, etc. They are like very small rods. The kind of bacilli, or to use accepted terms, the bacillus that produces foul brood is only one-thousandth of an inch long, and one 40-thousandth of an inch thick; while that producing bee-paralysis is only one 15-thousandth long and one 35-hundredth thick.

When bacilli have attained their full size, they break into two or more pieces. Each piece grows until full size, and breaks also, and so on. This process lasts as long as there is plenty of nourishment and sufficient heat and moisture. When these conditions fail, the rods become spores of a more rounded form. These spores will resist the disinfectants, poisons and other noxious substances; also the extremes of cold and heat, far better than the rods. They will keep alive without developing for quite a length of time, and then turn into rods when the proper conditions are met with. The body of a larva affected may contain, not thousands, but millions of these rods. When the larva dies they still consume the soft parts and multiply for awhile, and then turn into spores, escape, and float in the atmosphere. Some reach the honey and remain there, and likely some are taken in by the bees or brood in the act of respiration, or otherwise.

But here comes the most remarkable part of the program. These spores, which resist heat, cold and chemical agents so well, require a certain amount of moisture to keep up their vitality. Dry air does not contain enough. So those of the spores that have not found a safe lodgement in the honey or the bodies of some larvæ or bees, dry out and lose their vitality in the course of a day or two. And this is a general rule (there are some exceptions) with all kinds of bacilli. Every one knows how beneficial sunshine and dry climates are to the sick people.

## CULTIVATION.

Here the question might be raised, How do we know that these tiny creatures do the mischief—such little things that it takes the most powerful microscope to see them.

Well, we know it by *cultivating* them. Small glass vials about a half-inch in diameter and a few inches long are prepared. In these are placed some beef-broth, gelatine, milk, or anything on which we think the bacilli will thrive. The vials are stopped with some cotton, then carefully heated and otherwise treated so as to make sure that no germ from the air, or anything else, can get in and interfere with the *culture*.

Suppose we want to study the bacilli producing foul brood or bee-paralysis. We cut a small piece of the extremity of the tongue of a bee from the diseased colony. That piece contains a minute drop of blood, and that drop, minute as it is, a number of bacilli. We put it in the vial. Soon after the bacilli begin to multiply there just as they would in the body of a bee. We can study them easily, and ascertain all we want about them. Then, to be sure that we are right, we take some of that culture, feed it to some bees or brood that we know to be healthy. Then if the disease develops we know that we have the bacilli wanted, and that said bacilli are the cause of the disease.

## DEVELOPMENT.

The chief difference between foul brood and bee-paralysis is that the first is a rapidly developing disease, and the other a slowly developing one.

The first result is that in the cases of foul brood, the brood infected dies before ready to seal, or soon after. This does not occur with bee-paralysis. The malady develops so slowly that the affected brood would not die until some time at least after having emerged. It is possible—even probable—that the majority of sick bees contract the malady only after reaching the adult state.

It is often said that foul brood is a disease of the brood, but not of the adult bees. That is an error. All the microscopical investigations made have shown bacilli in the adult bees—workers, drones and queens, as well as in the brood. Even the ovaries of the queen have been found infected. Such being the case, it may seem strange that the malady is not propagated by the adult bees unless they carry some infected honey. It is a known fact that sick bees go out of the hive and die away from it. Cheshire thinks that since foul brood develops so rapidly, the bees which contract it get very rapidly too sick to remain in the hive, and go out to die before they can infect the others.

## INFECTION FROM THE QUEEN.

It is an indisputable fact that bee-paralysis may be transmitted by the queen. Probably by laying infected eggs. The malady is very contagious, anyway, and spreads very rapidly from one hive to the others.

Some writers have said that there are two stages, so to speak, of the disease. In the first the disease is about as I described at the beginning of this article. But sometimes a turn for much the worse comes all at once; the bees become shiny rapidly, the work is almost neglected, young bees just emerged, or only two or three days old, are shaking and quivering; and ere long the colony perishes.

When it comes to that point it is probable that the eggs laid by the queen are infected. I don't know whether any microscopical examination to that effect has been made or not. In fact, bee-paralysis has been studied very little yet, and much remains to investigate.

I had one case like that once, upon which I tried an experiment. While the colony had reached the worst stage of the disease, it was pretty strong yet. The honey-flow was good, and the temperature sufficiently high. I removed the queen and gave the bees a young laying queen. In due time her progeny hatched out, strong and healthy, or apparently so, and soon after they cleaned out the old bees. Of course, the disease reappeared, but nothing to be compared to what it was while the old queen was there. Evidently the old queen was infected and was laying infected eggs. I did not make a microscopical investigation. I have neither the time, the means, nor the ability necessary for that kind of work.

## REMEDIES.

A great many were tried during the years referred to at the beginning of this article. The most popular were re-queening, salted water, and sulphur.

Re-queening is not a cure, but always an improvement, especially if the old queen is more or less diseased already. In any case, a young prolific healthy queen would cause an increase of young, comparatively healthy bees, and that of itself would be a considerable improvement.

The other remedies are of but little account at the best. Every few days somebody reports having applied sulphur, salt, or something else, and met complete success—the shiny bees had completely disappeared. Unfortunately the disease invariably reappeared the following spring. As the old, shiny bees would have disappeared anyway—either died out or been driven out—the conclusion forced itself upon the mind that the remedies used had but little effect at the best.

## CAMPHOR.

My bees had the disease from the beginning. It kept on increasing during several years until I finally either had to do something or quit keeping bees. The bacilli are in every part of the bodies of the bees or brood, chiefly in the blood. The spores may be anywhere in the hives, and very likely like those of the foul brood in the honey and pollen. Feeding with carbolic or salicylic acid would fail to reach the spores, and perhaps act only in the digestive organs of the bees. Dusting with sulphur or other similar substances would certainly kill whatever spores or bacilli it would reach, but would fail to reach the honey, especially if sealed, or even the blood or other interior organs of the bees. Spraying would not be much better. Fumigating would be the thing, the vapors would penetrate everywhere in the hive, even through the cappings, and through the bodies of the bees also.

This may seem rather "off," but it is not. The bees and other insects breathe through a far more complete apparatus than the higher animals. What we might call their lungs ramify and penetrate everywhere throughout the whole body. Evidently some substance that would evaporate freely would be preferable, as then the fumigating would be done automatically. At last I decided to try my camphor and crude carbolic acid. By that time the winter was at hand. I put a piece of camphor in some hives and a very small dish of carbolic acid in the others.

When the spring came a considerable improvement was noticed. The colonies were much stronger, the number of shiny bees very much smaller than ever before. There was but little difference between the two remedies, and what may have been was in favor of the camphor, so I dropped the carbolic acid. Neither one can be used during the summer. The carbolic acid, if given in anything like an effective quantity, is liable to cause the bees to abscond. As to the camphor, they enclose it in an envelop of wax and propolis in less than 24 hours after it is given.

For several years I repeated the treatment every winter with the result that the disease became less and less, and finally disappeared, as far as I could see. Then I discon-

tinued the treatment. But last summer (1904) I saw again a few bees here and there twitching and scratching, showing that the cure had not been complete. The malady might have been re-introduced from abroad. If it was, it came through some of the queens I bought, as there are no bees near enough mine to give them the disease. But I rather think that the cure was not complete.

Bee-paralysis is a very erratic disease. Sometimes it appears, or disappears, or nearly so, without any cause or reason that can be assigned. And it is possible that the disease decreased of itself, and that the supposed effect of the camphor applied was a mere coincidence.

#### PICKLED BROOD.

This seems to be essentially a disease of the brood, or rather of the pollen first, and then the brood fed on that pollen. The first intimation of it is some larvae having a dull appearance, and stretched or turned in a wrong position. More and more are seen, and as the disease advances they become a kind of yellowish gray, eventually turning to brown. Most of them finally die before being sealed, others only after.

When a large portion of the brood has become diseased, the bees discontinue brood-rearing entirely, and cease to bring in pollen. Eventually the sound brood hatches out, and the dead larvae dry enough so that the bees can take them out, which they do. They also clean out the infected pollen, and if at that time the hive is examined, the combs will be found as bright and clean as they can be. The queen has died, and no attempt at rearing another has been made. This has invariably occurred in every case that I have seen, when left to themselves. It seems, therefore, that the queen also becomes diseased, which is likely to be, since she receives the same nourishment as the larvae. The adult bees and drones seem to remain healthy throughout. However, if a microscopical investigation is ever made, it may show a different state of affairs.

The malady is not contagious, or very little if at all, and does not spread from one hive to the other. Some one in these columns suggested that since the malady is not contagious, it would be best to break up the colony and distribute the combs among the other colonies. I certainly would not risk it. Because the malady is not contagious from *hive to hive*, it does not follow that it is not so from *comb to comb* in the same hive. In fact, it spreads over all the combs of an infected hive, and there is no reason why it should not do so where a diseased comb is introduced in a healthy colony. It would be easy to try, but I don't care to do it.

If the queen gets sick, the cessation of brood-rearing may be due to her condition. However, it is not so in all cases. I once removed the queen and put in her place a young laying queen. She laid a few hundred eggs and quit. The bees made no attempt at brood-rearing, and did not even resume pollen-gathering. The eggs remained unhatched some 8 or 10 days, and finally disappeared.

#### CAUSES OF PICKLED BROOD.

Some have said lack of honey, some lack of pollen. It is neither one. I never had a case yet where there was not some honey, and sometimes there was a considerable quantity of it. It certainly is not the lack of pollen. In my locality, pollen could be had by the ton the whole summer, from pumpkins, melons, corn, ragweeds, and lots of other sources in succession. When the disease reaches a certain point, the bees cease to bring in the pollen; that's all there is to it.

The investigations of Dr. Howard show that the disease is due, not to a bacillus, but to a fungus—*Aspergillus Pollini*. It develops in the pollen, and thence into the digestive apparatus of the brood. Dr. Howard thinks that the malady could be carried from one hive to the other by robber-bees. So far as I remember, the most I had of it in any one year was 4 colonies in one apiary and 3 in the other. Last year I had 1 case, and the year before none. That does not look much like contagion.

#### CURE FOR PICKLED BROOD.

The advice is usually given to melt the combs, pollen, brood and all, and start the colony on foundation again. That always seemed to me to be too much trouble, and I never have done it. I let the thing go through its course, and when the bees have cleaned everything I give them a queen and some brood to start anew. I have tried carbolic acid, given as described above, that is, letting its vapors do the work. It is effectual. The only trouble is that if enough is given to effect a cure within a reasonable time, the bees may abscond.

The case I had last summer was discovered early; there was but little diseased brood yet, and quite an amount of sound brood nearly all sealed. I didn't want to lose all that

brood, so I caged the queen, intending to come back 21 days later, after all the sound brood would be out, and then disinfect the combs by putting them in a box and burning sulphur. Somehow or other I was delayed, and when I visited the hive the bees had already cleaned everything thoroughly. I gave them another queen and some brood. The malady has not reappeared.

#### STARVED BROOD.

Several times dead brood has been sent to Prof. Cook for identification. In some of his contributions he states that the brood sent him looked merely like starved brood. It may seem strange that such a thing should occur more often in California than elsewhere, but in reading the "Rambles" of J. H. Martin, in *Gleanings*, we find the statement that in many parts of California the summer temperature during the day reaches 100, and even 110 degrees, sometimes more. And in looking at the half-tone engravings, we see the hives, single-walled at that, exposed to the hot sun without any protection whatsoever. More than that, the hives are right on the bare ground, in a climate where it does not rain the whole summer. Who does not know that in dry and hot weather the temperature of the ground exceeds considerably that of the atmosphere? And with the hot sun above, and the radiation of the hot ground below, the temperature to which these hives are exposed must be excessive. When the temperature is too high the bees are forced to abandon the hive. The brood left behind starves, or is overheated—likely both. Then the unlucky (?) Californian sends a piece of it to Prof. Cook, asking if it is pickled brood or bee-paralysis!

#### POISONED BEES.

Occasionally bees are poisoned by gathering nectar or pollen from fruit-trees that some ignorant person sprayed during blossoming time. Some cases of bees dying from the emanations of copper-melting furnaces or similar kinds of establishments have been reported. And, very often in such cases, the apiarist has thought that his bees had some disease.

Another cause of trouble is the gathering of nectar or pollen from plants having narcotic properties. Several kinds are known, but here (in the United States) the only important one is the yellow jasmine. The bees affected look, or rather act, very much like those having bee-paralysis, and frequently the two cases have been taken for each other.

#### DISEASES OF BEES.

Bee-paralysis and pickled brood have not been studied seriously yet. We barely know enough to recognize them, and none too well at that. Foul brood has been more thoroughly investigated, and yet it is only a short time ago that we finally learned to distinguish it from black brood and pickled brood. And the distinction is not yet as fully established as it might be.

A cause of mistakes may be the presence of more than one disease at the same time in the affected colony.

Recently, Prof. Lambotte, of Liege (Belgium), asserted that the so called *Bacillus alvei* was merely the well-known *Bacillus mesentericus vulgaris*. He was certainly mistaken, but it has since been suggested that both might have been present in the diseased colonies, and thus misled him.

More recently (last summer, 1904), Dr. Burri, of Zurich, (Switzerland), began a new study of the foul brood. He found in some cases the regular foul brood bacillus (*Bacillus alvei*), with all the characteristics described by Cheshire and Cheyne, and later by Prof. Harrison, of Ontario (Canada). In some other cases he found another kind of bacillus, which is extremely difficult to "cultivate," and therefore to study. Occasionally the bacillus mesentericus is found, but in small quantity, and seems to be accidental.

A third kind of bacillus has been seen, but seems to be very rare.

There is, furthermore, some acid brood—something like what we call here pickled brood—but Dr. Burri found it always in samples having also foul brood. It is caused by a kind of bacteria which do not form spores, and therefore is not a bacillus.

Other institutions in Germany have also taken up the question, and we may before long be thoroughly informed on all these questions.

Cheshire, in his examinations of diseased bees (see his book, Vol. II), found several organisms besides the foul brood and bee-paralysis bacilli, but he did not have the time to study them.

In Germany, in 1897, a peculiar disease was observed. Young bees incapable of flying came out and died in heaps. Much of the brood was dried up, retaining its form. It could not be cut with a knife, but broke to pieces under pressure.

The cause was ascertained to be a fungus similar to the one (*Oidium albicans*) which attacks the mouth of infants.

Prof. Leuckart has also described a fungus (*Oidium Leuckarti*) which causes injurious, but not disastrous, effects in the intestines of bees.

Much is to be studied yet. Knox Co., Tenn.

**Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904**

(Continued from page 485)

**A NATIONAL HONEY EXCHANGE.**

"Is there any movement on foot regarding a honey exchange or any method whereby the National Association can market its members' honey?"

Pres. York—There was a movement started in St. Louis to organize a National Honey Producers' Association, and there were some subscriptions of stock taken.

Dr. Miller—But not for the National?

The President—It was started in the National convention.

Dr. Miller—I think you are right that there was a movement started there to get up a honey exchange, but not that the National was to do anything about it.

Mr. Whitney—From the report which was sent me I think the Doctor is right. There was an attempt to organize something inside of the National, or by individuals who belonged to the National becoming stockholders of the new corporation if it was formed, for that purpose.

**CASH FOR PROOF OF ADULTERATED COMB HONEY.**

"I suggest that this Association offer \$500 for two pounds of comb honey that is proved to be adulterated."

Pres. York—I don't know who suggested that, or where the \$500 is to come from, but the intention no doubt is all right. It is proposed that this Association offer \$500 for two pounds of comb honey. I suppose it is meant two pounds that the bees didn't make. What are you going to do with it?

Mr. France—I think nearly all here are members of the National and this was threshed over very thoroughly at St. Louis. I don't know why it should be brought up again. We know that manufactured or so called artificial comb honey has not been made or placed upon the market, and there is no necessity of agitating that matter here at length.

Mr. Wilcox—I read the proceedings of that convention at St. Louis, and I think all who have read it understand if anything is to be done it will need to come in a little different form from this. But I hardly see the necessity or advantage of trying to do anything. But if we do, we should need to put it in proper form or else we would create a wrong impression and say something we didn't intend.

Mr. Whitney—It seems to me it would be better to let the individual who manufactures that pound of honey take the A. I. Root Company's \$1,000 for it. I understand they have an offer, and have had it for years, to pay \$1,000 to anybody who produces the proof. If I were going to manufacture that pound of honey I would rather go to them.

"What can this Association do to counteract the evil effect of the publication of the manufactured-comb-honey story in the press of the country? Can we do anything? If so, what?"

Mr. Dadant—Publish statements to the contrary.

Dr. Miller—I doubt very much the ability of this Association as an association to do anything, but I don't at all doubt the ability of the individual members to do something by working through the local press. They can do a great deal in that direction. I doubt the wisdom of any action on the part of this Association.

Mr. Whitney—On that question I have something interesting—to me, at least. I heard of a merchant in this

city who sold a lady a case of honey, and the next day she sent it back and came in in a day or two after to tell him she had sent that honey back. She said, "That is manufactured honey. It came from South Water street; it was made by machinery, and I never bought any such honey as that." He told her that she was mistaken, and convinced her it was not manufactured; that it was put in by the bees. She finally consented to let him send the honey back to her house. But there are plenty of people who really think that there is plenty of manufactured comb honey on the market. I meet them at home; intelligent people on everything else but bees and honey; they don't know anything about it.

Mr. Moore—Some of you may think we are threshing this thing out at unnecessary length. My specialty has always been honey for private families. Some of us visit the people who eat our honey on their tables, and you will all admit that they are not quite the biggest clumps on earth that are running the city of Chicago, large and small, rich and poor; and I want to tell you, from all those people, of all conditions in life, comes this question, "Is comb honey really manufactured?" And they ask me as an expert to answer it. "Is most of the honey on the market manufactured?" This comes to me in one hundred and one different ways. I have one answer. Of course I say that all comb honey is pure honey. Some of you perhaps do not come in touch with these folks in the way I do, and you think it is a question that we are putting too much stress upon, but every one of you ought to carry the idea through your lives, that whenever you can you want to strike a blow in favor of the right. Dr. Emma Walker, in the Ladies' Home Journal, put forth a statement in which she said that one of the largest uses of paraffin was to make manufactured comb honey. Then and thereupon I wrote to her contradicting it, and I wrote to the editor saying that it was absolutely false, and it was wrong for any one in her position to put forth a statement that would injure a large number of people. Mr. York also wrote to the editor a personal letter. We both got answers. I suppose that that department was flooded with letters from all over the country. We looked with a great deal of interest to see what would be done. Perhaps two months afterwards came the answer, an article in which she summed the thing up and said this and that authority said it was so; and that the Encyclopædia Britannica said that there was manufactured comb honey, and gave four or five different authorities stating that comb honey was manufactured and paraffin was largely used. But she summed it up at the bottom by saying that "after talking with practical bee-keepers and considering the matter in all its points we have decided that there is no such thing, and never has been, as manufactured comb honey." It was the result of our influence. Now, all of you go through life and remember to use your influence wherever you see the opportunity. Wherever you see in the newspaper an article with this falsehood, go to the newspaper, or write, and have it contradicted, if possible, and do not let a single instance go by of contradicting this infamous lie that has been passed around from one end of the world to another. That is the way in which this Association, and we as individuals, can do good; whenever we see a head, hit it!

(Continued next week.)

**Honey as a Health-Food.**—This is a 16-page honey-pamphlet intended to help increase the demand for honey. The first part of it contains a short article on "Honey as Food", written by Dr. C. C. Miller. It tells where to keep honey, how to liquefy it, etc. The last part is devoted to "Honey-Cooking Recipes" and "Remedies Using Honey". It should be widely circulated by those selling honey. The more the people are educated on the value and uses of honey the more honey they will buy.

**PRICES, prepaid**—Sample copy for a two-cent stamp; 50 copies for 70 cts.; 100 for \$1.25; 250 for \$2.25; 500 for \$4.00; or 1000 for \$7.50. Your business card printed free at the bottom of the front page on all orders for 100 or more copies. Send all orders to the office of the American Bee Journal.

**Some Facts About Honey and Bees.**—This is the subject of an article written by Mr. J. E. Johnson, and published on pages 581-82 of the American Bee Journal for Aug. 25, 1904. We have republished it in 4-page leaflet form for general distribution, and furnish it, postpaid, at 35 cents per 100 copies. Send all orders to the office of the American Bee Journal

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Mrs. and Mr. Honaker and Their Apiary

I am sending you to-day a picture of a portion of our bee-yard, showing Mr. Honaker and myself. The bee-keeper has a scowl on her face, which her husband declares is "quite natural."

The yard is located in the garden directly back from the dwelling-house, so that all hives are in view from the dining-room windows. There are in all about 60 colonies, 3 or 4 more than were taken out of the cellar last spring. This is the number usually kept. All colonies have stored considerable surplus this season, duplicate hives being generally used for supers. All supers have honey in them, all but two or three being practically full. Besides what is now on the hives, we have perhaps taken off 600 or 700 pounds. The picture shows the apiary as it is to-day, having been taken less than a week ago.

The shrubby back of the hives where Mr. Honaker stands is red raspberry bushes, which, at the present time, are well loaded with ripe fruit. The young trees shown further back are 6-year old walnut seedlings, some of which are perhaps 15 feet in height. Nearly all swarms that have issued the last two years have settled on these trees, often breaking down limbs with their weight.

Back of the garden is a cornfield, just now beginning to tassel. In the distance, on the line between our farm and a neighbor's, is a large cherry-tree, which may be seen for many miles in all directions.

We use a large 12 frame hive, something like the Dadant hive. We produce mostly extracted honey, using always queen-excluders between upper and lower stories. We have no basswood within reach, our main crop coming from white clover, although alfalfa is grown quite extensively on our own and neighbors' farms. We have a small field of alfalfa, which, if it does well, will be enlarged another season. I am fortunate in securing a bountiful honey crop this season, considering that we have only the one dependence from which to obtain it. I have never had any foul brood in my apiary, although it is possibly at no great distance from us.

MRS. MILLIE HONAKER.

Vernon Co., Wis., Aug. 4.

### Laying Workers—Bees Moving Eggs, Etc.

MY DEAR MISS WILSON:—You have helped me so often through the American Bee Journal that I am afraid my gratitude is of the sort described as "a lively sense of favors to come." So I am sending you some of my summer bee-puzzles.

You helped me when I first began keeping bees, 3 years ago; last year I wrote to you about making artificial increase with Italian queens; this time my questions are chiefly as to the "ways that are dark" of the bees themselves.

I was in California all last winter, and did not return to unpack my bees till the middle of May. I think this was rather an advantage, as the spring was unusually cold. Two colonies out of 33 were dead, but the majority were in splendid condition, having nearly double the amount of bees and brood they had in May of last year, and they had no feeding. Only one colony had the listless, dispirited look about it that made me say before I opened it, "I expect this hive has no queen." But there was a queen, and brood, too, though only on 2 combs; but the capped brood was all drone-brood in worker-cells, and there were 3 vacant queen-cells at the bottom, and I thought it must be a case of a drone-laying queen. An unusually early

swarm came out that day, and I put what bees there were (not very many) in with it, and killed the queen.

Lynch law—and the innocent murdered as usual! I put the brood in with the swarm, and a week later the rest of it was all beautifully capped worker-brood.

I have now another colony that I think has only laying workers. Over a month after swarming I found brood on 7 combs, but all the capped brood was drone-brood in worker-cells. This time I waited a week and looked again. Still there was no worker-brood, and there were a lot of queen-cells with little grubs in them. I cut these all out, and stapled 2 capped Italian queen-cells on the comb. Two days later they had not torn them down, and I hope the colony will right itself. If I do not find the worker-brood after 3 weeks, what should I do? Is it possible to find and destroy laying workers, and then give a laying queen? I was afraid they might kill one, if given with the laying workers in the hive.

I have been rather unfortunate with my queens. None of them are clipped, but I have found as many as 6 crawling on the ground. Three came out with first swarms, so I hived them as with clipped queens. Two are doing well, but the third has been another puzzle. I gave them one comb of honey at one side of the hive, and one comb of brood at the other, and the rest foundation only. A week later the bees had queen-cells on the brood-comb, and also on the corner of the new foundation next to it, and I could not find the queen. I gave them Italian brood, after cutting out the other queen-cells, and after 21 days I found a fine young queen and eggs on one comb.

I should have thought the old queen got hurt in swarming and died just after, if it had not been for the queen-cells—and queen-cells *only*—on the new foundation. The cells had good brood in them, which could only have been put there after swarming. Do you think they killed the queen as soon as they had gotten her to lay in their new queen-cells? Now ants carry their eggs about. Have worker-bees ever been known to carry eggs from worker-cells to more conveniently-placed queen-cells when deprived of a queen?

Now for my last puzzle, though I have a feeling that I am asking very foolish questions. But it is one of the best ways to learn.

A colony swarmed June 17. I did not know that it had swarmed before, but the brood left was all capped. I saw the queen that issued with the swarm go into the new hive, but I could find neither queen nor queen-cells in the old one. I gave them a comb of brood, and a day or two afterward I found 15 queen-cells on it. Feeling sure now that they had no queen, I waited till the brood was 7 days old; then I cut out all the queen-cells and gave them a comb of my best Italian brood, on which they immediately reared a number of fresh queen-cells. Ten days after I gave this brood, I looked again and found all the queen-cells capped, and some "nibbled" by the bees ready for hatching; and then, to my surprise, I saw on the comb among the capped brood several cells of baby brood. To make "sure" into "certain," I went home and got the magnifying glass. There they were, healthy looking larvae, some looking only a day or two days out of the egg, and only 8 in all, uncapped on the comb. There was not an egg anywhere or a queen, that I could see.

Not wishing to lose the Italian queen-cells, I divided the bees and put the comb with the cells on in another hive, giving the old hive a fresh comb of brood. On this they have reared a lot more queen-cells, but there has been no fresh brood in the hive.

Now with all these queen-cells I can hardly think there ever was a laying queen in the hive. But where did that tiny brood come from?

Bee-books say the eggs hatch at 3 days, and are capped at the 9th. This is of course the rule, but do they ever hatch when a week old? The eggs of other insects often remain a long time before hatching. The hive with the other half of the bees and the queen-cells reared a fine-looking queen, but misfortune pursued them, too, and I suppose she was lost on her flight. There is no queen there now, and they are hard at work at queen-cells again.

Thus far there has been very little surplus honey; most of my colonies have not begun to put anything in the supers yet. Hitherto I have used only a top starter in my sections, but as you and Dr. Miller so strongly recommend a bottom one also, I am trying them in a number of marked supers to see the result in this locality.

COLORADO.  
July 22, 1905.

No, it is not possible to find and destroy laying workers. A laying worker looks like any other worker, and the only way you could distinguish one would be to find it in the act of laying while you held the comb in your hand. You might spend a long time before succeeding in this, and then when you had succeeded you would have put out of the way only one of a goodly number of workers engaged in the miserable business of laying eggs that by no possibility can produce worker-bees.

You did a good thing to give them a sealed queen-cell, for they will accept a cell when they would kill a queen. In the meantime, however, the colony will be rapidly diminishing in numbers, and you can give it aid without waiting until the prospective queen begins to lay. From any colony with a laying queen, take one or two frames of brood, selecting the youngest you can find, and exchange for one or two frames in the invalid colony. If you are willing to take the extra trouble, it will be better to take only one frame from a colony, and by drawing one each from four or more colonies you can give your patient quite a set-up. Neither will this cost very much to the colonies from which the brood is taken, if you select combs mostly filled with eggs and young brood.

There are those who are very positive that bees carry eggs from one place to another; others are skeptical about it. But it is not necessary to suppose there was any such transportation in the case you speak of, where eggs were found in queen-cells on foundation. Did you ever stop to think that in the usual course of events *every* queen is superseded by the bees? That superseding takes place generally in the latter part of summer, and it would be nothing strange if a good many queens made preparation for a successor immediately after being hived with a swarm. A queen may do excellent work at laying up to a certain time, perhaps up to the time of swarming, and then fail rapidly. If she disappeared from your colony entirely, before her successor was ready to set up in business, it is not likely the bees killed her, but that she died from old age. And old age may come to a queen before she has lived a year, or not till she has lived 5 years.

Before any attempt at a guess in the case of your last puzzle, allow the remark that you need not worry as to any question about bee-keeping being considered foolish, unless it be one plainly answered in the books of instruction which bee-papers are supposed to supplement. Especially when one shows such intelligent powers of observation, any questions arising are likely to bring out points of interest that may be instructive to others as well as to yourself. A good questioner is, in an indirect way, a good instructor.

The presence of those few cells of young brood might be accounted for in more than one way. A queen might have been in the hive, and after having laid only a few eggs, she may have been accidentally killed by you when the hive was opened—queens are sometimes killed in that way. Laying workers might have begun work, and then desisted. As good a guess as any is the one you yourself have made. Eggs do remain in a hive sometimes without hatching for a number of days. Dzierzon reports a case of the kind.

After trying bottom starters, kindly report whether a success or otherwise.

**"The Honey-Money Stories"**

We have just issued a 64-page-and-cover booklet, 5 $\frac{3}{4}$  x 8 $\frac{1}{2}$  inches in size, printed on enameled paper, entitled, "The Honey-Money Stories." The cover has a picture of a section of comb honey, 3 $\frac{1}{2}$  inches square, the comb being in gold-bronze, which gives it a very attractive appearance. Then on the gold-bronze comb are printed these words: "From Honey to Health, and from Health to Money."

It is edited by Earl M. Pratt, and contains a variety of short, bright stories interspersed with facts and interesting items about honey and its use. The manufactured comb honey misrepresentation is contradicted in two items, each occupying a full page, but in different parts of the booklet. It has in all 31 halftone illustrations, nearly all of them being of apiaries or apiarian scenes. It also contains 3 bee-songs, namely, "The Hum of the

Bees in the Apple-Tree Bloom," "Buckwheat Cakes and Honey," and an entirely new one, called, "The Bee-Keepers' Lullaby." This last song has not been published before. The songs alone ought to be worth more than the price of the whole thing.

It is a booklet that should be placed in the hands of everybody not familiar with the food value of honey, for its main object is to interest people in honey as a daily table article. It is thought that it will be just the thing to sell on railroad passenger trains, on news stands, etc. The stories and items are all so short and helpful, and the pictures so beautiful, that it will likely be kept by any one who is so fortunate as to get a copy of it. Its postpaid price is only 25 cents, but the health-value of its contents would run up into dollars. We mail 5 copies for \$1.00, or club it with the American Bee Journal—both for \$1.10. It would be very nice for a gift to a friend.

I looked at it again, but it was not yet completely capped, so I left it for another week, and when I again opened the hive I found that every bit of the honey had been taken from the combs. What became of that honey? The last week has been a little cloudy, but there has been occasionally clear weather, so that the bees could fly out, and they seemed to be doing good work.

I suppose I should have put the empty super under the full super, but I did that last year and the bees carried all the honey down into the empty super, and of course lost a good deal of time. This year I put the empty super on top, and lost all the honey.

4. I had one colony that swarmed 3 times. The bees would settle, and before I could have them they would go back into the old hive. They did this 3 times. What was the matter with them? That was a month ago, and they have not swarmed since.

5. I never clipped a queen yet. In fact, I have never been able to find the queen in any of my colonies, though I have looked many times. The bees all look alike to me.

OREGON.

ANSWERS.—1. Yes, if weather is cloudy and rainy immediately after a swarm is hived, it should be fed. When they have used up the honey they carried with them in their sacs, the bees have no stores in the hive to fall back upon, and if not fed must starve.

2. As nearly as I can make out, after the specimen has been crushed in the mail, what you send is the egg of the cockroach, dark brown or black, and larger many times than the egg of the moth, which is white, and round as a marble.

3. Although it seems pretty rapid work for the bees to carry all the honey out of the super in 2 weeks' time, there seems no other way to account for it. The honey-flow must have stopped, and the bees carried the honey down into the brood-chamber. If the honey-flow stopped long enough, the bees would carry the honey down, no matter whether the empty super was under or over the full one.

4. Some would say they went with the queen on her wedding-trip, but Mr Doolittle says bees don't do that. It is possible that the queen was not able to fly with the swarm, and the swarm would then go back into the hive. The queen crawled back into the hive the first and second time, but the third time she was lost, and then the swarm did not go again. The usual thing would be for the bees to swarm again when the first virgin queen issued from her cell; but the stoppage of the honey-flow at that time prevented the swarming.

5. If you persevere you will undoubtedly succeed in finding a queen, and having found one it will be easier to find others. Look for a bee larger than the workers, with wings that look too short for her size.

**Why No Honey Coming In ?**

In this locality we have had no honey so far, and almost no swarming. There has been plenty of white clover and some other bloom, but absolutely no honey, while last year all supers were full by July 15, and there was free swarming. There is no disease. The bees simply stay in the supers and don't work, and but few bees are to be seen on the flowers. What is the trouble? KANSAS.

ANSWER.—I don't know. I only know that sometimes there is abundance of white clover in bloom and bees can get nothing from it, and at other times when no bloom is to be seen the bees fairly roll in the nectar. Some have said it was owing to electrical conditions.

**Bees Tearing Down Queen-Cells**

I had one colony queenless and gave them a frame of brood. The third day after, they had 4 queen-cells started. The next time I looked they were capped. When they had been capped about a week I looked into the hive again, intending to cut them out, but found that the bees had torn them down before it was time for them to hatch out. I also found that 2 artificial swarms with queen-cells

**Doctor Miller's Question-Box**

Send Questions either to the office of the American Bee Journal, or to DR. C. C. MILLER, Marengo, Ill.  
 Dr. Miller does not answer Questions by mail.

**Uniting Colonies—Space Under the Frames**

1. What is the best way to unite 2 colonies of bees at this time of the season?

2. Is it detrimental to best results to have a 2-inch space in the brood-chamber under the frames? NEW YORK.

ANSWERS.—1. I don't know. What might be best in one case might not be best in another. Here's one way that is good: Kill the queen in one of the hives, and 2 or 3 days later set this hive over the other with 2 or 3 thicknesses of newspaper between, making a hole in the newspaper large enough for one or two bees to pass at a time. A few days or a week later you will find that the bees have eaten away much of the paper, and you can then put into the lower story the frames of brood that were in the upper story.

2. Only good can come of it any time except during the gathering season, and then the space must be reduced to  $\frac{3}{4}$  inch or so. If the full 2 inches are left when bees are gathering, they will build comb below the bottom-bars.

**Plan of Superseding Queens**

What is the matter with the plan of killing undesirable queens, and changing their brood for the brood of the best queens? It looks as if this might be practiced to quite an extent in many apiaries. I am doing some of it now. IOWA.

ANSWER.—The plan will work all right, and you are wiser than the average to take that much trouble to improve your stock. The only "matter" I can see with the plan is the trouble it takes, but the gain ought to pay well for the trouble taken. Could not the work be lightened by having sealed cells ready in advance, giving a sealed cell in an introducing cage at the time of killing the queen? Better still, a virgin queen? I must confess that I have taken still greater trouble in superseding several queens, caging in the hive a laying young queen taken from a nucleus with the candy of the cage covered so the bees could not get at it, and two days later killing the old queen and leaving the candy so the bees could eat it and release the queen in the cage. This is the plan of introducing advocated by Emerson T. Abbott.

A private word shows a tendency to regret

having written about bees. Please don't cherish thoughts of that kind. I don't believe others are so different from myself, and I have always enjoyed seeing what you have written.

**Taking Off Honey—Bee-Keeping as a Business**

1. How early is it safe to take off comb honey that contains no bee-bread, and pack it away in shipping-cases?

2. I have 91 colonies with from 2000 to 3000 pounds of comb honey. This has been a good year, and if I had been prepared for the work I would have had a much larger yield. But I teach school 9 months in the year, 30 miles from my bees, so you will understand that my vacation is a busy one. I am thinking very strongly of going into the bee-business and dropping school work.

The American Bee Journal is a fine paper and full of valuable information. IOWA.

ANSWERS.—1. To get the best price for comb honey it is well to take it off as soon as it is sealed, because it is whiter then, and the market demands the whitest combs. If left on longer it will be better to the taste in all probability, but the comb will not be so white.

2. Don't think of depending upon bees alone till you have enough money ahead to tide you over one or more years of failure.

**A Beginner's Experiences**

1. I am a beginner, having started last year with 4 colonies, and last spring I bought 2 more colonies, with the expectation of getting 6 new swarms. Three swarms issued from them, but 2 of them died shortly after they were hived. The weather was cloudy and rainy. Do you think they should have been fed? I did give them syrup a couple of times.

2. I found some eggs in one of the swarms that died, and am sending them to you, and would like to have you tell me what kind of eggs they are. Are they moth eggs?

3. We had very nice weather last spring, and honey began to come in early. One colony had very nearly one super full of honey, but it was not quite all capped over, so to make room for the workers I put an empty super on top of this one. About a week later

had done the same thing. I gave one of them another frame of brood. What is the matter with these colonies? WISCONSIN.

ANSWER.—The probability is that a young queen had emerged from her cell. Her first care would be to see that all rivals were out of the way. Possibly you may say that you are sure that could not have been the case, for you looked the combs over very, very carefully, and every queen-cell was torn open at the side, the end of the cell being entire, showing that no queen could have emerged from it. In that case a virgin from elsewhere may have entered the hive. Oftener than you might suppose a virgin or a laying queen enters some hive other than her own. Sometimes, however, bees take a notion to destroy cells with no apparent reason for it.

### Italian Bees Practically Moth-Proof

What bees, if any, will keep moths out of hives? What bees are best to keep moths out of? ARKANSAS.

ANSWER.—No bees will succeed perfectly in keeping the moth entirely out of the hives. Any bees will succeed to a large measure, if colonies are kept strong. Italians are very much better than blacks. Even a nucleus of Italians will defend themselves quite well against the moth. Not a thought need be given to any danger from moths in strong colonies of Italians with laying queens.

### A Queen Experience

A colony that swarmed July 19 was put on a new stand and given a virgin queen, which the bees apparently liberated July 20. She immediately (I suppose) tore out all the queen-cells. July 21 the hive was opened, the cage removed, and the frames put in order. Twenty minutes afterward the queen was dead outside the hive. Was the queen accepted for a time, that is, long enough to destroy the queen-cells, then killed by the bees when the hive was opened? All of these bees were afterwards run through perforated zinc, and given brood in all stages, but no queen-cells were started, nor can I find any signs of laying workers. What is the matter? Would you try to reduce such a colony? INDIANA.

ANSWER.—Hard to tell just what was the matter. The supposition that the virgin you gave was accepted, allowed to destroy the cells, and then killed by the bees within 20 minutes after you opened the hive is hardly tenable. Left to themselves, it is very unlikely that the bees would turn upon the queen after she had destroyed the queen-cells. If your opening the hive made the bees attack the queen, they would be a good deal longer than 20 minutes in killing her, for she would be killed by balling, which probably means starving to death. It is possible that you might accidentally have killed her yourself. That the bees should have been sifted through an excluder so as to exclude any queen, and then should refuse to start queen-cells, is at least very unusual. It is possible that there is a queen in the hive, however. Virgin queens are up to tricks, and one of their tricks is to enter some hive other than their own. Just as soon as you got through sifting, and had turned your back, a virgin may have entered from elsewhere.

If you find no eggs present by the time the queen, (if they have a queen), is 2 weeks old, you have your choice either to break up the colony or to give it a queen. In the meantime, if you desire to keep the colony going, give it frames of unsealed brood and eggs from elsewhere, to keep up its spirits and its strength. It would do no harm also to give a queen-cell, which will be destroyed if anything in the shape of a queen is present.

## Reports and Experiences

### Poor Honey Prospects

The honey prospect for Grant and Crawford counties is very poor this year, owing wholly to the bad weather. It has been mostly rainy, cloudy, and cold. It has rained every day for 9 days up to to-day, and it threatens now. Not all the time, but from one to four showers a day, some of them very hard ones. It is impossible to make hay or do any farm work. We have about one-third of a usual basswood bloom, and it is open now.

The season is far advanced, the honey season is almost over, and our hives are not full—yes, they lack a good deal of it. May the American Bee Journal still come, and we will hope for a better crop next year.

Grant Co., Wis., July 8. L. G. BLAIR.

### Putting Weak Colonies Over Strong Ones

On page 570, in referring to Mr. Bevins' loss of queens when he put 2 weak colonies over at many strong ones, Mr. Hasty says, "The scheme is important enough to justify more reports, large and small." Here is a small one:

Early in April 9 colonies of a little less than medium strength were put over as many stronger ones. For an experiment 6 of the 9 pairs were left in that way till the middle of June, working peaceably in the same supers above the upper brood-nest, and each queen doing her full duty. The other 3 pairs were taken down at the opening of clover, and each pair put into a tenement hive, wide enough to give each queen 5 Langstroth frames on her own side of a bee-tight division board, and covered with a zinc-excluder. They have not only gone through the early harvest, but through a *three weeks' dearth*, and are still occupying the supers in common harmoniously. I consider that in this report 2 things should be noted which may amount to conditions: First, the bees used were pure 3-banded Italians, and Second, The upper colonies were strong enough to cover fairly well 3 Langstroth combs. I could not be confident of success with hybrids, and should expect a pint of dysentery-stricken bees to lose their queen regardless of purity or race. It may be well to say that the 6 pairs worked one above the other were on frames 5 $\frac{3}{4}$  inches deep, and the 3 worked in tenement hives are on Langstroth frames. E. W. DIEFENDORF. Cooper Co., Mo., Aug. 12.

### "Honey, Honey Everywhere"

I never could see much difference in the honey-flow one year with another in this vicinity during the past 16 or 17 years. Every year seemed to be about the same. Some years the fall flow would be good and the spring flow light. Other years the spring flow would be the better. But this year is an exception right through.

I started the season with 271 colonies and did not have over 30 swarms. The fact of it is the bees did not have time to swarm. The season started with a little robbing among themselves, and they cleaned out a few of the neighbors' hives. Then fruit-bloom started, and I noticed that the bees were humming quite loudly. I got the surplus boxes on nearly all, and the fruit-bloom lasted about 2 weeks. By this time the most of the colonies had their supers finished and one colony had 2 completely finished. Then the raspberry and white clover flow started. I run out of sections as I wasn't expecting such a flow, but I have a horse-power machine for making hives and I cut out chunk-honey frames for the surplus boxes. I cut out pieces 1 $\frac{1}{2}$  inches wide, and just so they would drop inside of the end-bars of the section-holders, and tacked a piece of tin about one inch square on each end to keep them from dropping down, the

tin resting on top of the end-blocks of the section-holders. I fastened the foundation on these top-bars by nailing a little strip right down on the edge of the foundation.

The flow seemed to get better all the time. The only trouble was to give the bees room enough, and to get the honey off the hives. Some of the colonies built comb on the outside and under the bottom-boards. The basswood flow was splendid, and there is a heavy buckwheat flow on now. I have honey piled up everywhere. Butter tubs are full; I bought all the barrels in the 3 nearest towns, and they are full; I built a large tank; the honey-house is piled full of supers clear to the top, and there must be 700 or 800 full supers on the hives that should be taken off at once. There would surely be a drop in the New York market if I shipped all this honey at one time, but there is no danger of that, as it will take me from now until next spring to get it all weighed! I can't sleep nights for dreaming about automobiles, big iron tanks, and bees. Wm. KERNAN.

Sullivan Co., Pa., Aug. 9.

### CONVENTION NOTICE.

National.—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel. Flint, Mich. W. Z. HUTCHINSON, Sec.

## Langstroth on the \*\*\* Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

Please mention Bee Journal when writing Advertisers.

# Tennessee Queens

Owing to the great demand for my TENNESSEE QUEENS for several seasons, and the quantity of standing orders from old customers, I decided not to advertise until my books were cleared of orders, and thus avoid disappointing customers.

I am now ready to fill orders by RETURN MAIL. Breeders used: Imported dark leather-colored Italian; my selections from light imported Italian; Moore's long-tongue; golden; Carniolan (mated to Carniolan drones in distant yard, and to Italian drones); imported Caucasian (lately received, mated for the present to Carniolan and Italian drones).

## Italian Queens by Return Mail

The STANDARD-BRED kind. Untested, 75 cents each; 3 for \$2.10; or 6 for \$4.00. They give satisfaction. Or the American Bee Journal for a year and a Queen for \$1.50. Here are some unsolicited testimonials from those who have had our Queens:

### What They Say of Our Queens

GEORGE W. YORK & Co.

After importing queens for 15 years, you have sent me the best. She keeps  $9\frac{1}{2}$  Langstroth frames fully occupied to date, and although I kept the hive well contracted, to force them to swarm, they have never built a queen-cell, and will put up 100 pounds of honey if the flow lasts this week.  
CHAS. MITCHELL.  
Ontario, Canada, July 22, 1905.

GEORGE W. YORK & Co.

The two queens received of you some time ago are fine. They are good breeders, and the workers are showing up fine. I introduced them among black bees, and the bees are nearly yellow now and are doing good work.  
A. W. SWAN.  
Nemaha Co., Kans., July 15, 1905.

GEORGE W. YORK & Co.

The queen I bought of you has proven a good one, and has given me some of my best colonies.  
N. P. OGLESBY.  
Washington Co., Va., July 22, 1905.

GEORGE W. YORK & Co.

The queen received of you a few days ago came through O. K., and I want to say she is a beauty. I immediately introduced her into a colony which had been queenless for 20 days. She was accepted by them, and has gone to work nicely. I am highly pleased with her and your promptness in filling my order. My father, who is an old bee-keeper, pronounced her very fine. You will hear from me again when I am in need of something in the bee line.  
E. E. McCOLM.  
Marion Co., Ill., July 13, 1905.

## An Untested Italian Queen-Bee FREE as a Premium

For Sending One New Subscriber

for the American Bee Journal for a year with \$1.00.

As has been our custom heretofore we offer to mail a fine Standard-Bred Untested Italian Queen to the person who complies with the following conditions, all of which must be strictly followed:

1. The sender of a new subscriber must have his or her own subscription paid in advance at least to the end of this year.
2. Sending your own name with \$1.00 for the Bee Journal will not entitle you to a Queen as a premium. The sender must be already a paid-in-advance subscriber as above, and the new subscriber must be a NEW subscriber; which means, further, that the new subscriber has never had the Bee Journal regularly, or at least not for a whole year previous, to his name being sent in as a new one; and, also, the new subscriber must not be a member of the same family where the Bee Journal is already being taken.

We think we have made the foregoing sufficiently plain so that no error need be made. Our Premium Queens are too valuable to throw away—they must be earned in a legitimate way. They are worth working for.

Address all orders to

GEORGE W. YORK & CO.

Office and Salesrooms, 2146-48 Central Ave. Warehouses, Freeman and Central Aves.

## Honey and Beeswax

CHICAGO, Aug. 18.—The demand has absorbed all the offerings of fancy and A No. 1 grades of white comb honey at 14c, while No. 1 has sold at 13@13½c. No call at present for other than the best grade, it really being difficult to place what ordinarily is called No. 1. Extracted, white, 6@7c; amber, light and dark, 5@6c. Beeswax, 28c. R. A. BURNETT & Co.

ALBANY, N.Y., July 26.—There is some call for honey, new crop, and if here would probably sell for best prices of season, as the general impression is there will be a large crop. White comb honey will start off at 15c to early buyers. H. R. WRIGHT.

KANSAS CITY, July 20.—New comb honey has made its appearance; fancy white in 24-section cases selling at \$2.75 per case; No. 1 at \$2.50, and good demand. There is no new extracted in as yet, market on old stock being quotable at from 5@6c. Beeswax, 25@28c. C. C. CLEMONS & Co.

CINCINNATI, Aug. 18.—The heavy requests for offers on honey recently, have a tendency to lower the prices. We are striving hard to maintain good prices, by giving our friends more than their honey is worth, to hold up the market. So far we have been successful. Still offer extracted honey as follows: Amber in barrels and cans at 5¼@6¼c, respectively. White clover at 7@8½c. We feel that lower prices will prevail in the near future.

Comb honey is coming in quite freely. We quote fancy white comb honey at 12@15c. The arrival of Western car-load shipments of comb honey is anticipated daily, after which the market will be shattered as to prices. Beeswax, 26c. THE FRED W. MUTH CO.

DENVER, June 26.—The demand for both comb and extracted honey is light at present, and there is enough of old stock on hand yet to last until the new crop comes in; the same is selling as follows: No. 1 white comb, per case of 24 sections, \$2@2.20; No. 2, \$1.75@2. White extracted, 6¼@7¼c per pound. Beeswax, 26c. THE COLO. HONEY-PRODUCERS' ASSN.

NEW YORK, Aug. 18.—No new comb honey on the market as yet, and very few inquiries so far. Extracted is in fairly good demand and we quote: California at from 5¼@7c per pound, according to quality and quantity. Southern in barrels from 5@6c per gallon. Beeswax remains steady at 26c per pound. HILDRETH & SEGELKEN

PHILADELPHIA, Aug. 7.—Some honey arriving, with prospects of a good crop all through the East, but no call for comb honey during the hot weather, so that prices are not as yet established. Extracted honey arriving freely. We quote as follows: Fancy white, 7@8c; amber, 6@7c. Beeswax, 27c.

We are producers of honey and do not handle on commission. W. M. HENDER.

CINCINNATI, O., Aug. 8.—There is no demand for comb honey on account of the warm weather. Extracted is in usual demand for this season of the year. We quote white clover at 7@8c; amber, in barrels, at 5¼@5½c; in cans, 5¼@6c. Beeswax, 28c. C. H. W. WEBER.

SAN FRANCISCO, Aug. 9.—White comb, 1-lb. sections, 9@10 cents; amber, 7@8c. Extracted, water-white, 5@5½c; white, 4¼@5c; light amber, 4@4½ cents; amber, 3¼@4c; dark amber, 2¼@3c. Beeswax, good to choice, light, 27@29c.

The honey market shows little change this week. All dealers have large stocks and all new arrivals show an excellent quality. White honey which has been received in this market is of a very superior quality and is meeting with a fair demand. Prices are being held at the figures quoted, though trading is very light.

## FOR SALE

Until further notice, fine quality new crop California Water-White White Sage and Light Amber HONEY in 60-lb. tins, 2 in a case; new cans and new cases. Write for prices and samples, and state quantity you want.

HILDRETH & SEGELKEN  
265 & 267 Greenwich Street, NEW YORK, N.Y.

# SEPTEMBER SPECIAL

## Cash Discount for Early Orders

We can not remember a year when we were not crowded with orders through the spring months, and somewhat behind, some years more than others. In order to divert some of this trade to the fall and winter months, we have offered inducements in the way of an early-order cash discount. This year we will be more liberal than ever before in the amount of discount allowed. For some months the price of some of the materials used has been a little lower, and we have stocked up heavily, and propose giving you the advantage of the saving in price. The abundant farm crops throughout the country are stimulating trade in almost all lines, and prices are already stiffening. The discounts which we propose to offer for early cash orders are as follows:

For cash orders before	Oct. 1.....	10 percent.
" "	Nov. 1.....	9 "
" "	Dec. 1.....	8 "
" "	Jan. 1.....	7 "
" "	Feb. 1.....	6 "
" "	March 1.....	4 "
" "	April 1.....	2 "

You will notice that, after January, the discount drops 2 percent a month; and if we find that advancing prices of materials do not warrant the larger discount, we reserve the right to reduce the amount of discount at any time. Your safest plan is, therefore, to order at once.

This discount is only for cash before the dates named, and is intended to apply to hives, sections, frames, foundation, extractors, smokers, shipping-cases, cartons, and other miscellaneous bee-keepers' supplies. It will not apply on orders for the following articles exclusively; but where these form no more than about 10 percent of the whole orders, the discount may be taken from the entire bill: Tinned wire, paint, Bingham smokers, Porter bee-escape, glass and tin honey-packages, scales, bees and queens, bee books and papers, labels and other printed matter; bushel boxes, seeds, and other specialties not listed in our general catalog.

## Beeswax and Comb Foundation

To compensate for the large early order cash discount we propose to increase the trade price of wax; and until further notice we will pay 26 cts. cash, or 30 cts. in trade, for average wax delivered here or at our branches. When you take trade at 30 cts. a pound you will not be entitled to the early-order discount on the supplies.

The price of comb foundation was reduced Aug. 1 two cents a pound, and the revised price stands as follows:

GRADE.	Size, and sheets per pound.	In lots of				
		1 lb.	5	10	25	50
Medium Brood.....	7 $\frac{3}{4}$ x 16 $\frac{1}{2}$ 7 to 8	55	53	51	49	48
Light Brood.....	7 $\frac{3}{4}$ x 16 $\frac{1}{2}$ 9 to 10	57	55	53	51	50
Thin Super.....	3 $\frac{3}{4}$ x 15 $\frac{1}{2}$ 28	62	60	58	56	55
Extra Thin.....	3 $\frac{3}{4}$ x 15 $\frac{1}{2}$ 32	65	63	61	59	58

The early-order cash discount applies to the reduced price of foundation, making a total net reduction of 7 to 8 cts. a pound for September orders. We recommend that shipment of foundation be avoided in extreme cold weather, and to that end it would be well to get in your supply in the fall. Use your leisure time in winter to nail and paint your hives, put up sections, and prepare other articles ready for the spring rush.

## Extra-Long Bee-Gloves

Having made arrangements for our supply of gloves from a factory making a specialty of their manufacture, we save enough in the cost to enable us to offer them either with or without fingers at 35 cts. a pair; by mail, 42 cts.

## No-Drip Shipping-Cases

Don't allow your Comb Honey to be sold at low prices on account of poor Shipping-Cases. Put your crop into Root's No-Drip Cases and it will reach the market in perfect condition, thus bringing satisfactory returns. Our Cases are made of selected basswood, with 2 or 3 inch glass front, which shows off the honey to the very best advantage. Below is a condensed price-list. Complete prices and particulars are found in our general catalog.

Shipping-Cases. Name and Size of Case.	Nailed each.	Price complete including 3-in. glass one side, nails and paper, in flat.			With 2 in. glass instead of 3- per 100.	Without the glass, per 100.
		1	10	100		
12-in. 4-row for 4 $\frac{1}{4}$ section.....	30	25	2 00	\$18 00	\$17 00	\$16 00
10-in. 4-row " ".....	30	25	2 00	17 00	16 00	15 00

6 $\frac{1}{4}$ -in. 3-row " ".....	25	20	1 40	11 50		10 00

## The Simplex Jar

The handsomest glass package on the market. It's a package you need not be ashamed of, and will find its way beside the finest of the grocery shelves. Create a demand for your honey.

This is a new jar with glass screw-top and rubber gasket fitted to the taper screw on jar, which seals absolutely air-tight. Put up in re-shipping cases of 2 dozen jars each, with corrugated protectors.

Price \$1.10 per case; 6 cases @ \$1.05; 20 cases or more @ \$1.00.

## 5-Gallon Square Cans

The above cut shows the favorite package for shipping extracted honey. There is no shrinkage and consequent leaking; no taint to the honey from wood, as is so frequently the case with barrels and kegs. The cans, being made square, economize space, and are easily boxed. They are used exclusively in the far West. Take 4th class freight-rate.

PRICE LIST OF SQUARE CANS.

No. in a box.	Capacity of each can in gallons, in honey.	Price of		Wt. of 1 box.
		1 box.	10 bxs.	
1	5-gal. can boxed.....	60 lbs. \$ 55	\$ 5 00	10 lbs.
2	5-gal. " ".....	60 " 85	8 00	15 "
10	1-gal. " ".....	12 " 1 50	14 00	20 "
12	1 $\frac{1}{2}$ -gal. " ".....	6 " 1 50	14 00	20 "
24	3 $\frac{1}{4}$ -gal. " ".....	3 " 2 40	23 00	25 "
100	1-gal. " ".....	12 " 11 00	105 00	110 "
100	1 $\frac{1}{2}$ -gal. " ".....	6 " 9 00	85 00	80 "
100	3 $\frac{1}{4}$ -gal. " ".....	3 " 7 00	65 00	60 "

## Porter Bee-Escape

The great labor-saver. No well-regulated apiary can afford to be without it more than a smoker.

Price 20c each; \$2.25 per dozen, prepaid.

Price with board, 35c; \$3.20 for 12, not postpaid.

## Editorial Notes and Comments

### Reserve Combs of Sealed Honey

Are you planning to have a goodly number of combs of sealed honey ready to give to needy colonies next spring? Perhaps it would be better not to speak of giving them to needy colonies, but rather to colonies that can take them. A colony may have enough honey to supply its wants up to the time the white-honey harvest begins, and the beginner may think, "Well, that is all that is needed."

There may be a good profit, however, in giving combs of sealed honey, even if those combs are not needed to prevent starvation. The dark fall honey is not worth as much on the market as the earlier light honey, and, indeed, in some cases it is hardly marketable. But before any of the white honey is stored in supers, the bees will fill the vacancy in the brood-chamber. Now, suppose you have sealed combs of dark honey to fill that vacancy. Every pound of dark honey you thus put in the brood-chamber means a pound more of light honey in the super, practically making that dark honey of the same value as the light. See the point? If you do, make preparations accordingly.

### An Imported Cyprian Queen

Dr. C. C. Miller sends us the following report on a Cyprian queen with which he has been experimenting:

Last year I obtained from the Government Apicultural Investigator, Prof. Frank Benton, an imported Cyprian queen. By the close of the season she was well established in a full colony, ready for business the past spring. She did good work at laying; so far as I could see, as good work as if she had not done so much traveling. Her workers are as beautiful as Italians—I'm not sure one would tell them from Italians. I was expecting them to be very cross, but they showed so little vindictiveness that I felt somewhat aggrieved at having been imposed upon by having been given a Cyprian queen without the proper quota of temper.

In storing, the colony fell behind the average in the apiary. I'm not sure whether that should be counted against these Cyprian bees. It is well known that a queen that has been through the mails may do very poor work, while her royal offspring will show excellent results. The ill effects of travel, however, while making the queen do poorer work at laying, ought hardly to affect the character

of the worker offspring, and the colony in this case being of average strength ought, one would think, to have done average work. They were not allowed to continue storing the entire season, and it is barely possible that they might have done better later on.

One fault was so grievous that it condemned them utterly for comb-honey production: They filled the honey so close to the cappings that they made watery-looking sections.

June 20 they were found to have started queen-cells, and in that they showed very plainly that they were distinctly different from the other bees in the apiary, for such a smattering of queen-cells and queen-cell cups I never saw before. It seemed a good thing to turn this peculiarity to account; so they were set to work at the business of starting queen-cells, and the result is shown on the first cover page of this Journal for Aug. 3—119 cells at a sitting.

Thus made queenless for cell-rearing, they redeemed themselves as to the matter of temper, and I had no further occasion to accuse Prof. Benton of having defrauded me out of my proper rights. They were vicious enough to give full satisfaction to any one desiring viciousness. They were also more prompt to start laying workers than any other bees I had ever known.

Just so far as could be judged from this one queen and her progeny, one would say that Cyprians, when not queenless, are hardly so vicious as generally painted, and that they should be used for the production of extracted honey only. And if one who is not an expert in the matter of queen-rearing may be allowed to express an opinion, I should say that if I were in that business I should be willing to pay a high price for one or more pure Cyprian queens, just for the sake of having queen-cells produced, feeling sure that with Cyprian bees and the right kind of material to give them for working upon, I could get as good cells as could possibly be reared, and with less labor than by Doolittle cups or any other method. C. C. MILLER.  
McHenry Co., Ill.

### Identification of Plants

Now and again some one finds a plant with which he is not familiar, wonders whether it may not be a honey-plant, and sends it to this office for identification. Usually it is hardly a matter of sufficient general interest to occupy space with a reply. The reader is not interested to know that a plant of which he has never before heard, and which he may never see, is not a honey-plant. If it were a good honey-plant, the matter ought to be

somewhat readily decided by watching to see how much attention is given to the plant by the bees. If the bees are seen to be in numbers upon any plant at a time when they are storing, it is safe to say that such a plant is a good honey-plant, for the bees are too good economists to waste their time upon something that yields no returns.

At a time of scarcity, bees may be seen working upon plants which are of little account, because that is better than nothing. That does not prove the value of the plant; the question is, Do they visit the plant in numbers when they are getting plenty of nectar? Neither is it a proof that a plant is without value because no bees are seen upon it in a time of plenty. It only proves that for the time some other plant gives more satisfactory returns. With these principles in mind, any bee-keeper ought to be able to decide without much trouble whether any plant is a good honey-plant for him.

It may be further said that such an answer, determined by the bee-keeper himself, is more reliable than an answer sent out from the office of any publication, because what is a good honey-plant in one place may not be such in another. Goldenrod, for example. In some localities it is esteemed as a honey-plant; in others it is worthless.

### Poisonous Honey

The following interesting clipping, copied from the London Lancet, has been sent in by Leo. F. Hanegan:

Poisoning by honey has been known since the days of Xenophon, when it seems to have been fairly common, and has been observed in various parts of the world—Germany, Switzerland, North and South America, India and New Zealand. In the New Zealand Medical Journal for April, Dr. E. D. Aubin has published an important paper on cases of poisoning due to wild honey, which were observed most frequently in Maoris. As the poison evidently is derived from plants visited by the bees, its nature varies in different countries, and so do the symptoms. In New Zealand only wild honey appears to cause poisoning. The symptoms usually followed ingestion of the honey in less than an hour.

Three modes of onset were observed, which Dr. Aubin terms, respectively, gastric, nervous and cerebral.

In the gastric form giddiness and nausea are followed by severe and persistent vomiting, which may last on and off for two days. There is usually some abdominal pain, but this is not, as a rule, a prominent symptom. The mouth feels dry and glazed. Apparently no irritant action is exerted on the bowels, for diarrhea was never observed.

In the second mode of onset Dr. Aubin attributes the symptoms to irritation of the peripheral nerves, which is indicated by tenderness in the muscles; pains, chiefly of a burning character, in the muscles of the arms, the legs, the back, and the abdomen; itching and a feeling of "pins and needles," or numbness in the arms and the legs. Such symptoms are observed in early stages of peripheral neuritis and in poisoning by muscles.

In the third mode of onset cerebral symptoms occur. For example, a Maori who had partaken largely of honey suddenly dropped down in a fit. He became unconscious, and fits recurred at intervals.

Delirium may be the first symptom. In severe cases, as a rule, the gastric, nervous and cerebral symptoms are combined, one set of symptoms predominating. The characteristic symptom of poisoning by honey as observed in New Zealand is the epileptiform fit. This, as stated, may mark the onset or may not occur for an hour or more. It differs in no way from an ordinary epileptic fit, and may be preceded by a cry. The head is jerked to one side with conjugate deviation of the eyes and tonic and clonic spasms occur. Cyanosis and frothing at the mouth are present, and the tongue may be bitten badly. After the fit the patient may be quiet and may sleep, or may be restless and delirious. In severe cases the patient is unconscious between the fits, which usually recur several times. In some cases the convulsions may be more or less continuous, and may result in death. The fits generally cease in less than 24 hours. Slight vaso-motor phenomena are usually present, the face and the skin generally feeling hot and swollen. Urticaria was never observed. The duration of the illness is from a few hours to two days, though nervous symptoms are sometimes complained of for a considerable time afterward.

In fatal cases death usually occurs within 24 hours. The symptoms, no doubt, are due to a poison in the honey, probably of the nature of an alkaloid which affects chiefly, if not wholly, the nervous system. The gastric symptoms, Dr. Aubin thinks, are of cerebral origin—a view which is supported by the absence of signs of intestinal irritation. We may add that in other countries such signs have been observed.

After reading the foregoing one might be inclined to think that poisonous honey is so common that the safe thing would be to let all honey entirely alone. As a matter of fact, poisoning by honey is such a rare thing that probably not one reader in a hundred of this Journal ever knew of such a thing happening in his own neighborhood. Even so dignified a publication as the London Lancet may be a

little astray as to its facts when it treads upon unknown ground, and may wander still further astray in making deductions. Note the statement, "In New Zealand only wild honey appears to cause poisoning." That may be accepted as straight goods among the medical fraternity, but hardly among beekeepers. What difference can there be between wild and tame honey? Will a colony of bees in a hollow tree work upon flowers at all different from those visited by the bees of an apiary in the same vicinity? If so palpable an error can occur upon one point, why may not other errors occur?

Those soldiers of Xenophon are paraded whenever poisonous honey is spoken of; if poisoning by honey is such a common thing, why not let the soldiers of X. rest quietly in their graves and trot out a fresh poison squad?

### National Association Nominations

Secretary Hutchinson has given this notice on nomination of candidates:

All members of the National are requested to send their votes on a postal card, or by letter, to N. E. France, Platteville, Wis., thereby expressing their choice of candidates to succeed each of the above-mentioned officers. Votes must reach Mr. France by Sept. 20. The two men receiving the highest number of votes for each respective office will be considered the candidates to be voted for at the annual election in November.

"The above mentioned officers" referred to in the foregoing are these:

President, Jaa. U. Harris; Vice-President, C. P. Dadant; Secretary, W. Z. Hutchinson; General Manager and Treasurer, N. E. France; Directors, J. M. Hambaugh, C. A. Hatch and Dr. C. C. Miller.

Among others, Mr. Hutchinson suggests C. P. Dadant, of Illinois, for President; Jaa. A. Green, of Colorado, for Secretary, and Frank Raufuss, of Colorado, for General Manager.

They are all right. While *we* might also present a full "slate," as Mr. H. has done in the Review, we refrain from doing so, as we have been foolishly accused of wanting to "run" the National Association. We are only an humble private in the ranks, and are quite content to have others "run" the National Association.

with their queen—blue, Mr. Whitney; red, Miss Rumsey.

Best general exhibit—blue, Mr. Whitney.

Miss Emily A. Hatch was the superintendent of the apiarian department and took great interest in it. She has 8 colonies of bees, and is getting along nicely with them. The Fair was well attended, and the exhibits in all departments were very interesting and instructive.

The Kansas State Fair is to be held at Hutchinson, Sept. 18 to 23, inclusive. J. J. Measer, of the same city, is the superintendent of the Apiary Department. The premiums offered on bees, honey, etc., are as follows, and should call out a good display:

	1st	2d	3d
Case of alfalfa comb honey.....	\$ 5	\$ 3	\$ 2
Case of amber comb honey.....	5	3	2
Display of comb honey.....	10	5	3
Display of extracted honey.....	5	3	2
Frame of white comb honey for extracting.....	4	3	1
Frame of amber comb honey for extracting.....	4	3	1
Best 5 pounds beeswax.....	5	3	2
Display of beeswax.....	10	5	3
One-frame observation glass hive.....	5	3	2
One-frame 2-story observation glass hive.....	5	3	2
Display in design of beeswax.....	5	3	2
Home-made hives, complete.....	5	3	2
Best display of bee-keepers' supplies.....	10	5	3
Best arranged apiarian display.....	10	5	3
Best display of honey-cakes.....	3	2	1
Best display of pies sweetened with honey.....	3	2	1
Best display plain pickles in honey-vinegar.....	3	2	1
Best display of sweet pickles put up with honey and honey-vinegar....	3	2	1
Best display of varieties of uses for honey.....	5	3	2
Grand sweepstakes, largest and most attractive exhibit.....	10	5	3

The Apiary of J. J. Measer—or a part of it—is shown on the first page. Mr. M. wrote us as follows when sending the picture:

I send you a photograph of a part of my apiary, taken the forepart of July, and showing the condition of the bees at that time. We have had no honey coming in up to date, scarcely enough to do the bees for food. Colonies are strong in bees but no bloom to work on, so the bees are loafing on the hives. The web-worm has taken all the bloom from the first and second crops of alfalfa and all wild flowers. During the past 3 or 4 days there has been some work done, as the third crop of alfalfa is now coming into bloom. I think there will be but very little section honey gathered in this part of Kansas this year—probably some from late wild flowers.

Reno Co., Kan., July 17. J. J. MEASER.

To Foreign Subscribers.—We wish to repeat a notice that we have given several times before. It is this: None of our special offers made in the American Bee Journal, or anywhere else, apply to foreign subscribers. So whenever we receive a foreign order with remittance we always apply it all on subscription to the American Bee Journal. If our foreign readers would think about it a little, they would quickly see that our special offers would not apply to them, on account of the extra postage to foreign countries. Also, we do not export any queens, except to Canada.

Maeterlinck's "Life of the Bee."—We have a few copies of this book, price, post-paid, \$1.40; or with the American Bee Journal one year—both for \$2.00, as long as the books last. It is a cloth-bound book, and has 427 pages.

## Miscellaneous News Items

The Western Bee Journal has been sold to Orchard and Farm, a monthly published at San Francisco, and will henceforth be published as an apiarian department of that publication, with Mr. Adelbach as editor.—Bee-Keepers' Review.

Lake Geneva Midsummer Fair.—The success of the first Midsummer Fair held at Lake Geneva last year was so great that another was held July 14 and 15 of this year. The prime object last year was to raise money for the Fresh Air Association, but the Fair itself became a matter of such importance that it almost supplanted the first aim. It was again held on the beautiful, shaded grounds of the late L. Z. Leiter, which are not only spacious but splendidly adapted for the purpose, extending to the edge of the lovely Lake

which is surrounded by the summer homes of many wealthy Chicagoans. These latter were the principal exhibitors in many of the departments of the Fair. The net proceeds of the Fair held last year were something over \$4,000. It was our privilege to be present as judge of the apiarian exhibits both years. We show this week a picture of the bee and honey exhibits made this year. Those winning the premium ribbons are as follows:

One or more cases section comb honey, not less than 24 sections—1st, or blue ribbon, Mrs. Henry Buell; 2d, or red ribbon, S. C. Ford. Extracted honey, not less than 10 pounds—blue, Miss E. Rumsey; red, Wm. M. Whitney. Beeswax, not less than 5 pounds—blue, Mrs. Buell; red, Mr. Whitney.

Best exhibit of vinegar made of honey—blue, Mr. Whitney.

One or more cages of Italian queens—blue, Mr. Whitney.

One-frame nucleus, 3-banded Italian bees

# Biographical

## WM. M. WHITNEY

The subject of this sketch is one of the oldest and most earnest readers of the American Bee Journal. At present he resides in Walworth Co., Wis. His life has been a very busy one from his youth, being obliged to make his own way—which isn't the worst thing that can happen to a boy—at about the age of 15. His father owned a farm of moderate size, and reared a large family—9 children—which was no easy task. How his father and mother endured the hardships attendant on making a home in the midst of a primeval forest as they did, is more than he can understand.

Mr. Whitney was born on a farm in the town of Ontario, Wayne Co., N. Y., Sept. 23, 1828; passed through the various vicissitudes attendant upon child-life—chicken-pox, mumps, measles, whooping-cough, scarlet-fever, etc., to say nothing of the ague and chill fever. He survived them all, through the faithful care given him by his mother and father. He attended the common school winters and summers till about 12, when farm-work was followed during the summer-time.

At the age of 15 he went away from home 4 miles in the winter to school at West Walworth Academy, and from there to Macedon, which was an institution of higher grade. He spent several terms at the last institution—in fact, finished his school-days there. He

taught school from the time he was 18, more or less, for 10 years; clerked in a dry goods store in Palmyra for a time, and a year in a book-store in Watertown, N. Y.

WM. M. WHITNEY

He married the eldest daughter of Nelson Clark, a farmer of Le Roy, N. Y., at the age of 23. He moved to Illinois in the spring of 1858, and engaged in mercantile business with a cousin of his wife; elected clerk of the Circuit

Court of the County of Du Page, Ill., in 1860, and held the office 8 years, and was ex-officio recorder during the same time.

In 1868 he formed a partnership with Isaac Cladin in real estate and loans; was elected to the 27th General Assembly in 1870, which had the remodeling of the statutes to conform to the new constitution that had been passed in 1869, holding 4 sessions in the 2 years; elected member of the State Board of Equalization of Taxes in 1872 for 4 years, representing the first Congressional district; in the Revenue Collector's office in Chicago for a short time, and in 1879 went to the Illinois Eastern Hospital for the Insane at the head of the business department, which position he held for 8 years. Since that time Mr. W. has not been engaged in any important business. He was burned out in the Chicago fire of 1871, that is, all his valuable papers—books, mortgages, notes, abstracts, etc.—entailing a loss of several thousand dollars.

Mr. Whitney's family consisted of his wife and 7 children—6 daughters and one son—of whom only 3 daughters are left. He took up bee-keeping as a pastime, as he had been very much out of health from over-work, anxiety and care. He has found the occupation most pleasant and instructive. His only regret is that he did not commence the study and care of the honey-bee in his younger days.

Mr. Whitney's 3 daughters married physicians, and one daughter is now a practicing physician. While clerk of the circuit court he studied law, and was admitted to the bar by the supreme court, but never practiced the profession.

The picture shown herewith is one taken several years ago, but is a good likeness of Mr. Whitney, we think. He now has some 60 colonies of bees, and has always been very successful as a bee-keeper.

### Something Interesting About Bee-Stings

BY G. M. DOOLITTLE

While at work in the apiary a few days ago, a bee-keeper of a few years' experience came in, and at about the same time a bee stung me on the hand, when, with a quick motion, the sting was rubbed out of the hand by striking the hand on my pants, with an upward drawing motion, thus getting the sting out so quickly that very little poison entered the wound. This part of getting the sting out was lost to my visitor through his curiosity regarding whether the bee would soon die from the effect of losing its sting. He was sure that every bee which stung a person or anything else, so that it lost its sting, must of necessity soon die, and said that he had been told by an old bee-keeper that such was the case.

At about this time the bee returned to another attack on both him and me, the white, thread-like substance where it had parted from the sting showing that this bee, which was so intent on stinging us (if it could), was the self-same bee which had stung me only a few moments before. I called his attention to the matter of this being the same bee, and told him that it did not look as if the bee was just ready to die from losing its sting, by the way it was still trying to sting us. He said that did look a little strange, but he still seemed to be sure that the bee would soon die.

Up to within the past 10 or 15 years most persons believed as did my visitor, arguing that in leaving the sting, as the honey-bee nearly always does in stinging an animal, a part of the intestines was left with the sting—poison sac, etc.—which would surely cause the bee to die. This seemed so reasonable that for many years I believed that this prevailing idea was true, till one day after a bee had stung me, leaving its sting, it came to the attack again and again, with all the fury and vengeance possible for a bee to work itself up to, getting in my hair and singing away as only an angry bee

can sing, which will make the cold chills run up and down the back of any but the most hardened individual.

As this bee apparently had no thought of dying, it was caught and caged with three or four others and kept a week or so to see what would become of the matter. At the end of the week it was apparently just as lively and healthy as any of the rest, when all the bees were set at liberty.

At another time, in putting up queens to send away, in catching the escort bees which were to go with the queen, one of them stung me on the end of the finger, leaving its sting, when it immediately ran into the cage. As I did not wish to remove all the bees and queen to get it out I let it go, soon after which the thought came to me that here would be a chance to test the theory of the death of the bee from losing its sting, as this queen was going a journey which would take eight or ten days.

Accordingly I wrote to the person to whom they were sent, telling him all about the matter and asking him to take notice particularly when the queen arrived and see if there were any dead bees in the cage. In due time he replied that the queen arrived in splendid shape, and that there was not a single dead bee in the cage.

Several times since then I have tried similar ways to see if such bees as had lost their stings were in any way inconvenienced thereby, and as far as I can tell by means of confining them so as to know that I have the same bee, I can see no difference between such bees and those which have their stings, as to length of life. Whether they gather honey or not, or whether they are allowed to live in the hive without their weapon of defense is something which would be next to, if not quite, impossible to tell, for in this case we have no means of keeping track of an individual bee.

As bees are not tolerated in the hive, which are in any way imperfect, it might not be unreasonable to suppose that the perfect ones might drive off such an one which had lost its sting, as being incapable of defense were the hive attacked.

That it was not the design of nature that the bees should always lose their stings when defending their hives is manifest where bees repel robbers to the extent of hundreds and thousands of slaughtered, when in such cases not one bee in one thousand loses its sting, but keeps it so that it can slaughter bee after bee till the attacking party is repelled, or they lose their lives in the combat. At times they do lose their stings in other bees, but not often.

Before closing I wish to say a word about getting the sting out of the flesh as soon as possible. We have been told

not to pick the sting out with the thumb and fingers, for in so doing the poison from the sac, attached to the sting, would be squeezed into the wound; but by using a knife or something of that kind the sting could be gotten out without injecting the poison into the flesh. This sounds pretty, but my experience is that while you are working to get the knife, the contraction of the poison-sac would pump in far more poison than the squeezing would do. The knife is better, if you have it at hand at the instant wanted; but if not, don't wait. Get the sting out *at once* in some way.

My way is to rub it out by a drawing motion against the clothing, if on the hands, and by a sliding motion of the hand against the sting when on any other part of the body; and if you are quick enough in these motions, the sting can be generally gotten out so quickly that very little pain will be felt.

Onondaga Co., N. Y.

## Work in the Apiary for September

BY C. P. DADANT

The honey harvest ends this month. Those who produce extracted honey must expect to extract all the crop before the end of the month. If the honey is thick and ripe shortly after it is harvested, as is usually the case with Spanish-needle honey, it is not necessary to wait until the last of the crop, which generally ends with the first frost, to harvest the honey. If the hives have two or more supers, all may be taken except those that are entirely unsealed and show evidence of being freshly harvested. If we have only a few combs left on the hives, at the end of the crop, the work of finishing the extracting will be short and but little chance will be given for robbing. We usually leave the empty extracting combs on the hives until October, as the bees protect them against the moths during the last warm days, better than we could do it ourselves.

The producer of comb honey must remove all sealed sections as fast as possible after they are finished to avoid the travel-stains by the bees. The fall blossoms and their yellow pollen cause the bees to produce and spread over the combs a quantity of coloring pigments which darken the white combs promptly. Honey that is removed as soon as sealed will show much whiter, even if it is of a deep color, if it is taken off before the bees have had time to stain the white cappings, for beeswax is always white when first produced.

Of course, supers left on until October will be still more stained, by the addition of traces of propolis all over the combs, for just as soon as the harvest ends the bees begin to prepare for cold weather by daubing the inside of the hive with propolis and filling all the crevices with this sticky substance. Some localities are much worse for this production of propolis than others. Trees of lowlands, willows, poplars, cottonwoods, etc., furnish an abundance of this which the bees seem to enjoy crowding into nooks and corners.

Towards the last of the crop the bees would best be crowded a little for room, for if too much space is given they will be building additional new combs and scattering their honey, while it is best to have all the cells finished and sealed if possible. There is no longer any danger of swarming by narrowing the available space to the minimum, in each hive, and we make sure of much better results, securing more finished sections.

Likewise, if we are producing extracted honey, we will find it well to crowd the bees a little for space, so they may be compelled to put enough honey for winter in the brood-combs. Colonies that have bred plentifully and spread through three or four supers are likely to find themselves with too little honey in the brood-chamber for winter if we do not compel them to place some there. However, I would not wish to be understood as giving this as a rule. In cool seasons, pure Italian bees will, on the contrary, crowd their brood-chamber too much, but hybrids or black bees are prone to scatter their crop, and this matter must be watched before the end of the harvest so as to compel them to fill their brood-combs sufficiently for winter. If too much honey has been placed in the brood-combs, it is advisable to extract only that which is unsealed, for unsealed honey is not very good for winter, as it is apt to become watery much more readily than that which is sealed.

The month of September is also quite suitable for the replacing of queens that are too old or that have proven unprolific. At this time queens may be purchased at lowest prices, because breeders rear them more easily and more

cheaply during the summer months than in the spring. We have also had good opportunities to become acquainted with the prolificness, or lack of prolificness, of different colonies, and can take the same opportunity of replacing the queens that are becoming too old and are losing. But I would warn the novice to be very careful, for queens that have lost their fecundity are often replaced by the bees themselves before we are aware of it, and we run the risk of destroying a young queen when we are thinking of replacing the old one. The longer I keep bees, the less profitable I think the custom of replacing queens that are supposed to have reached the term of their usefulness.

Small colonies, made by division, late swarms, etc., can be helped very materially during this month by supplying them with an occasional comb of sealed brood and honey. A weak colony, helped twice—two weeks apart—with a comb of brood each time, will often make a good colony for winter, and the powerful colony from which this help has been taken will hardly feel it.

Hancock Co., Ill.

## Report of the Chicago-Northwestern Bee-Keepers' Convention, held at Chicago, Ill., Nov. 30 and Dec. 1, 1904

(Continued from page 601.)

CASH FOR PROOF OF ADULTERATED COMB HONEY

Mr. Becker—It is a fact that there are many people who believe that there is adulteration both in comb and extracted honey. I sell honey right here in Chicago. I have bought it from Mr. York and from Mr. Dadant. I ship honey to Chicago. They wouldn't under any consideration buy the honey here in Chicago and believe that it actually was pure honey. They have told me so, time and again. I have tested the honey to-day that I shipped here ten years ago, and which has been kept in an open jar. I told them that the honey was too strong. They thought it was delicious. It was pure honey. A few years ago we brought in honey and I told some of the parties here that I would guarantee they would get pure honey here in Chicago, and I told them where to get it. They got some of it. They said, "Oh, that was not pure honey; that was not honey like you sent me." But it was pure. We all know that there is no adulteration in comb honey, but when it comes to extracted honey of course there is sometimes adulteration. There are so many varieties of honey; there is basswood, white clover, alfalfa, Spanish-needle, heartsease, and other varieties of honey, and one does not taste or look like the other, especially sweet clover and basswood. You give them some of your honey and they have been used to white clover or alfalfa, and they just declare up and down, and you cannot make them believe that it is not adulterated honey. I have sold honey in Springfield for the last 20 years, and one traveler there accused me two weeks ago of having a monopoly because he couldn't sell any. I told him I was glad that I had the monopoly, if I had it. But the only way I got that monopoly was by selling them an article that I stood behind. I said, "If this honey isn't pure, and if anybody does not like it, don't argue with them, but tell them to bring it back and give them their money back; it is my honey and I will take it off your hands." And to-day should I go to Springfield I am asked no questions as to its purity. I simply ask, "Do you need any honey?" And they say, "Yes, two, three or four dozen, and as high as a gross." I never buy on the Chicago market. I don't send any honey here. I am right the other way; I take it from Chicago and sell it at other places; and I sell it at home, and I will stand behind my honey, and never sell anything but what I know is pure, genuine honey. If you all do the same thing I think you will have no trouble in selling your honey.

Mr. Dadant—I wish to insist on the necessity of our explaining the comb-honey story wherever we can. We must do it. I have a better opportunity perhaps than any one else of finding out what the general public thinks of the comb-honey story. When I travel I come across business

men and we get into conversation. The first thing we ask one another is, "What is your business?" I say, "I have a little factory out here in the country." "What do you make?" "I make comb foundation." "What is that?" "Did you ever hear about comb honey being manufactured?" "Oh yes." "Well, there isn't any such thing. I make the nearest to comb that can be done." "Is that so?" Then comes the explanation. If I have a sample I show him and he is absolutely convinced there is no comb honey manufactured. But when I first meet him, if he knows anything about it he knows comb honey is manufactured and sold! I find very few people that do not believe it until it is explained to them. When I tell them, I know they believe me because there is no reason for me to tell them a story and they understand how the story was gotten up. But this extends to you; it is absolutely necessary to make this matter known widely because there are millions of people who have read that story and believe it simply because they have never been told better.

Mr. Smith—I want to say I have convinced some parties by exhibiting some of the thin foundation and explaining why it was used and how it was used, and that was all there was to it. It dawned on their minds finally that I was right. I think the more we do that, and the more we can explain this thing and talk it the better, because it is the fact, and it is easily demonstrated when we have the evidence, that is, the foundation, and show the people that that is all there is to it. I am like Mr. Becker, I believe in every bee-keeper standing by his honey.

Pres. York—Before Mr. Smith spoke I was wondering whether it would not be a good idea for every bee-keeper to carry a little piece of comb foundation; and I am going to suggest that comb foundation manufacturers get up a little pocket-holder with a piece of foundation in it, and give it to all the bee-keepers. I think it would be a good advertisement for them.

Mr. Abbott—If these comb-foundation men would find out when the Traveling Men's Association meets, and send some of this comb foundation there they would do more towards counteracting this than anything I know of. The traveling men who travel for wholesale houses do more to keep this story alive than any class of men in existence. I never met a traveling man in my life, who was not a bee-keeper, that did not think that comb honey could be manufactured. He wouldn't believe it at all when I came to talk to him. Every once in a while I meet one who wants to bet money on it. I met one in the streets of St. Louis one day, and he said when I told him it was not manufactured, "You are crazy. I know right where the man is; he is down the street here not more than four blocks away, and he was talking to a man that knew well." I put my hand on the man's shoulder, and said, "Am I responsible for \$500?" He said, "I think you are." I said, "My dear sir, come on down the street with me and I will give you \$500 in clean cash if you show me that man." He stopped and looked at me. He said, "I am awfully busy." I said, "Can you make \$500 in a day, or an hour? Come on with me. I want you either to stop this story or else go and show the goods." He said, "I didn't see it, but I saw a fellow that said he saw it." [Laughter.] That is all there was to it; but they keep sending it around.

Mr. Becker—The general public confuse foundation with honey-comb. They are all well aware that there are factories that manufacture comb foundation, but they call it "honey-comb." In that way the general public get the wrong idea, and they think it is the genuine honey-comb. Instead of that the word "foundation" should be used, and, as has been suggested, they should be shown a sample so that they understand just what it is. But it is commonly known as honey-comb, and that is the reason I believe the general public has that impression.

Mr. Pease—A few months ago I placed some cases of honey with a firm here in Chicago. At the time I did this one of the gentlemen said, "I want you to tell me something that I can tell the enquiring public about this artificial honey-comb story." I said, "I will not take time to do it now, but I will come in tomorrow and explain that to you." The next day I went down and took with me a section with a full sheet of foundation that was partially drawn out—drawn out more at the top than at the bottom; I used the extra-thin foundation and the bottom had not been drawn out at all. I went on to explain to him the process by which this foundation was used, and how it was made, and that that was the extent of this artificial honey-comb. I left a sec-

tion containing this partly-drawn foundation with him. Several weeks after that I went into the store and asked him about his honey, and spoke of this sheet of foundation that I had left with him; and he said he had experienced more satisfaction in using that to explain to the public exactly what comb foundation was, and what artificial honey-comb was, than anything else he had ever seen. I simply offer this as a suggestion. I believe whenever you place a consignment of honey with a firm, especially a retail firm, if you will take the pains to place with them a sample of foundation or a section containing the foundation, or partly drawn foundation, you will take a long step in educating the public as to what this artificial honey-comb is.

Mr. Wheeler—I always seem to have to differ from the public. I differ a little on this question of foundation, and I have had considerable experience in selling honey. I have explained foundation to the public, and I have had them go to their friends the next day and tell them, "Why, Wheeler had some manufactured honey there;" and they confused the foundation with the comb, time and again. I have had that happen. They say, "He buys comb and puts it into the hives." One or two years I went to the County Fair and explained foundation to the folks. I had that thrown back at me so many times that I made up my mind I never would speak of foundation at all unless people asked me if I used it. Of course I don't deny using it. But this explaining to the public that you put in a sheet of beeswax—they can't tell whether there is a "sell" there or not, and the trouble is you know how a story goes; they will repeat the thing to their friends, and put an addition to it, and the first thing you know it will come around that you really furnish the bees with comb.

Dr. Miller—"A little learning is a dangerous thing." The trouble in Mr. Wheeler's case is that he doesn't go on and educate them far enough, and keep right after them, and they will come finally to know enough. He gives them just a little sight of that, and they put a whole lot more to it. He should follow that up and show them it is not so. Get after them after they have heard the wrong thing. I do believe enlightenment on the subject will finally bring the public to the right place. I am just half German blood in me and sometimes it gets me into trouble. Mr. York suggested a thing that I had in mind, and by some sort of telepathy he got hold of it and told you to carry around foundation. That was a thing I had been thinking of before, and if he had just waited a little while I would have said that. I believe there is wisdom in it. I have thought after this I will try to have a piece of foundation in my pocket. I don't doubt at all that these foundation makers will approve of that, for we will "draw out" a good deal of foundation in that way!

Mr. Whitney—I would like to make another suggestion in regard to advertising this matter. If we would all write a short article on this subject to our local editor; there is no individual here but can do that in his own locality and publish the facts in regard to this foundation business, this comb-honey business, and this extracted-honey adulteration. By doing that we will do a great deal more than we can do in any other way personally. The editor of our paper at home has been importuning me to write a series of short articles for his paper, and I have partly promised to do it on that very subject, and touching upon bee-keeping generally—all the little things and facts about it. I think if we will all do that in our local papers we will do more to correct this impression that has gone abroad than we can do in any other way, and do it easily, too.

Mr. Meredith—Some three hundred car-loads of excursionists visited our Park the past season where I had an exhibit of bees, extracted wax, a press, and utensils used for the production of honey. Among those were comb foundation partly drawn out, finished and capped, and in almost every manner, and it was very interesting to the people as they had never seen the way extracted and comb honey was produced, in looking over and seeing how the foundation had been extended. And also I had a number of pieces of foundation coiled up in the shape of wax, and I used them for the purpose of selling, selling it for so much, taking an ordinary piece of foundation and winding it around a rod and selling that to them for beeswax. The biggest part of the people that looked over my exhibit could see what was considered artificial comb was practically pure wax drawn out by the bees, and I think it had a big influence in the enlightenment of people in regard to this artificial comb.

(Continued next week.)

## Our Bee-Keeping Sisters

Conducted by EMMA M. WILSON, Marengo, Ill.

### Stings and Honey

We don't like the bee-lady who stings with sharp words and then offers the honey of a smile.—Chicago Record-Herald.

### The Weather and Swarming

It must be nice to keep bees where there is no "weather." Out in Colorado or California, it seems, they can count on sunshine day after day, and plan their work accordingly. Here in Northern Illinois the weather must always be taken into account. No matter how pressing the work may be, there may come a day—yes, 2 or 3 days of wet, cool weather, when in all decency no one should go near the bees. If the work of the bees would stop when the work of the bee-keeper is stopped by the weather it would be less matter. To be sure, their work afield stops their stinging, but their troublesome work at building queen-cells goes right on, rain or shine. That's where the natural-swarming bee-keepers have the advantage.

Inconsistent as bees are in considering the convenience of the bee-keeper, they do have enough consistency to put off swarming when the weather is not appropriate. At least that is true as to prime swarms, and it isn't so hard to prevent afterswarms. But then, if swarming is allowed, either natural or shaken, it "cuts in" on the honey crop.

### The Sister Bee-Keeper

A prominent writer in the British Bee Journal, D. M. Macdonald, quotes in a complimentary manner from the letter in this department by Mrs. Honaker, on bee-keeping for women, and adds:

"I should like to see our ladies figure out more prominently than they do. We have it on the high authority of our Junior Editor that they make excellent manipulators, and I believe some of the best 'passees' he ever recorded in his examinations were given to sisters in the craft."

### A Summer Drink

Put 1½ ounces of bruised ginger into a pan. Add 3 quarts of water for half an hour, then add 3½ gallons of water, 2 desertspoonsful of lemon-juice, 2 ounces of honey, and 2½ pounds of sugar. Mix and strain and when quite cold add half a beaten egg and one teaspoonful of lemon extract. Allow to remain 4 days, then bottle.—National Daily Review.

### Honey-Cake

Half cup butter, ¼ cup sugar ½ cup honey one pint of flour, one teaspoonful of yeast powder, two eggs and one teaspoonful caraway seeds. Mix honey and sugar, add the butter melted, the eggs well beaten, the flour sifted with the yeast powder and seeds. Mix into a smooth batter and bake in a fairly hot oven 35 minutes.—Chicago Record-Herald.

### Building Queen-Cells

I trust that I am privileged to ask a question, although I am not a "sister," and if you will enlighten me a little on a certain point through the columns of the American Bee Journal, the courtesy will be appreciated.

You say (page 424) that no such thing happens as "destroying the partitions" when a queen-cell is commenced. In case the

queen-cell is started right among worker-cells I do not understand how there can be found a "cell which needs no enlarging." Kindly explain.

This is written in no controversial spirit. I have kept a few bees 3 years and have not yet seen a queen-cell in my own hives.

I read your articles with pleasure and profit each week. J. A. SMITH.  
Hartford Co., Conn.

Two kinds of queen-cells must be recognized: pre-constructed and post-constructed. When a colony contemplates swarming, or superseding its queen, the queen-cells started are cups having a diameter of about ⅓ of an inch. These are called pre-constructed because the queen-cells are prepared as such before there is any egg in them. When a colony becomes queenless by any means, the workers select a worker-cell containing a young larva (very rarely it may contain an egg) and change it into a queen-cell, which is called post-constructed because made into a queen-cell after it has an occupant.

Queens are "usually" reared in pre-constructed cells, "which need no enlarging," but when a worker-cell is turned into a queen-cell it needs a good deal of enlarging. The enlarging is done chiefly outside the worker-cell proper. There is a slight enlarging of the original worker-cell, the cell-walls seeming to be crowded apart, but not to any great extent, and not to any great depth. That destruction of partitions and making 3 cells into one is all a pipe-dream, as you can easily satisfy yourself by pulling off a post-constructed cell, when you will find the worker-cell still there, with its original walls intact.

Now to your question: You want it explained how, when a queen-cell is started right among worker-cells, there can be found a cell which needs no enlarging. No such cell can be found. But pre-constructed cells are not found in such a place. They are found on the edges of combs, or where some inequality occurs in the central parts of combs. If by any means the bees could be forced to start a pre-constructed cell "right among the worker-cells," it would be built outside those cells without doubt, and thus would need no enlarging. Post-constructed cells, however, may be found right among worker-cells, and these must be enlarged, as already explained. The answer to the puzzle, therefore, is that queens are "usually" reared in pre-constructed cells which need no enlarging, but pre-constructed cells are not found right among the worker-cells.

## Mr. Hasty's Afterthoughts

The "Old Reliable" seen through New and Unreliable Glasses.  
By E. E. HASTY, Sta. B. Rural, Toledo, Ohio.

### BOTTOM-STARTERS—LOCK-CORNER UP OR DOWN

No, Dr. Miller, I don't use bottom starters, although I confess the advantages they secure. Bottom starters call for a big piece of foundation above, and I use only small starters. Two knife-edges of comb built past each other instead of being joined—and the section spoiled—would occur pretty often with a narrow strip at both top and bottom, I think. But then, I haven't tried it to any great extent; and I'll be meek if you tell me you have tried it many times, and never a spoiled section. As to the mere look of the section looked at from above, extremes meet, it seems, in our two cases. You put lock down and case it the same way. I put lock up and reverse it in casing. You keep it carefully right side up lest the honey from a few unsealed cells run out. And I—I hardly know whether it's best to tell the lazy man's way I sometimes practice. Hist, while I just whisper it! Leave it on the hive so long that the bees empty all scattering unsealed cells. Page 487.

### BEEES ROARING OR FANNING IN THE CELLAR.

On page 489 the Northwestern folks start a query which is not worn out yet; but they seem to have abandoned it rather prematurely. Can you tell by the sound of bees that are roaring in the cellar whether they are roaring because they are too warm or roaring because they are too cold? On one side it can be said that wrong temperature, or some results of wrong temperature, makes them worry, and the worrying sounds nearly the same in both cases. On the other side it can be said that orderly fanning with wings, to make a current of air and cool the hive, is likely to differ perceptibly from the miscellaneous shaking of wings and members when they are stirring around to warm things up. How is it? I don't know. (Sentence stolen from—Herodotus!) If I were driven to a guess I might guess that bees never fan to cool the hive till the temperature gets quite a bit above 90°—and that a wide-open hive sitting in the cellar never gets so high as that.

### CHILLED QUEENS—DO QUEENS FREEZE?

Mr. Ernest R. Root contributes an important experiment, and also an interesting ob-

ervation. A dozen queens were chilled stiff on ice, and kept so for periods from 2 hours to 48 to see about the truth of a certain claim that has been made. It has been claimed that drone-layers arise by reason of chilling the organs of egg-production—usually in the mails. After this severe test the queens laid all right, and no drone-layers developed. Claim seems about busted.

The observation is one open to the most of us at one time or another. A dead winter-cluster is nearly spherical in form—same as a live one. If there is honey above them (as is the case sometimes) there is always a space—2 inches, more or less—between the cluster and the honey. This was contributed to help peel the dreary old chestnut, Do bees ever freeze in winter! Pages 489 and 490.

### AN EXPERIMENT IN DROWNING BEES IN WINTER.

I think the experience of Mr. Wilcox (when he was in heathenish darkness) is worth a good deal of thinking over. Wishing to "take up" a colony he took a notion to drown the bees instead of the usual killing of them with sulphur smoke. (Water damages sealed honey, and dissolves out the honey of what cells the bees have unsealed—but he didn't reflect much on that.) The hive was water-tight and the weather was very cold—far below zero. He turned the hive over and filled it full of water. (Of all things!) The day wore away and notwithstanding the fierce cold the water didn't freeze much, and so he left it over night. When about 24 hours had passed there was quite a bit of ice but still some open water showing that the heat of honey and bees was still effective somehow after a whole day of exposure to zero temperature. Most astounding! The fact was that the bees were still alive down in there. But when we know that, it is still just as astounding that they could keep on furnishing the amount of heat the above seems to call for. I don't believe the cluster was soaked through with water and then dried out under the stove. It is barely possible that a very compact winter cluster will repel water and not be soaked through—but I doubt that also. The way I imagine it was, is this: Inside the

cluster every cell had a bee crawled into it; and the rest were packed between the combs. As the combs are much thicker than the spaces much more than half the bees were in cells to start with. As the water rose all bees not in cells moved upward before it till they got to where there were open cells and then crawled in. Soon all were in cells except a negligible few too stiff to move. The confined air of a cell usually does a pretty good job at

keeping out fluid (we find when we try to fill combs with water or bee-feed) and with a bee crawled into each cell the fort would be completely impregnable. That part is no wonder. But how desperately chilly and sodden all their little tails must have got! Say, if it had only atrophied their stings now, and left the rest of the bee in working order, what a champion colony of safety bees there would have been! Page 489.

play a trick like this on me, I think I would have kept the money which I paid for her. If she comes to Chicago ship her and 4 frames of bees back, and I will clip her wings so she can't fly away again.

What made them swarm? They were under an apple-tree and faced east. If the one from whom I bought the queen would replace the bees free of charge, I would do business always with him only.

ILLINOIS.

ANSWER.—Without fuller particulars it is not easy to say why the bees absconded. But your saying that the bees left 4 empty combs and no brood makes it seem that there was little to hold the bees in the hive. In any case, there is no likelihood that the queen was at all at fault, and it would be very unreasonable to ask that she should be replaced. Instead of the queen "playing a trick" on your bees, it was your bees that played a trick on the queen, or you that played a trick on both. Under ordinary circumstances a queen is not likely to issue with a swarm until she is a year old; but I have had a queen issue with a swarm when she was not a month old, because I gave her to bees that were in a swarming mood. I have also taken a queen that had just issued with a swarm, and given her to bees with no inclination to swarm, and there was no swarming. So you see the queen is not the one to blame.

## Doctor Miller's Question-Box

Send Questions either to the office of the American Bee Journal, or to DR. C. C. MILLER, Marengo, Ill.

Dr. Miller does not answer Questions by mail.

### Foul Brood Treatment

1. I think I have a few cases of foul brood, and am going to try the Baldridge plan of treatment. Is it as good as any?

2. After the bees are all out of the diseased hive what is the best thing to do with it?

3. Do you think it could be chilled brood instead of foul brood? They built up good and strong and swarmed early, but after that they did not do much of anything, and upon investigating I found the combs full of dead brood. So I took the supers off these hives and reduced the entrance, and they seemed to do better. In fact, I had to put supers back on some of them. Again, looking into the hive I find that they are very loath to remove the dead brood, but are doing so very slowly. No had odor comes from the hives when they are opened.

IOWA.

ANSWERS.—1. Carefully managed it may be.

2. Wm. McEvoy insists that the hive itself may be used again without any disinfecting.

3. It is impossible to say whether it is foul brood or only chilled brood. In the first stages of foul brood the odor may not be prominent. Read up all the literature on the subject, especially Dr. Howard's pamphlet, and inform yourself thoroughly about bee-diseases. You can then decide much better from seeing the case than any one can from hearing about it.

### Brood-Frames Full of Wax and Pollen

There are a number of brood-frames in some of my colonies that are nearly full of wax or pollen, and the queen deposits her eggs among them wherever she can find an empty cell. Will it do to replace them with full sheets of foundation? If so, when is the best time to do it?

IOWA.

ANSWER.—The cells may be filled with pollen (not wax), but generally there is none too much pollen. Bees need pollen just as much as honey. It is nothing out of the way if the 2 outside frames are filled with pollen. Sometimes when a colony is queenless for a time there may be much more, but with a good laying queen the matter generally is righted of itself. If, however, there is something peculiar in your locality, you can replace a frame of pollen with one of foundation, but you would better not do it much before the honey-flow next year.

### A Breach-Lighting Smoker

I notice your answers to my questions (page 571,) and will say that Joe "gives in" that those flaky particles are wax, but Joe won't "give in" an iota on the other question. You think there is something wrong with Joe or his smoker or his fuel, or the fire would not go out. I don't think this is true, for I often have no further use for the smoker during the day, after having used it once, and not caring to let the fire burn out and thus exhaust the fuel in the fire-box, I slip a cork in the nozzle so that the fire will go out. The

next day when I have use for the smoke—again, I must unload it in order to get the fire started in the bottom. If I could slip the breach off would it not be much handier than to unload it? I don't want a breach-loader, but I do want a breach that can be slipped off for this very reason. I had a breach-loader smoker, and threw it away. I want a muzzle-loader with a breach-lighting arrangement.

IOWA.

ANSWER.—Yes, I understand the case now, and hereby apologize for the aspersions thrown upon the smoker or the man that uses it. What you desire is an arrangement whereby you can light the partly consumed fuel left in the smoker from a previous loading without the trouble of emptying out the fire-box. There ought to be no trouble, as before said, in getting a smoker of that kind specially constructed.

### Running an Apiary for Wax

I am a beginner in the bee-business, and would like to know if it pays to run an apiary for wax alone. I am located in a good section for producing honey, 15 miles back from the Coast, with a certainty of a good crop, and am 27 miles from the city and the railroad. The price obtained for extracted honey is only about 60 cents for a 5-gallon can delivered at Puerto Principe. Mr. Root says that bees and honey pay in Cuba. I have an idea that the profit must be very small.

1. Will it pay to run an apiary for wax alone?

2. What hives, frames, etc., are best for the purpose?

3. Will there be any advantage in using comb foundation?

CUBA.

ANSWERS.—1. In most places it would be foolishness to run for wax in preference to honey, but where honey is worth so little as it is with you it will no doubt be well to run for wax, and some are doing that very thing.

2. It probably makes little difference, only you must arrange for feeding back honey in large quantity.

3. It will be well to use foundation to get frames filled with worker-comb in the brood-chamber, but certainly it will not pay to use foundation upon which to build combs that you are going to take for wax.

### Bees Abscond With a Newly Introduced Queen

A short time ago I introduced a fine queen to a colony that had been queenless for 2 days, and when I put her into the hive they did not act as if they would kill her. When they released her I took the cage away. The next Sunday I opened the hive and saw 3 or 4 bees around one bee, and I knew it was the queen, so tried to touch her, but she ran down between the combs. I shut the hive and went to the house with the strong belief that I would have some large Italian bees. But today (Saturday) I looked in the hive, and there was not a bee to be seen. All had swarmed, leaving me 4 empty combs and no brood. If I had known the queen would

### Introducing Queens

I put a fine breeding queen into a small queenless colony having only drone-brood, placing her on a frame of hatching brood. Can I safely give another frame with adhering bees soon, or shall I shake the bees in front of the hive to get the young bees for help?

WISCONSIN.

ANSWER.—Don't give any but queenless bees unless there are already in the hive 3 times as many bees as the number you add. Or, cage the queen, then give as many bees as you like.

### Carniolan Bees

Are all Carniolan bees dark? and are they gentle? I had gotten the impression that they are hustlers, and are not gentle.

ILLINOIS.

ANSWER.—They are dark with whitish bands. Some say they are exceedingly gentle; others say they are cross. Either there is a difference in Carniolan bees or some are called Carniolans that are a cross between Carniolans and blacks. It is difficult to distinguish between the pure blood and the cross.

### Queen Entering the Wrong Hive—Rearing Queens

1. Some time ago I had a colony of bees that superseded its queen, and one day I found a virgin on one side of the frame, and the old queen on the other side. I caged the old queen and removed her. There were only 2 queen-cells in the hive, both had hatched, and I thought the queens would manage that part themselves. This colony was on the east end in the row, and I was very much surprised one day to be called home because the bees were swarming. When one of those 2 virgins mated she had gone into the hive just west of her own, had been accepted, and had stayed in the hive about 10 days (and had been laying) before they swarmed out with the old queen.

2. Early this summer I thought I would try to rear some Italian queens, so I made some queen-nursery cages of whitewood boards  $\frac{1}{2}$ -inch thick and 2x2 inches square, with a 1-inch hole in the center, and on one side I bored a  $\frac{3}{8}$ -inch and a  $\frac{1}{4}$ -inch hole, one for the queen-cells and the smaller for queen-candy. When the queen-cells were sealed I cut out the large ones and put them in the nursery, placing the nursery in a holding frame in the center of a very strong 1-story colony. Only about 4 out of a dozen queen-cells hatched, and the queens were weak and had no wings, otherwise they were large. Had they been

chilled, or wasn't the nursery made right? The nursery was covered on the sides with wire-netting, and a tin cap where the queen-cell and candy were. Would you advise me to try them again? If so, how?

INDIANA.

ANSWERS.—1. The usual thing, when two virgins hatch in the same hive, is for one to kill the other, and I hardly see how you can be sure that did not happen in your case. Is it not possible that the colony that swarmed reared a virgin queen itself? Still, it is true that not infrequently young queens enter the wrong hive.

2. Yes, you should try again; there is no reason why you should not succeed as well as others. It is possible that the cells were not ripe enough. It is better not to cage cells till they are within a day or so of having the virgins emerge. Your cages were not of the best kind. Being  $\frac{3}{4}$  thick, the bees might not get near enough to the cells, especially as one side was wood. You will do better probably with the common Miller introducing cage that you will find mentioned in all catalogs, or you may like the improved Miller cage described in "Forty Years Among the Bees," page 247.

## Reports and Experiences

### Dealing With Laying Workers

I note that bee-keepers are still troubled to know how to deal with that pest of the hive, the laying worker, uniting with another colony having a fertile queen being the only remedy I have seen proposed.

I have a remedy that has always succeeded with me, either to introduce a fertile queen or have the bees rear a queen from brood. It is this:

Take the hive from its stand and carry it behind the house or some building near by, then after placing an empty hive on its stand to keep the bees from going into other hives, shake or brush every bee off the combs on the ground, setting the combs to one side away from the bees, and after all are off and the hive cleaned, put the combs back in the hive and return it to its old stand. Then put a frame filled with brood and covered with bees into the hive, and the bees will do the rest. Or, if you want to give them a queen do it after a few hours. G. A. WRIGHT.

Mitchell Co., Iowa.

### A Satisfactory Bee-Veil

A very satisfactory bee-veil is made from  $1\frac{1}{2}$  yards of black netting, drawn in at the top and bottom, the same as any bee-veil, then dipped in cooked linseed oil. Wash it thoroughly in this preparation, rubbing it until all the bubbles have disappeared from the meshes, and pull it through a dry cloth. Then hang it up in a warm place to dry. Put a stick through it horizontally when drying, so that it will be spread out. This makes the veil stiff, and the bees do not attempt to sting through it as they do when it is flimsy. It will also last a good deal longer than an ordinary bee-veil. Raw linseed oil might answer the purpose as well as the cooked, but we have not tried it. HAYCK BROS.

Kane Co., Ill.

### Net Gain of an Average Colony

The net gain of an average colony brought up to good strength by feeding about a month before the harvest of this year, was as follows:

The first gain for the year was May 18, which was  $\frac{3}{4}$  pound; this slowly increased until May 31 when the gain for the day was 11 pounds; the next day it was  $8\frac{1}{2}$ , and for the following consecutive days, respectively: 12, 10, 3, 0, 10,  $6\frac{1}{2}$ ,  $7\frac{1}{2}$ , 4, 2, 9, 10,  $9\frac{1}{2}$ , 8,  $9\frac{1}{2}$ , 10,  $8\frac{1}{2}$ , 8, 1, 3, 2, 8. Then it dropped very rapidly, and in less than a week there was a loss of from  $\frac{1}{2}$  to one pound, and until Aug. 7 the loss kept up. Now, strange to say, they are storing honey from wild bonaset, about one

to two pounds a day. Week after week in July they worked on acres of white clover, with a steady loss every day. Last year the same colony stored 250 pounds of honey. But it must be borne in mind that they never lacked for empty comb to store in.

From about 50 colonies, spring count, I had only 2 swarms this year, but they are swarming some now. It is mostly on account of superseeded queens, but an old clipped queen came out yesterday.

There is barely half a crop of honey in this locality, as most bees swarmed in June.

Linn Co., Mo., Aug. 12. IRVING LONG.

### Easy Queen Introduction

A prime swarm came out this year on April 28, with 2 queens. I caught one of these queens and let her run into the hive of a queenless colony, without any restrictions, and she was received all right.

J. B. AUSMUS.

Benton Co., Ark., Aug. 16.

### Backward Spring Makes Poor Season

May and June were so wet and cold that the bees were very slow in breeding up, my first swarm issuing July 6, fully one month later than usual. However, since that date we have had a fair flow from white clover and basswood. I think I can count on an average of 30 pounds of comb honey per colony, which will be as much as I got last season. I have now 40 colonies, but have had only 14 swarms this season. GEO. STOUT.

Hennepin Co., Minn., Aug. 14.

### Swarm Clustered for 29 Hours

I started last spring with 4 colonies. I now have 5, and they are not swarming as much as I think they should.

One of my neighbors, who is afraid of bees, when coming through his pasture on the afternoon of July 4, at about 4 o'clock, saw a swarm of bees clustered on a bush. He wanted to let me know about them, so I could get them, but he was going away in the evening and had not time. The next day at 5 o'clock p.m., when he went after his cows, there was that cluster yet. In the evening he came to let me know and I hived them that night at 9 o'clock, so we know they actually hung in the cluster 29 hours, besides whatever time they may have hung before he saw them. I have "Langstroth on the Honey-Bee," and "A B C of Bee Culture," and I could find nothing like this in either. What do you suppose was, or could have been, the cause of their hanging so long? They were good Italian stock. I hived them in a double-super Wisconsin hive, and they are doing fine. Their queen was as fine as any I ever saw.

Adams Co., Wis., July 8. W. B. SMITH.

[Although such cases do not often occur, a good many have been reported. Sometimes the weather accounts for it, turning rainy after the swarm has settled, thus preventing the bees from taking flight. There have been a few cases in which the bees stayed permanently where they clustered.—EDITOR.]

### Record of a Good Queen

Here is the record of a queen which I got in 1904. On Aug. 17 of that year I gave her 2 frames with bees and brood, and gave frames with foundation as she needed them. When cold weather came on they had 7 frames filled with honey and brood (and lots of brood, I tell you.) This spring the colony was strong. I gave them a double hive, and it contained so much brood that I divided them, with good results, June 15. July 5 a monster swarm issued, and they now have 2 bodies and one super, and if the flow should return I will have to give them another. July 13 another small swarm issued, with a fine queen, so I put them in an 8-frame hive. They are doing well.

To-day I looked through the parent colony. The young queen has mated with a 5-banded golden Italian drone, and she has a fine nest

of brood. So you see I have 4 fine swarms of bees and 200 pounds of honey, all from one queen. If any one should ask me if I think it pays to get queens my answer would be yes, and, emphatically, yes. I got some 5-banded golden Italians from Texas which are very nice. I bought them as an experiment, and will report later as to how I like them.

I had 6 colonies, spring count, and now have 16. I am making them pay for everything they get (or everything I get for them,) so I am sure they will not bankrupt me. The neighbors say that I would tame the worst bees on earth and make them gentle. Bees are not as vicious as people think.

I owe much of my success to the good reading matter found in the American Bee Journal, and advise every one who keeps bees or is thinking of doing so, to subscribe for it.

Kane Co., Ill., Aug. 8. E. J. BRYANT.

### Poor Honey Year in Georgia

I mingle my voice with the other "busted" bee-keepers by saying that this has been a rocky year on bee-keeping in Georgia.

There was no fall flow last year, and the winter was hard on the bees. There were but few of them in the early spring, and no honey, though plenty of bloom, but bees never noticed it. There was a fine crop of honey from the gallberry in this and other sections.

We have had a fine fall flow and bees are in good shape for winter. I have taken off 40-1-5 pounds of honey per colony, but have had very little increase. J. J. WILDER.

Crisp Co., Ga., Aug. 14.

## Langstroth on the Honey-Bee

Revised by Dadant—Latest Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.20, or club it with the American Bee Journal for one year—both for \$2.00; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

### If you want the Bee-Book

That covers the whole Apicultural Field more completely than any other published, cost \$1.20 to

CONVENTION NOTICES.

**A Bee-Keepers' Field-Meeting** will be held at The A. I. Root Co.'s exhibition apiary at Jenkintown, Pa., Thursday, Sept. 7, 1905, in which will unite the Pennsylvania State Bee-Keepers' Association, New Jersey State Bee-Keepers' Association, Philadelphia Bee-Keepers' Association, New York bee-keepers, and all bee-keepers and others interested in bees, from the surrounding territory. Jenkintown is a suburb of Philadelphia. Orders for reduced rates on the local ticket agents for round-trip tickets to the convention can be secured free on application to Wm. A. Selsor, of Jenkintown, Pa., Hon. H. A. Surface, Harrisburg, Pa., and Dr. E. F. Phillips, Washington, D. C.

**National.**—The International Fair is to be held in San Antonio, Tex., Oct. 21 to Nov. 1. When this Fair is in progress there are very low rates in force on the railroads out for 600 or 700 miles. Then there are harvest excursions from the North on the 2d and 4th Tuesdays of the month. The 4th Tuesday in October comes on the 24th. Considering these facts, it has been decided to select Saturday, Oct. 28, as bee-keepers' day at the Fair. This will give ample time for members from the North to reach the city by starting the 24th. The regular sessions of the convention will begin Monday, Oct. 30, and continue three days.

The headquarters of the National Association will be at the Bexar Hotel (pronounced Baer, long sound of a), corner of Houston and Jefferson Sts., and rates are only \$1.00 a day, and up. The convention will be held at Elks' Hall, 125 W. Commerce St., only two blocks from the Bexar Hotel.  
Flint, Mich. W. Z. HUTCHINSON, Sec.

**Capital City Apiary!**  
**Fine Italian Queens**

Untested, after June 15, 75c; Tested, \$1.00; Breeders—the very best, \$5.00. Terms cash with order. Safe arrival and satisfaction guaranteed. **WALTER S. HOSS,**  
1123 Blaine Ave., INDIANAPOLIS, IND.  
27A131 Please mention the Bee Journal.

**Tennessee Queens**

Owing to the great demand for my TENNESSEE QUEENS for several seasons, and the quantity of standing orders from old customers, I decided not to advertise until my books were cleared of orders, and thus avoid disappointing customers.

I am now ready to fill orders by RETURN MAIL. Breeders used: Imported dark leather-colored Italian; my selections from light imported Italian; Moore's long-tongue; golden; Carniolan (mated to Carniolan drones in distant yard, and to Italian drones); imported Caucasian (late received, mated for the present to Carniolan and Italian drones).

Prices until Oct. 1.	After Oct. 1.	Tested—
