LONDON:
PRINTED BY STRANGEWAYS AND SONS,
Tower Street, Upper St. Martin's Lane.

INDEX.

- Abbott, Bros., their section-holders, 218; their patent fumigator, 537; their Southall fumigator, 533
- Abbott, C. N., his paper on hive construction, 459
- Abbott, J. A., his departure for America, 542
- Absconding colonies, 114
- Acacias, 292
- Acetate of ammonia, 496
- Adney, John, his death, 338, 357
- Adulterated honey, 44
- Adulteration of honey, 55; American, 137
- African bees, 129
- African queen, 282, 316
- After-swarms, how prevented, 141, 162
- Albino bees, 290, 449
- Albino queens, 285
- Alien queens, best mode of introducing to full colonies, 362. See Queen-introduction
- Allen, Septimus, his glass sections, 197
- Alley, Mr., his directions for introduction of queens, 233; his cage, 368
- Amateur, balance-sheet of, 128; hive-making by, 59; 69; diary of, 83; experience of, 109
- Amendment, a matter requiring, 203
- American cloth, 134, 216; gloves of, 494
- American queries, 137
- Anderson, James, of Dalry, his death, 448
- Anderson, Rev. C., *The Bee-keepers' Alphabet*, 549
- Andrena fulva, 263
- Andrenida, 216
- Anglo-Carniolan bees, 262, 285
- Anglo-Cyprian hives, 559
- Another triumph, but more red tape, 461
- Ants, 264, 347; destruction of, 481
- Aphidial honey, 77
- Apis, large, 467
- Apiarists, 581
- Apiary, general management of, 120; of twelve hives, best system to work, 243; work in, 439; position of, 494; establishing an, 533; art in the, 538
- Apiculture, 481; lectures on, 6, 89, 109, 113, 257; present and future prospects of, 55; patents relating to, 453; knowledge of, possessed by Americans and Germans, 482
- Apicultural statistics, 377
- Apis Europæa*, 189
- Apis dorsata*, 91
- April, plants flowering in, 139
- Artificial pollen, 91, 171
- Artificial queen, 157, 170
- Artificial swarm, 229, 250, 254
- Artificial swarming, 54, 186, 216, 229, 250
- Artificial swarms, too late for, 405
- Aspect of hives, 112, 392, 510, 539
- Association, advantages of, 64, 76, 238; the central and county, 103
- Association frame, 183, 238, 416
- Associations and the production of honey, 365
- Australasian Bee Manual*, 548
- Australia, bee-hunting in, 495
- Bacilli, 164; their effect, 158
- Bacillus, a new, 67; alvei, 302, 347; depilis, 182, 229, 264
- Bacon-hives, 144
- Bacteria, 229; are they harmless? 207
- Bacteriology, 208
- Bad start, a, 259
- Bazster hive, a, 18
- Bazster, Samuel, 3
- Balearic queen, 282
- Bar-frame hive undisturbed for eight years, 171
- Barley sugar, 3
- Beans and bees, 246, 261
- Bee, and carwag, fight between, 83; eyes of the, 100, 110; a, in his ear, 453, 465
- Bee-books, 250
- Bee-flowers, 186, 467
- Bee-gloves, 230, 494
- Bee-hive, a curious, 116; stealing a, 348
- Bee-hives, duration of, 101
- Bee-hives, 23, 52, 87, 99, 134, 230, 458
- Bee industry, 476
- Bee-keeper, advice to a, 145; fullalovelet to a, 378, 387
- BEE-KEEPERS' ASSOCIATIONS AND SHOWS.—Aberdeen, 385; Bath, 359; Berkshire, 27, 68, 176, 328; British, 2, 14, 26, 45, 57, 91, 105, 157, 147, 161, 175, 196, 231, 255, 286, 301, 313, 365, 393, 440, 469, 485, 498, 554, 579, 601; annual meeting, 33, 79, 82; Bucks, 15, 48, 56; Caledonian, 376, 543; Cheshire, 82; Clewer, 376; Cornwall, 36, 292; Derbyshire, 58, 82, 91, 449; Devon and Exeter, 47, 255, 384; Dumfries, 427, 450; Essex, 67, 292, 554; Faringdon, 410; Glamorganshire, 2, 58, 93, 148, 385; Glasgow, 429; and West of Scotland, 459; Gloucestershire, 398; Grantam, 532, 583; Hants and Isle of Wight, 105, 314, 337; Hawkshead, 449; Herefordshire, 57; Highcliffe, 411; Huntingdonshire, 565; Irish, 211, 244, 255, 292, 376, 488, 521, 583; Kent, 36; Lancashire and Cheshire, 139, 463, 495; Leicestershire, 37, 48, 126, 211, 244, 375; Lincolnshire Agricultural, 124, 179; Middlesex, 48; Monmouthshire, 375; Montgomeryshire, 2, 212; Norfolk and Norwich, 67, 155, 169; Northamptonshire, 57, 440; North-east of Ireland, 115, 175, 419, 521; North of Scotland, 93, 450; Northumberland, 437; North Wales, 2; Norwich, 232, 315, 325, 327; Oxford, 36; Portsmouth, 314; Reading, 382, 469; Royal Agricultural, 2; Rutherden, 429; St. Ives, 375; Selkirk, 439; Staffordshire, 92, 398, 412; Strathane, 399; Somersetshire, 244; Somerton, 398; Southampton, 357, 371, 413; Surrey, 138, 374; Swamere, 58, 109, 329, 522; Taunton, 198, 384; Torquay, 106; Warwickshire, 176, 221, 449; Wigtonshire, 429; Wilts Agricultural, 292; Wolverhampton, 339, 587, 589; Worcester, 68, 92, 153;
- Wrockwardine, 437, 596; York-shire, 19
- Bee-keepers, warning to, 108
- Bee-keeping, a branch of agriculture, 149; among the young, 381, 420, 431, 441, 452, 464; beginning, 134; calculation of profit arising from, 268; demonstrations, 413; in Minorca, 168; its 'ups and downs', 125; recommencing, 145; system of management of, 299; the extension of, 417; among Swiss peasantry, 584; in Canada, 605
- Bee-lose. See Braula cæca
- Bee management, 193
- Bee-naturation, 292, 279, 318, 477, 505
- Bee in syrup, 229
- Bee-run, an experimental, 423
- Bee-shows, rules and schedules for prizes at, 412
- Bee-sting, 72, 127, 213, 227, 238, 261, 443; has it ever been an ovipositor? 107, 156, 190; effect of, 402, 414. See Stings
- Bee-stories, 499
- Bee-tent, can we make it more attractive? 260
- Bee-trees, 178
- Bee vagaries, 157
- Bees, enemies of, 3, 85; near streams, 11; liberating, 15; lurring, *ib.*; predict weather, 21; dead, 22, 145, 228, 245, 248, 311; profit from, 38; flying in water, 41; shaluz, 41, 33; by rail, 42; the best for producing honey, 58; how they find their way, 61, 468; in bucket, 64, 75; not to be disturbed in winter, 65; preventing from propolis section-racks to frames, 75; have they a language? 82; smoking, 84, 85; in greenhouse, 88; suffering from dysentery, *ib.*; eating eggs, 100, 110; in bothose, *ib.*; dying with abundant stores, 101; race of, *ib.*; packing up, 111; breed of, 112; choosing a new home, 119; dying from want of food, 121; perishing in snow, 122; leaving hive, *ib.*; injuring grapes, 124; getting large numbers at work in single hive, *ib.*; wintering, 125; crossing water, 130; dwindling, 130, 205; living without food, 131; diseased, 133, 183; and poultry, 134; in a trance, 145; passing from hive to hive, 150; perishing in brewery vat, 153; and cholera, 155; croaking, 131, 156, 163, 168, 169, 181, 187, 196, 204, 416, 588; dislodging from a house, 157; dying from starvation, 171, 230, 588; do they hear? 178; and drouth, 179; refusing syrup, 181; flying from the hive, 204, 215; on paint, 206; French works on, 228, 236, 278; thoroughness of, 233; their visits to flowers, 246; telescoping their abdomens, 248; early, 249; petition of, *ib.*; at a lawyer's office, 249; deserting, 250, 261; with appearance of fungus, 290, 411, 426; and
- bean-, 246, 261; removing from wall, 263; sending from England to Scotland, 264; under station platform at Burton Agnes, 285; hanging out, 2-7; and swallows, 291; in refuse-heap, 286, 309; difference in energy of, 309; losing stung in sting of other bee, *ib.*; spiteful, 311; when queen-raising, *ib.*; selecting places for swarming, 322; in possession, 323; hanging in festoons, *ib.*; political, 327; removing from hole in wall, 333; swarming from a box-house, 334; irascibility of, 340; fighting, 342, 363, 390; a workroom invaded by, 344; not entering sections, 348; varieties of, *ib.*; hanging out and then returning, 364; in a church, 403; and flowers, 423; from a house, utilisation of, 438; taking down syrup, 441; why so few cottagers keep, 453; alighting, 453; general management of, 461; in a tree, 471; in a wall, *ib.*; kept in London, 431, 453, 478, 513; kept near London, *ib.*; swarm of, in October, 478; refusing to unite, 473; song of the, 481; savage race of, 483; and poets, 499; from a chimney, 505; enemies of, 511; at Albany house, lines on, 512; carrying eggs, 529; examining in cold weather, *ib.*; resuscitation of, 527; and odours, 528; stupefied or dead, 529; poisoned, 532, 573, 577; singular conduct of, 537. See Carniolan, Cyprian, Italian, Feeding, Moving, Transferring, Uniting, &c.
- Beetles in hive, 298

 Dines and Sons, their prize hive, 457; their reversible-section-rack, 503
 Direct introduction, 597
 See *Queena* introduction.
 Disease brood, suppose, 233
 Disinfecting hives, 66, 112, 147
 Distance between frames and live-floor, 76, 86, 98
 Distance guides, 205; hives without, 134
 Dividing, 210
 Division boards, 44, 170, 181; with foundation, 157
 Dog and bees, 202
 Dolan's leaf show-case, 218
 Donbluz, 76, 86, 98, 101, 114, 134, 147, 170, 171, 182, 193, 210, 229, 237, 243, 261, 303, 361, 456, 522; and removing upper storeys, 87; for extracted honey and prevention of swarming, 135, 147; for extracted and comb-honey, 185; in hive with high outside walls, 205
 Doubling hive, 186
 Doubling system, working on, the, 265
 Draining honey out of comb, 75
 Driven bees, hiving, 334; carrying, 455; a journey for, 465
 Driving bees, 38, 224, 234, 247, 261, 334, 346; failure in, 229
 Drone-brood cast out, 233
 Drone-foundation, 170; in sections, 157
 Drone-laying queen, 130; suspected, 455
 Drones, 158, 170, 214, 322, 334; in December, 12; and their uses, 60, 70, 97; killing, 143; Ligurising, 143; of unfertilised queens, 204; untimely, 215, 227, 347; early destruction of, 228, 247; large number of in stock, 250, 285, 309; easting out, 262, 279, 347; in worker-cells, 311; flying in the evening, 347; trapping, 344; wings of, 404; in presence of, 467; reduction of, 494; procreative power of those produced from fertile workers, 582
 'Drop' system of driving or bumping, 343
 Dry comb foundation, 223, 236
 Dryness of hives, 9, 17, 34, 39, 51, 53, 72, 107, 510
 Dry sugar, 184, 406; and early feeding, 64, 456
 Dry-sugar feeder, 54, 62, 151, 167, 169
 Dubini, Dr., his apiary, 150; appendix to *L'Apiculteur suo Gorzano*, 533
 Duke of Argyll's tea-tree, 453
 Duneau's pearl sugar, 162
 Dunster, H. P., *How to make the Land Pay*, 20
 Dysenteric bees, 143, 145; combs, 144
 Dysentery, 2, 24, 44, 83, 90, 112, 158; cure for, 142, 189; disinfecting combs after, 143; symptoms of, 264; treatment of, 364, 582
 Earthen jars for honey, 392
 Earthen pans as roofs for hives, 510
 Earwigs, 379, 416
 Echoes, II, *et passim*
 Echinops spheroccephalus, 439, 559
 Egg-laying abnormal, 183
 Elementary schools and bee-keeping, 432
 Enameled cloth and quilts, 3, 133, 181, 187, 192, 219, 347, 415, 439
 Encasements, 458
 Enthusiasm, value of, 8
 Entrances, 75, 91, 582; cleaning, 44; second, 144, 157
 Eristalis fossarum, 217
 Erslev, Hans, *Honningen og dens Avendelse*, 588
 Eucalyptus a cure for foul-brood, 239
 Examination of hives, 66
 Examinations, 161
 Examining examiners, 63, 108
 Excluder, zinc, 62, 183, 188, 205, 250, 456; under sections, 42, 53, 85, 165; and dead bees, 75; size of holes in, 274
 Exhibiting twice in same class, 390, 587, 589
 Exhibition, proposed, in London, 79
 Exhibitors at shows, 203
 Experience, a beginner's, 319; my, 463, 503; a lady's, 443; another, 503; further, *ib.*
 Experiences, 524; more, 477, 598; my second year's, 489
 Expert, visit of, 347
 Experts, and bee-tents, 164; as exhibitors, 319; at the universities, 272
 Extracted or section honey, which is the more profitable, 105
 Extracted honey, working for, 64
 Extracting, 64, 76, 122, 327, 382, 392, 395, 418, 458, 486, 131; sections, 595
 Extractor, 298; clearing, 170, 181, 204
 Extractors, 184, 423, 594
 Extraordinary bees, 534
 Failure and success, 308
 Feeders, 66, 112, 274; with zinc cap, 539
 Feeding, 12, 32, 41, 83, 94, 136, 145, 162, 171, 183, 192, 239, 363, 371, 378, 392, 418, 588, 463, 510, 516; in January, 11; with sections, 88; in spring and autumn, 237; at back of hive, 298; in weak colonies, 405; and feeders, 415; by day or by night, 455
 Fertile worker, 130, 443
 Fertile workers, 125; getting rid of, 104; treatment of stocks with, 192; probable use of, 243
 Fighting, 135
 Figwort, 249, 242
 Fiorini, M., his apiary, 152
 First-class certified exports, 454
 Five-pound swarms on six frames, 322
 Five swarms in one, 236
 Fixing foundation, 18, 52, 53, 153, 228, 229, 233, 251, 585
 Fixers for foundation, 149, 163, 223, 234, 274, 298
 Flat-topped hives, 250
 Flight of bees, rate of, 100, 120
 Floor-boards, 3, 91, 439; cleaning, 466
 Flowers, 54, 331; names of, 205
 Fly-catchers and bees, 344, 360, 377
 Food for bees, 44; for wintering bees, 37
 Foreign:—Burmah, 91; Canada, 125, 224, 271, 344, 390, 403, 424, 490; France, 174, 187, 212, 220, 245, 304, 390, 493, 424, 479, 535, 584; Italy, 174, 198, 245, 292, 230, 403, 424; Jamaica, 253; New Zealand, 253, 391, 392; Ontario, 499; Soudan, 391; South Africa, 126; South Australia, 391, 535; Switzerland, 423
 Foreign opinion, 319; bees, 608
 Formic acid a cure for rheumatism, 75
 Foul-brood, 70, 75, 77, 88, 204, 215, 225, 247, 264, 297, 311, 382, 426, 435, 426, 487, 536, 552, 561, 576; a test of the queen, *ib.*; and frames parallel to entrance, 63; stocks and combs, 145; cured by thyme, 159; and camphor, 195, 216; test of, 247; in good honey years disappears, 269; treatment of, 483
 Foundation, 230, 456; thin, for sections, 15, 233; for supers, 50, 97, 118, 128, 139, 154, 263; fixing, 18, 52, 53, 229, 236, 251, 585; experiments with, 174; thinning, 215, 228; hang-

ing perpendicularly, 251; drawing out, 587
 Foundling bee-hives, 560
 Four colonies from two, 363, 373
 Four-storied hives, 257
 Frame coverings, 114
 Frame-hive under skep, 217
 Frames, number of, for wintering, 27, 382, 405; hanging frame, 142; width of, for extracted honey, *ib.*; inserting in hives, 223; long, with strip of wood, 101; 11 in. apart, 122; altering for metal ends, 145; parallel or perpendicular to entrance, 410; space round, 158; fastening for travelling, 174; parallel with the sides, 183; removed with unsealed honey, 415; size of, 494, 544, 561, 575
 French works on bees, 234, 248
 Fruit-growers and bees, 200
 Fumigator, W. B. Webster's, 184, 193, 213; Mason's, 217; the Raitt, 233; the Southall, 533
 Fumigators, 250, 259
 Fungus or pollen? 414, 424
 Future, provision for, 25

Galvanised iron vessels, 575, 577, 593, 600

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, w.c.

[No. 185. VOL. XIV.]

JANUARY 7, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

TO OUR READERS.

In reply to numerous inquiries, we beg to say that no difficulty should be experienced in procuring the *Bee Journal* through local booksellers. In those localities where daily papers are supplied, the *Journal* should be delivered on Thursday morning. In the most remote districts, not later than Saturday. In publishing the weekly issue on a fixed day, the difficulties hitherto experienced in obtaining the *Journal* as soon as published, through the local booksellers, will cease. We feel sure our readers will welcome the change.

THE NEW YEAR.

The year 1885, with all its joys and sorrows, has passed away and we are entering upon the new year, 1886—the 14th of the existence of 'Our *Journal*.' This number is the first of the 'weekly' issue which we have decided the *British Bee Journal* should become in deference to the wishes of our subscribers. The *Bee Journal* was called into existence by the necessities of the times and was designed to advocate the cause of bee-keeping. For ten years it appeared once a-month, it has since, for three years, been issued regularly on the 1st and 15th of every month, and now it enters upon a new era of its existence by a weekly issue with the same grand object in view as when it first started. To support its high calling and to make it the leading 'weekly *Bee Journal*' we are determined to use every means within our power. We already number amongst our contributors the most experienced and successful bee-keepers in the country, and we take this opportunity to thank them for their assistance. We are grateful for past favours and we confidently look for an increased support in order to enable the *Bee Journal* to retain its position of being the *best* paper relating to bees and bee-keeping.

There are a great many bee-keepers in Great Britain who never write on bee matters at all although well able to do so, these we invite to answer queries in our columns and join in the correspondence. We wish to make the *Bee Journal* as instructive as possible, and we would remind all

that there can be no intelligent practice of bee-keeping unless it is founded on correct theory, and to get correct theory requires comparison and interchange of views with the most successful workers.

We invite the co-operation of all our friends to make the present volume of the *British Bee Journal* even more interesting than any of its predecessors. We wish all to take an interest in, and to make it, 'Our *Journal*.' Let us all do our work together, faithfully and well, always with reference to the ever-advancing principles of progressive thought and action.

Hoping that 1886 may be especially marked as one of progress and advance in bee-keeping, and that the honey season may be as good as the last. We wish our readers—

A Happy New Year.

A RETROSPECT.

Before we enter upon the duties and anxieties of another year, it may, perhaps, be desirable to cast a retrospective glance on that through which we have just passed. Several events during its passage have transpired which will leave their impress on bee-keepers and the progress of bee-keeping for many years to come.

The first of these occurrences which strikes the memory is the death of the Rev. H. R. Peel. The feeling of gloom caused by that event has not yet passed away. His loss was indeed great, whether we regard him as the editor of the *Bee Journal*, or as the active and pervading spirit of the British Bee-keepers' Association. In the one we miss his guiding mind and his wise counsel; in the other, we have lost a presence and an influence which left its effect not only on the Parent Association, but on all those affiliated with it. His untiring energy, his indomitable perseverance, his skilful powers of organization, his lavish expenditure of time, trouble, and means, had a marked result in creating an enthusiasm through the length and breadth of the land for the industry of bee-keeping, which will remain for many years to come. We trust that the spirit infused by him will continue to animate the secretaries of the County Associations, so that the benefit caused by his self-denying efforts may be continued and increased; so will they show their loyalty and respect for him who so laboriously and successfully worked for the best interests of bee-

keepers. At his decease the British Bee-keepers' Association invited bee-keepers and others to subscribe to a fund to perpetuate the memory of Mr. Peel, with the hope that the investment of the amount collected might be devoted to a prize to be given to cottagers in connexion with the advancement of bee-keeping. The Committee of the British Bee-keepers' Association have recently issued a circular announcing that this fund should be closed at the end of the year 1885. We have reason to believe that the sum collected has amounted to 1007.

Another event which will mark this year has been the establishment of Honey Companies. Mr. Peel took a great interest in the formation of the British Honey Company, and was elected the first chairman, and presided at the first public meeting, which was held on the 15th of April, 1885. The primary object of this Company was to promote bee-keeping by the ready sale of British honey, to assist small producers to dispose of their stock, and to check and to diminish the sale of the foreign honey, which has been imported into this country in such great abundance. The Company had many difficulties to contend against in the beginning of their career, chiefly through the misapprehension of bee-keepers as to their intentions. The financial year of the Company closed on the 31st of December, and we may soon be furnished with an authorised statement of the work achieved during the past year. We believe it will be found that, though they had taken full powers to sell foreign honey as well as home produce, the supply of British honey has been so abundant that these have not been brought into exercise. The number of shareholders may be reckoned about four hundred, thus indicating the great interest taken in it by bee-keepers. The desire for pure British honey is increasing, the virtues of honey and medicine are being recognised, there is a wide and an open field for the energies of the Company, and we trust that they will go forward and possess it.

The principal Exhibition in connexion with the British Association during the year was held at Preston under the auspices of the Royal Agricultural Society. This was eminently successful, as during the whole time the Exhibition was opened the bee department was thronged with an eager multitude of visitors desirous of embracing the opportunity offered of receiving instruction in the science of apiculture. The future of bee-keeping lies in the recognition of the closeness of relationship between Agriculture and Apiculture. These are becoming more mutually helpful to each other; and we are glad to note that this example of the Royal Agricultural has been followed by the Lincolnshire, the Hertfordshire, the Glamorganshire, the Isle of Man, and others. The next meeting of the Royal Agricultural will be held at Norwich, when we trust that the British will again come to the front and educe the great truth that bee-keeping is veritably a part of agriculture, and that it will realise to the farmer a larger amount of profit than any other of the minor industries connected with his work.

The British Bee-keepers' Association is making safe progress. The number of members is maintained. New Associations have sprung up in Glamorganshire and Montgomeryshire, and steps are being taken for opening up North Wales.

We must not omit from our review of the year the valuable contribution to bee-literature produced by F. Cheshire, Esq. This work has absorbed his mind for many years; he has literally followed the Horatian maxim, *nonumque prematur in annum*; and from the extreme pains and careful study of the physiology and anatomy of the honey-bee, and the delicately delineated wood engravings, we believe that no more valuable contribution to a knowledge of the honey-bee has been brought before the public since the time of Huber. The work, from being published in monthly parts, and therefore frequently breaking off abruptly, precludes it from being studied so closely or so sequentially as it can be when completed. The portion of the work now passing through the press is eminently scientific. This will make a volume consisting of 360 pages. It will be followed by Practical Apiculture, which will extend to an equal length.

We have also heard that the work on bees that has occupied for some time past the time and attention of the Rev. F. G. Jenyns, of Stevenage, Herts, will speedily make its appearance. The object of this work is not to assume the place of the *Guidés* which are now before the public, or to be considered in the light of a scientific treatise, but principally to impress the importance of the habits of observation on the rising generation, and to unfold to them one page of the book of Nature by portraying to them the wonders of bee-life, with the hope that it may create such an interest in the subject that it may lead them in after-life to desire to know more, and to take up bee-keeping for themselves with that knowledge which will add to its interest, and will enable them to make it more profitable. The work is illustrated with many engravings, and contains an introduction written by the Baroness Burdett-Coutts.

We have not yet received the complete statistics of the imports of honey into this country, but for the first eleven months of the year 1885 they amount to 58,022*l.*, as against for the same period in 1884, 59,628*l.* The value of wax imported in 1884 was 105,813*l.*, as against 97,142*l.* for 1883. When the statistics of honey and wax are fully before us we will take the opportunity of dealing analytically with them. There can be no doubt of the continued large importations of honey, and the only mode of checkmating them is, that the home production must be able to compete in quality and price with foreign honey. We cannot conceal from ourselves that apiculture, as other industries, is passing through a revolution. The sooner bee-keepers recognise this fact the better, and endeavour by more skilful management and by the employment of better appliances, to increase the produce of their apiaries. Small profits and large sales must in the future be relied on, and small sales and large profits be relegated to the past. We believe that Honey Companies

will prove a great factor in the solution of this commercial problem, and the future will indicate to what extent, and by whom, bee-keeping can be rendered profitable.

From all parts of the United Kingdom our reports lead us to the conclusion that the honey harvest for the past year has been an abundant one—with the exception of the heather honey, which has been a failure.

We here close our cogitations with the expression of the hope that bee-keepers and bee-keeping may flourish during the year on which we have entered.

USEFUL HINTS.

After severe frost and snowstorms, again we have a sudden thaw, and the temperature so mild that to-day—the last day in the old year—bees are gaily disporting themselves, and with open weather strong colonies will soon commence breeding in earnest. Then consumption of stores will increase daily, and it behoves the careful bee-keeper to keep a sharp eye over his hives to see that all have sufficient food. Hives well stored in the autumn will be in no want at present, but where feeding is a matter of necessity to prevent starvation, the 'Heddon Syrup' as recommended in our last, may be used.

FOOD.—A kind of food much used in America is 'Good's Candy,' which is made by mixing together liquid honey and very finely powdered loaf-sugar, until the consistency of dough, or stiff putty, is reached. The paste is then laid on the frames over the cluster, in the form of a cake, and covered with the quilt. In skeps it is pushed in at the feed-hole. Bees take it readily, and there is little or no disturbance caused to the colonies. But if preferred, barley-sugar may be given in a similar manner, or placed under a bell-glass or tumbler, over the central hole. Or sticks of it may be pushed down between the combs near to the cluster. For these operations, advantage should be taken of any fine day which may occur, and the bees should be disturbed as little as possible. These little attentions will tend to keep the bees in perfect health.

As regards QUILTS and FLOOR-BOARDS, we reiterate our former advice, occasionally to change both, giving them dry and warm. Floor-boards, when well scraped, should be sponged with carbolic solution and dried.

DYSENTERY.—If any hives are found to be foul from dysenteric discharges, transfer combs and bees to dry clean hives. In suitable weather this may be quickly performed in the open air, otherwise it is best done indoors. The filthy ends of frames should be scraped and brushed over with weak carbolic solution, the bees confined to few frames, and fed with 'Good's food.' Any unnecessary manipulation by causing excitement leads to consumption of food, and increases the evil.

ENEMIES.—Refer back for advice respecting SNOW, INSECTIVOROUS BIRDS, CLEARING ENTRANCES, &c.

PREPARATIONS.—Again we remind all to prepare hives, supers, sections, foundation, feeders, &c.,

against the busy time coming. Soon will the snowdrop, first harbinger of spring, appear,—and next the crocus,—arousing the bees to life and energy, and the queens to breeding. It will be found of great advantage to have all appliances in readiness, that time may be afforded for spring-feeding, manipulations, &c.

UPWARD VENTILATION, although advised by all modern apiarists of any note, appears to be in direct opposition to the ideas (instinct?) of the bee, since the free use of propolis entirely prevents it. In order to indulge this propensity, we are wintering a score of colonies, in frame-hives, covered with closely fitting enamel-cloths, propolised, as in the summer months,—although the bees use very little propolis on this material. Turning aside these coverings on a fine day last month (December 14th) we found all the colonies perfectly healthy, the hives free from dampness or mould, and the enamel bedewed with a little moisture above the clusters *only*. The summer entrances were left open to their full width, and, according to present appearances, the bees are wintering, at least, as well as those which are covered with felt, carpet, and cushions.

In future 'Hints' we hope to record the final result. The winter, so far, has been such as to afford a fair trial, the bees having been unable to fly for periods of several weeks at a time; and we are, at present, favourably impressed with the plan. On placing the hand upon the enamel-cloth, the exact position of the cluster may be at once discovered by the warmth at that particular spot. The enamel is covered by felt, carpet, and flat straw-cover, and each hive stands in an outer shell, protected by a waterproof roof.

A happy and prosperous New Year to all our readers, and may we all obtain more honey and better prices than during the year which has flown.

SAMUEL BAGSTER,

INVENTOR OF THE 'LADIES' SAFETY HIVE.'

More than half a century has passed away since Mr. Samuel Bagster, 'practical typographer and devoted apiarian,' as he delighted to call himself, made a not unsuccessful effort to minimise the objections to bee-keeping, and to render its pursuit a pleasant occupation for ladies. 'Having,' he says, 'the happiness of dividing the joys and sorrows of life with one in whom, in the words of Solomon, "the heart of her husband doth safely trust," for "she looketh well to the ways of her household, and eateth not the bread of idleness," I felt it my pleasure to save her as much annoyance as possible while pursuing her daily avocations. Bees claimed a great share of my individual attention; but the constant fear of being stung, or not managing the bees correctly, so strongly influenced my partner that she confessed her fear, and begged to decline the duty; unless something could be done to find bees without stings, or hives that could be so worked as to take away fear in management.' As a mark of our respect for the kind intention and gallant attempt to produce the hive required shown by a by-gone bee-keeper, we consider it a duty incumbent upon us to give in this, the first number of our new series, a short memoir of his life.

Samuel Bagster was the eldest son of Samuel Bagster, the founder of the publishing firm of Bagster and Sons

(now S. Bagster and Sons, Limited, 15 Paternoster Row), enjoying even to the present day a world-wide fame for the beauty and excellency of their Polyglot Bibles. Bagster the elder was born in the year 1772, and died at his residence in Old Windsor on the 28th March, 1851, aged seventy-eight. He was a frequent attendant at Salters' Hall Chapel in the City of London. He married on the 19th of March, 1797, Miss Eunice Birch, who survived her husband twenty-six years, attaining the venerable age of one hundred. The village of Old Windsor had intended to celebrate this attainment by Mrs. Bagster of her hundredth year by holding a fête in her honour. Her Majesty Queen Victoria, hearing of this intended demonstration, called upon her neighbour about a fortnight before the expected day, and sat chatting with her for some time. Mrs. Bagster was greatly excited by this visit, and by the approaching festivities. She became, from that time, restless and sleepless, and gradually weakened, and on the very morning of her hundredth birthday she peacefully passed away.

Samuel Bagster, jun., was born on the 19th October, 1800, and, after having been educated at a school in Oxford, conducted by the Rev. J. Hinton, was articled to his father in the year 1815. From his earliest youth, works on natural history were his chief reading. During his school vacations, and during his apprenticeship, it was his greatest delight to visit the rooms of the old menagerie in Exeter Change to learn the peculiarities of the various beasts there confined. Every opportunity to witness collections of living specimens was embraced with eager avidity, and a taste for the study of animated nature permeated his mind. As time passed on, he gradually concentrated his attention on one object, and he found himself most interested in the study of bees.

From an early age Bagster showed a serious tendency, and in October 1822 he joined the Baptist church in Blackfriars. Having acquired the necessary technical training in his father's establishment young Bagster commenced business for himself in Bartholomew Close. In June 1825 he married Miss Elizabeth Hunt, of Heathrow, near Harlington, Middlesex. He lived for some years in Bartholomew's Close, but towards the latter years of his life he took up his residence in Shepherd's Bush. He called his cottage after the old Italian printers, 'Aldine' Cottage. The village of Shepherd's Bush, at that time, was principally surrounded by cow-pastures, 'which are cut very early for hay, that the cows might get the earliest advantage of the grass, and the season for collecting honey was very short.' It was here that he devoted what time he could spare to poultry-breeding and bee-keeping. In his preface to his work on *The Management of Bees*, he says, 'I follow the profession of a printer; and while my earliest and latest hours have been spent with my bees, or for them, my days are devoted to the use of the public, and to the acquisition of an honourable income.'

It was during the summer of 1834 that he brought out his work on *The Management of Bees*, printed by himself, and published jointly by his father and Wm. Pickering. This book has passed through three editions. It contains much valuable and practical information, and contains a useful history of bee-keeping up to his time. In this work we find a minute account of his Ladies' Safety Hive, in which he considers the following desiderata in bee-management may be embraced,—'cool store-room, prevention of swarming, easy method of taking honey, promotion of swarming when wished, perfect inspection of the whole hive, protection from wet in the open air, and a method of feeding in the severest weather without exposure to cold.' In it are found full directions for the manufacture of this hive, which it would be impossible to render intelligible without giving the diagrams which accompany it. We add, however, in his own words, the result of his system:—

'The deprivation may be performed at any time, when the boxes are full. If it be determined to take honey on any particular day, an arduous duty in most hives, little or no care is required in this. The day before you intend to have a share in the honey, with a stiff wire close the slide of your honey box: this manœuvre will make many bees captives, and cut off their retreat to the queen, and of course they cannot get out through the closed door. What is to be done in such a case? Use the wonderful instinct of the bees to effect your purpose; open the little outward door of the room about one hour before dusk, and all your prisoners will rush round to the front of the hive to the queen, with an alacrity that is amazing. After dusk, close the outward door again, and you may take your friends to your hive on the following day, to see you deprive it of its honey without any fear of molestation. When you have taken out the combs, shut the door, and withdraw the slide for the bees to clean out the room: if they have space enough without it, cut them off again after cleaning, or leave them to themselves. Judgment is necessary.'

The hive, which may be considered to have been a great improvement on those which preceded it, has had its day, and we may now inscribe on it the word *Fait*.

Samuel Purchas, the son of the author of the *Pilgrimages*, issued in 1657, a quaint quarto, now extremely rare, styled, 'A Theatre of Political Flying Insects,' in two parts, the first being devoted to the history and management of bees, and the second to meditations and observations, theological and moral, upon the subject. The greater part of these reflections were reprinted by Bagster in a volume produced in the same style and at the same time as his own practical handbook. He contributed *The Treasury of Scripture Knowledge* to his father's Polyglot series, and projected a series of questions on the Gospels for Sunday-school children; but the manuscript of the latter remained unfinished and unpublished.

Although at first the progress of his business gave him cause for anxiety, it steadily increased in extent. Many of the Polyglot Bibles, and other learned publications of Messrs. Bagster & Sons, came from his press.

Mr. Bagster took a warm interest and an active part in the anti-slavery and temperance movements; and for this latter cause he wrote several pamphlets. He is described by an esteemed correspondent as being 'a pleasant, genial man, a general favourite, very intelligent, and very enthusiastic about bees.'

Mr. Bagster died at his residence in Shepherd's Bush on the 1st July, 1835, aged thirty-five years, leaving a widow and no family. His widow has been since twice married, and died in the year 1879. He was buried at Tottenham Court Chapel, and his remains were removed in 1843 to the family vault in Abney Park Cemetery. The last time we were in that cemetery we were attracted by the massive highly-polished granite slab which covers the vault. On it was deeply engraved in Greek characters the motto that appears on the title-pages of the Latin, Greek, and Hebrew Polyglot Bibles, Πολλὰ γὰρ ἕνεκεν θανάτου, μίαν ἀθανάτου.—('There are many languages for mortals, one for immortals.') The correspondent above referred to remarks: 'The granite slab on the father's grave was somewhat remarkable, because on it was engraved the date of birth of his wife some twenty years before her death. The incompleteness of the inscription looked incongruous, "Born August 1777" — and no more.' Mr. Bagster's business was sold at his death to Mr. J. Rider, and it is still carried on in Bartholomew's Close under the name of William Rider and Sons.

As an author Mr. Bagster showed marked diligence when we consider the absorbing nature of his business and other avocations. His works consist of,—1. *The Treasury of Scripture Knowledge*, consisting of a rich and copious assemblage of more than 500,000 Scrip-

ture reference, and parallel passages from Canne, Brown, Blayney, Scott, and others, with numerous illustrative notes; adapted to be the companion of every biblical reader. London: S. Bagster, 1834. Foolscap 8vo. and 4to., forming the second part of the *Treasury Bible*. 2. *The Management of Bees*, with a description of the 'Ladies Safety-hive,' with forty illustrative wood-engravings. London: S. Bagster, 1834. Small 4to. A second edition was published in 1838 by Saunders and Otley, Conduit Street; and a third (unaltered) in 1865 by Griffith & Farran. 3. *Spiritual Honey from Natural Hives*; or, Meditations and observations on the Natural History and Habits of Bees, first introduced into public notice in 1657 by S. Purchas, M.A. London: S. Bagster, 1834. Small 8vo."

REVERSIBLE FRAMES.

The above wood engraving represents a reversible frame invented by Mr. Webster of Wokingham. It is very clever and ingenious. By these ends a perfectly reversible frame is obtained without any diminution in its size. They will fit any description of frames, either plain or broad-shouldered. By cutting over the two binders they could be used with metal ends. Where used with broad-shoulders the two pivot levers form distance blocks at each end of hive. Mr. Webster says that he has tested them as to strength by hanging a 28 lb. weight on the frames. Our fear would be that when holding the frame with one hand while manipulating, the ends might slip off into the midst of the bees.

We have also received from Mr. John Rudge of Dursley a rough model of a reversible frame. It is very simple. A small piece of tin revolving round a screw, forms the end of the frame. When on the downward side, it can be turned out of sight. It evidently can be cheaply made, and easily managed. A flange on the side keeps the frame from the side of the hive. It looks weak, but Mr Rudge assures us that it will carry a weight of 20 lbs.; and that he has fifty hives on reversible frames.

Selected Queries.

[1.]—*Is it practicable to produce comb honey in marketable shape without the use of separators?*

Yes, it is to a certain extent practicable, by using narrower than the ordinary two-inch sections, by greater care, and by more frequent manipulation than when separators are used. I do not hesitate to say that more honey is gathered when separators are not used, but if we get the extra quantity at the sacrifice of hive, and have a quantity of ill-shaped sections, which I think cannot be avoided, the advantage of dispensing with separators is doubtful.—C. N. WHITE.

Yes; with sections not more than $1\frac{1}{2}$ inch through.—SAMUEL SIMMINS.

No; I have tried the $1\frac{1}{2}$ inch sections without separa-

* We are indebted for much of the above information to the *Dictionary of National Biography*, edited by Leslie Stephens, and to communications from J. W. Pewtress, Esq., Godalming.

tors and cannot get the combs built out with sufficient regularity to satisfy me.

Sections are the most marketable form in which comb-honey can be produced. Without the use of separators, or where they are too narrow, the honey-comb is generally bulged in such a manner that sections cannot be glazed without damage. The glazing of sections (to protect the contents from damage in handling, attacks of robber bees, and from dirt and dust) has now become a necessity. Sections thus protected command a higher price and a ready sale, whilst those unglazed are difficult to dispose of in the shops at any price.—JOHN M. HOOKER.

It is *practicable*, but not *desirable*, since the sections so produced are less evenly worked, not so well filled, and are of less value in the market. If the plan is tried the thickness of the section-box should be reduced from two inches to $1\frac{1}{2}$ inch. American apiarists have adopted the plan to a considerable extent.—GEORGE RAYNOR.

[2.]—*Is it advisable to clip the queen's wings? What has been the experience with such queens?*

My opinion has been against the practice, and I have never had a queen with clipped wings.—F. LYON.

I have had no experience in this.—J. LINGEN SEAGER.

Le jeu ne vaut pas le chandelle. To secure a temporary advantage the seed is sown for a crop of annoyances in the future. Queens with clipped wings generally disappear at a time when there are no means of supplying their loss. Queens leave and return to their hives oftener than most people imagine.—P. H. PHILLIPS.

It is *not* advisable to mutilate the queen by cutting her wings, if the apiary can be attended to. The only time it should ever be done is when the apiary is left without anybody to attend to it, as it then prevents the loss of the swarm, as the bees all return to the hive again.—WILLIAM CARR.

I should say where the queen is valuable, and apiary could not be visited each evening, no advantage is gained, for queen would most probably die during the night if swarming is attempted, as she would be most likely to fall to the ground. If queen is of no particular value, the swarm of course returning to the hive in such a case is delayed some days, but would then be more likely to abscond, being headed by a young unfertile queen. Of course where apiary is near at hand, and can often be overlooked, there is some advantage, as fallen queens may be picked up and returned or united to an artificial swarm. Have had no personal experience.—C. BROWN.

I think not; because there is always a great risk of injuring the queen, even in the hands of the more experienced, and because the principal objects of clipping—viz., to prevent a swarm escaping, and to ascertain any exchange of queens—can be attained in other more natural ways. There are, perhaps, cases where clipping may be advisable, but I should certainly not recommend it as a general practice. Whether clipping, if done properly, has any bad effect upon the queens, I should not like to say, as my experience is too limited.—F. ZEHETMAYR.

[3.]—*What is the best plan for ripening honey?*

Always keep honey in a warm room, and if it is not ripened, put it in open barrels, or cans covered with a piece of strainer. It can be rapidly ripened by heating it to 200° Fahr., as the excess of water is evaporated.—GEO. WALKER.

No honey should be extracted until the combs are three-fourths sealed over. When separated from combs, first strain, and then, in a dry room, store in large earthenware crocks, or galvanised cylinders, for better convenience, with treacle valve to draw off as needed, such storing receptacles to be tied over securely with sheet of calico. If left until granulated, place strong

paraffine stove under until the honey will run freely into smaller vessels, where it will soon re-set into a body of far more even consistency than is generally presented when bottled or canned straight from the extractor.—SAML. SIMMINS.

Leaving it in the hive until the bees have sealed it.—GEORGE RAYNOR.

The excess of water in unripe honey can be evaporated by applying a constant temperature of 95° (Cent.). The duration of heat applied will depend upon the quantity of honey subjected to evaporation. Two gallons require twenty minutes simmer after the above temperature is reached, larger quantities need a proportionate longer time.—HENRY DOBBIE.

Put the unripe honey in a jar or tin and place the same, resting on two pieces of wood, in a larger vessel. Fill the outer vessel with water and let it simmer until the excess moisture of the honey is evaporated. There is Mr. Cowan's honey ripener, a capital apparatus no doubt, but having the disadvantage of being too expensive for the average bee-keeper. The best plan to get ripe honey is to extract from the combs just when the bees are beginning to cover over the cells. There is, then, no need for ripening by any artificial means.—P. ZEHETMAYR.

The best plan is not to extract the honey from the comb until it has been sealed over. I do not believe in the artificial ripening of honey. 'In extracting green or unripe honey it is impossible, by human art or skill, to impart that exquisitely fine finished flavour that the bees give it when left with them until it is capped.' The Rev. L. L. Langstroth said, 'He believed there were many things that bees could do, certain things better than we can, and ripening honey was one of them. There was too much artificial work in bee-keeping.'

If a sufficient number of frames are used in hives on the 'doubling' or 'storyfying' plan there will be no difficulty in allowing the combs to remain until the honey is sealed over before extracting it. On the other hand, if a hive containing nine or ten frames is used without any second storey, the outside frames must be always emptied as soon as they are full without waiting for them to be capped, or the bees will have nowhere to store honey whilst that already stored is ripening and being sealed over. Honey of this kind is best put into some deep tank or vessel in large quantities and allowed to remain for about a week. The thin and inferior honey will rise to the top, and the good ripe honey will go to the bottom. This thin honey, which will generally be a small percentage, can be made thicker by evaporation; but it will lose all the peculiar taste and aroma that honey should have, and be little better than sugar-syrup.—JOHN M. HOOKER.

LECTURE ON BEES AND BEE-KEEPING.—Mr. Badcock, of Southfleet, Kent, gave a lecture on 'Bees and Bee-keeping,' in the schoolroom on December 16th. The lecture was illustrated by the Association's diagrams and had for its object the prevention of the wholesale destruction of bees which goes on in the neighbourhood, and the showing the advantages of the modern system of bee-keeping. The lecturer described the wonderful structure of the bee and showed how beautifully it is adapted to the creature's wants. The relation of bees to flowers was next noticed, and the indebtedness of fruit-growers to bees was pointed out. The moveable comb system was described and the advantages pointed out, the way of quieting and handling frames being shown, as well as the plan of supering with sections. The lecture was much appreciated by a small, though attentive audience, which included a few bee-keepers. The lecturer concluded by offering to help, free of charge, any bee-keeper in the parish in any way he was able during the next season.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangers and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

[1].—The value of honey imported into the United Kingdom during the month of November, 1885, amounted to 1185/. [From a private return sent by the Principal, Statistical Office, H.M. Customs, to E. H. Bellairs, Wingfield, Christchurch.]

BRITISH BEE JOURNAL.

[2].—On the 7th instant, Mr. Editor, we are, then, to have the pleasure of welcoming the first weekly issue of the *British Bee Journal*. I feel grateful to know this, and doubtless hundreds of your subscribers will be also, for it has been a long-felt want; and I venture to think no one has better knowledge of this fact than our lamented editor and yourself: hence, I presume, across your desire to carry out what he had himself intended, and so meet the craving of thirsty bee-keepers.

Many years have passed since the *B. B. J.* was first found amongst our monthly periodicals, and great indeed have been its strides onwards, giving new life to an industry so desirable, but which had well-nigh sunk into oblivion. Its birth and cradling (the most trying time) must ever be remembered with gratitude by all interested in bee-keeping, as given by that able and valued guide, Mr. C. N. Abbott, who, endowed with such great practical knowledge of bee-keeping, and the power of imparting it to others, after ceaseless labour accomplished his determination to place before the British public a Journal worthy of the name.

Though changes have since taken place as regards its owners and editors, the onward course the *Journal* is still making cannot fail to give pleasure to him by whose brains so valuable a work was first brought to light. I observe with much regret the *Journal* has not of late been adorned with writings bearing the well-known initials, 'C. N. A.:' his pen appears to have gone rusty. What delight it would give to read in the pages of the first weekly issue more of his parental and sound teaching, though in the way of a *poser* it would be interesting. Others, too, whose writings in earlier numbers gave so much valuable matter one would wish to see again to the fore with increased vigour. Can it be that love for the work has grown cold with them? Surely not! At no time more than the present do we need the help and guidance of the *sage practical observer*, half-swamped as we are by propounded theories, bewildering to the whole creation of bee-keepers. I hope the new management of a weekly issue of the *Journal* (entailing as it will necessarily so much additional labour to yourself and your staff) will prove satisfactory, and secure increased support, and so aid in extending its sphere of usefulness.

Good health and good luck to you, Mr. Editor, Mr. Sub., and the whole community of bee-keepers.—R. R. GODFREY, *Whatham, Jan. 4th.*

P.S.—I don't wish to appear greedy, but please give us more of 'Useful Hints.'

GREAT SLAUGHTER OF QUEEN WASPS.

[3].—Being very much annoyed by wasps in my apiary during the past summer, I determined to kill as many queen wasps as possible before next, and asked my bee-keeping friends, to, as Shakspeare puts it, 'take heed, have open eyes, for the same object: one of them did indeed do so.

A few weeks ago I found thirteen queen wasps in the stump of an old willow-tree near Daddington (three miles from here), and some friends living there destroyed eight or nine more a few days afterwards. W. Turner, of this town, also found twenty-nine beneath the felting on the top of a hive, and yesterday Wm. Ayre, Ehus-thorpe, an old bee-keeper (and a good one too), brought me 125 more of those yellow-jackets. They were found underneath the tiles of an old barn which is undergoing repairs, and my friend tells me that he lost quite as many as he brought, for a lot fell among the debris. I send the 125 queens by same post as this for you to see.

In conclusion I beg to wish you and all bee-keepers a happy and prosperous New Year, and to ask you to kindly hint to the brotherhood the necessity of keeping down those troublesome pests.—WALTER S. PRIDMORE, *Second Class Expert, Hitchley, December 29, 1885.*

[We received safely the consignment of queen-wasps. Their arrival created quite a sensation in our establishment. Having gratified the desire of those who wished to possess specimens, the remainder were taken to Mr. Cheshire to assist him in his vespal studies.—Ed.]

BLIGH COMPETITION.

[4].—The point in Mr. Owen's diary on which I animal-verted in my last was the improbability of the large swarm of $4\frac{1}{2}$ lbs. coming from his No. 1 hive after the treatment that hive had received at the hands of Mr. Owen (*vide* his diary in *B. B. Journal*). I do not insist that it did not issue from No. 1. Mr. Eyles must admit, if he is a *bee-master* like Mr. Owen, that it is a very remarkable occurrence for the young queen to leave the hive after she had began breeding, and likewise leave the hive queenless: there could not, by any possibility, have been another queen in the cells arrived at the age to pipe to the queen that came forth with the swarm on the 23rd. Mr. Owen's diary, as published at page 333, last vol., says, 'This swarm came out at 10.30 a.m., and remained clustered on a pole till 7.30 p.m., before I found it.' Here is a swarm of bees up a pole for nine hours. Now, as I have only the published portion of Mr. Owen's diary to guide me in my deductions, may I ask, Did any one see a swarm issue from No. 1 in the morning of June 23rd at half-past ten? and, if so, Was there anything to identify the swarm found at half-past seven in the evening as the swarm that issued from No. 1 in the morning? Mr. O. says, 'before I found it.' Was the hunt proceeding all those nine hours? and was it only by chance they were spotted in the cool of the evening? or was a swarm seen to come out of No. 1 and decamp no one knows where, but not finding a resting-place returned like the dove on a memorable occasion to the home from which it issued forth?

This, Mr. Eyles, is where my doubts crop up, taking the gross improbabilities of a swarm coming from No. 1 hive at all, and, allowing that it did occur, this losing and finding the swarm after a search of nine hours. I, as a practical bee-keeper (not a *bee-master*, like Mr. Owen), I don't aspire to that, but simply as a bee-keeper of some twenty-five to thirty years' experience, have never had a similar case, or anything approaching it. Now, I think Mr. Eyles will agree with me that in a public competition, or more properly defining the matter, I say in a 'National Competition,' everything should be perfectly straightforward and above suspicion; there

should be no loopholes through which a doubt can creep in.

Mr. Eyles implies in his letter in last issue that I would impeach the judges. Allow me, sir, to inform Mr. E. that I have as great respect for the three gentlemen who acted as judges in the 'Bligh Competition' as one man can have for another, either as regards their integrity, impartiality, and justice. I would add more, but do not wish to appear sycophantic.

Mr. E. must not forget that judges are human, and liable to mistakes. I don't say they made any mistake in this matter; but I consider I had a right to point out what I considered was doubtful, and also the mistakes in Mr. O.'s diary, viz., the discrepancy of 10 lbs. of honey between his diary and balance sheet and the tabulated form, also that my produce of honey is stated in tabulated form as 44 lbs. more than Mr. T. O.'s, and as per diary it amounts to 54 lbs. more than his.

And then, in closing, Mr. E. accuses me of keeping back part of the truth *re* the valuation, and says I did it carefully. I say the valuation was not my valuation, that I commented on the published facts as they appeared in the *B. B. Journal*, and if the valuation was excessive it was as per rules, and I may add for Mr. Eyles' satisfaction, included two twenty-one crates, and one fourteen-section crate, also section-frame with excluder zinc, extra frames of comb, &c.; and that the brood-frames had not been disturbed in my hive from June 24th till the hon. sec. of the B.B.K. Association came to value hive August 30th. The four frames I extracted the 16 lbs. from were the four frames at back of hive; and when I took them out, on August 19th, I did not run *re* the quilt farther than was required to lift them out: the empty frames, after extracting, were not even returned to excite the bees; they were left in a perfectly normal condition. I did not take advantage of the rule to extract all the honey from the hive, and then feed up, filling the hive with brood and stored syrup, to enhance the value of the hive at the end of competition. W. WOODLEY, *World's End, Norbury.*

RIPENESS OF HONEY.

[5].—I am under a further obligation to you for the trouble you have taken to write the long Editorial note in reply to my last communication on the above-mentioned subject. I have only means of approximating to the facts of the case in regard to spec. gravity, and, from what you state, I cannot do other than admit at once the apparent reasonableness of your standard. Very well; then I am thrown back on the alternative position that some bees have been storing honey which was not ripe, or that they did not ripen it before they had done with it. Now I am not quite prepared to assume that bees do not know their own business, and therefore I should prefer to have it that specific gravity should not be the equivalent for ripeness, if by ripeness is meant marketability. If it be otherwise, we shall find again, as I repeat I have already known, good crystallised, delicious, *bonâ fide* honey, pronounced, by authority, to be unmarketable, because of its being, technically, not ripe. This affects trade—public trade that is, though private purchasers are abundantly satisfied; and when bees greatly increase, and your fancy becomes a fact, and cannot continue giving away, and must try to 'make it pay,' and have more than private hands can take, why then the matter becomes serious,—serious for the bee-keeper and thus serious for British trade prospects if many such cases occur, notwithstanding your buoyant encouragement.

I have spoken of 'bonâ fide' honey, and this in reference to your definition of honey, which I entirely accept, even, if required, taking the word 'stored' to mean bottled, corked, and 'sealed.' To what I have in my mind your remarks as to sources of the sham article

do not apply. It could have had no possible connexion with molasses; of honey-dew there is always so little in this treeless district, as I expect you would call it, that it could have contained no greater proportion than our food does of the inevitable dust we eat; while as to the juices of fruits, inquiry and my own knowledge lead me to the conclusion that these had no share in its composition. Our clover (with various summer flowers) held out as long as the season lasted; day after day did the bees career away for their natural supplies; 'to-morrow to fresh fields and pastures new.'

That 'there *may* be pure honey that will not granulate,' does not touch my subject; I have been writing of honey that *did* do so after about two months, and, therefore, was presumably pure and good, though not what is called 'ripe,' and I fear the same thing may occur again until those bees get scales and measures and test-tubes and manage to use them. One word more if I am not too tedious. My 'fear and trembling' was lest every secretary should fly at me for venturing to hint that they had done their work so well that there were now pretty nearly enough bee-keepers in England. I should rejoice if they could prevent 62,000*l.* going out of the country again for honey in one year. Perhaps a few prosecutions might help to this result. For myself, I claim to be as patriotic as most people, but I fear I rather fail to share your beautiful vision of the 'Greater Britain.' The ship of trade, like the vessel of the State, requires a competent—which, to a great extent, means a cautious—helmsman, one who will not drive at full speed into unknown waters, and wreck the craft instead of making her way.

It is still, perhaps, true of most of us that 'hope springs eternal in the human breast,' but we know that there is a 'deferred hope' that 'maketh the heart sick,' and if it be deferred too long while the 'incubus' still presses, the heart may become sick unto death, or at any rate hope may yield to despair, and then apiculture and all the other depressed cultures will—But at this season I forbear.—SOUTH CORNWALL, Dec. 24.

[When writing our former Editorial note on this subject, we were in entire ignorance as to what our correspondent had in his mind when he wrote of 'unripe' and 'unmarketable honey.' Whether it arises from the bees, 'unbusiness-like proceedings,' or from some other cause, we are unable to say, but the fact that bees, under certain circumstances, do 'store,' *i.e.*, 'bottle, cork, and seal unripe honey,' is an undoubted fact. We have repeatedly removed sections which have been quickly produced and lightly sealed, in which the honey was so 'unripe' that fermentation shortly ensued, and the same may be said of honey stored in the body of the hive. But our friend writes of honey which 'granulated,' but had been pronounced 'unripe.' Well, although 'granulation' is so far a mark of purity that the glucose, and other adulterated stuff, sold as honey, is devoid of this mark, it does not follow that 'unripe' honey will not granulate. Both honey and syrup, of various degrees of consistency, will granulate, so that we fear, even when science shall have advanced so far as to supply the bees with 'scales, measures, and test-tubes,' there will still exist a difference of opinion as regards the 'ripeness' or 'unripeness' of various samples of honey; and the 'marketability' of any commodity, we opine, will have to be decided in the future, as at present, by the arbitrary decision of purchasers. We are quite in agreement with our friend as to the desirability of keeping the 62,000*l.* in our own pockets, and the urgent necessity for a 'cautious helmsman to guide the vessel of State,' &c., but we cannot despair of the future of our country. 'The darkest hour is nearest to the dawn,' and *nil desperandum* is a very favourite motto of ours.—ED.]

ERRATUM.—In the last line but one, 1st col. of page 408, for 'that' read 'what.'

OBSERVATORY HIVE.

[6.]—My observations with reference to the building of comb point to the bees (at least on foundation) being arranged side by side in a level row at the top. This may account for the uniformity and regularity of the comb. Now as I have to open my hives to see this, I wish to know if there is any description of Observatory hive that will enable me to expose the bees to view *without disturbing them at all*. I find it impossible to open my hives at all without some slight disturbance sufficient to prejudice and confuse the *accurate* observations I am now anxious to make. I have indicated a clue to the *rationale* of comb building, and am anxious to follow it up if possible.

As for the drone question, I have advanced a step or so, but am trying to find the answers to some two dozen questions, more or less, connected with it. I have not fully proved the correctness of the blanket theory, and doubt if I can do so beyond cavil; but think I have advanced far enough to completely refute the Prince Consort theory, and so to show that drones are not the lazy, useless incumbrance they are said to be.

For the future I intend to let my bees have their own way in proportioning the sexes, as I believe rejecting drones during the summer is false economy.—STUDENT.

[The Unicomb Observatory hive would suit your purpose. This is a hive to hold from three to six frames of comb between glass, only just enough space being left between the combs and inner surface of the glass to allow the bees to pass over them. The glass sides are hinged and open like doors. If the observatory is to stand indoors, the glass should be double, but if intended for out-of-doors, there should be at least three layers of glass with air-space between each, and next to the glass, outer doors lined and padded to keep the bees inside warm enough. In such hives all the work can be watched without disturbing the bees, but they are not suitable for wintering and the bees and frames have to be transferred to ordinary hives in the autumn.—ED.]

THE VALUE OF ENTHUSIASM.

[7.]—About six months ago, there was an exhibition at Taunton in connexion with the Somerset Agricultural Society. The County Bee-keepers' Association had a tent there, and the Hon. Secretary (Rev. C. G. Anderson) thought the effort a miserable failure; as the expenditure was much more and the income much less than he had anticipated. Very few people visited the bee-tent, but amongst the number was one who had just commenced bee-keeping, and who had an undoubted attack of the bee-fever. He brought his friends, pointed out to them the advantages of the bar-frame hive, showed them how easily Mr. Blow transferred bees from the straw to the wooden domiciles, asked the expert no end of questions, and imparted the knowledge thus gained to others. The result of this gentleman's enthusiasm has been remarkable. In about two months he secured orders for from thirty to forty bar-frame hives from friends and neighbours; and has roused the old-fashioned bee-keepers all round his district. Here, then, is a crumb of comfort for hard-working officers; and may we not be excused for reminding them that their reward will come in due season if they faint not by the way. Probably very few of the new converts have yet joined the Somerset Bee-keepers' Association, but surely the sphere of interest will widen; and the right work is being done if not exactly in our way.

I know a couple of young carpenters in the country who have made eighty splendid bar-frame hives this year—hives that would have done credit to the best firms in the kingdom. I have heard of another, who lives within a few miles of those referred to, who has been employed the best part of the year in making bee-

keeping appliances, thanks to the kindly interest of the rector of his parish, who gave him an order, put a like advertisement in the local paper for him, and recommended the hives to his friends. So the number of barframists is evidently increasing rapidly in the west. It remains for the County Association to show them what they would gain by joining such organizations: for they want to know that before they will spend even five shilling in becoming members. Lectures, travelling experts, and local shows, would certainly prove of great service: but in these days of depression of trade, the financial difficulty appears to be hindering the efforts of many local secretaries.—WEST COUNTRYMAN.

[Our correspondent has shown in the above communication what is to be gained from having County Associations. Had no County Association existed there probably would have been no show, no bee tent, no one to have become enthusiastic, and no converts made. Is it not something for the Society to have created this enthusiasm and been the means of rousing an interest in bee-keeping in the county? We hope that the makers of hives and those who have benefitted directly in the county will acknowledge that there is some good in the Association, and subscribe liberally. If every one subscribed to an Association for only what he could gain, no philanthropic society would ever exist. Directly or indirectly, every one is interested in the spread of bee-keeping, and it is pitiable to see County Associations struggling for an existence, and crippled for want of funds, whilst those who can well afford it keep aloof because they do not see what they are to gain by joining the Association.—Ed.]

REVERSING COMBS.

[8.]—At the recent Convention of the North American Bee-keepers' Society a paper was read on 'Reversing Combs,' by Mr. James Heddon, one of the most advanced and practical bee-keepers in the United States of America, a report of which will be found in the *American Bee Journal* of the 23rd of December last, from which it will be seen that, after using from 4000 to 6000 reversible brood-frames, and enumerating their advantages, he says, 'I feel positive that I never should again use a frame that would not admit of reversing.'

This is surely more reliable than the theoretical opinions expressed by you and others in the *B. B. J.* throwing 'cold water' on the system: and if you can find space to reproduce this report in your next, I am sure it will be a benefit to your readers, and induce not a few to try for themselves if there are any advantages to be derived from reversing brood-combs, and so giving space in the brood-nest.—JOHN M. HOOKER.

RAYNOR'S DIVISIBLE SECTION RACKS.

[9.]—Will you kindly allow me a little space that I may ask the Rev. Mr. Raynor to withdraw the imputation he has so carelessly cast upon me and my firm in respect of section racks? I am quite aware that he was the first public exhibitor of the set of crates which bear his name at the Kensington Show in 1881, and so far as I have been able, have always given him the credit due in that respect; but when he says, 'The next public appearance of the rack was at the Knightsbridge Show in July 1883 where Messrs. Abbott obtained for it under a different name first prize,' he casts upon us an imputation which is calculated to do us great injury.

Messrs. Abbott did not exhibit the section racks in 1883, and it therefore goes without argument that Messrs. Abbott did not take the first, or any other prize, for such racks at the Knightsbridge Show.

If Mr. Raynor had referred to his *Bee Journal* for July 15th, 1883, he need not have made us suffer a fortnight's public odium, for he would have found (page 92) in the list of awards, 'Supers, Class 13, for the neat-

est and best rack containing 1 or 2-lb. sections with separators, prepared for placing on a frame-hive, 1st, Dr. Benthall; 2nd, Dr. Benthall; 3rd, S. J. Baldwin, certificate.'

All that Messrs. Abbott had to do with the racks was the manufacture of them for Dr. Benthall; and instead of being held up to scorn, I think my firm deserves praise for showing that we can turn out for five shillings as good or better sets of racks, than those for which Mr. Raynor had to pay twelve shillings.

Mr. Raynor did not exhibit any racks at the Knightsbridge Show. Dr. Benthall did and took two prizes. Messrs. Abbott made the crates, and continue to make them, and that firm considers that there is no piracy on their part in selling what they make as the 'Abbott Benthall Crate.'—C. N. ABBOTT, *Southall, December 12th, 1885.*

Noticing the paragraph under the above heading in your last, in which Mr. Abbott demurs to my previous statement that—'Messrs. Abbott obtained for it (the section-rack), under a different name, the first prize.' I beg to acknowledge that, on reference to the Knightsbridge catalogue, I find that he is correct. When making the statement, I had not the catalogue beside me for reference, but merely private notes, taken at the show, where the rack was pointed out to me as 'Mr. Abbott's exhibit,' which should have been, I imagine, his 'make;' and knowing that he is advertising it as 'Abbott's Benthall Crate,' I assumed that he had exhibited it under that name. I trust, therefore, that he will acquit me of any intention to charge him with duplicity, and I regret that I made the mistake.

Now that the facts of priority of invention and exhibition by myself have been made public, I am perfectly satisfied.—GEORGE RAYNOR, *Dec. 18.*

DRYNESS OF HIVES.

[10.]—All bee-keepers know how essential it is for the interior of a hive to be dry in winter; but, as far as my experience goes, I think it is a matter of great difficulty to obtain this perfect dryness, owing to the faulty construction of the roofs of almost all hives. I have hives made by three of the very best makers, but not one kept the wet out satisfactorily until I covered them with thin sheets of zinc. They were well painted at first, and I painted them myself very thoroughly from time to time; but still in winter the wood became saturated. And I have no doubt that many bee-keepers, if they were to look at their hives now, after the weather we have lately had, would find the same.

Now that manufacturers are busy making hives for another season, let them, by all means, look well to this important, but too much-neglected point—a roof that will really keep out the wet. I do not mean a heavy shower, but the continued damp of a foggy winter.

I have tried the zinc now for some years, and, of course, my hives are as 'dry as a bone,' and this, I know, has much helped to strength of colonies in the spring, and thus to good results: for instance, 410 lbs. of super honey from my six zinc-covered hives.

Some little time ago, after a spell of wet weather, I was horrified to find that a new hive with a high-pitched roof, and well painted—made by a manufacturer who gets no end of first prizes at the greatest shows—the only hive I had without zinc, had so let in the wet that the quilts were thoroughly saturated.—F. G. JENYNS, *Knebworth Rectory, Dec. 28.*

[We have used calico and paper felt (both of which adjust themselves to the inequalities of the roof), when well painted to prevent any moisture passing through, and we think them better because they keep hives cooler in summer and are not as heavy as zinc.—Ed.]

Reviews.

TIDSKRIFT FOR BISKJØTSEL, UDVIGET OG DEN NORSKE BIAVLSFORENING. KRISTIANIA.—This is a new bee periodical, the first ten numbers of which we have received. It is published under the auspices of the Norwegian Bee-keepers' Association. The early numbers were edited by two members, J. H. Eger and Aug. Sundby, but the former retired from the editorship in July last, and his place has been taken by Halvard Torgersen. The Journal appears as a monthly, and consists of eight to twelve pages of matter. A great part of it is devoted to the work of the Association, which, we are glad to see, is in a flourishing condition. The Association, we find, was established June 27th, 1884, so that it is a little over a year old. Although so young, it numbered on the 1st of October last as many as 914 members, and is an example to many older established societies in Europe. This large number is probably due to the fact that the subscription is small, being only 2 kroner (about 2s. 2d.) a-year. For this subscription the member is entitled to the Journal. A member may compound for his future subscriptions by paying 20 kroner (about 1l. 1s. 8d.), which constitutes him a life member. Foreign members are admitted for 3 kroner and 40 kroner respectively. Although, as its organ, the Journal naturally devotes much of its space to the work of the Norwegian Bee-keepers' Society, there is besides very much useful information; and modern methods are described, and the moveable comb-hive advocated. Every month, under the heading 'Erindringsliste,' useful hints are given for the management of bees during the coming month. Useful advice is also given to beginners in bee-keeping by Th. Landmark. In these

articles, amongst other things, instructions are given for packing and sending bees some distance. We were so pleased with the simple appliance used for packing skeps, that we give an illustration of it for the benefit of our

British bee-keepers. It consists of two pieces of wood, crossing each other at right angles. To one of these are nailed two upright pieces, and a horizontal one on the top acts as a handle to carry the package. In the cross piece at the bottom is a screw, the part projecting above the wood being filed to a point. Also in the two uprights, at a short distance from the top, are two similar pointed screws. When it is necessary to pack the skep, the combs are secured and the crown placed on the lower point, which, owing to the weight of the hive, is forced into it. The side screws, which are drawn out, can now be screwed in, and their points will enter the straw sides of the skep, and securely fasten it in its place. The illustration shows the plan clearly, and we think this a better one than packing the skeps in boxes, because the railway people are much more likely to be careful in handling the package when they have something to take hold of, and likewise see that it contains live bees.

In the first three numbers of the Journal there is a literal translation of part of the first chapter of Quinby's book, which has not been continued, but has been replaced by a series of articles on the 'Natural History of Bees, and their relation to Plant-Fertilisation.' These articles are illustrated by the British Bee-keepers' Association diagrams, which are reduced for the purpose, each sheet occupying a space of 5½ inches by 4½ inches. The engravings are beautifully executed, all the minute details showing most clearly. The articles are very clearly written by Hilmar Young.

The Society, we find, held a most successful exhibition of bees, hives, and honey in Christiania on the 24th of June last and two following days. There were forty exhibitors, one of them, Ivar S. Young, exhibiting no less than 184 articles. Amongst the exhibitors, there were eight from Denmark and four from Sweden, amongst whom we find the name of H. Stålhammer, the editor of the Swedish Bee Journal. The prizes consisted of silver and bronze medals and money. Besides the exhibition of bees in hives, there were also manipulations with live bees, which instructed and astonished the visitors, as these exhibitions usually do. Upwards of one hundred members met for discussion and the subject chosen was, 'The Best Method of Wintering Bees.' This meeting was as successful as the exhibition, and both are likely to give an impetus to bee-keeping in Norway. We wish the Association and its Journal every success.

BUZ; OR THE LIFE AND ADVENTURES OF A HONEY BEE. By Maurice Noel. (Bristol: Arrowsmith, London: Simpkin, Marshall and Co.)—This little book contains the life history of a honey bee, from its cradle to the grave, woven into an interesting form. Its object is to interest children in the habits of bees, and to induce them to study for themselves the wonders of their lives. We hope this object will be attained, and that in many juvenile readers an interest may be awakened, so that as they increase in years a thirst may be created for more practical information on the subject of bees. We can assure our young friends that the work contains a very interesting tale, and proves that the honey bee can live a useful life and die a noble death. The book is well printed and tastefully bound.

THE BUSY BEE.—Few people have any idea of the labour that bees have to expend in the gathering of honey. Here is a calculation which will show how industrious the 'busy' bee really is. Let us suppose the insects confine their attention to clover fields. Each head of clover contains about sixty separate flower-tubes, in each of which is a portion of sugar not exceeding the five-hundredth part of a grain. Therefore, before one grain of sugar can be got, the bee must insert its proboscis in 500 clover tubes. Now, there are 7000 grains in a pound, so that it follows that 3,500,000 clover tubes must be sucked in order to obtain but one pound of honey.

Echoes from the Hives.

Alton.—Bees seem very strong all round about this neighbourhood. December 15th, weather mild, bees flying freely. December 16th, being out on journey, bees were on the wing in every quarter as numerous as they are in spring, generally.—F. G. AYLING.

North Leicestershire.—Bees have been in flight, more or less, on the following days, viz:—December 14th, 15th, 16th, 23rd, 26th, and 31st, and on January 2nd. On December 15th they were in flight nearly all day (a very bright calm one), although the temperature never exceeded forty-two degrees in the shade.—E. B.

Slinfold.—The following account shows the quantity and value of honey and wax raised during the past summer (the number of swarms, &c.) by twenty-four bee-keepers (mostly cottagers), residing within a radius of two miles of the Parish Church of Slinfold, to be as follows:—Quantity of honey raised, 2001 lbs., besides 97 lbs. taken from buildings in Slinfold, making a total of 2188 lbs.; and 31 lbs. of bees' wax. The value is given as follows:—2188 lbs. at 10d. per lb., 91l. 3s. 4d.; 94 swarms at 10s., 47l.; 31 lbs. wax at 1s. 6d., 2l. 6s. 6d.; total, 140l. 9s. 10d.—M. FREEMAN.

Llanerch Dinas Mawdry.—As I was examining my hives the other day (January 2nd) I was afraid that one of them had run short of stores, as they had taken down the cake of candy over the frames, and as I knew that they had very little stores besides, I thought it necessary to introduce a cake of candy over the frames. While doing so I took out the next frame but one to the back dummy, when to my great surprise I found brood in its various stages on both sides; not a small patch, but about half the frame; it is not a strong stock, covering only four frames.—H. P. JONES.

Minorca, December 8th, 1885.—With the exception of a couple of weeks in early November, our weather has been very fine. The fields are now carpeted in green with white and yellow flowers lasting all winter long, from which our bees gather honey and pollen. Great masses of the climber *Vitalba* cover the stone walls with their bell-shaped whitish-yellow flowers, and our industrious little insects are actually storing and capping considerable honey and pollen from them. It is a very interesting spectacle to see them fly away these fine December mornings, working as for dear life. At about half-past ten the reserve forces seem to issue, or it may be they exchange work with those outside, for forthwith an army of regulars pour out uninterruptedly for a quarter of an hour, some of the leaders, or larger bees, seeming to watch them from over the entrance, and joining them from time to time in their foraging expeditions. At two or three in the afternoon, they begin to return in large masses, and a constant stream flies in for an hour. The work of ventilation then succeeds for an hour more. On the 6th inst., I saw the first almond-blossom. By Christmas we shall have an abundance, and the bees will feast on them during January and February. After that, spring comes in, and winter is over. Our farmers are ploughing and planting all the winter months; potatoes are being dug now, fresh ones being planted for Easter. Then the principal crop is planted for the summer. You who have so recently been in Italy can thus realise the difference between our climate and yours. Of course our winter flowers are not very saccharine, but they keep the bees busy.—E. C. ANDREW.

[We presume our esteemed correspondent refers to *Clematis Vitalba*, which blooms with us from July to September, and is always covered with bees. Although these collect nectar from the flowers we have never seen them get any pollen with us. Will our correspondent make a further observation, and, if the plant he men-

tions is *Clematis Vitalba*, tell us if bees are really collecting pollen from it? What a country for bees! You make us wish to go and see the lovely flowers in your favoured island.—ED.]

Queries and Replies.

[1.] *Prevention of swarming.*—Can you inform me of any sure way of preventing swarming? I purchased a swarm last year which twice escaped before it was hived, and being in the centre of the town with no garden it caused a great deal of excitement, and to one gentleman (in whose yard it at last settled) some annoyance; and I am afraid unless I can prevent swarming I shall have to give up what I find a pleasant hobby. I keep the hive on the roof of an outbuilding, and shall make an artificial swarm, give extra room and cut out queen-cells, &c., and I thought of placing either a piece of zinc over the entrance, or an excluder inside during the swarming times, but I am doubtful if this will not prevent the bees *with pollen* from entering. I obtained a few pounds of honey in sections besides, about ten sections of comb only, and through feeding with cake in the autumn the bees cover both sides of ten frames. I shall be very much obliged for any hints in the *Bee Journal* addressed to—J. P.

Reply.—There is no certain method of preventing swarming. Dividing, *i.e.*, making an artificial swarm, as you propose, is the most likely way to prevent it, but we do not advise you to place excluder zinc over the entrance, since it impedes the bees when working, and very often does not prevent the swarm issuing.

[2.] *Feeding with syrup in January.*—Would you kindly tell me through the *B. B. J.* whether it would be safe to feed bees towards the end of January with the syrup described under the head of feeding in the 'Useful Hints' of the *B. B. J.* for 15th December? I think that one or two of my hives have not enough food to last them till the beginning of April, and I would like to give them some food toward the end of January, so as to be on the safe side. I have tried making candy according to Mr. Cowan's receipts, but found that it was either sticky, or if I tried boiling it longer it turned into large crystals and was very brittle. If you could answer me in your next issue you would greatly oblige me.—M. C. H.

Reply.—You must give it warm as directed. Candy is however the least trouble, and if you test it as advised in reply to 'S. J. C.', December 15th, you should have no trouble in making a good sample. The large crystals are sometimes caused by not stirring rapidly enough. The more a solution is agitated the smaller the crystals, and *vice versa*.

[3.] *Bees near stream.*—(1.) Is there any danger to the bees in placing beehives about eight yards off a small stream? I might say the stream does not overflow?—(2.) *Section crates.*—I am about to buy section crates. Would you recommend me to buy the divisional Raynor rack, or a crate to hold twenty-one sections?—(3.) *Removing Quilt.*—In putting on section crates do you remove the quilt, or only cut a hole through it?—(4.) *Saw Cuts.*—In fitting up new hives should I use frames with a saw-curf down the centre, or Mr. Abbott's frames with their new style of fixing foundation?—CUMBRIAN.

Reply.—(1.) There will be no danger in placing your bees near a small stream. On the contrary, such a position will be advantageous. (2.) We prefer the divisible section-rack, since (a) the parts can be used separately, or as a whole (b) it is more easily removed; (c) it retains the heat to perfection, and, in our experience, bees commence to work in it more willingly than in any rack we have tried. (3.) Yes, remove the whole quilt. (4.) We prefer frames with a saw-cut, as we find it more easy to insert foundation securely in these than by any other method.

[4.] *Feeding.*—In all the Bee-keepers' Guides, &c., we are told that when the bees are short of honey in the winter they should be fed with candy placed between combs (in a skep). Can you tell me how a beginner can tell when they do want feeding, and also when to place it in hive, as the hive is bound to be lifted up, and I suppose it would be harmful to disturb the bees in such cold as we are having now?—MILSON.

Reply.—Bees in skeps should have received in the autumn sufficient food to carry them through the winter. Skeps must not be turned up during cold weather, but if you have reason to suppose that the bees are perishing from want of food, which may be ascertained by the weight, either feed with barley sugar at the top, or with food made of finely-powdered loaf-sugar mixed with liquid honey to the consistency of dough. This latter food may be pressed down upon the combs through the feeding-hole. Giving food thus will not disturb the bees.

[5.] (1.) *Granulation of Honey.*—It is stated in the *B. Journal* of Dec. 15th that 'it would be an easy matter to prevent granulation, or to cause it, in all pure honey.' Will you be good enough to explain how to manage both, in comb honey and also in extracted? (2.) *Solution of Salicylic Acid becoming bitter.*—I had a bottle of salicylic acid solution (Cowan's receipt) which had been kept in the cellar, well corked, for over twelve months; it was so bitter, I never tasted bitterness to equal it. What would be the cause? Would it have injured the bees if I had used it? (3.) *Fumigating with Salicylic Acid.*—Can an ordinary smoker be used for fumigating hives with salicylic acid crystals; if so, how?—BEESWING.

Reply.—(1.) If you read the paragraph preceding that which you quote, commencing, 'The granulation, &c., you will find your query to some extent answered. Granulation of extracted honey may be hastened by vigorous stirring or beating, and may be retarded by heating to about 190° Fahr. (2.) We have just tasted a similar solution which has been made for upwards of two years, and no change has taken place with it. Are you sure that you used salicylic acid? Crystals of sulphate of quinine, which are intensely bitter, greatly resemble to an inexperienced eye those of salicylic acid, and possibly one may have been accidentally used for the other. This is the only suggestion we can make without seeing the solution. Do not give it to the bees.—(3.) An ordinary smoker would not answer; you require a heated surface on which the acid can be placed to evaporate.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

CHARLES DEARINS.—Zinc excluder with long holes prevents the queen passing through better than the round-holed. The former is generally used by bee-keepers.

BEE MAN.—The presence of drones in your hive in the month of December indicates either that is queenless or that the queen is too old to perform her duties.

A SUBSCRIBER.—*Bumping.*—See pp. 275 and 276, vol. xii.

THOMAS B.—Novice's Metal Corners may be procured from Messrs. Neighbour, Regent Street.

R. CHAPMAN.—*Sizes of Flat-topped Straw Skeps.*—You will find about sixteen inches in diameter and ten

inches deep a fair size. While you are about it, it would be as well if you made the wooden tops in skeps of one inch wide, similar to the top bars of frames. If you want straw caps for sale, you had better use them of a size to cover the whole of the hive, and four or five inches deep, but why not use sections? You can probably get skeps made to your pattern from Mr. I. Gadd, Wokingham, who might also give you the particulars you require respecting cane.

W. G.—1. *Sweet Biscuit for Feeding Bees.*—The sample you send may be good for stimulating in spring, and seems to offer an attractive form of artificial pollen, but is unsuitable for this season. The second sample of bee biscuits is better made than the first, and more likely to be accepted by the bees. We do not consider it a 'food,' as the proportion of sugar is small relatively to the pea flour, but as a stimulant in early spring it will probably be found useful. 2. Do not reduce the sizes of your entrances.

S. L. B. and FRANK M'D.—The dead bees have been forwarded to Mr. Cheshire for examination.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[1] How do the bees ascertain the presence or absence of the queen in a populous hive?—H. P. JONES.

[2] Is it generally advantageous to prevent swarming?—H. E.

[3] Is it desirable to have upward ventilation in winter?—X. Y.

* * Numerous letters and communications are postponed to our next issue.

A New Era in Modern Bee-Culture.

OWNING the largest Apiaries in the kingdom, I can offer great advantages to those who wish to study the true economy of Practical Bee-keeping.

Besides many Time and Labour-saving Inventions introduced by myself, I have now Two original methods for the *Total Prevention of Swarming* while working for either Comb or Extracted honey. The process is based upon rational principles and a thorough knowledge of the economy of the bee-hive; while at the same time, without the aid of excluders, the brood nest is regulated in exact proportion to the actual number of field-workers, and the condition of the honey resources; the whole of such advantages being gained with *no extra manipulations* at the busy time. No other bee-master has yet succeeded in so managing that the bees actually have *no desire* to swarm, and the knowledge of this system alone will prove invaluable to all who intend to make a business of Bee-keeping, as it is well understood that the act of swarming during the height of the season is a loss of at least 50 per cent. to the apiarist.

For further particulars and charges for Terms of Practical Instruction at the Great Sussex Apiaries, apply to—

S. SIMMINS, Rottingdean, Brighton. (119)

BRITISH BEE-KEEPERS' PRACTICAL NOTE BOOK. By THOMAS W. COWAN, F.G.S., F.R.M.S., &c. Crown 8vo, boards, 1s.; postage 1d. Indispensable for every Bee-keeper. Published by J. HUCKLE, Kings Langley; may also be obtained of all Hive-dealers.

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, W.C.

[No. 186. VOL. XIV.]

JANUARY 14, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

OUR WAX IMPORTS AND EXPORTS.

By the official publication of the Annual Statement of the trade of the United Kingdom with foreign countries for the year 1881 we are able to have a clearer idea of the amount and value of the imports of wax than it has been possible to arrive at with regard to honey. The following tabular statement specifies the countries from which wax is imported, with the amount and value thereof:—

	cwt.	£
Germany	7756	20,216
Holland	427	2601
France	750	4152
Portugal	269	1275
Italy	546	3336
Morocco	525	3067
West African Settlements	412	2326
Madagascar	405	2024
Mauritius	903	4774
British East Indies	340	2469
Japan	4951	8855
Australasia	624	3744
United States of America	5176	21,041
British West India Islands	1351	9142
Chile	620	4351
Brazil	2931	9860
Other Countries	481	2580
	28,258	105,813

From the above we note that the mean price per cwt. is 3*l.* 14*s.* 10*d.* There are many kinds of wax, such as vegetable, mineral, and insect wax, and we may, from the above table, deduce the nature of the wax imported. That from Japan is only 1*l.* 15*s.* 9*d.* per cwt., while that from Holland is 6*l.* 1*s.* 10*d.*; from Italy, 6*l.* 2*s.* 2*d.*; from British East Indies, 7*l.* 5*s.* 3*d.*; from Australasia, 6*l.*; from British West Indies, 6*l.* 15*s.* 4*d.*; and that from Chile, 7*l.* 0*s.* 4*d.* Comparing the countries importing with those of last year we mark the absence of China and South Africa, which were large contributors to the amount.

The following amounts are re-exported:—

	cwt.	£
Russia	1085	2925
Germany	1858	7021
Holland	1154	4264
France	1869	7337
Other Countries	4412	14920
	10,378	36,467

The total quantities of wax imported during the three preceding years are,—

	1882.	1883.	1884.
	35,538 cwt.	28,192 cwt.	28,258 cwt.

The value of the above for the same years is,—

	126,926 <i>l.</i>	97,442 <i>l.</i>	105,813 <i>l.</i>
--	-------------------	------------------	-------------------

The amount of the wax exported for the same years is,—

	16,441 cwt.	12,504 cwt.	10,378 cwt.
--	-------------	-------------	-------------

And the value thereof,—

	55,074 <i>l.</i>	41,339 <i>l.</i>	36,137 <i>l.</i>
--	------------------	------------------	------------------

From the above figures it is clear that the amount of wax imported is very large. Through the use of the honey extractor and its increasing use for comb foundation wax is becoming scarce and of more value. Bee-keepers themselves are large consumers of wax, and it is very desirable that more should be raised in proportion to its requirement in this country. Is it possible for the Honey Companies to direct more attention to this product of the honey-bee, and so enlarge the sphere of their labours by becoming honey and wax merchants?

OUR HONEY IMPORTS.

We are pleased to be assured, through a letter, to be found on p. 16, from S. Seldon, Esq., of the Statistical Office, Custom House, that the imports and exports of honey will, from January 1, 1886, be found in the Annual Statement of Trade with Foreign Countries.

In our number for February 1, 1885, we suggested that a representation should be made to the Board of Customs of the great interest now taken by the bee-keepers throughout the United Kingdom in having reliable and official information respecting the import and export of honey, and that the necessary returns should once more be restored to their place in the Annual Statement, from which they were eliminated in the year 1871 as being 'insignificant and of no interest to the community.' 'A change has come over the spirit' of the community respecting the importance of honey, and the information is no longer of no interest, but it is eagerly sought and earnestly canvassed by all bee-keepers. We desire to return our thanks to those who have made the representation, and congratulate them on the success achieved. From

this time forward we shall find honey take a recognised position, and we shall have in an official statement a greater amount of information respecting it than that hitherto kindly furnished to our columns by Mr. Bellairs.

The volume containing the Annual Statement of the imports and exports is not, however, published till a considerable portion of the year has passed, and, therefore, those returns that we are specially interested in would not in the ordinary way make their appearance till somewhere about September 1887. This would be a long interval, but happily, through the continued courtesy of Mr. Seldon, and the kindness of Mr. Bellairs, the monthly information that has been given in our *Journal* will still be forthcoming. We are sure that we are expressing the sentiments of all bee-keepers in tendering our best thanks to the above-named gentlemen for the trouble they have taken in furnishing the information we have received from them for the last three years, and also for their offers of promised assistance for the future.

A tabular statement of the value of the imports of honey for the years 1883, 1884, 1885, will be found on p. 17, from which it will be seen that the value of the imports during the last year has been 61,344*l.*, about 1000*l.* less than in the previous year. Now if we calculate that foreign honey realises 1½*d.* per lb. it will be found that this amount represents no less than 2,738,347 lbs. : and on the supposition that there are no re-exports it will be seen to what an extent honey is used in this country. The figures prove also the exertions that must be put forth by bee-keepers if they desire to checkmate these imports and to reduce their amount. There can be only one way by which this can be done, and that is, that the honey placed before the British public should be of superior quality, and not exceeding in price, that imported into this country. The foreign produce has many charges to defray, such as package, freightage, commission, &c., that our own honey is free from; and we trust, by increasing the size of our apiaries, by greater attention to production, by taking advantage of improved appliances, and by acting on the conviction that bee-keeping may be made a profitable industry, that in the future the amount of imported honey may be diminished and a wider field be given to our home produce.

BRITISH BEE-KEEPERS' ASSOCIATION.

FORTHCOMING MEETINGS.

Wednesday, January 20th, at 105 Jernyn Street. Quarterly meeting of County Representatives, to commence at 4.30 p.m. Quarterly Conversation at 6 p.m. The Secretary will be glad to receive notice from any member who may be desirous of bringing forward any subject for discussion. Microscopical and other objects are solicited.

Wednesday, February 17th, at 105 Jernyn Street. Annual General Meeting of members, the Baroness Burdett-Coutts, President of the Association, in the Chair. Notices of motions for this

meeting must be received by the Secretary not later than January 31st.

The following candidates were awarded certificates at the second-class examination, held on November 7th last, viz. :—

Burt, E. J., Tansley House, Gloucester.
 Coleby, H., Wargrave, Berks.
 De Lacy Ahern, W., Sutton, Surrey.
 Lewis, L. Oswald, Llandilo.
 Lily, E., Norwich.
 Meadows, W. P., Syston, Leicester.
 Pridmore, S., Hinckley, Leicester.
 Slade, W. D., Promenade, Cheltenham.
 Spurrell, W. Carmarthen.

GLEANINGS.

In the *American Bee Journal*, the Rev. L. L. Langstroth states that Italian bees, although disposed to rob when they have a chance, are much more courageous in self-defence than black bees. He relates that on one occasion when he was examining a stock of bees, and had several of the combs resting against the outside of the hive, the arrival of a visitor caused him to forget all about it until his friend called his attention to robbing going on. They went to the unprotected hive and found it besieged by thousands of robbers. The bees on the combs outside were vainly striving to protect them. Although many were killed, it made no difference. The combs were replaced, the hive closed, and the front entrance opened to full width. In a few moments the bees had their line of battle spread over the whole alighting board. Numbers of dead and dying were brought out of the hive, and not a robber was admitted, but attacked and killed if he could not get away. The robbing spread to all the hives, but as the bees defended them, in about half-an-hour it ceased. When robbing of this sort is going on, the Italian bees defend their hives much more courageously than the blacks.

He also relates of another hive, only having a slight touch of Italian blood, that when robbers made their appearance he closed the hive, but accidentally left a corner open. Attracted by the noise of the bees, he found that this large and very strong colony was being robbed, the cowardly black blood had not proved equal to the emergency. When the corner was closed tight, there was no line of battle formed, resistance had ceased, and it was necessary to close the entrance and cover the whole hive with wet cloths in order to save it. Robbing spread, but the Italians made such a fierce resistance that the robbers were soon beaten off.

With regard to black bees, Mr. Langstroth says that their eagerness to rob when forage is even a little scarce, and their deficiency in pluck, by which they are so often, when the yellow races would not be severely injured, are, with him, sufficient reasons for discarding them.

In *Gleanings*, W. L. Hutchinson gives his experience of living swarms with and without foundation, and states that foundation in the brood-nest is a damage when the swarms hived upon it are given access to a surplus apartment furnished with foundation. Twenty swarms were hived upon foundation, and twenty-five others were hived upon empty frames, except starters of foundation half an inch wide. The swarms were hived alternately, and those on empty frames stored 16 per cent more honey. Their brood-nests were 7 per cent lighter than those given foundation. In the aggregate, i.e., counting both the honey in the sections and in the brood-nest, those having foundation fell 5 per cent behind.

A. I. Root says in *Gleanings*, that it seems destined to be an established fact that new swarms that have an opportunity of working in sections well supplied with foundation are better off without foundation in the brood-frames. However, even this has its drawback, as many of the combs contain more or less drone-comb. Mr. Root prefers all his combs built on wired foundation, even if they cost something extra. He also thinks thinner foundations should be used both for brood-combs and surplus honey; he now makes thin foundation twelve square feet to the pound. Even this he thinks too thick for sections when full sheets are used.

In the *Bee Keepers' Guide*, W. F. Clarke maintains that bees hibernate, and quotes Kirby, who states that 'every gradation is to be met with between ordinary sleep, the imperfect or abnormal hibernation of some animals, and the profound hibernation of others, in which all the functions of life are suspended.' Mr. Clarke does not claim for the bee that its hibernation is 'profound,' but only 'imperfect' and 'abnormal.' Bees relapse into quietude and inactivity under favourable conditions, and when this takes place they consume the minimum of food. Under such conditions they either retain their faeces without inconvenience, or void them in the dry powdery form which does not befoul the hive. As science clearly shows that extreme retention of faecal matter is dangerous to all animal life, it is reasonable to believe that nature has provided a mode of relief when bees are kept in their hives by reason of the temperature. He sums up by giving the following as his formula for successful wintering:—Fix your bees in such a way that they will feel comfortable, relapse into a state of repose, become inactive, eat very little, void an infinitesimal quantity of excrement, in a dry form; and you may smile at the rigours even of such a winter as that of 1884-5.

In the *Bee Keepers' Magazine*, L. C. Root says, that before the moveable frame-hive was invented, if by chance fifty pounds of box honey were secured from a single stock in a very favourable season, it was considered a remarkable yield; after the moveable comb hive was more generally in use, 100 lbs. were as easily obtained. Then with more experience and better methods, twice this amount was obtained, and still we advanced until as much as 300 lbs. were reported. During the season of 1872, he took 225 lbs. from each of several stocks. Since the use of the honey extractor the honey which could be secured has greatly increased. From 100 to 150 pounds of extracted honey were easily secured by proper management in good seasons. In 1870 he took from a single stock 361 lbs., and since this time he has taken as much as 484 lbs. from one stock. In 1881 he took 9727 lbs. from forty colonies, or an average of over 243 lbs. per hive. His opinion, based upon close observation, is that the possibilities to which we shall yet attain are far from reached.

Christian Siehler, in the *Deutsche Illustrierte Bienenzeitung*, gives his experience of wintering three stocks of bees by burying them in the earth. A hole was dug in the ground three spades deep, one metre wide and two metres long, and as the ground was level another and a deeper hole was dug close by to receive the water draining from the former. The hole for the reception of the hives had a layer of straw placed at the bottom about a hand high, and the sides were also lined with straw. The hives were covered with cloths, and the entrances were protected against mice by means of perforated zinc. On the 2nd November, 1884, it being a fine day, the bees thus prepared, were weighed and placed in the hole. Straw was placed over the hives, and on this a spade depth of earth was put, then a layer of manure, just as potatoes are kept through the winter in Northern Germany. No air-hole was provided. It being fine on the 2nd February, 1885, and bees in the apiary flying freely and collecting hazel pollen, the opportunity was taken to examine the hives. On withdrawing them from

the hole, they were found not only alive but in a flourishing condition, showing no signs of damp or dysenteric spots. The average loss in weight per stock was 2 lbs. during the three months. As soon as the bees were placed on their stands they commenced flying out, and they were at once examined. The first one opened had seven frames, of which six were covered by bees in the autumn. Now there were enough bees to cover five frames, the third and fourth frames being filled with capped brood. The other hives were in an equally satisfactory state. The development of the bees in these three stocks was much more rapid than in any of his other hives.

ASSOCIATIONS.

BUCKS BEE-KEEPERS' ASSOCIATION.

The Committee of this Association has just issued its annual Report for 1885, which records much activity during the past year, and announces several important innovations for 1886. Amongst the latter, we find that the Association proposes to send experts, as far as possible, at any time when applied for, without the necessity of delay until the next expert's tour. Hives at cost price, upon easy terms of payment, are also to be supplied to cottagers. The *Bee Journal* is in future to be supplied at reduced price to members,—a specially large reduction being made to artisan and cottage members. The Association has, further, entirely revised its prize schedules and conditions of exhibition, with a view to increasing the efficiency of its honey shows.

We notice that the members now number 421, which represents eighty-three more than in 1884. The annual general meeting and drawing for prize hives are fixed for Thursday, January 28th, at the George Hotel, Aylesbury, at noon.

The annual general meeting of the Notts Bee-keepers' Association will be held at the People's Hall, Heathcote Street, Nottingham, on Saturday, Feb. 20th, at 3 p.m.

Selected Query.

[22.]—*What is the best method of securing surplus honey in sections during the honey season?*

I build up a strong stock to cover at least twelve frames. When the season arrives I remove three frames, returning the bees from them to the hive, examine all the other frames and cut out queen-cells, if any. Close up the divider and place the rack of sections on the frames. The bees being so crowded are forced to enter them, and being in them set to work at once. By this means I am enabled, even within 2½ miles of the Royal Exchange, surrounded by potteries, gas-works, builders' yards, &c., to obtain a return. Last year I got twenty-one good sections and ten partly-sealed off one stock; other strong stocks which I did not crowd before putting on sections gave little or no return. I prefer only one rack deep, and I do not remove the racks from the hives to take and replace sections, as I find far less disturbance is caused by doing it on the hive, and less danger of crushing queen or bees.—F. LYON.

The best method of securing surplus honey in sections is to put a tray of sections on an adapter placed over the bar-frames, and made as warm as possible. When the bees have about half filled the sections, raise them on the top of another tray of sections, and so on. As soon as the top sections are completed, they should be removed. If the sections are filled with new white combs, the bees take to them at once. The sections should never be filled with foundation, as it sticks to your teeth when you eat the combs.—WILLIAM CARR.

My plan is as follows:—Having calculated as nearly as possible the time of the honey flow, I decide which stocks to run for sectional honey, and by stimulating and assisting where necessary with frames of hatching brood from other hives, I get them to their full strength by the commencement of the honey flow. Each hive will at this time contain a strong colony on eleven frames. Before placing on the section rack, I take out two frames, the ones I can best spare, being careful to leave a good proportion of the brood at the point of hatching. The bees are by this plan crowded into the super, and, weather permitting, storing in the sections commences at once. When these are progressing satisfactorily, another rack of sections is placed underneath, and more as time goes on, if necessary, the uppermost rack being taken off as completed.—C. N. WHITE.

The above question seems too general for a short answer, but my own experience would suggest early careful stimulating, so as to ensure a strong stock. As soon as the honey begins to come in, and the cells at top of frame are beginning to be sealed, racks of seven, fourteen, or twenty-one sections (according to district, crops, or strength of hive) filled with foundation, to be placed on top of frames, and well wrapped up. If bees are slow to go up, open the front of hive right across, or lift front off floor-board about quarter inch, which will induce them to go up. When first rack is filled, if not sealed, it should be raised, and a similar rack placed between first rack and top of frames, so that bees may be building out and filling No. 2 while No. 1 evaporates and gets sealed. Of course sealed sections to be removed as soon as possible.—C. BROWN.

Have your stocks of bees strong and the frames of combs in the hives filled with brood by the first flow of honey.

To do this, commence stimulative feeding (if the weather is suitable) about six weeks before the time the fruit trees are usually in bloom, the bees being first crowded on just as many combs only as they cover from top to bottom, dummies being inserted on either side and keep all snug and warm with quilts. In a few days the centre combs will be filled with eggs and brood; they should then be spread, and the outside combs put in the centre of the brood-nest, any sealed honey being first uncapped. In seven or eight days more another frame should be inserted. An additional comb should (in favourable weather) be inserted once a-week until the hive is full. In good seasons the bees will by this time be working freely every day, and if the spreading of the brood and the addition of combs has been done with discretion, the increase will have been very considerable.

About the middle of a warm, fine day, the combs should be thoroughly examined, and eight of the frames containing the most brood should be closed up with the dummies in the centre of the hive. The remainder of the frames should be used for strengthening weaker stocks by inserting them in the brood-nest. A rack of sections, prepared with foundation and separators, must now be put on and closely fitted to the top of the hive, carefully covered up, and kept as warm as possible. Should the hive contain reversible frames, these should be inverted previous to the sections being put on. The brood-chamber having been contracted, the bees will of necessity be crowded into the sections, and will commence to work in them at once. If honey is coming in freely, considerable progress will have been made in a few days, and when the majority of the sections are three-parts filled with comb, the rack should be raised, and a second, similarly prepared to the first, should be placed between it and the stock hive. The bees will now be working in all the sections, and when those in the upper racks are nearly sealed over, or they show signs of over-crowding, a third rack of sections should be inserted as before immediately above the brood-chamber. The top rack of sections should now be examined, and

removed as soon as filled, and if the honey-flow still continues, another one should be inserted as before.

When space is given to the bees by judiciously tiering up the sections in this way, swarming will generally be prevented. If, however, they throw a swarm, hive it on six frames filled with foundation, putting the swarm in the place of the old stock-hive, which should be removed about three feet to the right or left. The next day the crates of sections on the old hive should be taken off and placed on the swarm; the bees will take to them at once, and finish them very quickly.—JOHN M. HOOKER.

By having strong stocks ready for the first glut. By supering on top of the hive. By judiciously enlarging the super as required, not to give a check to the bees' activity during a glut, and wrapping up the super according to the rise or fall of the thermometer.—AMATEUR EXPERT.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** * * In order to facilitate reference, Correspondents, when speaking of any letter or query preciously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

OUR HONEY IMPORTS.

[23].—The value of honey imported into the United Kingdom during the month of December 1885, amounted to 2318*l*.

[From a private return supplied by the Principal of the Statistical Department, H. M. Customs.]

This completes the third year of our regular monthly returns, for which we are indebted entirely to the courtesy of Mr. Seldon, the Principal. Below will be found the annual statement. The figures themselves, though of sufficient interest to bee-keepers generally, seem to call for no remark from me, unless indeed it be to say that British bee-keepers, notwithstanding the notorious ten-fold increase of their production, have so far failed to reduce to zero the purchase of foreign honey. The following letter will be read with interest:—

'Statistical Office,

'H. M. Customs,

'6th January, 1886.

'To E. H. BELLAIRS, Esq.

'DEAR SIR,—

'In sending you the December account of the importation of honey, I am glad to be able to inform you that, on a representation of the Board of Customs to the Lords of the Treasury, the suggestion contained in your letter of the 14th February last, that honey should become a recognised article in the list of Imports has been approved by their Lordships, and that from the 1st inst. the particulars of honey will be duly registered in the books of this office. The figures are at present too small to entitle them to a place in the monthly accounts of trade, but they will be given in the "Annual Statement of Trade," published by this Department, and I shall meanwhile continue to send you as usual each month a statement of the quantities imported, which I hope will henceforth be more trustworthy in consequence of the official recognition of the article. I send you one of our lists of Imports.

Yours very truly,

S. SELDON.

E. H. BELLAIRS, *Wingfield House, Christchurch, 8th January, 1886.*

ROOFS OF HIVES.

[24.]—Your note to my letter in the last number of the *Journal*, respecting the roofs of hives, contains a very 'useful hint'; but, with your permission, I would say that, if zinc is properly put on, it does not unduly increase the heat of the roof in summer, as you suggest: for, if it is put on the top of boards which overlap one another, it does not lie close to the wood, but allows a current of air to pass between it and the roof, so that indeed the temperature is kept more equable than without it. If the top of the roof be a smooth surface the same end can be attained by the use of two or three slips of wood. The additional weight I find but trifling, for my zinc is very thin.

But after all I still feel that hive-makers ought to be able to make a wooden roof perfectly waterproof without any such contrivance. Why don't they?—F. G. JENYNS, *Knebworth Rectory, Jan. 7th.*

DRYNESS OF HIVES.

[25.]—I have experienced similar trouble to the Rev. F. G. Jenyns, in keeping my hives dry, and as it is imperative that no moisture should be permitted to insinuate itself through the hive roof or sides, I contribute a few notes on my difficulties. I intend no reflection on the great makers of hives—as a rule their workmanship is excellent and timber well seasoned, if a reasonable price is paid. Many of the very cheap hives that I have seen it is impossible to keep the wet out of, unless they are covered externally with zinc, calico, or paper felt, and well painted; but all these are more or less objectionable to me. The zinc has sharp edges and corners, that will tear one's flesh or catch in one's clothing, besides adding to the weight, and paper felt and calico do not add to the neatness of the hives as seen in the garden.

Some hive-lids are made of feather-edge weather boards, others are sloped 'lean-to' fashion, and the joints in the boarding are covered with strips. These, when painted, are both alike weather-proof; but after a very hot sun has been shining upon them for a few weeks, and we get a spell of protracted wet, then comes the bee-keeper's trouble. For a dog's kennel, or fowls' coop, the amount of wet that gets in would do no material damage, although far better kept out even from them; but with bees it is often sufficient, if not detected at once, to lead to mouldiness and all the accompanying evils. If you are not so fastidious as 'A. E.' cover them at once by all means; but I adopted the style of cover in the accompanying cut, as, in my judgment, being preferable to the other two kinds I have enumerated above. I had prided myself on their weather-resisting powers, when I found my first trouble was at A., so I remedied that by plowing two grooves in the top board, as seen in the illustra-

tion. My next trouble was between the bottom of the lid and the top of the hive walls; this I cured by chamfering off the bottom edges of the plinths around the lids, as seen at B. I also painted the edges of the hive walls and lid, and last winter I was rewarded with dry hives. You will see the lids have ample eaves: but you will

remember how old Sol has blazed down upon us this summer. I thought I was secure: but the first soaking rain this autumn found out where the sun had drawn the plinths away from the sides of two of the lids, and on examination after the rain I find the quilts of these two wet, as a consequence. I am not to the end of my troubles yet. So when spring comes I had resolved what to do, as I never intended to be beaten by moisture. But on looking at our friend Walton's illustrated hive in the last number of 'OTR' *Journal*, I see he has forestalled my idea—the lid is made large enough to overhang the hive side without a plinth. This is a step in the right direction. He will take another if he does away with the plinth at the bottom and makes his hive-sides overhang his floor-board.

I am no manufacturer, as I have previously told your readers: but take a great pleasure in making my own hives. My experience is, that no amount of putty and paint, good as they are in their way, will effectually keep out wet when the wood is 'shaky,' or the sun can open joints, as in our changeable climate the soaking rain is upon you and the mischief is done before you have time to look around. There are certain things only experience can teach, and I believe the construction of hive-lids that are absolutely waterproof is one of them; and I am very glad Mr. Jenyns has opened the question.—AMATEUR EXPERT.

QUEENS LEAVING THEIR HIVES.

[26.]—I feel sure that your worthy correspondent, Mr. P. H. Phillips, will not think me ungracious if I totally join issue with him in the remark 'that queens leave and return to their hives oftener than most people imagine.' I have been taught, and have yet to unlearn, that there cannot be an effect without a cause. Why need *Majesty* unroll her royal wings and flash her splendour in the rays of the shining sun! Nature is an out-and-out Utilitarian. Just fancy her Imperial Majesty Empress of India and Queen of Great Britain, &c., walking out to one of her lodges at Windsor for a pocket-handkerchief!

I am almost certain of this that the mother bee *never leaves* the hive except for swarming purposes, or to get an opportunity of using those exquisite eyes in the choice of him who is in so large a measure to determine the nature of her offspring as long as she herself shall live. I have had a unicombe observatory hive in my house for the last few years, and always tenanted, and *never* have I ever failed, morning, noon, or night, to find the queen, though for scientific purposes or from mere motives of curiosity, I may have opened it twenty times a-day.

I should greatly have liked you, sir, to have seen our veteran East Anglian bee-keeper, the Rev. J. Lawson Sisson, of Edingthorpe, upon one of the days of our Norfolk Agricultural Show, held the year before last in this town, with his watch in hand, intent upon every second timing the various movements of the mother-bee in my spacious Observatory Hive! Talk about enthusiasm, we had it there in very essence! 'When,'

as numerous bee-keepers have said to me, 'shall we have the pleasure of seeing him again upon the Committee of the Norfolk and Norwich Bee-keepers' Association?' I do not think that—with all due respect to our present Committee—we can afford to dispense with the services of a man so highly honoured in the bee-world as the Rev. J. Lawson Sisson. 'Keep pace with the times' has been his motto evidently, as indeed it should be of every man, and especially of bee-keepers.—ALFRED E. BOOKER HILL, *The Chase, King's Lynn.*

FIXING FOUNDATION.

[27.]—I am glad to find that, besides myself, there are others who are taking up the system of fixing foundation and not selfish enough to patent them, as I think it detrimental to the bee-keeping world. But I must point out one or two things in these little inventions. First, they must be simple, with as little complication as possible, still maintaining the full strength of the top bar, which is a great consideration. My next point is to utilise all existing frames that have solid top bars into the new system. For this I have invented the very thing, simple, but effectual; so simple that even a school-boy could either make one, or convert an old bar into my principle. I should only be too glad to give every information respecting it.—W. WILLCOCK, *Bowers Fold, Doncaster.*

[We should be glad to have a description of the contrivance for the benefit of our readers.—Ed.]

BEE MANAGEMENT.

[28.]—Will you allow me space to suggest a system of bee-management, which I think may commend itself to some of the many bee-keepers who keep bees, not as a commercial enterprise with a view to profit from the abundant production of honey and swarms, but rather for pleasure, and with the object of obtaining some honey for their own use. With the former, the plan I am about to suggest cannot find favour, indeed to them it would be a step backward; with the latter it may, because of its simplicity, and because it does not altogether ignore the much-abused skep. For I think even the warmest advocates of the bar-frame will admit that bees can winter comfortably in a well-protected straw hive with plenty of store.

Each colony is wintered in a skep placed on a light floor-board, and within a large bar-frame hive, which provides an excellent wintering covering for the skep. If we use Standard frame hives it is advisable to have our skeps made in an oval form, as a circular hive measuring less than 14½ inches in diameter is much too small for a strong colony.

In the spring, when the bees are ready for swarming, it is a matter of choice whether we drive them and make an artificial swarm, or run the risk of securing the natural one. The skep is now placed on a separate stand beside the frame-hive. Into the latter we put the swarm on combs or foundation, making sure that, by placing it nearer the original position, the swarm is as large as the stock can possibly afford to lose, inasmuch as that from it we expect all our surplus honey.

With favourable weather the swarm in the frame-hive, presided over by a vigorous queen, will soon be storing honey; but as we do not want it for the early market, we need not trouble to extract. Let us watch, however, to prevent its throwing off a cast by giving timely, and in a good season, abundant room. For this purpose either a very long hive, or else a second or third storey, will be necessary.

When the honey season is nearly over remove the queen from the frame-hive; and twenty-one days afterwards unite the bees in it to the original stock in the skep, where an abundant supply of stores, to keep the

united colonies through the winter, will have been provided.

From the combs in the frame-hive we extract a lot of well-ripened honey, and then store them away for future use, they being clear of brood owing to the removal of the queen.

The skep is now placed in the frame-hive as before, and the bees are left to spend the winter in peace and plenty. Dare I suggest that they enjoyed peace too during the summer, at least, compared with those subject to the frequent manipulation of ordinary amateur bar-frame management?

If after-swarms come out, either unite them to the first swarm, or place them in a temporary frame-hive convenient to it, and treat them in the same way. If desirable, sections can be worked.

In a good season the original stock may be able to supply some super honey in addition to the winter store.

The advantages are:—Manipulation and attention reduced to a minimum. No feeding required. No permanent increase of stocks unless desired. Each colony goes into winter quarters strong in numbers, well stored, and provided with a young queen.

Again, let me say, this is not for advanced bee-keepers, but for those who desire to keep a few stocks, and who cannot give them much of their time and attention.—W. E. BEST, *The Cairn, Dec. 26th, 1885.*

A BAGSTER HIVE.

[29.]—I brought one of Bagster's hives that I made fifty years ago up to London, out of West Sussex, in 1837, and located it in a garden in the Holloway Road, near the Camden Road. There it remained sixteen or eighteen years. At that time I lived in the City, but I used occasionally to visit the garden, and look—rather superficially, I admit—at the hive. I had some honey to take several years. It used to swarm, and the bees always made off Highgate way. It kept very dry and healthy, till one very wet autumn the rain soaked through, and the bees perished. It was a source of pleasure to the friends with whom it was left, and to their visitors while it kept on at work. It was easy to manage, but, as you say truly, it has become obsolete now.—J. W. P.

'THE BUSY BEE.'

[30.]—Under this heading, there is, in your *Journal* of the 7th instant, an interesting calculation as to the number of clover-tubes that bees must suck, 'in order to obtain but one pound of honey.' That number is estimated at 3,500,000. But in order to show how industrious the busy bee really is, it should be taken into account that each bee explores many tubes from which the honey has already been sucked, and therefore does a great deal of work for which no allowance has been made in the calculation. Whilst watching bees at work, I have frequently been struck by the pertinacity with which they insist on exploring *each* cup or tube in a flower, though I longed to tell them that they were wasting time, because I had seen ever so many other bees do the same thing. I have also noticed how much they seem to be attracted by the larger and taller flowers, and this causes further loss of time, as I have endeavoured to show more at length in my little story *Buz*, of which you gave such a very kind notice last week.—MAURICE NOEL.

COMB SECTION HONEY.

[31.]—Referring to the various suggestions for helping cottagers by instructing them how to get larger harvests of superior comb-honey, by supering inverted skeps, &c., I should much like to hear the experience of people capable of judging in other parts, as I think the general

experience in this county is, that comb-honey in sections, however perfect, is practically unsaleable.—C. H., *North Devon*.

YORKSHIRE COUNTY ASSOCIATION.

[32.]—A few weeks ago a correspondent of the *B. B. J.* made some inquiries in its columns as to the doings of the County Association, and as I have seen no reply to his queries, I should be glad to supplement them by drawing the attention of the hon. sec. to our needs. It would be most unreasonable to expect him or the county expert (if we have one) to be acquainted with the names and addresses of bee-keepers who are not members of the Association, and who by that means would have their whereabouts made known. As I have only recently joined the B. B. K. A., I should be thankful to the hon. sec. if he will inform me of the steps necessary to be taken for the formation of a branch, and would have done this by letter direct did I not believe that through your columns general attention might be drawn by these remarks to the unworthy position Yorkshire (the largest county in the kingdom) occupies in bee-keeping, so far as it is exhibited in the returns and literature published in the *B. B. J.*—R. A. H. GRIMSHAW, *Crag Hill, Horsforth, near Leeds*.

Replies to Queries.

*. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[33.] *Prevention of Swarming*.—(H. E.) Yes, the great aim of the honey getter should be not to tempt the bees to swarm by keeping them at work, and not allowing the queens to get worn out. Once having prepared to swarm I prefer to allow them to do so.—AMATEUR EXPERT.

[34.] *Ventilation*.—(X. Y.) It is not only desirable but absolutely necessary to profitable bee-keeping, to cover bar-frame colonies with porous material during winter, and avoid draughts.—AMATEUR EXPERT.

[35.] *Is it desirable to have upward ventilation in Winter?* (X. Y.)—When bar-frames were originally used, it was the practice to winter bees on all the combs. The division-boards were then called 'dummies,' and the only use made of them was to remove them to give lateral space for extraction of the frames without rolling the bees between the combs. One hive-maker at least reduced the dummy to a hinged side to the hive to give the necessary room. Under this system it was found that the moisture from the cluster condensed upon the unoccupied combs, and rendered them damp and mouldy. To obviate this, porous quilts were introduced. Now that we crowd the bees into as few combs as they can cover, the danger of condensation no longer exists, and hence the need for porous quilts has disappeared. When feeding in autumn, it is absolutely necessary to give upward ventilation to allow the vapour from evaporation of the food, to a proper consistence for sealing, to escape. But in winter it is not required. I use the summer ticking on the frames, over this one thickness of house-flannel or felt carpet, on this I lay a board, and on the board a brick. It is only when I find it necessary to give a cake of candy that I alter this plan, and then only because a board will not make an air-tight joint all round. I then use a bottomless tray, with canvas tacked very loosely over it, filled with chaff or cork-dust. I place the cake of candy, made by pouring it into a papered saucer, on the frame, over it the ticking and flannel or felt, and over that the tray of chaff, which I tie down so that no draught can exist. I endeavoured to raise a discussion on this point as long ago as August, 1883, by a letter in the *Journal*, p. 135,

Vol. XI. headed, 'Shall we again adopt Crown-boards?' The only remarks made in reply were by Mr. Shumins, p. 154, who agreed with me.—F. LYON.

[36.] *What is the best plan for Ripening Honey?* [3]—Honey, when removed from the hive, is best ripened by the natural heat of the sun, which allows of gradual evaporation, and this will be attained by placing the extracted honey in open shallow pans (milk-pans) in a close-fitting (bee-proof) wooden house, tarred or painted black to attract heat. Honey in the comb will also be similarly improved by being placed in such a house for some days.—ALFRED NEIGHBOUR.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[37.] *Comb and Extracted Honey*.—What proportion does the yield of comb-honey bear to the yield that might be obtained from the same hive by the extractor?

[38.] *Honeycomb Designs*.—Can any one inform me how the honey-comb designs such as that exhibited at the Rutherglen Show, as I saw stated in the *B. B. J.* for October 15th, 1885, is made, as I should like to try to get my bees to work some this summer?—E. H. H.

[39.] *Winter Fighting*.—There has been a good lot of fighting at one of my hives this winter, when the bees have been out on fine days. I counted over one hundred dead close to the front one day. Those wishing to go in were calm, but those at the entrance pounced on the interlopers like bull-dogs, and soon disposed of them. In the middle of September I put a bar of comb and bees from one hive, and two from another hive, to strengthen a very weak lot; but I am not quite sure if either of these bars were from the one where fighting has been seen this winter. Is it possible that when they come out for flight that they may return to the home they knew at the early part of September, that is if any were from this particular hive? I have only four stocks.—E. P.

[40.] *Spring Management*.—May I trouble you for information as under, so that I may now know how to prepare for it? Can I do this to get section honey? Hive No. 3, stimulate March 15th; No. 4, stimulate March 15th; No. 5, stimulate March 15th; and when I find brood in every cell and hatching out with hive full of bees, say last week in April, give a top hive of ten frames, made up of two worker combs drawn out, and eight sheets foundation 'worker.' Then, May 7th, if warm, or as soon as all the frames are full of brood, add either a third hive of ten frames, or rack of twenty-one sections to draw out, then a second and so on, to keep them busy until after the swarming season is over. Then the last week in June, remove sections, and No. 2 or top hive, replacing racks of sections, and adding a new one; strengthening other hives with frames of brood removed, or placing two of these top hives together to make *swarm*, and *super them*, or can I safely super these three stocks with their top hives on, having twenty brood frames under section rack, with any chance of filling sections? The bees in question are Ligurians.—J. K. GOODALL.

[41.] *Rapid Mortality in a Wintering Stock*.—I send a box of dead bees, hoping that some of your correspondents may tell me what has happened to them. They were in a double-sided wood hive, which stood through last winter very well and gave me at least one swarm and 40 lbs. of section honey. When removing the last rack of sections I left them ten frames—some of them completely and the remainder half filled with

honey—and in every way as well supplied and protected as possible. I left all the frames as they were, filling up the hive and narrowed the entrance to a half inch. There is a tray of chaff covering the two calico quilts and all is quite dry. About three weeks ago I found several bees dead outside that hive. There are nine other hives all around the plot and not a dead bee is to be seen near them. Since that time the heap of dead bees has increased outside the first-named hive, and to-day it amounts to a large plateful. I partly examined the hive from the back only, and the five frames I saw were well stocked with sealed honey. I did not give any syrup to them in the autumn as they had sufficient stores after the summer. I do not like to pull the hive to pieces for a thorough examination at this time, and as they cannot want food I could do no good by it. It has been suggested to me that they may have contracted some disease which may be discoverable with a microscope.—FRANK McDONOGH, *Killarney, Dec. 26th, 1885.*

[42].—*Great Mortality in a Stock of Syrians.*—While my hives generally appear to be wintering quite safely, one hive is being almost exterminated from some unknown cause. This is a colony of pure Syrians, and a very full one, having nine or ten frames for the winter. The bees are now being carried out in hundreds and thrown over the flight-board, and sometimes left on the flight-board, in such heaps as almost to block up the entrance. I enclose a pill-box full of these by this post. Perhaps Mr. Cheshire, or some other *savant* among your friends, would be kind enough to make an examination—a *post-mortem*—to ascertain, if possible, what can be the disease.—S. L. B., *Troy Parsonage, Ballycassidy.*

Reviews.

HOW TO MAKE THE LAND PAY. By H. P. Dunster, M.A. (Longmans & Co., 1885.)—In this admirable work the Vicar of Woodbastwick supplies information as to the various profitable industries connected with the land and suitable to all occupations large or small. He shows by reference to the Custom House returns that a yearly sum of little short of thirty-eight millions of pounds is being paid for the importation of articles from abroad which might be equally well produced with profit in this country; and in a series of well-written chapters gives instructions, so clear that he who runs may read, by which the farmer, large or small,—nay, even the cottager—may undertake and carry out the production and marketing of numerous articles of daily demand and consumption. The subjects dealt with by the author extend from dairy-farming to lavender-growing, from orchard fruits to ensilage, from rabbit-farming to mushroom culture, from fish-farming to bulb-growing, &c., well treated in a vigorous practical manner, evidently the result of actual knowledge and experience. Let us take the chapter on bee-keeping. In ten well-written pages we have a concise account of the best modern systems of bee-keeping, and words of instruction and encouragement derived from the author's own experience. The following description of a Polish bee-farm shows what might equally well be done in this country towards meeting the demand for wax and honey, for which we are paying to the foreigner the annual sum of 150,000*l.* In all farms in Poland there will be found an orchard generally sheltered from the north by the farm-buildings, or forest trees, and a portion of this orchard is used as the bee-garden. When the larger landed proprietors go in for bee-keeping, the position selected for the apiary is often at the foot of some hill on the borders of a forest, the space of ground being enclosed with a wooden fence some six feet high. Within this enclosure, such hives as

we have described are set in rows, in quincunx fashion, five feet apart. The turf is pared off for two feet from each hive, and the surface strewed with sand, clean moss being placed round the bottom of each. The enclosure, if possible, is selected with a south-east slope. When the time for the honey-harvest has arrived, which must always be early enough to leave the bees time to get a fresh supply for their winter support, a new hive is provided for each colony of bees; and in the evening, when the bees are all at home, the new hive being smeared with honey, the bottoms of both are opened and joined together, and as the hives are all made to a scale and fit close, not a bee can escape. Smoke is then introduced at the top of the old hive, and by this means the bees are driven into the new hive and secured, so as to be set again in their proper standing places. The honey extracted thus is of two qualities; that from the early spring and summer flowers is of a light colour, that from the later flowers is of a darker hue; these two are kept separate, as the darker honey is considered the richest and commands the highest price; the wax is prepared by bleaching, and there is a good demand for it for candles for the churches, &c. Poland, by all accounts, has honey enough for its own people and a great deal to spare. Where it all goes to we have no means of ascertaining, but we do know from our own import statistics that Poland last year received of our people a large sum for honey and wax. Now that the Honey Companies afford a ready market for the honey produce, shall we not compete with and in the end supplant the foreign supply? The book should be on the shelf of every village book club and lending library, and we can promise to all who take an interest in country life both pleasure and profit from its perusal.—D. S.

Foreign.

AMERICA.

At the Convention of the North American Bee-keepers' Society, Mr. James Heddon read the following paper on Reversible Combs:—

My experience with reversing brood and surplus combs is nearly all confined to two seasons; but as I have had in use 4000 to 6000 reversible brood-frames, as well as quite a number of reversible comb-honey-cases, that experience has been somewhat comprehensive. I try to be practical in all my work, never jumping hastily at conclusions, nor adopting methods and fixtures which, although of some little advantage, still are not enough to over-balance the extra cost of construction and manipulation. Despite such endeavours, I realise that it is by no means impossible for me to make mistakes; yet I feel quite positive that implements arranged for reversing brood and surplus combs at will have come to me to stay.

During the past year I have been using a hive which I devised for the purpose, with which I can reverse, or, more properly, invert a whole case of brood or surplus combs at will. While we all here consider this a great improvement over reversing combs singly, yet were I to continue the use of such hives as necessitated reversing each brood-comb separately, I feel positive that I never should again use a frame that would not admit of reversing.

Some of our bee-keepers have paused to ask if there was not some serious objection to inverting combs. They had noticed that the cells were slightly inclined; that the workers nearly always built them in this way; and they believed that behind this almost universal method of comb-construction was a design for a purpose. Even if this be true (which I doubt), is it not quite evident that the designers are not aiming at our desired

end; that they do not purpose 'lots of surplus honey to sell?'

Let us not forget that our bees always and invariably construct their combs so that the cells are in rows horizontally—not vertically. This is an unvarying rule, while the incline of the cells is not. Now I found that, by the use of comb-foundation, I could make them construct their combs with the cells running in rows vertically. Much of Dadant's excellent brood-foundation is stamped in this way. Many believe that it is less inclined to sag when so placed in frames. I have found, by practical use of thousands of pounds of it, that the little worker, in so rigidly following her instinct in rowing the cells horizontally, was only 'just trying to fool somebody.' By the inversion of thousands of combs, I have proven that her less determination to incline her cells belongs in the same catalogue with placing the same in horizontal rows. I think the scientist has long since learned that Nature, when forming instinct in animals, is no more working for our interests than when she pours her rain-water back into the sea, while our crops are blasting and withering; or when she visits us with cyclones.

I know it is true that we cannot with impunity violate some of the instincts of our bees: that some of them run directly parallel with the ends we desire; but which are for, and which against us, we must determine by experiment. I have satisfied myself that in the inversion of combs we violate no instinct which is favourable to our success. We do, however, encourage certain actions on the part of our bees, that greatly favour the desired result.

By virtue of this reversing we get our frames completely and solidly filled with comb, which metes out to us no less than six points of advantage, which I will not consume space to detail. It also tends to keep the brood-combs the more completely filled with brood, the honey going into the surplus combs. When reversing is practised, as we can well afford to do when we can reverse a whole set of combs with a single motion, it gives us great control over swarming. I find that the reversing of the surplus combs, after I have learned the proper time to do it, is conducive of most favourable results. It causes the bees to more completely fill the sections, which is not only an economy, besides presenting a more attractive package, but adds greatly to the shipping-qualities of our surplus comb-honey. It also stimulates hasty and complete capping of the combs.

During my experience in reversing combs, I have never yet discovered any ill effects resulting therefrom; but besides the advantages above enumerated, I am always meeting with unexpected minor benefits resulting from the practice.

Dr. A. B. Mason: When is the proper time to reverse the combs?

James Heddon: The proper time to reverse brood-combs is when the bees are rearing large quantities of brood, and desire to increase the size of the brood-nest. To reverse the brood-combs late in the season, when they are contracting the brood-nest, will cause the brood-nest to be filled with honey all the faster. Sections should be reversed when the bees are inclined to store honey in them; if done after the bees cease storing honey in them, it will hasten the removal of the honey to the brood-nest. As soon as the outside sections are far enough advanced to bear inversion, change them to the centre of the case, then invert the whole case, and all the sections will be finished at nearly the same time. Inversion causes the bees to attach the combs to the sections all around, and thus makes them bear shipment much better. Swarming is also lessened by reversing the combs, as the removal of the honey gives more room for brood, and thus helps to destroy the desire for swarming. It also has a tendency to the destruction of queen-cells.

RUSSIA.

RUSSIAN AGRICULTURE AND LIVE STOCK.

An important Report has been issued by the American Government on the agriculture in Russia, which has been written by the Consul of that country at St. Petersburg. The facts given have been compiled with great care, the Report consisting of some forty closely printed pages.

Russia is the largest empire in the world, having an area of nearly 3,950,000 geographical miles, and occupies about one sixth of the land of the globe. It forms a compact mass, whilst our own British Empire, which is the next largest, is scattered over the whole world. Whilst 236,000,000 subjects obey the British, there are not more than 100,000,000 the Russian sceptre.

It is principally in European Russia that the agricultural statistics have been collected. It is found that one quarter of the land is waste, one quarter arable, three eighths forest, and one eighth meadow land. The principal crops are cereals, potatoes, flax, hemp, beet-root, and tobacco. Flax and hemp are grown in Poland only. Cereals occupy by far the largest portion of the arable land—about two thirds. With regard to domestic animals we find that Russia is behind most other European countries. Horse-breeding is widely cultivated in Russia, and is one in which she equals if not excels all European competitors. Without going into all the details we will compare the number of different live stock kept in Russia per 100 of the population with the same proportions in Great Britain:—

	No. per 100 of population in Great Britain and Ireland.	No. per 100 of population in Russia.
Horses	837	255.1
Cattle	331.5	335.1
Sheep and goats	1056.8	639.7
Pigs	107.0	143.3

The reindeer is an important branch of live stock, and poultry-keeping is universal. Russia consumes millions of eggs yearly, and exports more than 100,000,000. Many millions of head of poultry are annually consumed, yet Russia exports 1,000,000 head every year. Bee-keeping is also extensively practised, more than 1,000,000 roubles' worth of wax being every year produced for church purposes alone.

HOW BEES PREDICT THE WEATHER.—No. 17 of *Die Natur* contains an article by Herr Emmerig, of Lauingen, on German bees as storm-warners. From numerous observations the writer advances tentatively the theory that, on the approach of thunderstorms, bees, otherwise gentle and harmless, become excited and exceedingly irritable, and will at once attack any one—even their usual attendant—approaching their hives. A succession of instances are given in which the barometer and hygrometer foretold a storm, the bees remaining quiet, and no storm occurred; or the instruments gave no intimation of a storm, but the bees for hours before were irritable and the storm came. He concludes, therefore, that the conduct of bees is a trustworthy indication whether a storm is impending over a certain district or not; and that, whatever the appearances, if bees are still, one need not fear a storm.

DAME MARGARET'S BEES.—Margaret, the widow of John Norton, made her will on April 24th, 1506. She desired to be buried in the tomb of her late husband. She left six silver spoons to her grandson, Christopher Norton, and desired that her son William should find a priest to sing for her for a year. She left 12d. to Sir Thomas Oglethorpe, the curate of Bilbrough; her primer

and books of prayer to her daughter, Joan Nelson, and 3s. 4d. to each of the children of her son William, to whom she bequeathed the residue of her property. Finally, she left all her bees towards keeping up a light in the chapel of Billbrough Church as long as it shall please God to preserve them.—From 'Life of Admiral Robert Fairfax,' by C. R. Markham, page 264.

THE *New Zealand and Australian Bee Journal* has ceased to exist. At the end of the second volume it has been incorporated with the *New Zealand Farmer, Bee and Poultry Journal*. Although the new journal did good service and increased the number of members it never paid its way, and for this reason had to be given up.

Echoes from the Hives.

Bishops Waltham, Hants, Jan. 8th.—The weather in this district during the past month or six weeks has been rather variable, sometimes intensely cold, and again quite mild; but on the whole it has been a favourable time for the bees. All my hives seem quite strong and fly well on fit days. I heartily wish the *Journal* every success in the onward stride it has just commenced, and I am sure that many others with me look forward to getting their *Journal* every week with very great pleasure: to me it has during the past year been of very great service; and I know from my short experience that bee-keepers will find a great deal of advice in it which it will well pay them to follow.—H. W. WEST, Hon. Sec. *Swanmore Bee-keepers Society*.

Doncaster, January 9.—I am very pleased to receive the first number of the weekly *B. B. J.*, and I may say I have always looked forward to the dates when it would come. I always immediately jump into the middle of 'Useful Hints,' and unlike Mr. Godfrey I do wish to be greedy and cry for more and more, they will now be so much more useful, coming so frequently. I had more success last year with extracted honey than section, and easily sold it after taking some prizes. I have also sold all I can extract during the coming year.—NORTH LINCOLN.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

T. A.—While in our past numbers there are numerous directions for making Observatory Hives, there are none for the special ones desired by you.

W. T. JOYCE.—If you are disposed to bind the advertisements with the literary matter, the cases will comfortably include both.

F. F. Mc K.—*Dead Bees.*—It is the old bees that have died and have not been carried outside the hive on account of the cold. Bees frequently carry their bees out and leave them in the space if there is access to it. It is better to have a tunnel communication with the porch if you wish to have a division-board in front.—Thank you for your suggestion; we always try to carry it out as far as practicable; but it is not always possible to squeeze in all the literary matter without sometimes encroaching on the advertisement space. With a more frequent issue we shall be able better to carry out your suggestions.

C. J. H. FITCH.—*Reducing Propolisation.*—We reduce

propolis to a minimum by using 'Novice's' metal corners, described and illustrated on page 33 of Cowan's *Bee Keepers' Guide Book*. Propolis is easily removed from the hand with methylated spirits of wine.

ERRATUM.—In No. [1], page 5, 6th line of reply, for *hive read time*.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

JANUARY 21, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

SWARMING ACCORDING TO THE VIGNOLE SYSTEM.

It is usually said that swarms are got at the expense of honey, and if we get honey we must not expect swarms. The one is incompatible with the other. M. Vignole, however, who is one of the advanced bee-keepers of France, and President of the 'Société d'Apiculture de l'Aube,' says that this maxim is simply an error, and is the logical result of imperfect methods applied without science.

As M. Vignole's system has never been described in the columns of our *Journal*, we think this is a fitting opportunity to give such details as may enable our readers to form an idea of the theory, and, if they are inclined to do so, to experiment upon it.

M. Vignole starts with the axiom that the reproduction of bees must take place by means of swarming without detriment to the amount of honey produced. It is well known that, as a rule, bees do not begin to swarm until honey is being collected in plentiful quantities; it is also about this time that stocks are ready for artificial swarming, as usually practised. In opposition to this method, he proposes what he calls, '*anticipated swarming with multiplied permutation of hives*, based on rational principles.'

To prosper in bee-keeping it is necessary to have strong colonies; all are agreed on this point, because early swarms are always good and late ones are generally weak and valueless. If the populations developed by feeding in spring are more forward, they are also much stronger; they give stronger and better swarms. It is true this induces earlier swarming, but natural swarming cannot take place without the multiplication of drones, which must be avoided. As it is admitted that a large number of drones reduce the honey-harvest, we must not wait for natural swarming, but adopt a method which prevents in a great measure their development. The Vignole method effects this object. But this is not all. If it is necessary that artificial swarming should be performed early to be good, it is also important that the parent stocks which have had swarms taken from them should remain strong, so as to be able to store much honey, and also that after-swarms should be limited so as not to weaken the hive. Strong hives are wanted not only in the

spring but during the whole gathering season,—and also for wintering. To keep up this strength it is necessary to encourage the multiplication of our bees; and nothing effects this object better than swarming. The following are the laws upon which this system is based:—

1. To be strong the swarm must be made early.
2. To prevent the weakening of the hive which produced it.
3. To establish its strength by removing the cause of its weakening.
4. To prevent the raising of drones.
5. To limit the number of swarms.
6. Only to operate on hives well provided with brood.
7. To develop the laying powers of the queen.

Having given an idea of the system, we will now explain how M. Vignole carries it out in practice. He states that the swarming must be anticipated, and that it must be performed before queen-cells are started, which is always coincident with the great development of drone brood.

SWARMING THE PARENT STOCK.

This must be done, as we have stated above, before queen-cells are formed. All hives are not ready at the same time, but operations must commence with those that are in a fit condition. Examine the strongest hive, and if it is filled with bees and brood this is the time to make the swarm. Do not wait for drones, as the hive could not be in a better condition for swarming, according to this plan. Make your artificial swarm by driving, or otherwise, and place it upon the stand of the parent stock, which has to be removed and put in the place of another hive, equally strong. The swarm is then supered. The hive which has given its place to the parent stock is put on a fresh stand, at some distance from its original position. Thirteen days after, the parent stock will be strong enough to give a second swarm, equally as good as the first. He gives thirteen days, and states it is because the youngest larva that the bees can select to raise a queen from is hatched from an egg laid three days; consequently, these added to the thirteen days give the normal time of about sixteen days for the metamorphoses of the queen. If the parent stock is supered, the super is removed and a second swarm made. This time the swarm again takes the place of the parent, which in turn takes the place of the one removed to a distance,—which, in its turn, is again displaced. Eight days later, *i.e.* twenty-one days after the first swarm was taken, when there is no longer any brood in the hive which has given the two swarms, all the bees are driven out and the hive is removed, its work being accomplished. The driven bees take its place until they can be utilised in the way to be explained.

In this way, the parent stock, at the moment when it had a chance of becoming queenless, after the second swarm (as frequently happens in natural swarming), is saved from this danger. It also being free from brood,

and all other substances but honey, gives a more sure return, and renders the manipulation easier. It must be borne in mind that, when the first swarm was taken, the parent stock was left queenless; which, according to this system, is an advantage, because the bees, not having any fresh larvæ to look after, can devote all their energies to collecting and storing honey in the cells which would otherwise be occupied with brood. There being also very few or no drones, the honey they would have consumed is a gain to the bee-keeper.

Let us now look at our swarm. Its future prosperity has been secured. Already well peopled, it is considerably strengthened by the bees returning laden from the fields. Not the least of the advantages claimed for this method is that of being able to leave the hives to themselves for twelve days, and return on the thirteenth with the certainty of being able to make the second swarm.

This system of swarming can be continued as long as the honey flow lasts; and in places where it is of long duration, the first swarms can even have a swarm taken from them, always practising the permutation of the hives.

DISPLACEMENT OF HIVES.

In this system, the displacement of hives presents great advantages, and is a sure method of preventing natural swarming. The displaced hive, momentarily impoverished by the loss of a large portion of its population, feels the necessity of strengthening itself and sets to work to rear worker-brood just at the time it would ordinarily be employed in rearing drones, which in this case is prevented. These hives are always the strongest in the following season, and are well furnished with stores, and should be kept for building up the apiary.

If the honey-harvest is abundant, the second swarm can be treated in the same way as we have described for the parent stock, always bearing in mind to place the swarm on the stand of the hive from which it is taken. A hive that has been displaced must always be allowed to re-establish itself, and should never be swarmed before the hives which it has fortified.

The continuance of the honey-flow has a tendency to make the first swarms which have become very strong to swarm again; the hives which take their place prevent this, and the swarm is rescued. In this manner the permutation of hives, with judgment, strengthens the exhausted hives and prevents natural swarming.

So also the first swarms, being forced before the great flow of honey, and the second swarms thirteen days after, and in the midst of it, have as good a chance of success as, or better than, most natural first swarms.

DRIVEN BEES.

The driven bees, which result from this system of taking away the parent stock that has given two swarms, for the purpose of appropriating its honey, left to themselves, would not prosper. Sometimes, it is true, they could build some combs, but they are much more usefully used in strengthening weak swarms, or, by uniting several together, building up stocks.

In working this system, it is stated that not only is the amount of honey collected not diminished, as in the ordinary swarming, but that it is increased, because there are few drones to feed; and that an increase of the population is made without the desire to swarm being created. The system can be applied as well to moveable comb-hives as to any other. Although the bees cannot be driven in moveable comb-hives, swarms may be made by removing the queen, with a couple of frames of brood, placing these into an empty hive, and brushing enough bees to make the swarm. The hive is then placed where the parent stock stood, and this is removed just as we have described above. One thing to remember is, that a super or rack of sections be put on the swarm when it is made, so that it can at once commence storing honey. The renewing of queens can also be accomplished by

taking those first swarms having aged and defective ones, and preserving those with young ones.

To sum up, the advantages claimed for this system are that,—

1. The swarming is done on fixed days.
2. The number of swarms is limited.
3. The parent stocks are strengthened by permutation, and are harvested at certain periods determined by the bee-keeper.
4. The queen lays worker-eggs in the swarm, instead of drone-eggs in the parent stock, at the time of the honey-flow.
5. The drones, the raising of which is lessened, or entirely prevented, cannot interfere with the workers or rob their stores.
6. The parent stocks which have given the swarms are the heaviest in the apiary.
7. The strength of the apiary is kept up by swarming.
8. Queenlessness is unknown.
9. The bee-keepers' time is economised.

Such are the advantages claimed, and we have no doubt that, in the hands of an expert like M. Vignole, the results are satisfactory; but it seems to us that our hives are generally much too heavy to be constantly moved about in this manner. Dr. Bianchetti, of Ornavasso, and others, are enthusiastic about it; but their hives are certainly much smaller than ours. We hope some of our bee-keepers, especially those using skeps, will try it, and give us the result of their experience. To carry it out properly, it is necessary to follow the instructions given faithfully. We entirely agree with M. Vignole in the necessity of having strong colonies, and these we succeed in getting without having recourse to swarming, which in our large hives we entirely prevent, and at the same time encourage the full development of the laying powers of the queen. We also prefer to raise our queens by careful selection, and thus insure their good qualities being perpetuated.

USEFUL HINTS.

WEATHER.—The opening sentences of our last 'Hints' (January 7th) apply exactly to present circumstances—'after severe frosts and snowstorms, again we have a sudden thaw.' The latter snow-fall, however, has been much heavier than the former, and many hives have been buried beneath the banks of snow. Where the snow has been removed in its crisp state, and carefully brushed from the hives and entrances, the hives will remain dry and unaffected by the pouring rain, which is fast removing the white mantle from our fields.

FLIGHTS.—For nearly a month have our bees been confined to their hives without the chance of a flight. Consequently, on the first mild day, all strong colonies will rush forth from their hives as if on swarming bent; but, in fact, for a very different purpose, namely, that of cleanliness—to avoid fouling their hives by the voidance of feces. Whenever dysenteric symptoms exist they will then become manifest by the soiled alighting boards and fronts of the hives.

DYSENTERY.—Now although *perfect repose* at this season is most desirable for healthy colonies, yet there are exceptions to all rules, and fully-developed dysentery is one, to which, immediately the weather permits, a remedy should be applied.—See last 'Hints,' p. 3.

SEALED COMBS. **FOOD.**—If frames of sealed honey, ungranulated, are in store, we prefer such—given

warm, with a few cells unsealed—to any other food. We always store, in a dry, warm room, a number of such combs as a reserve, when making our winter preparations, in preference to extracting the whole; and the life of many a colony has been saved by these means.

Indeed in *every case*, where food is required in winter, or early spring, there is none equal to this, especially if the bees are confined to the combs they can cover. To colonies in skeps, food cannot be given in this form, but may be supplied as suggested in former 'Hints.' As a rough measure of the consumption of food, it may be considered that a strong colony will consume about fifteen pounds of honey between September and March; but from March to swarming time the consumption is very great, and this at a period when very little honey is coming in, especially in cold and late springs. Hence the necessity of liberal feeding at such times.

DAMP HIVES.—Another case in which examination at this early season is allowable, is where hives have been saturated by the admission of rain, or melting snow, through faulty roofs or coverings; or where the driving snow has penetrated to the interior through the entrance.

TRANSFERRING.—In either case a transfer of combs and bees to dry, clean hives, is most desirable; and clean floor-boards, with dry quilts, must be substituted for wet and soiled ones.

During the never-to-be-forgotten snow-storm of January 18th, 1881, the interiors of some dozen of our hives were so penetrated by the finely-powdered snow, driven through the entrances, and firmly wedged in between the combs to their very centres, that we were compelled to take them in-doors, and, manipulating by lamplight, to clear the combs from snow, and to transfer them, bees and all, to dry hives. This was accomplished with the least possible disturbance to the bees:—most of the queens were 'interviewed'; in most of the hives sheets of sealed brood were found; and the final result was perfectly satisfactory, all these colonies affording a good return in the summer following. Indeed, no injury, but much benefit, resulted from this unseasonable manipulation.

PROVISION FOR THE FUTURE.—Again we remind our readers of the economy of providing, so far as practicable, for future requirements. Of course, no bee-keeper can decide, so far in advance of the season, as to what the season will be—whether prolific of swarms or honey, or of both, or neither—hence he will be chary of ordering goods which he may never require. Nevertheless, those who are wanting hives, racks, crates, sections, &c., in store, will be wise to make reasonable provision *now*, when the warehouses of those who cater for the fraternity, in the supply of all things necessary for the craft, are already full to overflowing. Procrastination may prove an expensive indulgence, and required articles—as we know by experience—may be unobtainable at the precise time they are wanted.

THINGS-IN-GENERAL.—When casting about for 'Hints' to our readers—whom we cannot resist comparing to the 'two daughters of the horseleech,'

continually crying 'Give, give,' however flattering to ourselves—so many ideas, which can scarcely be classed under the category of 'useful,' cross the mind, that we shall not hesitate in future to conclude this department of our labours with the above comprehensive heading.

And first, as regards reversible frames. In our issue of the 7th instant, Mr. Hooker reverts to this subject: referring to Mr. Heddon's favourable report, after practical experience (related in a paper, which we were pleased to see transferred *in extenso* to our columns), and very much to the point indeed: he might also have added that Mr. Heddon had on his hands upwards of ten tons of honey, which he was unable to sell, obtained from the 6000 reversible frames.

This, however, is no argument, since an equal, or larger, quantity has repeatedly been obtained from un-reversible frames. Mr. Heddon is the *one* strenuous advocate of the system, which, assuredly, after a trial of five or six years, has not been taken up generally by prominent American apiarists. The articles on this subject in our columns can hardly be said to have been written with the intention of 'throwing cold water on the system'—nor are they entirely 'theoretical.' The summing up, certainly was not favourable to the system; but it was evidently the desire of the writer of those articles that the advocates on both sides should have a fair field and no favour. The system has yet, in a great measure, to be tried in this country, and we trust that many of our apiarists are preparing to give it a fair trial. As a specimen of special pleading Mr. Heddon's paper is clever, but we must join issue with him as regards the statement that, 'the upward incline of the honey-cell is not unvarying.' We have always found it so. Granted that the cells in the *brood-nest* are horizontal, we maintain that the cells around and above the nest, as a rule, have always the upward pitch, and this in so much the greater degree, as they become more and more lengthened for the reception of additional honey. And thus the cells *over* the brood-nest—often prolonged until the combs all but meet—form a heat-retaining canopy above the nest. To reverse all this appears to us so contrary to the natural instinct of the bee, that we must, in accordance with the dictates of common sense, adhere to the belief that by judiciously uncapping portions of the sealed honey, thus causing it to be removed to a higher level (*i.e.* into the supers), at least an equally favourable result may be obtained, without the great disturbance caused to the colony by the inversion of all its combs. Under certain circumstances, however, we can conceive the inversion of skeps to be advantageous.

FORMIC ACID—A REMEDY FOR RHEUMATISM.—*El Siglio Medico* relates the following singular case, which may prove interesting to the bee-keeping world:—'A woman had suffered so much from rheumatism that for six months she had hardly slept. Her right arm was so affected that it was quite useless; she could neither work with it, nor dress herself. While in this state she heard of a countryman who suffered in the same way, and who

had been cured by the accidental sting of a bee. As the pain caused by the sting could not be worse than that due to the rheumatism she determined to try the same remedy. Three bees were obtained and made to sting her on the right arm. The success of the treatment was surprising and complete. On the following night she was able to sleep, and the acute pain had all but completely disappeared; the arm was naturally a good deal swollen, owing to the stings, but the swelling quickly disappeared with cold water dressing. The use of the arm gradually returned, and since there have been no symptoms of rheumatism. It is reported that the same remedy has been equally successful in several other cases. The cure, no doubt, was caused by counter-irritation, and the treatment is analogous in its action to blistering, and the like.' Moral: 'Let all rheumatic persons keep Cyprian bees.'

Beware of the BLUE-TIT. He is very busy in our apiary. For him we are preparing traps baited with linseed—a never-failing inducement to him to enter.

BEE-HOUSES.

Having frequently been desired by some of our readers to give illustrations of bee-houses, we have much pleasure, through the kindness of the Rev. Geo. Raynor, in complying with these requests.

The advantages or disadvantages of bee-houses have ever been a 'vexed question' with bee-keepers; for while some of our most practical apiarists have been strongly opposed to their use, others are equally in favour of them. We are not disposed to discuss this matter at the present time. It has been exhaustively dealt with by Mr. Raynor in the paper read by him before the B. B. K. A.; and we would recommend our readers to procure this paper and study it, with the discussion that followed its reading. Mr. A. I. Root, in his *A B C of Bee Culture*, notes many 'good and desirable qualities' in bee-houses—or house-apiarists, as he terms them—and advocates their use.

To assist those of our readers who may desire to make their own bee-houses, we subjoin the specification which accompanied the drawings.

SPECIFICATION OF BEE-HOUSE.

Properly frame, and fix together with mortice and tenons, the bottom, side, and end rails into upright posts, also cross bearers; and fix upon same inch pine floor, properly jointed together.

Front Elevation.

Fix bearers on ends; also brackets at equal distances, and fix inch pine boards on same to form middle floor.

Provide and fix cross pieces, to project at least three inches at each end beyond legs to support same.

Back Elevation.

The ends and front of house to be covered with three-quarter inch matched boards.

Provide and hang at back two pairs three-quarter inch ledged, tongued, and beaded doors, with cross garnett hinges, two bolts, two locks for fastenings.

Provide and fix seven inch boards, as shown on front of house to divide entrances. Cut entrance ways, and fix alighting-boards and robber-slides to same.

Framed roof-plates to upright posts, and supports where necessary to prevent sagging; and cover roof with three-quarter inch square-jointed boarding, and fix chamfered fillets over same.

Paint the whole of the wood and ironwork three coats of good oil-colour of approved tint.

Section.

Ground Plan.

Scantling of Timber, &c.—Corner and middle posts, 3" x 3"; bottom and end rails, 1 1/2" x 3"; cross-bearers, 1 3/4" x 3"; roof-plates, 1 1/2" x 3"; ridge, 1 1/4" x 4"; fillets for roof-boards, 1/2" x 2"; entrances, 1/2" x 4"; alighting-boards, 3" x 8" x inch thick; cross pieces for legs, 3" x 3". The legs should be of pitch pine or oak.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

As we go to press the election of the Committee for the present year is proceeding. The voting papers have been issued, and doubtless many of the members have already recorded their votes.

The list contains the names of many who have done the Association and the bee-keeping cause good service in the past, and who, if elected, will no doubt continue their work and labour of love as hitherto.

In addition to the members of the old Committee we are glad to see such names as the Rev. F. T. Scott, who was formerly a member of the Committee; the Rev. J. Lingen Seager, Hon. Sec. of the Hertfordshire Association; and Mr. A. H. Heath, Hon. Sec. of the Staffordshire Association.

It is very desirable that a good strong Working Committee should be elected, consisting of those who

can and will attend the various meetings of the Association. The Association's work has considerably increased during the last few years, and it is only just that every member who may be elected should consider himself in duty bound to carry out the work which the office entails.

THE BERKSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held on Tuesday last, January 12th, at the Queen's Hotel, Reading, A. Sutton, Esq., in the chair; there was a good attendance of members. The report and balance-sheet were read, adopted, and ordered to be printed. The Expert's report we hope to publish shortly, as it contains some useful suggestions respecting spring feeding. The finances of the Association appear to be in a flourishing condition, and the increasing list of members shows that good progress is being made in Berkshire. The officers for 1886 are as follows:—Hon. Sec., Mr. John Bowly, Avenue Villa, South Eastern Avenue, Reading. Assistant Secretary and Expert, Mr. A. D. Woodley, 26 Donnington Road, Reading. Hon. Treasurer, John Simonds, Esq., The Bank, Reading. Hon. Librarian, Mr. F. Cooksey, 131 Friar Street, Reading; and a representative working Committee. It is pleasing to note that the second and third prizes in the Bligh Competition were awarded to members of this Association (Mr. W. Woodley, World's End, Newbury, and Mr. F. Woodley, Chilton Steventon, Berks), and first and second prizes for large supers at the Royal Agricultural Show at Preston, besides many others, reached the county, showing that Berks is by no means behindhand in the bee-keeping world.

It is hoped that the annual show of this Association will be held at Reading this year, and efforts are being made which it is hoped will make it even more successful than the one held there in 1884.

Selected Queries.

[43.]—*What is the best method of preventing bees from robbing?*

Keep all your hives strong. Be careful not to leave any honey or syrup about, especially in spring and autumn. If robbing does take place, contract the entrances of the hives, so that only one bee can pass through at a time, and by this means the hives are easily guarded.—GEO. WALKER.

Shut up hive being robbed, allow ventilation, and remove two or more miles away after dusk.—R. MCNALLY.

'Prevention is better than cure.' Leave no sweets lying about in any shape. During a dearth of honey open weak colonies and nuclei as seldom as possible, and none at all except early morning and at evening; the former at evening only, at such times. In cases of actual and determined robbing, contract entrance to quarter inch, and use watering-can freely to repel the intruders.—SAMUEL SIMMINS.

Keep all stocks strong; it is *the one* preventative against any attempts by marauders. It is at the close of the honey season when most danger exists from robber bees, therefore at such time especially closely examine all hives, and see there be no crevice by which it would be possible for a bee to gain entrance save by the front door, and that should be narrowed. Stocks that are weak from over-swarming or other causes are those generally attacked, and most easily overcome. The entrances to such should be closed to within two inches, and a piece of fine perforated zinc, having a small aperture to admit two bees only to pass, fixed at

opening, and the stocks carefully watched. Robber bees may very easily be spotted by their cautious dodging about close round and at entrance to hive, bent as they are on slipping in for plunder at any unguarded moment. Immediately on discovery of a stock being assailed, close hive, and let it remain so until near dusk, when reopen, that the robbers may clear out. In the meantime examine apiary, and if found that the guilty ones are home residents close their hive also until near dusk, then reopen it to admit returning bees. At the same time remove quilts, and uncap cells of two or three frames near top. When all is quiet, close entrance again, and let it remain so until next evening, then allow bees flight. Follow the same treatment for three or four days. Examine robbed stock, and if found worth preserving replenish their store so far as needed. Should, however, the robbers have come from abroad, keep entrance of robbed ones closed during daytime for three or four days. Perforated zinc should be used when closing entrances.—R. R. GODFREY.

The plan I have found most effective, if practised when robbing commences, is to place a tunnel four inches long with half-inch entrance on the alighting-board, through which only give the bees access to the hive. I then paint the hive front and the alighting-board from side to side at their junction with carbolic acid.—C. N. WHITE.

Keep your stocks strong, and take care that none are queenless. Do not give them more combs than they can well cover, and keep the entrances narrow in spring and autumn or whenever the honey flow is checked. Feed during the night only and spill neither honey nor syrup in the vicinity of the apiary, nor let the bees clean any combs outside their hives. Perform all operations on the stocks as quickly as possible and let all slinging of combs be done indoors.—F. ZEHETMAYR.

Have all colonies strong and able to defend themselves. Keep each hive supplied with a young queen (not over two years old). Avoid opening hives in the middle of the day in robbing season (early spring or autumn), and be especially careful not to spill any syrup or leave honey exposed. In fact, to be very cleanly in your manipulation and not to drop comb paring or other attraction on the ground. When bees have begun to rob they may be induced to desist by hanging a wet cloth or an old sack over the hive attacked, and sprinkle a little carbolic acid on the cloth not far from the entrance.—ALFRED NEIGHBOUR.

[44.]—*How many frames of comb should be left for bees to winter upon, and how much honey or syrup?*

Ten to twelve in autumn, reducing number in early spring to suit strength of colony. From twenty-five to thirty-five pounds of honey or syrup.—R. MCNALLY.

Seven to nine, according to strength of a colony, each of said combs respectively to contain not less than four pounds gross weight; or to be three-fourths sealed over by Oct. 1.—S. SIMMINS.

This depends upon the size of the colony. Four pounds of bees—about 18,500 in number—may be crowded upon eight standard frames. The eight frames should contain about twenty pounds of sealed honey or syrup, the former for preference.—GEORGE RAYNOR.

A stock which has crowded from ten to twelve combs, and worked well into supers besides during the summer, may generally be compressed into the space occupied by seven or eight combs for winter. These combs should have a border of honey weighing collectively from twenty to twenty-five pounds, and with suitable wrappings and properly arranged ventilation bees so provided will winter safely.—P. H. PHILLIPS.

The number of frames of comb left for the bees to winter upon should be *only* the number the bees can cluster between; and the bees' combs and food should

weight twenty-two pounds nett in September. My bees have consumed on an average for the last thirty years nine-tenths of an ounce per day per stock from September to April. Some stocks consumed nearly double that others did. Weak stocks consume the most, as they have to eat more food to make the necessary heat, instead of keeping themselves warm in large clusters.—WILLIAM CARR.

Five to seven. Twenty to twenty-five pounds.—C. TITE.

The number will entirely depend on the strength of the colony at the time you prepare it for winter. The frames of comb should be reduced until those left are crowded to overflowing with bees, care being taken to leave those having a good quantity of honey, and all with brood, should there be any. They should have from 15 lbs. to 20 lbs. of honey or syrup to winter upon. It is advisable to make winter passages through each comb, two inches down from the top of the frame, about in the centre, to enable the bees to pass from one comb to another without leaving touch with the cluster.—JOHN M. HOOKER.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangers and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

WAX PRODUCTION.

[45.] Seeing what a large amount of money we are paying annually for wax imported into this country, it is not surprising to find the Editor of the *British Bee Journal* endeavouring to impress upon the minds of British bee-keepers the desirability of raising more of that article at home. But if we follow the advice given by most advanced bee-keepers, and use full sheets of comb foundation, both in body, box, and supers, I fail to see how the desired increased production of wax is to be brought about.

The cost of foundation for use in my own apiary is considerably in advance of amount realised through the sale of wax. For instance, I purchase stock foundation at 2s. per lb., a pound of which will fill six Standard frames. But when I melt down six combs, no matter whether they have been used three months or three years, I am quite unable to get from same one pound of wax, and what I do get, although of the finest quality, will only fetch 1s. 6d. per lb. I consider, therefore, that I lose at least 9d. per lb. by every pound of wax I sell, that is, so far as the wax itself is concerned. I am fully aware of the great advantage to be derived from the use of comb-foundation, under certain conditions, but the system of using full sheets at all times and under all circumstances is, I think, open to objection, especially in the case of swarms. Natural swarming generally commences, in this district, in the early part of May, but the warm weather which is sufficient to bring about this (to many) desirable state of things is, as a rule, followed with a period of bitterly cold weather which often extends over several weeks. Swarms that are hived on full sheets of foundation of course very rapidly fill their hives with combs, and then have nothing further to do during inclement weather but to prepare for swarming upon

the very first hot day that suddenly occurs. And I am very much inclined to the belief that if, for these early swarms, strips instead of full sheets of foundation were used, the bees regularly fed so as to keep them busy comb-building as well as breeding, such swarms would, by the commencement of the regular honey season, be in equally as good, if not better, condition than those that have been furnished with full sheets of foundation; at all events, I intend trying it, and if my theory proves practicable, I may then think of enlarging my apiary for the purpose of wax production. The probability is, of course, that I shall get a larger proportion of drone-comb, but such combs make capital honey receptacles and could be weeded out at the end of the honey season, when they would, I presume, produce about the same quantity of wax as worker-combs, and whatever the production might be, all would be clear profit, there being no cost of foundation to deduct.

If you think the above worthy of publication, I shall be pleased to see it in your next issue, and will then give you a letter on 'Foundation for Supers.'—A. SHARP, *The Apiary, Huntingdon.*

'TEN YEARS SINCE'

[46.] It is about ten years since I intruded upon the pages of the *B. B. Journal*, not that I have felt any lack of interest in its contents, for they have always been full of suggestions that have been generally pleasing and profitable to me. I have indeed sometimes been furnishing my spear when I feared one of my brother apiarists was verging dangerously near to apicultural heterodoxy; but while preparing for the contest, some one, more prompt and agile, has entered the field and defended the truth as it is in modern apiculture, leaving me to the conclusion that reticence was for me the better part of valour. But probably you will allow me, Sir, to express my gratification that in so many matters your large experience has sustained my judgment and justified my practice. I, with yourself, ever since my early noviciate, have discarded distance-tacks, &c., trusting to the eye and the feel to adjust the frames to their proper distances, nor care to be encumbered with gloves; and, having no taste for smoking myself, I credit my bees with like good sense, so never use smoke except a little in driving bees from skeps, and have frequently taken out every frame from all my hives without a bee attempting to sting, judging that quiet, care, and patience will be less likely to irritate than smoke. I was also pleased to find your experience rendered it probable that the enamel cloth would be found preferable to other materials for covering the frames. I have seen fourteen stocks covered with it next the frames, and when examining them last month saw no reason to fear injury from its use. Indeed, I have long been sceptical as to the wisdom of the upward ventilation, for how can it be secured without loss of heat? And is not loss of heat, and increased consumption of food to replace it, a prolific cause of dysentery, sometimes resulting in foul brood? And for what object? Is it to let off the gases that would poison if confined? If so, what poison? Is it carbonic acid gas that is the principal danger? If so, is not that gas in specific gravity half as heavy again as the purer air of the hives, and will it not tend rather to sink than to ascend and flow out at the entrances, especially if left fairly open, as you recommend? And if the object be the removal of moisture, will not an adjustment and equilibrium of the internal and external moisture of the atmosphere be brought about by a process somewhat analogous to endosmose and exosmose, which takes place in the circulation of fluids of different densities and specific gravity in plants? And if an upward flow of the atmosphere of the hive takes place, however slow and indirect, must it not carry heat with it from the upper part of the hive,

and thereby suck the cold air in to replace it, and so produce the evil so much deplored—the condensation of the moisture within upon all parts made cool thereby? And if increased cold occasions increased consumption of food, and increased consumption of food increased moisture, and if the bees are confined, tends to cause diarrhoea and abdominal distention, with all its attendant evils, are we not then, by upward ventilation, imperilling the interests of the bees and bringing about the very evils we seek to prevent, and antagonising the instincts of the bees, which prompt them to propolise the insides of skeps, the perforated zinc over feeding-holes, and all coverings of whatever material, if sufficiently porous to admit of upward ventilation, if they can get any? And does not the fact that they do so little in the way of propolis the enamel cloth prove that it suits better their comfort than upward ventilation? And, again, if a certain degree of warm moisture is required for the production of healthy brood, and I have found repeatedly in my hives, both in December and January, brood in several frames, then why should we get rid of it from the top of the hives? Will it not, if in excess, escape from the bottom of the hive without a proportionate loss of heat and a consequence drawing in of a colder and heavier air from below? And if the bees are crowded, as you, Sir, recommend, on a few frames, and these surrounded by dummies and winter packing, will it not serve all the requirements of the bees, and render our bar-frame hives more like the skeps, propolised as they are, preventing upward ventilation, and yet remaining, if well covered and sufficient bees, dry enough for a safe wintering?

Or if any prefer the plan I have adopted for years, that of having three and sometimes four entrances in the floor-board of the hive, so that when I take condemned bees, instead of having additional hives to contain them by means of additional dummies, and the opening of additional entrances, you can crowd three or four stocks under one roof, then should you think it expedient to unite them if they do not happen to prosper or are queenless, it is only to withdraw a dummy, then two are united without further trouble, the scent generally being sufficiently mixed to prevent any fighting, and they that add additional heat to the advantage of all; and additional dummies may be cheaply extemporised by procuring cardboard from the drapers, which, if tacked on the side of a frame containing comb, and cut to fit, will suit either between the stocks, or to enable to fill in with chaff for winter packing. My entrances are all in the floor-boards, which I prefer, and the hives made long enough to contain two stocks in the summer; then, if all goes well, make hives enough to contain them, with room to work. Should any reply in reference to upward ventilation, that the packing above is enough to prevent the loss of heat, then does not that likewise defeat the professed intention of upward ventilation, and retain all the moisture?

I leave these queries for the consideration of apiariums more profoundly versed in scientific subjects than myself.

Perhaps you will allow me to express a fear that we are allowing one of the most interesting parts connected with bee manipulation to fall into disuse at our bee shows, I mean slinging the honey. In the first volume of the *B. B. Journal*, under the signature 'Alpha,' page 72, I mentioned my practice of using fine annealed wire for confining transferred comb into bar-frames. I have continued it ever since, finding it answer well when twisted and drawn a little aslant to tighten it. I object to tape, as recommended and used, as it is so often gnawed by the bees, and if left a few days a channel is made under it, showing that the bees seek to get rid of it, or find it in their way. And while foundation is a valuable acquisition to the bee-master, it is in my judgment poor economy to throw away good comb to substitute comb-

foundation when one is transferring. I use a small strip of a hat-box to prevent the wire from cutting through the bottom of the comb when too short to reach the bottom rail of the frame.

There is one other matter that I should like to be enlightened upon. I have often wondered who was the first person to use the honey-slinger in England. I sent to the *Bee Journal* in July, as I thought time enough for insertion in the August number of 1873, an account of my use of it, under the name of 'Alpha.' In the August number my friend and tutor in apiculture, Mr. Abbott, gave his account of having used the one he had received from America. My account was inserted in the September number. I must leave it with my friend, Mr. Abbott, to decide as to which tried his hand at slinging honey first in this little island, unless someone else lays claim to priority.

Now, Sir, asking absolution for the length of my epistle, and wishing you every success in your office as Editor, which your large practical experience and success lead all to anticipate.—D. W. PENNELL, *Nitcham, Scaffham, Norfolk, Jan. 16, 1886.*

BEST HIVE.

[47.] A discussion on the merits of the different hives in use now would be most seasonable, and valuable information should be gained by it, for I feel that I have not the best hive, nor, perhaps, the best way of managing it, when I find so much more honey taken by others per hive than I can. Is the hive of the future to be a long twenty-framer, or ten-frame boxes be built up one over the other, or a hive to be in one position to-day, to be turned upside down to-morrow? Hoping some of our advanced bee-keepers will give their opinions, I am sure much useful information would result.—JOHN J. SMYTH, *Ballinacara, Co. Cork, January 11th.*

REVERSIBLE FRAMES WITH METAL ENDS.

[48.] Whatever improvements are made in frames metal ends will be looked upon as a necessity by all those who have used them and know their value. This was kept steadfastly in view when I was endeavouring to invent a simple, cheap, and convenient reversible frame. I have three kinds of reversibles in my apiary, all metal-ended, and simpler than any I have seen illustrated in the

B. B. J. The above drawing is an illustration of the one you called attention to in the last issue. The flange A, at the side of the metal end, keeps the frame from the side of the hive, and also helps to keep the 'end' in its proper position. It is flanged only on one side, so that its revolution is not interfered with when it is necessary to turn it under the frame, as seen at the bottom. Before using I have tested each frame with a 20-lb. weight, and it bears it well. Ordinary frames can easily be fitted with these ends, and are then reversible.

In the issue of December 15th some editorial remarks were made describing reversibles, and stating that 'if

ever they come into general use a simpler and less extravagant device must be employed,' which made me think that the frame above, called the 'Acme,' is the one thing needful to make reversing popular. We have in this, at the cost of an ordinary wooden frame, simplicity, metal ends, commodiousness, and reversibility. From what I have been able to gather from the *B. B. J.*, very few have tried reversible frames, and still fewer who have tried them extensively. The reason for this, plainly, is because the frames have been too complicated and expensive. This is borne out by Mr. Simmins, in the same issue, on this subject, who wisely said, 'Let bee-keepers bear in mind that any complicated method which adds to the labour and expense of production . . . will not be adopted by those who are now compelled to reduce their working expenses to the finest limit.' It is true he does not approve of the principle of reversing, but he does not say he has tried it or seen it tried much; so I conclude that on this point he is an incompetent witness. Mr. Heddon, of America, has used from 4000 to 6000 reversible combs, and after this experience says that he would have none other. Last summer, out of a total of fifty-four hives, I had forty-nine reversibles. Now they all reverse. At first I tried the principle on one or two, and so far approve that I have entirely abandoned the old style. I believe the time will soon come when few frames that are not reversible will be in use.

In the above quoted number of the *B. B. J.* an editorial enumerates two advantages to be derived from reversing, and then proceeds to show that the same can be done without reversing. With your kind permission I will review a few of those remarks and add some further important advantages to be derived from the new process.

First: Combs become attached to the four sides of frame, giving strength. This, it was said, can be accomplished by cutting the comb from the frame, allowing it to rest on the bottom, and tying in for bees to rebuild the top. A person having many hives, and following this as a system, would find much of his time occupied with this operation alone. With reversible frames the bees need not be shaken off, and with the 'Acme' the operation is as quick and easy as turning the frame upside down.

Second: That by reversing the combs the honey is carried into sections above the frames. I was pleased to read the qualification which followed that: sometimes after this trouble has been taken the combs have to be put into the extractor to make room for the laying queen, for it accorded with my own experience. Last season I had one of my ordinary bar-frame hives supered. Although well protected the bees deserted the super early—and during fine weather—and on examining the hive I found the brood-combs three parts full of sealed honey. I went through the disturbing—and to the bees exciting operation of uncapping; then covered them up for a week, when on re-examination they appeared exactly the same as when I previously opened and looked at them. I put them in the extractor and made up my mind that those frames should be reversible before the year was over.

There seems to be a prevalent idea that the reversing of frames should not take place until the supers are put on; those who wait till then lose more than half the advantages. I reverse mine earlier than that for two reasons, both relating to the important point of spring breeding. It is well known that if supplies are stopped in the spring by bad weather or other unpropitious causes, the queen ceases breeding; sometimes also the bees have an abundance of food just before the honey is gathered freely, and the bee-keeper is anxious not to have too much sugar in the hive at that time. Yet if supplies cease to come in the queen produces slowly or not at all. I have found that reversing the frames in spring and giving the bees occasion to carry their food upwards has the same stimulating effect as feeding, and I have kept

hives fully at work breeding on a very trifling amount of food already in the hive.

Another advantage is, keeping the brood-nest large though compact. This is a point which cannot be over-estimated. The practice of introducing empty comb into the 'nest' to stimulate the queen is a common one, and is often carried to an extent detrimental to the hive; for if cold weather come the bees are driven from the outer combs to the centre, and 'chilled brood' is often the result. In a reversible hive we can have as much brood on the three centre combs—where the bees cluster—as can be found on five combs of an ordinary hive, and the fear of chilling is reduced to a minimum. Furthermore, everyone knows that the warmest air is at the top of the frame—just where the old style keeps the food, and the extra heat up there is so much waste. In the reversible frame we have brood in the warmest place—most compact yet most numerous on the least amount of food, and best fitted for the coming harvest and its ultimate acquisition by the bee-keeper. Keeping the brood in this manner leaves the outer combs for the incoming honey, and they can either be extracted early or reversed for supering.

I may say, in conclusion, that I have not found the bees nibble away the reversed comb and then rebuild it, as some have stated. It is only the cells at the top of comb that are given upward pitch by the bees, and in reversed combs which I have in stock, which have been well used, the top and bottom cells of the combs are pitched in an opposite direction to each other, so that whichever is turned uppermost has the pitch of the cells upward. This shows plainly that the bees did not bite them away, and there is abundant evidence that the queen did not refuse to lay in them. In fact, last year I had the bulk of my combs full of brood from top to bottom with not more than one or two ounces of food in each.—JOHN RUDGE, *Dursley*.

DRYNESS OF HIVES.

[49.] In reading the correspondence on the subject of hive-roofs, I am tempted to give a plan I have tried with perfect success so far as time allowed the trial to be tested. Like your other correspondents, I have found some difficulty with one or two roofs, and being connected with a railway company, my thoughts turned upon the perfectly waterproof roofs of railway carriages. I have travelled considerably on the railways of our own country, and yet I do not remember ever having noticed a leaky roof. I thought if these carriage roofs are so perfect, why not apply the same principle to hive-roofs? And so I got hold of a workman accustomed to this waterproofing, who has put me into the way of doing my own hive-roofs, and which I found very satisfactory. The roof is made of half-inch stuff planed, and the waterproofing is made of canvas bed on a paste consisting of white-lead, oil, and whiting. Before putting on the canvas, it is necessary to prepare the roof by giving it a thick coating of the paste made as follows:—Obtain some white paint mixed with oil only, just such as is used for outside work; to this add sufficient whiting to convert it when well mixed into a workable paste, which should be laid on with a brush. To stretch the canvas, get a lath A, which will screw to the whole length of the side, place the edge of the canvas between the lath and the side, and tighten the screws. The canvas must be pulled over the roof, but before it is fastened at B it must be thoroughly well rubbed on to the paste with a short piece of wood, such as a short ruler or rolling pin. This makes a perfect bed for the canvas, and is the secret of success in railway carriage roofs, which have to stand a deal of rough usage from hob-nailed boots of the porters when attending to the lamps. When this rubbing in is completed, it only remains to screw down the tightened canvas under the strip B, and treat the front and back similarly, cutting

off the frayed edges all round close to the strips. Two or three coats of ordinary paint over all will make a sound roof with a respectable appearance. As yet I have not found any difficulty in keeping out the wet at the fillets C C, and think possibly the reason is that they

are made thinner than 'Amateur Expert's,' and so the nails, or better light screws, have sufficient hold to counteract the little warping there may be. I do not find this description of roof inordinately heavy. There are no nails put through the canvas on the top. It is so bedded that it shows a perfectly even surface, and will not warp, as I have found the case with zinc when under a blazing sun. The slope may be made so slight that small articles may be placed upon the roof without falling off. The wood need not necessarily be very well seasoned, a point of importance to amateur hive makers. The gables are of simple form, and all is within the capabilities of a tolerably good amateur. I have enumerated the advantages, and on the other hand I must say that the cost in time and material will be something more than that of some ordinary roofs, but I do not think in the future these latter considerations will be sufficient to cause me to depart from my present style when I am increasing my stock of hives. I ought to say that ordinary flush joints are all that are necessary for the roof boards, and two small battens screwed to the middle of the under side makes all firm. Caution: Although the roof will stand a blazing sun, it will not bear the heat from a smoker in full blast, when the tin is actually on the canvas, so far zinc will have the advantage.—ROBIN, *Myrtle Villas, Hesthorpe, Doncaster.*

[50.] In reply to 'Amateur Expert,' (25), I think the hive I have been making for some time (for which I was awarded a certificate at the Derbyshire Bee-Keepers' Association Annual Show, 1885, for the best hive for winter and summer use) will meet the requirements mentioned. The roof-sides overhang the hive body, a plinth being fastened *inside* the lid to keep it in its place, the outer walls of the hive overlap the inside walls, so that they overhang the floor-board, and effectually prevent the entrance of rain.—DOUGLAS COOPER, *Spa Lane, Derby, Jan. 16th.*

[51.] I quite agree with 'Amateur Expert' from experience that the lid should overhang the hive-side without a plinth, and the hive-side should overhang the floor-board. If 'Amateur Expert' paints each roof with thick paint, and sprinkles fine river sand over it (by means of something like a pepper easter) while wet, and paints again after a few days I think he will succeed in keeping his hives dry.—W. MORONY, JUN.

[52.] Seeing the above is being discussed in the *Journal*, perhaps the way I make my hive-roofs waterproof may be of use to some of the readers of the *B. B. J.* I make the roof with about two inches of eaves, and then cut a piece of calico to fit it; soak the calico well in thin glue, and then stick it well on the roof; after it is dry give it two coats of paint, and then it will keep out any amount of rain or moisture, even after having passed the hottest summer. It is very cheap and looks neat, as

the glue keeps the calico well in its place. Roofs of caravans are covered the same way, and keep weather-proof for years.—H. ROWELL, JUN., *Odiham, Hants, Jan. 16th.*

[53.] I was much troubled by my hives letting in the rain until last year, when I tried 'Willesden' paper, two ply, to which I gave two coats of paint. Since then they have been quite dry. I also tack strips on the plinths if required.—A. W. S., *East Gloucestershire, January 15th.*

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[37.] *Comb and Extracted Honey.*—In point of weight for weight the average would be about one fourth more extracted than comb honey; but in running a hive for sectional honey a certain quantity of extracted honey must be taken.—W. B. WEBSTER.

[39.] *Winter Fighting.*—(E. P.) The idea that the bees endeavouring to enter one of your hives and being killed by the defenders of same were the same bees that you placed on a comb into a neighbouring hive is an error, as since the beginning of September we have had weeks of flying days on which they would have found their way back to their original hive; the solution to their fighting will no doubt be found to be that either one of your hives, or an neighbour's, have no stores; the calmness of the intruders is very noticeable during winter robbing.—W. B. WEBSTER.

[39.] *Winter Fighting.*—(E. P.) We never knew fighting, or robbing, to be carried on during the winter months. The dead bees are those aged bees which, as a matter of course, perish from senile decay, and are carried out of the hive. It is quite possible that the united bees may, even at this length of time, return to their former hive, when flight is possible, and their return would cause a little commotion, but no fighting to the extent you represent.—R.

[39.] *Winter Fighting.* (E. P.)—The probability is the bees you united in September being aged, have attempted to return to their old home. We once moved a beehouse, containing six skeps, four yards further south, in October; and though there were no other object in the garden larger than a cabbage, yet they flew over the house and hovered over the old site every fine day during that winter, and, of course, if there had been any hives there, they would have attempted to enter them. You would have been the gainer next summer if you had united them and wintered only three. We are more and more convinced of the uselessness of nursing weak stocks.—AMATEUR EXPERT.

[40.] *Spring Management.*—(J. K. Goodall.) It is quite impossible to lay down rules for future management to the extent of your forecast. All depends upon the weather, the fecundity of the various queens, the honey-flow, &c. These being favourable your plans may be successfully carried out, but in the actual working you will find that you are dependent upon circumstances. We think you will find that as many as *twenty* brood frames will not be required. Swarming may, or may not, be prevented. This again depends on the weather and other causes.

[40.]—*Spring Management.* (J. K. Goodall.)—If I were working my bees for section honey, I should not add a top-hive fitted with frames, &c., as you propose, not to speak of a third. Get your bees in good order by judicious stimulating against the first blossoms appear, then place on your tray of sections and increase the sections according to the amount of honey the bees are bringing in. It is impossible to answer your query as

you put it; you must make a study of each hive, no two will do alike, some will require more stimulating than others; all will require the minimum of manipulation, and probably, spite of all the care and experience any of us may bring to bear on any one particular hive, they will swarm in spite of us. Aptitude of resource is the chief factor in honey getting.—AMATEUR EXPERT.

[41.] *Rapid Mortality in a Wintering Stock.*—(Frank McDonogh.)—The dead bees thrown out are those that have died from old age; some stocks do not carry their dead very far from home, but simply throw them outside, especially in chilly weather, such no doubt is the case with yours; others on the contrary carry them away and drop them at a distance. Open the entrance to about three inches, which will be of service in ventilating the hive, and give the bees a better chance of clearing the dead away; half an inch opening is much too small.—W. B. WEBSTER.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[54.] *Moving Hives.*—As it is necessary for me to move several hives a few hundred yards, I shall be glad to hear whether the change may be safely made at this time of year at one move.—B.

[55.] *Finding Queen.*—By the exercise of what sense do bees find their queen when she is temporarily lost to them?—F. H.

[56.] *Feeding.*—I have some honey left from last season; would it be advisable to feed the bees with it this spring, and how to give it?—W. P.

Echoes from the Hives.

Hill Wootton, Warwick, January 9.—I like the plan you have adopted of selected queries for the subscribers to answer. I send you an answer to one, No. 3 Query: Upward ventilation is necessary where a crown board is used. Upward ventilation is unavoidable with some of my hives, the entrance being at the top, and bees winter well in them.—F. PERKINS.

Leigh, Tunbridge, January 11.—I have found the *Journal* very instructive, both for myself and my neighbours. Although I am only a novice of three years' experience, and not been able to attend lectures held here as others have, I am called upon for advice by old and young, some having kept bees thirty and forty years; for I love my bees and, therefore, take an interest in them, and they pay me for my little trouble—pleasure I call it.—JOHN HOUNSON.

Swaffham, Norfolk.—I intend again giving my mite to the good cause, and am pleased to be able to acknowledge that wise counsels have prevailed, and the Association has been doing of late years a good work indeed, the work for which it was professedly instituted, the instruction of the cottager, in the more excellent way. I am much gratified at the great success that has attended the endeavour to establish county Associations. My faith had hardly been large enough to anticipate so large a success.—D. W. PENNELL.

NOTICES TO CORRESPONDENTS & INQUIRERS.

COL.—1. *Making Section Racks.*—The description you send of your proposed make is not quite in accordance with our views, and is too small for convenience in extracting the filled sections and filling up with empty ones. You should leave sufficient room for separators, which you do not mention, and also for a board, with a pair of lock springs to insert behind the three rows of sections to keep them close together. Your dimensions seem not to agree. You say 4 $\frac{3}{4}$ deep and that a four-inch section resting on a $\frac{1}{4}$ inch lath comes flush with the top. We think you would expend a few shillings to advantage in buying a rack to copy. 2. *Candy.*—We prefer loaf sugar to Demerara. Instructions have been recently given in our columns, to which please refer. 3. *Pea Meal in conjunction with Dry Sugar.*—You can mix it with the sugar; do not overdo it, an ounce to a pound of sugar will be ample. 4. *Dark-coloured Foundation.*—If the reputation of the seller is such that you can rely upon its being pure, it would probably be as good as that of a better colour.

R. J. N.—Internal measurement of hive for standard frames 14 $\frac{1}{2}$ inches wide and 8 $\frac{3}{4}$ inches from upper side of floor-board to edge of wall on which the frames rest. Hints for amateur hive-makers have frequently appeared in our columns. We may shortly repeat them in a very plain and simple form.

JOHN BULL.—We should prefer the enamel cloth; but the sample sent would make a fair substitute.

J. GEORGE.—The dried pollen being removed from the combs, there would be little danger in using them again. If there should be any doubt as to the healthiness of the combs, use foundation.

J. BYLEY, *Bar.*—The Bligh Competition being now a matter of the past, it is not desirable to continue the controversy.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, w.c.

[No. 188. VOL. XIV.]

JANUARY 28, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee, held at 105 Jernyn Street, on Wednesday, January 20th. Present: Hon. and Rev. H. Bligh (in the chair), Rev. F. G. Jenyns, Rev. F. S. Slater; Captain Bush, Captain Campbell, J. M. Hooker, R. J. Hinton, H. Jonas, D. Stewart, G. Walker, W. O'B. Glennie (Treasurer), and the Secretary. Letters were read from the Rev. Dr. Bartrum and the Rev. George Raynor regretting their inability to be present.

The Balance-sheet for the year 1885, as audited by Mr. Kirchner, was submitted and approved. The Finance Committee recommended that the Association's Certificates, as awarded at shows, should be mounted on cardboard previous to being sent to the exhibitors. The leaflet, *Honey as Food*, was further considered and amended. The Secretary was instructed to procure estimates for printing the same, and to confer with the Finance Committee in reference thereto.

Quarterly Meeting of County Representatives held at 105 Jernyn Street, subsequently to the above meeting. Present:—C. H. Haynes (Worcestershire), Rev. W. E. Burkitt (Wilts), J. P. Sambels (Herts), Jesse Garratt (Kent), Mrs. Currey (Berks), Rev. E. Clay (Bucks).

The suggestions for the management of shows as prepared by the Committee of the B. B. K. A., were discussed and approved.

The mode by which exhibitors should be allowed to exhibit prize-cards won at previous shows was considered, the meeting being of opinion that such cards might be exhibited upon separate stands and upon such terms as local committees might decide.

Mrs. Currey (Berks) reported that she had been requested to suggest that in view of no annual metropolitan show being held, the B. B. K. A. should consider the advisability of extending the prize list of the Bee Department at the Royal Agricultural Show. It was resolved that this matter be discussed at the Annual General Meeting of the B. B. K. A.

Notice to Candidates who have gained 1st, 2nd, and 3rd Class Certificates during the Year 1885.

The Committee have resolved to provide a new form of Certificate. The same is in course of preparation. Candidates entitled thereto will receive them on the earliest possible date.

The members then resolved themselves into the Quarterly Conversation. Mr. W. O'B. Glennie was called to the chair.

The Chairman said he was glad that the last one or two quarterly meetings had resolved themselves into the form of *conversazioni*, at which several subjects were introduced and opinions ventilated thereon,

instead of one only being brought forward and discussed. The same rule would be observed on that occasion. Mr. Grimshaw had kindly consented to read a paper entitled 'The Identity of the Bee-sting with the Ovipositor of some other Insects.' An explanation of Mr. Green's 'Climax' hive would also be read: and should there be any time at their disposal afterwards he had in reserve a paper from Mr. Raynor, upon which they might found a discussion, 'On the Management of Bees in Winter.'

Mr. Grimshaw then proceeded to read his paper.—

ON THE IDENTITY OF THE BEE'S STING WITH THE OVIPOSITOR OF OTHER INSECTS.

I have often thought that in the ordering of things there was some seeming injustice done to the poor bee, in the fact that in the majority of instances it loses its life as a penalty for exercising that first law of nature, 'self-preservation,' or defence. There seems to be something wrong, some unfitness, in the unsuccessful attempt of the bee to remove its sting, which is left in the wound, and rends from the body of the insect a portion of its contents, the loss of which is fatal. Instead of the almost universal harmony in nature's 'adaptations of means to ends' here appears a discord. Then, again, if the sting were originally intended as a weapon of offence or defence, what has the poor, much-abused drone done that it should be denied one, open as it is to attack from man and beast within and without the hive? and why does not the queen use it, both genders being peculiarly stay-at-homes intrusted with the care and safety of the habitation? Why should the gift be confined to the female and the use of it by the female be death? Is it not that the sting is an organ which has fallen into disuse in consequence of the advance of some other organ co-equal with the growth of bee-intelligence, thus rendering its original 'occupation gone,' and that it is now in process of being adapted for a totally different purpose? The jaws of some insects become aborted and useless by having food prepared for them, and the wing-cases of others become united after generations of inaction; but if my hypothesis be correct, the honey-bee well justifies the assertion of a recent writer* as to its great proportionate brain-weight in comparison with other insects, by wisely using a useless ovipositor as a weapon of defence, until perhaps in course of time the sting-barb becomes aborted, and then disappears every objection to its being perfect for its requirements, used and withdrawn at pleasure, for attack or defence, prolonging, as it should, the existence of the bee and its race, instead of, as now, proving a suicidal act to use it. The intelligent use of the sting is shown by the care of the queen in searching for a suitably soft place, and time when to sting, during a queen-battle, and by the worker in its attempts to sting the eyes, nostrils, &c., and thus find the likeliest place from which the sting might be withdrawn. Sometimes, when examining a bee-sting under the microscope, I have failed by all means to find barbs and came to the conclusion that they were either abnormally absent or rested flat on the dart as the barb does on a harpoon, only coming into play on attempted withdrawal.

* Cheshire, *Bee-keeping*.

If we examine the ovipositor of the Ichneumon, *Pimpla manifestator*, we find its three-inch-long sides enclosing a boring instrument having seven or eight tooth-like processes on each side.*

The Gall-fly (*Cynips*) makes a hole in the plant before depositing in it an egg, by means of a horny ovipositor much longer than the body of the insect, of a chestnut colour, which issues from a sheath. We are told † that the female gall-fly 'ejects into the cavity a drop of her corroding liquor, and immediately lays an egg or more there; the circulation of the sap being thus interrupted, and thrown by the poison into a fermentation that burns the contiguous parts.' Kirby and Spence ‡ tell us the parent fly introduces her egg into a puncture made by her curious spiral sting. They also say (page 64) that 'the tremendous arms with which the Hymenoptera annoy us are two darts, finer than a hair, furnished on their outer side at the end with several barbs not visible to the naked eye, and each moving in the groove of a strong, and often curved, sheath, frequently mistaken for a sting; which, when the darts enter the flesh, usually injects a drop of subtle venom, furnished from a peculiar vessel in which it is secreted.' The writer was twice stung by an Ichneumon, and once by the *Pimpla manifestator*. Here we have saw-using insects converting the weapon into machines of offence; and it is not perhaps assuming too much if we assert that insects such as bees, provided with tools now used as stings, have in times past used these double saws in the process of ovipositing, and that this latter is indeed their proper office and function.

Let us look now at the *Cicada* (the tree-hoppers), to which the cuckoo-spit insect is allied. The male insect (like the drone-bee) is devoid of a cutting implement, this in the female (as in the female bee) is lodged (according to Réaumur§) in a sheath which lies in a groove of the terminating ring of the belly. A slight pressure causes it to protrude in both cases. In both cases the sides are finely indented with teeth. In the tree-hopper the barbs are nine in number on each side, in the bee they are variable in number. In both cases the three pieces (saws and a groove) are so united that the two saws or files can be easily put in motion, advancing alternately. In a quotation from *Insect Architecture* we read as follows:—

'In order to see the ovipositor a female saw-fly must be taken and her belly gently pressed, when a narrow slit will be observed to open at some distance from the anus, and a short, pointed, and somewhat curved body, of a brown colour and horny substance, will be protruded¶ (page 153). 'The curved plates which form the sides of the slit, are the termination of the sheath, in which the instrument lies concealed till it is wanted by the insect. The instrument thus brought into view is a very finely contrived saw, made of horn, and adapted for penetrating branches and other parts of plants, where the eggs are to be deposited.'

Is not this an almost accurate description of the sting of a queen-bee? Further on we read (page 156),

'When the female saw-fly has rendered the groove as large as she wishes, the motion of the tendons ceases and an egg is placed in the cavity. The saw is then withdrawn into the sheath for about two-thirds of its length, and at the same moment a sort of frothy liquid, similar to a lather made with soap, is dropped over the egg, either for the purpose of gluing it in its place or sheathing it from the action of the juices of the tree.'

Surely I might be reading an account of the queen-bee engaged in laying, substituting the words that the cell is ready made for her, and rendering the saw-like sting useless except for the purpose of exuding a drop of adhesive or protective liquid, which attaches the egg to the bottom of the cell. Let us now look amongst bees themselves for such gradations in intelligence as will guide us to the inference that the sting of the honey-bee (at the head of the family) is only a tool or instrument fallen into desuetude in countless generations and in process of adaptation to other purposes.

We have solitary bees in opposition to social bees; some eating their food as they get it as opposed to those which lay up stores which will enable them to survive through

winter. Bees building in holes excavated in bricks, making nests of clay, sand, earth, moss, wood, wool, leaves, petals of flowers; in holes in the ground, stone-heaps, posts and rails, on walls, or window corners, in ready-made holes in trees or rocks, or easily excavated out of soft decaying wood. Against and ahead of all these is the orderly social honey-bee with forethought, almost amounting to reason, which utilises its exudations of fat in building geometrically accurate cells, requiring neither the strong jaws of the mason bees for manipulation into cells or nests of cells, nor the saws of the saw-fly for cutting out apertures in which to deposit its eggs. The carpenter bee labours hard with its two sharp teeth in wood-chiselling and cements over her excavation with a preparation of sawdust; the mason cements grains of sand together; the mining bee digs a tubular cell in the ground; leaf-cutters form cell after cell of leaves or bark and ties them together with silk; and another (*Authidium manicatum*) will not even go to this trouble, though its mandibles are as strong as the masons or carpenters, for it, according to Kirby and Spence, makes choice of the cavities of old trees, keyholes, and similar localities, but will sometimes scoop out a cavity when it cannot find one.

We have, then, at the head of this list our own honey bee, which will have its nest ready made, and expends its intelligence in other directions. At the foot of the list, through various grades of 'cuteness, is a wasp gnawing a nest out of a hard brick (page 26). We have grades from simple bags or cells to beautiful hexagonal combs, and also grades from solitary life to a community of many thousands. If I cannot show similar degrees of bees using saws at one end, to those using jaws at the other extreme, I have shown Hymenoptera (Ichneumon) using saws as stings, stings ejecting poison; and I have also shown Hymenoptera (bees) possessed of stings, which have all the characteristics of saw-using insects,—stings with barbs moveable on alternate sides on a groove; and I lay it before you, as a reasonable inference, that their primary *raison d'être* was as nest-cutting implements. If as weapons, why not found in males, and why accompanied by the penalty of death in the females? Why are there races of stingless bees more populous than our hive-bees (page 144), as discovered by Clavigero in Mexico, and as found in the island of Guadaloupe? (page 143). Is it not a fair assumption that the secretion of wax renders unnecessary the use of the sawlike ovipositor, the sting, and that, in the imperfect female the worker, formic acid, not being in regular requisition during egg-laying, oozes out of the ovipositor on the least use of it in stinging? The perfect insects only of the hive have not the sting as we know it. The queen only uses it in a combat with another; she will neither attack others nor defend herself from enemies, and the drone can do neither, yet both together reproduce their kind exactly, a proof of their completeness. The sting-bearer, as we know it, is imperfect, not reproducing its kind, except under such abnormal conditions as feeding in the grub state on a small quantity of royal food, which imparts to it the power of laying drone-eggs. If the other condition of becoming perfect were granted it, the larger cell, doubtless the generative organs would be developed, and a perfect queen would result, with the curved ovipositing implement of the saw-fly, from which exudes the drop of protective adhesive substance which fastens the end of the bee-egg to the cell-base.*

The Chairman thanked Mr. Grimshaw for his paper, and said he could bear out the statement of that gentleman with regard to the saw-cutting instruments found in the hymenoptera and other insects. He had studied the subject under the microscope, and very recently had been engaged in taking notes of the cutting instruments of the saw-fly and others in company with a member of the Microscopical Society.

* The identity of the bee-sting to ovipositor of other insects was the subject of a work by Hermann Dewitz, published in 1874, entitled *Vergleichende Untersuchungen über Bau und Entwicklung des Stachels der Honigbiene und der Legeschilde der grünen Heuschrecke*, in which he traces the development of the organ from the larva to the perfect insect.—Ed.

* *Insect Transf.*, C. Knight, Publisher, 1830.

† *Spectacle de la Nature*, I., 119.

‡ *Introd.* II., 119.

§ *Insect Architecture*, page 118.

Mr. Garratt expressed his indebtedness to Mr. Grimshaw, but as no notice had been given of the subject he felt unable to discuss it. At first sight the matter appeared to be one more fitted for the consideration of a Physiological Society than of the Association, but when they had the opportunity of reading the paper in the columns of the *Journal* the writer's remarks would be closely examined, and would receive the attention they deserved. Mr. Grimshaw appeared to have taken it for granted that fertile workers were developed in greater degree than ordinary workers owing to their having partaken of the royal food. That was not a new idea, but he looked upon it as only a suggestion and not an established fact.

Mr. Stewart thought that the bee-sting was an instrument so thoroughly adapted for the use to which it was put that it could hardly be taken as an afterthought of the Creator. Although there were stingless bees, these existed under conditions where self-defence was not necessary. The sting was not required for the purpose of depositing at all. The propagation of the species was sufficiently provided for by the egg-laying power of the queen. He thought there was no ground for finding fault with Nature in this instance. The queen carried on family affairs with the assistance of the drones, whilst the others worked for the home and protected it with their stings. The subject should be considered a great deal before they accepted the theory set up by Mr. Grimshaw.

Mr. Baldwin said that if the sting of the bee was absolutely necessary for the defence of the colony, how unfortunate it was that the insect lost its life in such work.

Mr. Grimshaw said, in answer to Mr. Garratt's objection, that he only suggested it was a fair inference that a fertile worker was produced from an ordinary worker by partaking of small portions of royal food dropped into the cells over which bees passed in feeding the queen grub, seeing that it was generally admitted the queen herself was developed by feeding on royal jelly. But that consideration did not touch the position he had taken up. He had no desire to find fault with Nature; on the contrary, he looked on with admiration at the constant development going on in the insect world in common with all animal life adapting itself to circumstances. He, however, considered the sting a most imperfect as well as an unjust and cruel instrument, because it could not be withdrawn from the wound it inflicted, and because, instead of preserving the life of the insect using it, it caused death. It seemed to him that the sting was resorted to because it was the best weapon at hand when the bee found itself attacked. Again, he suggested that there was a fault somewhere, because the queen did not defend her hive or offspring, and that the drones, who always stayed at home and were peculiarly fitted as defenders of the hive, were unprovided with this means of repelling attack. He thought that if the Almighty had endowed the bee with its sting as they knew it, it would have been perfect as well as common to all bees alike.

Mr. Stewart saw nothing remarkable in the bee dying after having used its sting. It was like the soldier who went forth to battle and lost his life.

Mr. Grimshaw demurred to the analogy, because every soldier did not lose his life in battle.

Mr. Zehetmayr and Mr. Baldwin thought that the bee's greatest enemy was its own kind, and that when a bee stung one of its own species it did not lose its life.

Mr. Hooker said they had evidence of this in the case of two queens fighting: in reference to which Mr. Baldwin remarked that the queen's sting was most imperfect.

Mr. Grimshaw had seen stings with no barbs on whatever,

Mr. Sambels did not think that bees made choice of soft places to insert their stings. He knew they would sting clothing, and he had seen Eastern bees charge posts, hive-stands, and in fact anything that obstructed them. They would sting on any part of the body, and, he would say, showed no preference for one particular spot.

Mr. Grimshaw suggested that perhaps the reason of that was that the inhabitants of the countries whence the foreign bees came were not so well clothed as the people in England, and the bees were not accustomed to seek vulnerable places. (Laughter.)

Mr. Stewart thought that the cause of the bee stinging the bare flesh, especially near the eyes, was due to the fact that immediately one felt the insect alight there panic ensued, and the slightest disturbance irritated and frightened the bee, which at once endeavoured to defend itself.

Mr. Garratt said that the habit of the bees in turning out the drones at a certain time of the year seemed quite unique. The honey-bee formed large colonies, and was thus different generally from most other kinds of bees. The labouring bee seemed to have a superior power given it by which it rid itself of that encumbrance which was altogether unnecessary for the benefit of the colony.

Mr. Blow, in speaking of worker-bees stinging others and losing their lives, said, with regard to ordinary English bees, that several days were occupied by them in turning out their drones, which they did not sting to death, but gnawed their wings, whilst in the case of Eastern bees the drones were all turned out in one day and all killed by stinging. He had examined almost a peck of drones in front of a hive of Eastern bees, and not found a single worker dead amongst them.

Mr. Grimshaw, Mr. Hooker, Mr. Stewart, Mr. Sambels, Mr. Baldwin, and Mr. Zehetmayr, continued the discussion, the majority of speakers taking an adverse view of Mr. Grimshaw's theory. Mr. Stewart pointed out, in reference to the fact which Mr. Grimshaw seemed to attach so much importance to, namely, that the drones who remained at home, and ought therefore to be the natural defenders of the hive, were stingless, that naturalists had been unable to determine the precise functions of the drones in the hive. It was quite certain that they had other duties besides helping to rear the families, but what these were no one knew at present. He hoped Mr. Grimshaw would not think he had criticised the paper in a hostile spirit, than which nothing was further from his mind.

[We are obliged to postpone to a future number Mr. Green's paper on the 'Climax' hive, and the subsequent discussions.—Ed.]

HARRISON'S REVERSIBLE REMOVEABLE METAL ENDS.

We are pleased to note that so much study and attention are being bestowed on the new feature in bee-keeping, namely, reversible frames. From those which have recently been brought before our notice, we are inclined to think that the plan of the inner revolving frame is being dispensed with, which in a hive, say, of ten frames, as we intimated in page 383, Vol. XIII., would involve a loss of 5250 worker cells, and that an endeavour is now being made to utilise the whole of the space in the frame for the service of the bees. The various contrivances of ends for reversing frames have been very ingenious and clever, and that put forward by Mr. Harrison has a good claim on the bee-keeper's consideration. His plan is very simple, and utilises his metal ends. The ends of the frames are cut off, and the reversible removeable metal ends take their place. They are secured in their position by a single pin being pressed, not through the wood, but under the corner of the

frame. The pin being removed, there would be no difficulty in changing the position of the ends or frames. Used only as removable ends, they would prove serviceable to bee-keepers having shallow extractors.

HOLLANDS' CONVEYING AND INTRODUCING CAGE.

We have recently given an illustration of Mr. Frank Benton's admirable and ingenious cage for mailing queens from foreign parts. Mr. Hollands, of Waddon, Croydon, combines this with an introducing cage. The cage, which is one of Mr. F. Cheshire's clever and practical contrivances, is fitted in a block on Mr. Benton's plan of two chambers, one with ventilation and one without. In the lower compartment a tin tube is used for the reception of the candy, so that the wood should not absorb the moisture from it. With each queen sent out Mr. Hollands includes one of these combination cages. It is a very safe and secure mode of transmitting queens. Mr. Cheshire's introducing cage gives great freedom and comfort during introduction, is easy of application, does not damage the comb, and is perfectly safe.

ASSOCIATIONS.

KENT BEE-KEEPERS' ASSOCIATION.

The annual general meeting of the Association was, by the courtesy of the Royal Society for the Prevention of Cruelty to Animals, held, as on several previous occasions, at 105 Jermyn Street, St. James's, on Wednesday, the 13th January, at five o'clock in the afternoon. The Rev. Andrew Welch, vicar of St. Mary Cray, and Chairman of the Council for the past year, occupied the Chair. The Report of the Council and Balance Sheet for the year 1885 were read. The Chairman, in moving that they should be received and adopted, adverted briefly to the chief topics of interest referred to therein, and congratulated the meeting that the financial condition of the Association showed a decided improvement upon that of the previous year. Mention was made that Mr. Garratt had determined to relinquish the post which he had long held of Secretary of the Association, and the hope was expressed that in Mr. Waters an able successor to this important office had been found.

The adoption of the Report and Balance Sheet, together with a vote of thanks to Mr. C. Darrell for his kindness in auditing the accounts, was unanimously agreed to. The customary votes of thanks to the retiring officers, the council, and local Honorary Secretaries for their services during the past year, were duly and cordially given. The thanks of the meeting were also given to the Royal Society for the Prevention of Cruelty to Animals for their repeated kindness in granting the use of their Board Room for the occasion. The election of President, Vice-Presidents, Council, Treasurer, and Secretary for the ensuing year, and the appointment of representatives of the Association to the Quarterly Conference of the British Bee-keepers' Association, were formally carried out. The drawing on behalf of cottagers for two hives resulted in favour of Mr. R. Filmer, of Ruckinge, near Ashford, and Mr. W. Campany, of Hawkhurst.

I have to thank you for the kind assistance which you have given to our Association in its search for a Secretary by notifying the want in the pages of the *Journal*: and I have much pleasure in informing you that, owing to such notice, we have secured the services of a gentleman who is well qualified to carry on the work in our county. Mr. E. C. Waters, of Chislehurst, the able

Secretary of the West Kent Horticultural Society, is the gentleman referred to, and his appointment having been approved by the General Meeting of the Association on the 13th inst., he is now *de facto* Secretary of the Association.—J. GARRATT.

CORNWALL BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held at the Town Hall, Truro, on Wednesday, January 13. President, Rev. W. Rogers, in the Chair, Rev. A. R. Tomlinson, Rev. C. R. Sowell, Mrs. Polwhele, Mrs. Tomlinson, Messrs. T. R. Polwhele, G. H. Chilcott, J. W. Harrison, T. Treleven, J. Harris, G. Gradidge, G. E. George, and C. Kent.

The committee, in their Report, congratulated the members upon having passed a very successful year. At the close of 1884 the Association was 48*l.* 18*s.* 10*d.* in debt. This has now been reduced to 17*l.* 18*s.* 6*d.* The members now number 160, with annual subscriptions amounting to 46*l.* 3*s.* The total income during the past year was 82*l.* 0*s.* 4*d.*, and the expenditure 81*l.* 7*s.* 3*d.*, leaving a balance of 1*l.* 13*s.* 1*d.* in the bank. During the year the Committee completed the purchase of the bee-tent, and, with one exception, had paid off the prizes outstanding from the Truro Show in 1884. The past season had been most favourable for bee-keepers, and a very large quantity of honey was produced in Cornwall. A good deal of this was disposed of beyond the limits of the county, but the larger portion was sold in small quantities to retail purchasers.

On the motion of the Rev. A. R. Tomlinson, seconded by Mr. George, the Report was adopted.

The Earl of Mount Edgumbe was re-elected president, and the following as vice-presidents:—Hon. and Rev. J. T. Boscawen, Mrs. Digby Collins, Mr. T. Martin, Lord Robartes, Sir John St. Aubyn, M.P., and the Earl of St. Germans. The Committee are as follows:—Messrs. A. Bailey, Liskeard; W. K. Baker, Towdnack; J. Branwell, jun., Penzance; G. H. Chilcott, Truro; G. Dixon, Truro; G. H. Fox, Falmouth; G. Gradidge, Truro; G. E. George, Probus; Rev. J. Kempe, St. Breward; Messrs. H. B. Neame, Portreath; W. Prockter, Launceston; T. R. Polwhele, Polwhele, Truro; Mrs. Polwhele, Polwhele, Truro; Rev. W. Rogers, Mawnan; Mr. J. Rowse, St. Agnes; Rev. C. R. Sowell, St. Gorran; Mrs. Tom, Rosedale, Truro; Rev. A. R. Tomlinson, St. Michael Penkivel; Messrs. J. W. Wilkinson, Perranarworthal; J. Williams, Scorrion House, Scorrion; T. Treleven, Creed; W. Nicholl, Helland; and J. W. Harrison, Tregony. Mr. A. P. Nix was re-elected treasurer, and Mr. C. Kent secretary.

Votes of thanks to the Chairman, and to the Mayor for the use of the room, terminated the proceedings.

OXFORD BEE-KEEPERS' ASSOCIATION.

The annual meeting of the above Association was held at the Clarendon Hotel, Oxford, on Saturday, January 14th, under the presidency of the Rev. D. Thomas (Garsington). There were also present G. Herbert Morrell, Esq., the Rev. F. C. Dillon (hon. secretary, Eastone), the Rev. W. Neame (Forest Hill), the Rev. F. Sturges (Filkins), Mrs. Neville, and Messrs. Penny, Tite, Salmon, Crute, C. Harris, Grant, &c.

The report stated that the number of members showed a slight increase, and that the deficiency with which the year began had been wiped out. The annual show had been held in the gardens of Wadham College, in connexion with the Royal Horticultural Society, on July 31st, and drew large numbers of visitors to see the exhibits. The bee-tent had been erected at eleven different places with varying results, and a very satisfactory report was given of the visits of the expert during his spring and autumn tours.

The President (Lord Jersey) and the vice-presidents were re-elected, Mrs. Baskerville's name being added to the list.

The Hon. Secretary (Rev. F. Dillon) said he was sorry that he was obliged to resign his office. But afterwards at the earnest solicitation of those present, he consented to reconsider his decision and continue in office for another year.

It was agreed to elect a secretary for each deanery, and the following were elected:—The Rev. F. Sturges (Witney Deanery), the Rev. W. Neame (Islip), the Rev. D. Thomas (Cuddesdon), Mr. W. C. Hayes (Chipping Norton), Mr. C. Harris (Oxford), Mr. G. Harris (Bicester). It was decided that the preceding be *ex officio* members of the committee, which is composed as follows:—G. Herbert Morrell, Esq. (High Sheriff), Dr. Boyton (Watlington), Messrs. Salmon, C. Taylor, Crute, W. Grant, and Penny.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The general annual meeting of the members of this Association will be held on the last Saturday in January (Jan. 30th) at 2.30 p.m. at the Old Town Hall, Leicester.

Selected Query.

[57].—*What do you consider the best food for wintering bees upon?*

I prefer honey gathered in the natural way and sealed. But as it pays to extract the honey and give other food, I place next in order syrup made from refined sugar and water. I usually add a small quantity of solution of salicylic acid in alcohol as an anti-ferment. Some samples of sugar are so prone to crystallise when made into syrup, that it is necessary to add a small portion of cream of tartar to 'kill the grain,' as confectioners term it; but I do not like any chemicals if I can do without them. I place the greatest importance upon the food, whether honey or syrup, being sealed by the bees before going into winter quarters. If from any reason I find stocks insufficiently provisioned, when it is too late to feed with syrup, I prefer the old-fashioned deliquescent barley-sugar given in a float feeder to the modern candy. If I do use candy I remove the syrup from the fire at an earlier stage than recommended in books, and so obtain a softish cake consisting of very minute crystals, and I only give a small cake (two or three ounces) on the top of the frames at a time; replacing as consumed.—F. LYON.

Their own honey is undoubtedly the best food for wintering bees upon; but failing this, I prefer syrup made from the best loaf sugar. Artificial food should be given so that it can be stored and SEALED. All *hand-to-mouth* feeding should be avoided, and only resorted to when previous neglect has induced starvation. [I have ceased to believe in 'spring-stimulating,' and have found those bees to do best, which have had a large store of honey left for winter and spring use, with plenty of room for the natural expanding of brood.]—J. LINGEN SEAGER.

The best food for wintering bees upon is syrup made with loaf sugar, and boiled for five minutes with half of its weight of water, say ten pounds of sugar to five pounds of water (or two quarts). The honey should all be extracted by the beginning of September, and the bees immediately fed up to the right weight.—WILLIAM CARR.

I have not noticed that it makes much difference whether bees are wintered upon honey or syrup; but the stores should certainly be of one or the other and sealed. I have wintered a great number of colonies every year entirely on syrup, and with the best results;

but I should prefer the stores to be honey of good quality.—C. N. WHITE.

Syrup made from the best loaf-sugar. The way to prepare it will be found fully described in *Modern Bee-keeping*, published by the British Bee-keepers' Association.—JOHN M. HOOKER.

The honey gathered by the bees themselves with the exception of that from honey-dew and heather. Of the substitutes I considered syrup, made from white loaf sugar in the usual way, by far the best.—F. ZEHETMAYR.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal,"' c/o Messrs. Strauchmans and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

NOTES FROM THE SOUTH OF IRELAND.

[58.] My experience this autumn is, that the bees travelled considerable distances to the heather, as I found hives in my garden storing heather honey as long as the blossom lasted, for which they must have travelled a long way, three and four miles, as the patches of heather close at hand coming early into bloom were almost exhausted before the mountain heather was fairly in its glory. I have nine stocks comfortably packed for the winter. They are in eight cottage-hives and one Combination, with nine standard frames in each. They are wintered on five, six, and seven frames according to circumstances. As under very adverse conditions I brought my colonies through last winter with great success, it may be useful to say that each hive has a roughly-made outside cover, fitting loosely over the ordinary cover. It is made of thin unplanned woodpainted, and I found a 'handy-man,' glad to make and paint them for 1s. each. I supplied the materials, the wood, odds and ends of timber, and old packing-cases. On the roof of each I put three-pence worth of tarred felt, and for the protection they give against cold and damp I think they are well worth the small cost. With care they ought to last ten years or so. As I have a good many bee-keeping neighbours who starve their bees; I find my well-stored hives a mark for robbers, and am obliged to keep my entrances very much contracted during this mild weather; so, as I did not wish to cheek ventilation, I used strips of perforated zinc to contract the entrances, slipping it behind the sliding doors to steady it. With the exception of one week's frost and some cold days, this has been a very favourable autumn and winter for bees. Warm muggy days, letting the bees fly in such numbers that one half forgets it is December. The ivy bloom is not long over, and now the furze is beginning to bloom. It is easy here, if one has only experience and luck, to get hives strong in bees early in the season. Of course, weather has something to do with the matter also; but we seldom see snow, except on the mountains, and have little frost of the severe and enduring kind after the first of January. The masses of furze that come into bloom so early on our sunny sheltered banks, and the quantities of early pollen-yielding flowers and shrubs, are a great inducement to early brood-raising. I have often tried to get my bees to look at artificial pollen, but they utterly scorn the attention, feeling, I suppose, no need of it. I have to thank you extremely for your most valuable instructions about inverted skeps, and I trust I may have later on to announce that we have acted on them successfully.—IRISH NOVICE.

FIXING COMB-FOUNDATION.

[59.] As the plan adopted by me last season for fixing comb-foundation in bar-frames, appears to differ from anything I have seen noted in the *Bee Journal*, I beg leave to lay it before your readers. I have the top bar made in two pieces of equal width, one piece of which is firmly nailed to the sides, also one end of the second half, leaving the opposite end free; now if the frame is stood on a bench holding the loose end in the left hand, the comb can be introduced from underneath, tighten and nail down, when the comb will be found secure. I have been led to adopt the above plan through finding saw-cuts as usually made both troublesome and insecure. It will be seen from the above that the comb can with ease be fixed flush with the top bar, thus leaving no crevices for wax-moth to deposit. Perhaps some of your readers may think that by having the top bar in two pieces is a weakness; but I can assure them, that although I have used whole sheets of foundation in the above-mentioned frames,—I have not had a breakdown.—J. SHRIMPTON.

DRIVING BEES.

[60.] I have never seen any description of driving bees and carrying them home same as I have done it. If you think it would be of interest you might insert it. Herring boxes are very cheap. I have procured some for driving bees into them from skeps. Cover them with a piece of coarse material. I got a piece of hoop-iron and bend it in this shape. As you will observe a small box will fit in at the top while the hook will hang on one side of the skep and so drive the bees into it.

I leave an opening of two or three inches at one side of the covering which is fastened to a frame to open or shut. This can be fastened up while driving the bees into it by means of a peg on one side of the box. The hoop-iron frame as above is strapped to the hive or skep as tight as you can strap it, which fastens the box very tight, so it is in no danger of moving with the strap. I fasten all the boxes together to carry home. I have driven about forty skeps in this way last season. One might carry as many as a dozen on your shoulder home, as these kind of boxes are very light.—F. G. AYLING, *Privett, Alton, Hants.*

MY EXPERIENCE OF BUMPING.

[61.] With your permission I desire to give my experience of bumping and driving in 1884 and 1885. At the end of October, 1884, I had four lots of bees offered me. I did not hear of them till midday, but was unable to go before evening. They had to be taken that day or killed, so I was obliged to have them out sharp. Following Mr. Lyon's directions to the letter, I got the bees all out in fifteen minutes, but was obliged to bring them away in their own skeps, as it was too dark to put them into others. I did not think that bad for a first attempt. I had driven several lots before in from ten to twenty minutes each. This year I have bumped nearly twenty, all without stopping entrances, as I did those I took in the evening.

One hive took me five minutes without a single sting. Three (with a friend to help in taking combs, as I brushed bees off, uniting two, and packing up,) occupied thirty minutes. One matter I noticed about these last, numbers of them buried themselves in their cells, they preferred to be brushed asunder with a goose-wing than come out; yet they were extremely quiet, and I was not stung. A lot of five (with help) took me about thirty minutes to get out. A lot of six, forty-five minutes, uniting into three lots in my own skeps and packing up without any help. These were all done in September.

One lot I had great difficulty with in August. A cast that came out in June, and put into a large skep which was crammed with honey, bees, and brood in three centre combs. The weather being warm and the combs very tender, they broke to pieces when taking them out. I learnt more by that one than I did by all the rest. I received about thirty stings, and also learnt never to bump in August, as it is generally very warm and there is a quantity of brood, unless you are sure there is no brood. I have had no difficulty in September, when there is scarcely any brood and the weather cooler.

I have driven several lots besides, two skeps with foul brood.

I find when once the skeps are bumped on the ground it does not do to stand and look at them, or to think of a few stings, but lose no time and out with the combs sharp.

I heard one man say before he could get combs out the bees were up all over the top, and he preferred driving; but for my part I am very much in favour of bumping.—JOHN HOUNSON, *Leigh, Timbridge.*

A FEW WORDS ABOUT BEES AND THE PROFITS TO BE MADE FROM THEM.

[62.] There are very many cottagers who do not know that three good stocks of bees may be made to pay as well as a pig and with far less trouble and outlay. Wishing to try thoroughly myself if it really was true that such a large supply of honey could be obtained from bar-hives as often stated, I started with fourteen stocks, thirteen of which had to be transferred into bar-hives of standard size, and one I left in its skep. Eight of the hives were Abbott's large Irish hives, two their twin hives, one a Cottage hive, and two of Hole's hives taking ten bars; and I took from them over 700 lbs. of honey, including that from the swarms, as well as 4 lbs. of wax. The early honey harvest from fruit blossoms failed owing to bad weather, and it was not till the middle of June that the bees began to store the honey well; again in August there was some bad weather. This would, therefore, be a fair year to take for an experiment of the kind. Five hives lost their queens at the end of June and beginning of July, and had to be requeened; four swarmed, one swarm being lost. It will be seen the average yield was 50 lbs. of honey per hive, which sold at 7d. the pound would give 1l. 9s. 2d., and out of every three hives one swarm might be expected, making the profits stand thus:

150 lbs. honey at 7d.	£4 7 6
1 lb. wax	0 1 6
1 swarm.....	0 15 0
	£5 4 0

I had besides more than two dozen worked-out combs and a good many sections, which would also add about 2s. per hive to the profits.

A cottager wishing to start bees (women can manage them quite well) would not most likely want to buy three stocks at once, it would cost too much; so this is, I think, the best way to begin. In autumn many stocks in skeps can be bought for 15s. or 12s., or in spring a swarm always; and very often a good stock can be bought for 15s. He must buy enough wood, which would cost about a shilling, and a box about 21 or 24 inches long and 19 or 20 inches wide, 8 $\frac{3}{4}$ or 9 inches deep, at 1s. or 1s. 6d., and make a double-walled hive to take Standard or Association bars. The details of hive-making are so often given, I will not go further into them except to say there are very few neighbourhoods where a cottager cannot find some one ready to show him a good bar-hive and how it is made, if he really wants to know. Then when spring comes he can transfer an old stock into it in the way described in all bee books, or put a swarm in on six sheets of foundation, giving more as that is

worked out. In the autumn, if all has gone well, he will have taken some honey, learnt the management of a bar-hive, and have five or six worked-out bars of combs beyond what his first stock requires to winter on. If he makes two more hives and divides these combs between them, making up each to six bars, with foundation, in the end of September, any neighbour with skeps will be putting them down, and would give him or sell him the bees for 1s. a hive if he could either drive or get them driven.

Putting two or three of such lots into each of his new hives, and feeding for two or three weeks, he would have three good stocks at a small cost. I took seven such lots, and put them on two bars of comb, two and three of foundation in the middle of August, and have five good stocks from them. If the first hive was a stock—not a swarm—its owner will most likely have taken 50 lbs. of honey, or have a swarm and some honey; either way it will cover the first outlay thus:

	£ s. d.
50 lbs. honey at 7d.....	1 9 2
Or swarm	0 15 0
25 lbs. honey.....	0 11 7

£2 18 9

OUTLAY.

	£ s. d.
Three boxes at 1s. 6d.....	0 4 6
Extra wood	0 3 0
Nails	0 1 0
1½ dozen bars in piece at 2s. 6d.	0 3 3
1½ lbs. foundation at 2s. 6d.	0 3 3
Two feeders at 1s. 6d.	0 3 0
40 lbs. sugar at 2½d.	0 8 4
Material for quilts	0 1 6

£1 7 10

STOCK ON HAND.

	£ s. d.
Three hives value 4s. 6d.	0 13 6
Three stocks and combs at 15s.....	2 5 0
Two feeders	0 3 0

£3 1 6

I have priced the honey low, as though some may sell for 9d. some will only fetch 6d.—M. E. E., *Shropshire*.

RIPENESS OF HONEY.

[63.] The quick recurrence of numbers in the new series will, I fear, find those who have many some things else to think of besides bee-keeping sadly in the lurch. But it may not be too late to express the reflection that after all that has been written there is still much to be learned by the fraternity. I am not surprised at the statement that quickly gathered super honey is sometimes found to be unripe, as speedy fermentation indicates. Very likely I could find some myself at the present time in a doubtful condition, though it is well if it stands till this date; but I must confess my wonder at any sealed stores in the hot body hive not standing the test.

There is, then, honey and honey, leaving adulteration, that 'form of competition,' out of the question. But I must add that the granulated honey I have written about did *not* ferment, and I do not think will do so while any other keeps good, so that we must have a test of unripeness far short of fermentation. Of course I accept the dictum of the Editor of the *B. B. J.* to the utmost extent I can. If he is not an authority, who is? and have I not asked his opinion? But has he not a battle to fight over this subject with some of his friends? The new 'Selected Query' system ought to be a most valuable one, and No. 3 is, 'What is the best plan for ripening honey?' Our cottagers are producing great quantities; they want to sell; and if there is any reality about the professions of our Associations they are entitled to prime consideration.

I am going to pass on my *Journal* to two of them, and, poor creatures! what will they make out of the replies to this question? First they will be concerned lest this year their honey should be unripe. Then happily they will see that it may be ripened, but at what a cost of money and labour! They must have a warm room for storage, and are recommended, even when honey is three quarters sealed over, to use galvanised cylinders, paraffine stoves, treacle valves, and what not—no, stay, Mr. Zehetmayr says if the honey is extracted when the bees are only beginning to cover the cells no artificial ripening is needed, and that great authority Mr. Raynor curtly says, 'Leave it in the hive till the bees have sealed it.' 'Who shall decide when doctors disagree?'—SOUTH CORNWALL, *January 13.*

[We feel convinced that our cottagers will continue to leave the honey in the hives until it is ripened and capped by the bees, and they will act wisely in so doing. Our friend may therefore safely send on his *Journals*. Although sealed honey, in an abundant honey-flow, will occasionally granulate, it is rarely the case. Until apiculture shall have arrived at a much greater state of perfection than at present,—indeed, we had almost said, until human nature becomes perfect,—there will always be difference of opinion, even amongst experts (or doctors, if our correspondent will have it so). We need scarcely remind him of the trite saying, '*Quot homines tot sententia*.' However, we think there is a very general agreement amongst the 'doctors' in apiculture as to the superior aroma and flavour of honey ripened and sealed in the hive over that scientifically ripened by the human subject. By many apiculturists *quantity* is placed before *quality*, and such will continue to extract, and artificially to ripen the unsealed honey.—Ed.]

DRYNESS OF HIVES.

[64.] Like 'Amateur Expert,' and many other bee-keepers, I have suffered from dampness in hives, caused by the rain and snow driving in through any crevice made by the sun during a hot summer, more particularly in hives on which fillets are used, on which the snow lodges, and, when a thaw comes, soaks through and causes irreparable damage to the stock. In making new hives I therefore now use wood eleven inches wide, leaving half-an-inch projecting below the floor-board, which I make immovable. The roof, which is made of wood ½ in. thick, overlaps the body of the hive, but instead of being made immovable by the use of ordinary hinges, two pieces of iron are used of the shape seen at Fig. 1, which are 5 in. long and ½ in. thick; these are screwed on the inner side of the roof,

Fig. 1.

Fig. 2.

leaving 2 in. projecting down, which catches on the hive at A (Fig. 1) by means of a screw inserted in the hive side, and a small block of wood screwed in the opposite side of the body gives us a roof which can be opened as

though we had hinges on, but can be lifted off if necessary, and also does away with the use of a chain, as it keeps itself in position when opened. I should say that this is an idea I had from Mr. Cheshire, but I have never seen it adopted by any hive-maker. The make of the upper part will be readily understood by a glance at Fig. 2. It consists of one piece of wood, 2 in. wide, grooved so as to fit closely down on B. It is then well painted and screwed down while wet; at C the boards overlap each other 1 in., and a groove at D makes a thoroughly waterproof roof that will stand any kind of weather.—J. T. H., *Finchley*.

HIVE COVERS.

[65.] This is evidently an interesting subject by the correspondence it has drawn out. I am much obliged for the readiness our friends have shown to explain means whereby hive-covers may be made waterproof. May I remind them this is not the point in the minds of the Rev. F. G. Jenyns or myself? The question is, cannot the present wood-cover be replaced by another so constructed, of wood only, as to be waterproof? I am sure the discussion of the subject will be as acceptable to the hive-makers as to any of us; and if we cannot prove hives cannot be kept dry as now constructed they will alter their present patterns or find some neat and simple means of making them waterproof. I will not shrink from confessing that nothing short of actual compulsion will ever drive me to resort to zinc, felt, Willesden card, calico, &c.; and I may further add, paint laid on *thinly*, but a greater number of coats, always wears better than few coats and thick.—AMATEUR EXPERT.

SOME OBSERVATIONS ON HONEY AND POLLEN PRODUCING PLANTS.

[66.] During the past season I have cultivated about 150 species and varieties of native and exotic plants, with a view of ascertaining their respective merits as honey and pollen producing plants; but as the season was unusually hot and dry, the growth of most of the sorts submitted for trial was considerably retarded, and in a few cases entirely prevented. The result of my experiments, with a few exceptions, was very unsatisfactory and incomplete. I shall, however, continue my observations on the same varieties, with a few more additions, and trust the coming summer will be more favourable to the growth of vegetation, which I need not say materially affects the perfect development of the floral capabilities of annuals and perennials especially.

Out of the whole list of what I may call summer flowering plants, borage stands pre-eminent, then come horehound, marjoram, thyme, mignonette, and campanula pyramidalis, the latter during September was well patronised by bees the first half of the day, collecting honey, and totally disregarding the white pollen, which is produced in abundance by this plant.

A common garden weed (*Veronica agrestis*) afforded in March and April both pollen and honey. Speaking of early spring flowering plants, arabis (white), wall-flower, aubrietia, pyrus japonica, willow, are amongst the best, and succeeding these, the myrobella plum is *par excellence*. This valuable shrub continues in flower through March and April, and secretes honey equal if not superior to hawthorn honey; the first blooms open with the crocus, which, however, at first do not appear to produce much honey, but, later on, for six weeks or so in April and May, contribute an unending supply of nectar, the flavour of which I opine would satisfy the most fastidious. In my opinion, the myrobella takes precedence of all spring flowering plants for the secretion of honey, and I can unhesitatingly recommend it to all bee-keepers who can conveniently grow it. The thorn acacia is another addition to our bee flora, and should commend itself to those who plant for their bees.

It is of rapid growth, commences to flower at an early age, and produces its sweet, white blossoms in July, which claim a considerable portion of the bees' attention. I wish here to thank those gentlemen who kindly forwarded me plants and seeds for trial last year, but it will be seen before I can give any opinion as to their merit or value, I shall have to give them another season's study and observation, which I trust this year will produce better results.—H. Y. DOBBIE, *Thickthorn, Norwich, January 8th*.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[I. Special Query.]—If my opinion is of any value I can entirely endorse what Mr. Simmins sends as his answer to Special Query [1]. I have obtained a county silver medal with sections $1\frac{3}{4}$ inches wide, worked without dividers. It cannot be done, unless special care is exercised, with the 2-inch sections, and I think $1\frac{1}{2}$ inch will be found too narrow.—ASHTON E. RADCLIFFE.

[1.] *How do the bees ascertain the presence or absence of the queen in a populous hive?*—(H. P. JONES.) This query appeared in the issue of the 7th of January, to which I notice there has been no reply, and until much greater advances have been made by scientific research in order to gain a more extensive knowledge of the physiology of the occupants of our hives, can a satisfactory answer be given; that there is a means of communication between the occupants one with the other there is not the slightest doubt; but how this is accomplished has puzzled many scientists, some supposing smell, others sight, but by far the most give the preference to touch; until this is satisfactorily determined no one can say how the fact is communicated through the hive that the mother is absent.—W. B. WEBSTER.

[31.]—If my experience is of any benefit to 'C. II.' I am pleased to place it at his service. During the last few years I have produced a large number of sections of comb honey, and I am glad to say, I have always found a market for them at remunerative prices. Yet at the same time I have to chronicle a graduated table of average prices on a declining scale; and I am sorry to add that my average price for last season, 1885, amounts to only two-thirds the value of five years ago, as 'C. II.' will see by the following: year 1881, average 1s. 6d.; 1882, average, 1s. 4d.; 1883, average 1s. 2 $\frac{3}{4}$ d.; 1884, average 1s. 1d.; 1885, average 11 $\frac{1}{2}$ d., for good colour and good quality glazed sections. I quite expect if we get a good season in 1886, that I shall have to reduce my prices, and that another stock-taking will show a lower average still. Yet, at the same time, I hope (bee-keepers always hope) that we have nearly reached the end of the tether, and that we producers shall not have to accept less than 10s. 6d., or at least 10s., per dozen for good quality one pound glazed sections. Our aim in the future must be to increase our out-put, work up as large a retail trade as possible, thereby making a larger profit at less risk than selling to dealers to sell again. Perhaps other bee-keepers will give their averages; and if theirs coincide with my experience, it may give a hint to future authors of bee books, and present authors in new editions, to modify their extravagant quotations of prices realised for comb-honey, viz., their 1s. 6d. to 2s. per pound. That day is gone, and I fear gone for ever, like the 60s. to 80s. per quarter for wheat. If 'C. II.' wishes to sell his honey and is prepared to take a moderate price, I commend him to the British Honey Company, he will be dealing with a *bona fide* firm, who pay cash, which is a great consideration in these times.—WOODLEIGH.

[41.] *Rapid Mortality in a Wintering Stock* (Frank Mc'Donough).—As I have previously said there is much uncertainty in all determinations with regard to disease germs if the examination is made after ordinary putrefaction has set in. This uncertainty can only be overcome by the process of cultivation, for which time is of course required. The bees appear to have been carefully prepared for wintering, and while surrounding stocks similarly treated were doing admirably, this one is dying rapidly. I find the 'box of dead bees' to contain specimens which have certainly not died from starvation. The intestines are full and contain innumerable micrococci in rapid movement. These I *suppose* to be putrefactive only in character, and should not expect to see them in any number in honey bees of the same stock. With the micrococci, however, are many bacilli, almost certainly alvei, which I think are pathogenic or disease organisms, and this idea is strengthened by finding the same in the thorax and also in the brain. One of which I got out in a half dried state and mashed down with a needle-point in water. Nothing can be done now except, perhaps, putting a piece of camphor in a bag and placing it under the chaff-tray, not too close to the bees. Camphor at this period of the year is decidedly beneficial in bacillus diseases, of which I purpose writing hereafter.—F. C.

[42.] *Great Mortality in a Stock of Syrians* (S. L. B.)—The case is very similar to the last, with this difference, that the presence of bacillus disease (*alvei*?) is much more strongly marked. The question as to whether the bacillus is alvei or not is of great interest; and if the correspondent would favour me by sending a few bees direct, such being alive at least at the beginning of the journey, I will make a cultivation and report thereon for the general benefit. Kindly see what is said in reference to camphor.—F. C.

[43.] *Robbing*.—I have generally found a handful of hay or long grass put before the entrance of a hive where there is robbing, effectually prevent it. The hive bees will creep through it, but the robbers funk to do so. It is the same as the tube or tunnel, but more handy.—G. F. PEARSON.

[54.] *Moving Hives*.—(B.) They may be moved a few hundred yards with safety this time of year, it will be wise, perhaps, to place a piece of glass against each entrance, so that the bees' attention is called to the changed site as they leave their hives for the first time. If only a few yards, we prefer to cart them to a distance for a few weeks, and then bring them back to their new site.—AMATEUR EXPERT.

[54.] *Removing Hives a few Hundred Yards at this Season*.—(B.) Yes. It may be safely done now, but if delayed, only by a yard a-day. Be sure to place a board bush in front of the entrances in the new position, to call the attention of the bees the first time they fly, and ensure their marking the spot.—L.

[54.] *Moving Hives*.—(B.) You need have no hesitation in moving your hives a few hundred yards at the present time in one move, as the bees have now been confined to their hives by cold weather for upwards of a month; this is really the only time of year that bees can be moved such distances with safety. Endeavour to shift them so quietly that not a bee notices any disturbance; this can be done by placing two poles—laced together by cross pieces and padded—under the stand and lifted bodily by two persons *à la* stretcher, if carried steadily—the two carriers being out of step—the combs will not swing.—W. B. WEBSTER.

[55.] *By the exercise of what sense do bees find their queen when she is temporarily lost to them?*—(F. H.) By the foregoing question I judge that it is supposed that the bees and mother bee are not the occupants of a hive but are swarming, as in the event of the mother bee being taken out of a hive, their search

for her is usually only limited to the interior and a short distance around the entrance; but in swarming, this search is extended for many yards, and here the sense of smell seems predominantly exercised; this is proved in the circumstance of a mother bee alighting on a certain spot and taking flight again. Bees will congregate on the first and subsequent alighting places for days afterwards. Take a mother bee between your fingers and, after releasing her, present your fingers to a motherless stock, there is at once a sudden hush, and then a tremulous vibration of wings which will gradually extend itself to the bees further removed from your fingers, those nearest commencing to crawl over them, evidently searching for the lost one; here the sense of smell is first exercised, communicated after to the others by that of hearing, but most likely touch or rather a feeling of vibration. Take a mother bee from a swarm and place her in a well-stoppered bottle, being careful not to touch the outside and place the bottle close to swarm, no notice is taken by them of it, but uncork it and place a piece of perforated zinc over the mouth and the bees will instantly congregate around it, but how the few who actually find her communicate the news to the others is a question yet to be determined; that such is done is a certain fact: the vibration of their wings seems to be a method of communication which appears to point to the sense of feeling rather than that of hearing.—W. B. WEBSTER.

[56.] *Feeding*.—(W. P.) Liquefy the honey by water, heat, and feed with bottle feeder on top of hive. But don't you think you had better eat the honey and stimulate in spring with syrup, which is just as good, in fact preferable?—W. B. WEBSTER.

[56.] *Feeding*.—(W. P.) Add water if necessary to reduce it to the consistency of syrup suitable for spring feeding, by stirring both honey and water in a saucepan over the fire until they are well mixed, and give it to the bees in any syrup feeder you may have.—AMATEUR EXPERT.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[67.] *Bees coming out*.—What can be wrong with one of my bar-frame hives, the bees are coming out daily, they fly round about once or twice, then light on the snow and can't rise?—JOHN ROBB.

[68.] *Mixing Honey and Syrup*.—In the case of a hive having been fed up by syrup, is there any fear when the honey season comes on of the bees mixing the syrup with the honey gathered; also, is the case similar with a hive stored with honey, and fed in the spring with stimulating syrup?—O. P.

[69.] *Removing Syrup*.—Do the bees ever remove syrup from the brood frames in the stock hive and mix it with the honey in the supers? I have a stock of bees in a skep stocked with honey; in the spring it is my intention to invert the skep and place a small bar-frame hive on the top. Now, if I uncap the cells in the skep, will the bees carry the honey into the upper hive, and in this case will it be of service to feed them with stimulating syrup?—O. P.

[70.] *Storing Syrup*.—In stimulating feeding, do not the bees store the syrup, and is not the honey thereby adulterated. Can this be remedied?—O. P.

[71.] *Shading Bees*.—My bees come out and get on the snow when the sun shines, although I shade the

entrance. Will it, during the time the snow is on the ground, injure them to shut them in if I let them have plenty of air?—R. CARTER, *Ullesthorpe*.

[72.] *Excluder zinc under Sections*.—Would some of your readers who have had experience say whether it is really necessary to use zinc under sections? My opinion is that it is a perfect nuisance, and I have made up my mind to use it no more unless I am informed that it does some good. The cost with me is a consideration in the first place, enough for one hive costing 1s. 8d., more than the crate of sections cost me. I am not sure, but I think the queen will never go up into sections to do any harm, and I found it so firmly fixed to top of frames as to be almost past removing without jarring the combs very much; besides, it makes the top of frames so dirty with propolis. If no zinc is used, how much room should I leave between top of frames and bottom of sections?—T. JENKINSON.

[73.] *How to prevent Stocks from Swarming more than once*.—I have two stocks in good bar-frame hives to commence with this spring. Now I want to let each swarm once. By this means I hope to have four stocks strong enough to gather honey. What I am thinking of doing is to feed up well in the spring and get them to swarm early, then cut out all queen-cells but one, and give sections at once. If this should be right, what time after the swarm comes off should I cut out the cells, and is it difficult to do? If making artificial swarms would be better, would some of your experienced readers give me plain instructions how to do it successfully, as I am ignorant how to go about it?—T. JENKINSON.

[74.] Will some brother bee-keeper give traits of character of Carniolan bees, and first cross with English bees?—W.

[75.] Please give best known methods of packing sections of honey to ensure safe travelling per rail.—W.

[76.] What is the best height of hives from the ground?—W.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

H. C.—*Adapter for Section-Rack*.—If the rack is properly constructed with separators resting upon the ledges between the rows of sections, no adapter is required, the spaces between the sections themselves forming a barrier to the ascent of the queen. If the rack is not large enough to cover the whole of the frames which you are working, close up the space by strips of carpet.

J. GILBERT.—*Honey*.—The sample of honey forwarded has been gathered late in the season. It has distinct evidence of a mixture of honey-dew with the honey. It does not appear to having been well-strained, having a waxy taste.

L. HARRIS.—*Width of Frames for Extracted Honey*.—The frames placed behind the excluder at the back of the brood-nest should be $1\frac{3}{4}$ inches or 2 inches wide. If you want extracted honey you would only lose space by using sections as you suggest.

J. P.—*Use of Excluder zinc to prevent swarming*.—The objection to the use of excluder is that it confines the drones (if any) and does not always confine the queen; some queens being small enough to get through the holes. A drone-trap fitted to the alighting board would be better than an excluder inside the hive. A

piece of excluder over the entrance would not give sufficient exit and would most likely lead to destruction of the stock by suffocation.

T. FISHER.—*Honey granulated*.—The appearance of your honey is very remarkable, we never remember seeing any candy just like this; we can only suggest that as honey varies considerably in density, so this particular sample kept its place separate from the others by the law of gravitation, and so all found its way into one bottle. The caudied portion was evidently gathered from flowers differing from those from which the bulk was gathered. The honey is of excellent quality.

R. K.—*Close-ended Frames*.—The term implies that the side bars are $1\frac{1}{2}$ inches wide and thus touch one another, forming, as it were, an inner wall to the hive. When only the top bars are in contact at the ends the term 'wide-shouldered' frames is correct.

INQUIRER.—'Put your expected swarm on to six or seven frames of foundation and enclose with dividers. As the combs are built out add other frames. Your query has no reference to 'doubling.'

NIGER.—1. *Hive for working without Supering*.—The number of frames (eight) which you propose to allow in the brood nest is too small, give ten or twelve. Behind the excluder put two or three of the wider frames for extracting purposes. 2. *Bees by Rail*.—As a rule bees are allowed to go by rail, but we believe some lines have certain regulations on the subject. You had better apply to the station-master at the station from which you desire to send them.

3. *Skeps travelling inverted*.—No, the honey does not run out unless the combs get broken down. 4. *Inability to make Frames to hang true*.—We can only suggest want of sufficient skill. Perhaps you are not sufficiently careful to cut all the pieces perfectly square. You must use a frame-block for nailing.

E. H. H.—*Honey-comb Designs*.—Please communicate with Mr. R. McNally, Glenluce, N.B.

ERRATUM.—In reply to 'R. J. N.,' p. 32, col. 2, for $8\frac{3}{4}$ inches, read $8\frac{1}{2}$.

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, w.c.

[No. 189. VOL. XIV.]

FEBRUARY 4, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE PECTEN OR COMB OF THE BEE.

On page 370 of last year's *Journal* we gave a description of this contrivance on the anterior leg of the bee, which is used for cleaning the antennæ: but it has been suggested to us that an illustration would enable our readers to understand it better. We have, therefore, prepared the accompanying illustration (Fig. 3) enlarged direct from the natural object under the microscope. On a small scale, this is shown in Fig. 1, which appears in

Fig. 1.

Professor Cook's *Manual*, and A. I. Root's *A B C of Bee Culture*; but although it has been described by Shuckard, Girdwoyn, and others, both Cook and Root seem to have got into error as to its real use. The legs of bees consist of several joints, see Fig. 2, the first the hip-joint, *g*, being called the

Fig. 2.

coxa: the next, *f*, is called the *trochanter*, which is a short joint between the *coxa* and the next one, *e*, called the *femur*, or thigh; then the *tibia*, *a*, or shank; and, lastly, the *tarsus*, or foot. This last is made up of five joints decreasing in length, the first being as long as all the remaining put together. The large joint, *b*, in the anterior pair of legs being called the *palma*, or palms, and in the other legs *planter*, or soles; the small joints, *h*, are called the *digiti*, or fingers. The *palma* and the *digiti* collectively being called the *tarsus*. The terminal joint is furnished with the claws, *i i*, having both lateral and perpendicular motion; and between these is fixed the *pubvillus*, or cushion, *k*, the action of which has been so beautifully explained by G. Simmermacher and Dr. Rombouts. The middle pair of legs are provided with a moveable spine or spur near the lower inside end of the *tibia*, which does not exist

in the posterior legs. This spur is found on the anterior legs (see Fig. 3), also on the *tibia*, *a*, but has an important modification which enables it to perform another function to that for which the central spine is provided. Attached to this spine

c, is what is called a *velum*, or sail, which is a small angular appendage fixed within the spine by its base. Near the upper end of the *palma*, *b*, and opposite to this *velum*, there is a deep curved incision called the *sinus*, terminating with what is known as the *strigilis*, currycomb, or pecten, so named from the short stiff hairs like the teeth of a comb. This semicircular comb is shown at *d*. The teeth of the comb are all of the same length, but they appear shorter in the drawing from the position of

Fig. 3.

of the leg and the perspective view. Upon this opening the *velum* can act at the will of the bee. The object of this apparatus is to keep the antennæ clean. There is one on each of the front legs, the one on the right side being used to clean the right, and the one on the left to clean the left antenna. When a bee wishes to clean it, the antenna is placed into the semicircular *sinus* of the *palma*, and then, pressing the *velum* of the spur upon it, removes, by the combined action of the comb *d* and the *velum* *c*, all pollen. Bees are constantly seen doing this, and it proves how essential to the well-being of the bee is the condition of its antennæ. Root says that bees use this device for cleaning the tongue, but it is a remarkable fact that the *sinus* and *strigilis* are always adapted in size to the thickness of the antennæ, clearly showing the object of this apparatus. Cook states that other bees do not have it. Shuckard, however, says that all bees are provided with it. We have the anterior legs of a number of bees furnished with it, amongst others those of *Colletes*, *Dasygaster*, *Megachile*, *Cilissa*, *Bombus*, *Anthophora*, *Nomada*, *Xylocopa*, and others; and although the shape of the *velum* varies, we have never yet examined a bee without finding the *strigilis*. The *palma* are also

provided with stiff bristles, which are used for cleaning the face, bees being frequently seen performing this operation.

The above would have appeared sooner, but has been delayed by the engraving Fig. 3 not satisfying us at first.

USEFUL HINTS.

In consequence of the long-continued cold weather, which for many weeks has afforded no opportunity of a cleansing flight for the bees, we much fear that dysentery will prevail to a far greater extent than has been the case for several years.

Already we have numerous applications for advice under this distressing malady and can only repeat our former suggestions—to keep the bees confined to few combs, in clean hives, with wide entrances, sufficient and proper food and shelter with dry covers, warm wrapping and encouragement to fly on every suitable opportunity.

Food.—With fine weather and strong colonies the demands upon food stores will now rapidly increase. In frame-hives the consumption may be noted by turning aside the quilt and noticing the quantity of sealed honey in the upper and hinder parts of the combs, without further disturbance, or manipulation. A few of these cells, in immediate proximity to the cluster of bees, may be gently uncaped with a sharp knife, or the caps may be slightly bruised, when the bees will at once make use of their contents, and the queen, stimulated thereby, will soon become disposed for ovipositing. Such operations should be performed on mild days only. For kinds and qualities of food see former hints under 'Heddon's Syrup,' 'Good's candy,' 'Frames of honey,' &c. These latter should be placed close to the bees and having a hole—winter passage—cut through the centre, to enable the bees to pass to the outer side without breaking up, or wandering away from the cluster, always remembering that if the weather prove fine, enabling the bees to extend the cluster and to fly freely, food will be rapidly consumed, and the early gathered pollen will stimulate to breeding and to further demands on the stores.

CLEARING ENTRANCES.—When the weather is sufficiently mild to cause free flights, the apiarist, carefully noting any hives from which the bees are not flying, should thoroughly clear the entrances of such hives from dead bees and debris with a long piece of stout wire hooked at the end.

If the dead are numerous, examination from above must be made by turning aside the quilt to ascertain whether the colony be alive or dead.

Very weak colonies should be confined by division-boards to small space, if only to preserve the queens, which may prove most useful on the general spring examination—soon to take place—where queens have perished during the winter. Where upward ventilation is practised, a supply of water may be useful to strong colonies which are breeding freely. This may be given, sweetened with a little sugar, by means of a sponge placed over the feeding-hole and covered by a tumbler, or underneath the quilt. Where the loose floor-boards are used it may be advisable, after the long frost and snow, to change them for dry ones and so to clear away all dead bees and refuse with the least possible disturbance.

STIMULATION.—to any great extent, is to be deprecated at present. The time and method we shall hope to notify in future hints. Our own view is, that the middle of April is soon enough, and that it should be practised together with brood spreading, to a small extent, and with the equalisation of colonies. Too early

stimulation results in greater loss than gain from enticing forth bees to perish in the search of coveted sweets and farina.

SMALL COLONIES.—Wherever an attempt has been made to winter small colonies, unless extremely well protected, we fear the result will prove disastrous. In very cold winters small after-swarms usually perish more from lack of heat than want of food. We are wintering some half-a-dozen nuclei of three and four frames each, with young queens, chiefly Carniolan, fecundated as late as the middle of October. On the approach of severe cold in November, we removed these nuclei into a spare out-house, warm and dry, with a southerly aspect, and on mild, sunny days, place them out-of-doors for an hour or two, encouraging thereby to a cleansing flight. Three of these are now breeding freely, and all exhibit signs of perfect health. From their late fecundation, when none but Carniolan drones were flying, we anticipate pure fertilisation, and shall hope further to prove the qualities of these 'ladies' bees.'

THINGS-IN-GENERAL.—*Indian and Colonial Exhibition.* The *American Apiculturist*, in its 'Notes and Queries,' in this month's issue, takes us to task for having, in 'Useful Hints,' expressed a hope that 'our American cousins would abstain from sending glucose, with a piece of comb-honey floating in its centre,' to the above Exhibition at South Kensington, at which Canadians had expressed an intention of making a large display of their produce. The *Apiculturist* asks, 'Is it right or just to leave the public to suppose that on this side of the water bee-keepers do place such a mixture on the market?' As we yet have to learn of the practice of adulteration by the honey-producers of America, we must protest against any statement that would seem to convey the idea that they do practise adulteration.' Whether American apiculturists, or 'producers,' as our contemporary is pleased to call them, are the guilty parties, we know not, but it is a fact, acknowledged on all hands, that our markets have been plentifully supplied from America with the so-called honey to which we made allusion. Their own Journals have repeatedly contained far stronger condemnation of adulterated American honey than the Journals of this country. Witness, for instance, the following from the *American Bee Journal*, taken from a letter of Mr. C. F. Muth: 'It is surprising that a common swindle, as practised by New York and Chicago honey-dealers, of putting a piece of honey-comb in a glass jar, and pouring over it pure glucose, could last so long.' And Mr. Muth goes on to state that, 'after analysis, it was found that the comb was the only pure honey in the jar, and that the liquid was pure glucose, which had partaken of the flavour of the comb-honey.' In our provincial towns we have seen shop-windows filled with this imported stuff; and Mr. Hehner, Honorary Secretary of the Society of Public Analysts, and Analyst of the B.B.K.A., states that, 'Out of nine samples of American honey purchased from retail dealers in England, seven were adulterated, while out of twenty-six samples of English honey, purchased in a similar manner, twenty-four were genuine, and the other two (adulterated with corn syrup) he had good reason to believe were of American origin.' Let our contemporary, then, answer the question, 'Is there not a cause?' Our remarks were in no way intended to prejudice the colonial produce, but our market for pure English honey has suffered so much from adulterated imported honey that we must maintain our position. Our Canadian friends may rest assured that a hearty welcome awaits them here, and that we have room for all those fine qualities of honey for which they are so justly celebrated.

Upward Ventilation.—We were pleased to see the remarks of our old friend Mr. Pennell on this subject in connexion with enamel-cloth (No. 187, p. 28), which are very much to the point, and re-echo our own views. Dr. G. L. Tinker, a great American authority, in an

excellent paper on 'The Hibernation of Bees,' published in the *American Bee Journal* of January 6th, remarks, 'Somehow I am becoming impressed with the idea that a great part of our wintering troubles comes from upward ventilation in hives. The great success of Mr. Barber in wintering may be due to the fact that he gives his bees no top ventilation.' His views on 'hibernation,' and the proper winter temperature of hives, are striking, and worthy of a perusal by all apiarists.

Reversible Frames again.—Mr. Demaree, another American apiarist, of equal standing with Mr. Heddon, in the same Number of the *A. B. J.* as the above, utters a note of warning on this subject thus: 'I want to say a word about the utility of reversible frames. This idea is likely to be pushed as never before—patent interests will push it regardless of its real merits. Experience of years, with a thorough knowledge of practical mechanics, may not weigh much with some people, but my advice to *beginners* is, Don't be caught in the trap. Let me prophesy that when the great "blow" is over, the thousands of reversible frames that are now being pushed into use, will stand *unreversed*.' *Festina lente* is a good motto, especially for the inexperienced. By the way, could not the system be tried in the future 'Bligh Competition?'

INTRODUCTION OF QUEENS.—MR. SIMMINS' METHOD.

The introduction of queens has ever been a critical operation with bee-keepers, and numerous have been the methods recommended. Amongst those bee-masters who have devoted much of their time and attention to the study of this special branch of bee-culture, may be mentioned Mr. Simmins, many of whose contributions to bee-literature have from time to time appeared in our columns. Such has been Mr. Simmins' success in the safe insertion of queens that he was induced to give the result of his experience in a pamphlet, entitled *Simmins' Method of Direct Introduction*. This pamphlet has been in the hands of the public now for some years, and his further experience enables him to speak with still greater assurance of the success of his methods, provided his directions are implicitly followed. His first method, we believe, has never been given before, though it embodies some of the principles contained in his pamphlet. The chief point of this method is that the queen must be kept alone and without food previous to insertion. For the benefit of those who may be interested in this matter, we append his two methods:—

FIRST METHOD. *—Upon receipt of queen, go to the hive and remove that one to be superseded (or otherwise). At dusk, take the new queen *quite alone!* after keeping her so for not less than thirty minutes previously, but quite warm, and, moreover, without food meanwhile; lift quilt at one corner, drive bees back with very little smoke, and then permit the queen to run down. Close the hive, and make no examination until after forty-eight hours. Leave the operation until so late that a lamp is necessary.

SECOND METHOD. †—When queen is received, at once make up a nucleus to receive her, thus: From a strong colony take one frame of hatching brood, with adhering bees, and place in a nucleus hive, say 14½ in. by 4½ in. by 9 in. deep inside; then shake off most of the bees from another comb into such small hive, and on either side of the one containing brood place one comb of honey; close entrance with perforated zinc, and place on top a sheet of straining-cloth, tacked to a simple frame. Thus securely

* In case of a queen that has travelled this process of quarantine removes any scent she may have contracted while confined with other bees.

† By this means the bees are reduced to the same condition as the recently-confined queen.

confined, and having ample ventilation, they are to be taken into a warm, dark room. In a few minutes, finding themselves confined and queenless, a great uproar will be heard; now slide frame of strainer cloth just off one corner and let queen run in, keeping bees back with little smoke, if necessary. Close again, and let them remain indoors until the third day, when stand out where desired. After a day or two, give another frame of hatching-brood, which repeat at intervals of seven days, or as often as they appear able to cover more combs, until well established.

In our next number we propose to give Mr. Frank Benton's method of queen-introduction.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION CONVERSAZIONE.

(Continued from p. 35.)

In the absence of Mr. W. J. Green of Sudbury, the following paper on 'Clark's Climax Hive,' and on 'Smoking Bees,' was read by Mr. Henderson:—

GENTLEMEN,—Seeing that a meeting of the British Bee-keepers' Association is to be held on January 20th, I thought it desirable to make a statement respecting Clark's 'Climax' Bee Hive, which does away with the necessity of smoking bees.

It is possible that some might say, Why should I go to any expense in the matter?—the smoking is not much trouble. Perhaps so; yet it is some, and when the matter is thoroughly thought out I think that no one can deny that it would be much more merciful to the bees if it could be dispensed with. For what does smoking mean if not semi-suffocation, and seeing the number of times it has to be endured, how far does it, in the total, fall short of the punishment inflicted by burning, or actually total suffocation—which is what the burning amounts to? I will not trouble you with any further enlargement on the subject, but will at once proceed with the diary I kept of manipulations performed without smoke.

On September 16th, about six p.m., went to have a look at a hive of my own in a gentleman's garden. It was a middling strong June swarm, and I wanted to give them some candy, but having previously attended to another, smoker was out. I opened hive and could see through glass dummy that there was no food in end frame. I then ventured to pull up quilt (I was dubious about the matter), but the bees did not seem angry at it. I proceeded to examine them, and took out a few that had not many bees on them and found honey sealed in centre. I placed them at the back of hive and took out a few more of extreme front ones, placed them with them and stood a few on the ground leaning against legs of hive; as there were a few cappings at the bottom and I had room I proceeded to clean them out with a small piece of square tin lying by and a wing I had with me.

I was very much surprised, as I had not smoked the bees, to find them so quiet, none of them attempting to sting; but as it was getting towards evening there were many crawling about me, but all good-tempered, moving their bodies up and down in the usual way. After I had cleaned out front part, moved back frames to front, and cleaned remainder out, then replaced all the frames and made secure with dummies and quilts and left them, rather pleased and very much surprised at their taking it so quietly.

I thought over it next day, and as I had made arrangements with the gentleman where they were to clean out one of his hives for him next day, resolved to try them without smoke. I did so, and this time I had made preparations for taking out all the frames, that is to say, found up an old box about 18 inches wide which would catch arms and allow bottom of frames to drop in box. I began by taking off the quilt as on previous day, and then took out all the frames one by one and placed them

in the box, the bees all perfectly quiet. The frames being so easy to move, no propolis, and they were entirely unconnected, save that the bees on adjoining frames cling to each other and must of necessity be separated, but as I did this without any jar or shaking it did not affect them in the least, and they were very soon all in the box, and I cleaned and freed the hive from wax-moth, &c., and then put the frames with bees all back again and covered up everything snug and left them, very much pleased with continued success without smoke, and as this was also late in the day resolved to try another one in the middle of the day.

Sept. 21, 1:30 p.m.—Proceeded with another of my hives in another garden and had a box as before to receive frames. Opened hive, took off quilt as before, took all frames out of hive, and replaced them as in preceding cases. No smoke, and not in the least angry; they flew about more as it was quite the middle of the day, but all were good-tempered, not one of them attempting to sting. Must say I was very much pleased at continued success, and now felt sure that the cruel practice of smoking was quite unnecessary. There were two more hives I wanted to look at close to this one; they were bees I had driven about a month before, and had been feeding them up with honey, and some syrup, and candy, also broken comb containing bee-bread. I did both of these on the evening of the 23rd. These bees came from a different part, and had the character of being angry bees, so much so that they would occasionally sting passers-by, and I must say that they were more lively. I had gloves and a veil on, but not one tried to sting my gloves, one did crawl up my trousers and stung me in the leg; this would not have happened in the middle of the day, as they will not then remain on the ground, consequently no danger to one's legs, but with this exception all went well. I emptied them both and found them going on well; they had pulled out foundation and had sealed up the honey; syrup, of course, was not so. The old comb that was in the bottom, which I had given them to pick over, I cleaned out and put them back and covered up, leaving them all right and snug, as before stated all without smoke.

Sept. 25.—Examined three more similar hives standing in another garden (without smoke), took out some empty frames and closed up; no trouble with them, a few flew about, but not one of them attempted to sting.

Sept. 26.—Went to a gentleman to set a hive right. I had tried twice before to do so with smoke and had failed, this was before I found out how to do without smoke; this time intended to try without smoke. If not trespassing too much on your space, which I am afraid I have already done, I should like to give you an account of these manipulations, if so they can be called. On the first occasion I took off section crates, smoking them first, and took a frame or two of honey away, but owing to their irritability (savageness, in fact), for they literally covered my gloves, I had quite a dozen stings on one finger through the glove, and half a dozen up my arm, I was compelled to throw the quilt over them and leave them. Later on, perhaps a fortnight, I had another try at them, smoking them first, but I had no sooner taken the quilt off than, just as before, they literally covered my gloves trying to sting; they were common leather gloves, but as they were dry and hard did not penetrate. Used the smoke to them, but it was no good, they would not be driven down, they buzzed about from place to place, and in a second or two after as soon as I tried to get the frames right they were on to me again, and in pure mercy to them, for there were numbers of them twisting round and round or dragging and pulling and leaving their stings in my gloves, I covered them up again, and in despair at the time could see no better way of dealing with them than destroying and taking the honey, but, of course, as they were not mine could

not do so without first consulting the owner, and intended the first opportunity to advise him to do so. I may here mention that this lot bore a very bad character with those who had previously managed them, and just before myself some one else, a friend of the owner, put on the crates and had attempted to do something with the frames, but he did not succeed in leaving them right, consequently they had free access to the roof, built enlarged combs, and in his flurry he put the crates on wrong, and, I was told, was stung very much and would not have anything more to do with them. I may say that in my own mind I had decided that this hive should be a crucial test of the system of working without smoke, and I now without any smoke set to work and took off the quilts; they came out in pretty good numbers (I had a veil and gloves on) and were very busy flying round my head. I had a good look at all the frames. The reason I could not close them up was that during the time that had elapsed, or prior, they had enlarged comb so that frames could not be put close.

I took this frame out, sweeping the bees off with a small wing and closed up the other frames, took out the glass dummy, placing wooden dummy in its place; very few bees during whole operation alighted on my gloves, and only one attempted to sting. I put the quilts on again and finished by putting on an extra one for the winter, thus doing with comparative ease without smoke what I was utterly unable to do with it.

I may also add that before I had anything to do with them, a friend of the owner—a bee-keeper himself—had attempted to examine them before he put on the sections, using as usual a little smoke; but they turned up so angry that he could not properly close up the frames. He managed to put one crate on, but in his flurry that was put on wrong, so that the other would not fit when I afterwards tried to put it on, and I was told he was very glad to get away from them, and would have no more to do with them—all through the smoke, which in these 'Climax' hives is not required, the frames being diamond-shape; as soon as the quilt is removed they are fully exposed to both light and air, and being thus they very soon become perfectly manageable, and the longer the job lasts the quieter they are.

The question may arise in some one's mind as to how I know it is the light and air that quiet them. It is in this manner: if a frame is taken out of the hive, we will say, quickly, with the bees all lively on it, and it is stood down somewhere, the bees on it will soon be quiet. There is no other influence at work, so it must be that. Again, if in these same hives ('Climax') you attempt to do anything with them, by means of removing dummy at the end, without taking off the quilts, they will not allow you to do it quietly, but rush out from inside on to any strange substance, be it hand or anything else. They are not in this manner exposed to light and air fully. The internal part is darkened as much as the lower part of a skep or bar-frame hive would be; but take off the quilt, and conditions are immediately altered, and with such conditions the temper of the bees.

The Chairman invited the members to examine the hive, which seemed to him very much like an Anglo-Cyprian hive.

Mr. Hooker and Mr. Baldwin could not discover that this hive possessed advantages over any other, the manipulation of the bees being subject to the usual rules.

Mr. Sambels thought it was a pity Mr. Green was not present. It was pretty well known that when the bees were fully gorged they were quiet—at all events sufficiently quiet to permit of manipulation with the help of veil and gloves. All of them knew that if the quilts were removed and the bees exposed to the light they would go and gorge, after which they were as easy of manipulation as if smoke had been used.

Mr. Blow thought the idea of the hive in question had been suggested by an illustration of an Anglo-Cyprian hive, which appeared in the columns of the *Bee Journal* about three years ago. It was a hive entirely suited for supering purposes. The supering space would be two or three times as great as in a bar-frame hive. It was not a new thing to manipulate without smoke. Several eminent bee-keepers always manipulate without smoke—Mr. Raynor for instance. He did not think that hive would secure them immunity from stinging any more than bar-frame hives. He was also of opinion that the entrance was in the wrong place, owing to which fact the bees were not properly protected from sun and winds.

Mr. Hooker said with regard to Mr. Raynor dispensing with smoke, that gentleman always used dilute carbolic acid, which had just the same effect as smoke.

Mr. Baldwin could not see that this hive had advantages over others, for in manipulating with it the whole of the top would have to be exposed, and in fact a much greater surface than with an ordinary hive. Mr. Green evidently had no confidence in it, because he resorted to his gloves and veil. He thought the evidence in favour of this hive could not be regarded as conclusive simply because Mr. Green's plan had perhaps succeeded once or twice. He knew that Italian bees might sometimes be handled without carbolic acid or smoke, but it did not follow that that could be done always because it had been done once in a way.

At this point Mr. Hooker took the chair, Mr. Glennie being compelled to leave, and stated that he thought the general opinion was that this hive was in no way superior to others in use. He regretted Mr. Green's absence, who might have thrown more light on the subject.

Mr. Sambels said he would like to hear the opinion of the members on a question which had recently been asked by Mr. Jones and another correspondent in the columns of the *Bee Journal*, namely, how bees ascertain the absence of their queen.

Mr. Baldwin said that one might as well ask how the bees knew the queen was the queen. If they gave them credit for being able to recognise the queen he thought they might also give them credit for knowing whether the queen was present or not. Those bees immediately in the neighbourhood of the queen would instantly ascertain this and transmit the intelligence to the others.

Mr. Stewart was of the same opinion.

Mr. Grimshaw and Mr. Baldwin agreed that the queen emitted a strong odour, and possible the absence of that odour in the hive would be immediately detected by the other bees.

Mr. Garratt thought this fact was established by the circumstance that if the queen alighted on a place and moved away again out of sight, the bees would immediately cluster on that particular spot, and it was difficult to get them away. Sir John Lubbock had suggested that bees were deaf; but he thought there was no conclusive evidence on that point.

Mr. Zehetmayr had removed frames out and put them in a box and shut them up for half an hour without the queen. The bees soon after commenced lighting.

The conversation on this subject was continued for a considerable time, the chairman, Messrs. Baldwin, Zehetmayr, Garratt, Grimshaw, and Stewart, taking part therein. Some of the speakers thought that humming probably played an important part in the matter, because the humming sounds varied according to circumstances. The question as to how the humming was produced was also discussed, some submitting that the sounds were vibratory, and others that they were vocal. It was suggested at the same time that the difference in the sounds depended on the position of the cells, and whether they were emitted in a cell or not. It was generally considered that Sir John Lubbock's experiments were not

sufficiently conclusive to justify them in coming to the opinion that bees were unable to hear.

The Chairman invited Mr. Grimshaw to write a paper on the origin of the humming sounds, discussing the question as to whether they are vibratory or vocal, which Mr. Grimshaw kindly consented to do.

Mr. Henderson proposed and Mr. Garratt seconded a vote of thanks to the gentlemen who had been good enough to provide subjects for that evening's discussion, which resolution was briefly acknowledged by Mr. Grimshaw.

The proceedings terminated with a vote of thanks to the chairman, proposed by Mr. Garratt and seconded by Mr. Stewart.

DEVON AND EXETER BEE-KEEPERS' ASSOCIATION.

On Friday, January 22nd, the tenth annual meeting of the Devon and Exeter Bee-keepers' Association was held at the Guildhall, when there were present the Right Worshipful the Mayor (R. R. M. Daw, Esq.), the Sheriff (R. Ley, Esq.), Mr. W. Horton Ellis (president), the Rev. J. G. Dangar (hon. secretary), the Rev. J. Dickinson, the Rev. P. Williams, and Messrs. J. Thacker, R. P. Kitson (Torquay), J. H. Dangar, Pickings, and Cowan, Mr. and Miss Bale, and Mrs. Roberts.

The report stated that satisfactory progress had been made during the past year. An inspection of members' apiaries had been made by Mr. Baldwin, the Expert-in-Chief of the British Bee-keepers' Association, assisted by Captain Heysham, R.N. The Plymouth Show was held in connexion with the Devon Agricultural Society in May. The Tavistock Show was held on August 12th, which was the county show of the year. The report expressed the regret of the Council that Mr. Griffin is unable any longer to discharge the duties of an honorary secretary of this Society in consequence of the fact that he is now non-resident in the county of Devon, but he has consented to act on the executive as a member of the Council. Mr. Griffin's work as a bee-master, and his past services—to this Society in particular—in the cause of bee-keeping are so well known as hardly to need comment; but the Council cannot allow him to resign without testifying to the zeal, ability, and genuine *esprit de corps* which have always animated him in the discharge of his honorary duties. They have further to report with sincere regret that Captain Heysham's health necessitates his leaving the West of England for a more suitable climate.

The balance-sheet showed that at the beginning of the year there was a balance in hand of 6*l.* 3*s.* 10*d.*, whereas at the end of 1885 there was a balance in their favour of 53*l.* 13*s.* 10*d.* This, however, would be reduced by an outstanding liability to about 2*s.* The report was adopted.

It was moved and carried that Mr. Griffin and Captain Heysham should be made life members in recognition of their valuable services in the past to the Association. Mr. W. Horton Ellis was elected president with the following as vice-presidents:—The Mayor and Sheriff of Exeter, Lord Clinton, Viscountess Chetwynd, Lady Anna Maria Courtenay, and such members of Parliament for the borough and divisions of the counties as might consent to act.

The Council for the ensuing year was elected as follows:—The Rev. J. Bartlett, Mr. W. N. Griffin, Mr. P. R. Kitson, Admiral Moorman, Mr. J. Thacker, the Rev. P. Williams, the Rev. J. G. Dangar, and the Rev. J. Dickinson, with the Rev. J. G. Dangar and Mr. Griffin as the representatives to the British Bee-keepers' Association. The following were appointed local representatives:—The Rev. M. L. Gooby, Park View, Buckfastleigh; the Rev. J. R. Powell, Buckland Filleigh, Highampton; the Rev. F. T. Salmon, Gittisham Rectory, Honiton; the Rev. F. Gilbert White, Leusdown Vicar-

age, Ashburton; the Rev. J. B. Williams, Blackborough House, Cullompton; Mr. P. R. Kitson, Torquay; Mr. W. Hodgson, Colaton Raleigh, Ottery St. Mary; Mr. J. Parkhouse, Kingsbridge; and Mr. W. S. Spearman, George Street, Plymouth.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

The annual meeting of members took place at 105 Jermyn Street, on Friday last, January 29th. The Hon. and Rev. Henry Bligh presided; and there were present Messrs. Leach, Tatham, Zehetmayr, Jonas, Bedford, Neighbour, Rose, Henderson, Griffiths, and others. The report of Committee and the Treasurer's account were read and adopted. From the former it appeared that the Association has made satisfactory progress during the last twelve months, and that the list of members showed a net gain in that time of eighty-nine. The expert had made tours of the county both in spring and autumn. Bee tents had been provided at several flower-shows, and there had also been got together good exhibitions of honey, &c., at Ealing, Finchley, Harefield, Hanworth, Hampton Hill, and other places. It is proposed to send the expert again in the spring and also in the autumn of 1886, and the Committee are arranging for several lectures on practical bee-keeping to be given at various places early in the spring. The statement of accounts showed receipts amounting to 547. 7s., against an expenditure of 407. 13s. 4d., leaving a balance of cash in hand 137. 13s. 8d.

The cordial thanks of the members were voted to the Committee and retiring officers, also to the Royal Society for the Prevention of Cruelty to Animals for their kindness in allowing the use of their Board-room for this meeting and for Committee meetings. The Officers and Committee for 1886 having been elected, and representatives to the Conferences of the B. B. K. A. duly appointed, the business of the evening was brought to a close by the unanimous passing of a vote of thanks to the chairman.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of this Association took place on Saturday, January 31st, in the Mayor's Parlour, Old Town Hall, Leicester. The attendance was rather sparse, owing probably to the stormy weather; there were present:—Vice-President, K. K. B. De-la-Bere; Messrs. Carter, Walker, Foxon, Meadows, Pridmore, Bryan, Clark, Ward, Saunders, Marriott; Miss Taylor; Mrs. Ball; and the Secretary. Vice-President, K. K. B. De-la-Bere, took the Chair. The Report was adopted, and a discussion followed on 'the ways and means of paying the balance due to Treasurer;' as a means to this end it was proposed by Mr. Meadows and seconded by Mr. J. E. Saunders, 'That the Council of the Leicestershire Agricultural Society be asked to receive a deputation of two and the Secretary from the Leicestershire Bee-keepers' Association, for the purpose of submitting for their consideration a proposal to add to their annual exhibition a bee-department, as at the Royal Lincolnshire and other Agricultural Associations; and to offer prizes for bees, honey, hives, &c., and to give demonstrations in Bee-management with practical lectures;' which was carried, and selection of deputies left to the Committee.

It was also proposed by K. K. B. De-la-Bere, Esq., and seconded by Mr. Marriott, 'That the Secretary apply for subscriptions to the nobility and gentry of Leicestershire.' Carried.

The election of the Committee was then proceeded with; the following members of the late Committee being retained:—Messrs. Carter, Walker, W. S. Pridmore, L. Fosbrooke, Johnson, Ward, Rev. J. Bird, Rev. Canon Wiles, J. E. Saunders; and the

following new members added:—Messrs. Foxon, Meadows, K. K. B. De-la-Bere, and Marriott. The Secretary and Treasurer were re-elected.

It was also proposed by Mr. Meadows, and seconded by Mr. Carter, 'That Local Secretaries be appointed to assist the Hon. Secretary and make quarterly returns of their work.' Carried. Mr. Meadows then offered to act, and it was arranged that Mr. Felstead, of Remstone, Mr. Drake, of Lutterworth, and Mr. T. W. Goddard, of Donnington-le-Heath, be asked.

A suggestion that a Conversazione be held in Leicester in May was taken into consideration, and it was proposed by Mr. Carter, and seconded by Mr. Pridmore, 'That the Conversazione be held on the first Saturday in May.' Carried.

The Vice-President was obliged to leave at this stage of the business, and Mr. Walter S. Pridmore was voted to the Chair.

Mr. W. P. Meadows and the Secretary were then appointed representatives of the Association at the quarterly meetings of the B. B. K. A.

A gratuity of three guineas and a hearty vote of thanks were accorded to the Secretary; and after fixing March 13th for the next Committee Meeting, the meeting closed with usual votes of thanks.

BUCKINGHAMSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting was held at the 'George' Hotel, Aylesbury, on Thursday last, J. E. Bartlett, Esq., in the chair. The annual report of the Committee was submitted to the general meeting and unanimously adopted. The balance-sheet for the past year was also presented and passed. It is satisfactory to find that the Association is in a better financial position than it was a year ago.

The following gentlemen were appointed as the County Representatives to attend the Quarterly Conferences held in London, viz., the Rev. E. Clay and Mr. R. King. In the event of either of these gentlemen ceasing to act, the Rev. A. Newcombe or the Rev. J. Hill was appointed to fill the vacancy.

Upon the motion of the Rev. E. Clay, seconded by Mr. Pelley, the following additional rule was passed unanimously:—'That no alteration of the above rules shall take place excepting at a general meeting; and notice of such proposed alteration shall be given to the County Secretaries twenty-eight days previous to such general meeting.'

Cordial votes of thanks were passed to the President, Vice-presidents, and officers of the Association, and they were requested to continue to serve during 1886. The names of Viscount Curzon, M.P., and J. E. Bartlett, Esq., were added to the list of Vice-presidents.

A vote of thanks to the Chairman brought the meeting to a close, and subsequently the annual prize-hive drawing took place amongst those members whose subscriptions for 1886 had been received. The winners proved to be (1) the Rev. A. Barrow, Fenny Stratford; (2) Mr. J. Pollard, Tingewick; (3) Mr. W. Lowndes, Chesham.

A BEE-KEEPERS' ASSOCIATION FOR GLAMORGANSHIRE.

About the end of October, or early in November of last year, I wrote Mr. Huckle respecting the formation of an Association of Bee-keepers for this county. Mr. Huckle suggested that when about forty promises had been obtained from persons interested in the cause, and from various parts of the county, to call a general meeting and appoint a committee, &c. I followed this suggestion, and issued circular letters to as many of the bee-keepers of Glamorganshire as I could obtain the names and addresses.

Mr. Muir, of Margam, also kindly called attention to the matter in his notes published in two papers in the county. Then Mr. Davies, of Aberdare, wrote in your issue of December 15. That the subject is fully ripe and the county prepared for such an Association is shown very clearly by the numerous promises received, and the general expression of pleasure that a Society is to be started. Our first meeting is fixed for Thursday, Jan. 28th, at 2.15 p.m., in the Council Chamber, Town Hall, Neath (Neath is considered the most central). No doubt there are many bee-keepers in the county who know nothing about the effort being made to start the Association; it is therefore earnestly hoped every one interested in the cause will do what they can to spread the news, and make the first general meeting at Neath a thorough success.—E. THORNTON, *Hon. Sec. Bridgend Horticultural Society.*

[We regret that, through an oversight, the appearance of the above letter has been delayed. We have for a long time been anxious that an effective Association should be established for Glamorgan-shire, and we hope that the meeting on the 28th ult. was a great success. We shall be pleased to hear the result of the meeting. We feel assured there is no lack of earnest bee-keepers in the county. It only requires an earnest secretary to bring the scattered forces together.—ED.]

Selected Query.

[77.]—*Can you prevent swarms from issuing? if so how do you prevent them?*

In certain cases it is nearly impossible, especially when the weather is warm, and there is no large amount of honey to be gathered, as between the early and later gluts; I give plenty of room, put on sections, and cut one wing of the queen, looking in the hive every ten days or fortnight, to see that the queen is still in the hive, as on one occasion I found that she had crawled out of the hive, and been lost.—G. WALKER.

Not always, but to a great extent, say 80 per cent, by increasing size of hive and super space.—R. McNALLY.

In my experience, natural swarming should not be prevented. I have successfully practised Heddon's system, which gratifies the natural instinct of the bee for swarming, while it prevents increase in the number of colonies, if desired, and affords an abundant honey yield, especially if comb-honey be the object aimed at. There are two ways in which swarming may, to a great extent, be prevented (*a*) by the stonifying system, and (*b*) by dividing colonies. The former by doubling and redoubling when working for extracted honey. The latter by division and subdivision, if necessary; and, if increase be not desired, by uniting into large colonies in the autumn, reserving only the young queens. In this case the harvest reaped will be extracted honey taken from the back, or sides of the brood-nest.—G. RAYNOR.

By pursuing the following plan I have effectually prevented my bees from swarming for the last three years. I use long Combination hives, give abundance of ventilation and room, extract outside combs before they are completely sealed, and replacing them in brood-nest. Queen-cells *nil*, or only embryo ones, consequently no need of cutting them out. Four important factors in the prevention of swarming are (in order of precedence) Combination hives, extractor, ventilation, and room.—HENRY DOBBIE.

Not absolutely. Much depends on the breeding proclivities of the queen. The nuisance may be reduced to a minimum by careful and watchful management. There is no royal road to prevention. Excising queen-cells I do not recommend, far better let them swarm and work the swarms *à la Simons* when once they have taken the swarming mania.—AMATEUR EXPERT.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

PLANTS FLOWERING IN FEBRUARY.

[78.]—The following plants may be expected to flower in February:—Wallflower, aconites, crocus, iris, hazel, daphne, pyrus japonica, snowdrop, and furze. For difference of latitude an allowance of two to four weeks must be added between southern England and the north of Scotland.—H. DOBBIE, *Norwich.*

PRODUCTION OF WAX.

[79.]—For several years past I have been under the impression that bee-keepers were using comb foundation in many instances at a serious loss to themselves. Hitherto I have refrained from giving expression to my ideas upon the subject, considering that the matter would not be favourably received by the bee-keeping public. Our worthy editor has opened the way for discussion, and it is to be hoped that the whole thing will now be thoroughly sifted.

Year by year, though increasing more largely each season, I have used less foundation in the brood-chamber, while next season my consumption of that article for stock purposes will be almost *nil*.

Swarms returned on the original stand upon one or two (more should never be given) combs of brood, and the rest foundation, have done no better for me—and in some cases worse—than others which had starters only, instead of foundation.

Where the harvest is over, as it is in many places, by the end of July, all swarms should be returned on the parent stand with $\frac{1}{2}$ starters only, instead of full sheets of foundation; beside the one or two combs of brood, which latter will keep the queen below. In this case, instead of producing an excess of brood, the labour representing the food and attention required for the same, will of necessity be devoted to the surplus storage.

As the result of the closest observation I will state plainly, that in all districts where the honey season is of short duration, every pound of foundation used in the brood chamber after June 10th causes the bee-keeper a loss of not only nuptence, as mentioned by Mr. Sharp, p. 28, vol. xiv., but of ten times its actual value—and why? In such localities all swarming should be over by that date, whether natural or artificial, if every colony is expected to give a good result in surplus honey; and by then (if earlier the better) every stock should have its full complement of brood, on a limited number of combs. With the sections properly manipulated the brood-nest remains thus compact throughout the season, except that towards the latter part it is somewhat reduced (as it should be) by the accumulation of pollen and some little honey. Given this condition, and let the bee-keeper add but one sheet of foundation in the brood-nest, when the proper balance of population is at once overthrown, and the harvest is reduced by that amount of honey represented in feeding an extra 5000 young bees twice over, which are too late to become anything but consumers; and worse than that, there is the lost labour of those adult bees tending them, which otherwise would have

been adding to the surplus. Who shall say how many times its value that single sheet of foundation applied at the wrong time, has cost the owner?

Where one wishes to work for increase only this rule may not apply: each must judge as to what are his own requirements. It is a question, after all, whether such increase of colonies may not cost more than their worth, when it is remembered that a moderate rate of extension with less brood to feed and care for, would afford at least one hundred per cent in cash returns over and above the value of extra increase.

I have endeavoured to show how by setting a proper limit upon the use of foundation, we are taking the first great step towards the production of wax at a profit to ourselves; but there are other ways in which wax may be saved, such as I now enumerate. I do not suppose there is a single bee-keeper who does not save the cappings when extracting; but are there many who save that surplus wax which otherwise the bees waste, when reducing the combs in spring from storage thickness to the correct dimensions for receiving worker-brood? Very few there are who have realised the amount of wax lost to themselves in this way. All empty combs stored away for winter should be looked over. Consign to the wax-pot all irregular and drone combs not wanted for breeding, and with the honey-knife, nicely sharpened, slice off to the level of the frames all parts of other combs which project beyond. Much of this can be done when extracting from those combs to be laid by, and when adding combs of stores, or exchanging those outside the brood-nest to the centre, in spring, not one should escape the process. The bee-keeper cannot do better than carry around with him a small tin cylinder, with perforated bottom, to hold not less than a gallon; this again to hang in another, or a common crock, to catch the drip, leaving the wax dry and the honey or syrup for feeding. Some there may be who will say this is all too much trouble, but the methodical bee-keeper does not find that a trouble which piles up the pounds of wax—the best of wax, too—and at the same time saves the labour of his bees in shortening the cell-walls, and casting such wax out of the hive as so much refuse. Even supposing such wax was not wasted, this process should be regarded by the bee-keeper as a legitimate source of profit—much resembling the practice of plucking the down from living geese—the stock remaining to give further supplies.

There are the scrapings from frames and crates, which, like much of that from separators, edges of sections, &c., is often more wax than propolis, as during spring and summer the former article is so abundant that the bees use it in preference to searching for propolis; but when autumn comes they have little else to do than gather the more resinous substance. It must be admitted, however, that some colonies will at any time stop up every crevice with the most abominable black stuff. This seems to be an hereditary failing, and queens producing bees that behave so badly should be superseded as soon as others can be bred from such as use wax almost exclusively instead of propolis, as we have to look not only to our requirements for the wax-pot, but also to the more cleanly appearance of everything used in the hive. For all such scraps, as well as for every piece of comb found out of place, some convenient receptacle should always be at hand that nothing may be wasted.

It is considered by many that where foundation has not been supplied to swarms, much drone-comb is built, but if the one or two combs of worker-brood are given, as previously mentioned, this trouble will be reduced to a minimum.

Where old stocks are not swarmed and the increase made by nuclei, all worker-combs will be built by the latter, if judiciously fed, and at a much cheaper rate than with foundation. Again, old stocks will build none but worker-cells previous to the first honey glut. In this way,

weight for weight, we produce at least two natural combs for one sheet of foundation—six feet to the pound. The statement that twenty pounds of honey are consumed in producing one pound of wax, has of late been reduced to twelve pounds; but experiments have shown that even a less quantity of raw sugar is required to produce that amount of wax. Nevertheless, I will make no reduction in respect of that consideration, neither will I for the keep of the bees during the experiment, for they must live during such period, whether working wax or not. Now twelve pounds of raw sugar fed to obtain brood-combs previous to the honey flow, would cost two shillings, the value of six sheets of foundation; but instead of six combs built from foundation with other wax added by the bees (which is always the case), we have, at the lowest estimate, from eight to ten naturally built combs. Where, then, is the loss in doing without foundation in the brood-nest when moderate (the only profitable) increase is desired?

Under my present management, and with further experiments in comb-building to be carried out next season, I expect to do without foundation for stock purposes entirely. I am convinced that no apiary will in future be properly managed which does not produce more wax than is required for home use; and such surplus will be obtained, not at the expense of the honey crop, but in connexion with a much larger yield than has been obtained with the hitherto indiscriminate use of foundation.—S. SIMMINS.

FOUNDATION FOR SUPERS.

[80.]—For several years it was my practice when supering to feed each section with comb-foundation, the result of which, so far as rapidly filled sections go, was most satisfactory. But last year I decided to use it more sparingly, and the superiority of sections filled entirely by the bees themselves over those that are worked out from foundation is so great and so easily distinguished by consumers that, although I hope this year to get several hundred sections filled, I am determined to have nothing but the pure product of the bees, and shall therefore discontinue to use foundation—except as starters, say half inch deep.

The bee-keeper who wishes, in these highly competitive times to get a good market for his honey, must produce an article that is free from impurities and other objections. I am aware that we can get comb-foundation which is guaranteed to be made of nothing but pure bees-wax; but I am not quite sure that, if analysis were in all cases applied, the result would be universally satisfactory; but even if it was, there would still remain a very great objection to the use of foundation in supers, viz. the abominable backbone or midrim which it always forms. In fact I have often seen beautiful white sections, which to the eye are everything that could be desired, but when cut up are found to contain a sheet of foundation perfectly intact, the bees having built on to it instead of drawing it out. It may be argued that such cases are very rarely met with; but my experience is, that they are too frequent to be pleasant to either the producer or consumer of comb honey, which is, I think, calculable of doing an immense amount of injury to the honey trade—for who, having once bought such sections, will buy a second time, or recommend the article to their friends? But with sections that are filled by the bees themselves without the aid of foundation the case is altogether different. There we have something which not only looks nice but which is worthy of the name it bears, and instead of customers asking if the comb as well as the honey is good to eat, they will remark that 'there is no comb, for when you cut it, it all goes to honey,' and the purchasers of such a beautiful article do not forget to highly recommend it to their friends and acquaintances so that, although we cannot

get so much section-honey without, as with the use of, foundation, the extra custom we get through selling nothing but the genuine article more than counter-balances the loss in quantity we may sustain through not using foundation. It may be said that I have not used the right sort of foundation, with such I quite concur; nor do I think I shall yet be able to procure a foundation which when built out into comb will for eating purpose be equal to that made by the bees themselves. I have tried a great many different kinds, and my experience is, that if you have it strong enough to bear the weight of a section full of bees on a hot summer's day it is capable of, and most assuredly will, form the objectionable midrim here complained of.—A. SHARP, *The Apiary, Huntingdon.*

THE BEST HIVE. (47.)

[81.]—In the *British Bee Journal* for February 15th, 1885, a paper was published which I had previously read at a meeting of the Hunts Bee-Keepers' Association, in which I advocated a long hive to take not less than twenty frames; and I still maintain that such a hive is of all hives the most preferable. In the first place, if the bee-keeper makes his own hives, as he really ought to if he thinks of making bee-keeping pay, a hive to take twenty frames will cost only a few pence more than one to hold half that number. Thus, in using a long hive a very great saving is effected. 2. With a hive of the above description we can gradually build up our stock by adding one frame at a time until the whole number are added; but if we work on the doubling system, with hives that will take only ten frames each, this gradual building up cannot be so readily performed, only with the first ten frames. 3. With a long hive we can at any moment examine any particular frame without disturbing the remainder, but with the doubling system we are obliged to take off the top hive before the combs in the bottom one can be manipulated. 4. In doubling, a sheet of queen excluder, or a crown-board with holes in, must be placed between the two hives, either of which will incur extra expense, or the bees will join the combs in the top hive to those in the bottom one, and, when manipulating, the whole concern will be upset; and I don't know which will be the most irritated—the bees or the bee-keeper; but all this trouble and unnecessary expense is dispensed with where the long hive is used. 5. Hives for doubling are generally made with the sides level with the top of the frames, in which case there is a great difficulty in keeping on the quilt when feeding, &c., in windy weather; and, when manipulating, the bees will boil over the sides of the hive, and the chances are that the queen will be amongst them and get injured, if not entirely lost; and, when preparing such hives for winter, the extra quilts that are put on will prevent the top of the hive going in its proper place, leaving an open space for moisture to draw in, which ought always to be avoided. But with a long double-wall hive, with outer walls two inches higher than the inner ones, we are free from all the above troubles. It is true that hives for doubling can be made with outer walls the highest, but in that case the top hives have to be of such a description as to render them perfectly useless for any other purpose, and one may have fifty of these top hives on hand, not one of which can at a few minutes' notice be turned into a bottom hive. But the long twenty-frame hive can be readily converted into a twin-hive to accommodate driven bees, or to suit other emergencies. Of course the doubling system has its advantages, and, amongst other things, it is undoubtedly true that, as the heat ascends to the top hive, the honey in that chamber ripens quicker than in hives of only one storey; but I never extract until combs are sealed, consequently I never get any unripe honey.

There is also an objection raised against the long hive on account of the frames running parallel to the en-

trance; but when I find the yield of such hives less than that of hives that have the frames at right angles to entrance, I will conclude that there is something in the system adverse to the instinct of the bee; until then I shall continue to maintain that there is no hive to equal the long one.

As regards reversing, that is a system I have never tried, because I fancy I see in it the very essence of folly. If we had an unlimited market for sectional honey, and no market at all for extracted honey, reversible hives would, no doubt, be just the thing. But it is a well-known fact that the demand for run honey is several times larger than that for sections; and to go to the expense and trouble of reversing combs, involving upon the bees a lot of extra labour in transferring the honey from the bottom to top of hive, and then have to sell sectional or comb-honey for the same price, and in many cases for less than run honey, is a system which I think will never commend itself to bee-keepers generally.—A. SHARP, *The Apiary, Huntingdon.*

[82.] DRYNESS OF HIVES.—I. Mr. S. Giblett (Morecombe-lake) writes:—'I have twenty hives—my own make—and have never had any trouble from leakage; true, the roofs are not of wood, but if the subjoined description will be of any use to the gentlemen who complain, they are welcome to it. My hives are in four parts, viz., the floor-board, brood-chamber, section space, and roof. First, the floor-board fits into a rebate, on the back and sides of the brood-chamber, while the front is one inch narrower; thus the floor-board fits evenly, and all wet runs off. The floor-board projects four inches in front, and a porch the whole width of the box, with a grooved edge, carries off all wet. The section-chamber and roof are rebated $\frac{1}{2}$ in. deep, and the outer edges chamfered to make them look neat. The roof I have gable shape, covered with zinc, nailed with copper nails, and their heads all soldered over, so that they are perfectly water-tight. I provide ventilation by apertures in the gable ends, covered with wire net on the inside, $\frac{1}{8}$ in. gauge, and have seldom known the bees suffer from excessive heat in the summer. The best hive-makers cannot always ensure dryness. Wood is naturally porous, and in long spells of wet weather there is a tendency to saturate the wood, and produce dampness.'

2. Mr. Walter Willecock (Doncaster) writes:—'There are three kinds of wood generally used for making hives—pine, red, and white deal; pine or red wood are the best for the purpose; white wood is of little use, as it is a well-known fact that it will not stand, however well painted, compared with the two other kinds; it is useful for indoor work, but will not stand the weather. The most important part of a hive is the roof, which should never be made of wood broader than five inches wide; if nine or eleven inches are used without being thoroughly tested, when 'Old Sol has blazed down upon it,' as 'Amateur Expert' says, it will find out the tacks; in fact, if not shaken it will very often split them. My plan of roof-making is to use timber five inches wide, which is put into a testing-room, over 100 degrees of heat, for at least six months previous to being made up, which of course if not sound when it comes out I condemn as being unfit; I then convert it into narrow strips useful in other parts of the hive. The next part is the dryness of the hive, which is a very important part; to this I shall particularly call the attention of all who wish for a dry hive. But it must be thoroughly understood that a hive must be made in a workmanlike style to gain this point. First of all, when I am ready for painting I prepare the hive, I buy the best linseed oil raw, then give the hive a thorough soaking with it, we will say at night, in the morning it will be found to be all soaked in, then I give it another coat in twenty-four hours; after the second dose I mix 1-lb. red and $\frac{1}{2}$ -lb. white lead together with linseed oil raw until about the thickness of paint; then I give it two coats, all the better if you can afford to give the roof an extra coat, then let it stand to get thoroughly hard, then it can be painted to what colour is desirable. By preparing the hive with oil it stops the suction and feeds the grain, whereas if painted without being

prepared it draws all the oil out of the first coat and leaves nothing but the lead to remain; it will be found in time that it can be shelled, or rubbed off with the fingers even to the bare wood. But if done according to my plan it will be found impossible for any rain or moisture to penetrate through the lead. Before giving this information, when I saw the *Journal*, I made it my business to go and examine my own hives, which have never been lifted since November, and to my delight every one was as dry and comfortable as could be, so it is from my own experience that I write.'

3. Mr. Kinnaird Jenkins (Leatherhead) writes:—'The top of my hive is covered with calico and then painted with raw linseed oil, and when dry painted with two coats of good white paint. The dressing of oil prevents the enormous absorption of paint, which is, of course, very much more expensive than linseed oil. If you are in a hurry to complete the painting, boiled oil may be used in lieu of the raw, as it dries quicker.'

4. 'Mid Cornwall' writes:—'I am no carpenter, but have learned to make my own hives, as an amateur. I make them 3 feet long and 20 inches wide, of the best yellow pine, without any shakes or knots. The wood must be thoroughly dry; when worked it is $\frac{3}{4}$ of an inch, the body of hive is 11 inches deep, and the top $5\frac{1}{2}$ inches, or a plank cut in half. The joint is grooved so as to make the top and bottom fit quite tightly and fairly. The bottom is made of grooved and tongued $\frac{3}{4}$ worked plank, is halved up in the bottom of hive, and fixed quite tight, so that it cannot buckle in any way. I fix the bottoms of all my hives thoroughly tight and firm. The sides are made double-walled; the roof is made of three of my best plank of 11 inches, one on each side, and one put flat on the top, which forms a nice working table for smoker, knife, &c., when manipulating. I use no pieces on side of hive to throw in the water; my hive has a plain side. I have used such hives for three years now and have found them to keep quite dry. Of course they are kept well painted.'

RIPENING HONEY.

[83.] In the *B. B. Journal* of the 7th instant I notice the opinions of gentlemen respecting the best plan for ripening honey. Allow me to say that my views are with the Rev. George Raynor, as given in his simple eleven words. What sense can there be in taking unripe honey to give ourselves the trouble of trying to do what after all we cannot do, viz., ripen honey as ripened in the natural way by the bees; especially if the price of honey is to be knocked down to 6d. per lb., the trouble would not be worth the candle.—JOHN BOLTON, *Grantham*.

FIXING FOUNDATION.

[84.]—As it has been requested that I should furnish

a description of the contrivance, I do so now with pleasure. I think the following woodcut will clearly show the simplicity of the contrivance. First of all, we will take top bar, say $1 \times \frac{3}{8}$ inches, then get two strips of wood $\frac{3}{8} \times \frac{1}{16}$ inch wide by $\frac{1}{4}$ in. thick; chamfer down to $\frac{1}{8}$ inch. Make fast one side with fine wire-pins or brads; place the foundation against the fast side, then push the loose slip tight to the

foundation, then with about three tacks tack it down; it will be found quite secure. Then in the event of having to cut out an old comb, the side tacked down can be raised with a table-knife blade. It is then ready for a fresh insertion of foundation.—W. WILCOCK.

BEE-KEEPING IN IRELAND.

[85.] I have much to thank you for your article on the reversed skep, and the very clear and practical instructions for working it simply and cheaply. I shall get a few made, and give them to those cottagers who seem most intelligent and successful with their bees. I am leaving home for a fortnight, but on my return hope to try my hand at an improved skep for supering purposes, or the cheap production of honey for extracting. A skep-maker lives in a cottage close by, and I will get him to work from my pattern, and let you know in due time if the method is at all successful. I do not know what skeps cost in England; here a good-sized one is 1s. I hope my improved one will not be more than 1s. 9d., or 2s. at the very outside.

The only thing that discourages one is the miserable state of the country. There is little *law* or *order*. Under the circumstances, I fear it is useless to hope for very prolonged chances of usefulness to one's poorer neighbours, either in matters aparian or relating to domestic improvement. You will pardon my mentioning such a subject, but it may explain, possibly, small results, as far as this country is concerned, of the kind thought and instruction for which we are indebted to you. In our distressing uncertainty we have little heart to engage in philanthropic schemes for the benefit of our persecutors.—IRISH NOVICE.

BEE-HOUSES.

[86.] Will you allow me to make a suggestion or two on this subject, the result of my own experience?

When I began bee-keeping, I constructed a bee-house, copied from one belonging to a neighbour, greatly resembling the one depicted on the 26th page of your issue of January 21st. But in manipulation I found much inconvenience in having one row of hives above the other. To work at those on the lower shelf was a back-aching business, while those above required a pair of steps to get at them. I therefore cut the house in two laterally, and used one shelf only, placing it two feet from the ground, which I find a convenient height for all purposes. The roof is hinged on the front, and is simply a lean-to made of light wood, covered and with Craggon's felt. The back is *all doors*, opening the full length. I have, therefore, the fullest access to the hives, and at the same time perfect protection from weather. I enclose a sketch of my house, both opened and closed.

A good strong house of this kind, six feet long and 2 feet wide, and capable of holding four hives, with comfortable room for manipulation, can be made for 40s. or 50s. If the legs are set upon bricks, raised one inch from the ground, they will be kept dry, and may be made of deal two and a half inches square. My houses are seven years old, and are none the worse for wear.—SUBSCRIBER.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[47.]—*Best Hive*.—The hive in use by me is a longitudinal one, three feet without, takes twenty frames, and is worked with excluder behind nine or ten of them. These are allowed to remain as brood-nest, and the back part is filled up with frames for honey storage and ripening. Last season several hives worked in this way gave an average of 107 lbs.; some gave much more.—MID CORNWALL.

[50.]—With your permission I should like to correct a mistake in the last *British Bee Journal* of the 21st, on page 31, No. 50, with regard to the best hive for wintering and summer use. If you will refer to *B. B.*

Journal of October 1st, 1885, on page 315, in Class 12, of the Report of the Derbyshire Bee-keepers' Association annual show in September, 1885, you will find that for the best frame-hive, price not to exceed 10s. 6d., first certificate was awarded to W. Handby, Hasland, Chesterfield; the second to D. Cooper, Sunny Hill, Derby, and not the best hive as he states.—W. HANDBY, *Hasland, Chesterfield*.

[50.] *Dryness of Hives and Hive Roofs*.—D. Cooper's plan for hive roofs is one I adopted in 1881 in a hive for which I was awarded a B. B. K. A. certificate at South Kensington; but instead of inside fillets to support roof I use four screw-eyes in hive sides, which, when no papers or bottles are in use, are taken out and the cover drops down and cannot be blown off, besides making hive warmer. For three years I have covered all my roofs with $\frac{3}{4}$ rough deal board, covered with Willesden's 2-ply card—cheaper, lighter, and neater than zinc or any other material, and far less trouble. After a year's use I paint, and those made three years ago are as good as new now, and have never let in a drop of wet. The card must be put on wet and turned over the edges and nailed with $\frac{3}{4}$ tacks from below, any nailing on the top causes leakage. Most of Baldwin's Hives are fitted with the hinges described in No. 64, and a very good dodge it is.—W. E. BURKITT.

[59.] *Fixing Comb Foundation*.—Mr. Shrimpton's plan of fixing foundation is no new invention, but one brought out by E. M. Hart & Co., for which they gained a prize in the class for new inventions at Wilts County Show in 1883, only Messrs. Hart's frames required no nailing, the two sections of the top-bar morticing into the ends, which were $1\frac{1}{2}$ in. wide at top and $\frac{3}{4}$ in. at bottom: they answered very well.—W. E. BURKITT.

[67.] *Bees coming out*. (John Robb).—Keep the front of the hive shaded by a board placed in close proximity to the front, so that the sun does not shine in the entrance, and sufficiently large to prevent the entrance of the refracted light from the snow.—W. B. WEBSTER.

[68.] *Moving Honey and Syrup*.—(O. P.) Yes, if O. P. reverses his frames, but not if frames are allowed to remain in their normal position; and No. 10, to last part of his query. The stimulating food given in spring will be used by bees as fast as taken down if instructions in 'Useful Hints' are followed.—WOODLEIGH.

[69.] *Removing Syrup*.—(O. P.) Bees do not remove stored syrup or honey into supers unless it is uncapped for them, or the frames reversed; so if O. P. gently stimulates his bees five or six weeks before his honey harvest begins, he will be doing his bees a service and increasing his own chances of a larger harvest. But to begin stimulating breeding at the end of this month or early in March, and your honey flow not commencing till the third week in May, I consider a waste of energy.—WOODLEIGH.

[70.] *Storing Syrup*.—(O. P.) If the bees are fed gently, and the bottle removed before your sections are put on, how can any syrup be mixed with your honey? Of course if you put sections on and give your bees access to syrup they will store it, not otherwise.—WOODLEIGH.

[70.] *Storing Syrup*. (O. P.)—In stimulative feeding only a small quantity is allowed at one time, just sufficient to deceive the mother bee into the idea that stores are coming in; this small allowance is stopped when the supers are put on, so that there is little chance of any being stored in the supers.—W. B. WEBSTER.

[71.] *Shading Bees*.—I think your hives are not sufficiently shaded, the light is reflected into the hive from the snow. You must not shut your bees in or you will probably lose them all.—CHEMICUS.

[71.] *Shading Bees*. (R. Carter).—It is inadvisable to shut the bees in at any time, unless in a perfectly dark place, such as the wintering cellars and pits which our

American cousins use. You should so shade the hives that not only the rays of the sun are prevented from entering, but also the refracted light from the snow. This last precaution is very frequently neglected, perhaps it is so in your case. I have not lost a dozen bees on the snow this season by attending to both.—W. B. W.

[72.] *Excluder Zinc under Sections*. (T. Jenkinson).—It is not at all necessary to use excluder zinc under the sections. Your experience of such being a nuisance is quite correct. A spoilt section or two now and then being more than fully compensated for by the greater freedom with which the bees work up into the sections. Eleven or twelve frames below will give ample room for breeding, and keep the mother bee employed in her proper quarters; but the absence of drone comb below for the purpose of laying drone eggs. Allow not less than a quarter of an inch and not more than three eighths between rack and frames.—W. B. WEBSTER.

[72.] *Excluder Zinc*.—This should never be used under sections, with any other form of super it is almost a necessity. All bees hate it. I don't even use it with large supers (14 x 14 x 4), but cover the frames so as only to leave the two outside ones open to the bees. It is necessary in using sections in body of hive if placed parallel with frame, but turn them on their sides and place at right angles—in two tiers of seven each—as made for the last two years by E. M. Hart & Co., and no excluder zinc is wanted. Several of my best sections were worked in this way last year.—W. E. BURKITT.

[72.] *Excluder Zinc under Sections*.—In my opinion is a hindrance to bees working in sections, as the sections themselves form a queen-excluder, if the section crate is made to fit the sections. I have never had but one section with brood in this last three years out of eight stocks with crates on top of frames. Distance between top of frames and crate $\frac{1}{4}$ incl. —THOMAS ROSE.

[73.] *How to prevent swarms more than once*.—You may do as you propose, namely, cut out all queen-cells but one: you must be careful you leave only one, it is not at all difficult. If you have not had much experience I should work them to get the largest quantity of honey on the non-swarving principle. You will get more honey by preventing swarming altogether.—CHEMICUS.

* Some replies forwarded have been omitted, being similar in substance to those inserted.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[87.] *Dry Sugar Feeder*.—Would the cause of the bees not taking any sugar from dry sugar feeder last September be because they were not very strong or the weather cold?—HEATHER.

[88.] *Heather*.—Is there any heather in the midland counties, and whereabouts in or near Leicestershire?—HEATHER.

[89.] *Italians or Crosses*.—Is there any objection to Italians or crosses in a principally white clover district?—H.

[90.] *Carniolans or Italians*.—Which would be the more profitable of the above two races of bees, and which are the better-tempered of the two?—J. B.

[91.] *Price of Honey*.—What difference in price has there been the last season between 1-lb. and 2-lb. sections of honey?—R. T.

[92.]—Will the bees store an extra quantity of honey in the 2-lb. sections to repay the lesser price which they sell at?—R. T.

[93.]—What is the best to do with granulated sections?—R. T.

[94.] *Warmth of Manipulating Room.*—I have an extracting and manipulating house 12 × 8 by 7 feet high, gable roof. I require to warm it sufficiently to rear queens on Alley's plan; would an oil-stove be suitable?—J. E. L. G.

[95.] *Purifying Wax.*—Would any of your readers explain the process of purifying wax, and preparing it for sale or show? I have followed instructions already given in the *Journal*, but fail to produce a bright-coloured clear wax.—T. W. JONES, *Etwell, Derby, Jan. 21.*

[96.] *Material for Smokers.*—What is the best, most convenient, and quickest to light material for patent smokers?—A. P. HOWES.

[97.] *Trapping Birds.*—Can any of your readers give me information as to the best way of trapping or otherwise destroying smallbirds that are destroying my bees?—BEEB.

Echoes from the Hives.

Dorking, January 19th, 1886.—*Upward Ventilation in Winter. A Word of Encouragement.*—Let not Mr. Lyon (p. 19, 1886) be discouraged because no discussion was raised in August, 1883, on the above topic. No doubt it was read and acted upon, as a great many hints are when subscribed to by such names as S. Simmins and F. Lyon. Be not weary in writing to the *Journal*, for we shall all reap if you faint not.—W. HOLLIER.

Ongar, Essex, January 19th, 1886.—Having purchased a hive from a friend about the 15th of October, 1885, and on the 4th of January, 1886, I found to my great surprise that they were being cleared out by a stock of its own weight and strength when set up, but without the slightest disturbance or fighting going on. Weight about twenty to twenty-five pounds, which, I think, is enough to carry them through the winter.—A SUBSCRIBER.

Alfriston, Sussex, Jan. 20.—The weather here has been rather cold lately; bees flying very little. I have eight stocks—two bar-frame and six straw skeps. This is my first year to take in your *Journal*; I like it very much. Most of the bees kept about here are in straw skeps. My bees are all wintering well.—YOUNG BEEKEEPER.

Honey Cott, Weston, Leamington, 26th January.—It is now nearly a month since bees in this locality have had a chance to fly, having had several days of dark, cold, frosty, snowy and stormy weather. However, some are taking advantage of a nice change in the air to have a fly to-day. The snow is not all gone, and it looks as though we shall have some more frost and snow.—JOHN WALTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

Inquirer, Surrey.—We regret that we cannot afford the space for the list of all the bee-keepers in your county. But the Annual Report of your Association would give you considerable assistance.

RINGSTEAD.—Your suggestion has been complied with in the present number.

R. L. RICHARDSON.—*Flowers in Bloom.*—Amongst the flowers that may be expected in bloom during swarming in the north may be mentioned sycamore, horse-chestnut, apple, hawthorn, black currant, limnathes, broom, birdeherry, plum, raspberry, strawberry, &c.

WESTBURY.—*Artificial Swarming.*—By the plan you propose, unless you have a ripe queen-cell to give them, the swarm, consisting of old bees with only one frame of brood, would raise the queen. This is wrong, she should be raised in the stock. If your sight prevents your finding the queen, your better plan would be to divide the brood-combs equally, and place the two hives equidistant from the old stand, so as to divide the flying bees also. You will soon see which has the queen by the excitement of the other. You may either leave them in their then positions, or place the one containing the queen on the original stand and move the queenless to a fresh place. As this will be greatly weakened by the loss of so much brood it would be as well to place it on the stand of another stock, and move that one to a fresh stand.

M.—*Moveable Floor Boards.*—In the long hives now generally used, moveable floor-boards are not necessary, as the floor can be cleansed by pushing all the frames to the front, seraping the back part, then pushing them to the back and cleaning the front part. If you like to have it moveable you can either fit strips of wood into the space between the walls, or you may arrange to remove the packing if you please, without removing the bees, by lifting the whole hive with floor-board on to a large board or sheet, and then raising the hive body leaving the floor and the packing on the sheet.

CORRECTION.—In our list of candidates who gained second-class certificates the name of S. Pridmore is given instead of W. S. Pridmore, Hinckley.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

FEBRUARY 11, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

PRESENT AND FUTURE PROSPECTS OF APICULTURE.

It is well in these days of apparent depression in apiculture and diminution in the value of honey to pause and consider the reason of this revolution: and, having discovered the cause, endeavour, with renewed vigour and determination, to eradicate the evil. We are told on all sides that, with agriculture at such a low ebb, and all other branches of industry suffering around us, we cannot expect that bee-culture should be in the ascendant. Foreign competition and free trade have had somewhat to do with the present condition of bee-keeping, but, as will be pointed out, the obstacle is apparent, and can be grappled with. Taking a retrospect of bee-keeping for the past two hundred years, we find that bees, with but few exceptions, have been kept in one way, now styled the 'old-fashioned system.' When the ordinary domicile was a straw skep, and suffocation at the end of the season was in vogue, thousands of stocks were then annually destroyed, and the quantity of honey was never very great. With the nineteenth century opened the dawn of advanced apiculture, followed by better-constructed hives, improvement of supers, extractors, feeders, foundation, and numerous other appliances. A new era arose when the *British Bee Journal* was established, and since then there has been a constant onflow of leaflets and cheap publications inculcating the facilities and proving the advantages of bee-keeping. Immediately following the publication of the *Journal* was instituted the British Bee-keepers' Association, supported by numerous clergymen and other earnest men who had the real welfare of their fellow-creatures at heart. Then followed the establishment of the Lincolnshire, the Devon and Exeter, and a host of county Associations. Bee exhibitions were inaugurated, bee-tents visited each town, and even every village in the kingdom. Every English county has been canvassed, Scotland and Ireland have been visited. Experts have shown a laudable ambition to possess certificates in accordance with their respective abilities. And thus a new industry has been proclaimed—an industry which could be conducted by either sex—an industry which would add to the working-man's income, and bring hope and joy to many a poor man's hearth. What wonder, then, that many have embarked in this industry with the hope that good results would follow and fair returns be produced? Naturally, with these benefits brought home to the very doors of the community, bee-keeping revived

and spread with wonderful rapidity. It has extended not only through the whole of the United Kingdom, but to the most remote corners of the globe, and we can see monthly, through the kindness of Mr. Bellairs, the large importations of honey into this country.

What is doing the British bee-keepers for a time so great an injury is without doubt the adulteration of honey and the manufacture of a spurious article, large quantities of which, imported from Switzerland and America, have been palmed off to the public under the guise of honey: and people, because they can get it at a low price, are content to purchase it, innocent of the various concoctions of which it is composed. A quotation from an article that has been already alluded to in our columns, from the *Medical Press*, will illustrate what is going on in our midst:—

'The [manufactured] comb is filled with a better kind of treacle sold as "golden syrup," the sides of the skeleton frame enclosing the comb are covered in the usual way with glass, and to the eye of the purchaser cannot be distinguished from the genuine article. Of course it is offered to the unwary customer at a reduced price; but for all that the sophistication, or falsification, is, to say the least of it, a very improper one, although it may not in this instance be injurious to health.

'The falsification and adulteration of honey is carried on in an unusually barefaced manner. Large quantities of what is sold as honey is nothing more or less than clarified treacle and simple syrup, worth about 2d. per lb. Glass jars are exposed for sale labelled "New Honey," the only portion of which taken from the bee-hive is the piece of honeycomb occupying the centre, and from which the honey has been previously extracted by the process referred to above.'

The blame, however, does not rest so much with those that sell the articles thus described, as with the public. Do away with the demand, and the supply of such compounds must, as a natural consequence, cease. After such a bountiful harvest as the last, with so much pure honey, and a still greater quantity of adulterated compound bearing the name of honey in the market, can it be wondered at that the lawful industry has received somewhat of a check, that many apiarians are disheartened, and that we hear whispers in some quarters that the work of the various Associations is drawing to a close? This is certainly looking at it from a very gloomy point of view. We cannot but admit that apiculture does not appear so remunerative just at present, but the remedy seems within our reach, and there is hope for a much brighter future for our treasured industry. If there is such a demand for so-called honey, it is evident that there is a large scope for the production and sale of good British honey. The public have to be educated as to what pure honey is, it therefore devolves on us all to let them know what they are eating under the guise of honey. Let the desponding take heart and hope for an increasing and steady sale, and a growing demand, for all the honey

that can be produced in the British Isles; prices will go up, and there will still be left ample work for all.

If our voice could reach the ears of foreign importers we would counsel them to 'pause' before they venture to send to us further consignments of their superabundant honey. There are evidences abroad, clear and distinct, which show that the importation of foreign honey has been overdone. The importers have not been so successful this year in finding a market for their honey as in previous years; quantities still lying, unsold and unmarketed, in the docks. A few months ago there was a letter in the *American Gleanings* to the same effect from a gentleman in Cambridgeshire, who, in assuring Mr. Root of the safe arrival of some honey he had instructed him to send to him, informed him that in consequence of the cheap rate at which good British honey might be purchased in this country, there would in future be little necessity for procuring it from abroad. It would thus appear that, provided we are favoured with a good harvest during the present year, and bee-keepers proceed in their work with earnestness, importers may find it to their interest not to flood the country with foreign honey.

It would be very desirable for the encouragement of those farmers who are establishing bee-farms to see some comparative statement of the profits arising from bee-keeping and those of other minor industries. In our own mind, we feel assured that bee-keeping would be proved to be one of the most profitable of rural pursuits. In the annual report of the Devon and Exeter British Bee-keepers' Association, we note a report from one of the district secretaries, Rev. B. Powell, of Buckland Filleigh, who states: 'My bees have paid me more than five Alderney cows' butter and milk have done this year. I have planted eight acres of Alsike clover for my bees, from which I hope to get at least 12, an acre in honey, while the clover will be used for my stock.'

There is then, we consider, much to cheer the British bee-keeper in the steady and earnest pursuit of his calling.

JOTTINGS BY THE WAY.

During the month of January the Bucks Association collected nearly three hundred subscriptions for the year 1886. Agricultural depression prevails in Bucks as in other counties, and by its side exists one of the most perfect district organizations possessed by any County Bee-keepers' Association in the United Kingdom.

The Royal Agricultural Show of 1887 will be held at Newcastle-on-Tyne. Bee-keepers in the North will please note this.

A Reading Book on the subject of Bees and Bee-keeping, by the Rev. F. G. Jenyns, for use in schools, is now in the printer's hands, and will shortly be issued. The work has been revised by the Educational Committee of the B. B. K. A. The introduction has been written by the Baroness Burdett-Coutts.

It has been resolved that the certificates granted to experts by the B. B. K. A. shall contain an explanation of the requirements for each class. Holders of third-class certificates will gain considerably by this arrangement, being described as skilful in the management of bees. We are informed that the skill displayed by a lady in a recent examination led to this step being taken.

We have received from Messrs. Green, Rainham, two samples of reversible frames, which are simple and effective, and not liable to get out of order. One can easily be applied to Standard frames already in use by cutting off the projecting end of the top bar, and putting a small screw in the centre of the frame end or side. It is quickly taken off for extracting, &c. if required; but when manipulating it is kept firm by a wire

nail pushed in the upper angle. The other has some advantages over the first, and may be preferred by those starting with new frames, but the bottom bar must be of the same thickness ($\frac{3}{8}$) as the top bar.

We have also received from the same firm a moveable metal-end or distance block, which dispenses with any cutting of the top bar, and is at the same time interchangeable with Standard frames.

Mr. J. Perry, of Banbury, forwards a sample of his reversible frame, which is similar in idea to the frame figured in page 382, second column, in last volume, the end revolving from a screw in the middle of side-bar—an idea which commends itself by its great simplicity. Being broad-shouldered it can be worked with any other frame or hive. The top and bottom bar are $\frac{3}{8}$ thick; there is little room lost by this divergence from the size of the Standard frame. Mr. Perry guarantees that the ends will bear the weight of eighteen pounds.

We have frequently been urged to devote a portion of our columns to amateur hive-making. With this request we have now much pleasure in complying. In the present number (p. 59) will be found the commencement of some instructions in that direction, by a gentleman of great experience, and who, in February, 1881, read a paper before the British Bee-keepers' Association on 'Cheap Bar-frame Hives for Cottagers' use,' which we trust will be acceptable to our readers, and will assist them in their labours. Conjointly with this, as an aid to those who are about to manufacture a number of hives, we might direct the attention of such to the excellent properties of Markall's saw-bench, a representation of which is to be seen in the advertisement of the Messrs. Abbott. By the aid of these benches these manufacturers turn out every year hundreds of hives; and through their excellence they have attained a high character for their workmanship. The machine, we believe, was the outcome of many years' experience of a practical joiner, who so succeeded in perfecting it that its work, usually done by hand, can be effected at one-fifth of the ordinary cost. Six first-class medals were secured by the patentee, and the verdict of the *Builders' Circular*, in 1871, was, 'that in manual-power machines there is nothing to compare with Markall's, and that it is a great favourite in London joiners' shops.' We have no doubt that Messrs. Abbott, who have several of these machines in operation, would feel a pleasure in explaining them should manufacturers of hives favour them with a visit.

The above engravings illustrate improvements in moveable metal-ends brought under our notice by Mr. Alfred Neighbour. One block shows the front view and the other the back. The improvements claimed are that no cutting of the wood is required to adapt them to the frame, and the ends are held firm by knife-cutting projections on either side, and at the same time they can be easily separated from the frame when desired.

Although in America no contrivance is used to adjust the frames of comb and keep them the correct distances apart, it is common in this country to have either metal-ends or broad-shouldered frames, which answer the same purpose. Not unfrequently in the course of handling much convenience is found in being able to gently push several frames of combs bodily from one side of the hive to the other without danger of injury.

It is thought by some bee-keepers that bees are less likely to propolise metal than wood, and, if they should

attempt so to fix them, the dislodgment is more easily effected by using the former.

Mr. Neighbour informs us that his firm first introduced their improved metal-ends in December, 1884, and adapted them to their hives during last year when they were exhibited at the Inventions Exhibition. Further improvements have, however, been made this year by having the ends more solidly cast, so that the complaint of the metal sometimes yielding to pressure, and bending when pushed on to the bars, is entirely obviated.

INTRODUCING QUEENS.—MR. BENTON'S METHOD.

It is advisable to select always, when about to introduce a valuable queen, a stock of bees which is in a perfectly normal condition, and in prime order, that is, has a good laying queen, brood in all stages, honey, pollen, and plenty of young bees. I remove the reigning queen, and at once cage the imported queen in a pipe-cover cage such as is here illustrated, being careful to put

DIRECTIONS FOR MAKING.—Use wire-cloth having ten to twelve meshes to the inch. Cut a piece 2 in. wide by 1 1/2 in. long, roll it around a stick to give it a cylindrical form, lap the edges, and sew with a piece of wire. Then in one end of this cylinder make slits 1/2 in.

Queen-Introducing Cage.

apart and 1/2 in. deep, and bend over the wire-cloth so as to close this end of the cage. With the flat end of a pencil press warm wax or comb into the bottom inside of cage, it firmness then unravel five or six strains of the wire-cloth at the other end.

the latter over cells of honey, near the centre of the cluster of bees, so the queen will surely be kept warm and get food during her imprisonment. I usually put into the cage as companion-bees five or six just-hatched workers, taken from the hive to which the queen is to be introduced. The cage is pressed into the comb until the points reach the bases of the cells; and it is essential to place this comb in the hive in such a manner that the end of the cage will press against the adjoining comb, lest the bees by clustering on it pull it out by their own weight. On the following day, just about sundown, the queen is to be released, provided upon opening the hive the workers are not packed densely about the cage, trying to sting her through it. In the latter case, she may be left caged twenty-four, or even forty-eight hours longer. But, if left this length of time, it is necessary to look for newly-formed queen-cells, and destroy them before releasing the queen. It is best in all these manipulations to use a little smoke. Upon freeing the queen, drizzle diluted honey or sweetened water over the combs and bees. The queen may also be daubed with honey at the moment she leaves the cage. The combs are then to be replaced, and the entrance of the hive contracted so but one or two bees can pass in or out at the same time. It will be well not to touch the hive for two or three days thereafter, as the bees may attack the queen if the hive is opened before they are thoroughly accustomed to her.

The conditions necessary to success in introducing queens are complied with by the above plan, namely: The bees are queenless long enough to have become fully aware of the fact, yet not long enough to have started queen-cells; the strange queen is caged long enough to acquire the peculiar odour of the hive to which she is to be given; the bees are all at home when the queen is released, and thus all get thoroughly gorged with food and are well disposed towards the new queen. No robbers come about, and by morning all is in order. —FRANK BENTON, *Bees*.

ASSOCIATIONS.

THE BRITISH BEE-KEEPERS' ASSOCIATION.

The annual general meeting of the members will be held at 105 Jermyn Street, on Wednesday next, 17th inst., commencing at 3 o'clock. The chair will be taken by the President of the Association, the Baroness Burdett-Coutts.

The agenda contain some important motions for discussion.

Mr. Jesse Garratt will move a resolution in favour of an extension of the prize list in the bee department of the Royal Agricultural Show.

The Rev. E. Clay will call attention to the desirability of the Association holding a thoroughly representative exhibition of English bee-keeping during the present year.

Two resolutions will be submitted in reference to the election of the Committee and the filling up of any vacancies that may occur during the year.

It is hoped that every member of the Association who can attend the meeting will do so, and thus evince their interest in the Association's work.

NORTHAMPTONSHIRE BEE-KEEPERS' ASSOCIATION.

The Annual Meeting of the Northamptonshire Bee-keepers' Association was held in the Infants' Schoolroom at All Saints' Schools on Saturday, the 30th ult., when Mr. A. T. Adams (Crick) presided. The minutes of the last meeting having been read and signed, the balance-sheet for the past year was read by the Treasurer. Before doing so, he said it would be found that they were in a better position than they were a year or so ago. Although the Association was not in so satisfactory a state as he would have liked, still they were able to reduce some of the old liabilities. They had worked the expenses as low as possible. The receipts had amounted to 31l. 15s. 5d., and the expenditure to 32l. 7s. 9½d., leaving a balance due to the Treasurer of 12s. 4½d. The officers for the ensuing year were then elected as follows:—President, His Grace the Duke of Grafton, K.G., Secretary, Mr. J. E. L. Gilbert, Treasurer, Mr. J. Francis, Committee: Rev. A. W. W. Durham, Messrs. Adams, Hefford, Lines, Perry, Rooke, Cherry, T. Adams, Wood, Longland, Stimpson, and Manger. A vote of thanks having been passed for the use of the room the meeting terminated.

HEREFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of the Association was held on Monday, February 1, at Howlett's Hotel, Hereford, under the presidency of Dr. Chapman. There was a fair attendance of members. The hon. secretary, Mr. Alfred Watkins, read the annual report, and the reports of the experts, Messrs. Hole and Meadham. From the annual report we learn that the season has been a favourable one for the bee-keeping industry; and it is satisfactory to have to record a most plentiful harvest, many members having reported average yields of 50 lbs. to 60 lbs. of honey per hive, in one case from as many as thirty-one hives. Lectures on bee-keeping were given in the spring at Almeley, Marden, and Much Dewchurch, by the hon. secretary, with satisfactory attendances and results. A most successful exhibition of hives and honey was organized by the bee-keepers of Ross in connexion with the Horticultural Show. The Hereford Honey Fair and Hive Show was held at the Corn Ex-

change on Saturday, August 29th. About 6000 lbs. of honey were staged; 1624 lbs. of honey were sold at about 2d. per lb. lower price than in previous years. The quality was not quite as good as usual, being in many cases contaminated with honey dew. Thirty-two new members have joined during the year, and the members now stand at about 200. The experts' reports of their tours were very satisfactory. The report and the balance-sheet were adopted. From the balance-sheet it appears that the Association has in hand 25*l*. An interesting discussion took place as to the comparative value of the flat-topped hive and the bar-frame hive to cottagers. The meeting then proceeded to the election of officers. Mr. J. Rankin, of Bryngwyn, was re-elected president, and Mr. E. Hammond, Leominster, and Mr. W. T. Lawrence, Hereford, were substituted for Mr. J. H. Harper and Mr. L. Tilley on the committee. The officers were re-elected *en bloc*. A discussion arose as to the best market for the honey that was produced in the county in such large quantities, the hon. secretary advocated the display of advertisement posters, announcing that English honey was produced largely in the neighbourhood, and could be obtained from the owners or from any grocers. The proceedings terminated with the drawing for a prize bar-frame hive, which fell to Mr. W. Tomkins, Burghill.

GLAMORGANSHIRE BEE-KEEPERS' ASSOCIATION.

The above has at last been established. At a meeting held at the Town Hall, Neath, on Thursday, the 28th ultimo, under the presidency of the Rev. H. P. Williamson, Vicar of Margom, it was unanimously resolved, 'That an Association be formed for the county.' The meeting, convened by Mr. E. Thornton of Bridgend, was not numerically a success, but in every other sense it was. Mr. Thornton reported that he had received replies from a great many of the bee-keepers promising to join; and there is no doubt, judging from the enthusiasm displayed by those present, representing nearly every district in the county, that, although slow on being formed, the Glamorganshire Bee-keepers' Association will flourish, and do a vast amount of good among those it is intended to benefit. The Lord-Lieutenant is to be asked to become its first President, and a number of the county gentlemen Vice-Presidents. Mr. Thornton was appointed Secretary, and the following gentlemen acting Committee:—Revs. H. P. Williamson, Margom; Jones, Handough Rectory; S. Nichol, Cowbridge; Thomas, Dyffryn; Messrs. Lanford, Neath; W. Gay, Cardiff; J. Muir, Margom; Jones, Neath; G. E. Pyle, Aberdare; D. P. Davies, Aberdare; Gibbin, Neath; Hawkins, Ewenny; W. Mitchell, Swansea; H. Meagher, Numbles; and Singer, Bridgend. The subscription was fixed at 5*s*., 2*s*. 6*d*., and 1*s*., according to class.—D. P. D.

DERBYSIRE BEE-KEEPERS' ASSOCIATION.

Might I suggest through the *B. B. J.* to the Secretary of the Derbyshire B. K. A. that an account of the General Meeting of our Association, which took place about three weeks since, if published in the *B. B. J.*, would be very interesting to us outside members who could not attend.—HIGH PEAK.

SWANMORE BEE-KEEPERS' SOCIETY.

At a special meeting of the members of the above Society held at Swanmore Vicarage on Friday evening, January the 29th, present: the Rev. W. E. Medlicott, in the chair; E. H. Bellairs, Esq., Hon. Sec. H. & I. W., B. K. A.; the Rev. R. Parker, Miss F. Cockburn, Miss Medlicott, Miss Martin, Mr. E. Molyneux, Mr. C. Martin, Mr. E. Ainsley, Mr. G. Horner, Mr. T. Sharpe, Mr. C.

Selfe, and Mr. H. W. West, Hon. Sec. It was resolved unanimously that to prevent an impression growing that this Society is working in antagonism to the Hants and I. W. B. K. A., the Swanmore Bee-keepers' Society should be properly affiliated to the Hants and Isle of Wight Bee-keepers' Association, and that its title should be altered to the Hants and I. W. B. K. A. 'Swanmore Branch.' It was proposed by E. H. Bellairs, Esq., that the funds of the Swanmore Branch should pass into the hands of the county treasurer, with power to the committee of the Swanmore Branch to demand grants (all but a fixed per-centage) to the same amount for local purposes. This was seconded by Mr. C. Martin, and carried unanimously. The Branch now numbers nearly seventy members, and is in a flourishing condition.—H. W. WEST, *Swanmore House, Bishops Waltham, Hants.*

Selected Query.

[98.]—Which in your opinion are the best bees for producing honey?

I am strongly in favour of the first cross between a Ligurian queen and a black drone. I find this strain better than pure Ligurians. As to Ligurians I find a very great difference exists, which I can only suppose, as I do not import them myself, arises from the district in which they are produced. I have generally found small queens produce better workers than those very fine and handsome ones. For spiteful bees I can recommend the progeny of black queens crossed with Ligurian drones. The other cross are in my experience nearly as gentle as the pure race.—F. LYON.

The first cross between Ligurians and blacks.—J. L. SEAGER.

Cyprians.—SAMUEL SIMMINS.

The best bees for producing honey and every other purpose are the pure Ligurians or Italian Alp bees (*Apis ligustica*). As they are, if pure, so enormously prolific, and it was their hardness and great industry that made me go in for them in 1862. I happened to go to the Great Exhibition held in London in 1862 on a cold wet day, and my hobby being bees I went at once to the Agricultural department, where Messrs. Neighbour exhibited a stock of Ligurian bees, and close to him Mr. Marriott exhibited a very strong stock of black bees. The Ligurians were quite busy at work, coming in loaded, when there was not a black bee going out. I went to the Exhibition on several other wet cold days to see this sight. I said to myself, the Ligurians are good workers, whatever they are besides, so I at once went in for them.—WILLIAM CARR.

Our native bees I believe to be fully equal, if not superior, to any distinct race of foreign bees as honey-gatherers. As a cross breed I prefer the Ligurian with our native bees; they are excellent breeders and very even, pleasant to manipulate, and capital workers. I have generally had good results from such cross. The Ligurian and the Carniolan, as a distinct race of foreign bees, are, I consider, those best worth cultivating as honey-gatherers.—R. R. GODFREY.

Cross-bred bees are best honey-gatherers. A cross between English, Italian, and Carniolan, would produce the best progeny. You then have hardness, prolificness, and docility combined.—A. NEIGHBOUR.

Some bees are best for producing honey in frames for extraction, whilst others are best for comb honey. Carniolans are the most *gentle* bees of all to handle. They work very hard, are good comb-builders, and very prolific, but they are inclined to swarm very freely indeed. The *pure* Italians are very handsome and *gentle*, and if *quietly* handled, stick to the combs, and take little notice of what is being done. They are good

workers, early and late, and for producing *extracted* honey where a large number of frames are used in story-fying, are the best. They are very delicate, more subject to 'spring dwindling' and loss of queens than black bees. The dark, leather-coloured Italian queens I obtained from 'Paglia' at the Kilburn Show, were the hardiest and best bees of this kind I ever had. Black bees are the best for storing comb honey in supers or sections; they are hardy, the best comb-builders, take to the supers more readily than most kinds, and are less liable to swarm if they have sufficient section room given them. They fill the sections with beautifully-sealed straight combs, of uniform and delicate colour, better than any other kind of bees, so far as my experience goes. Hybrids, between Italians and blacks, are very much harder than pure Italians. They are very prolific, good workers, are, as a rule, very bad-tempered, but for those who are not timid whilst handling them, they are, perhaps, the best for both comb and extracted honey.—JOHN M. HOOKER.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

AMATEUR HIVE-MAKING.

[99].—In the following remarks I purpose giving such instructions as may enable an amateur to make a good serviceable hive. I purposely abstain from any details which will need tools not always in the possession of amateurs, such as are required for tonguing, grooving, rebating, &c. All the dimensions given are those when finished, and if strictly adhered to, the hive will be easy of manipulation, the necessary clearances to allow easy play being allowed. Before commencing work let all your tools be sharp and in good order. As you proceed, let every piece be accurately squared at the ends, and the edges shot true and square, otherwise you may find when nailed that the whole affair 'winds' and no part will fit another properly.

The hive I recommend for general utility is that known as a Combination hive having a long body, provided with an entrance and porch at each end, and an entrance (E, Figs. 1 and 2) at one side which may be

Fig. 1.

opened when required, and a temporary porch and alighting-board attached. The frames run across, i.e., parallel with the front. It has a 2-inch space between

the double walls filled with cork-dust. It may be worked as a single, twin, or triple hive; sections may be worked at the back or on the top of the frames.

Frames for extracting may be worked at the back, feeding may be performed either at back or on top. The roof case C is deep enough to contain a rack of sections or a feeder; and if tiering up is desired, it may be raised by the addition of the lift B, which will also give height enough for a box of frames for doubling. The walls are outside the floor-board, and the roof-case, when the lift is away, comes outside the

Fig. 2.

walls. The roof-cover, which is made separate for ease in lifting off when it is not required to remove the whole roof, has a deep flange all round, and is made perfectly waterproof, as will be described, so that no wet can possibly enter. The only plinths used are on the lift, which is of course only required in summer time. The dimensions inside are $14\frac{1}{2}'' \times 8\frac{1}{2}'' \times 30''$. The two former are, of course, fixed, but the length may be increased or decreased as desired. It is a simple matter of addition or subtraction of the necessary inches. Thirty inches, however, will be found a useful size, as it gives space at the back for spare tackle, such as feeders, dividers, frames, &c., which will be found a convenience.

The wood used may be either pine, yellow deal, or white deal, which are to be recommended in the order named. Whatever wood is used let it be well seasoned. The thickness for the sides is '4-cut,' i.e., four cuts out of a 3-inch deal, which will therefore yield five boards about half an inch thick when planed. For the ends, into which the sides are nailed, use '3-cut,' which will give four boards, about $\frac{5}{8}$ thick when planed, to the 3-inch deal. If not fond of hard work with little to show for it, get the wood planed for you, but run your smooth plane over it yourself. Although planing on both sides when one side is hidden is not necessary for appearance, yet it is better, as if planed one side only and not nailed together at once, the wood curls, the planed side becoming concave, giving some trouble in nailing. For the inner walls 9-inch stuff is wide enough, for the outer walls the boards must be cut out of 11-inch plank.

Each hive will require as follows:—

Inside Walls.—F 1 and 2, two pieces, each $30'' \times 8\frac{1}{2}'' \times \frac{1}{2}''$, one edge chamfered off to $\frac{1}{4}''$. F 1 to have a piece $4'' \times \frac{3}{8}''$ cut out of the lower edge to form E, Fig. 1 and 2.

Ends.—G 1 and 2, two pieces, $19\frac{1}{2}'' \times 10'' \times \frac{5}{8}''$. From one edge of each cut an entrance $8\frac{1}{2}'' \times \frac{3}{8}''$.

Outside Walls.—H 1 and 2, two pieces, $39\frac{1}{2}'' \times 11'' \times \frac{1}{2}''$, shaped as Fig. 3. H 1 to have a hole $4'' \times \frac{3}{8}''$, cut one inch from lower edge.

Fig. 3.

Corners.—J 1, 2, 3, 4, four pieces, $7\frac{1}{2}'' \times 2'' \times \frac{5}{8}''$.

Floor.—39'' \times $19\frac{1}{2}'' \times \frac{1}{2}''$, made of two pieces 9'', and two pieces 11'', jointed, glued, and battened with two

battens, $2'' \times \frac{5}{8}''$. After glueing, allow the floor to rest in a warm place for a few days to shrink, if it will, before battening; this will prevent any future opening.

Two strips, K, $30'' \times 2'' \times \frac{1}{2}''$ will be required to lay over the cork-dust between the inner walls, and two pieces, L 1 and 2, $20\frac{1}{2}'' \times 6'' \times \frac{1}{8}''$, chamfered, as shown in section Fig. 1, to nail on to the projecting ends of H 1 and 2, to form the porches.

Dividers.—Two pieces, $13'' \times 8\frac{1}{2}'' \times \frac{5}{8}''$, each having nailed to each end a strip $8\frac{1}{2}'' \times \frac{7}{8}'' \times \frac{5}{8}''$. Punch down the nails and plane down to *exactly* $14\frac{1}{2}''$. Along one edge nail a piece $17'' \times \frac{5}{8}'' \times \frac{1}{2}''$, and out of the other edge cut a piece $4'' \times \frac{3}{8}''$, and replace it with a French nail or screw, on which it can turn. See Fig. 4.

Fig. 4.

To build the hive.—Lay G 1 on the bench, nail J 1 along one end. See Fig. 5. Place F 1 on end on G 1, with chamfered side towards J 1 and nail to J 1. Lay a divider, made exact as above, against F 1. Lay F 2 against it, chamfered side out. Lay J 2 against F 2, and nail to G 1. Now take away the divider and nail F 2 to J 2, by this means you ensure the important dimension of $14\frac{1}{2}''$ between F 1 and F 2 being correct. Proceed in the same manner with the other ends of F 1 and 2, using J 3 and 4 and G 2. It is as well to just temporarily nail J 1, 2, 3, 4, to G 1 and 2 with a couple of nails, and nail from outside of G through J and clench the nails inside.

Fig. 5.

Nail H 1 and 2 to the ends of G 1 and 2; but note that, as shown in Fig. 5, while the bottom edges of F, J, and G, are flush, the top edges of H and G are flush, and as H are $11''$ and G only $10''$ a $1''$ overlap is formed to come outside the floor-board. Do not forget to bring the entrances E on same side in nailing. They form the entrance for use as a triple hive, as shown in Fig. 2. A little bridge must be made over it to keep the cork-dust in, and a piece of wood planed up to fit it as a plug when not required for use.

Now fit the floor-board, which may be either fixed or not as preferred. Nail L 1 and 2 on to the projecting ends of H, and the body of the hive is complete.—F. L.

(To be continued.)

DRONES AND THEIR USES.

A PROTEST AGAINST THE PRINCE CONSORT THEORY.

[100.] According to the prince-consort theory, the drones or male bees are produced on the approach of the swarming season with the object of providing consorts amongst them for the young queens then hatching, and after the accomplishment of this are killed or expelled as useless encumbrances from all hives possessing a laying queen.

Certainly this provision of consorts is *one* and an *important* service performed by the drones, but I cannot agree with the supporters of this theory in regarding it as the *only*, or (with a few exceptions) as more than an *incidental* service. Nobody will deny that in discouraging drone-breeding we are completely at variance with the wishes of the bees themselves. In fact, one of the objects of giving comb-foundation is to limit or prevent the production of drone-comb and brood, as every colony of bees will rear some drones each summer when they have the opportunity afforded them.

Some of the older authorities give the proportion of drones as about ten per cent. I cannot vouch for the correctness of this statement myself, but should expect to find the proportion varying from week to week. I should expect it to be greatest during the earlier portion of the honey harvest, and decreasing with the contraction of the brood-nest towards its close. I should also expect to find fewer drones in a hive containing a large proportion of newly-hatched or nurse bees than in one in which the proportion of foragers was greater.

From my colonies all being in bar-frame hives, the bees are under somewhat unnatural conditions. I should therefore esteem it a great favour and assistance if some of my readers would kindly favour me with the following particulars:—1. The usual position of drone-comb in skeps. 2. The relative proportions of (a) drones, (b) brood, and (c) comb in skeps as compared with worker ditto. 3. A comparison between the work done by hives containing (a) many, and those with (b) few, or (c) no drones.

As there is a general consensus of opinion among bee-keepers that a queen only mates once in her life, and that the result is death of the bridegroom, I propose to assume the correctness of this view in my inquiry. There are three classes in the hive, and I venture to submit that these do not all three look at the question in the same light.

On this theory, then, from the drone's point of view, the result of his honeymoon is eminently unsatisfactory, inasmuch as it means suicide. I think, therefore, that it would have been more to his own interest had he remained a bachelor. As the male, however, has the credit of being the wooer amongst the generality of animals, I do not deny that their mutual jealousy and competition for the royal favour might be sufficient to cause some drones to rush upon their fate even did they foresee the result. Still, this does not alter the fact that the successful suitor has only secured his own destruction, which seems to me to condemn this theory, as seen from the drone's standpoint. From the queen's point of view the theory (as might be expected) has more to recommend it at first sight. The greater the number of suitors, the greater is her range of choice, and the more precious does the royal favour become.

But when we come to assess the results by this theory, whether we adopt the views of the drone, queen, worker, or of the whole family generally, we find ourselves upon the horns of a dilemma, and a most serious one, too. Suppose the queen has mated with a drone from her own hive—that is, with her own brother—we have in-breeding in one of its most aggravated forms; and we have yet to find the animal or plant in which this does not mean degeneration of the progeny. So far as I can learn, this rule holds good throughout the whole world of life, from man downwards. The only exception I know is when it is a case of Hobson's choice, 'that or none.'

Supposing we take the other horn of our dilemma, we shall find it even more awkward, for if the queen mate with a strange drone, then, according to the prince-consort theory, her brothers are absolutely useless to the hive that reared them. Their mating with strange queens *may* be even prejudicial to their own hive, as merely increasing the competition, or, in other words, intensifying the struggle for existence. That in the great majority of instances the queen, as might be expected, mates with strange drones, I have ample evidence to produce if required. I can not only quote a case from my own apiary, in which the evidence is nearly, if not quite, sufficient to convict the culprits, if tried in a court of justice; but I can also quote Cheshire, Cowan, Woodbury, and others, as taking precautions against it, besides referring to Darwin and the evidence he has collected.—A STUDENT.

(To be continued.)

HOW BEES FIND THEIR WAY.

[101.]—Sir John Lubbock, in the *Contemporary Review* of November last, gives some 'recent observations on the habits of ants, bees, and wasps,' and, dealing in the first place with the instincts and powers of bees to find their way back after having been carried to a distance from home, observes that 'that this has by some been attributed to the possession of a special "sense of direction."' And, after alluding to Mr. Darwin's suggestion, that if animals were put into a box, and this box made to revolve, first one way and then another, this 'sense of direction' would be lost, he says, 'In parts of France it is considered that if a cat is carried from one house to another in a bag, and the bag is whirled round and round, the cat loses her direction, and cannot return to her old home.'

Sir J. Lubbock then relates some 'interesting and amusing' experiments made by M. Fabre:—

'He took ten bees, marked them in the usual manner with a spot of white, and put them in a bag. He then carried them half a kilometre in one direction, stopping at a point where a cross stands by the wayside, and whirled the bag rapidly round his head. While he was doing so a good woman came by, who was not a little surprised to find the aged professor standing in front of the cross solemnly whirling a bag round his head, and M. Fabre fears, strongly suspected him of some satanic practice. However, this may be, having sufficiently whirled his bees, M. Fabre started off back in the opposite direction, and carried his prisoners to a distance from their home of three kilometres. Here he again whirled them round, and then let them go one by one. They made one or two turns round him, and then flew off in the direction of home. In the meanwhile his daughter, Antonia, was on the watch. The first bee did the mile and three-quarters in a quarter of an hour. Some hours after two more returned; the other seven did not reappear. The next day he repeated this experiment—of course with different bees. The first returned in five minutes, and two more in about an hour. In this case again three out of ten found their way home.'

M. Fabre then, from time to time, repeated the experiment under different conditions, with 49 bees, with 20, 40, and 15, making in all 144 bees, of which number 47 were observed to find their way home. Some in a very short time, and some after several hours' absence.'

These experiments were to M. Fabre's mind conclusive that the instinct of the bees rose superior to the whirling process, and the various difficulties which he put in their way.

Sir J. Lubbock, however, combats these conclusions. He says that 47 bees finding their way home out of 144 is 'not a very large proportion,' and then goes on to say,—

'Out of the whole number no less than 97 appear to have lost their way. May not the 47 have found theirs by sight or accident? Instinct, however inferior to reason, has the advantage of being generally unerring. When two out of the three bees went wrong, we may, I think, safely dismiss the idea of instinct. Moreover, the distance from home was only one and a half to two miles. Now, bees certainly know the country for some distance round their home; how far they generally forage, I believe, we have no certain information, but it seems not unreasonable to suppose that if they once came within a mile of their nest they would find themselves within ken of some familiar landmark.'

Now, I do not presume to set up my humble opinion in opposition to such a marvellously close observer as Sir J. Lubbock, but I should like to point out one or two things which strike me in reading this interesting article upon a most interesting subject, and which seem to me to weaken his arguments. I should also like to invite the opinion of others on the subject.

And first, although, as Sir J. Lubbock says, 47 out of 144 bees finding their way back after the whirling process is 'not a very large proportion,' no account seems to have been taken of the fact that this whirling process—

the bees in a bag whirled again and again round the observer's head—very probably (I should say most probably) injured a considerable number of the bees, and really incapacitated them for the homeward flight. It was, at all events, a most unnatural process, and seems to have been done with some considerable violence.

Then, again, in the middle of the day, when the experiments took place, there were doubtless so many bees rushing in and out of the hives that some of the marked bees very probably entered the hives without being observed.

And so, although Sir J. Lubbock says that when two out of three went wrong, we may 'safely dismiss the idea of instinct,' I would say that we have no proof that two out of three did go wrong. Certainly one out of three were observed to go right; but this is a very different thing, under the conditions of the experiment, from saying that two out of three went wrong.

Then, as to their finding their way by 'sight or accident'—by coming 'within ken of some familiar landmark,' have we any proof that bees have 'familiar landmarks'? Does the bee, indeed, make its flight by sight? Certainly not, altogether, I think. Move a hive on a summer's day a yard or less from its stand. If the bees took notice of 'familiar landmarks' they would surely see their own hive as they returned home; but we all know that they fly at first straight to the old place, although no hive is there.

Again, I remember that, in the course of one of Sir J. Lubbock's own experiments, he induced bees, or wasps (I forget which) to come through an open window and to feed in his room, and that he found that, when they returned home, their first impulse was to fly, not to the window by which they had entered, but towards another which happened to be in the direct line towards their nest. This surely was not 'sight or accident,' but rather 'a sense of direction,' or instinct 'unerring.'

Again, in the case of dogs, taken even 100 miles away from home by railroad, and then finding their way back, and there have been, as we know, many such cases, we cannot for a moment suppose that they wander about aimlessly until 'by accident' they come within 'ken of some familiar landmark.' There is surely in their case some power of instinct far more mysterious. And, if so, why may there not be the same power in some degree in our bees?

At all events, I hope that neither M. Fabre's experiments on the one hand, nor Sir J. Lubbock on the other, will be taken as conclusive, but that further experiments will be made in the same direction. Without further proof I do not think we ought to accept the theory of 'sight or accident,' or that of the 'familiar landmark.'—
F. G. JENYNS, *Knebworth Rectory, Feb. 1886.*

'USEFUL HINTS' AND REVERSIBLE FRAMES.

[102.] Whatever may be the general opinion with regard to the reception of reversibles by the Editor, no one will charge the writer of 'Useful Hints' with a disposition to say anything in their favour. He shows his prejudice at the commencement by saying that Mr. Hoddon has so much honey on his hands. 'Tis true he says, 'This is no argument' against their use, but in the tone of the remarks he reveals his bias. He, like many others, objects to reversing because it is so contrary to the instincts of the bee. I think that if we use the word habit instead of that controversial word instinct we shall be less likely to have verbal quibbles, as I prefer to substitute that word, and I ask, 'Is it in accordance with the natural habits of the bee to have a large number of honey cells uncapped with a knife, as he suggests, and the honey carried into a separate receptacle above, in order that the bee-keeper may conveniently purloin it? to take their honey and give them sugar in

exchange? to make them swarm before they wish, or stop them when they want to? to make them build rectangular combs and fill the spaces top and bottom? and to build this comb, moreover, to a moveable bar when the bee appears decidedly to work for fixture of tenure? to make their combs by machinery with cells according to our desire? to interchange the combs with each other, and to make away their queen before they wish to give them another of a different breed? to partition their hive with loop-holed zinc through which their queen cannot pass, and a hundred other things? Are all these in accordance with natural habit or instinct? Yet we have reason to believe 'Useful Hints' adopts them. Naturally man is made to walk or ride an animal, but since the days of Stephenson there is nothing equal to the iron-horse. He who waits for the habits or instinct of the bee to make improvements in his methods will not gather much of the golden harvest. Placing a super above the body of the hive is not a natural process and reversing is only done, as a rule, as an extension of the same plan. We credit the bee with inability to improve its own state, and so we assist it. Perhaps if the bee had human intelligence it would reverse its own comb. We know nothing to the contrary. This we know from observation—they do not kick up so much dust at being reversed as they do at uncapping; so the testimony of the bees, as far as it can be gathered, is in favour of the former. If reversing were more unnatural than other processes the bees would refuse to work after it, and there is not a single instance of a 'strike' on record. Nothing that I have seen written against reversing has been of any value, save that methods were complicated and expensive, and these objections are removed since the introduction of the 'Acme' frame.

'Useful Hints' further shows his bias by stating as an argument against reversibles that which, to my mind, is decidedly in their favour. He says, 'The prolonged cells above the brood-nest form a heat-retaining canopy above the nest.' One is almost inclined to ask if his frames have any covering? A reversibilist, writing on the prolonged cells, would say, 'When the frames are reversed the brood gets placed in the upper part of the hive where there is most heat, while the prolonged cells nearly touching each other at the bottom act like hills, keeping off the cold wind coming in beneath the dummy while the brood lie enconcealed safely in the hollows behind them.'

I have read 'Useful Hints' with pleasure and profit, and think him very safe under that heading; but as he is taking to writing upon 'Things-in-General,' some of them, in his opinion, not useful and likely to lead to useful controversy, may I suggest that it would be well if he would give himself some short *nom-de-plume* by which he could conveniently be referred to?—JOHN RUDGE, *Dursley, Gloucestershire*.

[We are sorry to have touched the susceptibilities of Mr. Rudge. Perhaps if we had strongly advocated reversible frames, under 'Things-in-General,' instead of maintaining a waiting attitude, he might not have objected to our taking action in that direction. We have always been taught, 'from our youth up,' to *guide* instinct for our own advantage, but never to *oppose* it. If Mr. Rudge thinks that his knowledge is superior to the 'God-given instinct' of the bee,—which teaches it to bestow its pollen and honey in certain positions with regard to its brood-nest—and wishes entirely to oppose that instinct by turning its domicile topsy-turvy, by all means let him do so.

At the same time we beg to observe that since instinct guides the bee to store its honey *above* its nest, we by no means oppose that instinct by inducing it to increase that store in the same direction, by placing it in our supers and enlarging its nest up to the very base of those supers, while enabling it to store its pollen-mixture in the position dictated by nature, as most convenient for her purpose. In this age of scientific progress we may one day find the

inversion of human abodes advocated by some learned enthusiast, but until such topsy-turvy process has been proved advantageous to the human race, we shall prefer to live in our house as it stands at present—right side uppermost. Why does our friend object to both sides being heard? We are highly flattered by his estimate of our labours under 'Useful Hints' *proper*, and regret that he does not approve the enlargement of our department under the more discursive title of 'Things-in-General,' but we beg to assure him that whenever the latter 'heading' shall be generally disapproved by our readers we shall only be too happy to discontinue it. For a short *nom-de-plume* let him designate us by our initials U. H.—USEFUL HINTS.]

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[50.]—W. Handby accuses me of misstatement. The paragraph to which he refers is as follows:—'In reply to "Amateur Expert" (25), I think the hive I have been making for some time (for which I was awarded a certificate at the Derbyshire Bee-keepers' Association's Annual Show for the best hive for winter and summer use) will meet the requirements mentioned.' At that show I exhibited a hive in Class XII., 'For the best frame-hive with arrangements for summer and winter use.' For my exhibit I obtained a certificate as I state. But I do not state that my hive was the best hive. W. Handby's so-called correction is therefore incorrect.—DOUGLAS COOPER, *Sunny Hill House, Normanton, near Derby*.

[54.] *Moving Hives*.—You may move your hives without much loss. Prepare your stands, and on some cold evening remove your hives to their new situation as careful as possible. Wrap some light-coloured paper round them, and place a board slanting to the entrance. Remove all the stands from the old place and change the appearance of everything as much as possible.—FRED. WILSHAW, *Cheddleton*.

[72.] *Excluder Zinc*.—My experience is that excluder zinc under sections is quite useless. Four or five years ago I purchased some sheets and used one of them. It came off warped, having been propolised to the utmost powers of the bees, and these are never small. There was no sign of the queen having passed through, but neither has there been in any other case. I have never used another sheet, and in all the hundreds of sections which I have taken off during several years, I believe that not one egg has ever been laid. I place my crates immediately on the top-bars, and find my home-made flat knife—a piece of broad hoop-iron with a chisel edge—very useful for loosening them.—C. R. S., *South Cornwall*.

[87.] *Dry Sugar Feeder*. (Heather).—The weather, as you state, being, at the time alluded to, cold, and there being only a small quantity of bees, would be sufficient cause for their not taking the food from your dry-sugar feeder. You should crowd the bees by removing all unoccupied combs until they cover each comb left, and place the feeder close to outside of cluster; they would then feed. Remember the grand axiom of successful bee-culture, Keep your stocks strong.—W. B. WEBSTER.

[87.] *Dry Sugar Feeder*. (Heather).—Most probably from the two causes you name combined.—AMATEUR EXPERT.

[89.] *Italians or Crosses*. (II).—No. I do not quite see the force of your query, can you repeat it in another form? There is no objection to any kind of bees to work white clover.—AMATEUR EXPERT.

[89.] *Ligurians or Crosses in a white-clover district*. (II).—None whatever as far as honey-gathering is con-

cerned; but crosses, Italian ones, are exceptionally clever with their 'business ends.'—W. B. WEBSTER.

[90.] *Carniolans or Italians.* (J. B.)—They are about equal as workers, and Carniolans are the best tempers far and away. (The ladies' bee!) The reason is because the Italians have been improved (?) by crossing with the villainous Cyprians.—AMATEUR EXPERT.

[90.] *Carniolans or Italians?* (J. B.)—Bee-keepers are now giving the preference to Carniolans; they are exceptionally quiet to handle, and so have earned the title of the 'ladies' bees.' A more extended trial of their honey-gathering qualities is required before giving a definite opinion, but they are very good; their fault is having a too frequent desire for swarming. Italians are very gentle, much easier to handle than natives, are grand workers. The manner in which they protect their hives from robber bees is worth keeping a stock if only to watch this.—W. B. WEBSTER.

See also opinion by J. M. Hooker, Query [98] p. 58.

[91.] *Price of Honey.* (R. T.)—When selling sections of 1-lb. at 1s., 2-lbs. sold for 1s. 9d.—W. B. WEBSTER.

[92.] *Will the bees store an extra quantity of honey in the 2-lb. sections to repay the lesser price that they sell at?* (R. T.)—The bees will store an extra quantity of honey by using 2-lb. sections, but I have found hardly sufficient to repay the difference in price. 1-lb. sections are much more saleable.—W. B. WEBSTER.

[92 & 91.] *Honey: its price in 1 and 2-lb. Sections.* (R. T.)—We make nearly as good price *pro rata* of 2-lb. sections as 1-lb., but there is a far larger demand for the latter, which we study; under certain conditions, the bees store in the 2-lb. far more profitably than in the 1-lb.—AMATEUR EXPERT.

[93.] *The best to do with Granulated Sections.* (R. T.)—Sell them if possible. Who objects to buying them? Failing that, melt them down, skim off the wax and feed the bees with them. Failing that, eat them yourself. Failing that, send them to the local hospital, and—a few—to the Editor *B. B. J.* (N.B.—The Tower Street office boy has a sweet tooth.)—AMATEUR EXPERT.

[94.] *Warmth of Manipulating Room.* (J. E. L. G.)—A paraffin stove will raise the temperature up to 80° Fahr.; on warm days higher. Such a one I use for that purpose with the same size room. This gives a sufficient warmth to cut out and insert the cells containing eggs into the frames, and makes a capital contrivance for heating the resin and wax on the top of it.—W. B. WEBSTER.

[95.] *Purifying Wax.* (T. W. Jones.)—If you have followed all the directions in *Bee Journal* your wax is irretrievably dark. Why not use a wax extractor? If you make any quantity with this simple machine wax of a good colour is ensured; but in making small quantities the combs should be picked over, the light-coloured ones melted separately from the dark. Straining through flannel improves the colour very materially, but the 'game is not worth the candle.' You can bleach it by sunlight or acids, but this renders it of no use for any purpose connected with bee-keeping.—W. B. WEBSTER.

[96.] *Material for Smokers.* (A. P. Howes.)—Brown paper unglazed, fold round and round, occasionally turning it upon itself to ensure draught through the folds; don't be frightened of putting enough in. Fill the barrel diametrically.—W. B. WEBSTER.

[96.] *Material for Smokers.* (A. P. Howes.)—We have used nothing but dry brown paper for years. The chief fault is in the smokers; cut a piece off the top end with a file so as to ensure the outlet is larger than the hole in the bottom end through which the wind is forced, and keep it clean inside, they often get choked.—AMATEUR EXPERT.

[96.] *Smoking Substance.* (A. P. H.)—If A. P. Howes will get some peat, which is easily obtained from any nurseryman, and thoroughly dry it, he will, I think,

find nothing either light quicker or burn better or longer, and it has the great advantage of keeping alight a long time without blowing; and this is of great use when one wants to thoroughly overhaul a few hives. Brown paper (the rougher the better) rolled fairly tight is also a useful thing for the smoker; but nothing to my mind can equal the peat.—H. W. WEST.

[97.] *Trapping Birds.* (Beeb.)—The only bird which I have found eating bees at this time of the year is the great titmouse, sometimes wrongly called the great blackcap. These can be caught in small steel snap-traps, baited with linseed meal; but I always shoot them with fine shot when I find them attacking my bees, as I find that the best and quickest way in the end.—M. C. H.

[97.] *Trapping Birds.* (Beeb.)—Try common bird 'gins' baited with beef suet or linseed set at the entrance of the hives.—AMATEUR EXPERT.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[103.] Is there any substance which will prevent bees from fastening down the section-rack on the tops of the frames? Would vasaline smeared over the bottom of the rack be of any use? When large racks, holding thirty-three one-pound sections, are used, it is most difficult to get them off when removing sections without shaking the whole hive,—at least that is my experience.—M. C. H.

[104.] *Myrobella Plum.*—I shall be obliged if Mr. H. Dobbie, or any one else, will state in your *Journal* whether in their experience the myrobella plum is suitable for a hedge? It is said to be grown for that purpose in France. Is the said plum thorny, and likely to resist the biting of cattle? I should like to grow it for my bees close to the rail fence which separates my garden from a field.—O. B. T.

[105.] Will bees fasten oil-cloth down when used as a quilt in bar-frame hives?—O. B. T.

[106.] *Foul Brood.*—Can it be that this disastrous disease is in any way connected with placing the frames parallel to the entrance of the hives instead of at right angles? It could not, one may suppose, originate the disease, but can it pre-dispose the bees to develop it? For some years I kept the frames in my hives on the latter plan, and knew nothing (by experience) of the disease; but immediately, or almost immediately, I changed the frames to the former position, the disease appeared, and for three or four years it reappeared year after year, in spite of all my efforts to eradicate it. In 1883, however, I changed the frames back again to the latter method, and I am thankful to say that I have not seen any sign of it since. A bee-keeper in this neighbourhood of considerable experience has never had foul brood in his hives, but I find that he has always adopted the latter position for his frames; whereas several others who have adopted the former position have suffered severely from it.—D. A. DODDNEY, *Ore Rectory, Hastings.*

[107.] I have noticed with long hives and using queen-excluder at the back that dead bees accumulate in this portion of the hive, and if not looked to pretty often they get piled up on the floor-board. Would an entrance at the side in the back part in any way interfere with the working? or would a hole in the floor-board answer the purpose, of course having a shutter to close if

necessary? I have an idea that queen-excluder zinc stimulates swarming, perhaps by giving the bees an idea that they are more confined for space than they really are.—H. JENKINS.

[108.] I have a stock of bees in a wooden bucket. How shall I proceed to drive them?—WELSH NOVICE.

[109.] Will honey drain out of uncapped comb by simply laying it in a flat position?—WELSH NOVICE.

[110.] I see by last week's *Journal* that there is a likelihood of an Association being formed for this county (Glamorgan). What are the advantages of such an Association?—WELSH NOVICE.

[111.] How is the best way to put a swarm of bees in a Unicomb Observatory Hive?—H. BARLOW, JUN.

[112.] *Salicylic Acid Solution*.—I have about a quart of solution prepared last summer, will this do for mixing with syrup this year?—D. P. DAVIES.

[113.] *Extracting*.—My hives are situated in a garden about a quarter of a mile from the house. Which would be the better plan, extracting in the garden or bringing the frames in a box and extracting in the house?—D. P. D.

Echoes from the Hives.

South Cornwall, Feb. 2.—Very little can be heard under this heading now, but it may be stated that our bees soon came out after the post left us on the night of Wednesday, the 27th ult. The next day there was a gleam of sunshine which was taken advantage of, and yesterday again there were flights, though it was overcast. As the lesser eelandine is opening, a few fine days will set the bees pollen-gathering.—C. R. S.

Bishops Waltham, Feb. 4.—The weather in this district still keeps very changeable and unreliable, but still during the past fortnight the bees hereabouts have been able to get several good cleansing flights; and as far as I have heard all hives in this district are so far in a prosperous state, and promise well, with the solitary exception of one, and this one died off last summer, and after thoroughly cleaning the hive it was stocked again with a good swarm and a fine healthy queen, but it has again fallen a victim.—H. W. WEST.

NOTICES TO CORRESPONDENTS & INQUIRERS.

COTTAGER.—In the number for December 7, 1885, you will find an editorial article on 'Inverted Skeps.'

E. C. KERR.—The bees forwarded were cross-bred, several degrees, or rather generations, removed from purity. The queen was amongst them. The bees were not in a condition to detect the cause of death.

T. P. C.—*Comb-building from Sugar Syrup*.—Bees will produce wax as readily from sugar as from honey. Therefore you may feed with it when combs are being built.

J. B. S.—1. *Melilot*.—*Melilotus leucantha* is the specific name of the plant you are in quest of. It is frequently advertised in our columns. 2. *Transferring from Skeps*.—No. Place your combs in the frames the right side up.

C. G. MASON.—The specimen of oil-cloth would serve your purpose. It is pliable, and the particular odour would soon pass away. But the American enamel cloth is preferable, and there is little difference in the price.

BEESWING.—*Non-swarming*.—*Keeping Young Queens*.—As you say some of your hives have not swarmed for three years, and that they gave you 100 lbs. each of honey last year. It is evident you do not need advice upon the first point. As to the second, it is very probable that your bees have replaced their queens, although they did not swarm. If you have reason to suppose from any signs noticed that any of the queens are aged, you had better devote one stock to queen-

raising in nuclei, and when you have young fertilised queens, requeen your stocks.

G. W.—*Treatment of Stock in Skep*.—If you do not require increase, but simply to retain your one stock, you had better let them swarm; give the swarm in a bar-frame hive, about twenty-one days after transfer the combs from the skep to bar-frames and unite the whole. Although now a beginner, you will by then be able to find the queen readily. Preserve that which you find in the skeps, which is a young one, and remove the old one, which goes with the swarm. The easiest feeders to use are those formed of a bottle with a cap, inserted in a block with regulator to vary the number of holes. All dealers supply them.

J. W. BATCHELOR.—The 'white material' described is mould or mildew, caused by moisture. It can be dusted off by a soft brush. In conically shaped skeps there is no other way of feeding except from below.

W. J. GREEN.—Your paper on the 'Climax' hive was so clear and ample that there is no necessity for further explanation.

H. W. D.—1. *Dry Sugar Feeding*.—This plan has been found to answer well. Don't forget that moisture, either condensed or carried in, is necessary to enable the bees to take it. 2. *Candy*.—The object of this is to supply the bees with food in the form of minute crystals accompanied by a certain amount of moisture. The food made by kneading powdered loaf-sugar and honey comes practically to much the same thing. Granulated honey is not absolutely injurious to bees, but the crystals are not fit for food except when moistened. 3. *Non-swarming*.—Read our article on the subject in issue of January 21st. 4. *Working for extracted honey*.—The largest harvest is obtained by doubling. If you do not wish to adopt that system you can extract from frames placed either over or at the back of the brood-nest; and if the season is such as to give you a good surplus there is little doubt of sufficient food remaining in the main hive to last the winter.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

[No. 191. VOL. XIV.]

FEBRUARY 18, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

EXAMINING EXAMINERS.

There is an art of examining as well as that of being examined. Some candidates, with a very superficial knowledge of their subject, nevertheless manage to display their (mental) wares to such advantage as to delude an unwary examiner into a belief that their knowledge is profound; others, on the contrary, fail to get credit for the knowledge they possess. Their minds are like a pawnbroker's shop, full of valuable goods of every description, without any order or method, so that the owners cannot as a rule produce any article when it is wanted. An experienced examiner will soon recognise this class of mind, and by careful questions discover the virgin gold. But as it is not given to every one to go to Cambridge and be a Wrangler, so not every one is fitted to be an examiner.

If we wish to teach others, we ourselves must be thoroughly conversant with the subject, and not less so if we aspire to examine. Again, some examiners seem to take a melancholy pleasure in puzzling candidates, either by asking out-of-the-way questions, or by attaching too much importance to the knowledge of trivial and unnecessary details; while others with far more reason try to find out what a candidate does know, rather than what he does not.

Some years ago a candidate was being examined by two professors, one asking questions, and the other marking, so as to give the candidate every chance of passing. Some ridiculously minute question was asked by the examiner, to which the candidate replied that he did not know, and that, moreover, he did not much care. And the marking examiner, in narrating the story, said, 'I immediately gave him full marks. I thought it a most sensible answer.'

In looking over examination papers, we are often reminded of this story, and though the reply was no doubt wanting in respect, still we cannot help thinking that the examiner was wrong in asking the question, as it was really no test of the candidate's knowledge or ignorance.

The examination for the third-class expert's certificate, which is essentially a practical examination in the rudiments of bee-keeping, can be passed by any one who knows the life-history of the bee, and who is able to manipulate. We are frequently told that our bees now

are over-manipulated, and that this is no real test of a bee-keeper's knowledge, and that the object and aim of bee-keeping being the production of honey, the man who gets the largest harvest is the best fitted to be an expert. In some minds there seems to be a lurking belief that theory is opposed to practice, and we constantly hear the saying, 'That may be all very well in theory, but it is wrong in practice,' as if practice was deduced from theory, and not theory from practice. We can teach a parrot to speak, or a boy to learn by heart a proposition of Euclid, but neither one nor the other, in the full sense of the word, knows what he is talking about. Just in the same way a candidate may accurately describe the differences between a queen-bee and a drone, but fail to find the queen in a hive which he is manipulating. This failure would not prejudice the candidate's chance of passing, if we thought it was due to accident, nervousness, &c.; but we should be very careful to gauge his practical knowledge still further before allowing him to pass.

That some bee-keepers are too fond of meddlesome manipulation we are quite willing to admit, but the abuse must not blind our eyes to the use of manipulation; and before stamping a man with the impress of an expert, it is the duty of every competent examiner to find out whether he has the true ring, and will pass as current among bee-keepers.

USEFUL HINTS.

Severe frost still continues, and in many parts of the country the white mantle still covers the ground. For years we have not experienced a winter's cold of so long duration, and consequently so unfavourable for the safe wintering of bees. Long confinement invariably tells upon the health of colonies, and in a far greater degree upon small than large ones.

Wherever the accepted rules for safe wintering have been carefully observed the loss will probably not be great, but where carelessness and procrastination in making the necessary preparations prevailed, we anticipate extensive mortality and heavy loss. The last two or three winters were so exceptionally mild that bees wintered well in almost any condition; and the danger is that the large numbers of bee-keepers who have lately joined our ranks may have been inclined to consider the wintering of bees an easy matter, requiring no extra precautions, whereas the very contrary is nearer the truth, since safe wintering is the basis upon which—more than upon any other point—success in apiculture depends.

LET THEM ALONE.—So long as the present cold weather continues—the thermometer stands at 26° Fahr.

as we write—it is the height of foolishness to attempt to manipulate, or to disturb the bees in any way whatever. Of course if colonies are perishing for want of food they must be fed, but in the way which entails the least disturbance; and this, perhaps, is by placing a frame of honey beside the cluster in frame-hives, and by giving a pint of warm syrup about once a-week, over the feed-hole in skeps. The entrances must also be kept clear of dead bees and refuse.

EXAMINATION.—It has always been a rule with us towards the end of the present month, in bright and mild weather, quickly to look over any doubtful colonies to see that the queens are right and the food sufficient, and to confine them closely to the frames which they are able to cover, wrapping up and covering warmly as a finale to the operation. But these examinations must only be made on really *warm days*. We remember the month of February to have been so warm and bright that almost on every day the bees were flying, as in May or June. Such seasons have, nevertheless, usually proved disastrous from the bees being induced to very early breeding, and the following month turning out cold and sunless, with easterly winds prevailing; the brood has been chilled, breeding suddenly checked, and the latter state of the poor bees has been worse than the former.

In any case where doubt exists as regards sufficiency of food, let the quilt be gently turned aside and the fact be ascertained at once. This will in no way disturb or excite the bees if the act be neatly and quietly performed. A feather moistened with carbolic-acid solution passed over the frames as the quilt is being raised, will effectually keep the bees in check, and prevent crushing when replaced.

UNIONS.—Any colonies so much depopulated as to cover one or two frames only will be best united to other stocks. If the queen be alive, and worth preserving, she may be kept on hand, in case of emergency, such as loss of queen in populous colonies, &c.

With from fifty to one hundred of her subjects let her be placed on a piece of clean, dry, sealed honey-comb, in one of the small boxes in which Italian queens are sent to this country, and kept in a warm room. With care, we have kept queens in this way for more than three months in perfect health; by giving an occasional flight, replacing dead bees with live ones, and covering the box with perforated zinc, with felt over it, for ventilation.

The bees which are to be united should simply be removed, on their own frames, and placed outside the cluster to which they are to be added—without any jarring or disturbance—and as quickly as possible, using no smoke. Evening is the best time to perform the operation, and, the hive being carefully covered with its quilts, by the following morning the union will have been peacefully accomplished.

SPRING FLOWERS.—Those most frequented by the bees during the early spring are the crocus, snowdrop, swallow, wallflower, gorse, &c. The blooms of these may be seen covered by the bees on bright sunny days. By these they are stimulated to breeding, the signs of which may be noticed by the dried pollen, wax refuse, granulated honey, and other refuse on the alighting-boards, carried out by the bees when polishing the breeding-cells for the queen's use. There are no better marks of a healthy, flourishing colony than these.

FEEDERS, although not in full requisition at present, should be provided, or kept in readiness for the spring campaign. When breeding is in full force a constant income of food is desirable, to a smaller or larger extent, as the case may require, care being taken that the queen is not shut out from the brood-nest by the cells being filled with syrup.

THINGS-IN-GENERAL.—*Foul Brood.*—Respecting the disinfection of hives from foul-brood germs, Dr. Tinker writes: 'In my practice I have found one part each of carbolic acid, alcohol, and water, used with the atomiser,

to be highly effectual in the sick-room in destroying the contagion of typhoid fever, scarlet fever, and diphtheria. Probably the same strength of mixture would be strong enough to cleanse hives of the germs of foul brood.' This seems to be worth a trial in preference to destroying the hives. In our last issue Mr. Doudney raises a question which may have an important bearing on this subject, viz., whether the 'parallel' or 'hot' system of arranging frames in a hive may not tend to the retention, or fostering, of the disease when once introduced, and the instances he quotes are certainly striking. In our own apiary all our hives are on the 'right-angled,' or 'cold' system, and during more than forty years' experience we have had no case of this terrible disease. Of course, when the germs are present the disease must follow, despite any arrangement of frames, but one system may have a greater tendency to foster, retain, and spread the disease than the other. We are well aware of the advantages claimed for the 'hot' system, but it has often struck us as very remarkable that it has never been introduced—to our knowledge—into America, or, at all events, has never obtained favour there, the hives of this nation, foremost in the race of modern apiculture and in the application of scientific discoveries and resource thereto, being all built on the 'cold' system. The 'hot' advocates, no doubt, will retort, 'Nevertheless foul brood prevails to a greater extent there than here.'

REVERSIBLE FRAMES.—Mr. Pond writes on these in the *A.J.* thus:—

'When the matter of reversing frames was first presented, I became quite enthusiastic on the subject, and gave the opinion that they would be, or should be, universally adopted. A single season with them taught me that I was wrong, and that the benefits claimed by their use was not in accordance with natural law, and could be far more easily attained without the trouble and expense of fitting over frames, as would be necessary in order to adopt the plan. The queen will not use store-combs in which to lay her eggs, but only such cells as are of the regulation depth. Reasoning from this premise, and on the further ground that the attempt is always made to put honey *above* the brood, I decided that any plan that would keep the upper part of the comb at just the correct width, viz., seven-eighths of an inch, would at once cause the cells to be filled with eggs, and, as a matter of course, the stores to be deposited in the sections above. The question then arose, How can this best be done? Shaving off the combs I found to be too much labour, but upon testing the idea of putting the frames nearer together, I found the plan was a success. If the combs are placed just so near together as to leave a bee-space between them, and allowing the whole comb to be seven-eighths of an inch wide, no trouble will be found in keeping the upper rows of cells filled with eggs, and if sections are in place the bees will be found to occupy the sections whenever there is honey to be gathered and stored.'

Will our readers kindly understand that subjects introduced under this heading are not intended to be controversial? There are numerous matters which, although they cannot, strictly speaking, be classed under 'Useful Hints,' yet are of great interest to bee-keepers, and when such are not brought under notice in other departments of the *Journal*, our desire is to call attention to them, in no partisan spirit, but for the advantage of all; and on such subjects we have neither the time nor the inclination to enter into controversy. In endeavouring to guide our readers aright in these matters, we shall be careful, as far as possible, to infringe no personal interests.

JOTTINGS BY THE WAY.

It is well known that the late Rev. H. R. Peel took a great interest in all matters which tended to the well-being of the working classes. He founded, and subsequently became the president of, the Working Men's Club at Handsworth, near Birmingham, the committee of which have recently, by the consent of the rector,

erected a handsome tablet to his memory in Handsworth Old Parish Church.

It may be interesting to those who have read Mr. Grimshaw's paper in the January 25th number of the *Journal* to know that there is an edition of the *Insect Architecture* by John Rennie, probably of later date than that referred to by Mr. Grimshaw, edited by the Rev. J. G. Wood, who made considerable additions to it. The quotations made by Mr. Grimshaw, as at pages 148, 153, 156, 143, and 144, may be found at pages 164, 169, 172, 160, and 161, of the present edition of this very interesting little work. The title bears the imprint of Bell and Dally, 1869.

Mr. H. E. Roberts, a most successful Hertfordshire bee-keeper, will shortly embark for New Zealand. We wish Mr. Roberts every success in his new sphere of labour. If he does not forget in his adopted home his early love, we should be pleased to hear of his success in bee-keeping.

'Amateur Expert' writes:—'We shall be troubled with spring dwindling and dysentery this season, unless I am agreeably mistaken. As a cruel commentary on all the *gush* about the superiority of skeps and the let-alone system that we are hearing so much about in some quarters, my skeps are smothered in dysentery—I never saw them in such a sickening mess; while my bar-frames, which I have taken great pains to keep well supplied with dry, well-aired quilts, are absolutely free from it. They have all been brooding for some time by undoubted signs, but I have made no examination as yet.'

We are obliged to Mr. H. C. Whineop, 6 Cross Street, Finsbury Pavement, for forwarding to us a sample of his hinges for hives. On page 208, Vol. XII., will be found an illustration of hinges similar in principle to these now received. The top half of the hinge is screwed to the roof, the lower half slips into a socket. When you desire to take off the upper story the roof can be lifted straight up and the hinges come out of the sockets. They would be found of great service with double or treble-storeyed hives. Mr. Whineop's hinges are made of polished brass with bevelled edges, and are well finished off. They look quite ornamental on a well-made hive. The hinges are highly recommended by those who have tried them.

Mr. F. R. Erridge has sent us a piece of corrugated brown paper, which has been found very serviceable by chemists and honey-producers for packing bottles and other fragile articles. A correspondent states he has found it very useful as a material for smokers.

We have received from Messrs. T. B. Blow and S. J. Baldwin copies of their illustrated Trade Catalogues. The former extends to 60 pages; the latter to 48, and contains much interesting, sound, and practical advice to beginners in bee-keeping.

Mr. F. Cheshire writes:—'We have a *new* bacillus, and I believe the Rev. Mr. Erabey has another new one also; *i.e.*, new to our knowledge.'

ASSOCIATIONS.

NORFOLK AND NORWICH BEE-KEEPERS' ASSOCIATION.

The fourth annual meeting of the above Society was held on Saturday, January 30th, 1885, by kind permission of the Rev. A. C. Copeman, in the school-room, Old Post Office Street, Norwich, the Rev. A. F. Bellman in the chair. Present: the Revs. J. Blake-Humfrey, S. P. Garrick, H. B. Johnson, H. W. Harden, and H. J. Coleman, Messrs. W. H. Back, W. T. Godney, Captain Herring, F. T. Chevallier, J. O. Cattermoul, C. W. Middleton, L. Wren, and H. Beswick, Mrs. G. Day, Mrs. Wren, and the Hon. Sec. The annual report

showed that the Society had increased its members from 245 to 278. The expert, Mr. Lilly, has been working hard amongst members in all parts of the county during the busy months of the season, and there is every reason to believe that much good and permanent work had been accomplished. The annual show of bees and honey was again held in connexion with the Norfolk and Norwich Horticultural Society. The manipulations and lectures in the bee-tent by Mr. Lilly, the expert, were well attended and much appreciated. One very interesting feature was the bee-driving by a little boy, son of Mr. Emms, the hon. sec. The balance-sheet shows a small deficit, which is owing to the heavy expense incurred by the continuous demand for the expert during the season. The report and balance-sheet were unanimously adopted. The following gentlemen were then elected to serve on the committee for the ensuing year: The Revs. H. F. Bellman, J. Blake-Humfrey, H. B. Johnson, and J. P. Garrick, Messrs. R. Harvey, Mason, W. H. Back, J. O. Cattermoul, F. T. Chevallier, J. N. Aldridge, W. T. Godney, C. W. Middleton, H. Beswick, Captain Herring, Russell J. Colman, H. H. Harnard, and J. L'Estrange. The Rev. J. Blake-Humfrey proposed that Mr. J. J. Rue be hon. sec. in the place Mr. H. E. Emms, who had removed from Norwich, and that the thanks of this Society are due to Mr. Emms for his valuable services during his term of office; seconded by the Rev. A. F. Bellman, who spoke in very high terms of the efficient manner in which Mr. Emms carried out all details in working the Society up to its present flourishing state. It was thought that the expert should commence his spring tour as soon as the weather proved favourable.

ESSEX BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held at the Corn Exchange, Chelmsford, on Friday, January 22, 1886. Mr. G. H. Aubrey presided, and there were also present Miss Check, Mr. F. H. Meggy, Mr. E. Durrant, Mr. J. C. Chillingworth, Mr. W. T. Braddy, Mr. Chas. A. Christy, and Mr. W. Debnam.

Mr. F. H. Meggy read the Report, which stated that during the past twelve months 67 new members had been enrolled, while 39 had been removed from various causes, leaving a net increase of 28, the total number of members being 241. The financial statement was not so satisfactory as could be wished. This was caused by the increased cost of the experts' visits and grants for prizes. It was noticeable also that with a good increase of members the subscriptions were but 3*l.* in excess of last year. Visits to the apiaries were made by the expert, Mr. W. Debnam, in the spring and autumn, with the following results:—Spring skeps examined 320, bar-hives 505, other hives 53, total 878. Autumn, skeps examined 160, bar-hives 294, other hives 10, total 464. Colonies found dead in skeps 15, and bar-hives 7. The number of members of the Association visited were, in the spring 162, and autumn 86. Illustrated lectures were delivered by Mr. Durrant at Bradwell, Colchester, Stock, Sandon, and Good Easter. The committee were indebted to Mr. Durrant for delivering these lectures free of expense. The bee tent had, during the summer months, attended various towns in the county. Prizes for honey had also been given at seven exhibitions. The rules of the Association had been revised, and were presented for confirmation. The resignation of the Hon. Secretary, Mr. Aubrey, had been tendered and accepted by the Committee with regret on October 3rd. A vote of thanks was passed in acknowledgment of his five years' services. Mr. F. H. Meggy was elected to the vacant office for the remaining portion of the year.

The revenue account for 1885 showed that the income for the current year had been 87*l.* 9*s.*, the expenditure 88*l.* 15*s.* 6*d.*, the difference reducing a balance of 2*l.* 17*s.* 6*d.*, with which the year commenced, to one of

1*l.* 13*s.* to carry forward to the next account; but gratuities of 2*l.* 2*s.* to the expert for assisting the Secretary, and of 7*s.* 6*d.* to the man employed to put up the bee tent, which it had been customary to pay, had not been granted this year. The Association had, besides, their bee tent valued at 8*l.*

The election of president, vice-president, committee, sub-committee, hon. secretary, district secretaries, treasurer, auditor, and two representatives to the British Bee Association, was then proceeded with, Mr. Meggy being elected as hon. secretary, and, in conjunction with Mr. E. Durrant, representative of the Society at the British Bee-keepers' Association. Mr. Durrant then moved, and Mr. Chillingworth seconded, a vote of thanks to Mr. Aubrey for his services. This was supported by Mr. Debnam, who spoke of the valuable aid Mr. Aubrey had rendered him, and this motion was heartily carried. Mr. Aubrey, in response, expressed his gratification that the committee had secured such an excellent hon. secretary as Mr. Meggy, and added that he was willing to afford him all the assistance he could.

For several years no county show has been held, grants for honey prizes being made instead, to local horticultural shows in various parts of the county. In accordance with a general feeling that the time had arrived for holding a county show again, a determination was expressed to bring this about in July or August next if the necessary funds could be raised. Brentwood and Chelmsford were named as the most suitable places. The secretary was authorised to appoint district secretaries, who should by virtue of their office be members of the committee, to represent the Association in various parts of the county and assist its work by offering advice and encouragement to bee-keepers in their districts, also as far as possible by obtaining new subscribers to the Association and donations to cover the expense of prizes, beehive exhibitions, or evening lectures in their own districts; and to advise the secretary on any matters connected with their district. Between twenty and thirty divisions were shown to be necessary, and the names of more than half the latter number who were willing to serve were submitted.—*From the Essex County Chronicle, Jan. 29.*

WILTS BEE-KEEPERS' ASSOCIATION.

The general meeting of the above Association was held at Trowbridge on February 4th. The attendance, as is too often the case, was small. The Rev. J. H. Dixon was unanimously voted to the chair. The Association has lost forty-two members from various causes, many owing to agricultural depression, but has gained forty-six, of which thirty are of the cottager class, or just above. The Association is still but very feebly supported by the county families. The balance-sheet showing a serious deficiency (though subscriptions had increased from 30*l.* to 34*l.* 8*s.* 6*d.*), it is found necessary to discontinue the supply of the *Bee Journal* at reduced prices to members, but an arrangement has been made by which all members forming groups of six may have it in turn at a small charge. The expert tour having proved so successful last year, it was resolved that another be arranged for this year. The Hon. Sec. was able to announce that the Lord Bishop of Salisbury had accepted the office of President, and would subscribe 12*l.* per annum; the Very Rev. the Dean of Salisbury, W. H. Long, Esq., M.P., G. P. Fuller, Esq., M.P., Professor Wrightson, President of the College of Agriculture, and Rev. V. H. Moyle, being added to the list of Vice-presidents—and three ladies elected on the Committee: nearly all the former members of the Committee—the Treasurer, Hon. Sec., country representatives, and district advisers—were re-elected. Full particulars will be given in the report now in the press.—W. E. BURKITT, Hon. Sec.

BERKSHIRE BEE-KEEPERS' ASSOCIATION.

EXPERT'S REPORT.

On the 18th of May I commenced my spring tour. The early spring having been by no means favourable to bee-keepers, it was not surprising that at this time it was the exception rather than the rule to find stocks in anything like superior or swarming condition, and I feel sure that in no previous tour has my visit been of so much use, as almost every stock examined I found it necessary to advise the owner to feed at once. In some apiaries examined scarcely a pound of food was to be found among perhaps a dozen stocks, and what was the result? egg-laying suspended! brood destroyed! and colonies thrown back at least three weeks, for the want of a small quantity of food just to carry them over a spell of bad weather. Many bee-keepers imagine that if they feed their bees during March and April they will be able to take care of themselves after that time, *and so they will if the weather is favourable*; but after bees have been stimulated early in the season, large quantities of brood are being constantly hatched out and eggs laid, it naturally follows that there must be a great demand for stores; now, it is just at this time it often happens that the success or non-success of a colony is decided by *their owner*. In most cases feeding is discontinued at the end of April or early in May, and preparations are made to put on the supers, with every hope of success, but if, just at this time, we get (as we often do) a week or more of bad weather, our busy friends are soon in difficulties, their stores become completely exhausted, and, instead of a flourishing colony, the bees are found starved to death. It is at this critical period that the most careful attention is required, and I would impress this fact upon members, that it is just this attention which will often decide between success and disaster.

I am pleased to report that there is a steady and increasing interest being taken in modern bee-keeping, especially among cottagers; the sulphur-pit is giving way to the super, although the former has by no means died out, yet the working classes are fast coming to the conclusion that careful attention to their bees is amply repaid.

I have this year visited, and in many cases examined, over seven hundred stocks of bees, showing a considerable increase on last year, thereby proving that Berks is keeping well to the front in the bee-keeping world.

The bee tent has been erected on eighteen occasions with the most satisfactory result, earning upwards of 20*l.*, and making a profit of about 5*l.* in favour of the Association. It is pleasing to point out that the tent is doing a most useful work, and that without any loss. In this department I have received valuable assistance from Mr. H. Fewtrell, one of our members who has this year gained a first-class certificate as expert.—A. D. WOODLEY, 26 Donnington Road, Reading, January 11th.

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of the members of the above Association will be held at the Guild Hall, Worcester, on Saturday next, February 20th. The chair will be taken at 3 p.m. by A. W. Knott, Esq., Mayor of Worcester.

Selected Query.

No. 111.—*Do you consider Cyprian bees as superior to Italians?*

I have never kept Cyprians, and have only once manipulated them, but managed to survive. *Timeo Cyprios et mella ferentes*.—G. WALKER.

For quantity, yes; but for colour of comb honey, no. Cyprians can be handled equally as well as Italians.—SAML. SIMMINS.

I consider them superior in every respect, and as easily manipulated, when thoroughly acclimatised, and carefully handled without the use of smoke.—GEORGE RAYNOR.

My experience of this race is not extensive, and I should therefore hesitate to recommend the Cyprians to any but bee-farmers, whose object is the production of honey, and who, with great and varied experience, will be most likely to give that care in manipulation which their irritable nature demands. The almost unceasing activity and the vigorous defence of their stores from robbers and the ravages of the moth make the race, in my opinion, one not by any means to be despised. At present, taking all points into consideration, I am decidedly in favour of the Italian in preference to the Cyprian race.—C. N. WHITE.

I have no personal experience, but from what I continually hear from a good many different sources I am satisfied that the Cyprian is the inferior, except in colour and—stinging.—F. ZEHETMAYR.

Cyprians will work in weather that neither Italians nor natives will face, they consume more for breeding purposes than Italians, and are even more erratic in queen-breeding and swarming, and for temper. The pity of it! The whole question of foreign bees wants looking at in the broad light of day.—AMATEUR EXPERT.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "THE EDITOR of the British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

OUR HONEY IMPORTS.

[115.] The value of honey imported into the United Kingdom during the month of January, 1886, amounted to 424l. [From the Statistical Office Return sent to E. H. Bellairs, Christchurch.]

AMATEUR HIVE-MAKING. (99.)

(Continued from p. 60.)

The roof is to be made to overlap the hive-sides, and will require two pieces $\frac{1}{2}$ " stuff, each $33\frac{1}{2}$ " long, 9" wide at one end, and $4\frac{1}{2}$ " at the other. One piece $\frac{5}{8}$ " stuff, $21\frac{1}{2}$ " \times 9", and one piece of $\frac{5}{8}$ " stuff, $21\frac{1}{2}$ " \times $4\frac{1}{2}$ ", also four corner-pieces of triangular section, made by ripping a piece of 2" \times 2" stuff through the opposite corners. Two of these are to be 9" long, and two 4"; nail the sides outside the ends, and nail the four corner-pieces into the corners, keeping them $\frac{1}{2}$ " up, so that when the roof is on the hive it will drop down half an inch, being prevented by them from dropping any farther. And now for the waterproof cover, about which so much has been said (and very rightly, for nothing is more important) in the *Journal* lately. It will be seen, by reference to fig. 1, that the form of roof is flat, with a good slope. I prefer this plan, because the slope is the way of the grain of the wood, whereas, in the usual form of roof, with two slopes and a flat middle board, the wet runs across

the grain, and any small crack will catch it. As one or two correspondents express their dislike to the use of canvas for a cover, here is a plan which will give a good, thoroughly waterproof roof. Get some well-seasoned match lining, cut sufficient boards to cover the roof-case C from side to side, and leave an eave all round of 1 inch. The number of boards will be ruled by the width; some matching being 6", and some 7" wide. Cut two strips $1\frac{1}{2}$ " \times $\frac{5}{8}$ " \times $34\frac{1}{2}$ ", and two $1\frac{1}{2}$ " \times $\frac{5}{8}$ " \times $22\frac{1}{2}$ "; nail these four together, slightly level the top edges of the ends as to suit the slope of the roof, as seen in section on fig. 1, and note that the sides are not nailed on square to the ends, but on the slope. The top edges must be placed quite flush and true. Now paint the edges of this shallow frame with white lead, slightly thinned with linseed oil; take one of your cut pieces of match-lining paint it on the under side with white lead, and screw it with 1" screws to the frame, of course keeping it square. Paint both the groove of the first board and the tongue of the second freely with the lead, and work the tongue into the groove, expressing the excess of lead; proceed thus with each board, putting two screws each end, and painting the edges which come together with white lead; fill up the heads of the boards with white-lead putty, and you may feel quite sure that your joints will not leak, the only risk is that the sun may crack the wood; and as this risk always exists I prefer the following plan. Cut your wood, which may be either matching or plain, to fit the above-described light frame without any eaves; nail or screw it to the frame, and paint all over with thick white lead (if matching is used, it must be primed and the beads filled up with putty), lay a piece of strong unbleached calico, 6 inches larger every way than the roof to be covered, on the white lead, and smooth it down, pressing it in every direction, so that the lead oozes through the cloth. Turn it over, paint the edges, and draw the calico round them, nailing it inside the frame with tacks. Nail one side and one end first, and then the other side and end, draw the calico tight, looking occasionally at the top to ensure that you are leaving no ridges or folds. When the white lead is dry, give two coats of paint. The edges inside trimmed off neatly.

The lift B, figs. 1 and 2, will require two pieces of $\frac{1}{2}$ " stuff, $31\frac{1}{2}$ " \times $4\frac{1}{2}$ " and two of $\frac{5}{8}$ " stuff, $19\frac{1}{2}$ " \times $4\frac{1}{2}$ ", with four corner pieces, made as described above, each $4\frac{1}{2}$ " long. This lift is required to give extra depth of roof for doubling, or for a second tier of sections. As will be seen by fig. 1, it is the same size as the outer wall of the hive, and therefore requires fillets all round to break joint: these are to be cut bevelled, as shown in section. Paint the surfaces which come together with white lead and screw together. This completes the hive and roof. Punch down all the nails and stop the holes with putty, dress all knots with knotting, prime and paint two or three coats.

An objection has been raised to the appearance of a hive with overlapping roof. This may be obviated by the addition of mouldings neatly mitred at the corners; the cost is very trifling, and the ornamental effect, especially where the mouldings are picked out of a different shade of colour, is surprising. Where fillets are used they may be formed of mouldings, and if dressed with white lead and screwed on from the inside there is no danger of warping and admitting wet.

The Frames.—Each frame will require one piece $17\frac{1}{2}$ " \times $\frac{3}{4}$ " \times $\frac{3}{8}$ ", two pieces $8\frac{1}{2}$ " \times $\frac{3}{4}$ " \times $\frac{1}{4}$ ", and one piece $14\frac{1}{2}$ " \times $\frac{3}{4}$ " \times $\frac{1}{8}$ ". It is very important that the ends of the side-bars shall be perfectly true, or else when nailed the frames will not hang true in the hive. As this is so easily done with a circular saw, it hardly pays to cut your own wood, and the frames are best bought of a hive-maker having the proper appliances. Some makers supply frames with the end-bars morticed into the top and bottom rails, and these are better than if nailed. If

you elect to make your own, you must make a block thus: Take a piece of inch stuff 17" long \times 7 $\frac{1}{2}$ ", at each end fix, quite square, with screws, a piece of wood 7" \times 1 $\frac{1}{2}$ " \times 1", keeping them exactly 14" apart. This ensures your frames being the correct size outside. Across the board fix with one screw, on which it can turn, a piece of wood 13 $\frac{9}{16}$ " \times 1 $\frac{1}{2}$ " \times 1". By placing your end-bars inside the two end-pieces of the block and forcing the turning piece against them; it, being $\frac{1}{16}$ " too long, will keep them firmly in their places while you nail on the top-bar. A tap with the hammer turns it up and releases the frame, which is then turned over and the bottom rail nailed on. Before nailing, the top-bar must have a cut with a rip-saw made all along to within 2 inches of the other end. If you buy the frames, this cut, which is for inserting the foundation, will be made by dropping on to a circular saw, and will not extend through to either end. The distances are best kept with metal ends.

Section Racks.—To describe the making of these would occupy a great deal of space. Buy one and copy it. In selecting the pattern to copy, let it be long enough to take a backboard with springs to give room for removing the filled sections. If you prefer each row of sections in a separate case, on the system recommended by Mr. Raynor, make one side of each case or trough hinged to open and give ease in removing the sections.

Section Frames.—If you intend to use 4 $\frac{1}{4}$ " \times 4 $\frac{1}{4}$ " sections, make your side-bars 8 $\frac{1}{2}$ " \times 2" \times 1" full, or 1 $\frac{1}{2}$ ", the bottom rail 14" \times 2" \times $\frac{1}{4}$ ". No top rail. On the outside of the side-bars fix lugs at the top 2" \times 2" \times $\frac{1}{2}$ ". At first sight these dimensions appear to give only $\frac{1}{8}$ inch below the bottom rail, but it must be remembered that the metal ends raise the frames $\frac{3}{8}$ inch, and as the lugs rest on the hive sides, the top of the sections, flush with the side-bars, will be flush with the tops of the frames, and the bottom rail will be $\frac{1}{4}$ inch above the floor. The bottom rail will spring sufficiently to release the sections, and their own weight will keep them in by causing the side-bars to press upon them.

Sections.—No one thinks of making his own.

Queen Excluder.—Make a light frame of $\frac{1}{2}$ " \times $\frac{1}{4}$ " stuff, 14 $\frac{1}{2}$ " \times 8 $\frac{1}{2}$ " outside. Make a saw-cut along the edge of each piece $\frac{1}{8}$ inch deep, cut the excluder zinc 13 $\frac{3}{4}$ " \times 7 $\frac{3}{4}$ ", and insert it in the cut before nailing the frame, in the same way as a school slate is framed. Do not fix the zinc to the wood, a $\frac{1}{8}$ -inch clearance is left all round to prevent buckling, which would take place if the zinc had no room for expansion. Examine the zinc, and you will see that there is a burr on one side caused by the stamping. Place this side next the brood-nest.

Entrance Reducers.—Take a piece of $\frac{5}{8}$ -inch stuff 10" \times 1 $\frac{1}{2}$ " and divide it by two saw-cuts meeting V-shape, as shown in *Modern Bee-keeping*. These two pieces lie on the floor-board, being kept in their place by four round-headed screws, behind which they can be slid to leave any size opening.

Stand.—Four bricks on edge, or four flower-pots, are as good as any. Let the floor rest on them and the hive on the floor.

Alighting Board.—This is a very necessary addition, not always provided. Take a piece of small-hole perforated zinc, of the kind used for meat-safes, 19" \times 12", frame it as described for the excluder, put two hooks in one edge and two eyes on the edge of the floor-board, so that the zinc alighting-board slopes down to the ground for the weary or chilled bees to crawl up if they drop short of the hive. The perforated zinc will be always dry.

This completes the whole hive, but as the outer walls are both higher and lower than the inner, one hive cannot be placed upon another for doubling, nor is it necessary to use so cumbersome a plan. If the doubling system is desired make a plain box 8 $\frac{1}{2}$ inches deep by any

multiple of 1 $\frac{9}{16}$ " long, into which the frames of the second stock can be lifted and placed on the frames of the first.

When the hive is painted and ready for use, the spaces between the walls can be filled with cork-dust and the slips K provided for the purpose laid over it resting on the top ends of J. To prevent accidental raising the hive from the floor, it will be as well to put two screws on each side through the outer walls into the edge of the floor. Let them be brass: iron screws will rust in and become immovable.

It will be found an advantage to have the floor removeable at will. There is one thing more which is as well to provide, and that is, ventilation in the roof. A few $\frac{1}{2}$ -inch holes made at each end of C with a centre bit and covered inside with perforated zinc, and with a sloping piece of board or tin outside to turn off rain, will be all that is required.

It will be noticed that only the sides are double. The front and back need not be double, as in wintering it is intended that the bees shall be confined between the two division boards, pushed back far enough to leave an ante-chamber, exit being given by opening the swinging door provided in the bottom edge of the dividers. Another use of these doors is to give access to a feeder at back of hive. In fig. 5, H 1 and 2 should have been shown projecting below G as described in context.—F. L.

DRONES.

[116.]—In answer to 'Bee Man' in *Journal* of Jan. 17th, I notice you say that the presence of drones in December indicates either that the hive is queenless, or else the queen is too old to perform her duties. I think there are exceptions even to this rule. For instance, I had a stock of bees in the end of October 1884 without a queen, but plenty of drones, so I united some condemned bees and a queen with them, and the drones were allowed to live till the following spring, when the other bees went on well and did me good service; in fact I have the same queen now.—J. BURMAN, 4 Mill Street, Leamington, Feb. 5.

DRONES AND THEIR USES. (100.)

A PROTEST AGAINST THE PRINCE CONSORT THEORY.

(Continued from p. 60.)

The strongest evidence of all, however, is the fact that amongst social insects the reproductive individuals always leave the nest and fly out into the open air before pairing. Among the termites the numbers to be seen on the wing at such times are so striking that observers have compared them to a heavy fall of snow.

To sum up, then, we see that from the drone's view of the problem the prince-consort theory is incorrect, as it makes suicide the object of his existence,—an object, too, which is accomplished by a very small minority of the drones. Although, from the queen's standpoint, it is at first sight plausible, yet the eventual result is only a choice of evils, for in-breeding is mischievous, and if a drone mates with a foreign queen he is not merely useless to his own hive, but he may even injure them by increasing the severity of their struggle. A little reflection will show that this applies equally to all classes within the hive. If, then, we still cling to the prince-consort theory, we are reduced to the absurdity of believing that the drone is kept to render services which, when rendered to his own sister, are the ruin of the hive which reared him. For whether the increase in the severity of the competition resulting from the drone's mating with strange queens, by necessitating a correspondingly increased efficiency to cope with it; and whether his perpetuating the existence of other colonies, which in their turn may supply his own with

drones be beneficial; or if not, at what point it becomes injurious is an open question. In either case, however, *this* is certainly not the reason why he was reared, and so need not be here discussed.

Before finally dismissing the prince-consort theory, I wish to ask its supporters this question,—In all other matters, such as honey, comb-building, brood, and queen-raising,* the bee is strictly economical, and yet she strives with might and main to rear a large quantity of drones, although a few dozen would be amply sufficient for this purpose, and protests against our interference in this matter. How, then, can the advocates of this theory, whether believers in evolution or in fixity of species, explain or palliate such senseless extravagance? What is her object in it?

In a future paper I hope to offer a new explanation of the riddle, and to vindicate the drone's character at last by proving that during the honey harvest he is not an encumbrance to the hive which produced him, but a gain in the direction of increased economy and efficiency. I also hope to show that destroying the drones at this season is not only as cruel, but as foolish and pennywise a policy, as destroying the workers themselves.—
STUDENT.

FOUL-BROOD.

[117.] Since I last wrote to the *Journal*, much has been said *pro* and *con* in reference to this matter, while my continued investigations into the nature of bee diseases have brought many new facts to light. My present object is not to refer to these, but to draw the attention of the readers of the *Journal* to an article appearing in the *Bulletin de la Société d'Apiculture de la Gironde*, of November last, and written by no less an authority than Mons. A. Durand. The translation of this article I append beneath. It will be seen that Mons. Durand verifies my position completely, at the same time that he directs attention to camphor as yielding admirable results if the diseased brood be removed.

Two points that are personal, I also desire to canvass. When I first wrote in reference to this disease and its cure, I stated that I had arranged with two dealers for a small royalty, with the double object of securing the correct article to the purchaser, and also with the idea of partly providing funds for continuing extensive experiments. The result has been disappointing. The profit that has reached me has not actually paid the postage-stamps employed in the tremendous correspondence involved. The reason of this I can hardly explain in the pages of a public journal, but henceforth, I have no more to do with the commercial side of this question, but will guarantee Mr. Holland's phenol, if the purchaser would thus feel more satisfied regarding it.

The second point is this: although I have introduced germs of every kind into my apiary, and have recently destroyed three stocks by experimental treatment, all disease is so completely banished that I cannot even furnish a speck of *Bacillus alvei* for work I am now doing in conjunction with Dr. Crookshank in the Physiological Laboratory, King's College. (I am also busily culti-

* My experience is that bees do not rear more than a dozen young queens at a time, as often as not only two or three, and this although success or failure means life or death. This is rather a contradiction to the evidence of the combs as generally understood. I have found a larger quantity of queen-cells and cups built in a season, but owing to a change in the workers' plans the greater portion have never been used. A change in the weather, the loss of a portion of their stores, a sudden failure of their harvest, or an enlargement of the hive, would suffice to account for the change. Compared with this rigid economy in queens, the profuse expenditure in drones is somewhat startling, especially when we consider that the bees cannot help knowing of the proximity of other hives, each with its own quota of drones.

vating at home, so that all specimens received will be at once started in growth and reported of in the *Journal*.) This is some evidence that foul brood is curable. The stocks were destroyed by experiments with mercury salts, which are said to have been successfully used in America. It is quite unlikely that any of the readers of the *Journal* will touch them, but lest any should feel inclined, I strongly advise the contrary. Even if manageable and effective, they are in the greater number of cases so extremely deadly, that their employment might lead to some sad, even fatal accident, which would damage in no small degree the reputation of honey as food. In my difficulty will some of my readers kindly favour me by a few cells from a decidedly foul-broody hive?

Especially any unusual behaviour on the part of bees which might be supposed to indicate disease would command my best attention if I were supplied with a few specimens (living if possible). Our American brethren have amongst their stocks a germ disease which I well made out nearly two years since, and yet to the present hour they are clinging to the fallacy of poisonous food and I know not what to explain the observed facts. We also are not yet alive to the extent to which micro-organisms cause abnormal behaviour on the part of our colonies, for it is my conviction that we are far from the end of the discoveries that may be made in this direction, and none will, I trust, feel nervous when I state that yet another distinct disease has just come to light. Although it is in many points quite unlike foul brood, I am sanguine that the treatment curing the one will be equally effective against the other. How passionately I desire that it and all other bee diseases may be banished, for these are the most evasive and as yet the most terrible enemies of apiculture.

It is my hope to work out this new point during the coming spring, so that I may include it in the practical section of my new book.—FRANK R. CHESHIRE, *Avenue House, Acton*.

ABSOLUTE PHENOL AND FOUL BROOD.

In the earlier days of the month of July last the presence of diseased larvæ was verified in a hive of the apiary of the (Apicultural Society) *La Société d'Apiculture de la Gironde*. On the 16th seven combs were almost entirely filled with foul-broody cells. The very characteristic malady was recognised by all the persons who assisted at the course of lectures. I removed from the hive the four most seriously affected frames, as well as the useless combs, containing more or less honey, and commenced feeding immediately with the following: A half-litre of honey thinned with water, with $\frac{1}{2}$ in capacity of phenol No. 2† (the remedy No. 2 is composed of one measure of phenol with twenty of water, and it is this remedy which is mixed with the syrup in the proportions of one in twenty). By the evening of the next day the bees had taken all the syrup, but the feeding was similarly continued every two days for a fortnight, and on Thursday, the 30th, the hive was opened in the presence of those persons who were interested in the operation, and the most incredulous were obliged to submit to the evidence; in fact all the foul-broody combs which had remained in the hive were full of honey, all trace of decomposing matter had disappeared, the laying of the queen had been considerable, the brood was regularly sealed and in dense patches, and the bees were unusually active. This cure publicly made, and which is not the first achieved by absolute phenol, excited amongst the bee-keepers present the desire to procure for themselves easily absolute phenol, and at the cheapest rate.

Ordinary phenol is a watery and alkaline solution of impure phenic acid, contaminated with coal oil. By absolute phenol it is probable, if not certain, that Mr. Cheshire, the author of the treatment, intends phenic acid crystallised in white needles, called indifferently carbolic acid, phenyl hydrate, &c. (Codex).

* These proportions and this method are derived from my directions.

† Phenic acid is the equivalent of phenol.

Pure phenic acid is soluble in alcohol and glycerine, but, according to many chemists, insoluble in water; above all, four parts of the acid to one of water. However, a chemist of Bordeaux has tried and succeeded in the solution. He weighed out into a flask 10 grams of distilled water, and to this he added 40 grams of pure phenic acid. This flask was placed in a water bath at 50° Centigrade. The solution was complete in five minutes, the water registering at this moment 85°. This aqueous solution is stable without crystallisation, even at a temperature of 15°. Phenol is an extract of coal-tar at 185°, and the obtained product, which appears to be the 'absolute' of Mr. Cheshire, preserves some taste of its origin.

This remedy against foul brood is sovereign, and its effects are beyond contradiction; but it is only effective during egg-laying, and the more numerous the brood the more sure and prompt is the cure.

In autumn it is necessary to have recourse to another remedy—salicylic acid. Camphor in bags placed under the brood-chamber produces the best effect. M. L'Abbé M., a distinguished apiculturist, to whom I had advised camphor, announces to me that he has obtained surprising results. Two of his colonies have been cured by this remedy, which has been pointed out to us by a correspondent of the *Journal d'Apiculture de la Suisse Romande*, a journal of which Monsieur E. Bertrand is proprietor, and to whom we owe the knowledge of the treatment by salicylic acid more recently than by absolute phenol.

Madame Jarrié has pointed out a remedy for the treatment of foul brood by camphorated syrup, but she has neglected to give the proportions for the making up of the remedy; should these lines meet her eye we trust she will fill up this involuntary omission. Nevertheless, I have tried this remedy tentatively, and have obtained with two affected hives the best results. To one I gave syrup, into which I had put pinches of camphor in powder, and to the other syrup, to which I had added some drops of camphor dissolved in alcohol. The bees greedily consumed these foods in spite of their pronounced odour. For the success of this method, above all at this period of the year, it is necessary to remove the diseased brood.—A. DURAND.

DRYNESS OF HIVES.

[118.] I am at one with 'A. E.', as regards adopting zinc, calico, &c., as a covering to the wood roof of hives; and a few words as to my method, size, and shape, may not be out of place at the present hive-making season. I use 11 inch pine, three deep saw-cuts making four boards. I make the body of my hives 24 inches long by 18½ inches inside, and 11 inches deep; legs I cut 17 inches, taking off a wedge-shaped piece 7 inches long, thus splaying the legs to obtain great stability, and also allowing the top part of the leg to go up inside each corner and still make the hive more substantial as besides the nails to hold the four pieces forming the hive body, the mortice of the leg can be nailed to the hive and then the lining nailed to the mortice from the inside; then in the splaying the notch forms a good seat for the bottom of body to rest on, and with a fillet bevelled to a sharp edge and well coated with paint at the back before it is nailed on. The leakage of wet and consequent damp is often caused by not attending to the joints at the time of making; every one should be well painted before nailing together, thereby preventing percolation of wet after the hives have borne the brunt of a few years' wear, and at the same time giving the putty a good foothold. My cover I make 11-inch ends at centre of gable, and 8-inch sides, giving ample room for a box of ordinary frames, or brood frames for extracting, or abundance of room for two crates of sections working on the storifying system.

Of course, my hive is flatter on the roof than some hives are, but not so flat as 'Neighbours' is limned on front page of 'ours'; more after the pitch of roof of "Walton's" Muskham Hive. I make it a rule to select the soundest pieces of board for the roof and also free from knots, running a groove on each under edge of

top piece that covers the ridge—with fillets bevelled to sharp edge, and well painted before nailing, to cover the joint between hive body and cover; and I have never been troubled with any drift of wet or snow into my hives that has been made on the above lines, although my apiary is in a very exposed situation, from south and south-west. The advantages of the above hive must obviously commend themselves to any practical bee-keeper.—WOODLEIGH.

DRYNESS OF HIVES.—CAMPHOR.—BEE STING.

[119.] This is a subject of great interest and importance, both to hive-makers and their customers, and, I think, with 'Amateur Expert,' that roofs of hives ought to be constructed of wood only, and yet meet the requirements if made properly and certain points attended to, not the least important being to paint thinly with more coats in preference to few and thick.

'J. T. H.' (p. 39) has described exactly my idea of a simple, yet effective, roof, though the groove under the eaves is unnecessary, the narrower the boards the less liable to shrink and swell, even if we have to use six instead of four. Flat boards on the top, and fillets, or plinths, I have quite discarded, they may add to the appearance, but sooner or latter will certainly be a source of trouble. The hinge referred to, on the same page, was exhibited in 1879, at the Kensington Show, on a hive by Messrs. Green & Sons, and mentioned by Mr. Cheshire in the *Journal of Horticulture*, at that time as 'a very convenient form of hinge;' it has been improved since then, and I believe several hive-makers have adopted it.

I am very pleased to find Mr. Cheshire is recommending camphor as a specific for *Bacillus* disease. (I guess we must not say foul-brood now.) I can testify as to the efficacy of the phenol treatment, but in severe cases, I believe the queens are often diseased, which may account for some failures so called. I always try and give them a fresh, healthy queen, if it looks like a 'doubtful case.'

In July, of last year, I placed some camphor under one corner of the quilt of a diseased stock that was too far from home to attend to with phenol; I examined in September, and found very little, if any, disease, renewed the camphor and wintered up, am hoping to find them perfectly free next month; of course, this is but a single experiment, and other cases might not yield in the same way, but I really think it is worth a trial, if there is nothing but simplicity to recommend it.

Mr. Grimshaw's paper on the 'Bees' Sting' is interesting, and I must confess that I lean toward the theory of it being an aborted ovipositor. I should be one of the last to find fault with Nature's laws, but I have often thought it seemed unfair, that the wasp, a comparatively useless insect, as far as we can judge, is enabled to use its sting without detriment, while the poor little bee must sacrifice its life in the same act. I am of opinion that the reason why the vicinity of the eye is a part so often attacked is because the involuntary act of blinking attracts the attention of angry bees, such bees often seem to sting without giving themselves time to alight and get disturbed thereby.—ROLAND GREEN.

WASPS.

[120.] In the *B. B. J.* of Jan. 7th Mr. Pridmore gives us an interesting account of the destruction of a large number of queen-wasps. It is surprising what might be done in this way. Last spring a man near here killed thirty in one evening, and received one penny each for them. I killed nine on one morning myself, and many during the season in single ones; but the largest takes I have had were in one case 1000, and in another 500. These figures will, of course, appear enormous to some, and for that reason I have preserved the last-named

number in spirit to convince the doubting. The way I obtained so many was by taking large nests: smaller ones have of course a proportionate number. By taking a nest I do not mean simply blowing it up with powder, or digging it out and breaking it to pieces, thereby scattering queens abroad instead of destroying them. My method is to dig around it and lift the nest bodily, and tie it in a large handkerchief, thereby securing all the wasps, or nearly so (in daylight, of course). By contrivance you need lose but very few workers, and those can be secured in the evening or next morning congregated at the vacant spot.

I have some of the finest specimens of perfect nests taken in this way in my possession any one could wish to see. One is in the shape of a flat fish, and has been supposed by many who have seen it to be a petrified fish. It measures twenty-seven inches in length, and fourteen inches in breadth. Another resembles a huge cocoa-nut; it was taken from an excavated mousehole. It measures about thirty-three inches in circumference, and twelve inches in height. I have several other specimens, all differing.—J. J. ASHFORD, *Expert Dorset B. K. A.*, *Blandford*, Feb. 2.

SPRING STIMULATION.

[121].—Give me, an old bee-keeper of five-and-twenty years' standing—a local representative of, and one of the largest bee-keepers in, my county—just space enough to endorse every word of Mr. Lingen Seager's note, and to score it with a golden line, viz., 'I have ceased to believe in spring stimulating, and have found those bees do best which have had a large store of honey left for winter and spring use, with plenty of room for natural expanding of brood.'

Is it not written in the chronicles of my Rectory how I nearly brought my old cook some years ago to a timely or untimely end with my new syrup can? Do I not hear her now in fancy 'dratting them bees' many times in the day, and declaring to her mistress how often 'she had a-stuck to her chair' from 'maister a-sticking everything in her kitchen, all for them bees?' And for what end? Why, only for the bees in their mistaken gratitude to remove me the said syrup from some secret cupboard of theirs months and months after, by popping it into the sections, to my great disgust. Honey is cheap enough, goodness knows, and why not save our labour and time, and the stickiness of our cook's tempers, and let them eat the labours of their own hands, and that, too, with greater strength than if sugar fed?

Some two or three years since I astonished my friend Kempe, the Vicar of St. Breward, in Cornwall, one of the best and cleverest bee-keepers I know, by my slabs of honey and quantities of bees in the early spring, all done by the 'let-'em-alone' system. My bees have given me over half a ton of honey last season, and I am sure I have left them nearly as much again (not anticipating any loss thereby), with plenty of combs to move about on if they so list.

I quite rejoiced when I saw Mr. Lingen Seager standing up for the 'let-'em-alone' system, more especially as he is an authority, which I do not profess to be. I tender him—and I am sure your correspondent 'J. P.' will also—my heartiest thanks. I could tell you some amusing tales of my bee-keeping adventures in these remote wilds of north-west Devon since I left Wiltshire.—RECTOR, *Buckland Filleigh*.

[Our readers would be pleased to hear them.—Ed.]

COMB SECTION HONEY. [31.]

[122].—One great difficulty with cottagers in these parts (and certainly not with them only) is want of time. If labourers go home to dinner, and live fairly near their work, they may have half an hour at their disposal at midday; after that they must wait till

evening, and bees will not suit their proceedings to our convenience.

I am surprised to find 'C. H.' [41, p. 18] in the neighbouring county making so very broad a statement respecting the sale of comb honey in sections, but I should certainly say from my experience that packing is a very serious obstacle to getting rid of supplies. A crate full will travel fairly well, if not too late in the season, and carriers are not too rash, or smaller quantities may be taken short distances; but not many cottagers will have sections in number worth the notice of dealers, or time to pack and convey a few. A cottager's wife goes to town 'a-shopping.' She 'gets a lift' and takes a dozen sections in a basket. At the end of her journey half of those are damaged, and she spends hours in placing those that are saleable. It is market-day, and people are too busy to attend to her, or they don't care about honey, or they bought of some one the day before. A friend says to me, 'If you have any spare sections I wish you would send me five shillings' worth.' I will with pleasure, but the job is to get a little wooden box of exactly the size you require, or to secure the lot in thick cardboard, and the time required is a more serious matter still, while as for carriage, on wheels and by rail, it must absolutely be delayed till a suitable opportunity occurs, if the article is not to turn out 'all of a mash.'

I think the establishment of local depôts ought to be seriously considered, whether in connexion with or independent of the Honey Company, and I shall be anxious to know the result of my friend Mr. Griffin's venture.

But if at last cottagers go in for run honey only, what will they think of the work which Mr. Neighbour cuts out for them [36] [3] if they would believe that their honey is 'ripe!'—SOUTH CORNWALL.

COUNTY ASSOCIATIONS.

[123].—There can be no doubt that it is 'rank heresy' for 'South Cornwall' to 'hint that we may be within an appreciable distance of the end of the work for which our Associations have been started;' and I hope that some county secretary will rate him scoundily. At the same time many will sympathise with the feeling which appears to lie at the bottom of his heresy, and will suspect that there was a wee bit of rose colour in the editorial spectacles when the brave vision of the 'Greater Britain' was described. The County Associations are nowhere near the end for which they were started. They have, indeed, done much in the past; but they have far more to do in the future. As to the past, they have to take the lowest view, immensely increased both the production and consumption of honey, and if they have diminished the gains of the few, they have been good friends to the many.

And yet they do not receive anything like adequate support. If it be unsafe to count upon a grateful return from an individual it is almost hopeless to expect it from a class. The many *will* demand a direct and substantial return for their subscriptions. Let us not call them hard names for so doing. Rather let us make allowance for diminishing incomes and increasing claims upon them, and let us see if we cannot *give* them what they ask for.

The great desideratum is a means for the ready and fairly remunerative disposal of members' honey. Honey fairs most certainly do not supply this. They are attended with too much uncertainty and risk. The Honey Companies have met, and can meet, the demand only partially. What is wanted is, not necessarily the establishment of a regular depôt, but some arrangement, in every market town, which members, and members only, may rely upon for the disposal of their surplus, even if that surplus be but a few pounds, and of getting a better price than the wholesale one which alone the Companies

can offer. I would not absolutely exclude even honey which had been taken by the brimstone method; for cottagers are slow to learn; but, of course, the same price could not be expected.

In the *Journal* for September 15th, 1884, p. 339, Mr. Anderson stated that he knew a man who intended working a truck with glass sides, in the streets of Weston-super-Mare, and that he expected to do a good business. Perhaps Mr. Anderson will be so kind as to tell us how the plan answered. I have often thought that a similar one might be profitably adopted in many places. And in other cases some grocer might perhaps be prevailed upon to expose members' honey for sale. There would always be the Companies to fall back upon.—CHARLES WOOD, *Winterslow, nr. Salisbury.*

[If our Editorial spectacles had too much of the rose-coloured tint we think it was an error on the right side. 'Hope springs eternal in the breast,' and we always like to look on the bright side. As well might we charge our Royal and County Agricultural Societies with neglecting the interests of their members, by not providing a remunerative market for their produce in these ruinous times, as attack the British and County Beekeepers' Associations for the same remissness. The disease is not to be eradicated by such means. It lies far too deep for that. By all means let these Associations use every effort to create both Metropolitan and provincial markets for our honey. Towards the attainment of this end we must *educate* our people to eat home-produced honey. This we are endeavouring to do, but it is not to be done in a day. Hope on, and work, and success will come at last.—ED.]

REMOVING BEES.

[124.] We often hear of the extreme precautions necessary in the case of removals—careful and steady methods by water, and by larch-pole hand-barrows, but rarely by the rough and tumble chances of the railway journey. I purpose therefore to give you a few details of a recent trip made by bees from Boulogne to my residence in central Yorkshire, with their cost of transit, so that more confidence, perhaps, may be given to those who are in some trepidation as to trusting their little friends in the hands of the uninitiated for a long journey. Late last September a trial stock in a bar-frame hive was prepared for travelling by having a strip of perforated zinc tacked on in front of the entrance; two quilts covered the frames, which were fastened in their places by four strips of wood nailed round the edges; strips of wood were also nailed together round the hive to keep it on the floor-board, and two nails driven into the rear end prevented the same from sliding either backwards or forwards. Now as, in view of this journey, there had been no autumn depriving, the bees were ready. They crossed the German Ocean to Goole (a long voyage) in a fearful gale, accompanied by rain, which must, one would think, have gone far to destroy the colony by soaking the quilt. But such was anything but the case with this experimental lot, voyaging as they were to save themselves from the sulphur-pit,—condemned bees, indeed. From Goole to Staddlethorpe by train, then transhipped to Leeds, again at Leeds for Horsforth, and then on to a jolting country railway lorry for two miles, from which they were anything but tenderly removed into my garden during my absence from home. All this was done, Boulogne to Horsforth, near Leeds, in forty-eight hours, at a cost of 9s. 8d. for transit.

I naturally expected to find a mess composed of combs, honey, and bees, on opening out the hive the next morning, but was most agreeably disappointed, for, on removing the zinc doorway and turning up each of the four corners of the quilt separately, bees appeared at all points, and before even 'taking a look round' commenced

turning out the dead, which amounted to some three hundred.

This done, they swarmed on the alighting-board, hanging in a beard-like mass down to the ground. I assisted them with a sloping board placed underneath them, and in about twenty-four hours they had slowly, but apparently unwillingly, re-entered their home. All the combs seemed quite in order, and as the bees in mild weather appeared on the side observation comb, retiring inwards on cold days, I judged it best to let the disturbance of the voyage suffice for the winter, and am assured that all is right by the quantity of bees enjoying a cleansing flight on mild days. I should state that the hive-cover travelled as a box containing spare frames and section crates. The next thing was to report progress to Boulogne, when a second stock and two empty hives were despatched, similarly prepared, and similarly unlucky as regards wind and weather, yet the bees arrived two days after despatch in even better condition than the first, for on 'uncorking' there was a grand vigorous roaring flight. Bearings were taken by the bees, but a hundred or so evidently got wrong on returning home, and entered hive No. 1, placed about two yards distant from their own; need I say there were a hundred or so corpses the next morning? Now the four hives, two stocks, and appliances came by steamer and passenger trains from Boulogne to Horsforth for under 12, and this I consider a lucky experiment. Perforated zinc might have been used instead of quilts, but in that case I anticipate the bees would have certainly perished by cold moisture: as it was the heat of the hive prevented this catastrophe. I trouble you with these remarks so that others may not be deterred from buying or selling stocks which have to travel considerable distances. We need not fear delay *en route*, for with bees, as with dynamite, the transit officials may be safely trusted to despatch the goods out of their hands 'all speed' without their being so labelled.—R. A. H. GRIMSHAW, *Crag Hill, Horsforth, near Leeds.*

COVERS FOR HIVES.

[125.] 1. I think if these were made with a curved top instead of the ridge shape they would be much more convenient as a table for the operator to place the sundries on when at work in the apiary. I have used such covers for years, and if they are covered with a piece of canvass before painting they can't let the wet through, and the top being curved the canvass is sure to fit close to the wood and only requires tacking down at the edges. I have mine made so that the roof or cover overhangs the hive-sides all round, and two plinths inside back and front, screwed on with two screws each. For winter these are taken off, when the cover will slip down over the hive, thus making the hive extra warm and very much reducing the height—a great advantage in rough weather. The eaves also protect the floor-board much better.—W. J. JORCE, *Farnborough, Hants.*

2. I find the most cheap and effective way of keeping the roof of my hives dry is as follows:—I give them a good coat of tar varnish on which I immediately sprinkle some good sharp sand, sufficient to thoroughly cover it, in about half an hour it will be dry and all the sand that does not adhere to the varnish may be shaken off; the appearance is very nice and the hive-cover will be perfectly waterproof. One that gave me a great deal of trouble last year, on being treated as above, is now perfectly dry.—JOHN SARELL, *Odcombe, Ilminster, Feb. 6th.*

3. I send sketch of a very simple cover (having no fillets) for hives which I have used for the last two years and have proved to be very satisfactory for keeping out rain and snow. The cover drops over the hive and rests on the porch in front, and at the back I screw a strip of wood just wide enough for the cover to rest on, it is therefore impossible for the rain or snow to get in, neither can the wind blow it off. It should be made so as to slip over the hive just easy so as not to jar and excite the bees; if the space

at the sides should admit bees (in case of robbing) a strip of flannel, or any soft material, could be tacked on inside which will keep it quite bee-proof. I have about a dozen hives and have had some trouble with the wet getting inside. In fact, one was so bad I had to remove all the quilts and replace with clean dry ones, but not so with my covers that slipped over the hives, which were perfectly dry, and I think another advantage it tends to keep the bees warm, being another outer wall.—J. P., *Kingsbridge, South Devon.*

5. Those who cannot afford costly hive-roofs will find my plan cheap and efficient. Give the roof a good coat of gas tar, while wet spread unbleached calico over it, at once give another coat, working from the centre of calico to the edges to get out all fullness. Three coats will make a good rain-proof roof. A pint of benzoline to two gallons of tar will make it dry quick and hard. I am much indebted to Mr. Simmins and others for their valuable information.—G. J. LENNY.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[95.] *Purifying Wax.*—Wax may be refined and the colour improved in the following manner:—Take half an ounce of the best roll annatto, cut it into thin pieces and put it in a clean copper or enamelled vessel with a pint of water, and boil it until it is perfectly dissolved; then add 14 lbs. of melted wax, and continue the boiling until the wax has taken up the colour and the greater portion of the water has evaporated, then, withdrawing the heat, carefully sprinkle over its whole surface about half a fluidounce of oil of vitriol; attention must be paid or it will froth up and boil over. The melted wax should now be covered and left for some hours to settle and cool slowly, care being taken not to disturb the sediment. All the impurities will be at the bottom of the cake and should be scraped off.—JOHN M. HOOKER.

[96.] *Material for Smokers.*—Old corduroy.—JOHN J. SMYTH.

[96.] *Material for Smokers.* (A. P. Howes.)—Out and away the best material for smokers, in my opinion, is corrugated brown paper (used by chemists and others for packing up fragile articles to go by post), it lights easily, gives a thick volume of smoke, and, if used dry, does not go out as long as there is any left to burn. I have tried peat, ordinary brown paper, fustian, &c., but nothing comes up to it. The only drawback is that it consumes rather quickly, but a good roll of it will burn for half an hour or more. I always have spare rolls of it at hand when about a long job.—F. B. G.

[97.] *Trapping Birds.*—Have you used snares about your hives? If not, make a few with horse-hair and try them.—R. J. S., *Cavan.*

[97.] *Trapping Birds.* (Beeb.)—Being constantly on the watch, *Parus major*, or the larger tit, is the only formidable bird bee-enemy I can see, and a well-directed shot the easiest and most merciful way of getting rid of him. *Parus ceruleus* is not to be mistaken for the above. With me it lives mostly on grain, and seldom goes near the hive.—JOHN J. SMYTH.

[103.] *Preventing bees propolis section rack to top of frames.* (M. C. H.)—The natural instinct of the bees prompts them to cover the interior of their hives with propolis, and consequently the crate receives its share with the other parts, which fixes it firmly to the tops of the frames; the less surface exposed the less propolisation. Your rack of thirty-three sections would expose a greater surface than one holding only twenty-one; this latter size is quite large enough. By using strips of quilting between the bars and edges of the rack and top of frames, the rack can be removed with greater ease. Last season I used strips of American enamel cloth with even greater success than ordinary quilting. Some hives of bees use much more propolis than others.—W. B. WEBSTER.

[103.] *Propolis Section Racks.* (M. C. H.)—The best preventative is to give the bees little or no cause for pro-

polis by ensuring as good a fit as possible. Other remedies are as bad as the disease.—AMATEUR EXPERT.

[104.] *Myrobella Plum.* (O. B. T.)—The Myrobella plum makes an impenetrable hedge when properly attended to. It is rapidly becoming a great favourite for fencing purposes in England, as it grows well in the poorest of soils. Cattle are not likely to eat it any more than white thorn.—HY. DOBBIE.

[105.] *Fastening Oil-cloth.* (O. B. S.)—Yes, more or less, usually but slightly.—AMATEUR EXPERT.

[105.] *Will bees fasten oil-cloth down when used as a quilt in bar-frame hives?* (O. B. T.)—Yes, but not to so great an extent as with woven material; it is also more easily removed.—W. B. WEBSTER.

[106.] *Foul Brood.* (D. A. Doudney.)—Rather a difficult matter to prove. I have always had a great aversion to frames across the entrance, as having turned up many hundreds of skeps found the greater portion of them—ninety per cent.—were not built so. I have never had foul brood.—AMATEUR EXPERT.

[106.] *Foul Brood.* (D. A. Doudney.)—Yours is a very strange coincidence. But that the difference in the position of the frames could pre-dispose the bees to develop foul brood is against all the ideas of such a development of the disease; if it were so, foul brood would be ravaging every apiary in the kingdom, both bar-frames and skeps, as now most bar-frame hives are made with the frames across the entrance, and the bees themselves build their combs in skeps very frequently after the same manner. Your cure of foul brood by the alteration is even more singular than your prevention. Cannot you trace the disease—if foul brood—to some other cause? try one or two hives this next season with frames across the entrance, and note result.—W. B. WEBSTER.

[107.] *Entrances.* (H. Jenkins.)—Two entrances for the same colony except in the honey flow are harmful, causing draught and a far worse evil—robbing. If only opened at times, the dead bees would probably be carried out, but at the cost of bewilderment and probable robbing. Excluder-zinc does stimulate swarming sometimes.—AMATEUR EXPERT.

[107.] *Excluder Zinc and dead bees.* (H. Jenkins.)—There is a right and a wrong side to excluder zinc; one side has a slight burr, caused by the punching of the holes; if this side is placed innermost it catches the articulations of the dead bees, and so prevents their being drawn through by the scavengers.—W. B. WEBSTER.

[108.] *Bees in Bucket.* (Welsh Novice.)—Close drive as if it were a skep. You will have to 'drum' a little more violently, probably. But why drive them? Let them remain as a private 'Bligh Competition' of your own, cut a hole in top of bucket with a key-hole saw, and super if necessary.—AMATEUR EXPERT.

[108.] *Driving bees from Wooden Bucket.* (Welsh Novice.)—You can drive them in same manner as done from a straw skep; but the best plan would be to saw the hoops, taking care not to break the combs, and then removing each comb and brushing the bees off into a skep; placing the skep afterwards on the stand previously occupied by the bucket, in order to collect the flying bees. If the bucket is larger at the top than the bottom, you can break the attachments of combs by 'bumping,' and then brush bees back into bucket instead of using skep for that purpose.—W. B. WEBSTER.

[108.] *Drive bees from a Wooden Bucket.* (Welsh Novice.)—Drive the bees into a skep in the ordinary way, i.e., as from one skep to another. The driving pins must be fixed firmly in the bucket with a hammer, and the skep kept in position at the junction by two iron skewers pushed into the back of the skep, about four inches from the bottom, one coming out again at the back to keep the edge of the skep from slipping into the bucket, and the other coming out inside the skep to keep it from falling backwards. The only difficulty is in jarring the combs sufficiently to make the bees leave the bucket, it is almost impossible to do so with the hands. You had better use short thick sticks.—F. B. G.

[109.] *Draining Honey out of Comb.* (Welsh Novice.)—We doubt not that at this time of year if placed in a warm position it might, but even then it would be a great trial of patience. Sling it!—AMATEUR EXPERT.

[109.] *Will honey drain out of uncapped comb by simply laying it in a flat position?* (Welsh Novice.)—Yes, in the case of very unripe honey, and then only that gathered from certain flowers. It is of no use trying to drain ripe honey in such a manner.—W. B. WEBSTER.

[110.] *Advantages of Association.* (Welsh Novice.)—Ah! W. N., we are well-nigh ashamed of you. Where would bee-keeping, as you find it to-day, have been but for Association? What about Shows, Bee-tents, Experts, Weekly *Bee Journal*, and voluntary helpers to give you information, not to mention a score of other benefits as the result of Association?—AMATEUR EXPERT.

[110.] *What are the advantages of joining a Bee-keepers Association?* (Welsh Novice.)—First and paramount is your duty towards your neighbour, such being represented by the poorer class cottager, whose lack of education and slender purse prevent his gaining a knowledge of the craft without the assistance of his more well-to-do brethren; this, it grieves me to say, is very seldom thought of by would-be Association members, by far the greater number of such considering before joining, will it pay. I am frequently asked that question by well-to-do people when canvassing. Next in order come the advantages you derive by conversation at meetings with other and more experienced bee-keepers, and the different little wrinkles you get posted up in. Visits—usually provided by Associations—from an expert, at least once a-year, but frequently twice, spring and autumn, for the purpose of instruction and practical illustrations. The circulation of books and journals,—I ought to have put journals in the singular, as this is THE JOURNAL—devoted to apiculture for members' perusal; these and other minor advantages are sufficient to induce any lover of apicultural pursuits to join at once and enter into the well-doing of his Association with heart and soul.—W. B. WEBSTER.

[111.] *How is the best way to put a swarm in a Unicomb Observatory Hive?* (H. Barlow, jun.)—Towards evening remove a frame from a well-stocked hive with the mother-bee, and place it in the Unicomb Observatory Hive, brushing a few bees off another frame at entrance and allowing them to run in if there are not sufficient on the frame already placed inside. If you intend keeping the Unicomb Observatory Hive near the stock more bees must be put in, as the old bees will return to their companions; the stock must be requeened. There is not room enough for a swarm in a Unicomb Hive.—W. B. WEBSTER.

[111.] *Observatory Hive.* (H. Barlow.)—Place the combs into an ordinary bar-frame hive that they will fit, give the swarm as recommended in *Modern Bee-keeping*, or Mr. Cowan's *Guide Book*, allow the bees to work out the foundation or build their combs as the case may be in the bar-frame hive, taking care to keep the combs straight by changing their positions while being built; the hive must stand on the stand intended to be used for the observatory hive while this is being done, and the same flight-hole used, and when the combs are built—say, from six to ten days—much depends on circumstances, place the combs and adhering bees into the observatory hive and shake the few stragglers remaining in the bar-frame hive, in front of the flight-hole, and allow them to crawl in. If this seems too formidable a job for you—and it need not be—place the observatory hive on its permanent stand, fitted up complete, and well closed up and darkened, and shoot your swarm on a board propped up in front of the flight-hole, encourage them if necessary with a wing or a few puffs of smoke to enter and hope for the best, choose the evening if possible. You will find the work of comb building will be much slower by this method.—AMATEUR EXPERT.

[113.] *Extracting.*—By all means extract indoors, make sure the hives you extract from are securely covered down before leaving them, or it will cause very much fighting. Why not build a cheap garden-house?—THOMAS ROSE, *Lamcote, Radcliffe-on-Trent*.

[113.] *Extracting.* (D. P. O.)—Bringing the frames in a box and extracting in the house. But cannot you build a small shed near your apiary for extracting in? On no account try extracting in the open air near your bees or any one else's.—W. B. WEBSTER.

[113.] *Extracting.* (D. P. O.)—In a honey glut you may do it in a retired nook of your garden, at other times you must get under cover, or set up a temporary screen of network around you. You are unfortunately circumstanced.—AMATEUR EXPERT.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[126.] *Substitute for Smoker.*—Can anyone suggest a substitute for the smokers now in use, suitable for poor cottagers unable to buy 3s. 6d. smokers? The smoker is a great difficulty in the way of poor Irish cottagers, both as to price and the care that must be taken of it.

[127.] *Manipulating House.*—There is a house in my garden near the apiary which would be useful for manipulating in cold or wet weather, as I can easily warm it to summer heat. As I have to leave home often it is an object to me to be able to manipulate a hive at the right time, regardless of weather. Half the house is roofed with glass, and I am afraid the bees would all fly up to the light. Can anyone tell me how to work in such a house? Should the hive be left in it till night to enable the bees to return, or would they make their way out through chinks or under the door to the stand where the hive was before its removal into the house?—IRISH NOVICE.

[128.] Will the use of section boxes $1\frac{1}{2}$ to $1\frac{3}{4}$ inches insure a quicker filling and sealing of their contents than those of 2 in. width, and where can such be obtained?—JOHN J. SMYTH.

[129.] *Doubling.*—My bees have increased to twenty hives—five skeps and fifteen frames—double the quantity I require. Would it answer to double every two nearest to each other, so as to reduce them to half? and if so, when will be the best time to do so?—MAURICE ORMOND.

[130.] *Queen Rearing.*—I intend to swarm my bees artificially in the following spring in the usual manner. That is—when the hive is full of brood in May remove it from its stand to a distance, and at the same time take out two or three frames of brood and the queen and insert them into a new hive on the old stand with two or three frames of foundation or empty comb. The old hive of bees will then proceed to raise queen-cells; and now comes the point on which I wish to obtain information. If I allow a queen to be hatched, as I have at present only one hive, she will in consequence be fertilised by the drones laid by the old queen. Now as I wish to infuse new blood into the hive that is now raising a queen, without entirely changing the breed, which would be the case if I imported a strange queen, would it be practicable to procure a dozen or more drones of a good breed and insert them into the hive, just before the hatching of the new queen, so as to be ready for the wedding flight?—WALTER CAMPBELL, *Hornfield, Tottenham*.

[131.] *Chilled Bees.*—How long can chilled bees remain in a state of suspended animation and yet be revived by warmth? According to some statements a lengthened period may elapse, but that is not according to my experience.—F. L.

[132.] *Distance between Frames and Hive-floor.*—How great a distance may be left between the bottom of the frames and the floor of the hive? Root says $\frac{1}{4}$ inch is perfection, but he recommends $\frac{3}{8}$ in. for fear of accidents. My hives leave $\frac{3}{8}$ in. without metal ends—some of which would make the distance over $\frac{1}{2}$ in., and the least I have seen could make it fully $\frac{3}{4}$ in.—F. L.

[133.] *Brazilian Bees.*—Can any one amongst your subscribers give me any ideas upon bee-keeping in Southern Brazil, south of Santos about 300 miles?—B. C. W., *Appleby, Doncaster*.

[134.] What are the points to be observed in the judging of black and foreign bees in an observatory hive at a show?—LOUTH, *Lincolnshire*.

Echoes from the Hives.

Shepton Mallett.—We had a very good season last year, and took upwards of 2 cwt. of section honey, which we easily disposed of among private friends at 1s. per lb. The bees have so far wintered well without extra feeding, and we trust we shall be blessed with another good harvest. I have not seen in your *Journal* a plan which is used in these parts successfully to prevent the queen ascending and spoiling supers. A piece of tick as broad as a man's hand placed across the middle on the top of the bars. The queen seems satisfied to remain under this. I mean to try it with a reversible hive this year. Queen excluders of perforated metal I have found obnoxious.—OWEN B. TYLER.

North Leicestershire.—After forty-one days' incarceration the bees came out on the 12th inst., and, although the snow which fell on Jan. 3rd lay in considerable patches around, there was scarcely any loss, the sun being very warm and the air quite still: the thermometer stood at 41° in the shade. *Queen Wasps.*—Thirteen live queen-wasps, one dead one, and one live humble bee, were found hibernating under about a square yard of moss growing on the tiles of the north side of a porch. They lay close to the tiles, in cavities formed among the matted rootlets of the moss. At the time the moss was pulled off it was thoroughly saturated with water from melting snow, but the insects were all quite dry. The moss was in vigorous growth, and nearly ready to shed the spores.—E. B.

Wokingham, Berks.—For the last seven weeks the bees here have been confined by frost and snow to their hives, but at last we have had a cessation of such weather! Saturday, the 13th inst., was a glorious day, like spring, and our little friends took every advantage of it: each hive seemed to have the idea that they must make the best use of their time and swarmed out in thousands. I took advantage of the weather and had a look to see how they were off for stores—everything satisfactory. One hive that I have—as an experiment—fed entirely from a feeder since end of October with thick syrup, is in first-class condition. When put in hive they had not a single cell of stores.—W. B. WERSTER.

Doulish Wake, February 12th.—What a glorious day for our pets, which as I write are thronging my snow-drop beds for pollen by *thousands*. This is the second time this season I have seen bees gathering pollen, namely to-day and on February 2nd, but to-day they are in right good earnest clearing out all accumulations of dead bees and rubbish from every corner of the hives, and in front of some there are literally heaps of such as the bees have so few opportunities of flying for several weeks. I have about forty stocks, and my apiary seems all life and activity, as if by magic after such inclement weather, which no doubt has saved a lot of energy. I notice two or three stocks that gave plenty of evidence of breeding all through December now seem the worse in point of numbers. I have not attempted to raise a quilt, nor do I intend doing so for a time, as I satisfied myself on the point of stores in October. I have not heard of any losses of stock yet, and as for myself I have never had any mishap, such as the loss of a single queen or the like, since I adopted frame-hives.—J. CHURCHILL.

Lismore, Feb. 12th.—My bees have come well through the winter, including three stocks formed of condemned bees. Yesterday was gloriously sunny and warm, and there was a great flight in front of my nine hives. It seems curious, but I observed pollen going in very freely into the stocks formed of the condemned bees. Most of it was bright yellow: I fancy from the furze, which has now a good deal of blossom. Our crocuses are only just coming out, and the bees never seem to go near them much in my garden. Quantities of pollen were taken in by the condemned bees as late as November 24. I can

see no pollen going into any of the other stocks. I believe if I had the courage of my convictions I should begin stimulative feeding in them, but I am afraid to venture on so bold a course.—IRISH NOVICE.

Ringstead, Feb. 15th.—The bees, as far as I can hear, are in a good condition in this district; some of them are getting short of food, especially those that were made up of driven bees, the owners not giving them sufficient food in autumn. On Friday last, Feb. 12th, being a mild day, my bees (seventeen stocks, all in bar-frame hives), came out in great numbers for a cleansing flight. One of them is in a very strong condition. They went into winter quarters crowded on eleven frames, and they cover all the frames now. On the above date they were fanning at the entrance as if it were summer. The chaff between the inner and outer walls was quite warm, and the condensed moisture had run under the back dummy and stood in a pool. Surely they have sufficient moisture without using enamelled cloth.—JOHN BULL.

NOTICES TO CORRESPONDENTS & INQUIRERS.

H. WELCH-THORNTON.—*Aphidian Honey.*—Honey (so called) collected from aphides, is considered injurious to bees as *winter* food, but in the spring months, when flying freely and breeding extensively, it is harmless. If it is in sections or in comb in any shape, we advise you to place it, uncapped, *below* the brood frames. This can be done, in frame-hives, by using a square box, without top or bottom, 4½ inches deep, which should be placed, with the sections or comb, beneath the hive, when the bees will carry the honey into the combs above, and by swallowing and disgorging will improve its colour and quality. Strong colonies about the middle of next month, if the weather prove fine, will quickly dispose of the quantity you mention.

J. C. T.—*Direction of Sections.*—Whichever way the sections are placed the bees will build their combs in the same direction in which the foundation is placed in the sections. It matters little whether the sections are placed parallel to, or at right angles with, the combs beneath, provided 'starters' are used.

WEST MIDLANDS.—*The Stewarton Hive.*—The Stewarton Hive has been successfully used in many parts of England very far from the heather districts. We have ourselves used Stewarton hives for a great number of years, and, although for some reasons we prefer the moveable comb hive, we would certainly consider the Stewarton very far in advance of the skep. If you will consult our back volumes you will there find the experience of many English bee-keepers.

CAPE COLONY.—Mr. Cheshire says that the bees forwarded are *Apis mellifica*, but that they have distinct variations, which he will be pleased to enumerate if a few pinned specimens are forwarded. It is exceedingly difficult to distinguish mere variations from specimens in spirit.

J. H., *Kent.*—*Foul Brood.*—Foul brood is not a necessary evil in bee-keeping. This disease has never occurred in many parts of England (see 'Useful Hints' in this number, p. 66). At the same time it should be borne in mind, that salicylic acid is a preventative of foul-brood. Its addition to the food can do no harm, and may prevent serious mischief.

D. H. D.—The bees have died a natural death—through old age.

R. J. S.—Willesden card can be had from Messrs. Spalding and Hodge, 34 Cannon Street.

C. R. S.—*Moving Stocks.*—The stocks could be removed safely in the manner described at this season of the year, if the road be not too rough, the hives placed on a good thickness of straw in a spring cart, and the journey performed at a reasonable rate.

W. STOKES.—It would take up too much of our space to give you the information you seek respecting driving

and transferring. We would rather refer you to Abbott's leaflets, *Modern Bee-keeping*, and Cowan's *Guide Book*.

II. W. II.—*Death of Queen*.—The death of the queen was not caused by her not having been fertilised in the autumn. We require more information respecting the bees than that given in your letter. Did all the bees in the hive dwindle away and die, or merely those forwarded?

MARCUS J. A.—There is no necessity for apprehension as to the queen; she is unhurt; but we would advise you not to repeat your manipulations until there is a necessity for them.

B. W.—*Two Storeyed Hive*.—The preferable plan would be to raise a portion of the combs only, replacing them with frames containing sheets of foundation, and filling out the upper hive by spreading the combs, and putting in sheets of foundation at intervals, as space is required according to the increase in bees.

NEW SUBSCRIBER.—*Taking Honey*.—Wait till the bees swarm naturally, and place the swarm in the Irish hive in the position of the old skep, which must be moved to a new location. The bees returning from the fields will augment the swarm; the young bees remaining in the skep will nurse the brood, which will all have hatched out twenty-one days after the swarm, when the honey can be taken without destroying any brood. 2. *Covering for Frames*.—Enamel cloth would be suitable at certain times of the year, or tick and three folds of flannel. 3. *Position of Section*.—In your long hive it would be allowable to put sections in the rear of brood-nest. 4. *Time for Feeding*.—By examination you might discover when the necessity arises. For stimulating you might commence six weeks before appearance of fruit-blossoms. (See opinion of J. M. Hooker on the best means of securing surplus honey in sections during honey season, p. 16.) 5. *Somersetshire B. K. A.*—Apply to the hon. sec., the Rev. C. G. Anderson, Otterhampton Rectory, Bridgwater.

CORRECTION.—P. 64, line 3 of Echoes, for post read frost.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

Apicultural Appliances for 1886.

Bee-keepers, and others, please note the undermentioned:—

BEES.—Now is the time to book Swarms for May delivery. The system adopted last season will be followed in every case this season: *i. e.*, the Swarm is so packed that no possible mistake can arise as to the presence of a Queen with the Swarm. Intending beginners please note:—Native Swarms, with grand Queens, safely packed on rail, 15/-.

CANDY (Salicylised), 6d. per lb., postage extra; 7 lbs. free 3/9. Stimulative Candy, superior to Flour Cake, reduced to 6d.

CANE.—For sewing Straw Skeps, 1/3 per lb., post free; much better than Briar, and cheaper in the end.

COMB FOUNDATION of Pure Bees-wax at current prices.

FEEDERS.—The DIVISION BOARD or DUMMY FEEDER maintains its position as at once simple and practical. No Frame Hivist should be without this form of Feeder, for Spring stimulative feeding, for Swarms, or for rapid Autumn feeding. A cheap, simple top Feeder, for Skep or Frame, complete with stage, &c., post free, 9d. An adaptation of Simmins' Dry Sugar Feeder, 8d. free; four Feeders, 2/- free.

HIVES.—Well made with seasoned yellow pine. Important improvements without complication. Prizes at every Show where exhibited last year.

HONEY EXTRACTORS, taking one, two, or four Combs, 10/-, 21/-, 25/-, and 30/- each.

METAL ENDS.—A cheap New Metal End will shortly be ready.

PLANTS for Bee-ferage generally in stock. Limnanthes may be planted out to end of March. 1/- per 100, free; 3/6 per 1000.

QUEENS.—Choice young native Queens, 3/6 each from end of May. Carniolans, Cyprians, and Ligurians imported of best quality. See Catalogue for particulars. HOME-BRED QUEENS a Speciality.—Working an Apiary for this purpose, in a district where no other Hive-Bees exist, I have unequalled facilities for producing a large percentage of purely-fertilized Queens of any desired race.

SALICYLIC ACID, pure as imported, 1/- per oz. Should find a place in every household, as besides its utility in the Apiary it is invaluable for preserving Meat, Fish, Milk, Butter, &c. Receipts for use if desired.

SECTIONS.—American One-piece V-cut, 4 1/4 x 4 1/4, best quality, at current prices, according to quantity. Dove-tailed Sections, any size, cut to order.

SMOKERS.—Cold Blast, 2/6, postage 3d. Why pay more? These Smokers will burn in any position, and keep alight as long as any fuel remains. Unbreakable springs.

SUGAR.—Guaranteed from the refiners as Pure Cane and free from chemicals. Good for dry-sugar feeding. Candy or Syrup in 2 cwt. lots, 20/- per cwt.

TINS.—Patent Self-closing. A great success. Keeps Honey in splendid condition, perfectly preserving the flavour and aroma. Air-tight when closed, and easy to open. Sample, five Tins, free, 1/-.

VEILS.—Blued Woven Wire all round. Cool and comfortable to the eyes, not liable to rust. Post free, 2/- each.

WIRE for making the Veils, 1 yard 6 ins. wide, selvage both edges, post free, 1/3.

ZINC QUEEN EXCLUDERS, and every other necessary appliance.

'MODERN BEE-KEEPING APPLIANCES,' an Illustrated Descriptive Catalogue, full of useful information. Post free, 1 1/2d.

Editorial, Notices, &c.

PROPOSED BEE EXHIBITION IN LONDON DURING THE COMING SEASON.

The annual general meeting of the British Bee-keepers' Association was held on Wednesday last, it was of an intensely interesting character. The discussion on the various agenda was unusually prolonged, the time occupied being nearly three hours. The report of the meeting which we append will be read with deep attention. The discussion on the several motions was carried on with much animation. It had been feared by some that the sad loss that had befallen the Association during the past year through the decease of the former Hon. Secretary, the Rev. H. R. Peel, would have, to some extent, affected the well-being of the Association; but we are pleased to say that this apprehension needed not to have been entertained. The numbers of the members present were larger, and the interest in the proceedings more sustained, than at any previous annual meeting. This at least proves the deep hold which the progress of apiculture has taken on the public mind, and that the members of the Association are fully alive to their responsibilities and to the demands and necessities of the times.

Mr. Jesse Garratt very ably endeavoured to make provision for a fairly representative exhibition every year by extending the prize-list at the Royal Agricultural Society's Show. Probably the schedule, as now issued for the R. A. Show, could, as Mr. Garratt remarked, be considerably improved at a very small additional expense. The Committee will no doubt give this suggestion the consideration it deserves. Any improvement made at the present time must, however, be sustained in future years. It would not be desirable to arrange an extensive schedule for the R. A. Show in 1887 because no London show was held, and in 1888 to reduce the same to its former dimensions on account of a determination formed to hold a London show. An important Society like the Royal Agricultural could not be expected to tolerate a retrograde step of this nature.

Mr. Clay's motion was of a more specific character, seeing it deals with the exhibition for this year only. We cordially agree with it. The President's remarks were much to the point, showing that if an exhibition on an extended scale be arranged for this year in London, it should be thoroughly well done and energetically carried out.

It was proposed, if possible, that the Exhibition should be held in the grounds of the Royal Horticultural Society

while the Indian and Colonial Exhibition was in progress. The meeting showed great anxiety to prove to Canadian and other exhibitors that British bee-keepers were alive to the present importance of apiculture: and they felt that this proof would be afforded by having a thoroughly good exhibition representing the present position and capabilities of English bee-keepers. They also hoped to be able to have the opportunity of adopting some means of showing their cordiality towards foreign bee-keepers by inviting them to some social gathering.—a *conversazione*, or in some other mode that might be afterwards determined upon.

As the funds of the Association were not in a condition to sustain the expense of the proposed exhibition, it was determined by the meeting to institute a Guarantee Fund. The sum of 200*l.* was calculated to be the amount that would be required. This was heartily entertained, and we are happy to announce that a sum of nearly 100*l.* was guaranteed by those present, including 25*l.* from the President. A noble commencement, which, we trust, will be generously seconded by bee-keepers generally.

We believe that the spirit exhibited by the meeting will animate the hearts of all bee-keepers in the kingdom, and prove that bee-culture in this country is rapidly progressing, and that its votaries are prepared to show that, if favoured with genial weather, the capabilities of this country for honey production are quite equal to all the demands which may be made upon them.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was celebrated on Wednesday, February 17th, 1886, at 3 p.m., in the spacious Board-room of the R.S.P.C.A., 105 Jermyn Street, St. James's. The noble president (the Baroness Burdett-Coutts) occupied the chair, and amongst the large audience of ladies and gentlemen present were the following members of committees, county representatives, and supporters of the Institution:—Mr. T. W. Cowan, the Rev. E. Bartrum, D.D., the Rev. F. S. Selater, the Rev. G. Raynor, Mr. D. Stewart, Dr. Walker, Captain Campbell, the Rev. T. Sissons, Mr. J. Garratt, the Rev. J. L. Seager, Mr. J. M. Hooker, the Rev. F. G. Jenyns, Captain Bush, R.N., Mr. R. J. Hinton, Mr. T. B. Blow, the Rev. W. E. Burkitt, Mr. Zehetmayr, Mr. F. H. Meggy, Mr. Baldwin, Mr. G. Henderson, Mr. Fox Kenworthy, Mr. Easty, and others.

The Secretary read the minutes of the previous annual general meeting, which were confirmed by general assent.

The President moved 'That the report and balance-sheet issued for the year 1885 be received and adopted,

with a vote of thanks to Mr. Kirchner, the Auditor: which resolution was seconded by the Rev. F. S. Selater, and carried unanimously.

The Rev. J. L. Seager, in proposing a vote of thanks to the retiring officers and committee, said they well deserved that compliment, for their duties were very arduous. Mr. Meggy seconded the motion, which was carried *nem. con.*

The President moved a vote of thanks to the Council of the Royal Society for the Prevention of Cruelty to Animals for the gratuitous use of their Board-room for committee and other meetings. Her ladyship said it had been a great pleasure to the committee of the R.S.P.C.A. to be of assistance to the Association.

The Rev. G. Raynor, in seconding the vote, congratulated the members on their good fortune in being able to secure the use of a beautiful room in the best part of London for meetings. This concession was equal to a large subscription towards their funds. The objects of the two Societies were in a great measure identical, and the B.B.K.A. was happy in having so good a friend at court as the Baroness. The resolution was carried unanimously.

The Rev. E. Bartrum, D.D., proposed the re-election of the President, Vice-Presidents, Treasurer, Auditor, Analyst, Librarian, and Secretary for the year 1886, and remarked that the Association was deeply indebted to all of these officers for the unceasing interest they took in the prosperity of the Association.

The Rev. F. G. Jenyns seconded the motion, which was carried unanimously.

The President acknowledged, with hearty thanks on her own behalf, as well as in the name of the other officers, the cordial vote just carried. It was a pleasure to her to find herself surrounded by such a body of earnest workers. She congratulated them on the increasing success of the Institution during the past year. Referring to the unhappy condition of Ireland, of which country one almost despaired, she thought it remarkable that the industry they were banded together to promote was nearly, if not quite, the only one that had flourished there despite the bad times. It was satisfactory to know that their aims and objects were spreading in that land. She felt inclined to linger on that point, because it seemed to her that the development of Irish industries was a matter of the most important national concern. She was glad to say incidentally that her own and Mr. Burdett-Coutts' efforts in regard to the fisheries on the west coast of Ireland had been attended with the most beneficial results—not only in the direction of making the lives of the fishermen more comfortable, but particularly in the moral elevation of the people. She had noted with interest that Bucks had been the most successful of the County Associations during the past twelve months. She could testify from her own observation to the increased interest taken during the last year or two in different parts of the country in bee-keeping and the production of honey—a result, no doubt, due to the labours of the B.B.K.A., and the Honey Company which they had floated. She did not know whether they had any return, or any means of ascertaining what amount of honey had been sent up to London within any specified period. It would be rather desirable if they could ascertain the amount of honey which had been sold throughout the country during any one year, because it was important to know to what extent the trade was increasing. Many changes had taken place during the year just past, and one in particular, which must come home with great sorrow and regret to all present. They had lost an invaluable friend in Mr. Peel, and one whom every bee-keeper must recall to mind with the greatest gratitude. It would be impossible to overrate the value of the services they had lost by his death.

The Secretary read the results of the election of the

Committee for the present year, the following being elected, viz.:—Mr. T. W. Cowan, Hon. and Rev. H. Bligh, Rev. G. Raynor, the Rev. F. S. Selater, the Rev. Dr. Bartrum, Mr. J. M. Hooker, Mr. D. Stewart, the Rev. F. G. Jenyns, Mr. H. Jonas, Mr. G. Walker, Captain Bush, Captain C. D. Campbell, the Rev. J. L. Seager, Mr. W. H. Dunman, the Rev. F. T. Scott.

Captain Bush, R.N., proposed a vote of thanks to the scrutineer of the voting-paper, which was seconded by Mr. J. M. Hooker, and carried unanimously.

Mr. J. Garratt moved: 'That owing to the abandonment of the annual Show, formerly held by the Association in or near London, it is desirable that the occasion of the Royal Agricultural Society's Annual Show shall be utilised for a more extensive and representative exhibition of bee-keeping appliances and products than has been usually secured.' He said it was a matter that had been mentioned from time to time, and had been brought under their notice before at a meeting of county representatives by a body appearing for the Berks Association. He was sure when they looked back on the annual Shows held in London they would remember a time of very pleasant meetings, which did a great deal of good. Unfortunately the expenses attendant upon them prevented their continuance for a time, but now the finances of the Association were in a more flourishing condition, he would like to see a return to the old custom of holding annual exhibitions. It was three years since they had done so in London. During those three years the occasion of the Royal Agricultural Show had been used to give an exhibition of bee appliances, and he thought that if that occasion was to be the only one on which the Association could have an exhibition, it would be better to make such exhibition far more comprehensive than it had hitherto been. He had been favoured with a schedule of the last show held in London. Comparing that with the rather meagre schedule for the Show of the present year, he felt sure there was plenty of scope for extension in the way indicated. All interested in the subject must desire to see a larger exhibition. To give an illustration—prizes were awarded for similar hives year after year which had apparently reached the last stage of excellence and perfection. The result was that only hives of one particular character were exhibited. There were other hives besides the bar-frame hive, and if cottagers were to be instructed in the use of simple means to make bee-keeping popular and profitable all kinds of hives should be shown in the exhibition. He thought his proposal would involve no more expense than the giving of a few extra prizes.

Mr. Easty seconded the motion, and said that every hundred visitors who attended an exhibition of the kind in London, thousands would see it if undertaken in connexion with the meetings of the Royal Agricultural Society. It was at one of these shows that he first became interested in the subject. They would be surprised to hear that he had been very successful as a bee-keeper in Bermondsey. His honey was dark-coloured, but nevertheless perfectly genuine.

In reply to the Rev. T. Sissons, Mr. T. W. Cowan said that the resolution could not affect the arrangements for the present year, as the schedule of the Royal Agricultural Society had already been issued.

Mr. T. B. Blow supported the resolution.

The Rev. Dr. Bartrum said that the B. B. K. A., like every other institution, had felt the effects of several years of commercial depression, and he feared the funds at their command would not permit of the extension proposed. Before attempting to carry out the project a guarantee fund of 200*l.* ought to be raised.

A lengthened discussion followed, in which Messrs. Garratt, Sissons, Jenyns, Cowan, Easty, Raynor, Selater, Meggy, Dunn, and Seager joined. Two amendments were submitted to the meeting, and negatived on a show of hands, after which the resolution was put by permis-

sion of the original mover and seconder in the following form, and carried unanimously:—'That it is desirable that the occasion of the Royal Agricultural Society's Annual Show shall be utilised, if funds allow, for a more extensive and representative exhibition of bee-keeping appliances and products than has been usually secured.'

The Rev. E. Clay moved, 'That it is desirable that a thoroughly representative exhibition of English bee-keeping should be held during the present year, and that the Committee be empowered to arranged such an exhibition, providing a sufficient guarantee fund is raised for the purpose.' He said the ground he intended to take up had been partially trodden upon by previous speakers. He strongly advocated a bee exhibition in London that year, because it was most necessary to convince the British public that they were able to compete successfully against Canadian produce. There was no doubt that the public interest in bee-culture was on the increase, and the Association should endeavour to profit by this point.

At this point, the Baroness, owing to a prior engagement, was compelled to vacate the chair, which was taken by Mr. Cowan.

Mr. Stewart, in seconding the motion, said that so long as they were enabled to hold exhibitions in the gardens of the Royal Horticultural Society, and show the manipulation of bees in a bee-tent, the venture had been a success; but on the last occasion, when the show was held at the Riding School, Knightsbridge, it resulted in a serious pecuniary loss. There ought to be no difficulty in having such an exhibition as would prove to home consumers that they could produce really good honey cheaper than it could be imported. A guarantee fund might be raised to fortify them in carrying out the project.

The discussion was continued by Messrs. Garratt, Clay, and Seager.

The Chairman said they had every reason to believe that Canada would endeavour to run them close in the production of honey, and it was most important that they should strain every nerve to compete successfully with them, and that it would be most desirable to hold the exhibition in some part of the grounds of the Royal Horticultural Society. It might be possible to do so in the Conservatory, in which case most of the visitors to the Colonial exhibitions would also be visitors to their show. He feared that an exhibition held anywhere outside the grounds would be a disastrous failure like the previous one. To show that a change in public opinion had been wrought on the question of bee-keeping, he need only say that when the Association started it numbered between 200 and 300 members. At the time he was speaking, including county Associations, it counted something like 10,000 bee-keepers in its ranks. He thought it important to teach the British public that pure honey would granulate, on which question there seemed to be a great deal of ignorance.

Mr. Stewart quite agreed with the Chairman's remarks, and thought that if a conversation were held in connexion with the Show to which the Colonial exhibitors should be invited, additional interest would be evoked in the proceedings.

The Rev. T. Sissons suggested that each of the forty-one County Associations should guarantee 5*l.* towards the expenses, by which means the difficulty about funds would be met.

The Rev. J. L. Seager submitted that the guarantee fund should be personal, and said that if every one present would make an offer of 3*l.* or 4*l.* each the sum required might be raised at that meeting.

A paper was thereupon handed round, on which several gentlemen placed their names, and the amounts they were prepared to guarantee.

The Chairman announced that he had at that moment

received a letter from the Baroness Burdett-Coutts promising a donation of 25*l.* towards the expenses of the London Show, and expressing a hope that they would use every effort to make the exhibition a good one.

The subject of the resolution was debated at great length by Messrs. Garratt, Selater, Hinton, Bush, Meggy, Stewart, Campbell, Clay, Baldwin, Hooker, and Blow, several matters of detail in regard to the exhibition being canvassed. Ultimately the resolution was unanimously adopted, and it was also decided to communicate with the Council of the Royal Horticultural Society for the purpose of obtaining space in their grounds for the proposed exhibition.

The Chairman read a letter addressed to the President by the Royal Society for the Prevention of Cruelty to Animals respecting cruel methods of destroying bees, and the same was referred to the Committee on the motion of the Chairman, seconded by the Rev. Dr. Bartrum.

Dr. Walker moved, 'That the existing rule as to filling up any vacancy which may occur on the Committee during any current year be rescinded, and that such vacancy (if any) be filled up by the remaining members of the Committee from those members who are eligible and willing to serve;' and pointed out several anomalies in the present system of electing the Committee.

Mr. Hinton seconded the motion, on which a general conversation ensued; and the Rev. T. Sissons proposed an amendment, which was carried, and the resolution finally passed in the following modified form:—'That the existing rule as to filling up any vacancy which may occur on the Committee during any current year be rescinded, and that such vacancy (if any) be filled up by the remaining members of the Committee from those members who are willing to serve.'

Mr. Stewart moved, 'That inasmuch as the present qualification for the Committee, viz., subscribers of one pound per annum and life members, is not found to supply a sufficient number of good candidates, the rule be altered as follows:—That the present qualification and mode of election shall continue in respect of the election of ten members of the Committee, and that the persons so elected shall from the general body of the Members add ten names to be submitted to the General Meeting, of whom five shall be elected by such meeting to serve with the ten persons elected as the Committee for the year.'

The Rev. T. Sissons seconded the resolution, and said he strongly deprecated the system by which eligibility to serve on the Committee was obtained by the payment of a certain sum of money.

The discussion was continued by Messrs. Garratt, Campbell, and Walker.

The Rev. F. S. Selater proposed an amendment to the effect that an annual payment of 10*s.* should qualify a member to serve on the Committee.

The Rev. F. G. Jenyns proposed that the qualification should be reduced to 5*s.*, which amendment was seconded by Mr. Hooker, and carried by eleven votes to six.

The Rev. G. Raynor protested against such a fundamental alteration of a rule of the Association without due notice being given to the members, and considered the step taken to be illegal.

Messrs. Hinton, Sissons, and Stewart, contended that the notice (No. 10) given on the agenda was adequate.

The Rev. F. G. Jenyns felt, after what had fallen from Mr. Raynor, that it would be undesirable to give effect to the amendment just passed, and he therefore moved the previous question.

Mr. Hooker seconded the motion, which was carried with about half-a-dozen dissentients, and the consideration of the whole subject raised by the original resolution was deferred.

The Chairman proposed a vote of thanks to the Baroness for her generosity and increasing interest in the Association, which was carried by acclamation.

A vote of thanks to the Chairman, proposed by the Rev. T. Sissons and seconded by Mr. Garratt, brought the proceedings to a close.

OXESHIRE COUNTY BEE-KEEPERS' ASSOCIATION.

A special general meeting of members of the Association will be held in the 'British Workman,' Ashley Road, Altrincham, on Tuesday next, February 23rd, at half-past seven p.m., for the purpose of considering the advisability of altering the name from the 'County' to a local association.—DAVID MORRISON, *Hon. Sec.*

DERBYSHIRE BEE-KEEPERS' ASSOCIATION.

During the past year the number of members has increased from 207 to 263; and the experts of the Association, Mr. Wm. Handby and Mr. Thos. Austin, have been enabled, through the improved condition of the funds, to visit all the members in the spring, and those who required their assistance in the autumn. The expert for the Northern Division of the County, Mr. Wm. Handby, reports that he commenced his spring visiting in April, and made a few autumn visits in October; that in 17 days he made 96 visits, and examined 158 stocks in bar-frame hives, and 155 stocks in skeps; and that the cost of visiting amounted to 5*l.* 1*s.* 6½*d.* The expert for the Southern Division of the County, Mr. Thos. Austin, reports that he commenced his spring tour in April; that he made 120 visits in 18 days, and examined 466 hives—314 bar-frames and 152 skeps; that in the autumn he made 10 visits in 2 days, and examined 49 hives—26 bar-frames and 23 skeps; and that the cost of visiting amounted to 6*l.* 3*s.* in the spring, and 1*s.* in the autumn. Several lectures on bee-culture have been given in various districts, and practical instructions in the manipulation of bees have been given in the Bee Tent, at Barlow, Creswell, Derby, Matlock Bath, and Tibshelf. The following members have been elected to be District Hon. Secretaries:—Mr. W. Wilkes, for Church Broughton District; Mr. T. M. Bryan, for Clay Cross District; Miss Nodder, for Ashover District; Mr. B. Skermer, for Alfreton District; Mr. S. Hawkins, for Belper District; Mr. T. A. Hoyle, for Staveley District; Rev. C. E. Drew, for Clowne District; and Mr. Henry Cook, for Selston District; while the Rev. G. M. Hubback has resigned his secretaryship for the Ridgway District. By the kind permission of the Derbyshire Agricultural Society, to whom a vote of thanks is due from the members of the Association, the Annual Show was again held on their grounds, on the 9th and 10th of September. The Show was the largest and most satisfactory exhibition which has been held under the auspices of the Association. The judges were Mr. R. R. Godfrey, of Grantham, Mr. Henry Goodall, of Derby, and Mr. C. N. White, of Somersham, one of the experts to the British Bee-keepers' Association.

BEE-CULTURE IN EGYPT.—The Egyptians exhibit great skill in cultivating the bee. The flowers and the harvest are much earlier in Upper Egypt than in lower, and the inhabitants profit by this circumstance in regard to their bees. They collect the hives of different villages on large boats, and every proprietor attaches a particular mark to his hive: when the boat is loaded, the conductors descend the river slowly, stopping at all places where they can find pasturage for the bees. After having thus spent three months on the Nile, the hives are returned to the proprietor, and, after deducting a small sum due to the boatman for having conducted his hives from one end of Egypt to the other, he finds himself on a sudden enriched with a quantity of honey and wax.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

WINTERING BEES.

[135].—In the year 1878 I tried an experiment on wintering bees in two hives so altered as to have the entrances on the top, some particulars of which I send you. The hives stood on four legs, and the floor-board was drawn out between the legs from right to left. The frames were taken out at the back, and a space left behind them to put in the sections. My first swarm came off on 30th May, and was put in, say, No. 1; my second swarm came off 18th June, much larger than the first, and we put it in No. 2 hive. No. 1 hive before the bees were put in, weighed 30 lbs., No. 2 hive, 27 lbs. The season was nearly as bad a one as I ever experienced, but I did not feed them. On 21st September No. 1 weighed, gross, 44 lbs.—hive 30 lbs., bees, &c., 14 lbs.; No. 2 weighed, gross, 43 lbs.—hive 25 lbs., bees, &c., 18 lbs. I did not feed them, but left them as they were. Weighed again in February, No. 1, 37 lbs., No. 2, 36 lbs., each of them were 7 lbs. less than in September, which had sustained them, being ½ lb. weekly. Now the 1878-79 winter was a regular old-fashioned one; there was scarcely an opportunity from November till February for the bees to take a flight, snow on the ground continuously, excepting a few days end of December. I took out the floor-boards in February, and found about 100 dead bees, but no dirt.—G. F. PERKINS.

HAVE BEES A LANGUAGE?

[136].—We all know the answer given by the late Mr. Pettigrew to this question. But then he almost defied the bee. Still I really believe that it was his book and and those fascinating letters of his to the *Journal of Horticulture*, which clenched the nail and riveted the bee firmly on my mind.

I have always been of opinion that bees have a power of communicating their ideas to one another, *i.e.*, those ideas necessary for their preservation, as for instance, when they are attacked; when there are stores to be obtained; when they have decided upon the moment for swarming; the loss of their queen; and so on, but I am certain of this, that they have no direct means of making instantly known their ideas one to another as we have, for if so, how comes it that it takes a colony of bees from three to six hours, and in some cases twelve to eighteen hours, before they discover the loss of their queen? Bees have the power of communicating this fact to each other, we well know, but the process—whatever it may be—is a comparatively slow one. It may be that influences, or states, of this kind, act like a disease, and spreads itself little by little over the entire mass.

Now let us look at the subject of honey-gathering. How comes it about that the whole hive, or at any rate all the old bees, all of a sudden start off for the fields at apparently a given signal, on foraging excursions? How comes it that the hive, which a few minutes before was as quiet as the night, is now reverberating with the roar of a thousand wings? What could have caused

all this commotion? Let us see. One, or perhaps more, of the bees whose duty it is to keep a watch for honey and weather, have returned with their honey sacs filled, and pollen 'baskets' burdened, and with the warmth of the sun still aglow in their little frames. They enter, and are met by hundreds of others, who stop them at every turn, and thoroughly inspect them; they offer their proboscides to all around, who all take an infinitesimal portion of the nectar, and they likewise pass it on to others till, in a minute or so, the whole colony is alive to the fact that there is honey to be obtained. But here comes another difficulty, where is to be obtained from? I contend that the bee or bees, who in the first instance brought honey or pollen into the hive, and therefore the cause of imparting the knowledge that something was to be got, have no power to inform their sisters *where* they obtained it; and so what do they all do? Why, all sally forth in search of it, and by means of those powers which Nature has richly endowed the bees with, most of them soon find out Nature's Insect Larder. To my own mind, this solution of the difficulty is the only one which will account for the fact that so many of the bees return without even obtaining any treasure at all.—A. E. BOOKER HILL, *King's Lynn*.

SOUTH CORNWALL AND HIS DIFFICULTIES.

[137.] My cousin 'South Cornwall' (all Cornishmen are cousins) seems full of troubles, they seem on the increase; and like a brave man in despair he strikes out right and left, now at the bees, now at his honey, at the Editor, then the Associations (only it was Christmas), statesmen, Free Trade, Greater Britain, the people that offer the market women a 'lift' and give her a 'jolting' gratuitous, and, last of all, at Mr. Neighbour's dodge for 'ripening' honey.

I admit it is very sad to produce any article and then not find a sale for it. I met another 'cousin' in our market town recently. She had come into these parts with her husband, who had taken a farm near at hand; she had her basket of butter as at home, she was looking decidedly 'blue,' there were no stalls in the market for butter, and apparently no one that ate butter in the neighbourhood. I helped her with what advice I could: 'Cold comfort,' say you, 'it costs nothing.' The results in detail I need not give. Six weeks after I saw her again. 'Where is your basket of butter?' 'No trouble to sell it now,' says she; 'they come to the farm and fetch it; we wish we had brought thirty cows instead of eleven—this was over three hundred miles from home.'

I have given you this because it illustrates honey selling; I could not sell mine once, but now it is all 'fetched,' I have no need to go a-begging with it; some of it fetches fancy prizes too, but I always put it up tastily. 'But you are only one.' Quite so, but I have a near neighbour, he removed here from about fourteen miles distant and brought twenty-five stocks of bees with him. He came to me for help, I sold some for him at a small commission, and I gave him a 'wrinkle' as well. He acted on it and went to a large grocer in the town and arranged with him to put a stock on his counter and keep it up to that amount, taking all risks, but giving the grocer a commission on all sales, and a monthly account. He staged the goods very tastily, they sold well, and the demand has increased by leaps and bounds. This year he was cleared out of six cwt. of section honey before Christmas, and the stock was exhausted, and the grocer was in trouble because he must keep it in stock; it had become a necessity. I was again appealed to. I at once applied to a 'poor' fellow, who, as I expected, had a large stock by him that he could not sell. I told him what I wanted, and I found if my friend would pay carriage, glaze them, and put them up as he did his own, taking all risks and pay cash, my 'poor' friend was willing to submit to be bled to the tune of ten per cent.

I need not say I turned from him with disgust. I do not mind working hard for the good of my neighbour gratuitously. You, Mr. Editor, know something of that, but if it is to be a business transaction I look for something like business terms. Don't think depression does not reach to that happy county wherein 'A. E.' now dwells; it does, and very aggravated; but still we have sufficient 'rose' in our vision to keep alive 'the eternal spring of hope.' 'But hope that is seen,' &c., &c.

Just a word, in closing, to Mr. Wood ('County Associations,' 123). The work he points out cannot possibly be done by them: it is a matter of supply and demand simply, and must be done by trades. You cannot expect any committee of a semi-philanthropic organization, as Bee-keepers' Associations are, to engage in and successfully carry out trading operations as dealing in honey involves.

'South Cornwall' has a further trouble in store. If he will read the rules for the guidance of secretaries organizing shows, as agreed on at our meeting of representatives at the B. B. K. A.'s last quarterly meeting, I fear in his present state of mind he will not derive much comfort from their perusal, and yet they were considered a necessity by all there assembled, including—AMATEUR EXPERT.

THE PORTABLE HIVE.

[138.] This hive is a facsimile of 'Abbott's Copyable or Improved Irish Hive,' except that it is so arranged as to take to pieces. This hive is so well known to the public for its simplicity of construction, cheapness, &c., that it will be unnecessary for me to dilate on it here. The advantages gained by the Portable hive are several. Amongst them are:—1. People shifting their quarters can, without much expense, take their hives with them (the most expensive part of their apiary). 2. In case of foul brood, &c., the hives can, in the course of a few minutes, be so thoroughly cleaned and brought into a thoroughly sanitary condition, every corner and crevice being get-atable. 3. Persons (especially those of a non-mechanical turn of mind) wishing to take hives to our colonies or elsewhere. 4. The enormous weather-resisting powers and strength making it suitable for any climate. Therefore, with one's hives taking to pieces, likewise the frames and the section-racks unscrewing, what before were so cumbersome in transit will now occupy one-fourth or one-sixth the space they did before.—JENKINS KINNAIRD, *Leatherhead*.

[Our correspondent has forwarded a very neatly made model of his Portable Hive. If our memory serve us right, Messrs. Abbott have intimated their willingness to forward hives in pieces; and it is not an infrequent practice of the American manufacturers of the Langstroth and Quinby hives.—Ed.]

REMARKS FROM AN AMATEUR'S DIARY FOR 1885.

[139.] Having been very successful last year, and noticing the numerous inquiries made in the *Journal* as to manipulations and time of performing the same, I believe the following remarks will be found of practical use to many who, like myself, have been induced to commence bee-keeping by reading the *Bee Journal*.

In autumn 1884, I put four stocks in bar-frame hives, into winter quarters, on seven, eight, six, and eight frames respectively. Nos. 1 and 2 were old stocks—swarms of 1883—when, and with which, I commenced bee-keeping. No. 3 was a June (1884) swarm, and No. 4 was a stray swarm found in a hedge on July 26th, 1884. January 1885, was cold and dull, the sun shining on five days and bees flying on seven days. Tom-tits were busy about the hives at the end of the month.

February was favourable, the sun shining on twelve days, and the bees out on twenty days. From the 1st

to the 15th, yellow excreta were abundant on the hives and surrounding bushes. I consequently dried and warmed the chaff cushions, which speedily checked what seemed to be indications of dysentery. On the 11th the bees were working on the snowdrops, being two days earlier than last year. On the 28th, at noon, with bright sunshine and the thermometer at 58°, I overhauled the stocks, and found brood on the three central frames. Removed the frames to the front of the hives, crowding the bees on to five, five, four, and five frames respectively. The crocus blossoms began to open at the end of the month.

March was a very cold month, the bees flying on nineteen days. Upon examining the hives on the 28th, and spreading the brood, I found less brood than at the end of February. During the month the stocks were fed slowly with dissolved cakes of candy, left over from the winter.

April, from the 1st to the 17th, was cold and unfavourable for bees. On the 6th, with thermometer at 60°, examined hives, and spread brood by placing back frame in centre and adding one frame each to Nos. 3 and 4—found abundance of brood, but little food. From the 17th to the 30th was splendid, the bees daily working on the blooms of gooseberries, damsons, pears, and the buttercup. On the 20th, I popped a frame in the centre of Nos. 1, 2, and 4; spread brood in No. 3, and found queen-cells started in No. 2. On the 27th, spread brood and popped fresh frame of comb into Nos. 1, 2 and 3—drone brood in No. 2. Total frames in hives: seven, seven, six, and seven, respectively. Fed slowly during the month.

May was cold and unfavourable up to the 24th. Cherries and currants began to bloom at the beginning of the month; apples and forget-me-not, at the middle; and chestnuts, ivy and holly, towards the end. On the 5th, added one frame to every hive, and found drone-brood in worker-cells in all the hives. Cut out queen-cells in No. 2. On the 19th drones were flying; added a frame of foundation to Nos. 1 and 2. On the 24th removed two frames from No. 1 to No. 2, and placed super of eighteen sections (1-lb.) on top; the number of frames below being eight. In No. 3, removed one frame to No. 4, and placed super of eighteen sections (1-lb.) on top; the number of frames below being seven—also placed frame of foundation in No. 4. On the 29th, doubled No. 2 by removing six frames of old comb from the brood-chamber to a hive on the top of the other, and replacing with two frames of foundation, thus leaving eight frames in the lower hive. On the 30th, added two frames of foundation to No. 4, and to-day a neighbour had a swarm out of a skep, being the first in this neighbourhood.

June.—The first fortnight was splendid honey weather. From the 15th to the 25th was dull, cold, and showery, with very little honey coming in. From the 26th to the end of the month was good honey weather. The flowers open this month were sycamore, may, ivy, strawberries, forget-me-not, raspberries, and white clover. I should encroach too much on your space to chronicle all that was done this month; but to summarise. No. 3 swarmed on the 11th, which I temporarily hived into No. 5, and supered. No. 4 swarmed on the 11th, 12th, and 27th, and were returned every time. By the 30th I had taken ten sections, and extracted twenty-eight pounds.

July.—The first fortnight was splendid honey weather. From the 15th to the 22nd was not so good, being dull and cloudy; the rest of the month was splendid. The flowers open were white clover, and towards the middle of the month the limes opened. A large acacia, in bloom at the beginning of the month, was crowded with bees all day long. No. 4 swarmed again on the 1st, and this was also returned. No. 5 swarmed on the 12th, and was given to a friend. This month's yield brought the total to 110 sections and ninety-six pounds extracted.

August.—The honey season being over, on the 8th I united Nos. 3 and 5; and on the 10th removed my last super; the total yield for the season being as under:—

No.	Sections.	Extracted.
1	80	15
2	—	82
3	25	6
4	—	76
5	16	6
Total	121	185

September.—At the end of the month the bees were removed into clean hives, and the number of frames reduced. September was on the whole favourable; but a sharp frost on the 28th cut most of the summer plants. Winter passages were cut at the end of the month, and the number of frames reduced to seven, seven, nine, eight, in the respective hives.

October was a cold, wet month, the bees being indoors most of the time. On the 16th I placed a 3½ lb. slab of candy under the quilt of every hive.

November was dull and cold; but the bees were able to fly on eight days.

December was also cold, the bees flying on two days only.

The honey extracted in July and August was very light, but had a greenish tint. The wax extracted was very dark, with a greenish hue.—G.WENYX.

THE BEST HIVE.

[140.] I was very pleased to read Mr. A. Sharp's letter on the above subject, and am gratified to find that others think as I do that the long hive is the right one. I came to that conclusion last year, after having tried many ways, and told some of my friends never to make another hive unless they would take in from eighteen to twenty bars. The doubling system has, I think, many objections, one great one I found to be the large extra amount of room given all at once, beside the expense of the sheet of excluder zinc, which must be placed over the lower hive. I have found that always required, or the queen will get up into the top hive, it may be on account of warmth.

New, on the subject of hives. I am at a loss to know why so many go to the expense and trouble in making double-walled hives (I am speaking of those who make their own hives and not for sale), for I have found that my bees have always done just as well in single walls, and in future I intend to make all single. I do not believe that bees are hurt much by cold if kept dry; the one thing I always fear is the heat of summer, but with care that can be got over. This winter we must call a cold one, and I may mention a fact in my apiary that in two boxes with one-inch walls and ¾ tops high enough to take sections, I have had no extra covering but a piece of calico, and the bees are well and strong with plenty of food. I tried this as an experiment, but as the cost is so little to place something over them, I would not like to advise on the matter. These hives seem to me to be much dryer than those I have covered with thicker material. I should like to hear what others think on the subject.—H. F. HILLS, *Earls Colne, Essex.*

SMOKING BEES.

[141.] Having read in the *B. B. J.* of the 4th inst. Mr. Green's paper on the 'Climax Hive,' advocating the system of non-smoking in handling bees, I venture to send the following notes from a lady's management of bees in the county of Surrey during the past spring, which may, I trust, invite others to give their experience.

'May 10th, 1885.—I am quite *freely* manipulating bees in the body hive now without *any* smoking. In fact smoking takes too much time. I am only particular to wear always a veil for the bees' sake, that they might

not be entangled in my hair and unnecessarily irritated thereby, as also gloves covering my sleeves that the bees may not tease me by crawling up the arms. Out of eight hives shifted about one day for introduction of fresh frames only one was spiteful, and I had almost to fly the cottage, where I was fastening old combs into new frames. I then prepared the smoker and used it, after which all went well. This hive was the worst-tempered hive also last season. This shows a very different effect to that described by Mr. Green and his 'savage hive.'

May 13th.—Two days ago I manipulated seven hives and only smoked two of them. Yesterday, again, eight hives and smoked only one. This morning three hives and no smoker even lighted.—F. H., Kent.

SMOKING HIVES.

[142.]—I have read with much interest Mr. W. S. Green's paper on the above subject, and with your permission will give my experience. And, first, I am an amateur, and never had bees until last August, when I got a skep, the bees and combs I transferred into a bar-frame, as per 'Cowan,' with the exception it was done in the morning. After a few days I went to try and put in a new queen (and trying it was). I marched up to the hive with every expectation of success. Alas! soon to be dispelled—behold me flying before an infuriated army of bees, who are not content until I go into the house, and it was hours before I could get the smoke; the queen was lost, so I had to get another. This time I did better, but the smoker was conspicuous by its absence. From that time I have never used a smoker, and do not intend. I do not use gloves, as I have found them in my way.—R. J. S., Cavan.

ENEMIES OF BEES.

[143.]—Whilst we are on the subject of death's-head hawk moth, tomtits, &c., as enemies to the honey bee, it may not be out of place to give an account of a case coming before me on my autumn tour. The apiary in question consists of some six or eight hives (Abbott Bros.); quite lately these hives have been attacked by a bird, or birds, which have made holes in the roofs and sides, the latter by standing on the porch. One hive has as many as six holes in various stages of completion. The holes are about $1\frac{1}{2} \times \frac{1}{4}$, and taper to about $\frac{1}{4}$ square at the base. The hives are $\frac{3}{4}$ in. wood, and perfectly sound. It was certainly disheartening to see the wet state of the interior when the roof was taken off. Have any other bee-keepers met with like experience?—C. W. SUMMER-SKILL, *Expert Warwickshire Bee-keepers' Association, Hartlebury.*

Reviews.

A BOOK ABOUT BEES. *Their History, Habits, and Instincts; together with the First Principles of Modern Bee-keeping for Young Readers.* By Rev. F. G. Jenyns, Rector of Knebworth. (London: Wells Gardner, Darton, & Co., 1886.)—This work of Mr. Jenyns will prove a valuable and a welcome addition to bee literature. The object of the book is to make the study of the honey-bee interesting to young readers. It does not aim, on the one hand, to be a guide-book to the management of bees, or, on the other, it does not affect to partake of the nature of a scientific treatise. Its design is more lowly. It desires to occupy an open field which hitherto has not been occupied by any previous treatise. It impresses on the youthful mind the importance of the habits of observation, and seeks to unfold one page in the great book of Nature. Mr. Jenyns, we consider,

has succeeded in the object he has set before himself. He has a special aptitude for making his subject thoroughly intelligible to his young readers. His style is lucid and simple; and from the beginning to the end the interest in the subject is well sustained. It is written with much painstaking and with great conscientiousness. It will, besides effecting the purpose for which it was primarily compiled, create a desire to study matters which are cognate and collateral to the subject treated by the author. The study of the bee can be readily grafted on many other branches of knowledge, while many other branches can be grafted on it. This is very apparent in the work before us. Its revelations and its teachings will create a desire to know more of entomology, and to penetrate the mysteries of botany. It inculcates lessons of kindness to all living creatures, and it teaches the value of habits of order, cleanliness, and thrift. The book will win the support of ministers and teachers, and we should be pleased if it has a foremost place among the prizes given to the young. Lecturers on bee-keeping will find in its pages a repertory of illustrations and anecdotes which will greatly assist them in their labours. Parents are frequently disturbed by the nature of the books read so greedily by their children in their spare time. They have an almost unlimited supply of exciting tales which unfit them for more requisite studies. It is to be desired that children should be delivered from this unnatural tension of mind, and be brought more in contact with the sobrieties of daily life. Natural history should be taken up as one of their studies, and Mr. Jenyns' work is well calculated to produce a salutary effect on their minds, and allure them to take an interest in the special subject it so well illustrates. The work is introduced to the reader by a carefully-written preface by the Baroness Burdett-Coutts. It has been written at the request, and published with the sanction, of the B. B. K. A., with the hope that it may be accepted as a reading-book in schools. It is abundantly illustrated by many engravings, some of them of a very superior order. We wish the work all success, and heartily recommend it to bee-keepers as a model of conveying instruction to the young on the habits and structure of the honey-bee.

Replies to Queries.

*. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[54.] *Moving Hives.*—The safety of moving your hives much depends upon the weather in your locality; if very severe, and the bees have not been able to fly much, I should say move them.—J. S. LAWTON.

[72.] *Excluder Zinc under Sections.*—(T. Jenkinson.) In working two hives with crates of sections on top, I found that in one case where I had no excluder zinc, but where the crate rested on metal ends raised above the frames so that the space between frames and sections was about $\frac{1}{2}$ in., I lost several sections with drone-brood. In the other, where the space between frames and sections was only $\frac{1}{4}$ in., there was not a single case of brood in the sections, although I did not use excluder zinc in this either.—Boz.

[126.] *Substitute for Smoker.* (Irish Novice.)—I used a piece of indiarubber tubing, as illustrated in Cheshire's *Practical Bee-keeping*, when smokers were more costly, but do not recommend it. A tobacco pipe is the most simple and effectual of all smokers, but you cannot wear a veil with comfort, and a pipe becomes both fatiguing and injurious if you have prolonged manipulations.—AMATEUR EXPERT.

[126.] *Cheap Smoker.* (Irish Novice.)—There is a cheap little smoker made by W. P. Meadows, Syston, near Leicester, which is blown by the mouth, and any one with a good natural pair of bellows will find it act admirably.—PRATA.

[126.] *A cheap Smoker.*—A poor Irish cottager can make a very good smoker with a $\frac{1}{2}$ -lb. coffee tin by inserting a short piece of the elder, with pith out through the lid and bottom, and blowing through with the mouth; if a piece of wood $\frac{1}{2}$ -inch thick is nailed to the bottom and the lid, boring a hole for inserting the elder tube, a permanent, strong smoker can be made that will last for years.—J. E. GROCOTT.

[127.] *Manipulating House.* (Irish Novice.)—The bees would fly up to the glass and waste their energies in endeavouring to get out; a small portion of them would get through the chinks, but very few, as the bulk fly to the strongest light; it is a most unsuitable place. By darkening the glass roof with boards or curtains outside, and opening the doors, the bees would fly out and join their companions, if hive is placed on original stand; very few would find their way back into the hive if same was left in the building. Presuming that you manipulated a hive in the house as it is, the flying bees would, when quite exhausted, gather in clusters on the sashes; they could then be—towards evening—collected and placed in entrance to front of hive, but this is a most cruel and unwarrantable proceeding.—W. B. WEBSTER.

[127.] *Manipulating House.* (Irish Novice.)—Notwithstanding what you say about being compelled to leave home, &c., I advise, do not manipulate in weather that requires an artificially warmed house. You may use it as you suggest; you would find the bees that took to the wing while the hive was open would fly to the glass and there worry themselves to death; those few that did effect an escape from the house would return to the stand, except the young bees who were then flying for the first time; these would hover around the house attempting to return, and would consequently perish.—AMATEUR EXPERT.

[128.] *Narrow Sections.* (John J. Smyth.)—Sections of such a size are filled quicker; they are generally used without separators. Cut down some two-inch sections to the width you require.—W. B. WEBSTER.

[128.] (J. J. Smyth.)—They would take longer, 'weight for weight,' than 2 in.—AMATEUR EXPERT.

[129.] *Doubling.* (M. Ormond.)—No; you will only be wasting your bees, except in the case of motherless or depopulated stocks, when unite. Advertise those you do not wish to keep in the *B. B. Journal*.—W. B. WEBSTER.

[129.] *Doubling.* (M. Ormond.)—The probability is with proper management it would increase your harvest 200 per cent. Do it the first really fine spell of weather in March.—AMATEUR EXPERT.

[130.] *Queen Raising.* (Walter Campbell.)—If there are no bees kept within half a mile of your house, which at Tottenham is very unlikely, you might stand a chance of getting the unimpregnated mother bee fertilised by selected drone. Even at that distance the chances are that she will mate with just the drone you least desire. Consanguinity among bees is of not so much importance as with the higher order of animals, although it must be taken notice of to some extent. Your idea that fertilisation must take place with a drone of the same hive, that is, with a brother, is a mistake; it as frequently takes place with a drone of some other hive, which in queen-rearing we often find out to our disgust. You would find it an extremely difficult job to catch all the drones in the two hives, and then introduce a few strangers. You could form a nucleus, into which place a queen-cell, and remove same to a distance of a mile from any other hives, and place the hives having the selected drones near. See that there are no drones in the nucleus.—W. B. WEBSTER.

[130.] *Queen Rearing.* (W. Campbell.)—Divide them, not when the hive is full of brood merely, but when it is full of bees as well, and leave the fecundation of the queen to mother Nature, she will take care of that.—AMATEUR EXPERT.

[131.] *Chilled Bees.* (F. L.)—The time varies according to the degree of cold that they are exposed to. A temperature below 32° Fahrenheit would kill them in twelve hours, but in higher temperature I have revived them by warmth after forty-eight hours of suspended animation.—W. B. WEBSTER. [Some bees were forwarded to us from a distant

part of Devonshire, with an inquiry as to the cause of their death, and on their arrival we found them alive and stinging.—En.]

[131.] *Chilled Bees.*—(F. L.)—Much depends on the weather. From a few minutes to some hours; but frequently bees that have been restored by artificial warmth again succumb on exposure to the cold air and never even reach their hives alive.—AMATEUR EXPERT.

[132.] *Distance between Frames and Hive-floor.* (F. L.)— $\frac{3}{8}$ inch is a very good distance, but even with $\frac{1}{4}$ I have never found the bees to build comb underneath the frames; they will do so in such a space at any other part of hive.—W. B. WEBSTER.

[132.] *Distance between Frames and Hive Floor.* (F. L.)—Never exceed three-eighths, five-sixteenths is ample, half—or as you say four-eighths—is too much and the bees will build comb in the space. This is the great objection to some kinds of metal ends; if you are making new hives you can allow for it, but it is awkward when first introducing them, we found it so.—AMATEUR EXPERT.

[134.] *Judging.* (Louth.)—Healthiness, strength of colony, correct and regular markings of workers, size, condition, and correct marking of mother bee, regularity of brood nest, regular building and cleanliness of combs, and, lastly, the 'get up' of the hive.—W. B. WEBSTER.

[134.] *Judging Black and Foreign Bees.* (Louth.)—Declined with thanks. I want to keep a whole skin for a short time longer.—AMATEUR EXPERT.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[144.] *Preventing Casts.*—As I am away from home all day and could only get home occasionally for an hour or so, I purpose driving an artificial swarm of bees from my hive (a straw skep). Can you kindly tell me how to prevent the bees from sending off casts that would be likely to issue during the twenty-one days that should elapse before transferring stock to wooden frame hive, which I purpose doing when the brood is all hatched? Also, what is the easiest and best method of fixing foundation in $\frac{1}{4}$ × $\frac{1}{4}$ sections which have no groove or saw-cut?—MILSON.

[145.] *Dead Brood.*—In overhauling a hive the other day I discovered that two frames were more or less filled with unhatched brood of last year. May I ask if this necessarily means foul brood. The cells are capped over and not indented. What had I better do?—W. H. H.

[146.] *House for Extracting Honey, &c.*—I have a beehouse in my garden partly occupied with bees, and the remainder of my hives are close to it; as it would facilitate my work and be a great convenience to me, I should like to partition off this house and use it for extracting honey, transferring skep, combs, &c., but the information I wish to obtain is whether being so near the hives the bees would be disturbed by the smell of the honey and thus cause fighting and robbing. The house is built of wood with corrugated iron roof. I suppose it would be difficult to make it bee-proof.—A. SNOOK.

[147.] *A Query.*—Why is it that when one takes a bee or a wasp between thumb and forefinger by its legs it never stings? Our peasantry, ever superstitiously inclined, say that it is because during mass the sacred wafer is thus held up to view (between thumb and forefinger.)—J. C. ANDREW, *Port Mahon, Minorca.*

[148.] *Bell Glass.*—Could I work successfully a bell glass super on a frame-hive without excluder-zinc, or would queen enter super and spoil it for exhibition?—ALBION.

[149.] *Tinned Wire.*—Would you please tell me where I can buy fine tinned wire same as used in wired foundation?

and if I were to lace a frame with it (say every 2 inches) and then to press in a starter of foundation of about 2 inches deep, would the bees build the comb as usual, or would they refuse to work, or build crooked combs? I want to make the combs stronger for extracting, but cannot afford wired foundation.—ALBION.

[150.] *A Beginner's Desiderata*.—1. What kind of bees and hive would you recommend for the district of Blackburn? 2. What would be the appliances really necessary to commence with? 3. What would be the probable cost of all required, and the best time for purchasing? 4. The names of any bee-keepers in this district who would give me information and instruction should I find myself able to commence?—JAMES HODGKINSON.

[151.] *Bee-houses*.—I intend putting up a bee-house this spring, and shall feel much obliged to any of the readers of your *Journal* who can give me particulars of such a building? I wish it to be of wood and about 10 feet square. I should also be glad of the experience of bee-keepers with such a house as to its advantages or disadvantages?—EDWD. J. GIBBINS.

[152.] *Moving Hives*.—I have to move half-a-dozen large Combination hives three miles between now and March 25th. Will it do to simply close the entrances with perforated zinc and put them on a spring wagon, or must I remove quilts, &c., as in summer moving? It seems to me no danger of suffocation would arise as the bees are now not crowded. Had I better move them at once or wait a month? In the former case I cannot look after them.—E. J. G.

Echoes from the Hives.

Norwich.—I am wintering twelve colonies on aphidean honey and am feeling a little anxious about their fate, as it is said that this sort of honey causes dysentery, as yet I see little or no symptoms of this disease.—H. DOBBIE.

North Cornwall Apiary.—I send a few notes from my diary, thinking it may interest some of your readers to know what is doing in this part of the world. Jan. 11 was the first fine day of the year, very mild, and the sun bright and warm. I examined my stocks, and found all, except one, in good condition, and well provided with food; Jan. 14 also a fine day, but the rest of the month was quite wintry, with deep snow on the ground. The present month has been more favourable. Feb. 4, 10, and 12, were beautifully bright days, the bees rejoicing in good flights. Feb. 14 was better still, quite a spring day, wonderfully mild and the sun hot; the bees came out in great numbers, and were busy cleaning out every corner of their hives, and gathering from the crocus and arabis. This is the *first* day they have carried pollen this year. From Feb. 14 to 20 the weather was bitterly cold, sky cloudy, with a strong east wind blowing, when it again cleared off and became bright and frosty, the bees being able to take exercise freely in the middle of the day. It may be well to add that I visited a neighbour's apiary on Feb. 10, and I found it in good condition, over two-thirds of his stocks being strong and healthy.—THE MANAGER, *Rowe-Bodmin*, February 22nd.

Hunts, Somersham, Feb. 22nd.—This has been the most severe winter experienced for several years, and an opportunity has been given of fairly testing the various systems of wintering. The candy-alone method, I should imagine, has almost received its death-blow. I am satisfied that bees cannot exist on such food during a long and severe winter. I promised in my 'Echo' last December to say how and with what result I wintered several lots of bees, which I was unexpectedly asked to drive on November 7th, when I had nothing but empty combs on which to place them. Here is the result. All were well and closely packed on empty combs with cakes of candy on the tops of the frames. Some I left thus,

and not one lot has survived; the others received, in addition, syrup in small quantities as the weather permitted, and at present they are doing well. Like 'N. II.' I tried wintering in *nuclei*. Several lots of Ligurians I left in three-frame *nuclei* with single side-walls, but I regret to say I have lost every one. Three died in the midst of plenty! A nice lot of honey, but all candied, being around them. In the others the consumption of food had been so rapid that, though well supplied with sealed food (mainly syrup) in September, when examined during the first week in January they had consumed all but a little candied next to the outer walls. All my other stocks, with slight exceptions, are in good trim and breeding fast. A few weeks since I was in a neighbouring district, where I was informed that stocks were being lost in great numbers. From inquiries I made I believe the losses were due to scarcity of food, which, owing to the dry weather last summer, was scarce in nearly all late swarms and casts. This morning the sun is shining delightfully and the bees are enjoying a flight after being closely imprisoned for more than a week by dull, cold, and damp weather. A gentleman called last week to tell me that the bees, in an apiary I have established in the next village, *being without food* (?) have robbed the stocks in a neighbouring apiary and killed their queens. I am inclined to attribute the complaint to jealousy and the loss of stocks to starvation. However, being in enforced idleness, through an epidemic, I intend, while visiting neighbouring bee-keepers and members of Hunts B. K. A., to inspect the scene of slaughter.—C. N. WHITE, *Hon. Sec., Hunts B. K. A.*

Dunmurry, Ireland, Feb. 22nd.—Frost at night and cold bright days has been the rule here this last ten or twelve days, and the bees only fly between twelve o'clock noon and 2 p.m. Weather a little milder to day and like rain.—J. N. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

G. G.—*Vignole's System of Swarming*.—If your hives are constructed like skeps, the only way to find out if they are in a fit state for swarming on the Vignole system, is to lift them off the floor-board, turn them up and by blowing in a few puffs of smoke to disperse the bees; some idea of the condition of the hives may thus be obtained. If they are full of bees with brood down to the bottom edge of the combs, they would be ready for swarming.

F. C. ANDREW.—*Doubling and Removing Upper Storeys*.—At the end of honey season the upper storey can be removed, and when the combs have been extracted, remove the next storey and put the one with the empty comb in its place, and continue in the same way with the others until all the honey is taken. Then, as the bees decrease in numbers, the upper storeys can be removed. You need not wait for the combs to be filled to put on second storey, but do it as soon as the bees feel the want of more room. On this system the hives are not divided, but more room given as the colony increases.

WEST MIDLAND.—*Doubling*.—Doubling is performed by selecting two very strong hives, removing all the bees from one of the hives and placing it, containing only the frames of comb and brood as a super, on to the top of the other hive. Nothing is placed between the two hives, and the bees finding comb containing brood above them soon ascend, and by the brood hatching above and below, the hive is soon very much strengthened and is enabled to spare a large number of bees for work. The bees which have been removed from the hive are treated as a swarm, put on a foundation or given empty combs, and at once supered. If you wish to leave your honey in the hive to ripen,

you may find it advantageous to put on a third storey as a super.

LIEUT.-GENERAL BARNARD.—*Feeding with Sections.*—

If the sections are not granulated they may be given as food to the bees at the top of the hives or skeps in float-feeders, the floats being removed and the comb being cut into cubes of an inch. If granulated, melt the section honey at about 190° Fahr. and when cool the wax will be set on the surface. The honey may then be brought to the consistency of syrup, by mixing with hot water, and given to the bees.

N. E. R.—Bees never do well in a greenhouse. Flying to the light and being unable to escape, they beat themselves to death upon the glass. We should prefer placing the hive outside the house, and occasionally opening the door and the lights for the bees to enter and to escape, at such times as they are in full work.

JOHN P. SMYTH.—*Foul-brood.*—Yes, we advise you to feed with phenolated syrup according to Mr. Cheshire's recipe, say for a fortnight. The bees take it readily, and it will prevent the disease spreading should any germs remain. We fear the neglected skeps of cottagers often contain and spread the disease unknown to their owners, and neighbours, although it is so easily discovered.

HIGH PEAK.—*Dysentery.*—The symptoms you name are those of dysentery, but there are various degrees of malignancy. It is quite possible that the length of confinement may have caused the defilement of the alighting-boards while the hives may be clean within. Examine on the first fine day and refer back to 'Useful Hints' for treatment.

CONSTANT READER.—1. *Feeding.*—For spring and autumn feeding we prefer syrup. Duncan's granulated sugar is the best for syrup. 2. *Transferring.*—No, the queen would not descend. We advise you to transfer. If you wish to increase the number of colonies allow the skeps to swarm, and twenty-one days afterwards transfer combs and bees from the skeps to frame-hive. This is the best plan, and will prove least troublesome in the end.

W. WILLIAMS.—*Queen taking Flight.*—We think it most probable that the queen did re-enter the hive. Do not attempt to ascertain her presence or absence yet. If absent, you could do nothing now to remedy it. In six weeks' time there should be brood existing, which you can see at a glance, if she is present. If, then, you fail to find either her or brood, you may know she is lost, and had better unite the bees to another stock.

A. S. HUGHES.—*Syrup with Vinous smell.* The smell of the sample seems to be derived from the bottles. If there is a muddiness, or sediment, or a crust on the surface, there has been fermentation, and the syrup must be boiled before giving it to the bees. Your bees survived their journey more by good luck favoured by cold weather than good management.

R. L. RICHARDSON.—*Bees suffering from Dysentery.*—While the weather remains so cold you can only look to the dryness of the hive, exchange the quilts for warm dry ones, and place under them on the frames a cake of candy containing phenol. You can get it from Mr. Saddler, High Street, Forfar.

M.—*Hive-making.*—You will find an answer to your questions in the last part of the paper in question.

J. LANDER.—The portion of foul-brood comb has been forwarded to Mr. Cheshire for examination.

LASSWADE.—The appearance of the bees indicates that they died of starvation. It is quite possible that the

back frames may have been full of honey; but if the cluster of bees were at a distance, and there was an absence of winter passages, the supply of honey would have been of no avail.

A. K. B.—The granulated honey, which is of excellent quality, can be utilised for spring feeding. For mode of giving it, please refer to reply to 'Lt.-gen. Barnard.'

FIGHT BETWEEN A BEE AND A EARWIG.—A few Sundays ago I was walking by one of my hives when I noticed that on the floor-board a tremendous fight was going on between a bee and a large earwig. The bee was apparently trying all she could to drive the earwig off the floor-board, but he evidently desired to remain there, and admonished the bee by squeezing her with his pincers. Upon this the bee waxed wroth, biting the earwig and rushing round him till at last the earwig seemed to lose his temper entirely, and pinched her very hard in the tail; the bee finding herself thus held fast, and doubtless remembering the old motto 'Death or Victory,' made a loud cry, or rather buzz, and stung him with all her strength between his pincers. They then both began a tug of war, the earwig pulling one way and the bee firm in her purpose endeavouring to pull him off the alighting-board. This was most exciting, neither seeming able to draw the other along, but was stopped through other bees in the hive coming to the rescue of their mate. These caught hold of the enemy, and at last the bee got free, leaving her sting behind. It being very cold the bees went indoors again. I secured the earwig, who died very shortly, his last efforts were convulsive, and I presume it was a case of death from poison. I shall be pleased to send the earwig, with sting, as left by the bee, to any one who collects curiosities of this kind.—**W. ZACHARY, Cirencester.**

Our next Number will contain the first of a series of papers by Mr. T. B. BLOW, of Welwyn, Herts, entitled, 'Among the Queen-raisers in the North of Italy,' which will be illustrated by Numerous Engravings.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, w.c.

[No. 193. VOL. XIV.]

MARCH 4, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

GREAT NATIONAL APIARIAN EXHIBITION, 1886.

The great advantage to the cause of bee-keeping in the United Kingdom which is expected to accrue from the National Exhibition proposed to be held by the B.B.K.A. in London in connexion with the Indian and Colonial Exhibition is so obvious, and the promises of support so encouraging, as to induce us to keep the question before our readers with a desire to receive further suggestions as to its full development.

At the general meeting of the B.B.K.A. the proposal was most favourably received, and a fund was opened not only for donations towards the expenses, but also as a guarantee to cover all charges. It is to be remembered that the expense of holding such a show will be considerable, and that there will be but little in the way of receipts from the show itself to meet this expense, which is, moreover, quite beyond the usual resources of the Association, and will therefore have to be provided by special subscriptions. The 'Donation Fund' is already well started, and is headed by the generous contribution of 25*l.* from our noble President the Baroness Burdett-Coutts. It is hoped that the whole cost, which is estimated at not less than 200*l.*, will be so met; but in the event of its not being fully covered, the 'Guarantee Fund,' already well inaugurated, will supply the deficiency, the guarantors contributing *pro rata* according to the amounts which they may have severally guaranteed.

The Committee cannot do much in the matter beyond inquiry and arrangement, or incur any serious cost, until these two funds, 'Donation' and 'Guarantee,' are very considerably enlarged, but active preparations and consultations are proceeding with every hope that the proposed exhibition will be found practicable, and be made of lasting benefit to the British honey-producer. It was suggested at the general meeting that there might be many persons who, though unable to give more than a small money donation to the fund, might be able and willing to supplement such gift by a donation of honey, which the Committee would sell at the Show, or otherwise convert into money, and in this way even the humblest producers might contribute to the cause. We have no doubt that the Committee would readily receive the promise of contributions in kind in the way suggested.

Until the scheme is far more advanced it would be

impossible to give any very definite indication of the plan to be carried out, for everything must depend in a great measure upon the locality in which the show is to be held. Our present idea is, that as many of our Colonies are to include in their exhibits at the great Exhibition specimens of honey and other apiarian products, our show should be made to take the form of a welcome to our colonial colleagues, and an exhibition of British products and appliances be displayed in friendly comparison with theirs. Such a display would give character and interest to the assemblage of bee-keepers from all parts of the world, and would be not out of harmony with the general object of the great Indian and Colonial Exhibition. This being so, we hope that the Council of the Indian and Colonial Exhibition will, subject to their other arrangements, place at our disposal for the necessary period the large Conservatory, where, in like manner as it is used for flower and fruit shows, a kindred show of bee products may be held to which all our bee-keeping brethren from the Colonies may be made welcome. Such a show, lasting six or eight days, and concluding with a *Conversazione*, could not fail to interest a very large number, and would, without doubt, also contribute largely to the instruction and profit of our home producers. The committee would have to make a careful and scrupulous choice of objects first for such a representative display in order to show 'the better way' employed in this country, and also to select as large and attractive a collection of honey in its various forms as the means placed at their disposal may admit.

British bee-keepers will perceive the importance of the occasion, and will, we have no doubt, give a ready response to the demand for funds, and a willing aid in the further arrangements to be made.

The amounts already contributed or promised are:—To the 'Donation Fund,' 25*l.*; to the 'Guarantee Fund,' 50*l.*

We would mention that subscriptions to either fund can be sent to Mr. J. Huckle, King's Langley, Herts.

LECTURES ON APICULTURE.

The courses of lectures in connexion with the Institute of Agriculture will this year be delivered at Jermyn Street Museum, Jermyn Street, instead of the Theatre, South Kensington Museum, as heretofore. Mr. Frank R. Cheshire, F. L. S., will commence a short apicultural course of six lectures on Wednesday, the 17th inst., at eight o'clock. The admission in conformity with the charges made for other courses in the Museum will be

sixpence per lecture. We shall publish a syllabus of the course in our next issue. These lectures will be illustrated by living bees and by models and diagrams. Mr. Cheshire's excellence as a lecturer is well known to our readers; and as the place of lecture is more central than South Kensington we have no doubt that many will avail themselves of the opportunity of attending this course.

USEFUL HINTS.

The weather, in East Anglia at all events, maintains its severity. Again we have to report sunless days and frosty nights, the night temperature ranging from 20° to 25° Fahr., and the day temperature but little higher. Our bees have no chance of a thoroughly good cleansing flight. We hear of many colonies lost. One we examined—a large cluster of bees defunct in the centre of the hive, no honey within their reach, although the outside combs contained abundance. This colony perished solely from the absence of winter passages, being unable during the cold weather to reach its food. Dysentery prevails in many apiaries, and will, no doubt, continue to prevail until the sovereign remedy is obtained—bright, warm weather—the only real cure.

The great evil attendant upon dysentery, in those colonies which survive, is a population so reduced that even if spring dwindling does not supervene, the sparse population is unequal to storing surplus honey, however plentiful the income may prove. Such colonies do little more than supply their own needs during the following summer. Hence the great importance of having a large spring population.

STIMULATION, SPREADING BROOD, EQUALISING COLONIES.—On these three points doctors decidedly differ. An experienced and most successful American apiarist adopts them all. In offering to our readers a short digest of his method we will say no more than that it sounds reasonable, and that we have successfully practised it in our own apiary; but it requires great care in carrying out details, indeed, as Cæsar required in military and maritime affairs, that 'all things should be performed at the signal and to the very moment,' (*ad nutum et ad tempus omnes res ab iis administrarentur*).

The first step towards success in apiculture is to produce plenty of bees in time for the honey-harvest.

With most of us white clover is the main honey-producing plant, which blooms about June 15th to 20th, and by June 25th is at its best; hence our bees must be in readiness at that time if we wish to succeed. About six weeks are required to build up an ordinary colony in the spring to the point at which they are in prime order for producing honey to the greatest advantage.

Therefore commence to stimulate brood-rearing about the 1st of May. (1.) Go to each colony and look them over, clipping all queens' wings, and equalising stores, so that each colony has enough to carry it on at least two weeks without starvation. At this time, as a rule, each good colony will have brood in four or five combs, the two centre combs containing the largest amount. Now change the position of these combs of brood by placing those which are on the outside in the centre of the brood-nest. This brings the combs having the most brood in them on the outsides. Thus, while the colony has no more brood than it had before, the queen finds plenty of empty cells in the centre of the brood-nest, in combs having some brood in them, and she at once fills these combs with eggs, so that in a few days they will contain more brood than those that were moved to the outside, while the bees will have fed and taken care of this as well as though its position had not been changed. Thus a gain has been made in regard to increasing the brood. (2.) In about eight days, if the weather is favourable, all the hives are again looked over,

and this time a frame of honey is taken from the outside of the cluster, and the cappings to the cells broken by passing a knife flatwise over them when the brood-nest is separated in the centre, and this frame of honey, thus prepared, placed therein. At each time of going over the hives be careful to ascertain that each colony has abundant honey to last it at least two weeks, since, when endeavouring to obtain the largest amount of brood possible, the bees must *never* feel the necessity of feeding the brood sparingly on account of scanty stores. Also take care that there are no cracks, or open places, at the top of the hive, to allow the warm air to pass out, but tuck all up as nicely as you would fix your bed on a cold winter's night. (3.) After seven days more have elapsed go over all the hives, and insert another frame of honey in the centre of the brood-nest of each, prepared as before. If at any time you are short of honey, use syrup made of Duncan's granulated sugar, dissolving it in hot water, at the rate of one pound of water to two pounds of sugar. The syrup should be poured from a syrup-can, held some distance above, into combs of worker-cells, both sides of which may thus be filled. (4.) The next time of going over the hives (after eight days) place the outside brood-frames in the centre of the nest—as at first—and put another frame of honey, or syrup, in the centre. (5.) After another week the hives are again looked over, and, if but nine or ten frames are used, this time will complete the stimulating process, for at the end of about five days more, or about the 10th of June, all frames will be full of brood, and the colonies in good condition for receiving the surplus boxes.

In carrying out the above system we have never clipped the queen's wings, nor do we deem it necessary as a part of the system. In the case of weaker colonies, whose queens are below par, we have occasionally supplied them with a frame of brood from a stronger neighbour. The date (May 1st) of commencing operations will require to be varied in this climate according to the season and locality, the variation being as much as two or three weeks; but we advise that the process should not be begun before the second week in April, in an average season and locality.

UNITING WEAK COLONIES.—Except as advised in last 'Hints,' we do not recommend unions at present. The union of three or four weak colonies in order to form one strong one is rarely successful. The better plan is to reserve till later in the season all colonies which about the middle of April occupy, say, five spaces, to confine them to the frames they cover, and to treat them on the same plan as the stronger ones, on the above system—inserting a comb of honey, uncapped, in the centre of the brood-nest, as occasion demands. When the honey-flow arrives, two such colonies may then be united by alternating the combs; forming, thus, one strong one, upon which the surplus boxes may be placed immediately after the union is accomplished. The surplus queens may be utilised for nuclei, or swarming, as desired. Queenless colonies form an exception, and should be united at the earliest opportunity.

Many apiarists will object to the above system of management, that it is all too late—that they want their surplus boxes on the hives by the 1st of May, in order to obtain sections from the early fruit-bloom. In our experience, in nine seasons out of ten, there is no section-storing worthy of the name before the last week of the month in the central parts of England, and but little then. Is it not much wiser to continue building up our colonies to full strength, so as to have them in the best possible condition to take advantage of the great harvest when it comes?

FEEDING.—Let it be borne in mind that populous colonies when breeding extensively consume a large amount of food and should be fed as occasion requires. The food at this early date should not be given too thin. Syrup of about the same consistency as well-

ripened honey is best. The Heddon receipt, as given in former 'Hints,' is a good one.

ENTRANCES must still be kept clear of refuse. When they have been kept open at summer width, let them be gradually, *i.e.*, day by day, contracted to about an inch in width for weak stocks, and 2 in. for strong ones, to prevent robbing, to which there may now be a tendency. It is very important to prevent a beginning, therefore be very careful to avoid the spilling of syrup or littering about of bits of comb, &c.

WATER AND ARTIFICIAL POLLEN will soon be required, and, when fine weather comes—as come it must at last—should be supplied according to former directions.

Continue to keep floor-boards clean and dry, hives well covered up, and disturb as little as possible. A fruitful summer and an abundant harvest often follow a late spring. Now is the time to make all possible preparations for the approaching campaign. Presently our hands will be full.

THINGS-IN-GENERAL.—*Burma*.—Since Upper, as well as Lower, Burma has now become British territory by annexation, and there is a chance of the two being created into a separate presidency, or governorship, which may rival the ancient Burmese Empire in importance and prosperity, it may be interesting to note the condition of apiculture, the various races of bees, &c., in that distant part of 'Greater Britain.' An American missionary, dating from 'Toungoo, Burma, September 1881,' after describing his schools and mission stations, to the number of seventy, scattered over a large extent of hilly country, refers to bee-keeping. Writing to an American firm for hives, he states that it would cost five times as much to make a hive in Burma as in America, cost of transit included. Carpenter's work of a good sort is very high and very slow, and, at best, is very poor. He speaks with enthusiasm of teaching his converts apiculture, and anticipates sending further orders for hives, so that it is probable that an improved system has already been introduced. The climate he terms 'sickly and hot,' but speaks of it as a splendid country for honey; but mentions that although there are wild bees everywhere, and on bright days their hum fills the air, and swells to a roar on the grand, old trees, covered with bloom, till they look like a bouquet of giants, and sicken the air with the richness of their perfume. He speaks of a large church which contains scores of swarms of the *Apis dorsata*, and announces his intention of obtaining from these a comb of brood, and placing it in a hive of ordinary bees. The common bees of the country are of two kinds—one small, building six and a half cells to the inch, in colour brown, and its wings giving out brilliant colours in the sunlight, gentle, and active; the other somewhat larger, building six cells to the inch, colour black, active and aggressive, and inclined to rob weaker colonies. Of these bees he had five colonies, all doing well. *Apis dorsata* has never, we believe, been domesticated. Although it is thought improbable that this magnificent bee—the largest of its species—can ever flourish, or even exist, in our climate, nevertheless we should rejoice to hear of its domestication in its native country. When transferred to the modern hive, it is said invariably to desert its brood and hive, and again to resort to its native haunts—the boughs of some lofty palm, where it stretches its enormous combs—or to inaccessible rocks, in the crannies of which it delights to suspend its Pædalian structures. In our own mind, there is no doubt that its domestication will be accomplished, and that speedily. Above all things, we should like to make the trial. What an opportunity for a Benton, whose former attempt was carried out and failed under insurmountable difficulties! Given (1) the neighbourhood of *Apis dorsata*, (2) a strong colony of domesticated bees, in a large frame-hive. Remove the queen of the latter. Seven or eight

days afterwards cut away all queen-cells. Insert combs of *Apis dorsata* (containing brood in all stages, and eggs), alternating them with the combs of the hive. From these eggs queens are reared. The stock is divided into nuclei, each possessing a virgin queen, which in due course is fecundated by a drone of the *Apis dorsata* race. These nuclei—say, four in number—are built up from other colonies, and may we not exclaim, Q. E. F.? This plan, at least, seems practicable. And then the pleasure of introducing these brilliant insects into our English apiaries, and endeavouring to acclimatise them! . . . Well, all this may be castle-building, but we should very much like to have the experiment tried.

REVERSIBLE FRAMES once more.—In looking through the published numbers of Mr. Cheshire's new book, *Bees and Bee-keeping*, figs. 4 and G. 36 struck us as having some bearing on this question. In fig. 4, not only is the upward pitch of the brood-cell clearly shown, but the spinning-larva and the nymph are represented lying upon their backs. The hive, or frame, being reversed (inverted) the larva and nymph will also be inverted. Will these develop as successfully in the unnatural as in the natural position? Again, in G. fig. 36, the curvature, or upward pitch, of the honey-cell is shown to be very great. Surely, facts like these, deduced by the highest powers of the microscope, must have considerable weight in arriving at a just solution of the cause 'Inversion versus Non-inversion.' Time and trial will solve the problem.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The first meeting of the newly-elected committee was held at 105 Jermyn Street, on Wednesday, February 24th. Present, the Rev. Dr. Bartrum, the Hon. and Rev. H. Bligh, Captain Bush, T. W. Cowan, J. M. Hooker, the Rev. F. G. Jenyns, the Rev. G. Raynor, the Rev. F. S. Selater, the Rev. J. L. Seager, D. Stewart, G. Walker, W. O'B. Glennie, Treasurer, and the Secretary. Letters were read from the Rev. F. T. Scott and Captain Campbell regretting their inability to be present.

Resolved unanimously that Mr. T. W. Cowan be elected chairman, and the Hon. and Rev. H. Bligh vice-chairman, for the ensuing year. The following sub-committees were formed:—Finance—Dr. Bartrum, H. Jonas, and G. Walker. County Associations' Business—Revs. F. S. Selater, J. L. Seager, Captain Bush, D. Stewart, and G. Walker. Educational—Dr. Bartrum, Hon. and Rev. H. Bligh, the Rev. F. G. Jenyns, the Rev. G. Raynor, and the Rev. J. L. Seager. Exhibitions—Captain Bush, J. M. Hooker, H. Jonas, Rev. F. S. Selater, and D. Stewart. The chairman to be ex officio member of each sub-committee.

The following resolution was passed, in regard to County shows, namely, 'That it is not advisable in the cases of shows held by County Associations that the name of companies be accepted as exhibitors of honey, except in the open classes.'

Various estimates for the printing of sundry pamphlets were considered. It was resolved that steps be taken as early as possible for printing the 'Skep' pamphlet in Welsh.

The Secretary reported that he had made inquiries in respect to the probability of the Association being able to hold an exhibition at South Kensington: the Secretary was instructed to communicate with the President upon the subject.

DERBYSHIRE BEE-KEEPERS' ASSOCIATION.

The fifth annual meeting of the Derbyshire Bee-keepers' Association was held in the Grand Jury-room, Town Hall, Derby, on Tuesday, January 19th, 1886. In the absence of Lord Denman, the Rev. J. Wadham pre-

sided until the principal business had been transacted, when he was compelled to resign his position to Mr. Newton, of Burton. Amongst those present were Messrs. W. T. Atkins, Newton, Austin, T. M. Bryan, Hartland, Handley, Cooper, Wilkes, and others. Mr. D. Cooper, the hon. secretary, read the fourth annual report, which we gave in our last issue. On the motion of the Chairman the report was received and adopted.

Mr. Cooper, the hon. secretary, resigned his position, which was accepted (temporarily) by Mr. W. T. Atkins, 6 North Street, Derby, who is to receive 5*l.* from the funds for the employment of an assistant. The following gentlemen were elected on the committee for the ensuing year:—The Rev. J. Wadhams, the Rev. Stafford O'Brien, and Messrs. W. T. Atkins, T. Walker Cox, H. T. Edwards, F. Holbrook, J. Longden, Cooper, Innes, J. Stevens, H. T. Bland, J. H. Richardson and Dr. W. Ogle.

It was decided to hold the usual show of bees and honey at the Agricultural Show at Derby, and the question of a proposed honey fair was referred to the committee for future consideration. The question of providing extractors for district secretaries for the use of members was left to the committee. Votes of thanks were accorded to the Mayor for the use of the room, to Mr. Cooper, the late secretary, and all who had assisted to promote the society's welfare. The meeting terminated with the drawing for two prize hives, which were won by Mr. J. McLean, of Kegworth, and Mr. Wood, of Brassington Street, Clay Cross.

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

On Saturday, Feb. 20, the annual meeting was held in the Guildhall, Worcester. The Mayor (Mr. A. W. Knott) presided; and there were also present—Miss Wilson (Crawle), Mrs. Davis (Welland), Miss Bullock (Kempsey), Rev. W. M. Kingsmill (Bredicot), Rev. E. Val. Williams (Malvern), Rev. R. T. W. Brayne (Whittington), Rev. D. H. C. Preedy (King's Norton), Messrs. A. H. Martin, Hon. Sec. (Evesham), J. Cleasby (Offenham), H. Goldingham, G. H. Latt, H. O. Huntley, Neal (Worcester), M. Alchurch (Church Lench), H. H. Griffin (Hartlebury), S. Tombs (Droitwich), C. H. Haynes, E. A. Dimmock (Hanley Castle), A. Thorpe (Hallow), J. Fehrenback (Kidderminster), E. T. Footman (Martley), J. W. W. Boughton (Wick), J. Hiam (Astwood Bank), and C. Brown, expert (Bewdley).

Mr. Martin, hon. sec., read the annual report, from which it appeared that the number of members show a steady increase, and, in spite of a good many withdrawals, now numbers, at the close of the year, 266, of which 89 are new members. The total income has amounted to 12*8*l.* 19*s.* 2*d.**, of which amount 59*l.* 5*s.* 6*d.* has been raised by members' subscriptions.

The expert of the Association, Mr. C. Brown, has delivered three lectures during the year—at Evesham, King's Norton, and Hanley Castle—which were illustrated by magic-lantern slides, showing photographs of scientific bee-keeping. These were kindly lent by Mr. Watkin, hon. sec. of the Herefordshire Association. The bee-tenant has attended horticultural shows at Redditch, Upton-on-Severn, Hagley, Bricklehampton, King's Norton, Astwood Bank, Blackmore Park, Kidderminster, and Madresfield. The net balance on the proceeds of the bee-tenant has amounted to 5*l.* 13*s.* 3*d.*

The annual show of bees, hives, honey, and apianian appliances, was held in connexion with the meeting of the Worcester City and County Horticultural Society at Rose Hill, Worcester, in the grounds of Walter Holland, Esq., on August 20th and 21st. Prizes were offered to the value of 18*l.*, and there were no less than eighty entries, a considerable increase on last year. In the honey classes there were three entries for the medals and certificate

given by the B. B. K. A. The silver medal was awarded to Mr. E. T. Footman, of Martley, for a very good exhibit of sections, mostly 1-lb., and weighing altogether 170 lbs. The bronze medal was taken by Mr. C. Brown, of Bewdley; Dr. Walker and Mr. James Partridge, of Alvechurch, acted as judges in all the classes. An examination for certificates as third-class experts was conducted by Dr. Walker, for which four candidates presented themselves, two of whom—Messrs. W. F. Paddison, of Malvern, and E. T. Footman, of Martley—were successful. One of the members, Mr. W. D. Slade, of Worcester and Cheltenham, has obtained a certificate as second-class expert at the examination which has been held recently. A very interesting report by the expert, Mr. C. Brown, was also read.

Earl Beauchamp was re-elected as president. The following were appointed vice-presidents:—The Bishop of Worcester, the Countess of Dudley, Lords Northwick, Lyttelton, Hindlip, and Edward S. Churchill, Lady Georgina Vernon, Sir Richard Temple, Bart., M.P.; Sir E. Lechmere, Bart., M.P.; Messrs. G. W. Hastings, M.P.; J. Corbett, M.P.; A. W. Knott (Mayor of Worcester). Mr. T. J. Slatter was re-elected hon. treasurer, and Mr. A. H. Martin was re-elected hon. sec., the proposer particularly eulogising the services that he had rendered to the Association, and drawing attention to the great help it had received from him, and to the unvarying courtesy with which he replied to all letters and communications addressed to him. The following were appointed the committee for the present year:—Revs. W. W. Douglas (Salwarpe), C. W. N. Ogilvy, J. Latham, E. W. Isaac, W. M. Kingsmill, R. T. W. Brayne, E. Val. Williams; Messrs. H. H. Griffin, C. H. Haynes, W. B. Henley, J. Partridge, J. Hiam, S. Tombs, H. Goldingham, W. F. Paddison, E. T. Footman, W. B. Williamson, E. A. Dimmock, S. S. Chillingworth, Mrs. Swindon, Mrs. Piers, F. Leigh, Miss Wilson, and Mr. M. Woodward. Messrs. Martin and Haynes were re-elected to represent the Association at the Conferences in London.

The annual ballot for three hives then took place, with the result that they fell to the following;—Messrs. S. S. Chillingworth (Torton, Kidderminster), J. Hiam (Astwood Bank), Geoffrey New (Evesham). A vote of thanks to the Mayor for presiding closed the meeting.

STAFFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The Annual Meeting of members of this Association was held at the Guildhall, Stafford, on Saturday afternoon. Mr. Thomas Salt, of Weeping Cross, occupied the chair, and was accompanied by Mrs. Salt. In all there were about fifty members of the Association present, including the Rev. J. D. Glennie (Croxtan), the Rev. A. R. Alsop (Bednal), the Rev. G. R. Bailey (Madeley), the Rev. R. Rigden (Penkridge), the Rev. F. Crewe (St. Dominic's Convent, Stone), Mr. A. H. Heath (hon. secretary and treasurer), Mr. F. D. Mort, Mr. J. Beaumont Piercy, Mr. Archer B. Smith, Mr. E. B. Crisp, &c.

The Hon. Secretary read the annual report, which stated that the society sprang into existence in 1883, and at the end of that year consisted of 218 members. The membership increased in 1884 to 355, and now the society had 501 Members. The spring and autumn visits of the expert had grown so popular in 1884 that the committee appointed two experts for the spring and autumn tours, finding it was impossible for one man to get over the ground in the time necessary for all hives to be carefully put in order for the approaching harvest and winter months. Accordingly, Mr. A. W. Rollins, who had now served three years as expert, and Mr. E. Clewes, of Milton, near Stone (who had been awarded a certificate at a previous examination), started on their spring tour in the first week in April, and between them spent forty-two days in the work of examining 415 frame and 321

straw hives, visiting in all 215 members, and dispensing advice as to future management wherever it was invited or required. In their autumn tour they spent fifty days in visiting 213 members, and in examining 632 frames and 478 straw skeps. Altogether, during the late season they were occupied ninety-two days, as against fifty-eight days spent in similar visits in 1884. The number of stocks examined was 1846, as against 1358 in 1884. All this was evidence that bee-keeping was growing more popular in the county, while the increase in the number of bar-frame hives also showed that bee-keeping was becoming more scientific, and that there was a stronger desire on the part of bee-keepers to make it profitable. The bee-tent, under the management of the Rev. G. R. Bailey, had proved a very popular institution wherever it had been pitched, and the Association was indebted to that gentleman for a handsome profit, which shone forth as a redeeming item in the year's balance-sheet. Mr. Hulme, who had been awarded three silver medals for 2-lb. sections, reported a profit on the last season of 49*l.* He had generously given one back to the Association for future competition. Thomas Bond, Shallowford, had been awarded a silver medal, and a bronze medal had been awarded each to S. Farrington, J. C. Colman, and Thomas Leese. The report also referred to the annual show at Tamworth, in connexion with the County Agricultural Society's exhibition, which was not financially successful, but gave bee-keepers facilities for seeing the best appliances, while the exhibits of honey were most satisfactory and encouraging.

On the motion of the Rev. J. D. Glennie, the report was unanimously adopted. A statement of the accounts was next submitted, and showed a loss of 2*l.* 8*s.* 11*d.* on the year's work, which would be easily covered by unpaid-up subscriptions. On the motion of the Rev. R. Rigden, the balance-sheet was passed. The Rev. J. D. Glennie proposed, and Mr. F. D. Mort seconded, that Lord Wrottesley, Lord Lieutenant of the county, be re-elected president for the ensuing year, and this was unanimously agreed to. The vice-presidents, the Ven. Archdeacon of Stoke (Sir L. T. Stamer, Bart.), the Hon. A. C. G. Calthorpe, Mr. T. Salt, and Mr. R. Heath, were also re-elected. Mr. A. H. Heath was unanimously re-elected hon. secretary to the Association. As Mr. Heath was desirous of retiring from the treasurership, Mr. George Farrington, of Smallthorne, was elected to that office. The committee was also elected. As the balance-sheet showed a deficit of 7*l.*, it was resolved, on the motion of the Rev. R. Rigden, that an additional charge of 6*l.* be paid for each expert's visit. Lots were then cast for a first prize of a bar-frame hive given by the society, and a second prize of a crate of sections by the Hon. Secretary. The winners were Joseph Lowe, Madeley, Newcastle, and Frederick Chell, Coton, Milwich. The meeting terminated with votes of thanks to the committee, to the Mayor for the use of the room, and to Mr. and Mrs. Salt.

NORTH OF SCOTLAND APIARIAN SOCIETY.

The annual general meeting of the North of Scotland Apiarian Society was held within the Café Buildings, Shiprow, on Saturday, February 13th. There was a fair attendance. Mr. Tait, Foveran, occupied the chair, and submitted the first annual report, in the course of which it was mentioned, that there were 141 entries at the show last year, and that 2500 pounds of honey were staged. The accounts showed the income to be 25*l.* 6*s.* 3*d.*, and that after paying all expenses there was a small balance in hand in favour of the society. The Chairman moved the adoption of the report, which was seconded by Mr. Beveridge, Torphins, and unanimously adopted. It appeared that Mr. Finlayson, the secretary, had not only given his services gratuitously, but in addition had given a handsome prize. A cordial vote of thanks was therefore passed to Mr. Finlayson for his services to the

society. On the motion of Mr. Grant, a cordial vote of thanks was also passed to the Agricultural Society for the prizes they had given them. On the motion of Mr. Ross, a special vote of thanks was also passed to the donors of special prizes. Mr. Grant handed 1*l.* to the society to be disposed of as the committee thought fit. In handing the donation, he mentioned that he had not only got all the honey he required for his own use, but made a profit of 2*l.* on each hive. A vote of thanks was cordially passed to Mr. Grant for his handsome gift. On the motion of the chairman, the Rev. Mr. Innes, Skene, was appointed chairman of committee for next year.

Rev. Mr. Innes, after expressing thanks for his appointment, said, one main object of our society is to encourage bee-culture among our rural population, and to popularise the use of pure honey as a check to the use of glucose and other foreign adulterations. Should new legislation favour a return of the people from the city to the soil, surely this simple industry is fitted to promote both the mental and material prosperity of our cottar and crofter brethren, and it may reasonably be expected that such an enterprise will win the sympathy and support of ministers, teachers, country gentlemen, and all interested in the elevation of rural life. Such associations in England command the highest patronage, and it is gratifying to be able to say that our worthy Lord-Lieutenant and county members of Parliament express their entire approval of the movement.

Mr. Innes handed round copies of the *British Bee Journal*, and Mr. Beveridge, Torphins, suggested that the person who sent them might be requested to send copies to the secretaries of local societies for distribution.

Mr. Black was unanimously elected vice-president for the year, and the committee were re-elected with several additions. It was agreed to form a sub-committee from members in Aberdeen, to assist the secretary. It was agreed to have only one show in the year in Aberdeen.

The rules were then revised, and after some alterations had been made in them, the meeting adjourned.—*Aberdeen Journal*.

GLAMORGANSHIRE BEE-KEEPERS' ASSOCIATION.

I have taken great interest in bee-culture for some years, and, like many other bee-keepers, for the want of a little practical knowledge on the subject have made mistakes. I am persuaded that my errors would not have happened had the Glamorganshire Bee-keepers' Association been in existence. I therefore heartily welcome its birth, feeling fully convinced that I shall benefit thereby—not only, as many bee-keepers are asking, 'What shall I gain in *£. s. d.* by joining the Association?' but even there I shall benefit; for the useful, practical knowledge diffused by such an Association must prevent the error, and consequently the expense, of former years.

In reply to 'Welsh Novice' and others:—Each district in the County will have its Secretary and representative, to whom any member can appeal in need of advice. But let 'Welsh Novice' send his address to Mr. E. Thornton, Bridgend, Glamorganshire, the Hon. Secretary of the Association, and I am sure he will get full particulars. Indeed the Secretary is only waiting for the leaflets the parent Society are generous enough to provide to send to many inquiries, it being impossible to answer every letter fully.

Friends, please notice this and have a little patience. The Society is young, and the Committee will not meet before the end of this month, or the first week in March at Bridgend, to complete a list of the rules and regulations of the Society.—GLAM. BEE.

AMONG THE QUEEN-RAISERS IN THE NORTH OF ITALY.

By THOMAS B. BLOW, F.L.S.,

Author of A Bee-keeper's Experiences in the East, &c.

The many controversies which have arisen during the past three years with respect to the merits or demerits of the Italian bees, induced me, in the interests of British bee-keeping, to pay a visit to the north of Italy to study them in their native habitats, and to come to some decision as to their qualities as compared with other races, and more especially with the English bees.

Those who have carefully noted the published accounts of the Italian bees from their first introduction will remember the surprising successes that were years ago achieved; and I could call to mind several who have kept Italians for many years, and still hold that they are far ahead of the blacks. The Americans, too, quite upheld this opinion, and hold it strongly still.

Carefully considering these facts, I was led to think that the root of the evil, and the reason of the many and grievous complaints that have lately been made, might lie in the inferiority of the queens imported during the last few years. Those who years ago went in strongly for Italians (and have succeeded), usually kept up their stock by breeding from the best, rather than by constantly importing queens. And the same method obtains in America, where most of the Italians are home-raised—not imported—and I think it will be admitted on all sides, that, as far as scientific queen-raising is concerned, the Americans stand at the head of the world: though the successful persons in England, that I allude to, are probably individually equal.

To get the best results we ought, undoubtedly, to import the finest Italian queens, and then to raise the best from them here; keeping up the stock by occasional importations, perhaps. In this way we can perpetuate the best features of the race, and at the same time get bees that are perfectly acclimatised. For it is an admitted fact, that the bees, the immediate progeny of imported queens, are far more liable to disease—especially dysentery—than the progeny of a home-raised Italian. And, with the facilities which modern bee-keepers have, there is not the least difficulty in getting the home-raised queens purely mated, and thus practically keeping our strain pure, if absolute purity is desirable.

The complaints made by those dissatisfied with Italians are: (1) They do not winter well; (2) As honey producers they do not equal the English bee; (3) That they are very vicious and unmanageable; (4) and lastly, some have asserted that a very virulent form of foul brood has been introduced by them. From an examination (extending over a considerable time) of many apiaries, I have come to the conclusion that most of the evil repute that has fallen upon Italians has been brought about by the inferior queens sent. In some cases the breeders knew nothing about their business, and procured the cheap queens which are sent so freely in the autumn, by going round and collecting them from the stocks condemned by the country people to be taken up for the honey; they get these and the bees for about a franc a stock. By this system many queens would be quite old and worn out, others unfertilised, and therefore drone-breeders; and in a district where foul brood occurred, of course the disease would go with the queens, and disastrous results would follow by its introduction into the apiary of the unsuspecting British bee-keeper. I have in my mind's eye one case of a well-known cottage bee-keeper, whose apiary was utterly ruined by the introduction of foul brood by Italian queens. This system of getting queens from condemned bees I saw in full swing in many cases (in one case by the servants of a well-known exporter); the time of year being most favourable for this

practice, and I certainly saw several fine examples of foul-broody combs.

In other apiaries no trouble seemed to be taken with the quality of the queens, such as selecting the best queens to raise progeny from, nor was any attention paid to the raising of drones from suitable stocks. These great considerations were quite neglected; the great point seeming to be, the largest number of queens in the shortest possible time, and with the least trouble; and, as far as I can judge, many were sent off without it being definitely known that they were fertilised, and I feel sure that some such queens arrive in England and are here fertilised, as, in the course of my experience as an expert, I have had shown to me many stocks of bees that I was assured were the progeny of an imported queen, but were certainly hybrids. Again, on inquiry after some of those who advertise their finest Italians in the Continental and American Bee Journals (American especially) I found that they were simply agents—people who hardly knew what a queen was; they bought their queens from the country folk, and all their part of the business was to sell them; need I add that these people did not wish to see me?

My visits to apiaries extended over the country between Bellinzona and Montselice; this embraced the mountainous district of the northern Italian lakes, the plains of Lombardy, and again the hilly country around Bologna.

I may say at once that I certainly prefer the bees from the mountains, as they seemed much more vigorous and hardy; and the results in the way of honey-gathering, as far as I could get at facts, were certainly far better. The bees from these hilly parts would, too, be better suited for our climate. The number of apiaries visited was large, yet I can count upon the fingers of one hand all those who knew anything about their business; and if those who took a real pride in the production of their queens, and who use really scientific means to insure the best results, then the number would certainly be less than five.

I shall describe the apiaries of the best of these raisers, and their methods; but before doing so, will give the conclusions which I have come to with regard to Italians: That, excepting perhaps Carniolans, there are no better bees than Italians, if care is taken to get the best queens from a raiser of recognised merit.

That the bees of the mountains are hardy, vigorous workers, great honey-gatherers, prolific, and certainly gentle, and in their own country not given to robbing much.

That, to get the best results from Italian bees, we must get a good strain to start with, and then, by careful selection, raise our own queens, and be constantly on the look-out for those having the most desirable characteristics, and to propagate from them only.

I can name one very striking case in my own county where all these points have had most careful attention given to them, and with the result that that bee-keeper is not only the best in the county, but one of the best in England as far as results go; and practical results (the largest amount of honey, of the highest possible quality, got with the least expenditure of labour on the part of the bee-keeper) are what we require in this age of keen competition.

The first apiary which I visited belonged to Jean Pometta, and was on the hills above Gudo, near Bellinzona. He had promised to meet me at Bellinzona station; but on account of the breakdown of the telegraph wires, owing to a heavy fall of snow, he failed to be there. However, it was not much trouble to find him. Everybody whom I asked was able to direct me to the man who had a lot of bees; and after a most picturesque walk of two or three miles I arrived at his home, in the midst of vineyards, and with a waterfall close by, which would have made the fortune of any man in England who possessed

it. He was from home; not having got my telegram he did not expect me. I had a chance, therefore, of looking at his apiary at my leisure and without any interruption, which is always an advantage. His father (a venerable old man) received me in a very hospitable manner, and,

a large number of small stocks with young queens in the autumn. In the spring two or three of these can be united, and one strong stock formed, and the surplus queens sold.

As the season advances, the nucleus hives are used;

The Apiary of Mr. Jean Pometta at Gudo.

as Mr. Pometta is a vineyard-owner as well as a queen-raiser, I was able to see all the vintage operations in full swing. I may say that he takes pride in his wine products as well as in his bees; and he showed me with great interest an ancient-looking, squat flagon of *Aqua Vita*, very old, of his own distilling, that had taken a gold medal at Zurich.

I found an immense number of stocks of bees, many of them in bar-frame hives with straw sides; the majority of them on the Italian plan, opening at back, and iron tongs being used to remove the combs. There were, too, a large number of nucleus hives, with bar-frames lifting out in the ordinary way. The bees were of the leather-coloured strain, not the bright yellow-coloured bees such as I saw later on in Lombardy. To show their energy, I may mention, that Mr. Pometta told me that they are usually at work at six in the morning, and that on one or two occasions he actually saw them at work by very bright moonlight. We have heard this same story from the Americans, and I fear every one has doubted it.

On Mr. Pometta's return we went through many stocks, and I had explained to me his whole system of queen-rearing. I found that I had just missed Mr. Cowan and M. Bertrand, who had called about two days before on their return journey from the bee-show at Milan.

The system used of rearing queens depends upon the time of year. In the early spring (when loss of heat must be much guarded against) a stock is taken, and, by means of three dummies, is divided into four nuclei, the hive being made with four entrances for this purpose. In this way five queens are secured from one stock; and, though the system is a somewhat wasteful one (Fig. 1), yet it answers, as the price obtained for queens in early spring is comparatively high. Another plan is to preserve

each nucleus being large enough to be again divided into two. (Fig. 2.) By this plan better queens can be reared, and

Fig. 1. Hive divided into four for early Queen raising.

in good quantity too. The bars of these are of just such a size that two will fit into the large bars of the Italian hives. This, of course, is of great service to the queen-raiser in many ways, such as making up nuclei for queen fertilisation, and afterwards for strengthening such with hatching-brood.

The finest queens are selected to raise progeny from; and to secure eggs all of one age two small frames are placed in one larger one, and this introduced into the centre of the stock containing the queens whose eggs we desire. Or, if this queen is in a small hive, one bar of comb is placed in the centre; the comb should be fairly fresh and new, as, if so, it will be more regularly and readily filled with eggs. On the fourth day these combs will be found filled with newly hatched eggs. The combs are cut from the bars, and sliced up as shown in illustration (Fig. 3). The egg in each alternate cell is then removed (Fig. 4), and the strip (Fig. 4c) fastened with pins into another bar half full of comb. See illustration (Fig. 5).

Fig. 2. Nucleus Hive.

If there is a very great demand for queens one bar can be made to contain two strips of comb fastened in this way, (Fig. 6), though usually only one strip is used. These bars are placed in a suitable stock, and we soon have beautifully regular rows of queen-cells produced. The cells can be cut apart without injury, and inserted in the nuclei for subsequent hatching, and consequent fertilisation, and we get thus far better results than by the old plan of notching combs to induce queens to raise queen-cells (Fig. 6a).

Fig. 3. Comb full of eggs. White lines showing how it should be sliced up.

Fig. 4. Egg in alternate cells removed.

Mr. Pometta thinks it of the highest importance that each grub should have a full supply of royal jelly; the test of this is that some should be left in the cell, after the queen has hatched; therefore, before the cells are sealed over, he looks through and picks out with his knife any with an apparent short supply. Still further, to secure these desired

Fig. 4a. Strip ready for fastening in.

Fig. 5. Strips of combs with eggs in small bars, and two small bars fixed in one large one.

Fig. 6. Method if large quantity of queens are wanted.

results, he takes care that the hive into which the rows of cells are put for feeding and rearing, does not contain brood in the larval state, as this brood would perhaps get food to the detriment of the queen-cells. In about a week the sealed cells are cut apart, and placed in nuclei to hatch and get fertilised;

Fig. 6a. The old plan of notching combs to induce bees to raise queen-cells.

Fig. 7. Queen-cage.

and after this has happened the young queens are packed and sent off, and fresh queen-cells introduced. It is, however, desirable to wait two or three days before introducing fresh queen-cells, especially if the bees are old; and then, if with one sealed cell, two or three open ones are introduced, it often prevents the sealed one being torn down. Of course, sometimes more queen-cells are ready for hatching than there are nuclei ready to receive them. In this case Mr. Pometta uses a very successful series of queen-cages. (See figs. 7 and 8.) The cells are put into these, and a bit of sponge with honey and water is put to each, and the whole affair placed in the hive. The queens hatch, and can be kept till nuclei are ready for them. Three or four days, however, is as

long as they should be kept in these cages. The larger cage (Fig. 9) is used for putting in fertile queens. When these unfertilised queens are introduced into the nuclei they must be caged; and if, when we go to release them, we find the bees attempting to gnaw the cage, then it

Fig. 8. Queen-cages in bar.

Fig. 9. Large cages in bar.

is unsafe; but if they are fanning, then we may release them with certainty of success.

The packing of queens was next shown. Heather honey being used to sustain the bees intended for Europe, whilst clover-honey is used for those going to America, and other long journeys; the heather not suiting the bees so well when they have to be shut up for a long period.

Though Italians are considered in this country as proof against wax-moth, they certainly cannot contend always successfully against it in their own country, for I saw several colonies much infested.

Next day we went to Gordola to see another apiary, and also the workshops where the queen-boxes are made up.

Mr. Pometta also has a considerable apiary at Airolo—just where the Gothard Tunnel comes out on the Italian side. The honey from this district is extremely fine, though the place is too high for queen-rearing.

Mr. Pometta notes three kinds of drones—black, white, and red-eyed. During our drives we looked at several country apiaries, and noticed that the bees were kept in tubs, boxes, pieces of trees, &c., with crossed sticks inside for the bees to steady their combs by, and that the entrance was often in the shape of a cross, the natives believing that this brings luck. The entrances were often halfway up the hive, so that the bees would not have so far to go to reach the cluster in the winter time, nor would the entrance be liable to be blocked by dead bees. This same style of entrance prevails very much in straw hives in Belgium and the north of France. Great carelessness seems to prevail in leaving about the apiaries fragments of honey and comb, and yet, to my surprise, this practice did not appear to cause robbing. I was informed that the average weight of the swarms ranged from two and a half to three kilogrammes.

Mr. Pometta is one of the few people in Italy who make comb-foundation: this he produces on a very fine Danham machine; but this he had never been able to get geared quite correctly, and consequently was not able to get absolutely perfect foundation. It was with great pleasure that I took off my coat, and turned up my sleeves, and had a turn at foundation-making; and having got the gear in order, we turned out some foundation in splendid style. I was glad thus to render some little return for all the information which he had given and all the hospitality he had shown me.

On my way to the station we visited the apiary of M. Mouna, who sends his bees to Germany principally: it is a fairly large concern, although the system employed was not, I consider, very advanced or scientific. There I saw a solar wax extractor, which in the rays of an Italian sun was answering well, and the resulting wax was all that could be desired.

There are many other devices which Mr. Pometta uses that space would fail me to tell; but I can say, that as I parted with him at the station, I felt that I was leaving a master of the art of queen-raising, and that I had added much to my stock of knowledge.

In later articles I shall give details of my visits to Dr. Dubini of Gallarate, to Sartori of Milan, Mdme. Chinni and Mr. Paglia of Bologna, and Mr. Fiorini of Montselice.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

**. In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

PLANTS FLOWERING IN MARCH.

[153.] The following bee flowers may be expected to flower this month:—Whin, peach, wallflower, elm, hazel, crocus, willow, apricot, snowdrop, laurustinus, white iberis, and Anemone hortensis.—HY. DOBIE, *Thickthorn, Norwich.*

FOUNDATION FOR SUPERS.—[80.]

[154.] On page 50, present volume, we find these words:—'For several years it was my practice when supering, to fill each section with comb-foundation, the result of which, so far as rapidly-filled sections go, was most satisfactory' (the italics are my own).

My own opinion upon the indiscriminate use of foundation in the stock chamber has already been given. For building up previous to the honey show, we have at least two months to make all needed preparations; while in the case of swarms returned on the parent stand, we have there represented the required standard of strength, and nothing further is to be desired than that just sufficient brood shall be produced to maintain that strength. This desideratum is best secured by arranging most of the stock frames with starters only, as before stated by me, thus limiting the production of brood; while by a careful manipulation of the sections above, one will there secure in surplus honey what would otherwise be expended in brood-raising to excess below.

I do my best to study true economy, but I see nothing but a 'cheese-paring' policy in the recommendation of Mr. Sharp following after his words quoted at the head of this article. When the season is upon us, we want every surplus receptacle in place ready for the honey to be poured in, and *nothing less than a full sheet of foundation* will place us in a position to secure all the nectar the bees should obtain from a given district.

Mr. Sharp considers that the extra custom obtained for natural comb will more than compensate him for the decreased yield he says he is aware will be the consequence if he discontinues large sheets of foundation in the sections; but he does not appear to be aware of the fact that the difference between supply and supers with full sheets of foundation and starters only, represents not less than the loss of 20 lbs. of honey to the colony. How then can Mr. Sharp supply an increased demand from his decreased yield?

Your correspondent, judging from above question, knows how to obtain satisfactory results, in that he says sections are rapidly filled where foundation has been used, but if he means in future to be content with the slower and less profitable process of allowing the bees to wait and build their own comb in the supers, while hundreds of pounds of honey are being lost for want of the necessary store-room just at the critical and fast-floeting moment, then he may as well give up at once, for of a certainty he will be far behind in the present race of keen competition.

After all, it is not the public which, as a rule, can judge between honey-comb built upon light foundation and that without it. The bee-keeper is to blame if he

permits any such imaginary distinction to gain credence among his customers; and when once such ideas are afloat, no one can tell what they may end in. Therefore, in the interests of the community at large, and their own in particular, I would caution your correspondent, and others, not to injure the honey trade by any such statements, as they will be among the first to wish their own words had not been uttered; for most certainly a season or two with small starters in sections will convince them of their error; and only too glad will they be to return to the ways they have but lately condemned.—S. SIMMONS.

THE USE OF DRONES.—A REPLY TO 'STUDENT.'

[155.] In approaching the subject of the natural history of animals kept wholly or partially in a domesticated state, there is great danger of reasoning simply from what we see of them in their domesticated state, and judging of their actions from that point of view alone. There is no apparent reason why a dog should turn round and round before lying down on a hearthrug. But follow up the action to the original wild state of the animal, and the object becomes evident.

Reasoning from a false and imperfect view of the case, founded upon his observation of colonies of bees in an apiary, 'Student' comes to some startling conclusions. Not the least being that such a thing as 'senseless extravagance' can possibly exist in Nature. His only ground for this startling being his opinion that a few dozen drones in a hive would be amply sufficient for the fertilisation of queens.

Let us turn to Nature for instruction and study the subject from what we learn as to the requirements of bees in a natural state.

The natural location of a colony of bees is in a hollow tree, or in a cleft in a rock on the face of a cliff.

Again; naturally, colonies of bees are not congregated together in apiaries of five, ten, fifty, or one hundred colonies, but are scattered according to where suitable spots for the nests may be found. The distance between any two colonies being measured by scores, or hundreds, or even thousands, of yards. Whether in a state of nature, or of domestication, if a colony which has sent out a swarm loses its young queen at a time when the larvae are too far advanced for raising another, it means utter annihilation; and did not Nature guard against this, there would be senseless waste indeed.

Now, how is this loss guarded against? I say by offering every facility for the meeting of queens and drones, and reducing the chances of failure to a minimum.

The queens and drones soar to the upper air. Why? To surmount the highest tree-tops of the forest and the brow of the cliff in which the nests are in a state of nature situated, and so afford to the queens and drones a clear and uninterrupted view of each other, and also to get above the flight of insectivorous birds.

Each colony produces some thousands of drones. Why? Because, if only a few dozen were produced there would be danger of a queen not meeting with a drone, or only meeting with one related to her; but, as it is, when, on a fine day, there are thousands of drones issuing from each colony all eager to meet with a consort, the upper region of the air must be traversed in every direction by them, and a queen, on arriving at the height (whatever it may be) at which they spread themselves, is certain to be spied out by one.

As to the drone having any fore-knowledge of his fate, that may be dismissed as a perfectly unfounded idea. The same might be said of a certain species of spider where the male after becoming a husband is devoured by his wife. Yet that species does not become extinct from the male looking upon his connubial bliss as suicide. The instinct or desire for propagating

its species is so deeply implanted in every living thing as to be invincible. I have often suggested, in conversation with other bee-keepers, that the upper region of the air is, on a fine day, fairly peopled with drones, notably, to Mr. Cheshire, nearly two years ago, when I suggested to him a plan, whereby the height to which queens and drones ascend *might* (possibly) be ascertained, viz., by attaching a virgin queen by a fine silken thread to a small captive balloon, trying various heights until success was shown. It would be an interesting experiment, although not probably of much practical value.

It would be instructive if 'Student' informed us how he proves that bees cannot help knowing of the proximity of other hives, and that each contain its proper quota of drones (foot-note, p. 71). If they did know it they might possibly restrict their own production of drones. But, as it is, they follow their own unfailing instinct implanted in them, in order that they might be fruitful and multiply, long before the invention of bar-frame hives, placed in quincunx order, and furnished with worker foundation, by 'Him who saw everything that he had made, and Behold it was very good!' For man to talk of 'senseless extravagance,' seems to approach the line at which impiety begins.—F. LYON.

GREETINGS—REMOVING SUPERS—WATER-PROOF HIVES.

[156.] How changed Britain is from that state, of which Horace wrote:—

'Visam Britannos hospitibus feros.'

I find myself—especially in the pages of our *Bee Journal*—in the midst of kind, indulgent friends; in fact, I meditate, 'shaking hands all round.'

As for our noble Editor and Chief, I stand in awe of him!

'Dis te nihorem quod geris, imperas;
Hinc omne principium, huc refer exitum.'

But to 'Amateur Expert,' and our excellent friend, 'Plate-layer,' Messrs. Simmins & Co., I send most cordial greetings, hoping that all their queens are prolific and their honey (at least) one shilling per pound.

I bear in mind a query of last year, and venture to give my experience.

In removing supers, with and without smoke, I have found the queen therein. Twice I have taken up her majesty, and having found her on the ground where I manipulate, I have carried her to her hive and placed her on her throne. I carry the whole super right away to a convenient apartment, invert a skep, take sections one by one, and shake the bees into the skep—they are always quiet—I then take the whole mass and pour them into their proper hive. This is very easily accomplished, so I would add, by way of general caution, take care not to lose your queen. The question that now appears to flutter my bee friends, is, 'How to manufacture a cheap waterproof roof?'

I venture to add my experience, but it is adapted for small hives only of twelve frames and under.

I obtain a common box about two inches wider and longer than my hive, open at one end—the wide end. I flatten down some sawdust in the bottom of it, nail over that firmly a hive-sheet cover—canvass or calico. Turn it over bottom up, and place it on my hive. It completely covers the hive, and, projecting all round, keeps it quite dry in winter, and quite cool in summer. I make the bottom (which is now the top) waterproof in this way, I nail a strip of felt, a little larger than top surface, along one of the outer edges; stuff some hay under it to curve the surface; then finish nailing. I paint it all over, box and all. It can be fastened down in many ways—two or three coats of paint will be necessary.

This is a cheap cover, and readily made; any amateur

can construct one. I find it large enough to cover a crate of sections, and my hives are perfectly dry. With a weight on the top it fits very close on the frames, and those I have so treated are now very strong in bees.—UBIQUE, *Horetown Rectory, Wexford.*

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[126.] *Substitute for Smoker.*—For the convenience of every poor cottager not being able to purchase a good smoker, which every bee-fancier cannot very well do without, it would be desirable to ask some hive-manufacturer if a club could not be formed upon easy terms, namely, 6d. per week, until a good smoker, or any other bee appliance, is paid for. This could be done with safety through any member of the B. K. A. or our District Secretary.—C. COX.

[126.] *Smoker.*—Yes, a roll of cotton rag or old corduroy will answer fairly well. I have used it many times when examining hives away from home, and if a piece of brick or tile is placed on it when not in hand it will smoulder very slowly.—WOODLEIGH.

[126.] *Smoker Fuel.* (A. P. Howes.)—If those who fad with brown paper knew what an excellent material German peat moss is, I venture to say the paper would be discarded. I get a bale about 42 inches \times 21 \times 24, costing 3s. 6d. and carriage from Mitchell and Jackson, importers, Princes Dockside, Hull. When it is dried I think there is nothing to equal it for keeping alight and quantity of smoke emitted. When on the moors last autumn I tried the peat used by the residents there in place of coal and found it not nearly so good as the above. Same may be said of gardening peat. I have found for the first time in eight or nine years' experience several hives slightly dysenteric, caused no doubt by protracted cold.—J. C. LAMBERT.

[127.] *Manipulating House.* (Irish Novice.)—If the hives can be placed permanently inside the house with holes made in the walls for the bees to pass through, the object will be gained. There is no doubt great advantage in being able to manipulate in bad weather, and this can be accomplished in a bee-house by throwing open ventilators and allowing the bees to return quickly to the hive, which for the purpose need not, and must not, be moved from its stage.—T. F. WARD.

[128.] *Narrow Sections.*—No. Taking weight for weight they must of necessity take longer, as there would be a larger surface for the bees to seal. Many people think that the dividers prove an obstruction to the bees in filling sections, but a little consideration of the subject would soon dispel any such ideas.—WOODLEIGH.

[129.] *Doubling.*—Double by all means, say at end of this month or beginning of next; and you will undoubtedly increase your take of honey (extracted of course) during the coming season if you attend to 'Useful Hints' and use your own judgment.—WOODLEIGH.

[132.] *Distances between Frames and Floor-board.* (F. L.)—Don't exceed $\frac{1}{2}$ inch; but I have never known bees build combs below the frames, and not very often to the bottom bar.—WOODLEIGH.

[144.] *Preventing Casts.*—Milsom had better drive his bees and transfer his combs at once—(not now, March 1st, I don't mean)—to his frame-hive. The only way to prevent casts issuing would be to cut out all queen-cells but one; but I think with straw skeps he would find it a rather awkward job. I find the small rotary disk of wood fixed on handle with screw answer well for fixing foundation in sections; any of the appliance-dealers keep them in stock.—WOODLEIGH.

[144.] *Preventing Casts.* (Milsom.)—This is a most difficult matter to do with a straw skep, and exemplifies one of the numerous advantages bar-frames possess over them. As an expert I do not care for such a mode of transferring, preferring to do it right off in early spring, and have found it pay better, but with novices it is best to advise such a course as you propose to do. There is a

chance—but very slender—of your being able to cut out the cells; if you cannot, you must let them take their chance, and return casts. The easiest way of fixing starters in sections is by rubbing a piece of wax on the section where starter is to be fixed, then lay the starter true on it, and rub the edges of same with the wet handle of a table knife, then turn it up at right angles, and it is fixed as firmly as required.—W. B. WEBSTER.

[144.] *Preventing Casts.* (Milson.)—About a week after you have driven the swarm, turn up the skep and cut out all the queen-cells you can see *except one*, you will probably miss one or more even then. So late at night and early morning, from the ninth day on to the sixteenth, listen for 'piping,' if you hear it they will cast in a few hours. (2.) *Fixing Foundation.*—Melt a little wax of good colour, and use it as you would glue, work in front of a fire and let your sections be warm, test each one when cool to see that your work is sound.—AMATEUR EXPERT.

[145.] *Dead Brood.* (W. H. H.) If the combs are very old, melt them up; if new and otherwise serviceable, let them alone to the bees.—AMATEUR EXPERT.

[145.] *Dead Brood.* (W. H. H.)—This is not necessarily a case of 'foul brood,' but it looks very much like it. You ought not to have been manipulating the other day. If you have been doing so lately, in such weather as we have had, I am surprised you have any bees at all. Send some of the capped cells to the Editor, when no doubt he will be kind enough to get them microscopically examined, when you will have a correct answer.—W. B. WEBSTER.

[146.] *House for Extracting, &c.* (A. Snook.)—If possible to make it bee-proof it would be very suitable and, as you say, 'convenient.' Give it a good coat of tar outside, the bees abhor that, and do not use it, if tarred, to ripen honey in, *because in very hot weather the honey will absorb the flavour of the tar.* Honey and Tar!! Oh!!!—AMATEUR EXPERT.

[146.] *House for Extracting Honey.* (A. Snook.)—It will do very nicely if you make it bee-proof. Stop up crevices with any material suitable, and cover open windows with gauze.—W. B. WEBSTER.

[146.] *House for Extracting Honey.* (A. Snook.)—It would be very unwise indeed for you to form a room in your bee-house for the purpose you state. All such work should be done as far away from your stocks as convenient, and in a closed building; bees having a strong liking for honey quickly scent it, besides other bees than your own might pay you a visit, and the result probably would be a regular *nuisance* in your apiary. Allow me to suggest to you to convert the unoccupied portion of your bee-house into a little smoke-room, from which watch your bees working, or even a store-room for sundries, of which bee-keepers, as a rule, generally have plenty.—R. R. GODFREY.

[147.] *A Query.* (J. C. Andrew, Minorca.)—Why indeed? Give it up. Why does a plunging horse when held by the tongue stand perfectly motionless? Or why is a donkey with a heavy weight suspended to its tail never known to hee-haw?—AMATEUR EXPERT.

[147.] *A Query.* (J. C. Andrew.)—I am almost ashamed to own that I was simple enough to try it twice, and was twice rewarded for my pains.—W. B. WEBSTER.

[148.] *Bell Glass.* (Albion.)—If you require the bell glass for exhibition, it will be much the safest plan to use excluder zinc; place it with the burr side downwards.—W. B. WEBSTER.

[148.] *Bell Glass.* (Albion.)—I see no reason why you may not work successfully a bell-glass as you wish without excluder-zinc. My first experience of a glass super was last season. I bought one of Messrs. Neighbour the diameter of which is about 14 inches, depth 9 inches; this I put on the top of an eight-framed hive, having previously fixed comb guides about an inch deep. I then cut a hole in quilt about 3 inches in diameter, and gave the bees free access to it. I padded well with sacking both at the top and round to keep up temperature. The bees soon began drawing out the comb, and rapidly filled it with about 16 lbs. of first-class honey; there was no trace of any brood or brood-comb. When super was completed I took it off, bees and all, put it in a box made quite dark, and left a hole just large enough for one bee to escape at the time,

and on looking in about an hour's time found both super and box quite emptied of bees. The super also acted as an observatory hive, being a source of much pleasure to me to see my favourites working.—A. E. SNOOK.

[148.] *Bell Glass.* (Albion.)—Cut one or two slits in a quilt, about $\frac{1}{2}$ inch wide and 5 inches long, and stand the bell glass over the slits and try the result.—AMATEUR EXPERT.

[148.] *Bell-glass.*—'Albion' will err on the right side if he uses the zinc (oblong holes); he may not get it filled quite so quickly, but he will get it purer, as the zinc prevents to a great extent the storing of pollen in supers.—WOODLEIGH.

[149.] *Tinned Wire.* (Albion.)—Sorry I cannot tell you where to purchase the right kind except through the usual dealers. I never use it. It is important to get the right kind or the bees will not breed in each cell through which the wire passes, we have seen it so repeatedly; very fine copper wire SILVERED is the best. The bees would build the comb as usual, working to the wire, and by warming the wire and foundation you may press in full sheets, if not you will probably get an excess of drone comb. AMATEUR EXPERT.

[149.] *Tinned Wire.*—Albion should obtain some No. 32 wire—to be had of most ironmongers—and lace his frames as proposed; it is a most excellent way and I have had great success with it. You must warm the foundation before pressing on to the wires. You will require a piece of board same size as inside of frames, and three-eighths thick to place the foundation upon while pressing the wires into it.—CHESTER AMATEUR.

[149.] *Tinned Wire.*—If 'Albion' or any other bee-keeper will correspond with me, knowing the difficulty there is to obtain fine tinned copper wire in small quantities, I will guarantee to supply them with the same on bobbins at a reasonable price.—C. WILSON, *Oakmoor, Stoke-on-Trent.*

[149.] *Tinned Wire.* (Albion.)—Use sheets of foundation and press the wire into it with a button hook, having a slot filed in it lengthways. All respectable ironmongers keep it or will get it for you.—W. B. WEBSTER.

[150.] *A Beginner.* (Jas. Hodgkinson.)—Write to T. S. Bull, Town Clerk's Office, Preston, who will, no doubt, supply you with the required information, and may be able to give you addresses of bee-keepers in your vicinity.—CHESTER AMATEUR.

[150.] *A Beginner's Desiderata.*—1st. Black bees for Blackburn district—a natural swarm of 3 $\frac{1}{2}$ or 4-lbs. weight. 2. Bees, hive, smoker, veil, foundation. 3. About 2l. if you start with a good substantial hive, &c., or 30s. will start you with a 12s. hive. Month of May.—WOODLEIGH.

[150.] *A Beginner's Desiderata.* (James Hodgkinson.)—1. Cyprians if you have good nerves, some amount of skill, and a tough skin; otherwise natives. 2. Hive, veil, smoker, feeder. 3. Purchase now and refer to catalogues, and—your own pocket. 4. Sorry I cannot help you, perhaps the Editor will.—AMATEUR EXPERT.

[150.] *A Beginner's Desiderata.* (James Hodgkinson.)—1. Ligurians or Carniolans. If you do not care to go to the expense of such bees, then English blacks, and a bar-frame hive. 2. Bees, hive, rack, sections, smoker, foundation, feeder, and book. 3. About 2l. 5s. or more, according to description of bees and hive. 4. Look around you, or go to the Secretary of your County Association and join. I am willing to give you any advice providing you don't mind paying postage.—W. B. WEBSTER.

[151.] *Bee Houses.* (E. J. Gibbins.)—Root's *A B C of Bee Culture* gives a description of such a house.—W. B. WEBSTER.

[151.] *Bee-houses.* (E. J. Gibbins.)—The former part of your query would require an answer too long for this column. There were the dimensions of one given very recently (page 26, No. for January 21st), but I presume you want one large enough to work and manipulate in; if so, see answers given recently to 127, and Mr. Raynor's pamphlet on bee-houses. The chief advantages are, you can keep the hives in them ranged on shelves, with light-holes cut through the walls of the house, and they give you protection from bees and weather while manipulating, but there are the very decided drawbacks given in answer to 'Irish Novice' (127).—AMATEUR EXPERT.

[151.] *Bee House.* (E. J. Gibbics.)—I should strongly advise you not to build a bee-house, but have your bees in separate hives; the disadvantages of a bee-house are almost innumerable. The one I had experience of contained ten stocks, and I had to carry the top ones into the open whenever manipulating.—CHESTER AMATEUR.

[152.] *Moving Bees.* (E. J. G.)—You may leave them until the end of March and not suffocate them; give as much air as possible at the entrances, closed with perforated zinc; place the hives on straw in the bottom of the waggon and go as smoothly as possible, and choose the evening.—AMATEUR EXPERT.

[152.] *Moving Hives.*—You can move your hive with safety at any time to suit your own convenience. I should take the morning for the job when the weather was temperate. Confine them with zinc at entrance, and fasten a strip of wood with screws to prevent frames rocking on the journey. If you cannot manage that, place a section-erate on top of quilt, and tie with cord over the top of erate and outside of hive between legs, thereby fixing the frames. Some straw in bed of van will help to break the shaking and jolting.—WOODLEIGH.

[152.] *Removing Bees.* (E. J. G.)—It would have been better to have removed your bees to their new quarters at once, but as you could not be there to look after them, let them remain where they are until such time as you can, as so soon as the weather breaks in all probability they will require your attention. In packing for the journey, open the entrance to its full extent and close it with perforated zinc, do not disturb quilt, but see that it is secure, fasten down roof. This work must, of course, be done at evening when the bees are in; on having placed hives on a spring van, pack between each small bundles of straw to keep them steady, and to prevent jarring.—R. R. GODFREY.

[152.] *Moving Hives.* (E. J. G.)—I should, at the present time, have no hesitation in moving them as you purpose doing, but fix the frames by nailing two flat pieces of wood along the ends, and place a piece of small-holed zinc over feeding-hole. With a plentiful supply of straw in the bottom of the van they will travel such a distance nicely. Move them when you like. Three miles is a sufficient distance to prevent them returning to old stand.—W. B. WEBSTER.

[152.] *Moving Hives.*—Having within the last fortnight successfully moved nine bar-frame hives a distance of fourteen miles, my experience may be of assistance to 'E. J. G.' Each hive was wintering on seven frames. I removed the top cushions, and saw that the side cushions kept the dummies snug and firm. Then I tacked a piece of calico on the top of the frames, the tacks fastening in the wood of the stock-box. I used plenty of cabinet-maker's tacks. Two nails kept the moveable floor-boards in their places, and pieces of perforated zinc four inches long were tacked over the flight-holes. When all were thus fixed I piled three in a pile, the super covers of all being removed, and the topmost hive having its roof nailed on with four nails. Thus packed they were put on a light spring van, and the three piles filled it. All reached their destination in safety, and are alive and well, even though six of them had to be kept shut up, as they had travelled for five days, in a dark barn, owing to their roofs having been accidentally left behind. An hour sufficed to untack the temporary covers, draw the nails, and settle all up as they had been in their old home. Of course, such a method of moving could only be adopted in winter. All the hives have fixed legs.—H. W. LETT, M.A.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[157.] *Removing Ticking.*—Would it be advisable before removing the ticking from the top of frames, to smooth it over with a hot iron (just off the burn); it would melt the

propolis, and wax, and kill the moth grubs? The ticking would come off easily, and the enamel cloth could be put on at once, without scraping the frames, which generally makes the bees very angry. Would the heat from the iron injure the bees in any way?—J. B.

[158.] As I want some kind of a manipulating house, would a tent of mosquito net, suspended under a tree in the shade, answer the purpose?—T. T.

[159.] *Ligurianising.*—I introduced last August a Ligurian queen to a stock of blacks. I have some forty other stocks, all blacks, and want to Italianise some at least of them. What is my best way to go about it? Having but one stock of Ligurians the breeding will be very close. I suppose the first thing is to insert drone-comb in the middle, and to stimulate. Is it too soon yet? Could I procure and introduce a Ligurian queen at this time of year to a stock? Had I better remove the Italian hive away from the other stocks?—F. P.

[160.] *Bees in Hot-house.*—I have at side of my bees a very long hot-house filled with peach-trees, consequently the bees get in when the trees are out in bloom, and die in enormous quantities. Can any of your readers be so kind as to tell me how to avoid it?—A. P. BARRY, *Sumpting.*

[161.] Is not the 'Hill Device,' so much used in America and favourably noticed by A. I. Root, a good thing? and equally or more useful than passages?—J. C. LAMBERT.

[162.] *The Eyes of the Bee.*—Will any of your readers be so good as to state how many eyes are contained in the compound eye of the worker-bee?—H. S. S.

[163.] *Rate of Flight.*—At what rate does a bee travel? and what is the greatest distance a bee has been known to fly?—H. S. S.

[164.] *Bees Eating Eggs.*—Have bees ever been found eating the eggs of the queen?—H. S. S.

[165.] *Queen-raising.*—Can you inform me if queen-raising can be performed as I propose? By taking a frame of brood in all stages, and placing with one of honey on either side, in a small hive, and placing it on the stand of a stock of bees, after removing them a short distance, would the returning bees, finding their own hive gone, raise a queen from the brood in the frame, or what other method can it be done by?—F. GOLDSMITH.

[166.] *Transferring, &c.*—When is the best time to transfer bees from skeps to bar-frame hives? I have three stocks in straw skeps which I want to put into bar-frame hives, when would be the best time to put them in? Would it be best to wait until they have swarmed, or can I put them in before? Ought I to put the comb from the skep into the frame-hive?—YOUNG BEGINNER.

Echoes from the Hives.

Hull.—On Saturday, February 20th, my hives were overhauled to see how supplies lasted. I found a few queenless, and one that had died of starvation, with honey in the hive. Winter passages might have saved them; though punching holes in combs of forty or fifty hives is quite a task.—J. C. LAMBERT.

South Cornwall, Feb. 27th.—Frost again to-day, but bright sun, so, as bees were moving, I examined some hives at noon and found them strong with good supplies, and some rather too lively. An Abbott's combination hive is in rare good condition as to stores and numbers of healthy bees, but there is no brood. I tried a form of carbolic acid to-day—the disinfecting powder on my garden gloves, but not with satisfactory results. I shall try again.—C. R. S.

Bullinacurry, Co. Cork, Feb. 20th.—Every fine day bees are flying freely, and collecting pollen off snow-drops, aconite, and laurustinus—this latter is not much fanned by bees, for as soon as gorse blossoms, it is abandoned. Berberis Darwinii promises a plentiful and abundant bloom. Each leaf axil shows an orange bunch ready to burst, and cover each bush as if with a shower

of gold: it is in bloom about a month, and crowded with bees while it lasts. I have not seen a queen-wasp as yet, having destroyed every nest about here I could find. I saw a worker-wasp at a hive on the 21st. One ounce cyanide potassium, economically used, is sufficient to destroy fifteen or sixteen wasps' nests.—JOHN J. SMYTH.

World's End, Newbury.—The Ides, the Ides of March remember. To-day we have entered on the third month of '86, and if the advent is any criterion of the subsequent days and weeks, it will prove as memorable in the annals of bee-keepers as the two preceding months. During the whole of January and February, with one solitary exception, my bees have been confined to the hives, that one relaxation from the iron grip of Jack Frost was on Friday, Feb. 11th, and every stock of bees in the apiary was humming a joyful psalm, and taking advantage of the opportunity to survey their new positions. (I have moved my apiary a few yards.) Now, to-day, March 1st, the snow is falling fast, and Boreas is playing high jinks with the fine dry particles of snow as they fall, sending them with pitiless pertinacity into every crevice and corner, and into the entrances of the hives, with force sufficient to carry the small particles of snow to the remotest corner of the interior of the hives. Having an empty hive standing in my apiary, I have proved the truth of the above. I shall attend to every hive at the earliest possible moment, and would advise other bee-keepers to do the same, if they are in any fear as to snow-drift.—W. WOODLEY.

Chester, March 1st, 1886.—March 1st, and a furious gale blowing with blinding snow. February 23rd, visited four apiaries and found all stocks wintered well so far. They do not seem to have consumed quite so much store as usual to this date. Small patches of brood in some instances. Weekly issue of *B. B. J.* is quite to my liking.—CRAS. ROBERTS.

Harborne, Birmingham, Feb. 27.—We have had a severe winter here, and it still continues, there being no sign of any change yet. February 12th was the only day on which the bees flew for two months, and then I believe every bee took advantage of the weather to enjoy a cleansing flight. So great was the number of bees flying, that it reminded one of a July day. Crocuses, snowdrops, &c., are only just above ground, so there has been no pollen collected yet, nevertheless, on opening one of my hives, which I feared was short of food, I was surprised to find a good patch of brood on three frames, and plenty of stores. As an encouragement to dwellers near large towns to keep bees, I may say my best hive last year yielded me sixty pounds of very fine honey.—LORDSWOOD.

LECTURE ON BEE-KEEPING.—On Tuesday evening, February 23rd, at the Mutual Improvement Class, Tunbridge Wells—under the presidency of Mr. H. Holmwood—Mr. F. M. Spaulding read a very interesting paper upon the 'Physiology and anatomy of the honey bee.' Much interest was evinced, as Mr. Spaulding is known to possess a thorough knowledge of the bee, its habits, &c., and has earned for himself a reputation as being an authority on bees, and in the swarming season his services are constantly in requisition. The lecture was very instructive, and Mr. Spaulding received the hearty thanks of the audience.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column. Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

TIPP.—The single-comb observatory mentioned has an entrance at end for use as a nucleus hive, in which one may witness the process of queen-hatching, egg-laying, &c. It is found useful for the lecture-room and for conversations. It is only for summer use.

C. CHAPPELL.—*Candy.*—The specimen sent will do, only it is rather hard, showing that it has been boiled too much. The pea-flour should have been added when the syrup was of the proper consistency. In your case it had been boiled too long; this caused it to become like coarse brown sugar. Your specimen is also full of holes, showing that the boiling was continued too long.

EBENEZER MCNALLY.—*Quilt.*—The sample of silk sponge cloths would make an excellent substitute for a quilt. Its cheapness would also be a recommendation for its use.

J. SANDER.—*Bees Dying with Abundant Stores.*—The combs are affected with *Bacillus alvei*, but the queen, although not tainted by this disease, was suffering from the form of *torula* which I have now under investigation, and which I first clearly made out rather more than a year ago as the cause of true dysentery. In the absence of the bees, and in the ignorance of the symptoms exhibited, it would be rash to say which ailment brought about the fatal termination. But the combs are so bad that the lacillus not improbably was the most active cause.—F. C.

LINCOLNSHIRE BILLS.—1. *Bees.*—The bees sent are black or English bees. No. 3 shows traces of a remote cross with Ligurian or other yellow-banded bees. The drone is one of this year's. 2. *Working without increase of stocks.*—By doubling you can get a larger harvest, but to obtain it you must have a full-sized extractor. You will find it slow work extracting from sections one at a time.

R. WATT.—The bees were crushed flat: but they seem to be blacks, showing traces of yellow blood.

J. J. CHINNICK.—That constitutes a nuisance which is an occasion of trouble to others. The special nuisance that has annoyed your neighbour will probably not occur again.

A. J. RAYMENT.—There is no objection to using with long frames a strip of wood down the middle to facilitate extracting.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

- ABBOTT BROS., Southall, London.
- BALDWIN, S. J., Bromley, Kent.
- BLOW, T. B., Welwyn, Herts.
- BURTT, E. J., Stroud Road, Gloucester.

WALTON'S COMPETITION.

FEEDERS,
BEE VEILS,
EXTRACTORS,
SECTIONS,

SMOKERS,
FOUNDATION,
KNIVES, &c.,
always in Stock.

PRIZE £4 worth of Goods, to be selected from Catalogue. Limited to 50.

PRIZE £3 worth of Goods, to be selected from Catalogue. Limited to 200.

48 page
Illustrated
CATALOGUE
Free
on application.

PRIZE £2 worth of Goods, to be selected from Catalogue. Limited to 300.

In order to show the efficiency of E. C. WALTON'S HIVES, and to create a further development of Bee-keeping, E. C. W. has decided to offer the following inducement to intending purchasers. The Prizes are for the largest quantity of Honey, gathered from one of the above Hives in one Season, by fair means, the producer being allowed

PRIZE £1 worth of Goods, to be selected from Catalogue. Limited to 100.

to work for Comb, or Extracted Honey, but the quantity of Extracted must exceed the Comb by one-third.

Anyone wishing to compete for the above must order their Hives before May 31st, and send in their report before Sept. 31st, 1886.

The winning numbers will be published in the *B. B. Journal*.

E. C. WALTON will be willing to purchase the Honey produced.

E. C. WALTON, Muskham, Newark.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE CENTRAL AND THE COUNTY ASSOCIATIONS.

At the recent general meeting of the British Bee-keepers' Association Mr. Meggy, representative of the Essex Association, proposed an addendum to the motion of Mr. Jesse Garratt to the effect that the Central Association should make grants of money towards the annual exhibitions of the County Associations. The motion was not seconded, and consequently there was no discussion on it. Mr. Meggy, in the course of his remarks, said that 'many bee-keepers were of opinion that little was received in return for the affiliation fee.' To this the Chairman replied that 'this was quite a matter of opinion; the Central Committee knew as a fact that the benefits derived from the County Associations, when they were taken advantage of, cost the Central Society something considerably in excess of the amount paid in affiliation fees.'

Mr. Meggy, we consider, did not, in formulating his motion, take a sufficiently comprehensive view of the work of the Central Society or of the relationship that subsists between it and the County Societies generally.

The Central Society is the heart of the system. Its purpose is to lend efficient aid to counties where a desire has arisen to initiate Associations. Every successive year brings forth some counties where the glimmering flame is to be fanned, and where the weak are to be encouraged and strengthened; and it is pleasing for the Central Society to note that many of those counties where they have sent forth their lecturers, and where they have extended a supporting hand, have now strong, stalwart, self-sustaining Associations, some of them almost equalling the British in numbers. Last year the Central penetrated into North Wales, Cumberland, and the Isle of Man; and this year its attention will be directed towards others.

The Central Society recognise the great fact that their duty is to teach the artizans and the agricultural and labouring classes of this kingdom the most humane and profitable systems of bee-keeping, and they have found that the most successful and the simplest method of accomplishing this object is by the institution of County Associations affiliated with the Central in every county of England and Wales where bee-keeping is possible, and where there is an interest taken in the pursuit. There has been much earnest and uphill work for the Central to have overtaken the task they have set before themselves; but the present aspect of bee-keeping, the numerous societies

formed, and the many members rallying round these Associations, are no slight compensation for the labours they have undergone. But this height would not have been gained, this success would not have been achieved, had there been no unity between the Counties and the Central; it is the mutual support cordially and sympathetically given, both advancing foot to foot, and shoulder to shoulder, that has raised the bee-keeping industry to its present position.

This mutual sympathy has received expression from the Counties on several occasions. In 1883 a considerable deficiency arose upon two shows, the Bridgwater and the Knightsbridge, which amounted to 150*l*. A Deficiency Fund was started, and by the general and generous support of all bee-keepers of all classes and from all parts of the kingdom, the debt was extinguished, and the hands of the British set free. Especially would we mention in connexion with this the generosity of the Hampshire in giving 5*l*., the Oxfordshire 2*l*. 2*s*., and others rendering such assistance as they could.

Societies are as they are made use of. There are some, we are aware, who are very hesitant about the payment of the small affiliation fee, who confess themselves dubious as to the advantages of association, and who prefer to revolve in an orbit of their own creation; but when a retrospect is cast on the work accomplished since the starting of the British, and the nature and amount of that work candidly considered and thoughtfully weighed, we feel assured that any assistance the Counties can give, or they may be called upon to render, will be at all times loyally and ungrudgingly accorded.

BEE-KEEPING APPLIANCES.

We desire to acknowledge from C. Redshaw, South Wigston, Leicester, the receipt of several articles useful in the apiary:—1. A spirit-level for levelling hives; 2. a tube for sending samples of honey through the post without further packing; and, 3. a set of assorted labels, in plain colours, in blue and bronzed, and red and gold; these are suitable for jars and sections. The whole of these articles are remarkably cheap, and will be found serviceable to bee-keepers. The labels are very neat and chaste.

GLEANINGS.

In *L'Apiculteur*, speaking of the advantages of large hives, M. Gressier states that he got 317 kilos (about 700 lbs.) this last autumn. His hives are very large, having a capacity of 200 litres (12,200 cubic inches), and a breeding capacity of 140 litres (8140 cubic inches).

In such hives a queen develops her laying capacity to the fullest extent, which gives birth to a large number of workers,—a condition greatly to be desired by the bee-keeper, because, to obtain the maximum of honey it is necessary to have strong colonies which cannot be better obtained than by having large hives. It may be objected that the queen never requires so large a capacity in a hive as 8140 cubic inches to develop her laying powers. This is true, but at the sides of the brood-nest the workers find plenty of room to store honey, and this storage place should never be wanting.

In the *Elsässisch-Lothringische Bienen Züchter Ch.* Zwilling mentions a simple way of getting rid of fertile workers. He takes an empty hive, and between ten and two o'clock (when he is sure to have hardly any other but young bees on the combs—the collectors being out-of-doors) he places a frame from another good hive, containing brood in all stages, with the adhering bees into it. He then places a frame of empty comb by the side of this, and puts this hive into a dark cellar. During the night the young bees finding themselves queenless commence to form queen-cells. The next day, or the day after, this hive is placed on the stand occupied by the one containing the fertile workers, and this last taken away to a distance of about thirty yards from the apiary, and all the bees are brushed out on the grass or on to a large sheet. These will return to the old spot and join the young population. Any trying to enter other hives should be killed, as it is generally among these that the fertile workers are found. The drone brood is then destroyed, and the frames of comb given to the new hive. It is needless to say that if there are any queen-cells available one of them should be given to the young bees instead of making them start a fresh one.

In *Gleanings*, G. M. Doolittle states that it is not an unusual thing for a queen to be kept in her cell for several days after she is ready to emerge, and says that when the queens are thus confined the bees put more wax on to the cells so as to make sure that no harm should befall the occupants from the queen which is at liberty biting through them. They also have a small hole in the end, through which they feed the prisoner. On one occasion he saw a queen issue from a cell whilst the frame was in his hand. He made up a nucleus with it, and the queen commenced to lay on the third day. He has no doubt the queen was six or seven days past maturity when she crawled out, the bees having fed her all the while through a hole in the cell, so that she was as strong and able to fly as the one that went off with the swarm which had issued from this hive. After much experience and many experiments, he states that he can safely say that no queen can fly as soon as she emerges from the cell, where she is allowed to hatch as soon as she is mature.

A. L. Swinton says in *Gleanings* that yellow jessamine honey is considered poisonous by the people of Eastern North Carolina if eaten before it is ripe or capped over. It abounds in the woods in large quantities. He has heard of many instances where people were made sick and partially blind from eating unripe jessamine honey; and in consequence of this, the box-hive bee-keepers of that part are very careful to save no honey in the comb—except that capped.

With regard to Holy-Land or Syrian bees, W. S. H. Searey says in *Gleanings* that he regards them as superior to Italians in several respects,—

1. They multiply more rapidly and swarm less. Their colonies are full to overflowing at all times. Although Italians with him are constantly swarming, he has known the Holy-Lands to swarm but once.

2. They never disturb anyone unless they are first disturbed. The Italians are constantly stinging somebody, and he was obliged in self-defence to change them to Holy-lands, and the trouble was over as these attend to their business.

3. They do not dwindle away in the spring like the

Italians, but are always strong, healthy, and industrious. There is but one objection to the bees: They require more careful handling than the best strains of Italians.

In *Gleanings* J. W. Burgess says his experience with reversible frames convinces him that there are advantages besides having the comb built to the bottom bar; but he doubts if it pays, or if they will ever come into general use. He finds with eighty colonies and his office work, he has no time to manipulate frames, but feels the necessity of working hives instead of frames.

In the *Bulletin de la Société l'Apiculture d'Alsace-Lorraine*, M. Dennler states that the following five requirements are indispensable for safely wintering bees:—

- a. The hive must contain a good queen.
- b. It must have a strong population.
- c. Sufficient stores to last until the spring.
- d. It must be constructed in such a manner as to protect the bees from cold.
- e. It must be in a quiet place.

In the *American Bee Journal* a discussion has been going on for some time respecting large *versus* small hives. C. P. Dudant advocates large hives, and says that, although he does not wish it to be understood that each queen will fill every comb of a twelve-frame hive with brood before the honey crop, it is not a good hive unless it allows each queen to exercise her utmost prolificness in producing bees for the honey harvest. The twelve-frame hive allows itself to be contracted for the needs of the queen and of the season, while the eight-frame hive does not allow itself to be widened to suit the prolificness of the queen. Mr. Dudant makes the assertion, which he challenges anyone to disprove, that 'a hive is too small if it does not allow the queen to lay to the utmost of her breeding capacity previous to the honey crop.'

In the *American Bee Journal* C. Mitchell advocates a space being left below the brood-frames for wintering. He says, as this space is only required in the winter, almost without expense or trouble, when nailing hives together, the entrance can be made $1\frac{1}{2}$ inches high. For summer the bee-keeper can push in loosely a $\frac{3}{4}$ -inch board cleated at both ends, which leaves a $\frac{1}{2}$ -inch entrance the full width of the hive. For wintering the cleated board may be removed, which will then leave about $1\frac{1}{2}$ inches of space below the frames. We suppose it is meant by some means or other to reduce the size of the entrance in winter, but nothing is stated on this point.

In the *American Bee Journal* C. P. Dudant says that a bee-hive and its combs in ordinary circumstances, and with a careful owner, will last at least fifteen seasons. We are ourselves using hives made nearly twenty-five years ago, which are as serviceable now as they were then, and are likely to last many more seasons.

In the *Bee-keepers' Magazine* Rev. L. L. Langstroth speaks of Mr. W. Cary as one of the first and most successful breeders of Italian queens. In 1860 Mr. S. B. Parsons, of Flushing, imported a number of Italian queens with the purpose of breeding and disseminating them over the country. Mr. Langstroth recommended him (Wm. Cary) as the best man for this purpose, as the person who came in charge of most of these bees could not do the work that was expected of him. Mr. Cary's work in Mr. Parsons' apiary fully justified his selection. While the foreigner with the same facilities for breeding queens in a separate apiary established by Mr. Parsons, failed to rear enough even to pay for the black bees and food that he used in his operation, Mr. Cary supplied all the queens needed in Mr. Parsons' apiary and filled all his numerous orders. To appreciate fully the extraordinary success of Mr. Cary as a breeder and shipper of Italian queens, it needs only to be stated that during that year but few queens came alive out of many sent from Europe, and that for years after a large part of the imported queens either died on the way or

arrived in such poor condition that they were of little or no value. Mr. Cary was the first to send a queen across the ocean to this country in a single comb nucleus with a few workers; she was consigned to the late Mr. Woodbury, of Exeter, and reached him in excellent condition.

The *Canadian Bee Journal* states that one of the most remarkable yields of honey ever heard of had been, during last season, gathered at an apiary near Riverside, Cal. The yield from thirty-three colonies was seven and a quarter tons, an average of 414 pounds per colony. Is there not some mistake here? If the average is 414 pounds per colony it would give us 6 tons 1 cwt. 3 qrs. 26 lbs., but $7\frac{1}{4}$ tons ought to give an average of 492 lbs. per hive.

Selected Query.

[167].—*Is it more profitable to produce extracted honey, or honey in sections?*

Extracted honey is much more profitable to produce, and working on the doubling principle, double the quantity of extracted honey can be got than section honey, which we understand by comb honey.—EDITOR.

Assuming that equal facilities exist for the disposal of both kinds, and considering the time and expense involved in each system, I am of opinion that, at the present time, there is little to choose between them; but, having regard to the risk to which section honey is exposed in transit, and the greater care necessary at all times in handling, and also bearing in mind the probability of its deterioration through granulation if not early disposed of, I think it highly probable that the extracting system will be found the most practicable.—J. GARRATT.

Honey in sections I consider the most profitable, taking the extra time and trouble of extracting into consideration.—W. WOODLEY.

Experience has satisfied me that a two-fold system of obtaining extracted honey and comb honey from the same hive is the most profitable. This may be accomplished by extracting from the lower hive and piling sections on above, the hive being adapted to the system.—REV. G. RAYSON.

It is not a question of one or the other being more profitable. To obtain the best results both must be produced in the same apiary.—S. SIMMONS.

Honey in sections.—AMATEUR EXPERT.

The bees will produce about one-fifth more extracted than comb honey.—R. THORPE.

This depends upon locality, whether there is a market for comb honey in the neighbourhood at a fancy price, and upon the skill of the bee-keeper in having the wood of the sections clean and getting them *evenly* filled with honey-comb of uniform colour. Half as much again, if not more, extracted honey in weight can be obtained than comb-honey in sections. The same skill in management is not required for obtaining extracted honey as for first quality sections. I think, all things considered, extracted honey well ripened is the most profitable to produce.—JOHN M. HOOKER.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The next quarterly meeting of County Representatives and Conversazione will be held on Wednesday, April 28th.

Notices of motion for this meeting must reach the Secretary not later than the 31st of March.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

The fourth annual General Meeting of the Members of this Association was held at Southampton on the 4th inst., at which there were present the Rev. Walter E.

Medlicott (chairman), Mrs. Shears, Miss Palmer, Rev. P. P. Izard, Rev. R. Parker, Messrs. J. J. Candey, J. Preedy, H. West, C. Martin, E. H. Bellairs (Hon. Sec.), and others. The minutes of the last General Meeting were confirmed, the usual votes of thanks passed; the reports, balance-sheet, and accounts for 1885, adopted unanimously, and the following gentlemen elected upon the committee for 1886: Revs. W. E. Medlicott, P. P. Izard, R. Parker, A. B. Cotton, T. B. Robinson, H. W. Bull, J. P. Bartlett, Messrs. T. J. Beckford, W. H. Baigent, C. Martin, Jas. Tee, Commander Sudding, R.N., Drs. S. Andrews, T. W. Blake, and Ticehurst.

The report opens with a reference to the well-known glut of the honey-market, and expresses a hope that the difficulty may shortly be overcome by a more general appreciation of the value of honey whether as food or medicine, and successful competition of home-produced honey with the foreign article still so largely imported, adding that there is no reason why England should not in the future export honey instead of importing it.

The report further states that the growth of the Association during the year has been most satisfactory, the number of its members having increased to 291. It is especially encouraging to note that among the new members is a large proportion of cottagers, since the special object of the Association is the encouragement of bee-culture with a view to bettering the condition of the poor. Mr. Davenport, who made the expert's visit for inspection and advice among those members who wished for it in the spring and autumn, reported most favourably on the condition of the various apiaries he visited both with regard to the adoption of new methods and the care with which they are kept, particularly those at St. Denys, Godshill, Marwell Hall, Portsdown Hill, and North, near Hambledon. The apiary at Portsdown Hill interested him most of all. It is located in a disused chalk-pit, rented for the purpose from the War authorities, and he looks forward to the time when many more of our waste places and down-lands shall be utilised in a similar manner. Though satisfied with the progress he witnessed in the methods and style of bee-keeping, he has found here and there among the country people an unreasoning and almost superstitious adherence to old-fashioned ideas on the subject which it requires much energy and patience to overcome. He mentions further with regret that he found a good deal of the nauseous black 'honey-dew' about, and calls attention to the fact that much prejudice is created against the use of honey by the existence and sale of this stuff.

With regard to the propagandist work of the Association by means of shows, it appears that no less than five important exhibitions were held during the summer in the county, in all of which honey and bees had a place, in addition to which there have been various minor occasions utilised for imparting instruction to all who wished for it, by means of public lectures, and encouragement to all by means of prizes, which have been awarded to the value of 65*l*. A handsome marquee has also been acquired by the Association, and has proved of great use in making the exhibitions as effective as possible.

The first show of the year was held in connexion with the Royal Counties Agricultural Society at Southampton on June 23, 24, 25, and 26. There was a good show of honey, and the lectures were a great success. The next event was at Newport, I.W., July 21 and 22, in connexion with the I.W. Agricultural Society (we may notice, by the way, that increased appreciation of the work of the Association has been shown in the Island this year by a marked increase in the number of new members enrolled from among the Islanders).

The annual fair was again held this summer under the auspices of the Royal Horticultural Society of Southampton, Aug. 1 and 3. The Association was enabled, by the liberality of that Society, to award prizes of the value of 23*l*. 10*s*. The silver medal of the B.B.K.A. was

awarded to Mr. H. W. West, of Swanmore, and the bronze medal to F. J. Beckford, Esq., of Winchester, Mrs. Best, of Red Rill, winning the certificate. Here, again, the attendance at the lectures was most encouraging, as was also an event of great interest and significance, the presence of two cottagers earning twelve or fourteen shillings a-week who had cleared respectively 20*l.* and 28*l.* by their bees last year. Then followed the show at Romsey, on Sept. 9, 10, and 11, at which Mr. Baigent replaced Commander Suckling (whose duties have removed him to Folkestone), and Mr. Davenport acted as lecturer in the absence of Mr. Bellairs. The Highcliff Show (Oct. 6) was again a decided success, and especially noteworthy by reason of the increased numbers of cottagers who attended and competed for prizes. Exhibitions and lectures in the bee-tent also took place at Froxfield, Ringwood, I. W. and Milton near Lymington.

Eight members of the H. and I. W. B. K. A. have passed the examination for third-class certificates conferred by the British Bee-keepers' Association.

Touching the question of finance, the Association, owing to the heavy drain upon its resources from the fact of five important exhibitions having been held in the county during last summer, has somewhat lost ground, and the accounts for the year show an overdraft of about 30*l.* The total income (including last year's balance brought forward) amounted to nearly 300*l.*, and the expenditure to 318*l.* 8*s.* 11*d.*, which includes two large items, namely 65*l.* for prizes, and 58*l.* for show expenses.

TORQUAY BRANCH OF THE DEVON AND EXETER BEE-KEEPERS' ASSOCIATION.

The first meeting of the above Society took place on Saturday, January 30th. The following were present: Messrs. E. H. Boord, G. Pullen, W. Brewer, Vail Coombes, R. P. Kitson (member of the Council, D. and E. B. K. A.), Vallance, Davey, Rendall, Edwards, Elliott, Ward, Eastlake, and others. Mr. Kitson was voted to the chair.

The chairman explained that at the annual meeting of the D. and E. B. K. A., held in Exeter January 22nd, it had been decided to form a branch at Torquay, and that he, as a member of the Council, had been requested to form a committee and work it as it was thought best. He then read the rules and privileges of the County Society, and the special rules and privileges of the branch, which will work a district five miles round Torquay, and asked if anyone present would join. Several people responded, and received their tickets of membership. Mr. Boord then addressed the meeting, explaining the advantages of the modern system over the old one.

A discussion on a hive, kindly exhibited by Mr. Vail, followed, and the very successful meeting terminated with a vote of thanks to the chairman.

The second monthly meeting of the above Society took place on Saturday, February 27th, at the same time and place, the Rev. W. B. Davies in the chair. Mr. Kitson explained the plan of getting appliances and the privileges of membership. Mr. Boord read the 'Useful Hints' and extracts from the *Bee Journal*. The chairman started a discussion on spring-feeding and one or two other interesting subjects. The following are the names of the committee:—R. P. Kitson (chairman), W. Winget, W. Brewer, J. Coombes, A. E. Beattie, T. Rendall, G. Vail, S. Vallance, G. F. Pullen, E. H. Boord (hon. sec.)

Any bee-keepers residing within five miles of Torquay who may wish to join the Association can obtain all particulars from the chairman, R. P. Kitson, Collaton, Torquay, or the hon. sec., E. H. Boord, Holmesdale.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

THINGS IN GENERAL, AND SPRING STIMULATION IN PARTICULAR.

[168.] Kindly give a young bee-keeper space to ask a few queries, the solution of which will, I feel sure, be beneficial to many who, like myself, have been recently brought into the business by the County Association, and who are now desirous of increasing their stocks and appliances in the cheapest and best manner possible.

My first query is, Why are two or three sizes of 1-lb. sections used? Last season I ordered a stock of these, and on arrival was disgusted to find they would not fit my section-crate. I thought there was 'Association standard size' for everything, but I was mistaken. My next muddle was getting some spare 'Standard frames' with broad shoulders when my bar-frame hive was fitted with metal ends. Now I want to have all my frames and sections interchangeable, and before buying more I should be glad if some of your readers would advise me which to adopt, and the reasons in favour of either kind; also, are frames with 'saw-slits' best and easiest for fixing foundation?

Last season I used whole sheets of foundation, but in a recent issue of the *B. B. J.* (more power to it!) I find one of your correspondents advocating starters only, as being more economical, and better than whole sheets; and when I think of the swarm I hived in a large skep last year, and the short space of time it took them to fill it with comb, I am inclined to think it a dead loss of four shillings in filling a bar-frame hive with whole sheets of foundation. What do you say?

Last spring I used thirty-six pounds sugar stimulating two stocks from March to end of May; result at end of season, 107½ lbs. honey and seven stocks, one of which, a virgin cast, has died out. And now Mr. Lingen Seager says (and 'Rector' in your issue of the 18th endorses every word), 'I have ceased to believe in spring stimulating, and have found those bees do best that have had a large store of honey left for winter and spring use with plenty of room for natural expansion of brood.' 'Rector' also speaks of 'plenty of combs to move about on if they so list.' Now, sir, if this 'let-'em-alone' system is best, why so much expense and trouble, 'a-sticking everything in the kitchen all for them bees?' And why contract the size of hive in autumn, and carefully spread the brood in spring, 'so necessary to ensure strong stocks in time for the honey flow?' Does Mr. Lingen Seager 'let 'em alone' in these matters as well as in stimulating?

Another trouble is, Ought I to go in for reversible frames? and another trouble—no, I won't trouble you further. I have already taken up too much of your valuable space. Talk of County Associations being near the end of their work, I think it is only the beginning if that work is, as my county report states, 'to advance bee-keeping, and to afford information to members as to the most profitable manner of managing their bees and disposing of their produce.' I would suggest that instead of carrying the bee tent about the county at a loss to the Association, and instead of enlisting more

recruits, who will only increase the production and consequent depression in the honey trade, that each county should 'advance bee-keeping' by establishing an apiary presided over by the county expert, whose experiments could be carried out to prove 'the most profitable manner of managing bees.' Suppose each county undertook to investigate one subject each, the question of 'Things in General, and Spring Stimulation in Particular,' would soon be settled.—NUCLEUS.

[We think it a great pity that there is not a standard size for sections. A year ago the Committee of the British Beekeepers' Association recommended two sizes for adoption; viz., $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ for 1-lb. and $6\frac{1}{2} \times 5\frac{1}{2} \times 2$ for 2-lbs., as it was found that there were more of these sizes used than all others put together. The matter came before the General Meeting, and the opposition offered to adopting these sizes was so great that the matter fell through. The want of uniformity is certainly a great drawback to their sale, and we should be glad if the Association could decide on a standard size. The Standard frame has no broad shoulders or metal ends, and we never use them ourselves; they are, however, preferred by some, and in ordering frames it should be stated what ends are required. Our reason for not using broad shoulders or anything for keeping the frames at a certain distance apart is, that we can manipulate our hives much more rapidly, also can have the frames at what distance we like from each other; if we wish to restrict the combs to the production of workers only they can be brought closer together, if wanted for honey or otherwise they can be put further apart without any difficulty. We have always found it pay to use whole sheets of foundation, and have had combs drawn out sufficiently to be filled with eggs in twenty-four hours. There are times when it might be more economical to use only starters, and make the bees consume what would otherwise be unsaleable (honey-dew for instance) into comb. When the honey season is late the let-alone system may be well enough, but we should never get any honey at all in our district if we did not stimulate our bees in the spring, and contract the space. No doubt there is a great deal too much meddling with bees and more harm done by injudiciously stimulation and spreading the brood, but we have always found that if properly carried out with care it is marvellous how rapidly a colony can be built up ready for the honey harvest. We have tried both ways and have no hesitation in advocating stimulating in spring, but always recommend caution in not overdoing it. Your suggestion of model apiaries is a very good one, which we should be glad to see carried out.—ED.]

HAS THE BEE-STING EVER BEEN AN OVIPOSITOR?

[169.] Having read with great enjoyment Mr. Grimshaw's most interesting paper in your *Bee Journal* for January 28th, may I ask him to mention one or two instances in which British insects (1) 'have lost the use of their jaws,' (2) 'have had their wing-cases united' after generations of inaction? If the sting of the honey-bee is in a state of transition, has not that of the hornet and wasp arrived at a state of perfection, since they are able to withdraw their dart? Yet how are the circumstances of wasps and hornets altered from what they were hundreds of years ago? and have they ever passed through a transition stage? or was their sting ever used solely as an ovipositor? And why does *A. mellifica* require weapons of defence now more than they did in the days of old? (perhaps to resent the interference of bee-masters with the domestic economy of the community?)

If bee-stings are still in a transition state they are many thousand years behind those of their hornet consins, who, according to Moses (Ex. xxiii. 28), then used their quasi-ovipositors as 'stings,' as indeed did the bees of Palestine. Whether both, or either, forfeited their lifeblood with their sting we do not know; at any rate both were then able to sting—so now—but one only does it at the cost of its viscera, and therefore of its life.

After 'generations of constant inaction' caused by compulsory 'curtailment,' the sterna of some sheep-dogs are now by nature unadorned at birth with caudal appendages, yet years of docking have not improved the fleecy tails from off the spines of modern sheep. Would it be possible to breed a perfect stinging-bee by selecting a queen of barless sting? — MATRICE C. H. BIRD, *Abinger Rectory, Dorking.*

PACKING BEES FOR WINTERING.

[170.] I beg to offer my humble protest against the system so much recommended of late years in regard to winter packing; namely, cramming as many bees as possible on as few combs as possible—the said combs being parallel with the entrance to the hive, and also at the back part of the hive, the dummy forming an open court between it and the front of the hive. I am a very old hand myself, and I never saw such miserable failures as this style of wintering seems to cause. I have tried it the last few years in a few instances in my own apiary, and I have seen the very best and strongest stocks (covering seven frames, standard size, in November) hopelessly suffocated through the entrance being choked up with dead bees; and as the present is the proper time to look into this matter, it will be interesting to know what other bee-keepers have to say on so important a subject.

I have always found my stocks winter better without any special packing—except the usual and necessary precaution to keep out wet, and the combs arranged at right angles with the entrance, with plenty of stores and plenty of room, and such stocks I now find in excellent condition.—THOMAS F. WARD, *Church House, Highgate, Middlesex.*

SPRING STIMULATION.

[171.] I am glad the Rector of Buckland-Sedleigh is giving us some of his experience on this point. I quite agree with him that we are apt to meddle too much with our bees. Stimulation under certain circumstances is most useful and efficacious, but a wholesale practice of the system is a grand mistake. I have over and over again noticed that stocks that were put well into winter quarters, with a sufficient supply of food, and not meddled much with in the early spring, gave me the best results. For some years past I have had several stocks which were at too great a distance for me to do much with them. I saw them at long periods, doing what was necessary till I could pay them another visit; these proved my most profitable colonies. I advocate manipulating them when it is necessary, and then letting the bees have a chance to work, and not like the child who, a few days after planting seeds, dug them up again to see if they were growing. If Mr. Powell will give us some of his experiences we shall indeed have a treat; his adventures with some of the country people are most amusing, but not many are gifted with the power of relating them as he does.—WM. N. GRIFFIN, *Freshford.*

DRYNESS OF HIVES—QUILTS.

[172.] I have lately seen in the *B. B. J.* several communications on the dryness of hives. Most of the writers attributing the cause to defective roof. I have not noticed that any have blamed the humidity of our atmosphere, although I do not think I should be far wrong in saying that probably that is one of the main causes of dampness of hives.

In reading Mr. Hill's letter, Feb. 25th, p. 140, I noticed that he is wintering some of his bees under a piece of calico, one thickness or more he does not say. I presume from his manner it is only one thickness, and that these seem dryer than some others with thicker covering. Now

taking the average throughout the winter, probably they are much dryer for this reason: the roof of hive has to be pierced to provide for ventilation in order to prevent mould; but it has this ill effect, that it lets in the damp air, which oftentimes is nearly as bad as rain, and from the heat underneath quilt from the bees, there must be a great tendency to condense on quilts, hence damp quilts with a roof either good or bad. Now, if quilts are very thick they must absorb a great deal, and it will be much longer evaporating (when it has the chance) than the thin quilts, hence the advantages of a thin quilt as far as dryness is concerned; but certainly I think that they would be warmer with a thicker covering, provided we can keep it dry.

I have noticed one or more writers recommending, or we will say are using, a kind of oilcloth as a quilt to prevent propolis. As far as I am concerned I should not use it for that purpose. As I have rather a belief that nature generally provides the best means, and that a propolised chamber is better for them than the surface of an oilcloth (I do not wish to discuss it further), but have an idea that the oilcloth, put down nice and close over the calico, face upwards, would have the effect of keeping quilts dry despite humidity of atmosphere, and also would not be a bad safeguard against any possible defect in roof, and any other covering though proper might be placed over that, which might also be covered by a damp resisting surface.—W. J. GREEN, *Sudbury, Suffolk.*

'EXAMINING EXAMINERS.'

[173.]—I am quite of the same opinion with our Editor in the remarks on this subject in the leading article of Feb. 18th. With the experience I have had (and I feel sure many will agree with me) we are not to be led away with the idea because a man can talk to you a lot about bees that he is fit to be an expert, as when we carefully weigh what he has to say, and then put him to some practical test, he is nowhere; whereas another may not be able to answer some of the questions put to him, yet by a little judgment and quietly drawing him out of himself, we discover that he is a first-class bee-keeper, and well competent to teach others. A certificate of the British Association is a great help to a man, but if held by a novice with plenty of talk and not much practical knowledge much harm is done to the cause.—WM. N. GRIFFIN, *Feb. 22.*

WARNING TO BEE-KEEPERS.

[174.] As a warning to other bee-keepers I wish to say a few words respecting a certain hive of bees of mine. I may say that the hive in question was attacked with foul brood last spring, and I removed it to a friend's fruit plantation about two miles away from my house, and treated it with Mr. Cheshire's remedy. As the hive being so far away it often got neglected, although I kept a bottle of medicated syrup over the frames. But the bees would not take much from the bottle, so it had to be poured into the combs. No doubt I should have performed this operation every day, but sometimes I could not get there for three or four days together. It took me all the summer to reduce the disease. However, I got them nice and strong, and packed them up for the winter on five standard frames and combs about half filled with honey. I put a 3-lb. cake of phenolated candy on top of frames under quilt to make sure that they would not want before spring. This was done about the middle of September; I did not go near them until the 24th of February. I could see by the appearance of the entrance that the bees had not been about much. It was very cold at the time, but I wanted to see how the inside was, so on opening the hive and removing the chaff cushion I saw that a mouse had been in and eaten a hole through the quilt and into the cushion. I turned up one corner of the quilt, but not a bee was to

be seen, and by the appearance of the combs all the bees had been dead for a long time. On turning the quilt further back I saw a large mouse between the combs, so I replaced the quilt and grasped the five combs and two dummies and pressed them together and removed them in a body from the hive and laid them on the ground, and began to shift them about so as to pinch Mr. Mouse. One made his appearance and I pinched him between the frames and killed him; soon his mate appeared and met the same fate. I thought that was the finish of my sport. On shifting the combs a little more a third and a fourth made their appearance and met the same fate. They were four very large fieldmice with long tails and white bellies, the four weighed six ounces. Now, I think they must have entered the hive before they were so large, as I cannot see how they could have got in through the entrance, as it is only $\frac{1}{16}$ of an inch deep, but I had left it four inches the other way. They had built two very nice nests in between the combs, they had eaten all the candy and had about five or six lbs. of honey in the combs. At the bottom of the hive lay a heap of wings and shells of bees mixed up with small fragments of comb and other waste. I cannot but think that the mice killed and ate the bees soon after entering the hive; the appearance of combs and fragments of bee lead me to this conclusion.—A KENTISH BEE-KEEPER, *February 25th.*

HOW BEES FIND THEIR WAY.

[175.] When the extremely delicate organization of the bees is considered, it is surprising that of those subjected to the rough treatment described by Sir J. Lubbock, one-third found their way to their hive. The delicate wings, eyes, antennæ, could scarcely have escaped injury in being whirled round in a bag, so that the experiment cannot be regarded as a fair test. But the question is, How do bees find their way? and can it be doubted that it is by a true mathematical instinct? This may be claimed for them no less than their practical chemistry, converting the produce of flowers into the sweetness of honey, the virulence of the poison bag, the pungency of royal jelly, the elaboration of wax, and no less than their marvellous architectural skill. We see a rush of young bees leaving the hive for the first time, and observe their flight to be full of purpose. It is no heedless, joyous liberty, the business of life is begun. After advancing two or three inches, they turn round, then advance and turn, and so on till the edge of the alighting-board is reached. Then they take wing, but not in a straight direction. The flight is in circles, the radius gradually increasing, and on the return decreasing as the hive is approached. Thus the distance of surrounding objects is measured; and after a few excursions, the position of trees, buildings, hills, in relation to the site of the hive, become landmarks, and unerring guides.

This instinct was curiously illustrated by a queen raised in a skep from worker brood, whose progress was watched with solicitude. I was on the look-out when she was due to leave the hive for the first time. There was the usual rush of workers, and at the instant the queen rose from the board she was struck by a worker and they dropped together about ten or twelve inches and then became disentangled, and the queen rose and flew in circles. But the circles were not measured from the alighting-board, but from the point in the air to which she had fallen, and from which the flying began. Then the radius was reduced, and the puzzle was to find a standpoint—there was only empty space. So the poor queen continued flying, sometimes close to the hive and surrounding bees, but steadfastly returning to the starting centre point. At length she alighted exhausted, and after resting again flew round the vacant space; and this continued till I was satisfied she would be lost without assistance, so raising her on my finger I placed

her at the mouth of the hive. The next day the exit was accomplished without misadventure, the measurements being taken from the alighting-board, and she became a good queen.

It is to be observed that though the bee flies in circles till it becomes acquainted with the locality, when this is learnt it darts off in a straight direction, certain of its bearings. The familiar landmark has been scientifically defined, and in a state of nature the hive never changes its position. When man interposes and moves the habitation, the natural system becomes deranged, the angles are altered, and the instinct is at fault. Therefore, it is advisable, on moving a hive, to attract the attention of the bees to the change before taking flight.

Perhaps we have yet much to learn in the habits, and instinct, and wisdom of our pets. The microscope opens a wide field for research, and adds fascination to the interesting study of the bee.—A.

PRODUCING AND SELLING. [137.]

[176.] I am quite glad to find that 'Amateur Expert' is a 'cousin,' for it will enhance the pleasure with which I always read his contributions to your columns. He has a poor opinion of mine apparently, but they have done good work in drawing just a column of interesting matter from him. If I struck out at all, let it be remembered that it was in the first place at the question of the ripeness of honey, an important condition in its sale. If other things have received blows, it is because they have come in my way; that 'A.E.' says they have is, of course, for the purpose of effective grouping.

Verily some of our 'cousins' are enterprising: to take eleven cows 300 miles from Cornwall, and then to regret not having brought thirty. The wonder is that a person in her position did not send her butter instead of lugging about a basket of it on her arm. Anyhow I am glad she got a sale, and hope equal success will attend the efforts of our country honey-producers. No! I am not in despair either for my own produce or that of my neighbours, but in remote localities the work of disposal is not quite easy, and I do not wish to be urging on cottagers to produce what they cannot sell; and that I too have some experience of work in this direction, if 'Mr. Editor' does not know, 'Mr. Secretary' does.

I am anxious to know what the new rules are that will trouble me. They do not appear in the *B. B. J.*, but will doubtless come into my hands in due time.—SOUTH CORNWALL.

ANOTHER AMATEUR'S EXPERIENCE.

[177.] Amateur bee-keepers, it is plain, are not too modest to rush into print and give their fellows the benefit of their experience. A very proper spirit, on the whole, and worthy of encouragement. To other beginners it is very encouraging to hear of such good results in the cases of those who, like themselves, are yet in the novitiate, I sometimes wonder at the silence of the unsuccessful ones. Is it possible that there are none? I do really hope that there are a few. The knowledge of the fact would make my non-success less galling. Allow me to tell my tale. I shall be as brief as possible.

Autumn, 1881.—Enthusiasm for bee-keeping created by coming across a bee-keeping work of the bell-glass period. Wrote to one of the advertisers therein for catalogue. Got it. Ordered stock of Ligurians in frame hive. Guide-book ditto (*6d.*). Bees arrived. Couple of combs smashed. Bees gave me a warm reception. Placed hive at window of loft of outhouse. Bees provokingly persisted in dashing themselves against the window, and getting entangled in cobwebs. Removed them to a farm. Didn't feed them. They died.

Autumn, 1882.—Extinguished zeal re-kindled. Drove a couple of stocks of condemned bees very successfully. Placed them in the frame-hive with six frames of foundation. (Had wisely melted the combs of the previous venture.) Fed them niggardly. They died.

I have nothing to record for the two following years. (Circumstances forbade me the mortification of passing through my usual trials during this time.)

Autumn, 1885.—Drove two stocks. Placed them in hive with strips of foundation remaining from my previous disaster in the frames. A divider between the two stocks, and separate entrances. Two stocks gradually became one. Fed them with syrup first, then with flour-cake and candy. Alive as yet, but not as strong as I wish.

I did not this time confine myself to one lot. I got a 'Copyable' hive and proceeded to get the bees. A friend had two stocks in skeps. He had not touched them for three years. Whether in good condition or not, and whether they had swarmed or not, he didn't know—nor care. My previous successes in driving had made me confident, so I told him with the air of a man who knew what he was talking about that I would relieve him of his bees without trouble. 'Twas a dull day, and the bees were in a dull, shady position. The skeps were overgrown with ivy. My near approach to the skeps was the signal for an uncompromising onslaught on my person by the inhabitants thereof. A quick retreat followed. A newly-acquired smoker was brought into use. Smoke or no smoke, 'twas all the same. Each advance was met with the most unqualifying resistance. But I had come to have those bees, and have them I would whatever the result. I had them. Results of having them,—stings innumerable, followed by swelling all over my body, accompanied by a sensation the most uncomfortable I ever felt.

I wanted more bees in my new hive. Proceeded to the place of another friend the same day, my brother-in-law, who accompanied me, stating his intention of driving the bees. Covered by a veil he made a move towards one of the skeps. Was soon in full retreat, the bees having discovered a flaw in his armour and showing a desire to explore his hair. Went to my brother's rescue and again donned the veil. Bees not to be pacified by any means. We were not to be denied, however. Did battle with our antagonists in turn, until we had secured the bulk of four stocks. Took them home and united with the other two lots. Frames contained only small portions of brood-comb tied by tape, the lot making about $1\frac{1}{2}$ square feet of comb, in eight frames. Fed with about 7 or 8 lbs. of syrup. No sealed food when I fixed them for winter. Gave them at different times flour-cake and candy to the amount of 8 or 9 lbs. Looked at them on 22nd February. Found them in flourishing condition, with a quantity of sealed stores and the amount of comb nearly doubled.

I begin to feel that I am at last on the highroad to success. My hopes and expectations have been considerably raised since I began my subscription to our *Journal* at the beginning of the year. I think it should be impressed upon all intending bee-keepers that a constant perusal of the *Journal* is an indispensable condition to success.—WELSH NOVICE.

P.S.—I am, it will be seen, very much of a novice, and I hope 'Amateur Expert' and others will bear the fact in mind and keep an even temper when a query or observation should appear above my signature.—W. N.

[154.] *Foundation for Supers.* Corrections.—In second par., 3rd line, read 'previous to the honey flow.' Fourth par., 6th line, should read, 'difference between supplying supers,' &c. Fifth par., 1st line, for 'question,' read 'quotation.'

SWANMORE BEE-KEEPERS' SOCIETY AND THEIR LECTURES.—The Swanmore Branch of the H. and I. W. B. K. A. has thriven so amazingly fast since its formation that a few notes on its success may not be out of place in the pages of

your valuable *Journal*, by way of further inducing additional cottagers in the immediate neighbourhood to commence bee-keeping on modern principles. The committee of the Swanmore Society have arranged a series of lectures, or what may perhaps be better termed a homely chat explanatory on the advantages and disadvantages of using certain kinds of hives and materials in connexion with bee-keeping. The first of these lectures was given on the evening of the 23rd ult. in the schoolroom, Soberton, kindly lent for the occasion by the Rev. J. Morley, who also took the chair on the night in question. Before describing the lecture, it would be better to dot down a few notes on the Society of Swanmore bee-keepers. When the Society was first formed a year ago, it was through the instrumentality of the Rev. W. E. Medlicott, who is an enthusiastic cultivator of bees, and an encourager of all that is good for the interest and benefit of cottagers. A list of officers and a committee was formed, and with such an amount of energy and zeal as was infused into the matter by the Hon. Secretary, Mr. H. W. West, the Society now numbers eighty members. One of the objects of the Society is to raise sufficient funds with which they may hold a large show of honey in the neighbourhood, as it has been found that offering prizes for honey is one of the best incentives for others to commence bee-keeping. Another object which deserves mention is the wish of the Society to assist deserving cottagers with advancing a hive or any other article required. Mr. C. Martin, Swanmore, was the lecturer on the present occasion. He commenced by describing the disadvantages of the old-fashioned straw hive, both as a non-profitable method, and in a pleasurable sense compared to the more modern bar-frame hive, the construction and management of which he detailed in a lucid manner, with the aid of a hive of excellent make, and by the views on the same subject; Abbott's Copyable Hive was strongly recommended as the one the best adapted for the use of cottagers as a practical, cheap one. The various kinds of bees were next explained, pointing out the uses of the queen, the drones, and the worker bees, the number of bees in a hive, and the time required for hatching the eggs, the reasons of swarming and the best method of hiving a swarm of bees, both in favourable and awkward positions, the time to place the supers on the hives, and the best methods of extracting the honey; by way of example, showing what can be done by careful attention, it was mentioned that one resident of Swanmore had, during the summer of 1885, taken off one hive 110 lbs. of honey; in fact, all matters appertaining to successful bee-keeping were thoroughly and clearly explained, and richly merited the cordial vote of thanks which was unanimously accorded at the close of the lecture, which was very much enhanced by the dissolving views, which conveyed a much clearer idea to the uninitiated than could possibly be without their aid.—E. M. S.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[157.] *Removing Ticking.* (J. B.)—The effect of heat on propolis would be to partially soften it, so that it would adhere more strongly to both ticking and frames, and draw up into strings, requiring more scraping to remove, than if the ticking were stripped off when cold and the propolis brittle. The heat would not be likely to kill the grubs unless sufficient to burn the ticking, but would very likely rouse the bees and make them angry.—F. LYON.

[157.] *Removing Ticking.* (J. B.)—Remove it in a proper and workmanlike manner, clean the frames with a scraper; by your method you would simply remove it from the tops, and stick it on the edges of frames, the quilt being fixed down firmer than the bees fixed it. If your iron is hot enough to kill the moth larvæ, surely it will be hot enough to injure the delicate antennæ of the bees, when they come up to feel what all the noise is about.—W. B. WEBSTER.

[157.] *Removing Ticking.* (J. B.)—The heat would excite the bees. If done on a warm day I see no objection. Try one hive as an experiment.—AMATEUR EXPERT.

[158.] *House of Mosquito Net.* (T. T.)—I have long thought of a portable tent of net or wire cloth, to drop over the hive and oneself while manipulating, not for myself, but for very nervous manipulators. I should prefer that to one under a tree in the shade. A good preventive from robbing for the time being.—AMATEUR EXPERT.

[158.] *Manipulating Tent.* (T. T.)—A tent, similar to your description, is frequently used to manipulate in during cessation of honey flows. It is made portable, and of sufficient size to cover over the hive and manipulator.—W. B. WEBSTER.

[159.] *Ligurianising.* (F. P.)—You will get full instructions in many bee-books. A proper answer would take a couple of columns of the *Journal*. Cheshire's *Practical Bee-keeping*, 1s. 6d., will give it you fully. Is the game worth the candle? You are almost certain to get several young queens fertilised by Italian drones without any effort of yours.—AMATEUR EXPERT.

[159.] *Ligurianising.* (F. P.)—It is impossible to keep all your stocks pure without a regular system of queen-rearing; this is most easily done by means of nuclei, a description of which would occupy two or three pages of this *Journal*. Read *British Bee-keepers' Guide*, by Cowan, 1s. 8d., post free, Alleyn on *Queen Rearing*, Root's *A B C of Bee Culture*, &c. You will require at least two stocks of Ligurians, the one with selected drones will have to be kept near nuclei, at least half a mile from any hive stocked with bees of other varieties. It is too early yet to stimulate, stimulate first, introduce drone comb when stocks are strong. It is much too cold now to purchase queens, even if you could find any one to sell, they would be injured in transit. Purchase a stock.—W. B. WEBSTER.

[160.] *Bees in Hot-house.* (A. P. Barry.)—The bees are excellent fertilizers of the peach blooms. Which is of most value to you, the bees or the peaches? Mosquito net will exclude them.—AMATEUR EXPERT.

[160.] *Bees in Hot-house.* (A. P. Barry.)—You cannot avoid it entirely; by keeping the windows open during sunny weather, the bees—after a time—find their way in and out. The dead bees are those that have worried themselves against the glass in their fruitless endeavours to get back to their hives.—W. B. WEBSTER.

[160.]—*Bees in Iothouse.*—The only way I know is to provide an easy exit near the head of the front sashes where the bees always collect when they try to return home. My plan is to cut a piece of the last pane of the top glass and insert a zinc slide, which can easily be opened in fine weather. If this is done about every fourth pane the bees will all draw out. I have a range of orchard house fitted in this way, and find it work very well. Another plan is to groove the head before glazing; but I find the zinc slide works best.—ARCHIBALD SETH SMITH.

[161.] *Hill Device.* (J. C. Lambert.)—Some of my hives I have so fitted this winter, but do not consider it so good as winter passages; there must be a greater escape of heat, especially when the hive has become depopulated, and the outside frames tenantless. With winter passages cut through the combs, the cluster of bees covering the passages, prevent any very considerable escape; it is also much easier for the bees to gradually draw through to the next frame, as the hole is about the middle of the cluster.—W. B. WEBSTER.

[162.] *The Eyes of the Bee.* (H. S. S.)—Mr. Cheshire—than whom no higher authority exists—gives the number of facets or simple eyes contained in one compound eye of the worker bee, at 6300, of a drone 13,090, and a mother bee 4920.—W. B. WEBSTER.

[161.] *Bees Eating Eggs.* (H. S. S.)—Yes, frequently, when laid improperly, such as dropped on floor-board. I had a number of eggs disappear from a comb at the end of the season, where they went to I did not see, but the fact of bees being addicted to this habit led me to infer that they had made a meal of them.—W. B. WEBSTER.

[165.] *Queen Raising.* (F. Goldsmith.)—Do not think of doing such a thing, it is imperative that you have young bees, and plenty of them, to feed larvæ; under your management you would only have old ones. See answer to (159.)—W. B. WEBSTER.

[165.] *Queen Raising.* (F. Goldsmith.)—They would

probably, but you would deprive the nucleus hive of its natural nurses by this method, and the stock of its gatherers and warriors. Mr. Blow's article will give you some good hints.—AMATEUR EXPERT.

[165.] *Queen Raising.* (F. Goldsmith)—Queens can be raised as you propose, but why proceed thus? A better plan would be to introduce into the centre of the brood-nest a frame of comb or foundation, preferably the former, first marking the frame with lead-pencil. In three days remove to fresh hive, having satisfied yourself that it contains the desired eggs, and treat as you propose. Of course you would cut away a portion of comb beneath the eggs, and it would be well to feed gently to induce cell-building.—PLATELAYER.

[166.] *Transferring, &c.* (Young Beginner.)—If you want increase of stocks, let them swarm, and live the swarms in bar-frame hives on foundation, and later on, after the young queens are well established in the skeps, you may transfer combs and bees into bar-frames without danger to brood, the weather being warm, or you may transfer combs and bees on a fine day in April, and the shift would act as a strong stimulant, and if well fed and cared for they would probably give you good returns. If you adopt this latter method you must not hope for increase, but honey.—AMATEUR EXPERT.

[166.] *Transferring.* (Young Beginner.)—They can be transferred before swarming, but as your *nom de plume* implies inexperience, wait until they swarm, and three weeks after transfer; use all the worker comb in filling frames, reject drone comb, and any very old.—W. B. WEBSTER.

[166.] *Transferring.* (Young Beginner.)—You may transfer at any time when the weather is warm enough for manipulation. Be careful not to chill the brood. Bump the skep to break out the combs, and leave the bees in it. Take out the middle comb, brush the bees off it into the skep, tie it into a frame and hang it in the frame-hive. Brush the bees off the other combs as you lift them out one at a time, on to the comb or combs in the frame-hive. By this plan, the brood and bees will be separated for but a short time. Tie all the worker comb into the frames, but discard drone comb. Fill the frames from side to side with comb piecing, if necessary. When all are tied in, brush out the remaining bees from the skep on to the combs, close up the divider, and cover up warily. Put all comb cuttings containing honey behind the back divider, giving access to them to the bees of the hive, but carefully excluding strangers.—F. LYON.

[We much regret that the valuable replies forwarded by Mr. J. Walton and Mr. J. Saddler reached us too late for their insertion in last week's issue. We should be obliged by those correspondents who favour us with replies being prompt and succinct.—ED.]

Queries.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[178.]—How can you tell from which hive a swarm or east has issued if in one's absence, to enable it to be reunited to the parent stock if required?—W. G. E.

[179.]—*Sealing Wax.*—Could you inform me how to make sealing wax?—TYNO.

[180.]—*Kohler System.*—Is it practicable, and am I likely to be successful, in getting young queens in nuclei fertilised on the Kohler system, viz., putting them in a cellar and bringing them out to their stands in the evening?—TYNO.

[181.]—Is it possible in packing up stocks of bees in autumn to overdo it? On examining a stock on March 4th, to my surprise I found brood in four frames, and not a cell with honey, bees eating the grubs and dying for want of food. Now this stock at end of October had over 20 lbs. of honey, bees crowded on nine frames with calico quilt, piece of felt carpet, four thicknesses of hop-pocketing, besides two sacks folded to eight thick on top, and bars to back of hive, dummy in front.—J. H.

[182.] *In a dilemma.*—Should I be satisfied? I commenced bee-keeping in 1883. Expenditure to present time is 35*l.*, receipts, 26*l.*; stock-in-hand, twelve bar-framed hives (cost 8*l.*), ten with stock of bees, extractor (Blow's), and sundries, over 200 pounds of honey (some sections), sold this year for sixpence. 2. Placing two or more crates of sections, I noticed in the *British Bee Journal* constantly recommended. My difficulty is, that the covers of my hives have only room for one crate. What should I do? I had a hive made to my order which covers two crates, and that did fairly well last year.—A. P. J.

Echoes from the Hives.

Chester.—Weather since the 1st inst. has been intensely cold, with heavy falls of snow. Bees have been tempted out one or two days when the sun has been bright. Expect this is a critical time for many stocks. Am convinced that wintering at the back of hive is the best; two of my stocks treated so have lost very few bees.—CHARLES ROBERTS.

North Leicestershire.—Bees were in flight on the 20th ult., and had a 'little go' at the acornites. Since then they have been snowed up. On Sunday, 7th inst., the thermometer ranged from 17° to 35° Fahr., but the sun was so bright and warm that the bees, in spite of slading, came out to perish by the hundreds. During the middle of the day very few fatalities occurred, but later in the afternoon the bees were unable to rise again after once floundering in the snow. Stocks in large numbers must soon perish if this cold weather continues.—E. B.

Weston, Leamington, March 2nd.—A little over a fortnight ago the bees had a good flight on two days; since then the weather has been very severe for the time of year, March being ushered in yesterday by a terrible snow-storm. I had to put bits of flannel in the entrances to keep the snow (which was like fine dust) from blowing in. All vegetation is very backward, scarcely a sign of the buds moving yet.—JOHN WALTON.

Moushill, Surrey.—Packed last autumn a nucleus colony of two frames of honey (the hive would not hold more, as I made it especially for two frames). Examined to-day, February 26th, and found the bees in a healthy condition, and sealed brood on the outside of one frame. Found the food was getting rather low, so gave them a good dose of moist sugar on the top of frames, which they soon began to work at. The hive is packed in warm material in a bee-house.—W. EDWARDS.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or whose appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

W. NOAKE.—The two experts of Staffordshire are Mr. A. W. Rollins, of Stourbridge, and Mr. E. Clowes, of Milton, near Stone, who, according to their opportunity, will be pleased to give you the information you seek respecting your bees. You may begin to stimulate your bees about six weeks before the appearance of the apple-blossoms.

MONTGOMERYSHIRE.—*Zinc Covers.*—There is no objection to zinc covers either for winter or summer use. In summer they rather attract the heat; but that disadvantage may be reduced by painting them. If you would look over the trade catalogues of Messrs. Abbott, Harrison, Neighbour, and others, you would see that considerable attention has been given to render these covers ornamental.

M. C. H.—*Management.*—If your honey season does not come until the middle of June, there is ample time for your bees to complete the combs if they are fed gently, commencing in April, provided they have sufficient food to last them to that time. You should remove some of

- the frames and reduce the space occupied by the bees, and let them complete some of the combs and gradually add the others as they require more room.
- C. N. W.—The sample of sugar forwarded is either Porto Rico or Barbadoes, and is of excellent flavour.
- UNCLE TOM.—Your letter has been forwarded to 'A. E.,' whom it alone concerns; his reply is, 'Drone "wasps" make a noise, but they have no sting.'
- J. B. S.—1. *Moving Hives a few feet.*—You can move your bees only on those days when the bees are able to fly. We should recommend you to begin at one end of your bench and move the first hive a couple of feet, and the next one a foot, and the next a few inches, and gradually spread them out in this way until you have got them as far apart as required. If you move them forward you can take three feet at a time. 2. *Dysentery.*—You had better wait until the weather is a little warmer, and then change the floor-boards and feed with warm syrup. 3. P. H. Phillips, Esq., Crowborough, is acting as secretary of the Sussex Association.
- R. J. S. *Cavan.*—*Cowan's Practical Note Book.*—Your entries in Table 10 are quite correct, only you could with advantage enter more details,—for instance, under the heading 'Condition of Bees,' you might say how many frames they covered and how many frames you had in the hive. 'Quantity of Brood,' you might say how many frames had brood and what quantity on each, also the superficial area of 'Food remaining' on a valuation of the weight. Table 2 should be discontinued as soon as you have taken your bees out of winter quarters, and begin to work them up, to which time Table 1 would be in use. It is merely a record of the weather, and the 'Observations made on Individual Stocks,' should state if the bees are active or quiet, or if they are bringing in pollen, &c. Table 8 is to record the quantity of food given to each stock during the year. You can judge of the principal flowers by observing what you have most of in the neighbourhood and which are most frequented by the bees, such as clover, limes, tares, &c.
- W. C. THOMAS—*Sending Stocks of Bees to the West Indies.*—Have all the combs well fixed in the frames with wire, and see that the frames are secure to the hive so as not to shake about. The older and tougher the combs are the better, and they should contain a good proportion of sealed honey. If short of this, a frame of candy sugar should be inserted; but as the voyage is generally under twenty days, the supply of food need not be very large. It is essential that the bees have access to a little water. This may be given them by means of a moistened sponge at the side. The sponge should be damped about every other day. A piece of perforated zinc being fixed on the inside against an inch hole, through which the water may be taken. The hive should be ventilated by having a false roof of perforated zinc with a board above, raised about three quarters of an inch and screwed down. The amount of ventilation depends on the time of year and the number of bees,—a few holes at the side are sometimes useful, of course covered with perforated zinc. The hive should be kept in the dark, if possible and where there is air, but not too strong a current or otherwise exposed to the weather.
- W. C. J.—*Breed of Bees.*—The bees which you send are hybrids, a first cross between blacks and a yellow race. According to the observation of a recent correspondent, black crossed with yellow are more irritable than yellow bees crossed with black.
- MELLIOTUS.—1. *Uniting Bees in Hives with Non-interchangeable Frames.*—Brush the bees off the combs of each hive to be united into a separate skep. Turn one lot into the other and mix them up by shaking them about, leave them for a short time to form a cluster, and then turn the whole among the combs of the hive which had the queen. 2. *Uniting Skeps to Frame-hive.*—Transfer such combs from the skeps as contain brood to frames, turn the bees among them, and when settled down place the frames of comb alternately with those of the other hive—previously picking out the queen which you value least.
- D.—*Disinfecting Hives and room which have had foul-broody bees in them.*—Thoroughly wash the hives inside

- and out with a strong solution of carbolic acid. The room, if of boards or brick, should be lime-whited, adding half a pint of carbolic acid to each pail-ful of lime-white. If this is not practicable spray the walls and floor all over with solution of carbolic acid.
- E. M. C.—*Feeders.*—The caps of feeders are usually made of tin. The stages may be of tin or zinc as preferred. Two holes will be sufficient for stimulation.
- NIL DESPERANDUM.—*Hives, Position, &c.*—1. We do not recommend you to place your hives in the stable-loft, as you propose, with a northern aspect, and sheltered by yew-trees. Bees would not prosper in such a situation. A south or south-easterly aspect, and hives on single stands, are best. For such, according to your sketch, there is plenty of room on the lawn, running in a westerly direction 200 yards, without causing annoyance to any one, if rightly placed; at least, so we are inclined to think, not having seen the site. 2. As regards the kind of hive, the simplest are the best, only be careful to use the standard frame. For a garden, a plain hive, containing twelve frames with roof and stand, are all you require, and such, a really sound article, may be obtained for about 15s. A much cheaper hive would answer for a loft, since neither roof nor stand would be required. If you utilise the loft, place your hives on the south side, and cut a separate entrance for each through the wall, so as to exclude the bees from the interior of the loft. Thus, when manipulating, the bees taking flight might be allowed to escape through the open window. No annoyance could arise to neighbours except from the occasional settling of a swarm in an adjoining garden. We cannot undertake to recommend any particular hive further than stated above, but refer you to our advertising columns where you will find plenty of choice of good, plain, inexpensive hives advertised. As a beginner, avoid all complicated ones.
- BLACK BEE.—1. We are not able to say whether section or extracted honey will be in most demand during the coming season. But we would suggest that you should work for both kinds. There is less labour in getting section honey; but a greater quantity may be obtained by extracting. (See replies to Selected Query in this number.) 2. From the numerous testimonies which we possess of the superiority of hybrid bees in honey-gathering, and as your object in keeping bees is the acquisition of honey, we do not advise that you should make the change you suggest.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

[No. 195. VOL. XIV.]

MARCH 18, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

CHOOSING COMMITTEES.

From the earliest times of the world's history mankind has been striving to attain the ideal form of government. The rule of the one, the few, and the many, have alike met with varied success and failure, and the conclusion of the whole matter seems to be that the best form of government is that exercised by a despot and—an angel. There is no difficulty in finding men endowed with the former characteristic. All of us, or at least nearly all of us, love power, though we may show it in different ways; but the angelic characteristic is an unknown quantity, and as a result we are obliged to resort to the government by the few or the many. As it would be nearly impossible to manage any business by having to refer every petty detail to the consideration and vote of every individual, the system of representation has been followed, by which the general body depute their power to certain of their number; and so long as the latter keep touch with their supporters, and carry out their wishes, so long do they remain in office. In our Association the business is managed by certain officers and a committee of fifteen members, all of whom retire every year, but are eligible for re-election.

At the general meeting various plans were proposed to ensure the election of the best possible committee, but no definite alteration of the existing plan of election was agreed upon. We venture to think that improvement is wanted and could be effected. At the present time the general body of electors know little or nothing about many of the candidates, and many vote for the old members so long as they have no reason of complaint against the general policy of the committee in the past. It would be invidious to influence the electors by advising them to choose certain candidates, but we think it would be only fair to publish the attendances of the members of the committee during the past year some time before the election, and that only those of the old members who had regularly attended the meetings should be eligible for re-election, unless they had some valid excuse to offer. Again, it might possibly happen that some of the new candidates might not be acceptable to some of the members. For instance, some members might know that a certain candidate had sold foreign honey as pure English honey. Unless those members took the trouble of writing numerous 'private and confidential' letters to

the other members, this candidate might get elected through other members not knowing what he had done. It would be advisable that there should be the power of black-balling such a one, just as is the case in club elections, and as this power would not be exercised unless there were sufficient reasons, it would be a safeguard against the election of any undesirable member.

We can praise as much as we like, but we have to be very careful how we blame any one, even though righteously, and the power of black-balling would prevent any unsuitable candidate from being proposed as a member of the committee.

Mr. Stewart's proposition to elect ten members, and then let these ten nominate another ten, out of whom five should be elected, would be taking away, to a certain extent, the popular representation.

All representative bodies are naturally jealous of their committee having too much despotic power. It might happen that the first unsuccessful candidate might not be nominated by the ten, though there was nothing against his moral (bee) character, and if such a case were to happen, it should be open to any one to propose any or all of the unsuccessful candidates.

LECTURES ON APICULTURE.

The following course of lectures will be delivered by Mr. Frank Cheshire at Jermyn Street Museum, Jermyn Street:—

March 17—	The Bee at Home	..	Economy.
" 18—	" Abroad	..	Fertilisation.
" 19—	" a Structure	..	Anatomy and Physiology.
" 24—	" at Work	..	Comb-building, Honey and Wax.
" 25—	" under Management	..	Swarming, Queen-raising, &c.
" 26—	" a Source of Profit	..	Honey raising, &c., &c.

USEFUL HINTS.

Since our last we have no better weather report on which to congratulate our readers. Snow-storms—trains and passengers entombed for two or three days—hitter, black frost, and biting winds, ice four inches thick in Kensington Gardens, &c. Such are the reports from all quarters, and our poor bees are at present close prisoners. An old bachelor friend suggests that the 'clerk-of-the-weather' cannot be alone guilty of such atrocities, and very much suspects his wife of the greater part of the mischief! But this view we con-

sider most ungallant, to say the least. Although we have experienced a few bright, sunny days, there has been no day warm enough to encourage a thorough cleansing flight, and we fear to many a colony such a day will come too late. 'Hope on, hope ever,' must be our motto.

MANIPULATION.—When the weather changes examine hives—in the evening, preferably, to avoid inciting to robbing. Half-a-dozen may be well examined in an hour. Where foul with dysentery remove the cluster, on its four or five frames without separation, to a clean, dry hive, which should be in readiness. Supply clean floor-boards, and cover up warmly. If short of food, give warm syrup, and feed at evening. Disinfect foul hives and frames—spraying, syringing, scrubbing with strong carbolic solution—afterwards thoroughly drying them—by fire if necessary—when they will be ready, by the next evening, to receive transfers from other hives. Our own plan is to give every colony about this time a clean, dry, disinfected hive.

While manipulating, separate the brood-nest as little as possible. Be anxious only to ascertain (a), that the queen is breeding; (b), that the colony has sufficient food to carry it over the next two or three weeks; (c), that there is no disease, or fouling of the hive.

FRAME COVERINGS.—Supply enamel-cloth covers, enamel side downwards, upon the frames: upon those, quilts of felt or carpet, and, finally, a crown-board, slightly weighted, to hold all tight together. Flat straw crown-boards are best.

POLLEN.—Within a few hundred yards of our apiary is an old-fashioned windmill, on visiting which, on a bright day of March, we noticed numerous of our bees, with busy hum, collecting and piling on their legs the farina, or meal-dust, lodged upon the weather-boarding of the mill. The miller informed us that every year, during the early spring, he had plenty of these visitors. This fact indicates the necessity of a supply of artificial pollen—wheat, rye, or pea meal, nearer home. Therefore, in a sheltered nook in our apiary, where Sol's rays have ready access, we place sundry hives with frames of comb which have been previously dredged with flour. On a bright day a frame of honey unsealed, placed in the vicinity, soon announces the fact to all colonies. Near by are shallow troughs of water, which are constantly replenished, and a handful of salt is sprinkled over the surface, which is covered by thin perforated boards to prevent drowning. Here the bees regale themselves, and carry home hence, in large quantities, the pabulum for their offspring. In a late cold spring, like the present, when little or no pollen is to be obtained from the fields and gardens, such supplies are of great value in encouraging breeding and bringing up colonies to full profit point by the time the honey flow sets in. Some argue that a sufficient supply of last year's pollen is always present in the hives, but experience teaches that little use is made of this, since, dry or mouldy, it is usually cast out in hardened pellets from the hives.

SPRING DWINDLING AND ABSCONDING COLONIES often occur simultaneously. There may be, therefore, some connexion between the two. The causes usually assigned for colonies absconding in the early spring are (a), want of food; (b), some dislike taken to the hive; (c), a failing, injured, or unfertile queen. To these we add a reduced population, whether arising from spring dwindling, dysentery, or other cause. Instinctively the bees seem to become aware that the small handful of population remaining, however well provisioned, are powerless to produce sufficient progeny for building up a strong and successful colony. Hence they desert in a body on some fine day, and, clustering as a swarm, if not secured, wandering from hough to hough, finally enter a neighbouring hive, where they are slaughtered without mercy. We have often returned the vagrants to

their deserted hive, but never knew them to remain, even when good and wholesome honey was there in abundance. It is probable that a comb of brood might retain them, but this we have not tried. Mr. A. I. Root assigns another cause. After stating that, at times, a whole apiary will become so crazed with the idea of absconding as to be utterly demoralised, he relates a story of a neighbour who made a hobby of small hives—less than half the usual size—who, one fine April day (we have a fancy that it must have been on the first of the month) 'had as many as forty colonies leave their hives and cluster together in all sorts of promiscuous combinations.' He does not attribute this dire misfortune entirely to the small hives, but, from the advice he gives in the succeeding paragraph, and which we heartily endorse, to a variety of causes: (1.) Do not divide, or commence swarming your bees until they are abundantly strong. (2.) Put them into winter quarters with an abundance of sealed honey in tough old combs. (3.) Keep them in hives with walls thick and warm of some porous material, such as chaff or straw, with a good thickness of the same above, and you will have little cause to complain of bees absconding in the spring. The queen, we believe, is usually the motive cause of absconding. After returning the wanderers, we have repeatedly seen her desert the combs and lead out the swarm anew. We have caged her, but on being released she has again deserted. In fact the colony has seemed utterly disheartened and demoralised, in which case the only thing to be done is to unite to another. As a rule the only cure for spring dwindling—as for dysentery—is warm and bright weather. *Di sint faciles.*

DOUBLING.—We have often been asked, even at this early period, if it was not time to begin doubling. Such querists we beg to refer to Mr. Cowan's *Guide*, p. 155, where, under the heading 'Summer,' he directs us to double those colonies intended for extracting, and to extract at suitable intervals. We can only remark, *very feelingly*, that summer has not yet come. Mr. Cowan's instructions for working on the doubling system are given concisely, but very clearly, in his book, p. 55, and cannot well be improved. Our belief is that section-honey will pay as well as extracted, if obtained in *proper form* and on a good system. Except at our best shows, and perhaps in Mr. Neighbour's window in Regent Street, we never see a *first-class* section. This we know, that where we are asked for one pound of extracted honey, we find ready sale for half a dozen 1-lb. sections at double the price.

ROBBING.—When the cold weather departs and the bees begin to fly in full force, a watchful eye must be kept on weak colonies and their stronger neighbours, since it is just at such a time that robbing begins, especially when forage is scarce. A remedy which used to be in vogue we have not seen recommended, viz., to stop up the entrance with dry earth, which prevents the entry of the raiders for the time, and is soon cleared away by the imprisoned bees. It seems to be worth a trial. Rubbing an onion over the alighting-board, and continual application of carbolic acid are also considered remedies.

COMBS.—When colonies have unfortunately perished, let the combs be thoroughly cleansed of dead bees, sprayed with carbolic acid solution, and stored in a dry room after being exposed to the air and dried. Look after them occasionally to see that moth does not attack them until wanted for swarms, doubling, &c. Mr. Root speaks of having put into hives, when honey was coming in, combs that were full of dead bees, filthy from the effects of dysentery, and mouldy besides, and has found them in the afternoon of the same day clean, bright, and sweet, holes patched, and partly filled with eggs, honey, and pollen.

After the very interesting paper by 'Nucleus,' in

our last issue, under the title of 'Things-in-general,' &c., we forego our remarks under the same heading for this time.

CORRIGENDA IN LAST 'HINTS.'—Page 90, col. 1, line 20 from bottom, read:—'Go to each colony and look it over, clipping the queen's wing, and equalising stores, so that each may have enough to carry it on at least two weeks without starvation.' Also at page 91, col. 1, line 36 from bottom, read:—'The climate he terms "sickly and hot," but speaks of it as splendid for honey, and mentions that there are wild bees everywhere.' &c. &c.

ASSOCIATIONS.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION ANNUAL REPORT.

In presenting their second Annual Report your Committee feel that they may congratulate you on the success that has attended efforts put forward during the year in extending the knowledge of bee-culture. They regret, however, that more bee-keepers have not joined their ranks, feeling that strength means success; and as their means are small they cannot yet attempt such things as they would like, but hope in the future to bring bee-keeping more prominently before the agricultural labourers, so that when they get their three acres and a cow they may be induced to get another sort of a cow that will produce honey. The bee-tent of the society has been sent during the year to Banbridge and Castlerock, and there is every reason to believe that some who at these places saw the practical working of hives, will be induced to commence bee-keeping and become members of the society. The annual show at Belfast was a great success. There was a larger quantity and finer assortment of bees, honey, and bee-keeping appliances exhibited than has ever yet been placed before the public of the North of Ireland. The Treasurer's balance-sheet shows, we are glad to say, a balance on the creditor's side of 117.7s., which we consider excellent. The committee wish to offer their best thanks to the gentlemen who so kindly gave medals and prizes to be competed for at the show, and also the press for the able way in which the claims and the working of the society were set before the public.

Fifty members of the N.E.I.B.K.A. who sent in returns of bees and honey have, in 1885,

284	bar-framed hives of common bees
58	" " hybrid
12	" " Ligurian
70	other hives, straw skeps, &c., common
1	" " " hybrid

425

and the total quantity of honey taken from the above was 8300 lbs. The largest taken from any one hive was 121 lbs., and the next three 118 lbs., 104 lbs., 98 lbs., respectively.

At the general meeting the following resolutions were passed, Mr. Hamilton McCleery having tendered his resignation as hon. sec., Mr. Morris moved, and Mr. McHenry seconded—'That the best thanks of the society be given to Mr. McCleery for his exertions during the past two years on behalf of the Association, that much of the success it has obtained is due to him, and that they are sorry he could not see his way clear to continue to act for them.'

Proposed by Mr. McCleery and seconded by Mr. Cunningham—'That Messrs. A. Crawford and P. McHenry be appointed hon. secs. for the coming year.'

Mr. McHenry, in forwarding the above report, writes:—'I am pleased to inform you the knowledge of humane bee-keeping is being largely diffused, and the N.E.I.B.K.A. hope to extend this knowledge much more, having had a considerable addition to their membership since report was issued, and hope the year 1886 will be a successful one for the fraternity in general. I am much pleased with the weekly Journal.'

BELFAST NATURALISTS' FIELD CLUB.

The fourth meeting of the session was held in the Museum, College Square, on Tuesday evening, February 16th, the president (Rev. Canon Grainger, D.D., M.R.I.A.) in the chair, when two communications were brought forward. The first was by the Rev. John Andrews, on 'The British Bees.' Mr. Andrews's paper was well illustrated by a series of specimens beautifully mounted on cards, and of parts of the various species set up for microscopic examination.

The second paper was read by the Rev. H. W. Lett, M.A., T.C.D., on 'The Races of the Honey Bee.' The reader stated that no other insect has so much attracted in all ages the attention of naturalists in temperate regions as the honey bee—*Apis mellifica*—and there is none which has such an extensive literature of its own. People that know nothing about bees beyond the shape of a straw skep or hive, the taste of their honey, and the effect of their stings, would be greatly surprised at first reading any of the numerous articles that appear from time to time in the journals and periodicals devoted to bee-culture on the improvement of the race of honey gatherers, for just as the English breed of shorthorns has been developed by the care bestowed on the selection of the best stock from which to rear calves, so have bee-keepers, especially the Americans, been carefully selecting the parents of the future honey bee. The necessary qualities, according to authorities in bee-culture, are—1st, hardiness—able to bear bad winter weather without diminishing too much; 2nd, good breeders, the queen laying early and abundantly; 3rd, being gentle and quiet, not attacking without provocation, and allowing themselves to be examined when the combs and bar-frames are lifted out of the hives for that purpose; 4th, good honey gatherers, working from sunrise to sunset; 5th, strong and active in flying long distances for honey and vigorous in defending their homes; and 6th, long-tongued, thereby able to get honey from many flowers which some bees cannot use. To procure bees with these qualifications has been for many years the study of bee-keepers in Europe and America, and it is to give a short sketch of the races or varieties of the honey bee from which they have been and are selecting the queens and drones that these notes are compiled. The reader then proceeded to give the properties and habits of nine races or varieties of the honey bee, principally European, or found in the countries bordering on the Mediterranean Sea:—1st, the black or brown bee, which is our well-known ordinary hive or honey bee. 2nd, the Italian Alp bee (*Apis ligustica*), sometimes called the Ligurian bee, indigenous to the mountain districts that lie to the north of Italy and south of Switzerland. 3rd, Cyprian bees, which, as their name indicates, are natives of the island of Cyprus and parts of Turkey in Asia. 4th, Syrian bees, found on that portion of the mainland of Asia, that is situated north of Mount Carmel. 5th, the Holy Land bees, or, as the natives call them, Holy bees, found in Palestine, south of Mount Carmel. 6th, the Tunisian bees, inhabiting Tunis, on the north of Africa. 7th, the Carniolan bees, natives of Carniola, a province in South Illyria, in Austria. 8th, Hungarian bees, a race peculiar to Hungary. 9th, Egyptian bees (*Apis fasciata*), which abound all along the Valley of the Nile, and which, without exception, are the most ferocious bees known outside of India. Both papers were listened to with great attention, and elicited an interesting discussion.

BEE-KEEPING IN INDIA.—Bees are pretty generally domesticated in the middle and higher hills, but are rarely seen in the lower valleys. If a little care and management was bestowed on them, they would be very plentiful, and might be a source of considerable profit. The domesticated bee in the village of Gurwhat, and the wild one in the forests, is one and the same insect, and swarms often come from the

forest into the houses and leave the houses for the forest. These that may be called domesticated are kept in the walls of the houses or outbuildings; but no trouble is taken with them, the young swarms even being left to go where they like, and the only time a Puharie troubles himself about his bees or their hives is when he takes the honey. In building a house or any substantial outbuilding, small oblong apertures are left at intervals in the walls, generally of the lower storey, about twelve inches by nine, and an oblong piece of board with a small triangular hole in the centre—secured in the wall while building—closes the aperture outwardly; and a similar board, without any hole and made so as to be removed at pleasure, serves a similar purpose inside. Six or eight of such hives is the usual number made in a moderate-sized house. Sometimes a portion of a hollow trunk of a small tree—if a piece can be found adapted to the purpose—is made into a hive by closing each end with similar pieces of board, and building it into the wall. All is now left to chance for swarms of bees to take up their abode in the hives. They may all get occupied, or only two or three, or perhaps more. To take the honey, the board which closes the hive inside is taken off and a piece of ignited cowdung is held inside, and soon fills it with smoke. The bees hurry out, and the combs are separated from the roof of the hive with a knife, and drop into a dish held beneath to receive them, scarcely a single bee being killed. The board is then put into its place, and as soon as the hive is free from smoke, the bees, which have been during the time clustering to the wall outside re-enter it. The hives are taken twice a-year, in May or June, and September or October, but are sometimes opened to take out a small quantity in the interval. The honey taken in spring is very dark-coloured, rank, and of a disagreeable flavour, while that taken in autumn is white and of excellent quality. In the forest the bees make their hives in hollow trees and sometimes in the cleft of a rock, and a great many of these wild bees are found and taken by the villagers.—*Summer Ramble in the Himalayas*. Edited by Mountaineer. (Hurst & Blackett.)

A CURIOUS BEEHIVE.—An unusual discovery has just been made on the premises of Mr. Richard Skinner, clothier, Market Place, Wisbech, which may interest our readers. Mr. Skinner is having some alterations made at the back of his house, and on Tuesday, Jan. 26th, as the workmen were taking out the window of a bedroom they found that a swarm of bees had taken possession of the panelling, beneath which they had accumulated about two stones weight of honey. Portions of the comb were at once removed, and Mr. A. Bothamley, a local expert, kindly undertook to remove the swarm from their singular place of settlement. In his opinion the honey was all deposited during last year, and his belief is that the bees consist of a swarm which got lost, and took up their abode in their strange beehive upon accidentally finding ingress to the panelling. Mr. Bothamley states that it may interest bee-keepers to know that thus early in the season, and after very cold weather, the queen of the stock in question had begun to lay eggs, and that there was a large patch of brood from which the young bees would have very shortly escaped—a warning to bee-keepers to keep their bees warm. The whole of the honey taken was in a purely liquid state, not a particle of it being set.

WASPS.—Last spring I offered my little friends in the village a penny for every queen-wasp they would bring me, and fourteen of them brought me 362 queen-wasps. I am sure my honey harvest was better on that account, for the bees were not bothered as they had been the summer before. So the youngsters had each a 1-lb. section of honey as well, and are looking forward to catching queens again when the time comes.—**BEE-SWING.**

TO FASTEN STARTERS IN SECTIONS WHICH HAVE NO GROOVE.—Split in half the top of an old section for a guide. Warm the edge of the strip of foundation at the fire, and place it on the new section, place the guide upon it the warmed edge projecting about the eighth of an inch beyond the middle, and beyond the guide, then with the handle of a teaspoon dipped in cold water, press the wax well into the wood. Turn the guide up on edge and straighten the starter up against it. I never dip the corners of new sections in hot water, or glue them up—the bees fix them up better than I can do.—**BEE-SWING.**

Selected Query.

[183.]—*Is a hive with two storeys, having together twenty frames, or a one-storey hive having the same number of frames, best for the purpose of obtaining extracted honey? Which interferes least with the ordinary working of the bees?*

A two-storey hive having twenty frames is unquestionably better, according to our experience, for producing extracted honey than a long hive having the same number of frames. Bees naturally carry their stores much more readily upwards above the brood-nest, and store only at the sides when they do not find room above. The frames being in two storeys, this plan also interferes least with the ordinary working of the bees. No queen excluder being used, the queen has free scope to lay to the utmost of her ability in either of the storeys, and if these two are not sufficient more can be added, but always above. We have always got the best results when working on this plan.—**EDITOR.**

I am strongly inclined to think the plan of placing the frames in two storeys preferable to that of putting them in one long hive, the doubled hive preserves a more equal temperature, presents greater facility for manipulating, and interferes less with the working of the bees.—**J. GARRATT.**

As far as my experience goes, the hive with two storeys is far preferable to a hive containing twenty frames in one long storey. With the storified hive the zinc need not cover the entire length or width of frames, thus tending to induce the bees to travel up the sides of the hive rather than through the brood-nest, the square zinc acting as a barrier to the queen. Consequently the storified hive would interfere least with the ordinary working of the bees, and, as a sequence, the honey in a storified hive ripens much quicker than in a single long-storey hive.—**W. WOODLEY.**

I prefer the doubling or storifying plan. For this purpose hives containing ten frames each are large enough. This plan is most in accordance with the natural instinct of the bee, viz., that of storing its honey above the brood.—**G. RAYNOR.**

Long hives of twenty or less frames as hitherto used require too much manipulation of frames, do not economise the heat of the cluster, and are limited in capacity. The storifying principle exceeds any other for the production of extracted honey: a whole set of ten (more or less) frames can be shifted at one operation; such complete storey can be given, and will be fully occupied at one time, because of the heat being economised to the greatest advantage in this direction; and, moreover, because of the sectional nature of the storifying hives, any amount of space may be given by adding hive above hive.—**S. STIMMINS.**

I believe a two-storeyed hive interferes least with the ordinary working of the bees. But more depends on the bees and their master at all times than any particular form of hive.—**AMATEUR EXPERT.**

I began with the Pettigrew hives, made by himself, and which were especially adapted for two storeys, but adopted the hive as recommended by me in *B. B. J.*, 1883, thirty inches long, holding nineteen frames and a dummy, with extra entrance on the east side for nuclei, and doubling for utility in obtaining extracted honey, and which interferes least with the ordinary working of the bees.—**R. THORPE.**

A hive of two or more storeys is much the best for obtaining extracted honey. After stimulating, spreading the brood until all the frames are well filled (which I explained in *Selected Query* 22, and which was more fully explained in 'Useful Hints' of March 4), and the honey season has set in, I would put on a zinc queen-excluder, and place a second storey upon it. I should myself prefer a shallower hive than one with Standard frames for the purpose of 'storifying' or 'tiering up'—a hive not more than six inches deep, similar to the 'Carr Stewarton' supers. As soon as the second shallow hive is nearly filled and partly sealed over, it should be raised and a similar one placed under it, and a third can be added in the same manner. In this way the extracting may be done at the end of the season after the busy time. This plan does not interfere with the brood or the bees in stock hives, as in no case would I extract from combs containing brood.—**JOHN M. HOOKER.**

JOTTINGS BY AMATEUR EXPERT.

'Mel sapit omnia.'

Comb Foundation.—Bee-keepers are democrats—I don't mean in politics—but nothing, however old or supported by 'constituted' authority, is sacred to them, they attack it and pull it down or uproot it with scant ceremony. The praises of foundation have been sung by all, but some would have us believe it had become a delusion and a snare. I advise, Don't be hasty, read Mr. Simmins' reasons carefully; his method is peculiarly his own, and in his able hands is successful; but should any be tempted to copy him in some small matter, and meet with failure, do not blame Mr. Simmins. Foundation is a case in point; his reasons for not using it *at the time he names* are weighty, but 'Nucleus' (168) would go off into another extreme by discarding it under all circumstances; and with the Editor I say it is a decided gain, and not a dead loss of four shillings to fit up a hive with foundation. In June, 1884, we had seven sheets built out, and nearly every cell laid in, even to the top row but one, in thirty-two hours. And what about excessive drone-comb, and the 'good old days' of drone-traps, are we to go back to them? But as to its use in sections, I quite agree with Mr. Sharp (80), and I can assure Mr. Simmins (154) that the distinction between sections in which full sheets or simply pointed starters have been used is not imaginary, neither amongst 'judges' nor customers.

Spring Stimulating.—Now, Mr. Seager, stand out and take your turn. I noted what you wrote at the time, and nodded assent; I knew what you practised, and your method of stimulating by brood as well as food, but you see how 'Rector' (121) and 'Nucleus' (168) have taken it. Well, now, like a doctor who recently advised a friend of mine to take *no* intoxicants (knowing he would take a *little*), I preach to some people, 'let 'em alone,' as I did last year to one who for five years never got a section from his bees, and begged of me to sanction his dividing his only strong stock, but he resisted the temptation, got a 40-lb. super, and—experience. And so with stimulating: up to the present I have done nothing to my bees but let 'em alone; but let the weather break, and the nice, clean, sweet combs that I have in reserve will be inserted where necessary (having been slightly warmed previously), and the days of let-'em-alone will be ended for this season. Let me say 'Hear, hear,' to Mr. Griffin (171), and keep an even temper if Mr. Seager don't let 'em alone.

Standard Sections.—An attempt was made at the last Quarterly Meeting of County Representatives at the B.B.K.A. to induce the latter to settle the question of standard sections postponed from the previous annual meeting, but the answer was that the question was settling itself, as could clearly be seen by what was offered to the honey companies, and $4\frac{1}{2} \times 4\frac{1}{2}$ for 1-lb., and $6\frac{1}{2} \times 5\frac{1}{2}$ for 2-lb. would soon be considered the standard sizes without the especial sanction of the B.B.K.A. But if 'Nucleus' can induce his county representative to introduce the question at the next quarterly meeting, 'A. E.' will be most happy to support him in an endeavour to get the B.B.K.A. to schedule the two sizes given above as 'standard.'

Open Court in Hives.—Mr. Ward (170) is smashing into that in a style that I greatly admire. I believe many bees worry themselves to death in these chambers, and I know many stocks have been suffocated as Mr. Ward asserts, and, what is more remarkable, if the bees are packed in front instead of back, they generally begin to breed on the front comb. Who possesses the wisdom in these matters, the bees or their master?

'South Cornwall' has treated me in true 'cousinly' fashion. If I said he struck out I did not say any of those things I enumerated had received blows, not even for the purpose of effective grouping; and will he please note our 'cousin' with the butter *took*, she did not *send*?

Was it Caesar who said something about 'serving yourself if you would be served?' The new rules are in effect that honey must be staged in a uniform way, bottles must be corked and capsuled, and sections must be glazed and the glass fastened with strips of white paper, 'cigar-box' fashion, not covering the whole of the wood, as now practised by some, and only to overlap the glass quarter of an inch;—more education for the cottagers. But I want to 'hark' back to his unripe honey; we seem to forget that honey will absorb not only various odours, but water as well in large quantities. It wants storing in a dry place, and if warm as well so much the better for you as well as the honey.

'Welsh Novice' must change his *nom de plume*, or his present one will soon become a misnomer. He has the make of a good bee-keeper, having a large store of what is the chief factor for beginners—pluck. If you can stand the stings you can put up with all the other ills bee-keeping is heir too, no profits included; and his own tale of woes so modestly told shows he has not had a bad breaking in. Will he try to remember the greater portion of these innumerable stings were the result of his being a 'novice,' and as he gains in practice he will lose in stings; and never forget to ask plenty of questions in our *Journal*, as in getting an answer for himself he is doing service perhaps for scores of others?

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements.)

In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

[184.] The value of honey imported into the United Kingdom during the month of February, 1886, amounted to 451l.—[From the Statistical Office Returns sent to E. H. BELLAIRS, Wingfield, Christchurch.]

SPRING STIMULATION.

[185.] I do not agree with 'Rector,' page 73, Vol. XIV., where he considers the 'let-'em-alone' policy to be the best for bee-keepers to pursue: but, nevertheless, there is truth in his statement that stocks heavily stored in autumn (generally) come out best in spring.

I have myself stated in this *Journal* that no amount of after care will make up for neglect in the autumn preparation of stocks. It is at that time when *true Spring stimulation must be provided for*, if we wish to make the most of our bees.

They should not only be judiciously stored, but it is imperative that the combs be old and tough, and also that the top of the hive should be arranged with warm material, equal to three inches of chaff; it is there where the heat escapes, and the sides will do just as well if one-eighth inch instead of three inches thick. There is nothing like tough old combs for keeping the bees warm, and a single wall is very desirable in winter, because the sun penetrates more readily, and warms up every seam of bees, enabling them during the coldest spell to repeatedly bring up the distant stores to the immediate vicinity of the cluster.

Now, while it is an evidence of bad management, when

at the end of the season a hive has its stock-combs stored sufficiently to carry it through the spring (unless in the case of very late districts), it is an undoubted fact that such colony needs but little more care before the next season; but, nevertheless, it is just these grand stocks which dare not be left quite alone until time for supering again, as at the last moment it but too frequently happens, because of their very prosperity, they either die outright, or else, for want of the needed assistance to tide them over the last bare time, they become so reduced as to destroy the whole of their brood, and then of course the season is lost.

A medium course must therefore be pursued; the 'let-'em-alone' policy does not do at all where the harvest is over by the latter part of July, as few colonies from that time onwards could possibly make their stores hold out, even if bad management had allowed them to fill most of the stock-combs; and, moreover, unless breeding had been carried on after the honey flow ceased, they stand a fair chance of dying out before the spring breeding will enable them to renew the population with young bees.

In my own district, where honey is obtained in greater or less quantity until after the middle of August, the bees continue to breed well into September; and if heavily stored before the end of that month, they require little more attention until late in spring, and I find the best stocks generally want the greater care towards the last.

I am not myself particular about stimulating and brood-rearing in autumn, because the condition of the locality provides for that. I simply close down at once by giving in one or two doses all the bees require; but where the harvest is of short duration, I strongly urge that at the middle of August (or beginning of that month if the queen has ceased to deposit eggs) every colony should have twenty pounds of syrup given as fast as they will take it; and then keep dry-sugar feeders going until end of September. Meanwhile the brood requirements will simply use up the unsealed syrup which is not desirable as winter food.—S. SIMMINS.

(To be continued.)

FOUNDATION FOR SUPERS.

[186.] In criticising my letter on the above, Mr. Simmins has omitted to make any mention of the most important point of my argument, viz., the superior quality of natural built combs compared with those raised from foundation; and as silence gives consent, I take it for granted that upon that question Mr. Simmins and myself are agreed.

But according to your correspondent's dictum we are to go in for quantity regardless of quality. We are to fill our sections with foundation consisting of we know not what, and which may or may not be worked out by the bees, and when such sections are completed, our customers are to be palmed off with the same under the designation of pure British honey. If any complaints are made, or any questions asked, respecting the hard substance found in the centre of every comb raised from foundation, we are to be sure and not let our customers know anything about the use of foundation. Such proceeding may suit the inclinations of some, but I would rather be exempt. I prefer supplying my customer with an article which I can guarantee absolutely pure with a certainty that such will give entire satisfaction, and thus extend my reputation as a vendor of a genuine article.—an article which I could stand and see cut up, or even analysed, without a blush or any unpleasant feeling being raised. But Mr. Simmins wants to know how I am going to supply the increased demand which I say will be sure to follow, if I cease to use foundation, when by pursuing such a course I shall, he says, sacrifice at least twenty pounds of honey per hive. Mr. Simmins is evidently under the impression that I am going to work my apiary entirely for comb honey; such, however, is not

the case. If we are favoured with a good season, I hope to raise at least a ton of honey, but of comb honey I shall not attempt to raise more than 300 pounds, which amount I hope, with careful management, to obtain from fruit and other early blossoms. And by the time the honey glut comes, which as a rule does not commence until after the 15th of June, I shall endeavour to get every hive cleared of sections, and each stock furnished with abundance of storeroom wherein to store the hundreds of pounds of honey, which Mr. Simmins anticipates will be lost; and under such circumstances, I fail to see how I am going to sacrifice twenty pounds of honey per hive through not using foundation. But even if such a loss were incurred, there would be the cost of foundation to deduct from the product of the hive which, with the aid of such, had yielded the extra twenty pounds of honey. So that the intrinsic difference in the result of the two systems would not, after all, be so very great, especially if we take into account the many sheets of foundation which the bees make practically no use of whatever. I always try to under-do rather than over-do the quantity of comb honey I am likely to require. Raising sections on 'spec' is attended with too much risk, but the increased demand, which I still maintain will be brought about through selling none but natural built combs, will induce me to enlarge my apiary so as to get more sections filled during the month of May and early part of June, or I shall buy more largely of bee-keepers who have practically no market for their produce. But those who have supplied me in the past, and wish to avail themselves of my assistance in the future, must please bear in mind that I resolutely refuse to deal in sections that have been raised from foundation anything beyond starters.

Mr. Simmins says, that 'after all it is not the public which, as a rule, can judge between honeycomb built upon light foundation and that without it.' My experience is that they not only can, but in nine cases out of ten do, distinguish the difference. Let only one who doubts this supply a customer with a given number of sections of honey-comb, half of which have been raised from foundation, the remainder without it, and mind if you don't soon hear that some of the combs are considerably better than others; or, sit down to tea with a number of friends where honey of both kinds is supplied, and you will see that those who partake of that raised from foundation will leave the mid-rim on the side of the plate, while those who partake of the genuine thing, will make a clean job of it, and will make such remarks on the delicacy of the comb as will be more than gratifying to the producer. Having tried the above experiments, you will no longer labour under the false impression that the public are just such fools as you would like them to be.

No one is more anxious for the development of the honey trade than I am, and if I have made any statement calculated to injure such, I am certainly very sorry for my indiscretion. Although, at the same time, I contend that a trade which will tremble and become menaced at the mere mention of a genuine article is not worthy of the dignified name it bears. It has always been and is still my firm belief, that the only way to permanently develop the honey trade, as well as any other trade, is to sell nothing but a genuine article. And in following such a course I fear none of the keen competition Mr. Simmins speaks of.—A. SHARP, *The Apiary, Houghton*.

THE WEATHER AND THE HIVES.

[187.] More ungenial weather for bee-keepers in the North Midlands can scarcely be conceived. Frosty weather prevailed uninterruptedly throughout February, and thus early in the season those apiarists whose hives were well stored with honey had no great cause to complain—desiring only a few warm days to allow their bees to take their much-coveted flight after a long en-

golden rest; but with the arrival of March, and the golden buds of winter aconite appearing, weather, suitable for the denizens of the hives, was naturally looked for and expected, and instead of a promise of spring we have had the grim reality of the most inclement period of the winter season. Heavy falls of snow, giving an average of four inches on the ground, and intense frost, 14° on the 5th, and 20° on the 7th, and 28° on grass; but it is not of this that as a bee-keeper I bewail the weather.

In well-secured hives frost is not of much consequence, my trouble began with the appearing of bright sunshine which, striking on the hives, tempted the bees to leave their homes; then, away from customary shelter, the cold air chilled them, and they alighted in numbers on the frozen snow never, alas! to rise again. A few minutes seemed sufficient to paralyse them, but while in this state they met another enemy more prompt in its destructive power, their always watchful and alert hunter of hives, Titmouse major, pounced down upon them, and finding so much food, so savoury and welcome in these hard times, the word was passed, numbers of other tom-tits assembled to share in the good things of the feast, and when the living and dead were cleared from the snow these marauders stationed themselves at the entrances to the hives and snapped up every bee that appeared. Of course this could not be tolerated, and in two days no less than fifteen were trapped. The relation of an experience altogether exceptional may be of use and interest to some of your readers, and induce them to watch their hives.

I have stopped each passage of egress with wire gauze, and when the sun shines I hang thick shading in front, as the snow still covers the ground, and the hives would be depopulated if the bees were permitted to leave them.—WM. INGRAM, *Belvoir Castle, March 10th, 1886.*

P.S.—14th, frost still continues. The sum of frost (that is below 32°) up to this date amounts to 115.

SPRING STIMULATION.

[188.] May I inform the readers of your excellent *Journal* that our good friend, the Rector of Buckland Filleigh, Devon, is not only 'sound' in his opinions as to spring stimulation, but in every point he is most wonderfully practical, and is a thorough bee-master on the most natural principle. I hope, therefore, that the Rector will not only narrate his anecdotes, which certainly are most amusing and interesting, but will frequently give us his valuable help by telling us how to manage our bees and apiary.

The apiary at Buckland Filleigh Rectory is known far and wide and is visited during the summer and autumn by a large number of persons, rich and poor, anxious to see and hear some new thing about apiculture. The kind and warm-hearted Rector gives to each and all a hearty welcome and spares no pains in making their visit a happy and an instructive one. He is also a first-class lecturer on bee-keeping, and would do an immense deal of good to the cause in this way.—OLD DRONE, *March 12th, 1886.*

MOVING (?) BEES.

[189.] I have seen several remarks, Mr. Editor, lately in the *B. B. J.* anent moving bees. Let me tell your readers an incident that happened to me a year or two since, when engaged in a small undertaking of this kind. I had gone down alone from my upland rectory amidst the lonely wilds of north-west Devon to the T—station some ten or eleven miles away for parcels, late one beautiful summer's evening, and on my return was asked by a cottager to buy a 'butt' of bees. To save the trouble of sending for them so many miles the next day, I stripped off some brown paper from one of

the parcels, and with the aid of the man's pipe I soon drove the bees up into the skep sufficiently to enable me to wrap my carriage-rug round them, and popped them under the back seat of my four-wheeled dog-cart, and renewed my way at a brisk trot homewards, when, after I had gone three or four miles, I overtook an old man, who sang out, 'Will your honour give me a lift as far as St. Ebb's Cross?' I pulled up sharp, and said, 'Jump up behind, my friend;' and up he got. Well, he seemed rather a taciturn old fellow, and did not seem inclined to talk, though I tried him from pigs up to politics; so I let him be. We had gone about a couple of miles when I heard a very forcible ejaculation from my friend to this effect: 'Darn them knats, how they do stang a body.' To this I thought it wise to make no rejoinder, fearing the sharp jerk to the pole in pulling up might have disarranged the rug round the bees. After a while came a direct question, 'Do them a darned knats ever stang your honour?' With hardly-restrained laughter I muttered, 'Sometimes.' But ere I had scarcely finished the word came the soliloquy, 'I be blest if it baint a bee a crawling up my braches. Ye 'ant a got any baes, have ye, in the carriage?' I said in the broadest Devonshire, 'Ees, there's be a butt of 'em inside.' Before I could pull up he took a flying leap from the top of the dog-cart, and was soon making an extempore dressing-room, or rather undressing-room, by the edge of the moor, while his remarks on parsons in general were anything but complimentary to the cloth, and too strong for repetition. To bring my tale to an end, I left him seated on a hillock busily pulling out the stings from his legs nearly in a state of nature, all the while muttering curses on them 'drratted bee-keeping parsons,' who had 'a mile 'un sit on the top of a butt of baes,' and 'he'd a see if he'd ever a let his old missus go to church agin, no, not he.' Finding all apologies on my part entirely unsuccessful, I left him, musing to myself that if his 'old missus' only got it as hot as I did, she must be accustomed to rather a warmish climate. So you see, Mr. Editor, to use a convertible term, if I moved my bees, my bees certainly moved my fellow-traveller in more ways than one. I need not say it has been a standing joke in my parish ever since, and if I am seen picking up any old folks, they are sure to be asked the next day, 'What did the parron give ye to sat on?'—RECTOR, *Buckland Filleigh.*

BEES CHOOSING A NEW HOUSE.

[190.] I should like, with your permission, to offer a few remarks upon what to many is a most mysterious occurrence, viz., the fact that swarms, frequently on leaving their hives, or the spot chosen as a rendezvous, take up their quarters in an evidently previously selected place. Now, probably, few will deny that when the bees have decided to swarm—many hundreds, it may even be thousands—set off as scouts to find a suitable habitation. Well, a bee being almost above everything else a social insect, would be adverse to finding herself comparatively alone, and in the choice of an abode this instinct of love of society would probably be increased when in the act of preparing for swarming. One bee, or even small company of bees, would feel themselves only an atom or atoms of the great mass, and would feel an aversion to it, in proportion to their numbers being great or small. I do not believe that any individual bee has the power of communicating her ideas to her fellows, hence every scout would at first start off 'on her own hook.' But in time each one, or each company, finding out by investigation that the places they had chosen only commended themselves to a minority, would gravitate at last to the spot where the greatest numbers predominated, following a well-known law of nature of smaller bodies being attracted by greater ones. Their future home being decided upon, what next? I do not say there may *not* be a consultation as to when they should return

to their hive, but then a mere climatic disturbance may be sufficient to send them home. Now these scouts would of course be perfectly well acquainted—from constantly keeping up communication with the two places—with the bee line from the old home to their intended new one.

A suitable day at last arrives, the old home is overcrowded, and otherwise unpleasant—even men know what a jolly thing it is to clear out of an unpleasant house, the quicker the better. Off they rush like so much water out of a tank, but where are they to go? Ah! that's the question! The very fact of their nearly always settling, and that settling generally being for so long a time, proves that most of them, at any rate, have no idea where they are going to. After a time, feeling themselves certainly not 'busy bees,' there is a general consensus for doing *something*. They mount into the air. The scouts take the lead to the place they had determined upon, the greater number acquiesce as following in the line of the least resistance to their love of society, just as a balloon ascends because the presence of the air, so to speak, is greater upon the sides and the bottom than it is on the top.—ALFRED E. BOOKER HILL, *The Chase, King's Lynn*.

PRINTING OF THE 'SKEP' PAMPHLET IN THE WELSH LANGUAGE.

[191.]—I see from the *Journal* report of British Beekeepers' Association Committee meeting that it is the intention of the Committee to publish the above pamphlet as early as possible. As a Welshman I hail with delight any means that may be introduced to induce my fellow-countrymen to adopt the 'humane system' of bee-keeping. If I understand matters aright, the object that the Committee have in view is to place in the hands of Welsh bee-keepers the means of acquiring a knowledge of bee-keeping; now, is the publishing of this pamphlet in pamphlet form the best way to attain the object in view? The Committee I hope will pardon me for expressing an opinion contrary to that of publishing it in book-form. As a bookseller, I have a little experience to back me, and I fully believe that the best means to reach the majority of the bee-keepers of the Principality is by publishing it in some of the newspapers. These are circulated in the remotest corners, and as a rule the whole of the paper is read. It would therefore, as a part of the newspaper, be read. I would secure it being published in the leading Welsh newspaper of South Wales, having a circulation of 10 to 12,000 in the counties of Glamorgan, Monmouth, Brecknock, Pembroke, and Carmarthen. Lest anyone should think that I have an interest in this paper, for their benefit I inform them that I have no more interest in it than your readers. Trusting that the Committee will see its way clear to publish it in this way, and that its members will pardon me for suggesting, I am, &c., A WELSHMAN.

HONEY.—From Liverpool we hear that the demand continues very poor, and is almost confined to the lower grades: 112 tierces of Cuban have been sold at 17s., and 150 barrels Chilian at 15s. to 25s. 6d. per cwt., according to quality. For to-day's sale, 677 packages were catalogued, of which 500 cases of Californian went off well at 26s. to 34s. for sorted, 20s. to 27s. 6d. unsorted. Minceing Lane Market, Chemist and Druggist, March 4th, 1886.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[144.] *Preventing Casts*.—Instead of driving swarm from skep as proposed, I would now place it inside of bar-hive, and when skep is full of bees place five or six combs or sheets of foundation under it and allow them to work down, and

when the combs are nearly full of brood lift off the skep and see that the queen is on the bars; if not place it on again and look in it next day or until you find her on the bars. Then lift the skep to a new stand and next day give it a young queen, or a cell from another hive. If a laying queen is given to the skep it can be placed on bars again in ten or fourteen days and treated the same way.—J. SADDLER.

[146.] *Manipulating House*.—I have a honey house in my garden, right amongst the bees, and do not find much inconvenience from the bees getting in. Of course, it would be necessary to stop up all openings to keep them out; a window to open is a good thing to let them out if any do get in.—J. WALTON.

[148.] *Bell Glass*.—It would not be advisable to put on a bell glass without excluder zinc, as the queen would be almost sure to go up.—J. WALTON.

[150.] If *A Beginner* will communicate with me at No. 2 King William Street, Blackburn, I will give him the information he requires for a starter.—R. MIDDLEBROOK.

[152.] *Moving Hives*.—Wait a month and get half-inch square pieces of wood four inches long, bore a small hole on one end and thread on twine and place them between the end of frames, and frames and dummies, and jam the dummies hard up, close doors with perforated zinc and cover with thin quilt, then you may drive them anywhere.—J. SADDLER.

[152.] *Moving Bees*.—Perforated zinc tacked over the entrances, and the hives placed on some straw in a spring van or trap, would be all that is necessary to move bees three miles at this time of year.—J. WALTON.

[163.]—*Rate of Flight*.—(H. S. S.)—Last autumn I frequently observed my Italian bees on the heather on the neighbouring grouse mountain, two and three quarter miles distant from their hives, and at 983 ft. greater elevation (figures from Ordnance map) most of the black bees there were probably also from the same apiary. The Italians could have come from nowhere else.—R. E. LLOYD.

[178.] *How to tell from which hive a swarm has issued*. (W. G. E.)—By the diminished number of bees in the stock: this is easily ascertained by examination; usually you will find a few very young bees—that are unable to fly—crawling about the ground in front of hive. These have been crowded or carried out in the *mêlée* and not been able to follow the swarm; of course you will be unable to find these if any considerable time has elapsed since the exodus. In a frame-hive you can see the queen-cells in various stages of development.—W. B. WEBSTER.

[178.] *Swarm Issuing*.—(W. G. E.) If you only have one swarm in the day, and your hives are all supered, the supers will be empty of bees in the hive that swarmed.—YOUNG BEE-KEEPER.

[178.] (W. G. E.)—You will find, in examining your hive, the one the swarm has issued from will appear almost depopulated from what it did a day or two before, and less ventilation will take place at the hive door.—JAMES BALL.

[179.] *Sealing Wax*. (Tyro.)—Venice turpentine 2 oz., shellac 4 oz., colour with either 1 oz. vermilion, or sufficient lamp-black mixed with turpentine to colour it. For common bottle-wax, melt together 18 oz. resin, 1 oz. shellac, 1 oz. bees-wax; and colour with either red lead, Venetian red, or lamp-black.—NUCLEUS.

[179.] *To make Sealing Wax*. (Tyro.)—Red sealing-wax is made by taking, say, six ounces of rosin and powder it; add four ounces of red lead, two ounces of vermilion, or less if expense be objected to, and the same of shellac reduced to powder. Mix all these well together, and melt over a slow fire. When thoroughly incorporated and fused, work into sticks. *Black*.—Same way, ivory black being used instead of red lead and vermilion. *Green*.—Colouring matter, finely powdered verdigris. *Blue*.—Colouring matter, verditer, or smalt. *Yellow*.—Colouring matter, massicot, or chrome. *Purple*.—Colouring matter, vermilion and smalt.—W. B. WEBSTER.

[180.] *Köhler System*. (Tyro.)—This system is said to be perfectly practicable by the author of it. I tried it on two separate occasions last season, but failed. It entails a vast amount of trouble, with—in my case—very unsatisfactory results. I shall have another 'go' this next season.

Why not treat your nuclei in the ordinary manner?—W. B. WEBSTER.

[181.] *Bees dying for want of food.* (J. H.)—By what method of reckoning did you know that there were twenty pounds of honey in your hive? You must remember that a frame weighing six pounds, which has been much used for breeding, will very often not contain more than three and a half pounds of honey, pollen very often being stored in same in considerable quantities. To a hive crowded on wide frames, I should allow quite thirty pounds of stores. Your packing was not at fault; there are much better ways of doing it; a box without top or bottom, about three inches high, having a piece of calico loosely tacked on in place of bottom, and filled with cork dust, is the best and cleanest method of top packing. You ought to have gently turned up your quilt during February, on one day of which, the 13th, we had splendid, warm, spring-like weather; you then would have discovered their condition, and so could have used means to save what would have been a splendid stock.—W. B. WEBSTER.

[182.] *In a dilemma.* (A. P. J.)—In quite a mediocre—for honey-gathering—part of the country, I should be anything but satisfied with such a balance-sheet; if in a large town you have done fairly well. Your price received for sections (*bid.*) is too low, consequently your profits have been very much reduced. Doubling section crates is the correct thing, if done with judgment. Make raisers to your hives between stock hive and roof, high enough to allow of sufficient space for your racks.—W. B. WEBSTER.

Queries.

Queries and answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[192.] *Fertile Worker.*—Does a 'fertile worker' differ in appearance from the other workers in the hive?—A. B. JOHNSTON, Co. Down.

[193.] *Bees Crossing Water.*—Would bees fly from an apiary situated on the northern margin of a lake three miles broad to the opposite side to collect honey?—A. B. JOHNSTON, Co. Down.

[194.] *Drone-Laying Queen.*—Is there any probability that a healthy-looking queen, which performed her duties rightly until July last, and then commenced to deposit drone-eggs *only*, would return to her proper duty and deposit worker-eggs in worker-cells this spring?—A. B. JOHNSTON, Co. Down.

[195.] *Removal of Fertile Worker.*—What is the best method of removing a 'fertile worker' from a populous colony of bees in bar-frame hives in month of April? also in month of July?—A. B. JOHNSTON, Co. Down.

[196.] *Mouldy Combs.*—I found it impossible to extract all the heather honey, which appeared in patches, in my spare combs last autumn. The bees also failed to clear out completely what remained. The consequence is, that a good many of my extracted combs, stored for future use, have become mouldy. May I safely give them to the hives by-and-by? and will the bees be able to clean them up?—R. E. LLOYD.

[197.] I have about 2 lbs. of run honey; what quantity of water should I put for spring stimulating?—WEST STURREY.

[198.] How long at this time of the year will bees live without food?—WEST STURREY.

[199.] *Extracting House.*—What would be the cheapest thing to erect for extracting purposes near the apiary? Last year I was greatly troubled with robbing by extracting in the open.—Br. W.

[200.] *Holes in Bottles.*—How can I make holes in thick glass bottles for feeders?—Br. W.

[201.] *Quilts.*—Can any reader inform me if the quilt is required when sections are used, and also the safest and best way of driving bees from a common box hive?—INEXPERIENCE.

[202.] 'TREF-EGLWYS' requests some correspondent to describe or give drawings of porches and alighting-boards, suitable both for winter and summer use; the entrance may be 8 in. by $\frac{3}{4}$ in.

[203.] 1. *Mouldy Combs.*—On examining one of my hives to-day I found an outside comb slightly mouldy, the comb is full of pollen—is it needful to remove it or will the bees clean it when the weather gets warmer? also, what is the cause? The hive is perfectly dry, the frames are at right angles with the entrance, which has been wide open all the winter. 2. *Croaking Noise.*—I also noticed a peculiar croaking noise among the bees—what is it? I remember hearing a similar noise in a hive last summer, when I opened the hive to ascertain the cause, but failed.—NUCLEUS.

Echoes from the Hives.

Clippenham, Wilts.—I have not disturbed my bees from October to the present time (March 10th), as I fully believe in the let-alone system during such period; and although the winter has been an exceptionally long and a *persistently* cold one, I am glad to find all my stocks are alive. In such a winter, it is not surprising to find that a larger number of old bees than usual has succumbed, and will sneemuck to the weather and long confinement, and in this district the stocks will be, no doubt, somewhat weakened from these causes. The thermometer here has, during every day and night in March, stood at freezing point, with a cutting east wind. But notwithstanding this, many of the vigorous bees in my hives have, during gleams of sunshine, ventured forth, much against my will, and their own safety.—W. A. WARRLOW.

North Staffordshire, March 3th, 1886.—My bees had two flights in February. On the 1st inst, a severe snow-storm set in, and the snow has not yet cleared away. The 7th and 8th were very bright; all my hives were shaded from sun except one, the wind having blown down the board, when the bees came out and hundreds perished in front of the hive. To-day I removed all shades and all have had good flights. Examined four stocks and found brood in all stages in each, although the night of the 6th registered twenty-two degrees of frost and eleven degrees the following night, with several degrees of frost every night since.—NUCLEUS.

Affrison, Sussex, March 13th.—Weather keeps dull and cold, as it has been for two or three weeks; bees flew a little on one or two days this week, a little pollen coming in. Have had to feed one stock of driven bees a little with warm syrup and candy. One or two of my stocks have had dysentery slightly, but since I changed quilts have not seen any more signs of it. I hope we shall soon have some fine weather so as to begin stimulating.—YOUNG BEE-KEEPER.

Chester, March 15th.—Yet another week of 'beasterly' winds and hard frosts at night. Dysenteric signs at entrance of some hives; the ground is still covered with snow. I saw one bee carrying pollen yesterday, this in a stock of hybrids. I suppose the pollen was obtained from some tall growing plant in the neighbouring nurseries. I am quite close to some hundreds of acres devoted to nurseries.—C. ROBERTS.

Ballyskeagh, Dummurry, 6th March.—On March 1st (Monday) we had a very heavy fall of snow here, fully nine or ten inches, but which drifted, and in some cases almost covered hives. On Friday, 5th, sun was very bright, and I fear many bees were enticed out never to reach their hives again. We have very severe frosts at night, and up to time of writing there is no sign of change. I saw bees busy on snowdrops during one or two fine days last month, which gave an opportunity for cleansing flight, as I did not see them out during the previous six weeks. Have not got opportunity to report how I have wintered my stock.—P. M'H.

Lucan, Co. Dublin, March 14th.—The winter here has been by no means so severe as in England. We have only had two heavy falls of snow, each disappearing within a week. We had one day's skating in December, but have had no hard, continuous frosts since. I had a very good season last year, taking 170 lbs. of honey from three hives,

two of which were only swarms, all of which I have sold, realising 1s. 2d. per lb. on an average all round. I went into winter quarters with six stocks, giving each of them rather more than 30 lbs. of syrup, which they sealed before the end of September. They have kept very quiet all the winter, and on no day that I saw were they flying in any numbers. March winds have set in now, and though the crocus and snowdrops are in full bloom, they are not working at all. I do not intend to examine till the last week of this month, as I am sure all are well.—WALTER J. STANFORD.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

R. J. S. Cavan.—I. Sugar.—Porto Rico is the only sugar suitable, and needs no preparation farther than to be given as recommended by Mr. Simmins for spring stimulation. 2. Bees do not store it as honey. While being highly stimulative, the above process ensures that nearly all is used as fast as it is reduced to the liquid form. 3. Extracting.—Yes; being built where they are at once toughened by being bred in, they are quite equal to combs built on foundation in the same situation.

E. A. S.—Bees attracted out by warm Sunshine to perish in the Snow.—Your case will be found to exactly represent that of many this season. The snow lying on the ground at this season, when the sun has such power in the middle of the day, leads to great loss of bee life. You do not mention the construction of your hives, but we presume they have the frames at right angles to the entrance. When this is the case it is difficult to prevent either direct or reflected light entering the hive. When the frames run across the hive and the bees are located at the back, forming an ante-chamber, no light can enter and thus the bees are not tempted out. If perforated zinc is used it would be likely to lead to suffocation. You may safely raise the quilt and push a cake of candy under it on the top of the frames.

REV. S. HARDINGE.—Granulated Honey.—Granulated honey is not injurious to bees, but much of it they are unable to consume unless plentifully supplied with water, or moisture of some kind, by which they are enabled to melt it. It is much better to melt the granulated honey over a fire, keeping it just below boiling point, and to thin it down to the consistency of feeding syrup by mixing hot water with it.

J. BALL.—The examination of a candidate for a third-class certificate is not very difficult. It is necessary for him to prove to the judges that he has a fair knowledge of bees, and an ability to manipulate. The second and first-class examinations are more difficult, and require a considerable acquaintance with the literature of apiculture. He is also required to be able to write and speak upon it. The place and time of examinations are determined by the secretary of the Association of the county where the candidate resides.

ONCAB, Essex.—1. Fixing wire in frames having saw-cut in top bar.—Drive thin wire nails horizontally through the two halves of top bar and pass the wire through the saw-cut and over the nails. 2. Bees leaving Hive.—We cannot give you a reason unless you give us some particulars. Was the honey left granulated, and in what part of the hive was it left? Were there any dead bees amongst the combs? Was there a young queen in the hive in November? Was there anything unpleasant near the hive?

GEORGE D. CLARE.—Good and bad points of frames 1½ inches apart.—We have always advocated frames without projecting shoulders or distance guides, and our reasons have been that we were able to bring our frames to 1½ inches from centre to centre, and in this way prevent any production of drone brood and restrict the combs to worker

brood only. This has also the effect of making the bees store their honey in supers. If we wish drone brood, the combs can be placed further apart, and if wanted for honey only they can be gradually brought to two inches from centre to centre with advantage. We do not think it would do to have the shoulders cut, so as to keep the frames permanently at 1½, as this is too close for winter. We have only had one instance of bees refusing to work on foundation in Stewarton honey boxes, and that was owing to the foundation being made of paraffin, and in this case the bees built combs in between, refusing to use the adulterated foundation.

E. T.—Vignole system of Swarming.—It is claimed for this system that it is an advantage for the hive to be queenless at this particular period, and if you wish to give it a fair trial do not deviate from the description given by either adding frames of brood or giving a new queen. If you wish to manipulate further you can work on swarms from A before B and C stocks, but by the time A's first swarm is in the best condition B stock ought to have re-established itself sufficiently to be displaced by it. A stock, after the bees are driven, is removed from the apiary, its work having been accomplished.

T. JENKINSON.—Place yourself in communication with the Secretary of the Cumberland B.K.A., the Rev. J. Phelps, Houghton Vicarage, Carlisle, who will be pleased to give you the information you seek.

We have received from Messrs. Abbott their abridged price list, also a sheet illustrating the goods they have now on sale at their newly-opened agency in Paris; this latter also contains very pertinent instructions as to the management of bees in France. We have much pleasure in noting this outlet of the abundant energy of this well-known firm, and hope they will reap much advantage from their new venture.

Messrs. Edey have forwarded a sample of their reversible frames. Their mode of reversing is unique. Thick wire revolves from the centre of the frames; and it is so twisted that the distances between the frames, and between the frames and the side of hive, are kept. We should fear from the springiness of the material that the position of the frames in the hive could not be sufficiently rigidly maintained.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

[No. 196. VOL. XIV.]

MARCH 25, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE PROPOSED CANADIAN APIARIAN EXHIBITION.

At the last meeting of the Committee of the British Bee-keepers' Association, a suggestion was made that during the time that the Colonial Exhibition was being held it would be desirable that a British exhibition of honey and bee-appliances should be held in the large Conservatory of the Royal Horticultural Gardens; and to give effect to this suggestion, a number of those present expressed their willingness to contribute towards a Fund to cover the preliminary expenses and other possible charges. Since that meeting the members of the Committee have been using every effort to make arrangements to carry out the above suggestion: but we are not at present in a position to say to what extent their endeavours have met with success.

While, then, the matter of the British exhibition is still pending, it will be desirable to look abroad and see what is being effected in our Colonies, and the position they desire to occupy in the forthcoming International Show. We are not able to state to what degree Australia, New Zealand, the West Indies, and other colonies, intend to exhibit: but as the time approaches for the opening, they will, doubtless, give evidence that they have not overlooked the opportunity now afforded them of proving to the world the ability of their respective countries to produce honey and wax.

Canadian apiarists, however, have taken the initiative in the matter, and they are evidently determined to use every effort to make an effective exhibit of their honey produce. We must give all credit to Mr. D. A. Jones, of Beeton, Ontario, for having taken the lead in stimulating his fellow-countrymen to take the first step, and for pointing out the advantages that would accrue to the honey industry of Canada in acquitting themselves worthily in, and acting earnestly on behalf of, this exhibition. From the antecedents of Mr. Jones, we might have been led to expect that in undertaking an object of this nature he would carry it out effectively and thoroughly. It was Mr. Jones who, in the summer of 1879, to use the language of Professor Cook, inaugurated 'the grandest enterprise ever undertaken in the interests of apiculture,' viz., the importing of queens from the East. In that year, having secured the services of Mr. Frank Benton, at that time a graduate in the Michigan Agricultural College, an excellent linguist and a skilful apiarian, he

visited the apiaries of the principal bee-keepers in Europe. They then located themselves in Cyprus, and there established an apiary composed of Cyprian and Syrian bees. Leaving Mr. Benton in charge of the apiary at Larnica, in Cyprus, Mr. Jones betook himself to the Holy Land, and there came across the race of Palestine, or 'Holy' Bees—a race which he pronounced to be superior to both the Cyprian and Syrian variety (see his interesting letter to the editor of *Bee Journal*, vol. viii., p. 32). The following summer Mr. Jones returned to America with several hundreds of Cyprian and Syrian queens, leaving Mr. Benton to continue the work of rearing and exporting queens—a work which that gentleman has continued to prosecute with assiduity to the present time. Mr. Jones is the owner of several large apiaries in Canada, conducted with the greatest amount of intelligence and skill. In April, 1885, Mr. Jones established a weekly periodical called *The Canadian Bee Journal*, which he has edited with the greatest advantage to apiculture, and which has given a great impetus to bee-keeping in that country. Mr. Jones, appreciating the great service that the Colonial Exhibition would be to Canada, made application to Sir Charles Tupper, the Canadian Commissioner, for 4000 feet of space, which were at once granted to him. This grant Mr. Jones has handed over to the Ontario Bee-keepers' Association, who, having accepted it, have shown great activity in prosecuting the work, with a full sense of the responsibilities they have undertaken. Mr. Jones has promised to furnish supplies, honey-plants, &c., so that the space allotted may be occupied until the honey harvest of 1886 is ready.

Mr. S. T. Pettit is the chairman of the Ontario B. K. A., and he is now the medium of all communications respecting the Canadian Exhibition. It was determined by Mr. Pettit and his Committee to interview the members of the Ontario Legislature with a view to obtaining from them the necessary assistance in carrying out their purpose. The members having been appealed to, the result has been most gratifying and hopeful. The Government have expressed their willingness to give the Association the assistance they required, and have granted them the sum they asked for, namely, \$1000, and have also promised to incorporate the Association, and give it annually a grant of \$500.

The Committee have passed the following resolutions:—

'That all goods sent forward by the members of the Association, through the Commissioners, shall be at the risk of the producer.

'That the Commissioners shall be empowered to dispose of the goods after the exhibition is over on such terms as in their judgment is best.

'That the Commissioners shall give their time free of charge, but their necessary expenses shall be borne by the Association.

'That all necessary expenditure in connexion with the exhibit over and above the amount granted by the Ontario Government to be made *pro rata* from exhibits sold.

'That all members of the Association desirous of for-

warding any goods with the first shipment, will need to forward them by freight or express (prepaid) to Beeton, Ont., to be shipped from there at the cost and charge of the Government.'

The services of Mr. Neighbour will be put in requisition, and he, assisted by Dr. May, of Ontario, will arrange the first exhibit.

Provision will be made for exhibitors to sell honey while the exhibition is going on, provided the main exhibit is left in order, and the goods can also be sold in the lunch-room or dining hall.

It was the purpose of the Commissioners that all exhibits of honey should be conveyed to Beeton, Ontario, at the expense of the exhibitors; but the distances between places in Canada are very great, and the probability is that the Ontario B.K.A. will defray the expenses of transit to Beeton, and the Government subsidy be utilised in paying the expenses from Beeton.

It is therefore seen from the foregoing summary that our Canadian brethren are proceeding very systematically and successfully with the work they have undertaken, and that their exhibits of honey will not only be large in amount, but the best and the purest that the country can produce. They have the right men as their leaders, who are ready to prove their ability to take a proper advantage of the opportunity now offered them, and to see that Canadian apiculture is worthily represented at the forthcoming Exhibition.

LINCOLNSHIRE AGRICULTURAL SOCIETY.

LINCOLN EXHIBITION.

We have received the schedule of prizes offered for bees, honey, hives, &c., by this important County Society, who have arranged to hold their annual exhibition at the ancient city of Lincoln on the 21st, 22nd, and 23rd of July, as announced in our advertising columns. The bee department will, by desire of the Council, be under the direction of members of the Lincolnshire Bee-keepers' Association as heretofore; and judging from past events of this Society's doings, we may look forward to a grand show: the city of Lincoln being favoured with easy rail access from most quarters of the country, will doubtless draw many exhibitors and *bee visitors*.

In looking through the schedule, we notice class 15; 'The competitor who shall show the greatest skill in driving a stock of bees from a straw skep, and capturing the queen, and who shall best explain the method and object of the operation,' five prizes are offered; and to us it appears to point at something more than at first thought might occur; perhaps, however, we might not be far wide of the mark in a surmise that the framer of this novel class had something in his mind in the way of testing and bringing to the front the skill and knowledge of Lincolnshire bee-keepers, and so to show practically the value of the work carried on by the Association, and further to be able to note to anyone asking aid one competent of giving it in the various districts.

LOCKE'S PERFECTION FEEDER.

This feeder, of which we give a sectional drawing, is made of tin to hold from one pint to several quarts. It is simply a shallow cylinder with a hole in the top, and another one at the bottom, the top one being provided with a screw cap, and the one in the bottom closed by means of a piece of sponge. When wanted for use, a hole is cut through the quilt about $1\frac{1}{4}$ inches in diameter, and the feeder placed over it. The food is then poured into the hole at the top, and the cap screwed down. The chaff cushion is then placed over the whole to keep it warm. The bottom edge of the feeder has a rim to

raise it off the frames, and the under side is covered with cloth secured to it with bees-wax and resin, which renders it impervious to moisture, and forms a non-conductor of heat for the bees to cluster under it and round the sponge without becoming chilled. The syrup

Locke's Perfection Feeder.

soaks and passes through the sponge as fast as the bees take it. The feeder must be filled as rapidly as possible, and the cap screwed down, or there would be a risk of the syrup running out too fast. This feeder is on a similar principle to the Raynor feeder, in that it is placed directly over the cluster of bees, and this is not disturbed in their endeavouring to obtain food. The temperature of the food is also kept up by the heat rising from the cluster of bees below. Mr. Alley, one of the most advanced bee-keepers in America, has used it extensively, and speaks favourably of it, and says that one of these feeders large enough to hold sufficient food would keep a colony for a whole winter without any capped honey at all. Being made entirely of tin, their cost places them within the reach of all. They can be used equally as well for supplying bees with water if this be required. To manufacturers we would suggest that the hermetically fitting caps of the 'Self-opening Tin-box Company' are admirably suited for closing the opening, and would be not only cheaper, but more effectual than the metal screw-caps.

GLEANINGS.

In *Gleanings* we find an interesting discussion at the Ohio State Bee-keepers' Association meeting on the subject of bees trespassing and injuring grapes. A. I. Root states that he has several hundred grape-vines right over his hives, and never finds his grapes injured by the bees. He also states that a Massachusetts fruit man once compelled a bee-keeper to remove, because he claimed that his bees injured his fruit. A trial of several seasons without the bees was a failure, and the bee-keeper was prevailed upon to come back.

With regard to moving bees during the working season, Dr. Besse states: 'Move five or six swarms every evening, after bees are all in the hive, and set the hives far enough apart to set others between them when moved next evening. Set a board or three or four sties of storewood in front of the colony moved. I moved one hundred colonies 250 or 300 feet, and very few bees, if any, went back. They were caught in a nucleus hive on the old stand. I would advise removing strongest first, then the returning bees would reinforce the weaker ones left.'

In *Gleanings* A. Benedict advises beginners to go slow in extracting and learn the business, or they may produce bad results and get discouraged. He uses a moveable bottom hive, and ties up in extracting. If the colony swarms he hives it on foundation-combs under the old colony, placing a wire cloth between the two for a day or two. The queen begins to occupy the lower storey, and as the bees hatch out above the honey is stored in the frames. By this method he gets a large body of bees at work in a single hive.

In *Gleanings* J. M. Shuck states that in his effort to get comb-honey in the brood-chamber he divided the brood-nest with cases of sections. In these experiments he invariably got queen-cells in all, except the division occupied by the old queen. He has also raised queen-cells in an upper storey when the lower was occupied by a laying queen. Ordinarily the cells are larger, and the queens of better colour when thus produced. The cells, he says, must of course be removed for the final emerging and perfecting of the queens.

In the *Prairie Farmer* Mrs. L. Harrison states that when there is a great flow of honey the queen is crowded out, as the bees will encroach upon the brood-nest in their eagerness to save as much as possible. She has at such times inserted an empty comb in the centre of the brood-nest, thinking to give the queen some room, but found on investigating a day or two later that every cell was filled with honey. Their motto is, 'Make hay while the sun shines.' She also states that the empty space in a hive beyond the division-board can be utilised by filling it with frames of empty comb, and the bees will protect them from the ravages of the larvæ of the moth. She also noticed that in the spring, in hives containing honey where the bees had died, the robber bees destroyed the larvæ of moths. Italian bees war with them continuously, while black bees let them revel in their choice comb.

In the *Bee-keepers' Guide* A. G. Hill states that fertile workers, if once well established, it is quite difficult to get rid of them, as they will often destroy introduced queens, queen-cells, and prevent the rearing of queens. If, however, you change the brood-combs with a good colony, shaking the bees off the combs before making the change, they will disappear, and you can introduce a cell or laying queen at once. A few brood-combs exchanged is not effectual; it seems to require a host of hatching workers to stop the work of a fertile worker.

In the *American Apiculturist* Arthur Todd, in speaking of M. Ossipow's camphor treatment of foul brood, says that when living in Algeria some years back, he found that great reliance was placed upon the emanation from the leaves of the eucalyptus trees as a curative agent against fevers, especially those of a typhoid character. These trees, he says, belong to the camphor family, and he was informed that bees were always healthy when placed under one of these trees.

In the *American Apiculturist* one of the editors says: 'Like all other business, bee-keeping has its "ups and downs," but no one should be discouraged by meeting with an occasional drawback; we must expect to experience disaster and ill-luck sometimes. Neither should we expect or look for a large crop of honey every year. Last season Californian bee-keepers sent an immense crop of honey to market; this year they have but little if any to send. Last year bees did poorly in Vermont; this year they have done extra well. Do not get discouraged, push on as if nothing but prosperity was certain to crown your efforts. If disaster comes, repair the damage as quickly as possible, and push right on the same as though nothing of consequence had happened.'

In the *American Apiculturist* we read that not far from five thousand queen-bees are reared and shipped from the State of Massachusetts each year. While Vermont and Maine are noted for their fine honey, Massachusetts bee-keepers have the credit of rearing the finest queens in the world.

In the *American Bee Journal* the Rev. E. L. Briggs says to make bee-keeping a successful business 'muscle and brain' must go together. It is no small business, but covers a great field of labour. We cannot expect to make a living by keeping only one colony of bees, any more than by keeping one cow or one hog; but any man or woman with a quarter of an acre of ground well stocked with bees can compete with a farmer having 160 acres of land.

In the *American Bee Journal* James Heddon says that some bee-keepers are fearing the result of the coming winter because their colonies ceased breeding early, and the hives contained no young bees; and he thinks this fear is ill founded. Bees, he says, do not grow old with time, but with exertion. Colonies of bees that have not bred late have not exerted themselves like those that have. The creation of young bees is always at the expense of the vitality of the older ones. Young bees do not enter the quiescent state, so desirable for safe wintering, as do old ones. In this state little food is taken, and scarcely any vitality lost. Bees preserve this vitality (age) wonderfully during autumn, when conditions are such as to discourage breeding.

THE DEATH-CRY OF THE BEES.—'Ave, pungende! morituri te salutant.'

Foreign.

CANADA.

Paper read at the Convention of Canadian Bee-keepers held at Brantford, Canada, February 21th and 25th. Honey, what is it? What shall we do with it?

The subject before me is, in its fullest sense, a very broad one, and, as many of us are aware, a very difficult one to answer.

As to the first question, Honey, what is it? The question can be viewed from a great many standpoints as a natural product. It is the secretion of, and found to a greater or less degree in all, or almost all, flowers at the particular time when they are in a state to be fertilised. There is no doubt our Creator has ordained it, that the aroma which the flower is distilling shall attract the insect, which must in its visits come in contact with the pollen, and in that manner assist in fertilising the flower. If the flowers are not fertilised we would have neither seeds nor fruits. Darwin gives the following experiment: 'Twenty heads of white clover visited by bees produced 2990 seeds, whilst twenty heads so protected that bees could not visit them produced not one seed.' The sources of honey are, then, as numerous and as varied as the flowers from which it is gathered, as we know in Canada our principal honey crops are secured from clover, basswood, and thistle, and an inferior quality in some localities from buckwheat. The three first named are excellent; they differ somewhat in flavour: clover is very mild, basswood is lighter-coloured (a somewhat stronger flavour), thistle has a very nice colour and flavour.

Canada, as we know, produces a honey second to none. At Philadelphia it took the first prizes and sweepstakes of the world. The reasons assigned for our honey being of such quality are, the extremes of winter and summer, the nature of the soil, its flora, and other favourable climatic influences. In quantity, for a decade of years we are favoured. Chemically, honey is largely composed of carbon, hydrogen, and oxygen; the proportions vary, and how held together it appears the chemist has not yet revealed to us. Honey appears to have peculiar medical properties. From the oldest time it has been used and valued as a nourishing food and restorative to health, as well as a preventive of disease, keeping active the pores of the skin, and restoring its nervous action. For colics of all kinds it is known to be invaluable. For children it is the most nourishing and wholesome of foods, and as such stands without a rival.

Honey appears to be assimilated by the bee under proper atmospheric and other conditions, with little or no effete matter, and appears to have in combination almost all the elements necessary to sustain life. One of the reasons honey is such an excellent food may be that the bee as she gathers stores it in a sac for the purpose, and in this sac the honey may be acted upon by secretions which facilitate the assimilation in our systems. As food for the economic housekeeper, none can aspire to the highest place as such unless it is constantly found in their larder. Honey will, under any ordinary conditions, keep for months without deteriorating in value, and has been kept for years without appearing to deteriorate in value as a food. Unlike fruits canned and preserved, and many other such foods, honey can be opened and contact with the air permitted without souring, moulding, or in any other way destroying it. Take an ordinary quart jar; it holds about three pounds of honey, say 45 cents. Now take the fruit for preserving. Strawberries will require about three 'boxes,' and a proportionate quantity of sugar. Strawberries are about, if not quite, the cheapest of small fruits, and they cannot be preserved for less than 15 cents per quart, probably more. They may be canned for about 37 cents. We all know where honey is habitually used a quart of it will last longer than a quart of canned or preserved fruit. As an actual food, which the man who 'eats to live' should always estimate upon, honey heads the list by far. In baking and pastry honey has the effect of giving a rich flavour, and keeping cake moist and fresh for a great length of time—quite an item for a house which does not generally use such luxuries, and still

desire to have them on hand for any friend who may unexpectedly visit them. It is also used to great advantage in preserving and canning fruit if not of too liquid a nature. Our honey is used by the pork-packers, tobacconists, &c.

New, with our honey, the best in the world, and the article valuable in so many ways, the question, What shall we do with it? should not be a very difficult one to solve. We know that where one pound of honey was used six years ago there are twenty-five if not fifty pounds used to-day. The demand has increased very rapidly, and if our product were not as good as it is we might be surprised at the increase, for we certainly have not done much to increase the demand. A few of us have exhibited at fairs, &c., and a few more have canvassed in towns and country localities, and what have the remainder done? Sat down and waited until some one knocked at our doors and gently inquired, Would we sell them some honey? Or, as they were following other pursuits, they made the sale of honey a bye consideration, and in that way disposed of it. But to-day, in this whirl of activity we must be active or we will be swept off our feet. It will not do for us to wait for customers, but we must look for them and convert them. We must educate the public to use honey, and with few exceptions once introduced in homes as a staple article its merits will shine forth, and a demand remain year after year. We must push the sale of it in every manner, and develop the home market. There is undoubted room, and if not ample, at least a large and undeveloped field in Canada. How to go about it I will not discuss in this paper. Space will not permit. Lest it should be said I am in any way attempting to hinder or throw an obstacle in the way of the contemplated display at the Colonial and Indian Exhibition, I would say, No, let us make the display. The larger our market the better. But let us remember our success will depend upon ourselves. It lies in our power largely now to work for good or ill. It is imperative that the display should be a gigantic one, and the quality should be of the very best. We must expect to find there as here the ready sale of honey limited, of a certain quality a plentiful supply. What must we then do to develop a market for ourselves? First, if possible, and if we send only our best it is highly probable, we must have a better honey than they have at present upon the market. Poor lots of honey will do us an injury which it will take years and hard work and expense to efface. Good honey will require to be pushed to supplant an inferior.

Let us take a lesson from the story of the large English butter-dealers—what do they say? 'We do not want to handle your (Canadian) butter. We cannot depend upon the quality. Five per cent is good, a small percentage fair, and the rest bad. We have to examine it all to see the quality, and we must probe to the bottom of every package. We can buy Danish butter and resell it and never look at it, every package is just as it is represented to be.' Brother bee-keepers of Canada, let us be the Danes in our honey dealings, and from the commencement establish a reputation above suspicion. But I think our work will not cease here. We will there have to develop the honey market. We will have to make every effort to place the honey in the hands of people who have never used it before, and cultivate a more general use for it.

I think the Exhibition will be an important factor in this development, and the more exhibited the better. Therefore Canadians should send and aid in perfecting this display. I think every package should have a brief history of how extracted honey is secured and its merit, to aid in educating the public, and disseminating apicultural knowledge. And do I think we will push other honey off the market? No; not unless it cannot compete as to quality. In fact, I think the coming display and our united push will draw the attention of the public to honey, that the consumption will be wonderfully increased for the benefit of home and foreign producers, and—not to be forgotten—the consumer.—R. F. HOLTERMANN, Brantford, Canada.

SOUTH AFRICA.

Among the 'passengers' that left by the *Norham Castle* on Saturday last, Feb. 20, for England, was a colony of live honey-bees, sent by Dr. Stroud, of Port Elizabeth, to Dr. Walker of Wimbledon, under the care of Mr. John Harris, of Graaff-Reinet. Though small numbers

of bees have many times been brought to the Cape from England, these are probably the first of their race that have ever been removed from South African shores. If they survive the voyage, and every provision has been made for their well-being, and every contingency arranged for, the South African 'natives' will, no doubt, be an object of interest at the Colonial Exhibition. Mr. Harris, of the firm of Cleghorn and Harris, Port Elizabeth and Graaff-Reinet, is himself an experienced bee-keeper, and under his auspices and intelligent attention it is believed that they will reach their destination.

[The above is an extract from a Graaff-Reinet paper. From a communication from Dr. Walker, p. 129, we learn that the bees have reached him safely. We hope he will be able to render a good account of them.]

ASSOCIATION.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

At a Committee meeting held on Saturday, 13th inst., there were present, Messrs. Carter, Foxon, Meadows, Pridmore, Walker, Saunders, Ward, and the Secretary. Mr. Carter was voted to the chair.

The minutes of the last meeting were read and confirmed, and after a short statement respecting the financial condition of the Association the prize schedule for the ensuing annual show was drawn up.

The Rev. J. Bird, T. Brooks, Esq., Mr. W. P. Meadows, and Mr. Walter S. Pridmore, were then selected to form a deputation to confer with the Council of the Leicestershire Agricultural Society on the subject of providing for the Annual Show. It was then proposed, seconded, and carried, that Mr. Bickley's name be added to the Committee.

The forthcoming *Conversazione* next came under consideration and arrangements were made to hold it on May 1st, in the Mayor's Parlour, Old Town Hall, Leicester, at 2.30 p.m. The Secretary was directed to ask the Mayor of Leicester to take the chair, and to give notice of the *Conversazione* to the members by circular. Some interesting papers on bees and bee-keeping have already been promised.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

**.* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

SPRING STIMULATION.

(Continued from p. 118.)

[204.] It is useless to say 'let-'em-alone,' because it simply shows bad management to permit the brood combs to become clogged with sufficient honey to keep the colony supplied until near another season. All the time sugar can be supplied at one-third the cost of extracted, or one-fourth that of comb honey, we must appropriate every pound of nectar, more particularly in these times when prices have gone down considerably; though for that reason 'Rector' considers the bees should have only honey to live upon.

With the stock combs comparatively clear when last surplus is removed, we have a much larger population, and by then feeding as mentioned in my last we main-

tain that strength without undue breeding. At the same time having secured a larger honey-crop than where the bees have been allowed to store themselves at the expense of the surplus we also have them in better 'heart' than any which are allowed to provide for their own welfare.

It is not the practice of feeding, but its abuse, which has induced some to think with 'Rector,' that bees are best left entirely alone; though the 'let-'em-alone' policy is far before that which induces bees to breed heavily out of season. Where a colony breeds extensively right up to November, the queen does not again begin to deposit eggs until the bees are flying freely in spring, when there is great loss of life before young ones are hatched to take their place, and spring dwindling is the result. On the other hand, with the brood nest closed down from the middle to the end of September, providing the hive is well stored with both liquid food and pollen, the queen *always* commences to breed about the 'turn of days,' whatever the weather may be, and from that time onwards nothing will check the production of young bees, but the occasional dearth of water, which, however, should be provided against, by supplying all hives with American oil cloth, laid smooth side downwards on the frames.

It does not pay to let the stock combs become stored with what ought to have been placed above. Even supposing we may not lose double the quantity through the brood nest becoming cramped too early in the season, if twenty pounds are found below, this would represent at least ten shillings for extracted: or, if above, quite fifteen shillings for comb honey. What then is gained by such a proceeding, considering also that we are at the same time crippling the strength of our stock for the following year? But, nevertheless, if such honey has not been extracted from the stock combs by the middle of August, by all means allow it to remain there or more harm than good will be done. However, be wise, and add to that store, and induce the bees to breed moderately until the middle of September.

I am quite at one with 'Rector' if he means to say that colonies heavily stored, and which have bred up to September 15th, will give good results the next season with but *little* more care; but, at the same time, I can assure him that those stocks bare of food when the surplus is removed, and which are then judiciously fed as before stated, will do far better.—S. SIMMINS.

ON THE BEE'S STING. [169.]

[205.] Mr. Bird asks me to (1) 'mention one or two instances in which British insects have lost the use of their jaws; (2) have had their wing-cases united after generations of inaction.' The words I used in my paper read before the Association were, however—'The jaws of some insects became aborted and useless by having food prepared for them, and the wing-cases of others became united after generations of inaction.' There is not much difference, but it is best to be exact.

(1.) '*Formica rufescens*'* is absolutely dependent on its slaves; without their aid the species would certainly become extinct in a single year. They are incapable of making their own nests or of feeding their own larvae. When they migrate (it is the slaves which determine this migration) they actually carry their masters in their jaws. The masters are utterly helpless, and when shut up without a slave many perished of hunger.† So says Darwin. On page 113 of Nicholson's introduction to Zoology, we are told *Formica rufescens* are so entirely dependent upon their slaves that they cannot even feed themselves without the help of the latter. Q.E.D. they have lost the use of their jaws, seeing that the rest of their species possess useful jaws.

(2.) Darwin again says,† 'How unutterably inexplicable is it . . . that the shrivelled wings under the soldered

wing-covers of many beetles should so frequently occur.' And on page 109, 'These several considerations make me believe that the wingless condition of so many Madeira beetles is mainly due to the action of natural selection, combined with disease.' W. F. Kirby says, * 'The elytra in some cases being either moveable, but of course useless for flight, or soldered together at the suture.' The Carabidae have moveable elytra, but no wings. The Melæ have no wings, and only rudimentary elytra. Will your correspondent admit the blindness (born-blindness) of fishes found in subterranean waters?

Had we not better promote that fraternal feeling which exists amongst bee-keepers by placing the Bible above a scientific discussion, as its mission is, and was, in another direction? In a controversy of a purely scientific and speculative nature, evidence in support of speculation should be entirely scientific. For instance, I am not disposed to admit the chronology of Genesis and Exodus, nor of the accuracy of the word (translated) 'hornet' in the quotation given. No mention being made of its sting, the insect of that day might use its ovipositor in driving out the Hivites and others, seeing that to-day insects use ovipositors aggressively. Then, again, if Mr. Bird will kindly read the two verses following the one quoted he will find the expulsion was to be 'by little and little, not in one year.' So that the insect alluded to cannot have been very formidable, not more so, perhaps, than the locusts and flies which immediately brought the Egyptians to their senses. Let us please leave the Book tranquil.

Mr. Bird facetiously introduces the stump end of the sheep-dog's tail into the *Journal*. I will leave it there; it wags (stump as it is) against the door of a great argument I should not like to see discussed in your columns—the doctrine of evolution by natural selection.

If I give the perfect-stinged wasp and races of stingless bees can we not conceive of all grades of sting development between these two extremes? Our own honey-bee is eager to use its sting in its Cyprian and Egyptian varieties, passing through grades to the quiet pure Ligurian and almost entirely harmless Carniolan. With a hybrid Cyprian, as perhaps the most vicious, at the top of the chain of honey-bees, and the genus *Melipona* along with *Trigona* (both stingless) at the bottom, the humble-bee about the middle, with its curved sting of few and short barbs, may we not fill in a complete gradation of developing, adapting, or aborting probabilities? Just to show how bees and wasps, stingless and stinging, run into each other, I may say that *Apis dorsata*† in form and style of flight much resembles a wasp, is very clumsy in its attempts to sting, and that pain is not so great as that from a common bee-sting.† Again, 'the stings of *A. florea* and *A. indica* are very small.'

Mr. Bird, with the caution of a skilled debater, keeps from us his opinions on the subject of my paper, contenting himself by queries, the tone of which (perhaps inaccurately) seems to place him in opposition to my conclusions.

Question A. 'Would it be possible to breed a perfect stinging-bee from a queen of barbless sting?'

Question B. 'And why does *A. mellifica* require weapons of defence now more than they did in the days of old?'

Question C. 'Have wasps and hornets ever passed through a transition stage?'

Answer A. Certainly, in the slowly grinding mills of the Creator, to whom the few thousand years from the time of the prophets to the present are but as a grain of sand in an hour-glass; but certainly not by the artificial selection of man, who denies possibilities because he is unable to advance by miraculous leaps and bounds.

Answer B. I do not say that they do, though I believe that when animals advance or retreat in the scale of nature the change is constantly going on, from creation to the crack of doom; always some on the bottom rung of the ladder and its consecutive steps; with bees, then as now, varieties being stingless and stinging. Remember the male sex is stingless.

Answer C. I believe they have, though this cannot be more than conjecture by inference.

For the benefit of those who doubt the accuracy of my

* *Origin of Species*, p. 216.

† *Ibid.*, p. 420.

* *British Butterflies*, &c., p. 7.

† *Professor Cook's Manual*, p. 33.

deductions I beg to append a few confirmatory quotations. Professor Cook says,* when speaking of the female organs of insects, 'The end of the oviduct called the ovipositor is wonderful in its variation. Sometimes it consists of concentric rings, like a spy-glass, which may be pushed out or drawn in; sometimes of a long tube armed with augers or saws of wonderful finish, to prepare for eggs; or, again, of a tube which may also serve for a sting.' Again,† 'The males (of *Mutilla coccinea*) are said to sting. This is certainly a mistake. The sting is a modified ovipositor, an organ not possessed by males.' Nicholson‡ states, 'The abdomen of the female Hymenoptera is generally furnished with an instrument connected with the process of laying eggs (ovipositor), and this is often modified to form a sting.' Kirby§ says, 'The saw-flies (*Tenthredinida*) derive their name from the horny apparatus of the female being modified into a pair of saws.'—R. A. H. GRIMSHAW, *Crag Hill, Horsforth, near Leeds*.

SUMMARY OF AN AMATEUR'S BALANCE-SHEET.

[206.] In continuation of my remarks in your issue of Feb. 25th, I append a summary, showing my expenses and receipts since I commenced bee-keeping. I make most of my hives and supers, thanks to the hints given in the *Journal*.

RECEIPTS.		EXPENSES.	
1883.		1884.	
Nil.		Bees	£ s. d.
(Cr. by 3 Stocks, Hives, &c.)		Hives, Wood, &c.	1 12 6
		Apparatus	2 7 6
		Subs. to <i>Journal</i>	0 4 1
		Sugar	0 15 0
		Total	£6 10 9½
		Bees sold	£ s. d.
		Honey, 87 Sections or 1s.	4 7 0
		" 49 lbs. extracted @ 10d.	2 0 10
		Wax, ½ lb.	0 1 0
(Cr. by 4 Stocks and Apparatus.)		Profit	4 15 8
			3 13 2
		Total	£8 8 10
		Bees sold	£ s. d.
		Honey, 121 Sections	1 0 0
		" 185 lbs. extracted	11 9 6
		Total 306 lbs. or 9d.	0 6 0
		Wax, 3 lbs.	0 17 6
		Prizes, Cash	4 0 0
		Extractor, which is credited with the 4 Stocks and Apparatus.	9 12 5½
		Profit	4 0 6½
			9 12 5½
		Total	£13 13 0

The bees sold in 1884 were a stock hive and super; those sold in 1885 were in a skep, presented for managing an apiary during 1884 and 1885, but as the queen died, or got lost, a swarm was given the buyer on July 12th. By adding the profits, it will be seen that I have obtained more than double my original outlay, besides having four stocks and a good supply of apparatus.—GWENYNN.

FOUNDATION FOR SUPERS.

[207.] I can fully endorse almost every word Mr. Sharp says with regard to foundation for supers. It is quite true, from my experience as well, that people do not care for sections, &c., that are worked on foundation, and will often complain to the vendor afterwards of the 'hard part' in the middle, and will not purchase any more; but, on the other hand, if, as Mr. Sharp so truly says, the public are offered the *genuine* article, there will

* *Manual*, p. 60.

† *Ibid.*, p. 328.

‡ *Introduction to Zoology*, p. 112.

§ *British Butterflies, &c.*, p. 19.

be no lack of purchasers. Mr. Simmins seems to think that there is a great loss in quantity by not using foundation freely in supers (and perhaps he may be right), yet the quality will be so far superior that the gain which the apiarian will obtain in his price and in the recommendation by his customers will amply make up for the loss.

I think Mr. Sharp's letter on this subject, instead of doing harm, is calculated to do much good, for it will be the means, I hope, of stimulating bee-keepers to produce the real, genuine article, which they can warrant as such, and which will greatly enhance its value in the eyes of the public. It is in vain that we sit down and complain of the 'dulness of the honey market' if we are not doing our best to rid that market of all that is inferior and spurious.—THE MANAGER, *North Cornwall Apiary, Roue, Bodmin*.

GRAND NATIONAL APIARIAN EXHIBITION.

[208.] It appears we are to have a 'Grand National Apiarian Exhibition' in London this year, and since apiculture in this country is a branch of industry of no small importance (and, growing as it is, we may expect under the improved systems of management a gradual increase in the amount of its productions) I think it only right that it should be represented on all occasions where other branches of industry are exhibited, and the time and place, therefore, for the said G. N. A. E. are well chosen, and its promoters deserve the thanks of all bee-keepers in the United Kingdom, Baroness Burdett-Coutts deserving special praise not only for her munificence, but for the earnest interest she takes in the welfare of bee-keepers generally.

Granted that the Exhibition is to be held, the question arises as to what will be the best means to employ to insure some *real* benefit to the bee-keepers of this country. Are the Colonials going to bring over large quantities of honey, wax, &c., for exhibition only, or are they expecting to increase their sale of honey in this country by making a grand display of their apiarian productions? If so, our exhibits ought to be vast in quantity and superior in quality to show the Colonials that it is not really necessary for them to assist us in supplying the demand for honey, &c., in England at any rate. One would have thought that foreigners, enterprising as they are, and supplying us, as they do, with everything except ready-built houses—and I expect seeing them advertised shortly—would have allowed us the monopoly of our own honey trade, and, instead of bringing their surplus into a country already supplied, have endeavoured to increase the demand in their own. However, they have a perfect right to bring honey just as any other article of consumption, and so long as they can make a larger profit by bringing it into England than selling it in their own country, so long we may expect to see it in our markets.

I am of opinion that the present bee-keepers of the United Kingdom could produce honey enough for the demand of these isles; and if so, why not their produce be bought in preference to any other? The fact is we have been *undersold*, just as has been nearly every branch of industry in this country. The farmer is undersold in his own stackyard, the manufacturer in his own factory, the bee-keeper in his own apiary. Prices have gone down and consequently demand increased, and purchasers are naturally pleased with all reductions, whereas manufacturers and producers generally are somewhat grieved, and, I am sorry to say, in many cases actually *ruined*. Well, Sir, since politics are not allowed to enter your columns, it will not do to attribute anything to our laws even if one wished to do so; and, therefore, I am content to leave politics to politicians, and shall try to consider apiculture as something apart from our laws altogether, and instead of looking forward to our legislators for

assistance, trusting to our own wisdom, energy, and perseverance.

But, Sir, my chief object in writing was to ascertain, if possible, what are the principal objects in view, and what are the means to be employed by the committee for securing some good for our bee-keeping interests?

My humble opinion is that it would not be a bad idea to astonish the Colonials by showing them that our resources are not quite exhausted, that we have got the men and got the honey, too,—not money—and impress them if possible with the notion that there is some danger of their meeting our English agents in their own streets selling English honey to their neighbours. But above all to convince them that we can sell pure honey as cheap as they can; and not only them, but the public generally. Some may not agree that we can sell our honey as cheap as they, but I believe we can, and we shall most certainly have to do so or be driven out of the market to a great extent. I am not referring to adulterated honey. I am afraid I am already trespassing, or else I had intended offering a few ideas with a view to our successful competition with foreigners.—A. GREEN.

AFRICAN BEES.

[209.] Through the kindness of Dr. Stroud, of Port Elizabeth, South Africa, I have received a nucleus of African bees. Last year I sent him a small Cyprian stock, but unfortunately they died before arrival, and in announcing their sad decease he wanted to know if I would like him to send me a Zulu in exchange. As the season was getting late, and as I had made arrangements for a tour in the Isle of Man, I asked him to send the bees to arrive here about May. But as a well-known African bee-keeper, Mr. J. Harris, of Graaf Reinet, was coming to England, he sent them by him, and they arrived here ten days ago. As the weather was very cold, I left them in their travelling crate till March 17th, when I put them in a small queen-raising hive with plenty of sealed honey.

As I found my other bees were rather too attentive to them, I selected one of my strongest hives, and removed the queen, and caged her Zulu majesty in a pipe-cover cage after some trouble, as she was rather a lively customer. I could not find her in the nucleus, though I looked carefully for her, and when I looked at the hive from which I had removed the queen, I found the Zulu balled on a frame, and when I took her out, she again took wing, and I finally found her on the stand where the nucleus had been placed.

Having caged her for forty-eight hours, I released her, only to find her again balled twenty minutes after, so she had to be re-caged. I will let your readers know how she fares.

The bees are like the Ligurians in colour—three distinct orange-yellow bands; the first, that near the thorax, being much broader than the other two. They are very much smaller than the Ligurians, and the queen looks like an undergrown Ligurian queen.

The travelling crate was a three-frame nucleus, all the combs being carefully wired and protected by half-inch wire netting, the end of the frames being screwed down. At the side was a very ingenious plan for supplying water, by means of sponges in a trough, to which the bees could get access, but so arranged that any excess of water would overflow outside the hive. I propose to show the crate at the next Quarterly Conversazione of the B. B. K. A., and at the 'Colonies' Exhibition, if it can be managed.—GEO. WALKER, *Wimbledon*.

KILLING DRONES.

[210.] I have been a bee-keeper of nearly fifty years and seen a marvellous change. Mr. Woodbury, of Exeter,

a neighbour of mine, helped us considerably with his Woodbury bar-frame hive.

My object in writing is to say in the *Journal* (which I have been long a subscriber to) that one of my frolics last year was, with two skeps and one bar and frame-hive, to kill every drone in August, and now all three have perished leaving a quantity of honey in all. I am an old man and not able to manipulate as well as formerly, but can say bee-keeping has been a source of pleasure to me always; had for more than forty years from forty-five to six hives, but I am fond of a skep from 18 in. diameter in bottom and a cone top for glass. I have large glasses on my sideboard, several years old, very good. *It is the killing of drones which I want to call attention to.*—JNO. E. ADAMS, *Belfield Villa, Kingsbridge, Devon*.

GENERAL MANAGEMENT OF AN APIARY.

[211.] I think that it would be an advantage to many bee-keepers, especially to those whose time is limited, if some simple and easy method could be devised for the general management of an apiary, which could be readily understood, and yet secure the results of more elaborate systems. Several methods have been mentioned in your columns, but all seem difficult and more or less open to objection. Your readers are not likely to approve of the method commended some years ago by a correspondent of a weekly paper, who stated that he kept bees, but that they gave him very little trouble, for he never did anything to them, except twice a-year, when first they swarmed, and he hived them, and secondly he took their honey, and half destroyed them. But when we carefully notice and compare the various methods mentioned in your columns, it is clear that there are considerable differences between them, and it must be difficult for an amateur to decide as to which method he shall adopt. *E.g.*, Mr. Sharp recommends strengthening half the hives of an apiary by adding to them frames of brood, &c., taken from the other half, so as to have the former very strong and ready for early swarming; then anticipating swarming by removing all frames from the strengthened hives, substituting empty frames of foundation, and giving the removed frames to the previously weakened hives; and afterwards destroying all old queens, and cutting out all queen-cells except one, or forming nuclei, according as increase of hives is desired or not. This method seems feasible, but it is open to the objection that it excessively weakens half the hives, and also that the bees, having all their frames taken away, may be driven up with pollen, &c., into the sections; and will not the suddenly augmented hives have to be watched, or in their turn have to be artificially swarmed? Mr. Simmins, again, recommends permitting the bees to swarm naturally, and returning them to their old hives with two frames, cutting out queen-cells from the latter, and subdividing old stocks for nuclei or for increase. Here is involved the trouble of watching for swarms, and the risk of losing them. Another method—practised by a bee-keeper in the north who has been very successful in securing large honey harvests—is to allow his bees to swarm naturally, but he returns them immediately upon all their frames, cutting out all queen-cells, and repeating the process if they swarm again, which he says they seldom do; also always raising a supply of young queens in nuclei formed from his best hive to supply the place of old queens dethroned. But here, again, there is the risk of losing swarms, and the chance of missing a queen-cell. The Vignole method, lately described in your columns, seems to be open to other objections, although I should like to see it fairly tried by some experienced bee-keepers in our land. Is it not possible to devise some simple method which would combine the advantages of all without the disadvantages?—D. A. DOUDNEY, *Orre Rectory, Hastings*.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[178.] *Swarms or Casts Issuing.*—If you will remove the queen from such swarm or cast at evening, or early next morning, they will return to their parent hive of their own accord.—E. CLOWES.

[178.] (W. G. E.)—If you capture the queen with your swarm the bees will soon return to the hive from which they issued; if it is a cast there may be more than one queen, so if after capturing the queen they do not begin to return in a few minutes, search again for other queens. I have found as many as seven queens with one cast, and after they were all captured, the bees soon returned to parent hive, and without doubt related the contretemps, and if 'W. G. E.' should have two or three swarms or casts settle together, if he capture all the queens, they will all return to their respective hives.—WOODLEIGH.

[181.] (J. H.)—No, not if right materials are used. Very probably the stock has been breeding all through the winter; if so, and considering the large number of bees put into winter quarters, viz., nine frames, crowded, the consumption of food has not been abnormal. It is not much above a pound per week, and with breeding going on that is not a large quantity of food to consume. I don't think the wraps have anything to do with the impoverished state of the hive, as I have proved year after year that those stocks that are most carefully wrapped up consume less as a rule than those not so snugly enshrouded in their winter quarters. Some of my best results hives last year had the chaff cushion on it till I removed them for the crate of sections to take their place.—WOODLEIGH.

[182.] 'A. P. J.' can make ekes to raise the covers of his hives to give room for stori-fying crates of sections on top of frames. When purchasers of hives decline buying hives that will not take at least two crates of sections one on the other, then, and not till then, will manufacturers discontinue the present form and size. I, myself, have seen first prizes awarded to hives that had hardly room for one crate and a suitable wrap. I don't blame the judges, as it was the only type of hive submitted to their judgment. But why don't manufacturers launch out into an all-round hive—one suitable for extracting and stori-fying combined?—WOODLEIGH.

[182.] *In a Dilemma.*—I should have a frame made of 6-in. by $\frac{3}{4}$ -in. or $\frac{1}{2}$ -in. wood, just the same size as the hive body. You can fasten plinths on to the bottom to keep the junction with the hive-body rain-proof, and by cutting the wood a trifle out of square at the ends, so as to make the top very slightly narrower than the bottom, you would ensure the roof fitting comfortably over all. Of course, if the roof is hinged to hive, the hinge must be unfastened.—TREVOR SAYNOR.

[192.] *Fertile Worker.* (A. B. J.)—These do not differ in appearance from ordinary workers.—M. C. H.

[192.] *Fertile Worker.* (A. B. Johnston.)—The fact that 'fertile workers' are so indistinguishable in appearance from ordinary workers constitutes them the pests that they are.—AMATEUR EXPERT.

[192.] *Fertile Workers.* (A. B. Johnston.)—These put me in mind of a certain dark-complexioned gentleman, who—we are supposed to know—exists, but whose presence we are only aware of through his works. If fertile workers were recognisable, a hive would be easily cleared of them without the usual means employed.—W. B. WEBSTER.

[193.] *Bees crossing Water.* (A. B. Johnston.)—They have been known to cross water even a greater distance than three miles; but if the honey-crop necessitated such a lengthy and dangerous journey, I wouldn't give much for the apiarian's profits.—W. B. WEBSTER.

[193.] *Bees crossing Water.* (A. B. J.)—Yes, especially if honey was scarce on the north side and plentiful on the opposite, or of a superior quality.—AMATEUR EXPERT.

[193.] *Bees crossing Water.* (A. B. J.)—Bees frequently cross lakes when there is a scarcity of bee forage at home, or nearer home, and it is plentiful elsewhere. Bees frequently cross the lakes here, but they are not so wide; but

it appears they are too wide, as I have several times been told by the boatmen and others of their seeing thousands on the surface of the water. Those bees are either chilled or otherwise exhausted by their long flights. If you have heather at the opposite side, and none nearer home, your bees will go there.—R. PHILIPSON, Keswick.

[194.] *Drone-laying Queen.* (A. B. J.)—More possible than probable. I am rather inclined to the belief that she has been superseded.—AMATEUR EXPERT.

[194.] *Drone-laying Queen.* (A. B. Johnston.)—Kill her and introduce another, or unite now, after removing her; she is no good to you. If she has laid only drone-eggs since last July, your colony by this time must be almost valueless.—W. B. WEBSTER.

[194.] *Drone Laying Queen.* (A. B. J.)—You probably gave the queen a squeeze by accident when you were examining the hive, so caused her to become a drone breeder. You should send her to Mr. Cheshire for microscopic examination, as she will probably never recover.—M. C. H.

[195.] *Removal of Fertile Worker.* (A. B. Johnston.)—A 'fertile worker' in a populous colony of bees in April would be rather a *rara avis*; such are only to be found in motherless stocks, where there are no means of rearing one. There being little chance of losing a mother-bee before April, your stock, if containing a 'fertile worker,' we might venture to conjecture, must have been motherless for some time, and consequently depopulated to a considerable extent. Unite the colony to one having a good mother bee; you can then divide it afterwards, and provide for either, allowing them to rear; but, better still, introduce a mother-bee to them. There are other means of ridding a hive of these pests, but this way I consider the simplest and best.—W. B. WEBSTER.

[195.] *Removal of Fertile Worker.* (A. B. J.)—Take a frame of brood with adhering bees from one of your best stocks, and place it in an empty hive on the stand now occupied by the stock containing the 'fertile worker.' Remove the last-named stock a few yards in front of its present stand, and turn the entrance towards the old stand on which you have placed the empty hive. Open the stock which contains the 'fertile worker,' use as little smoke as possible, as you do not wish to gorge them, and with a wing brush off every bee into the hive from one comb at a time, and carry each comb so treated and place it in the hive on the old stand. It must of necessity be a bright day when bees are flying, and the bees will rapidly fly home to their old home. Leave one comb in the old hive, and the 'fertile worker' will be amongst the very few bees remaining on this comb. These may be shaken on to the ground, and all will probably leave and the 'fertile worker' will perish; and the young bees that were given with the first comb will raise a new queen, or be the most likely to accept a new queen that you may wish to give them. This will apply to both April and July, but we hope you are not troubled with these pests so frequently.—AMATEUR EXPERT.

[196.] *Mouldy Combs.* (R. E. Lloyd.)—I should be inclined to melt them down if they were mine; but as you have a number of them spray with phenol solution, and give phenol in the food as well; and if there are degrees of mouldiness amongst them, select the best only.—AMATEUR EXPERT.

[196.] *Mouldy Combs.*—If R. E. Lloyd will hang up his mouldy combs for a few warm days out in the air, a little distance from his apiary, the bees will thoroughly cleanse them for him, and the mildew will disappear and they will be fit to return to the hives when required. The combs should on no account be left out at night, and when thoroughly restored they should be stored in a warm room until wanted.—THE MANAGER, North Cornwall Apiary.

[196.] *Mouldy Combs.* (R. E. Lloyd.)—Place combs—which you ought to have done when you took them from hive—in a warm, dry place for a week or so; then brush off mould—which will then be powdery—as much as possible, and spray with salicylic acid solution. You can then give them to the bees with safety.—W. B. WEBSTER.

[196.] Yes, give a frame of comb to each of your strong stocks, and they will soon set matters right with your mouldy combs.—WOODLEIGH.

[197.] (West Surrey.)—About half a pint.—M. C. H.

[197.] *Diluting run Honey.* (West Surrey.)—Much depends on the density of the honey. Try one pint to two pounds, and if it is not sufficiently thin add more.—AMATEUR EXPERT.

[197.] *Honey for Spring Feeding.* (West Surrey.)—About one part water to six of honey. Heather honey being thicker would require more water; use your judgment, and bring it to the consistency of thin clover honey when cold.—W. B. WEBSTER.

[197.] A pint of water will make your honey the right consistency, or you may boil five pounds of raw sugar in three pints of water, and then stir in your honey after you have taken your syrup from the fire—you will have a good syrup. Feed with two holes for stimulating.—WOODLEIGH.

[198.] *How long will Bees live without Food.* (West Surrey.)—This entirely depends upon the conditions under which the bees are at the time of their fast; they do not die *en masse*, but to a great extent individually. To enable a correct answer to be given would necessitate such cruel experiments which, considering the absence of any utility in knowing the same, would be unpardonable. Moral: Rather allow too much than too little stores.—W. B. WEBSTER.

[198.] *Bees without Food.* (West Surrey.)—Should not like to guess, not having tried the experiment. Suppose you have a 'Dr. Tanner' contest with one good strong lot and report results to *B. B. J.* if you survive.—AMATEUR EXPERT.

[198.] Not more than a few hours, except sustained by artificial heat.—WOODLEIGH.

[199.] *Extracting House.* (Dr. W.)—Much depends on what you can cheaply procure in your neighbourhood. It must be weather-proof and bee-proof, or a portable one of net or wire cloth.—AMATEUR EXPERT.

[199.] *Extracting House.* (Dr. W.)—A house about 6ft. square and 7ft. high, frame-work of 2in. x 1 1/2in. quartering covered with 3/4in. matchboards, roof of Willesden card painted white; plenty of ventilators covered with net, is a short description of a house I saw last season which I considered perfection. Don't forget the ventilation. It's rather warm work.—W. B. WEBSTER.

[199.] I should think a small wooden house constructed of light quartering and half-inch matched boards, with sloping roof similar to Irish hive, and with window made to revolve on a centre pivot at top and bottom of sash, when by simply reversing the window all the bees attached to the light would be on the right side to fly, also have the door to open outside like a cupboard, thus economising the room inside.—WOODLEIGH.

[200.] *Holes in Bottles.* (Dr. W.)—By means of a glass drill purchased at tool-maker's, lubricated with turpentine.—W. B. WEBSTER.

[200.] A small diamond drill, such as is used by china riveters, or a drill made of old saw file, with point moistened with turpentine, will do; but of course will be longer doing the job. Why not cut a notch in the cork instead of making a hole in the bottle?—WOODLEIGH.

[201.] *Quilts.* (Inexperience.)—When sections are placed in a rack on top of the frames the quilt must be removed. If the rack does not entirely cover the tops of the frames, cover all means of entrance into the sectional cover with strips of quilting, enamel cloth is the best, allowing it to lay under the edges of the rack; the rack then is more easily removed. Drive in the same manner as from a skep. See answer to query (108), 18th February.—W. B. WEBSTER.

[201.] I should advise the removal of the quilt when the crate of sections is put in, but if 'Inexperience' intends using the Benthall or Raynor crate, he can cut a long square hole in his quilt. And again, why drive your bees from your box-hive? Let your bees swarm naturally, hive in frame-hive, stand same on old position, and move your box-hive to a new position, when your bees with nearly all of the fielders will go back to old stand, thus making your new hive stronger, and also giving good chance of an abundant produce.—WOODLEIGH.

[201.] *Quilts.*—(1.) Certainly use quilts; I find that by wrapping them up warmly, the bees store and seal the honey much faster in the sections. (2.) I suppose you

mean a hive in which the combs are immovable; in this case proceed as you would with a straw skep, only you will have to drum on the sides of the box with sticks so as to shake the combs sufficiently to make the bees run.—M. C. H.

[201.] *Quilts.* (Inexperience.)—If you have excluder-zinc, relegate it to the limbo of antiquated appliances, and take a good thin quilt, and cut it so that it only covers, say, eight out of ten frames, and place your super on the quilt and try results. *Driving Bees from Box.*—If you simply want a swarm, treat the box as you would a skep; if you wish to empty the box, *knup* and treat as you would a skep.—AMATEUR EXPERT.

[201.] (Inexperience.)—Leave one layer of quilt between hive and super, out of which cut a strip about an inch wide near to each side of hive, or back and front if frames are at right angles to the entrance, and extending across as many of the bars as the super will cover, in which case the queen is not so likely to enter super as when the quilt is entirely removed. Two or three layers of quilt should be put on top of super, carefully tucked down, so as to keep all snug and warm. The best way to get bees out of a box-hive is to invert the hive, and then, with a sharp turning saw, cut out one side. The combs can then be readily cut out, and the bees shaken off. A little smoke will keep the bees quiet while the turning operation is being performed.—A. SHARP.

[202.] (Tref-Eglwys.)—A catalogue of any appliance manufacturer will give you the information you require.—W. B. WEBSTER.

[202.] *Porch.* (Tref Eglwys.)—The accompanying is a plain sketch of what seems to me the best porch and alighting board I have ever seen. I am sorry to say my

hives are not so fitted, but one of my most successful friend's hives are; they are in a very exposed position on the top of a hill. He is an amateur carpenter and makes his own. The sketch needs no dimensions.—AMATEUR EXPERT.

[203.] *Mouldy Combs.* (Nucleus.)—The bees will clean slightly mouldy comb; remove same, the bees evidently do not cover it, and it is desirable now to remove all unoccupied combs. Dampness is the cause; outside combs frequently get into this condition during the winter months from the condensation of the atmosphere, produced by the warmth of the cluster. 2. *Croaking Noise.*—Perhaps you lean against the hive and so produced the noise; bees do not croak.—W. B. WEBSTER.

[203.] *Mouldy Combs.* (Nucleus.)—(1.) Dry pollen invariably turns mouldy during winter, in the driest hives. The bees will clear it out. Bees also store pollen mixed with honey, and seal it over; this does not turn mouldy, and, I believe, is invariably used for early breeding. (2.) *Croaking Noise.*—Do you mean 'piping'; it is the only croaking noise I have had the pleasure of hearing?—AMATEUR EXPERT.

[203.] 1. The bees will attend to the cleansing of comb and removal of the dry mouldy pellets of pollen. 2. Possibly the burr caused by wings of bees touching some substance.—WOODLEIGH.

[203.] (1.) *Mouldy Combs.*—I should advise 'Nucleus' to remove his outside mouldy comb on the first warm day, and to hang it out in the air (see answer to Query 196). If the mildew from this comb filled with pollen does not disappear after this process has been tried, it is better to

destroy it, as it would be unwise to return it to the bees. (2.) *Creaking Noise*.—I have very often heard this in my apiary, especially in the summer, and last season it was so peculiar and audible in two of my observatory hives that I determined to find out the cause, and after long, careful, and very minute watching I found it was made by a drone. Has 'Nucleus' any drones left in this hive he speaks of?—**THE MANAGER, North Cornwall Apiary.**

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[212.] *Boiling*.—Can syrup for spring stimulation be made without boiling? If so, how?—**J. C. B.**

[213.] *Curing Dysentery*.—What is the best way of curing dysentery in skeps?—**YOUNG BEE-KEEPER.**

[214.] *Dysenteric Bees*.—What should be done with frame hives that have had dysenteric bees in them?—**YOUNG BEE-KEEPER.**

[215.] *Skeps*.—Would it be practicable to work skeps for extracted honey by using boxes nine inches deep, to fit over the skep, and using frames six inches deep and a wood or zinc cover?—**YOUNG BEE-KEEPER.**

[216.] *Ligurianising*.—What is the best way to Ligurianise an apiary of, say, fifty hives, as early as possible, without interfering with the honey-harvest?—**F. A. W.**

[217.] *Stinging Gloves*.—Is any means known by which bees may be prevented from stinging gloves worn by a manipulator? I find that it is pleasanter to wear gloves than to be without them; but it is grievous sometimes to see, when once a bee has fixed its sting in one's glove, the poor creature wriggling about in agony, and, perhaps, many others following its example. Could not the outer gloves be dipped in some chemical solution distasteful, or *tasteful*, to the bees?—**RECTOR, Ore, Hastings.**

[218.] *Drones—Ligurianising*.—(1.) When do bees cease rearing drones? (2.) Would it not be better to purchase two Ligurian queens after all drones are reared and the swarming season is over? (3.) If a Ligurianised hive swarms, would not the purchased queen accompany the swarm? If a young Italian queen is left in the hive is she worth keeping, as she would meet black dones?—**VICTOR.**

[219.] *Obtaining Honey*.—Is a hive with about twenty frames the best for obtaining honey in sections? or would a two-storey hive, holding altogether the same number of frames, be better.—**M. C. H.**

[220.] *Honey-comb Designs*.—How long is it since honey-comb designs were first introduced? and to whom are we indebted for the invention of letter-printing and other artistic designs wrought out by bees?—**APIS.**

[221.] *Disinfecting Skep*.—What is the best way to disinfect a skep with 12 or 14 lbs. sealed honey in, the bees dead, and signs of dysentery? and would there be any risk in putting a swarm into it in June?—**VILLAGER.**

Echoes from the Hives.

East Yorkshire.—As I seldom see any report from this district, perhaps a few lines may be worth inserting in the *Journal*. After one of the most miserable summers experienced for many years, we are now having a most protracted winter. Frost and snow set in here the first week of the new year, and has continued with but slight intermission ever since, until we now find ourselves in the middle of March with snow still deep on the ground. I need scarcely say that such a long period of low temperatures

has had a very injurious effect on the bees, at least it has had on mine. I entered winter quarters with forty-six hives all told; about eight of these were nuclei in make-shift boxes, but the great majority of them were very strong colonies, and ten of these were left with all the body boxes of their hives full of honey, just as they came off the moors; these were intended as a trial against others with reduced combs as usually recommended. Others are strong lots of driven bees fed entirely on sugar syrup. So far my casualties have been three—one of them I found out to be queenless when too late; another died in the midst of plenty for want of passages through the combs; whilst the third, a grand lot, were victims to the weather, the hive-cover and quilts being blown off during a heavy storm of wind and rain, and when I found them the hive had two inches of water in it and all the bees and combs exposed. I put them into a new hive, but they never recovered. To return to the weather. This long confinement of the bees has brought on an attack of dysentery with more or less severity in some colonies, without apparently any regard to the condition of them, but solely, as far as I can judge, owing to the position and aspect of the hives. Mine face either due south or due east, about equally divided as to numbers. Now, not one hive facing south is affected with dysenteric symptoms, whilst a large number of those facing east, I am sorry to say, are. How is this? It is easily explained, and shows that the aspect of hives is of more importance than is usually thought to be the case, and especially in exceptional seasons. During this protracted cold weather we have had on two or three occasions just enough sunshine to raise the temperature sufficiently to induce the bees to take short cleansing flights, but these glimpses have generally taken place about noon, when the sun's rays did not strike the fronts of those hives facing east, so that these colonies lost the opportunity of flying and are in consequence suffering from dysentery; and numbers of bees, with their abdomens distended, are vainly endeavouring to fly, or are tumbling out of the mouths of the hives on to the snow and perishing. What can be done to save them? Nothing—warm weather and the melting of the snow alone can save them. The confinement in their hives has been longer than they can bear, and if prevented from coming out they will die indoors with worse consequences. A few days ago the sun broke out in earnest, and I saw the bees would soon be out, as it became quite warm and the snow began to melt. I made no attempt to shade the hives, but allowed the bees to have their own sweet (?) will. The result was a sight not often witnessed; they came out in thousands and fairly covered the snow with their faces until it was tinged all round of a mahogany colour. Hundreds perished in the snow, melting little holes as if a walking-stick had been thrust into it; and though this apparent waste of bee life was grievous to see, I am convinced that the result would have been worse had they not been allowed to come out. It is snowing again whilst I write, and I fear we have not seen the worst.—**F. BOXES.**

The Apiary, World's End, Newbury.—Bees out on Thursday, 11th inst, for an hour or two in middle of the day, and one little solitary crocus—first harbinger of spring—opened its golden cup, soon to be revelled in by the busy bee. I sprinkled some pea-flour in the crocus blossom and around on the grass and very soon the bees were rolling themselves in it and going home as dusty as millers.—**W. WOODLEY.**

Winterlow, near Salisbury, March 19th.—At last we have a mild day, and bees from all my ten hives were enjoying themselves right merrily in the sunshine this morning. I have lost none, and all appear healthy, but I have not yet examined them; as it has come on raining now, and I know they must have plenty of stores. The only days on which they have been able to fly freely this year have been January 2nd and February 12th.—**C. W.**

North Leicestershire.—On Friday, 19th inst., a sudden rise in temperature set the bees at liberty once more. On the following day they were carrying in pollen all day from aconites, snowdrops, and a few early crocuses. Scores of young bees perished through alighting on the cold ground just freed from snow. The following extracts from Dr. Emmerson's diary gives a good idea of the general state of bee matters: 'March 21st, hive No. 1, Swarm of 1885.—

Seven frames well covered with bees, brood in all stages on two combs, stores in four frames. No. 2, old stock which swarmed and cast in 1885.—Ten frames crowded with bees, stores in seven combs, sealed brood in three combs; no eggs, no unsealed brood, and no queen observed in cursory examination. A fortnight previous this stock had a grand turn-out. Was queen lost then, as there were several queen-cells? one of quite recent build with jelly in it. No. 3, observatory hive.—Bees covered four bars, one comb of brood and eggs, and one with eggs only, stores in six combs. No. 4, skep.—Bees carrying in pollen. No. 5.—Seven frames well covered with bees, a large amount of stores in six frames, brood in all stages on one comb.—E. B.

Chippenham, March 20th.—Yesterday a magical change in the weather took place here. The icy grip of winter suddenly gave way, and the thermometer rose twenty degrees in twenty-four hours. My hives soon presented a lively scene. My heart rejoiced to see the bees turn out in such strong force, glad, no doubt, to get a cleansing flight, which they much needed. The fields are quite bare, not a blossom to be seen, and only a snow-drop here and there in sheltered gardens; but a few of the bees found forage somewhere, and returned with their first load of pollen, showing that breeding had commenced in the hives.—W. A. WARRILOW.

Olcombe, Ilminster, Somerset, March 20th.—The long spell of bitterly cold weather has now given place to some splendid mild weather, of which the bees are taking full advantage and are cleaning out the hives in earnest. I do not think there is much pollen to be gathered in this part, and I am supplying pea-flour, strewn on tiles, first damped with syrup, with which they appear very glad. I put twenty-two stocks into winter quarters and all appear now very strong and no trace of any disease. One lot, driven at the end of September, I put into a small single-walled hive of $\frac{3}{4}$ -inch wood, not even painted, with two combs of sealed honey and five empty ones. To-day I have transferred them to a new hive on five combs; they have brood in all stages. I put this lot away as an experiment, and quite believed they would not survive the late severe weather.—J. SARELL.

Keswick, March 20th.—The weather here has been something similar to other counties; by other reports perhaps more severe. We had here close on three weeks' frost, and it ranged from 10° to 26°, and on the 1st of March it snowed from Monday till Tuesday evening, and scarcely ever ceased. All the lakes in the district have been frozen over since March came in, and at times it has been very warm in the middle of the day and very tempting to the bees. On Friday the 5th I had not my hives shaded, and they came out in thousands and many never to return; since then I have had them shaded at the entrance with old sacks: I find that darkening the front of hive in this way answers better than a board or slate. Bees' forage is going to be late. Crocuses are only just above ground, arabis is looking very dull, palms are five or six weeks later than last year, and my bed of wallflowers are all killed with the frost. But now the main object is the bees. I am unable to say further than that they are all alive, as they made their appearance on the 19th, and brought their dead out on to the flight-board. But how they are situated for food I am anxious to know, but I dare not examine them till the weather is more suitable. Many of them will have sufficient food, yet, as I did not put them into winter quarters with a stinted number of frames of combs, as I have done other winters,—I suppose this is rather on the let-alone system, but I do not believe in let-alone when breeding gets fairly started. As soon as suitable weather comes I shall encourage breeding and other necessary means to help them forward.—R. PHILLIPSON.

Chester, March 22.—What a climate! A week ago and everything was frost-bound. Yesterday the bees were reveling in glorious sunshine, carrying in pollen to their hearts' content. Numbers in some cases sadly diminished. Now for a little gentle stimulation with rather moist candy, syrup later on.—CHAS. ROBERTS.

Bishop's Waltham, Mar. 22.—At last, after a long spell of severe weather, we have had two days on which the bees have been able to take a cleansing flight. On Sunday, the 21st, and again to-day, my bees have been out quite strong, and I am glad to say that out of my nine hives all appear

to be fairly strong and in good condition except one, and this I fear I shall lose through dysentery. The hive is one I bought in the winter, and I fear was not carefully packed, &c. for winter. Last week on a warm day I looked over some thirteen or fourteen hives, with the result of finding them, I am glad to say, in fairly good condition, and in two or three cases there was a nice lot of brood. But in nearly the whole of the cases feeding must be carefully kept up, for, after the long winter, the stores were nearly exhausted.—A HAMPSHIRE BEE-KEEPER.

Alfriston, Sussex, March 22.—On the 19th we had beautiful warm weather; bees were flying as if it were swarming time. I examined a bar-frame hive, and found brood on four or five frames with plenty of honey. Some of my skeps are rather lighter than I would wish them to be, but I shall commence feeding in a day or two. I have heard of two hives being starved, one a straw skep. I examined afterwards and found no comb in it, only a few dead bees; a fortnight before it had got a nice lot of honey in it. I think that somebody helped themselves to it.—A.

Leamington, 22nd March.—At last the change in the weather has come; and haven't the bees enjoyed it? Yesterday I scarcely remember ever seeing so many on the wing at this time of year; it appeared as though they were all bent on turning out, and in the rush many young bees were knocked down on the cold, wet ground, where they became chilled. Having a lot of crocuses, they were in and out of them to such an extent I never saw before; I counted about eight in one bloom, and many others were the same. It is to be hoped the bitterness of this year's wintry weather will not return.—JOHN WALTON.

Ottershaw, Chertsey, March 22.—My bees up to the present are doing well, and most cottagers I can say the same of. Last Thursday and Friday was a treat to see them. We have *Erica carnea* and *Erica codonoides* in full bloom, and they gathered from it by hundreds.—FREDK. S. FLETCHER.

Lismore, Ireland.—Very cold weather, and a most unusually severe spring for the south of Ireland. In the last fortnight the bees were only out in any numbers on two days. There is plenty of sun, but a perishing cold wind, and the mountains covered with snow. To-day, March 16th, is sunny, with a north-east wind of the most cutting description.—IRISH NOVICE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

REV. — ROUTH.—*Bees, what Race?*—The bees forwarded are as entirely black as will now be found. The traces of foreign blood are only to be observed after critical examination.—F. C.

INQUIRER.—*Bees Diseased.*—A parcel of bright-looking dead bees, including the queen, have been sent me for examination in order that I may report upon the case and state the cause of death. In the absence of any information, beyond that obtainable by microscopic examination of a few specimens which may or may not correctly represent the condition of the whole population, the question is, perhaps, too exacting, but yet sufficient is evident to point to a few particulars touching all interested in wintering. The bees are in some cases apparently diseased. The blood of fifteen was examined, and in four bacilli abounded. A trace of the blood containing bacilli from one worker I placed in a sterile culture tube on Saturday morning, and now (Monday) I have a beautiful crop of short definite forms, certainly neither *alvei* nor *Gaytoni*, and presenting peculiarities of a remarkable kind. (It is worthy of note in a parenthesis that in some respects *Bacillus alvei* is more extraordinary than any bacillus known to science, and that

through it two or three moot points have been settled.) But to return: Have we here a new bacillus? Possibly not. As the bee was not living at the time I received it this bacillus may be merely putrefactive and not pathogenic in character, *i.e.*, it did not attack the bee until after its death, of which clearly it could not then be the cause. This matter can be cleared up, and I intend following it, but it will involve no little labour, which would have been saved if the bee had reached me before death. Correspondents will, therefore, kindly, when possible, forward living bees only, and for these a Benton travelling box is not to be beaten. These bees had not died of starvation, as sugar was found within each, and in most cases large crystals of cane sugar were visible. This would seem to indicate rapid autumn feeding with insufficiently boiled syrup, to which little or no acetic acid (vinegar) or tartaric or citric acid had been added. The crystals may have formed in the bodies of the bees after death in consequence of low temperature throwing the sugar out of solution. A thin hive permitting the persistent cold to chill the bees below the point at which vitality can be maintained may have brought about the fatal result. This winter will, I apprehend, do something towards exposing the fallacy that thin hives are equal to thick ones, but in making comparisons, of course, all the circumstances will have to be considered. That we have now before us twelve or fourteen disease organisms furnished by the bee-hive should not disconcert bee-keepers. Their discovery does not add to their destructiveness, and it may be the means of ridding them of their terrors in every case, for it is reasonable to conjecture that, since all these organisms are near relatives, what will destroy one will destroy the others, of which we have so far a corroboration in the case of *B. Gaytoni*, which yields to phenol, although it seems to be especially likely to attack the queen. In conclusion, I must add that correspondents ought not to expect private replies from me, but if they do they should enclose a directed envelope. As I am willing, in the cause of science and apiculture, to incur so much expense and to give so much time and attention, it is at least fitting that I should be saved needless trouble. Living bees in a Benton box, with a description as short and complete as possible, will never be neglected, and when anything is ascertained a reply in the *Journal* is all that I can promise. That valuable progress, if I am assisted thus, will be made is certain. A new point of great moment with regard to *Bac. alvei* has presented itself, and seems to promise a way of disinfecting combs which will greatly assist the bee-keeper.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

IRISH NOVICE.—*Doubling.*—You can use the board as you propose, but we do not see the use of it. We never use excluders or anything between the two hives. We hope next week to be able to give full instructions for working on this principle. We use the ordinary quilt, and have a cover over, and allow a free circulation of air outside. Raise the hive an inch off the floor-board in front, and this will give the bees plenty of ventilation. Do not trouble about the queen ascending, but give a third or even a fourth storey, if necessary.

A. B.—*Using Hives without Distance Guides.*—Probably your hive is constructed for broad shoulders, as on page 27, *British Bee-keeper's Guide Book*. On page 26, you will see a section of hive used with frames without broad shoulders. To adapt your hive to this style you would have to nail strips of wood on the outside to come level with the top and enclose frame ends.

H. A. PERRIN.—The exigencies of our *Journal* prevent us from carrying out your suggestion, though we would fain do so if we could; perhaps in time we may be able to accomplish it.

F. A. W.—1. *Bee-houses.*—Consult Mr. Raynor's pamphlet on Bee-houses; also Root's *A B C of Apiculture*. 2. A larger size of bees might be a doubtful advantage.

R. E. C.—Your suggestion has already received our very careful attention, but we are unable to undertake it.

A. B.—If there is space in your garden, there is no objection to your having poultry and bees there. Sometimes, when too neighbourly, the poultry will snap up bees;

and on one occasion in our own experience, the bees attacked a brood of chickens and stung six out of seven to death.

INQUIRER.—The drones forwarded have been hatched this season.

BALLIE.—The Secretary of the North of Scotland Apian Society is Mr. Finlayson, of Aberdeen.

COL.—1. *Tin Separators.*—You can get tin cut to your size at any ironmongers, or almost any hive dealer can supply you. 2. *Size of Sections.*—By far the greater number of bee-keepers use $4\frac{1}{2} \times 4\frac{1}{2}$, and if any standard is adopted, it is more likely to be that than $4\frac{1}{2} \times 4$. 3. The bees forwarded appear to be blacks. We cannot, however, judge from one or two bees whether a stock is of pure race or mixed, as, if mixed, some bees will be quite black, others as yellow as pure Ligurians, and others slightly yellow. You can judge better yourself by observing them. 4. *Stimulation.*—Begin at once, and continue gently when commenced, not by fits and starts.

C. W.—1. The sample of American cloth is suitable for use with Simmins' dry sugar feeder. 2. The sugar forwarded does not appear to us to be either too hard or too dry to be used for dry-sugar feeding, and it would be suitable to make into flour-cake mixed with pea-flour. 3. *Spring Stimulation.*—Flour cake is the best while the weather is likely to remain cold and uncertain, as the bees can obtain the all-necessary food for the brood without leaving the hive. 4. *Doubling.*—If you can get eight frames crowded with brood and bees fly 1st May in each of the hives, double at once, and so get fruit blossom honey. If, however, that source is past, or nearly so, by the time your stocks are ready to double, let them go on increasing until just before the next honey flow commences, and then double.

R. C. WILLIS.—*Beginning Bee-keeping.*—We advise you to begin with a simple frame-hive containing ten or twelve standard frames. Such a hive may be purchased for 7s. 6d. or up to 15s. A lesson or two from an expert will be of advantage in teaching the manipulation, which is easily and quickly learned. To a cottager who has little spare time and less understanding, we should recommend the skep, but not to an educated person. Apply to Mr. Huckle for the 'leaflet' *How to Commence Bee-keeping*.

R. L. RICHARDSON.—*Decoy Hives.*—We believe there is in existence an old statute which has never been repealed that renders the placing of hives in a garden as decoys for a neighbour's bees penal. It is a very dishonest practice, but one which, in our own experience, is constantly made use of. If the brace-combs are in a frame-hive when manipulating, cut them all away; if in a skep, it is best to leave them.

We have received from C. G. Harrison, of Halesowen, Worcestershire, his price list of hives and bee-keeping appliances. This catalogue is very comprehensive, and the various hives and other bee-gear are marked at very reasonable prices. We note some well-designed zinc covers for hives, which would secure the desired dryness of hives.

Received from W. T. Falconer, of Jamestown, N.Y., his catalogue of apian supplies. Mr. Falconer's speciality is his Simplicity hives, his one-piece sections, and the Vandervort foundation.

CAMBRIDGE IN NEW ZEALAND.—The food was tolerable; we found for one thing New Zealand honey especially excellent, taken from the nest of the wild bees, which are now in millions all over the colony. They are the offspring of two or three hives, which were kept, when I was at Oxford, in the rooms of Cotton,* of Christchurch, between whom and his bees there was such a strong attachment that a bodyguard of them used to attend him to lecture and chapel [?]. Cotton went to New Zealand with Bishop Selwyn, and took his bees with him, and they have multiplied in this marvellous manner.—From *Oceana*, by J. A. Froude.

* The late Rev. W. C. Cotton, of Frodsham, Cheshire, author of *My Bee-Book*, &c.

WALTON'S COMPETITION.

FEEDERS,
BEE VEILS,
EXTRACTORS,
SECTIONS,

30s. HIVE.

SMOKERS,
FOUNDATION,
KNIVES, &c.,
always in Stock.

PRIZE £4 worth of Goods, to be selected from Catalogue. Limited to 50.

15s. HIVE.

PRIZE £3 worth of Goods, to be selected from Catalogue. Limited to 200.

In order to show the efficiency of E. C. WALTON'S HIVES, and to create a further development of Bee-keeping, E. C. W. has decided to offer the above inducement to intending purchasers. The Prizes are for the largest quantity of Honey, gathered from one of the above Hives in one Season, by fair means, the producer being allowed

Any Person ordering for the Competition must say they are going to compete, or they will not receive a Ticket.

E. C. WALTON will be willing to purchase the Honey produced.

For Description of
HIVES, see 48 page

Illustrated
CATALOGUE
Free
on application.

10s. HIVE.

PRIZE £2 worth of Goods, to be selected from Catalogue. Limited to 300.

to work for Comb, or Extracted Honey, but the quantity of Extracted must exceed the Comb by one-third.

Anyone wishing to compete, must order their Hives before May 31st, and send in their report before Sept. 30th, 1886.

The winning numbers will be published in the *B. B. Journal*.

7s. 6d. HIVE.

PRIZE £1 worth of Goods, to be selected from Catalogue. Limited to 100.

E. C. WALTON, Muskham, Newark.

Special Prepaid Advertisements.

No reduction made for continuous insertion.

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

Situations, Publications, Bee Plants, &c.—Twenty words and under, One Shilling; for every additional Three words, One Penny.

1. **SIMMINS' ORIGINAL NON-SWARMING SYSTEM** includes also other subjects of the first importance to all who hope to compete successfully with present low prices. 2s. 6d., post free.

2. **SIMMINS' METHODS OF DIRECT QUEEN INTRODUCTION**, 6½d. Of the AUTHOR, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, and 127 High Holborn; and J. HUCKLE, Kings Langley, Herts.

MODERN BEE-KEEPING. An Illustrated Handbook for Cottagers. Fourth Edition, considerably enlarged. The soundness of its information, the simplicity of its instruction, combined with cheapness, make this Handbook invaluable to all intending Bee-keepers. Price 7d., post free. J. HUCKLE, Kings Langley, Herts.

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. 3932

WANTED, good Cylinder Extractor, cheap, for Cash. Address The Grange, Hnutspill, Bridgwater, Somerset. E 78

COLLATERAL HIVE, 4 boxes; stand, Neighbour's; Crystal Palace Super; two others; lot, 21s. Several strong Stocks. Address CRISP, Halstead. E 79

FOR SALE, owing to Removal.—A few strong Stocks in capital double-walled Bar-frame Hives, and in Stewartons. Carniolans and Cyprian-Carniolans (Benton's Selected Queens of last year); also Ligurians and Blacks. Also about 20 lbs. of capital honey, and Abbott's 'Little Wonder' Extractor. Address W. BADOCK, The Limes, Brownlow Road, Bounds Green, N. E 80

JOURNAL, three days old, 3s. 2d. and postage a year. Address CRESWELL, Pennfields, Wolverhampton. E 81

STRONG Stocks of Bees in Straw Hives from 20s. each. Bee-house for five Hives, 25s. Also a young Queen Bee. Address WM. LEDGER, Weybridge. E 82

Seventh Edition. Twelfth Thousand.

BEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By THOS. WM. COWAN, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of HOULSTON & SONS, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. HUCKLE, British Bee Journal Office, Kings Langley, Herts.

The oldest Weekly Bee Paper in the World.

Editorial, Notices, &c.

DOUBLING FOR EXTRACTED HONEY AND PREVENTION OF SWARMING.

In order to succeed in producing extracted honey the method adopted must differ considerably from that recommended for honey in sections. Opinions may differ as to the relative values of extracted and comb honey in different localities, but the bee-keeper must consult his own interests and produce that which he finds most saleable. We have successfully produced both and have never had any difficulty in selling either, but we have been forced to the conclusion that if we were going to make a business of it and produce honey in large quantities, we should certainly give the preference to working for extracted honey. On the whole there is very much less work connected with its production, also the quantity of apparatus is considerably reduced and it is of a simpler kind. The principal part of the work is done in spring and autumn, and during the swarming season we are comparatively free; and now that by doubling we effectually prevent the bees from having any desire to swarm, much time which would be otherwise idly spent by them is turned to good account and with profit of the bee-keeper.

To get the largest amount of extracted honey we must have—

1. Strong colonies.
2. Young and vigorous queens.
3. The power of preventing swarming.
4. Hives large enough to allow of the full development of the colony without creating a desire to swarm.

In order to get colonies strong, the bee-keeper must be regulated by the time of the great honey flow in his district and commence preparing his hives six weeks before. It is absolutely necessary that there should be an immense population directly the honey harvest commences, and it is well known that one strong colony will do better than two weak ones; we must, therefore, endeavour to get each individual colony strong. We do not recommend more meddling with bees than is absolutely necessary, and the object of moveable comb hives is to enable the bee-keeper to manipulate his hives only when absolutely necessary. Many do so a great deal too much, and at times when very much more harm than good is done.

We have advocated stimulation and spreading the

brood, and have practised these for upwards of fifteen years with great benefit to ourselves, but both these operations require some judgment, otherwise their object is not accomplished, and instead of strong hives the bee-keeper will find to his mortification that they will be suffering from *spring dwindling*. A celebrated painter was once asked what he mixed his paints with to produce the wonderful effects he did. His answer was, 'With brains, sir;' and so it is that brains must be used to produce the wonderful effects obtained by stimulation and spreading brood.

To a certain extent we are restricted to the size of our hive by the size of our standard frame, and the hives we use contain ten frames and division board, but when this is removed one more frame can be put in, making in all eleven frames, which are placed $1\frac{1}{2}$ inches from centre to centre. Our bees winter in one of these hives, but then the combs are placed from $1\frac{1}{2}$ to $1\frac{3}{4}$ inches from centre to centre, and if properly prepared for wintering in the autumn, by the middle of March we usually find enough bees to cover about eight combs.

In different localities the honey harvest begins at different times, but we take as an example a district where it commences at the end of April or the beginning of May. At the middle of March, when we make our inspection, the outside combs not covered with bees are removed and the remaining combs are closed up by division boards in such a way as to rather crowd the bees. We generally find that, by this time, the bees have already brood on three or four of the frames. We encourage the extension of this by uncapping some of the sealed honey cells and the bees are not disturbed again for a week. The examination of the hive and uncapping the honey cells will have the effect of stimulating the queen to lay; and at the end of the week when the next inspection is made we shall be agreeably surprised to find that the brood has increased considerably. We then examine the combs containing brood, and may possibly find it is all at one end of the combs, and if this be the case every alternate comb containing brood is turned end for end and the hive left for another week. At the next examination it will be found that the brood has still further extended, and that not only are the frames which contained brood nearly covered with it but that the queen has also been laying in those combs on either side of the brood-nest. We then make the combs containing the most brood, and which are in the centre, change places with those containing the least brood, and in this way examine the hives and change about the frames every four or five days until every comb is filled with brood in every part from top to bottom bars of the frames. Of course, if the bees are short of food, as they are most likely to be, they must be fed with syrup.

If there are not enough bees to cover eight frames they must be crowded upon as many only as they can occupy; and as at this time of the year there is danger

from cold we take care that not only are there enough bees to cover every comb, but that they overflow beyond the division-boards into the space containing our spare combs. With this object in view we make our division-boards to reach to within half-an-inch of the floor-board, and when the weather is warm the bees pass under this and fill the space more or less, but when it is cold they return to the brood-nest and protect the brood. If there are sufficient bees to do this—and the intelligent bee-keeper will always take care that there should be—there will be very little danger of the brood becoming chilled. As soon as all our frames are filled with brood in every part of the comb we move the division-board and place one of the spare frames in the centre.

By this time young bees will be hatching out rapidly, and the hive should be full of bees and there should be brood on every one of the eleven frames by the commencement of the honey harvest. We are careful to keep our frames $1\frac{1}{4}$ inches from centre to centre, and thus prevent any attempt at raising drones.

As soon as the honey harvest commences we proceed to double our hives, and there are two different ways of doing this. One consists in selecting two strong stocks and from one of them remove all the combs, shaking and brushing the bees back into the hive. These combs, full of brood, are placed into an empty hive on to the top of the other stock and form a second storey. The lower hive being crowded with bees and the weather warm they immediately ascend and take care of the brood.

Quantities of this will be hatching out daily and increasing the population, whilst every cell, as it is vacated, will be filled with honey, which as soon as capped can be extracted. Although we were amongst the first to use and advocate excluder zinc when working large supers, we have long since discontinued to employ it, as we found that it interfered with the work of the bees, and that we always got much more honey without its use than with it.

We do not mind the queen ascending even to lay, and we have not, for extracted honey, got to consider the appearance of the combs, as those that have been bred in are even better and stronger for use with the extractor than new combs which are more liable to break.

Another plan and which gives us still better results, and has enabled us to get 1360lbs. of honey from seven hives in one season, is by piling three or four hives one upon the top of the other, only one set of brood combs being used to start with.

(To be continued.)

USEFUL HINTS.

Since our last 'Hints' a most agreeable change in the weather has taken place—a change from piercing cold to abnormal warmth—which, however trying to the human constitution, seems to have admirably suited our insect friends. The loss of bee life in many districts, we fear, will be found enormous, as we are not infrequently accosted with such salutations as 'All dead, sir,' or 'Only one or two left and they very weak'—the result, no doubt, of imperfect winter preparations, or total neglect, nevertheless to be regretted as terribly discouraging to the tyros in the art. All—or nearly all—our 'Echoes from the Hives,' Mr. Editor, are of the most encouraging description, and we rarely see losses, and unfavourable items, there described. Is it that such never occur? or are the spectacles of the writers slightly tinged with *couleur de rose*, as your own were said to be on a certain recent occasion? Could you not, sir, establish a 'Blasted Hopes Column,' after the example of your contemporary *Gleanings*? It would certainly be consolatory to some of the unfortunates to know that others had suffered losses as well as themselves. We fancy that even you, sir, will not maintain that art and science have rendered the system of

apiculture, under this 'vile climate,' so perfect that, even in the hands of experts, losses never occur. Pray, sir, consider our suggestion.

ROBBING has been very prevalent since the fine weather set in, so much so that it has been impossible to open hives during the daytime. Continue to manipulate in the evening only. However bright the day, bees at this time of year cease to fly about 4 p.m. when operations may at once commence. All entrances should have been closed ere this to one bee space only. Inadvertently we omitted to reduce the entrances to one of our strongest hives, which was immediately attacked, and the queen encased and destroyed before we could rescue her.

ENAMEL CLOTH.—Our hives experimented upon with this as a winter covering have come through the winter well. The strongest colonies are in a perfectly dry condition with no sign of dysentery. A few of the less populous ones have their outside combs slightly damp and discoloured, but those occupied by the bees are dry and clean, and the bees are active and healthy. Those colonies under carpet or felt have not wintered nearly so well. Consequently we shall in future adopt, as winter covering, the enamel cloth. If bees can pass well through a winter, in which they have been closely confined for three months to their hives under enamel cloth, *a fortiori* they will winter still more successfully during a mild season.

FEEDING.—Continue to feed regularly all colonies which have consumed their winter's supply, of which not a few instances will be discovered by the careful painstaking apiarist. The drain upon the stores of strong colonies, breeding extensively, is enormous. For such colonies we prefer food of the winter consistency for the next week or two. Crocuses and snowdrops are at present our only flora yielding pollen, but soon the elms and willows will supply their place.

UNITING.—Where necessary—as from loss of queen, &c.—unions should be made at once. The following method of uniting queenless colonies with colonies which possess queens has been recommended:—Remove the queenless hive from its floor-board, and place it on the hive which contains a queen, with a sheet of zinc excluder between the two, closing the entrance to the upper hive, and giving a little smoke at the top of the upper, and at the bottom of the lower hive. The operation must be performed in the evening, when the bees have ceased to fly. Leave the hives in this position for twenty-four or forty-eight hours, by which time the bees will have united peacefully. If, on removing the upper hive, bees are found upon the combs, brush them off on to the lower one, having previously removed the zinc. We have operated successfully on this plan without using zinc excluder, and have never lost a queen.

QUEENLESS COLONIES are likely to be more numerous, after the late trying winter, than many apiarists suppose. An examination, therefore, is desirable, and where such are found, as a rule, it is best to unite them to others, fairly strong, and possessing a queen. Delay in such cases is serious, since queenless colonies dwindle rapidly, and encourage robbing and commotion in the apiary. If a queenless colony, however, be strong, possessing brood, it may prove advantageous to introduce a queen, caged upon a frame of brood, in which case she will usually be favourably accepted after twenty-four hours.

COMB-HONEY.—Taking one year with another, we get from two-thirds to three-quarters as much comb as extracted honey, supposing that we adopt the best known methods in both instances. Whatever prices the two honeys command, at those prices comb sells more promptly. Not only in quality, but in appearance, it really has no competitor. To the *taste*, syrups, butter, sauces, may ask for competition, but for the eye—for a table ornament—no edible dare presume to compete with comb-honey. The labour connected with the production

of extracted honey must, almost all, be performed out of doors, amongst the bees, at a busy season of the year, by skilled help. Not so with the production of comb-honey. Sections and crates can be made, foundation adjusted, surplus cases all fitted for the hives, by cheaper hands, in cheaper times. The same is also true of cleaning and crating the filled sections. All can be done indoors, at chosen times, regardless of weather. Surplus comb-honey is handled by cases, not by sections, and there is not more than one fourth of the amount of outdoor labour connected with the production of comb-honey, as compared with extracted honey.—JAMES HEDDON, *Canadian Bee Journal*.

The above remarks appear to us reasonable and true, and we recommend the careful perusal of them to our readers, at the same time reminding them that now is the time for preparing 'sections, crates, foundation, surplus cases, &c.' Very soon the busy time will be upon us. As regards the *quality* of comb-honey, in a long experience, we have invariably found that gathered in May, June, and the early part of July, the finest in quality, *i.e.* in colour, flavour, aroma, and general appearance. After the latter date, as a rule, the colour is much darker, and the flavour inferior. The late gathered honey, therefore, even from sections, is extracted, with us, and put to inferior uses. Its market value is barely half that of good sections. So far have we digressed from our usual routine, impressed with the importance of the subject to apiarists in general.

THINGS IN GENERAL.—Do Italian bees, Syrians, and Cyprians, collect honey in quantity from red clover? We have proved to our satisfaction that they do, although many deny the fact. Mr. Vandervort, an American apiarist, has made a statement to the effect that fifty Italian colonies of his gathered at least 50 lbs. of honey per colony solely from red clover, while the black bees did not gather an ounce. We have found the other Eastern races quite equal to the Italians in this respect, but our experience relates chiefly to the second crops of red clover, usually in bloom during August and September. Can any of our readers confirm our views in this respect?

ADULTERATION OF HONEY.—*Sera nunquam est ad bonos mores via.* The following resolution, passed *nem. con.* at a late convention of the 'New York Bee-keepers' Association,' is most satisfactory:—'That this Association has read with pleasure the public announcement made by Thuber, Whyland, & Co., that they will hereafter put up no more comb-honey in glass jars with glucose around it, which they have heretofore done, to the detriment of the honey industry, and which has subjected them to severe criticism by this Association and bee-keepers at large.' We could have wished that the pledge could have extended to '*jars or utensils of any material whatsoever,*' or rather to an abjuration of the use of glucose, or any other adulterant, in preparing honey for the market.

AMERICAN QUERIES.—Which man seems to know most about bee-keeping—the expert or the beginner? *Ans.*—The beginner, every time. Are not tin separators on the whole the best? *Ans.*—from several *novices*—'No.'

HEDDON'S REVERSIBLE HIVE.—We have been favoured with a sight of Mr. Heddon's book, entitled, *Success in Bee Culture*, in which he describes fully his new hive, and of which he gives several engravings. It consists of an ordinary hive, nearly approaching the Langstroth in size and shape, containing eight frames, and divided into two horizontal sections, each section being reversible as a whole. The depth of the frame is $5\frac{3}{4}$ ins., length 18 ins., outside measurement. On these, which are considered brood compartments, section-frames (also reversible) are used, on the tiering-up system. The frames are close-ended, which in our opinion condemns the whole thing, and are held together by thumb-screws worked

from the outside. The frames, as well as the horizontal sections, are reversible. We should not like to attempt to reverse close-ended frames after they had been in use for a twelvemonth. The hive is on the storifying system, and resembles the Carr-Stewarton, except in the size of its frames and reversibility. This is the hive which is to revolutionise bee-keeping all over the world, and of which the Rev. W. F. Clarke thus writes:—'I shall use no other hive in my future dabbings with bee-keeping. This is what I want and all I want. It is long-looked-for come at last. I have dreamed of a hive like this, and the reality passes the dream. It will henceforth be a luxury to keep bees. The hard slavish work is all taken out of the business, and what remains is merely pastime. The danger now is that bees and bee-keeping will become too common. Everybody will want to rush into a business so inviting. Little honey will "waste its sweetness on the desert air" in the good time coming. Honey will become as cheap as sugar, and will rank among the necessities of life, &c., &c. Happy Mr. Heddon, with his 450 colonies and a large trade in appliances, to have enlisted such a 'Boswell' to sing the praises of the heaven-born hive, for such it must assuredly be, since nothing terrestrial could ever prove so perfect.'

Seriously, we know of nothing more injurious to the best interests of apiculture than this incessant hankering, like the Athenians of old, after something new. No sooner has a man taken up the pursuit and established an apiary than he finds his hives, feeders, extractors, *et hoc genus omne*, superseded and become old-fashioned; and he is told that, in order to keep up with these times of depression, he must discard the old and adopt the new—a doctrine, however comforting to purveyors of apiarian appliances, by no means consolatory, and not a little confusing, to beginners whose means are limited. It is almost enough to make one say, 'Keep to the old skip system of "eke" and "super," and "let-'em-alone," rather than run into all the extravagance and expense of modern inventions, and after all to realise from 6d. to 8d. per pound for your honey.'

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Committee Meeting held at 105 Jermyn Street on Wednesday, March 24th; present, the Hon. and Rev. H. Bligh (in the chair), the Rev. F. G. Jenyns, the Rev. F. S. Selater, the Rev. J. L. Seager, Captain Bush, R.N., Captain Campbell, H. Jonas, J. M. Hooker, D. Stewart, Dr. Walker, W. O'B. Glennie (treasurer), and the Secretary. Letters were read from Dr. Bartrum, the Rev. G. Raynor, and Rev. F. T. Scott, regretting their inability to be present.

Upon the motion of the Hon. and Rev. H. Bligh, it was resolved that after the month of April the Committee Meetings be held on the Wednesday falling on the 15th, 16th, 17th, 18th, 19th, 20th, or 21st, of each month (third Wednesday) at 3.15 (carried). Reports were read—

(1.) From the Examinations Committee, recommending that Saturday, May 15th, be fixed as the date for holding the first-class examination. The Secretary was requested to make inquiries for rooms suitable for the examination.

(2.) From the County Associations' Sub-Committee, recommending that arrangements be made for sending a lecturer to various counties in South Wales, in which County Associations had been recently formed. Captain Campbell reported that the organization of the Surrey Association had been considerably improved, various local committees having been formed in new districts, resulting in a considerable increase of members.

The Secretary reported that a new edition of *Modern Bee-keeping* would shortly be required. Resolved that

a copy be sent to each member of the Committee for revision, and that the Hon. and Rev. H. Bligh, with Messrs. Hooker, Stewart, and Walker, be appointed as a sub-committee to make the necessary arrangements in respect to the final revision and publication of the new edition. The next Committee Meeting was fixed for Wednesday, April 14th, Quarterly Meeting to take place on April 28th.

INSTRUCTIONS AND REGULATIONS to be adopted by the B. B. K. A. in relation to all Shows of Honey and Bee-Appliances held under their authority, and recommended for similar adoption by County Associations, the object being to secure uniformity as to the mode of placing exhibits before Judges, the simplification of the work of Secretaries and Managers of Shows, and the better protection of exhibits.

REGULATIONS.

All entries must be made on the forms provided for the purpose, which, with the declaration thereon, must be properly filled up, and signed by the exhibitor, and forwarded to the Secretary.

Upon the receipt of entry-forms and declaration correctly filled up, address-labels for the despatch of the exhibits to and from the show will be sent to each exhibitor.

All packages of exhibits must have the address-label (forwarded by the Secretary) attached thereto. The name and address of the exhibitor must be legibly written on the reverse side, with proper instructions for the return journey, and no exhibit will be received without being thus labelled.

No prize or other cards awarded at previous shows can be displayed on the exhibit.

No portion of the exhibit to be removed during the show without the consent of the Secretary.

The Judges are empowered to withhold any prizes or to award extra prizes; their awards shall in every case be final. During the judging no exhibitors shall be present.

Hives.—Hives sent to the care of the Secretary for exhibition should be securely packed in crates, opening at the top. The top of crate should be screwed down (not nailed), with as few screws as are necessary for its safe transmission to and from the show. The various parts of the hive, stand or floor-board, body box, super, and cover, should be securely fastened, and a strong cord tied firmly round the hive previous to its being placed in the crate.

When hives are not forwarded in crates, the legs (if any) should be braced together, and the various parts of the hive secured and tied as above.

The number of the exhibit, and the class in which it is intended to be exhibited, must be legibly marked on each detachable part of the hive, previous to its being forwarded to the show: but no label, trade-mark, or name of the exhibitor, is to be placed thereon before the judges have awarded the prizes.

The Committee cannot undertake to repack hives that are not sent in accordance with the above instructions as to packing.

Comb Honey.—Supers should be packed in boxes with a thick layer of straw at the bottom, sides, and top, so as to protect them from sudden jar through careless handling by carriers, &c.

Supers should always be exhibited on stands made so as to prevent any leakage of honey, and also to enable them to be lifted out from the boxes in which they are packed without danger to the honeycomb.

Supers having bars, Stewarton boxes, &c., travel more safely turned upside down. They should be exhibited in this position with the exposed parts covered with glass.

Sections.—Should be packed in exhibition crates, each

section must be glazed on both sides, to protect the honey from the attacks of bees, or other injury. The glass may be secured by metal clips, or with white paper edging, which must not cover the glass or side of the sections more than a quarter of an inch on either side, or in any other neat way capable of easy removal by the Judges. Each section may be exhibited in a small box with glass on both sides, instead of glazing the section itself. Sections for each class must be separately packed with the number of the exhibit and class legibly marked on the package, and on each section included in the exhibit, previous to being forwarded to the show, but no label, trade-mark, or name of exhibitor, is to be placed on any part of the exhibit before the Judges have awarded the prizes; and then only such as are approved by the Secretary.

Run or Extracted Honey.—All run or extracted honey should be exhibited in white glass bottles or jars, all being of the same size and form in each exhibit. They must all be securely corked, and covered either with a metal or other screw top, a metal capsule, or neatly tied over with parchment, or strong parchment, or other paper. The number of the exhibit, and the class, should be legibly marked on the package, and also on each bottle or jar included in the exhibit.

SURREY BEE-KEEPERS' ASSOCIATION.

The sixth annual meeting of the members of the Surrey Bee-keepers' Association was held on Saturday afternoon, the 13th ult., in the large room at the Royal Arms Coffee Tavern, North Street, Guildford. Mr. Archibald Seth Smith, of Silvermere, Cobham, presided, and the room was filled with members, amongst whom were the following:—Mr. T. Chapman (chairman of committee), Captain Campbell (secretary), Mrs. Brownrigg, Mrs. Tickner, Mr. and Miss Bulbeck, Mr. Daw (treasurer), Messrs. F. Lemare, P. Waterer, W. de Lacy Ahern, J. Harrison, J. Siggery, F. Gence, F. S. Fletcher, Milton, J. Elson (expert), Osborne, Browne, J. Browne, of Bramley, W. Williamson, and others. Captain Campbell read the report, which stated that good progress had been made by the Association during the past year; its operation had been extended over the county, and new districts arranged at Sutton, Leatherhead and Cobham, Cranleigh, Haslemere, and Wotton (near Dorking), under energetic local secretaries, with a very large increase of members, making a total of 316 against 211 as reported last year, including forty-four cottager members, who are steadily advancing in knowledge of bee-culture, though better opportunities of disposing of their honey and wax are greatly to be desired. The annual county bee show was held at Sutton on the 12th August, in the grounds of Mr. H. L. Antrobus, in conjunction with the Sutton and Cheam Horticultural Society's Show, and proved to be by far the largest and finest show of honey and appliances that had ever been exhibited in Surrey, but through bad weather in the afternoon all hope of a financial success from the show had to be abandoned. The silver and bronze medals, and the certificate of merit of the British Bee-keepers' Association, were respectively awarded to Mr. W. Hollands of Croydon, Mr. J. Chater, and to Mr. F. Hewetson, of Sutton, and the certificates of merit of the Surrey Bee-keepers' Association to Mr. H. Lyndon and Mr. Nixon, of Sutton, and a sum of nearly 30*l.* was given in prizes at Sutton, Croydon, and other shows. The bee-tempt of the Association was in constant demand during the summer. Honey shows and honey fairs were also held at Croydon, Chobham, and Bagshot, but the severity of the winter prevented the usual number of winter lectures on bee-culture being given. The visits of the cottagers' expert (Mr. James Elson) had been much appreciated. The financial results of the past year were not so satisfactory, but showed a deficit of 8*l.* 15*s.* due to the treasurer,

but there were no outstanding liabilities, and there was property to the value of 35*l.* in hand. The committee acknowledged with special thanks a donation of 10*l.* from their president (Mr. J. Steward Hodgson). The report was adopted, and the committee and officers re-elected, Mr. T. J. Witt, of 44 Dingwall Road, Croydon, and Mr. William de Lacy Ahern, of Sutton, being elected as representatives at the meetings of the British Bee-keepers' Association. Captain Campbell then read notice of a motion, which he explained would give those who paid 5*s.* and upwards the service of the expert free, and that the *Bee Journal* would be circulated weekly to all who paid one shilling a-year for two days' reading, it being sent free to all cottagers who wanted it. The first motion was carried unanimously, and the second was also carried, after some discussion, in which Captain Campbell explained it was not his proposal, but the committee felt it was needed from the state of the funds, and that it was for the members present to decide yes or no. After a vote of thanks to the chairman and officers for the past year, the business concluded. Mr. Ahern read a paper upon the advantages said to be obtained by reversing the combs in the hives, and quoted the results of several bee-masters who had adopted it. Captain Campbell moved the thanks of the meeting to Mr. Ahern for his paper, Mr. F. Lomax seconded the motion, which was carried by acclamation. A general conversation followed, and after tea had been served, the meeting concluded, much anxiety being expressed as to the prospects of a honey harvest after so severe and long a winter.

THE LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

The Fourth Annual Meeting of this Association was held at Liverpool on March the 9th, and was well attended. The new and rapidly growing Lancaster Branch was well represented, and great interest was manifested in the proceedings.

Mr. Sitherley having been voted to the chair, the statement of accounts for the past year was brought under discussion, and was approved of. It showed a balance of assets for the new year of 13*l.*, which, with the present depression of trade, and the Association's heavy outlay for expenses of shows and expert's visits to members, was considered very satisfactory. There has also been a considerable increase in the number of members during the year.

The results of the election for the new committee were then announced, Mr. C. P. Sitherley being elected chairman for the year. The Earl of Lathom was re-elected president, Captain Cotton, M.P. for Wirral, patron, and amongst the new vice-presidents elected were the Mayor of Liverpool, the Mayor of Chester, and Canon Blundell, who have consented to hold office in the Association for the present year.

The Rev. J. F. Buckler next moved that the Executive Committee be elected in future at the annual meeting, and that only six of the Committee retire each year.

A good deal of discussion ensued, and ultimately an amendment, proposed by Mr. J. P. Jackson and seconded by Mr. W. Broughton Carr, was carried to the effect that such election take place at the annual meeting, but by ballot, and with the use of proxies; also that all the members of the Committee retire each year, but be eligible for re-election.

An important equalisation of the franchise was also proposed by the Rev. Mr. Buckler, and was carried unanimously, namely, that all members of the Association have equal voting power, and that no distinction be made in the number of votes to be given by five-shilling as distinguished from twenty-shilling subscribers.

Various other routine and minor matters having been attended to the meeting closed with the usual votes of thanks.

R. F. ANDERTON, } Hon. Secretaries.
J. F. LITTLE, }

Selected Query.

[222.] Which do you consider the best sized sections for general use, and which are the most saleable?

We have always used $1\frac{1}{2} \times 4\frac{1}{2} \times 2$ for one pound, and $6\frac{1}{2} \times 5\frac{1}{2} \times 2$ for two pounds. When visiting shows we have noticed more of these sizes than of all other sizes put together. We have always found the small sections much more saleable than larger ones.—E. H. R.

The $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ section is undoubtedly the best size for general use, and also the most saleable size. For 2 lbs. I like the $6\frac{1}{2} \times 5\frac{1}{2}$ size, as when they are well filled they contain 2 lbs. net.—W. WOOLEY.

The $4\frac{1}{2} \times 4\frac{1}{2}$ for both purposes.—J. GARRATT.

For 1-lb. sections I prefer the dimensions $1\frac{1}{2} \times 4\frac{1}{2} \times 2$. For 2-lb. sections $6\frac{1}{2} \times 5\frac{1}{2} \times 2$. These sections are so generally used, all the world over, that I consider the B. B. K. A. would act wisely in establishing them as its standard sections. One-pound sections are most saleable.—G. RAYSON.

The $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ bars are best and most saleable if separators are used in the racks.—JOHN M. HOOKER.

One-pound sections are the most saleable when well filled; but they are not worth the trouble of producing at present prices.—R. B. GORNEY.

I find the $1\frac{1}{2} \times 1\frac{1}{2}$ 1-lb. sections the best for general use, simply because they are the most saleable, and also the most convenient size for use on our own table. The 2-lb. sections are certainly most readily taken to by the bees.—P. H. PHILLIPS.

The $4\frac{1}{2} \times 4\frac{1}{2}$ sections are, I believe, not only the most generally used, but the most convenient; and being readily saleable in any market I consider them preferable to any other for general use. I have long since ceased to use other sizes, except 2 lb. ($5\frac{1}{2} \times 6\frac{1}{2}$) for exhibition, and those I have always had to consume at home or give to friends.—C. N. WHITE.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are expected to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the library department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Streeter, Pears and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

PLANTS FLOWERING IN APRIL.

[223.] The April bee flora will be composed, to a great extent, of those that usually flower in March. The following sorts will flower during this month: crocus, willow, alder, blackthorn, myrobella plum, Ulex auribotia, wallflower, cherry, red flowering currants, gooseberry, pears, plums, apples, phacelia, and borage (autumn sown), &c.—H. Y. DOBBIE.

FOUNDATION FOR SUPERS. [186.]

[224.] I fail to see the superiority of naturally built combs in sections as compared with those drawn from full

'Production of comb honey with and without separators in wide and narrow sections.' This was the subject of an address by L. S. Newman of Florida, N. Y., at the Convention of New York State Bee-keepers' Association, held at Rochester, N. Y., on February 16th. The sense of the meeting was afterwards taken on 'The use of separators.' The Association expressed its preference for separators. In Selected Query No. 1, the question of the use of separators was raised, and the above may be taken as a valuable addition to the several replies thereto.—JOHN M. HOOKER.

sheets of thin foundation, notwithstanding the remarks of Mr. Sharp [186] and also those of 'Amateur Expert,' p. 117, present volume.

When I offer a customer sections of comb honey, I find those combs are required which appear to be *most completely filled*, and I am sure both of the above-named correspondents will admit that combs built from starters *are never* built out and filled closely all round, as is the case when a full sheet of foundation is used, allowing no bee-passages or 'pop-holes' whatever. Particularly is this the case where, by my new process, every section is completely filled with comb, whether previously built from foundation, or naturally, in the larger brood frames.

Contrary to Mr. Sharp's supposition, I *do* use, and recommend, natural combs for sections, but not as being superior to those built on foundation. By careful management, many such can be obtained in brood-frames, and should then be fitted into sections close all round, allowing no bee-passages whatever; but I repeat that no bee-keeper will be able to compete with present prices, if he expects to have natural combs built from starters only in sections; and, moreover, no bee-keeper of the future will follow such a plan, if he intends to produce comb-honey at a wholesale rate.

I candidly admit that in producing large quantities of comb-honey of the first grade, I cannot dispense with foundation, but it must be of the *right kind*, and even thicker than is generally supposed to be necessary for section-honey.

While using foundation 'ten-feet to the pound' I could find nothing better than the flat-bottom 'Van Deusen;' but requiring my combs first built out in full sheets in brood-frames, I looked about for something stronger, and at the same time a foundation with a base equally as thin, but with the side walls much heavier. I find that known as 'Pelham' a more suitable foundation than any I have tried; it has a very thin base, while the side walls never having received the slightest pressure, are soft and pliable, and, therefore, are drawn out as thin as can be desired. Instead of ten-feet as before, I am now able to use the 'Pelham' eight-feet to the pound: and so far from the judges and consumers being able to detect the difference, I have known of the highest honours being gained by most perfect combs built upon 'Pelham' foundation of even greater weight to the pound.

Mr. Sharp endeavours to draw distinctions which are simply imaginary, and, moreover, such as are likely to do incalculable injury to the honey trade. If sections naturally filled are absolutely pure, so also are those built upon natural wax remoulded by man; and no one need be ashamed to state that he uses such, but when it comes to saying that those without foundation are the only kind which can be recommended as pure British honey, we shall indeed be verging upon the 'ridiculous.'

Mr. Sharp brings in the subject of extracted honey, which has nothing whatever to do with our present discussion; but he expects to obtain such as soon as the first honey-glut occurs, about the middle of June, while he 'hopes'—a forlorn hope—to obtain what little section honey he requires *before* the honey-glut occurs. I should have thought Mr. Sharp was aware of the fact that no comb honey can be obtained unless the state of the atmosphere is such as to cause the secretion of nectar in large quantities, hence the term 'honey-glut;' and if he obtain any section honey from fruit bloom, &c. early in the season, it will most certainly be done *only* during a 'glut.'

It is not generally known that the month of May is the one above all others when honey is most abundant in many localities, and more frequently it is not the much-abused weather, but the backward condition of stocks at that early date, which really is to

blame. Until last summer, for many years in succession, I found there was not a single year but what (in the South of England) honey was obtained in considerable quantities during some part of May. It is not always fruit-blossom honey that is obtained in this month, even in good fruit-growing districts. If the bee-keeper will take the trouble to look round, he will find what is of far greater value—many acres of yellow trefoil, from which much of the so-called fruit-blossom honey is derived. Last year the wind held so persistently to the N.E. that little or no honey was obtained until the first week in June. An easterly or south-easterly wind, however, is always favourable to the secretion of honey during the latter part of May, becoming at that time quite hot; and, besides the trefoil, we have at the same time the sycamore, one of the very best honey trees. The plant and tree mentioned are of more value during May than any gorgeous show of fruit bloom, which latter I am satisfied does not produce anything like the amount of honey generally supposed to be derived from that source alone.—S. SIMMONS.

ROBBING.

[225.] The above being an evil which not only the inexperienced, but also the advanced bee-keepers, have to contend with, I venture to give what I believe will be a useful hint to anyone who may at any time be placed in such a critical position as I once all of a sudden found myself to be.

In the latter part of September, or the beginning of October, of 1884, I purchased twenty stocks of bees in straw skeps, which were brought to me by road a distance of about nine miles, reaching me about midday, that being the only time of the day at which I could attend to the unloading and liberation of bees. They were carefully packed mouth upwards, covered with coarse canvas, and were conveyed in a carrier's large spring cart. As each stock was handed to me and turned right way up, I was very careful to put my hand under the canvas to ascertain if the combs were all secure, and was pleased to find that there was no sign of a single comb having given way. The hives were set up in a row, and after a little time the bees were liberated, and by the time I left my apiary all was comparatively quiet.

I was gratified with the success that had accompanied the transition of bees, and congratulated myself upon the bargain I had made, but which ultimately turned out to be a profitless one. In the afternoon the sun came out very hot, and not knowing what effect it would have upon my enlarged apiary, I thought it would be advisable to go in my tea-time and have another look at my newly-purchased stock, and thus make doubly sure that all was right; but when I reached my apiary I found to my horrible surprise that during my absence the combs of about a dozen of the hives, all heavily laden with honey, had broken down, and that honey was running out of the hives very freely! My apiary was all alive, and robbing was going on at a most terrific rate. What to do I did not know. I knew, theoretically, of a hundred-and-one ways of dealing with robbing, all of which in such a critical moment appeared to be altogether impracticable. At first I thought of narrowing entrances to the utmost extent, but when I took my smoker to clear away the bees to admit of such being done, my hand, smoker, and legs were instantly covered with a cloud of bees,—a more critical position I as a bee-keeper was never in. My apiary consisted of nearly sixty stocks of bees, which represented several years' hard earnings, and I was quite certain that unless I could instantly and effectually stop the malady, I should run the risk of my whole apiary being quickly destroyed. As I stood with my studying cap on, as the saying is, trying to devise some speedy remedy, my eye

fell upon a large heap of grass which I had mown a day or two previously. This was quickly utilised, every skep being entirely covered up so as to make it look like nothing more than a heap of grass. The result was of a magical character, robbing not only at once ceased, but the robbers did not even stop to lick up the honey which was laying around the hives in large quantities under the grass. Next morning the broken combs were taken out in the quickest possible manner, each hive being again covered up with grass, and later on the bees were united and put into frame-hives. Since then I have never suffered through robbing. If I see any signs of such, I cover up the hive with grass, hay, or straw, hanging it rather loosely over the entrance so that the rightful occupants can find their way in and out, but through which the robbers dare not pass. A few days later on the covering is removed.—A. SHARP, *Huntingdon*.

THE ZULU QUEEN.

[226.] Alas, alas! She is now the dear departed, though the carriage from South Africa was only 4s. 6d. When I first cast my longing eyes upon her I could have said, with ancient Pistol, 'A fountra for the world and workings' bees! I speak of Africa and golden queens.' Lovely was she in life: her golden bands shone like burnished plate, and now she is no more—alas! poor Zulu.

Why she deceased I know not, unless the bees suffocated her when in the cage. When I reared her she was perfectly lively, and there was plenty of honey unsealed. She was not 'curled up on the floor,' but was extended in the cage. So her death was not due to a sting from one of the worker-bees.

Introducing foreign queens is always ticklish work. To put it mildly, they stink like badgers; and bees, though accustomed to their own scent, don't hanker after a nigger.

Here were my blessed bees, queenless, and not a drone egg even laid! A sweet young thing is introduced to them, with proper formalities, and they treat her with such disrespect that 'there burst her mighty heart.' Don't you think, Mr. Editor, that it would be a good subject for discussion at a Quarterly Conference? Is the idiocy so common to the human race (including doctors) analogous to, or homologous with, the prevalent predisposition of worker-bees to ball a strange queen?

Thou art dead as a herring, my beauteous Zulu—

A herring, I mean, that is real;

The cause of thy death I wish that I knew.

Though it would not bring thee back from the dead.

How the news of thy death will grieve Dr. Stroal!

For 'tis the pity, the pity, heigho!

My sorrow is deep, my wailings are loud,

You are as dead as Cetewayo.

(GEO. WALKER, *Wimbolden*.)

HUNTLEY & PALMER'S HONEY CAKE,— COCOA-NUT CANDY.

[227.] In the *Confectioner* for February 20th, 1886, is a paragraph to the effect that Huntley and Palmers are bringing out a new honey cake, and are advertising for twenty tons of honey per week. Is this so? or is it an echo of the honey-drop business of Healthies fame, which has only now reached the ears of Mr. *Confectioner*?

In the same number is a recipe for cocoa-nut candy, which without the cocoa-nut, or with pea-flour substituted for it, is just the thing for bees. Here it is:—6lbs. of white sugar, $\frac{1}{2}$ oz. cream of tartar, slightly over a pint of water. Boil to "soft ball"—248 by thermometer. Rub against side of pan with the spatula until it becomes white, then add cocoa-nut chips (or pea-flour) and turn out on to the slab, or into moulds. Notice the low degree to which it is boiled—not until it sets hard and brittle.—F. LYON.

SPRING STIMULATION.

[228.] May I trespass upon your valuable space to make a few remarks on the above?

I quite agree with Mr. Simmins that stocks should be fed in the autumn, especially in districts where the honey harvest is over by the middle or end of August, so that each stock should have at least enough stores to carry them over to the end of March, as I do not believe in letting my bees feel that their stores are running short, as if this should happen at any time breeding is carried on, breeding would be checked and young grubs cast out, which would be a great loss.

A strong stock with plenty of stores may give good results on the 'let-'em-alone' system, provided that there is an early supply of honey and pollen to stimulate them before the regular honey harvest sets in.

But in a country like we have here, where there is hardly anything for our bees to have before the appearance of fruit blossoms (as it is grazed by sheep), it is a great benefit to stimulate our bees to early breeding in order that they shall be strong enough by the time fruit trees will be in bloom. But as for weak stocks, these without being stimulated would give hardly any surplus honey till the best part of the honey harvest is over.

Of course there are rules to be attended to in spring stimulation as well as with any other undertaking, and if these rules are not kept it is sure to turn out a failure, and the bee-keeper has no one but himself to blame. There are a few rules which I think are very important:—

1. Never commence to feed too early, six weeks before the appearance of apple-blossoms is quite early enough.

2. Feed slowly; about a gill a-day is sufficient to commence with. The right quantity is the most difficult for a beginner to arrive at, as it is not the same quantity that will suit every stock, although they be equal as regards stores and number, as will be seen by the following:—I had a twin hive with a stock at each end, both covered six standard frames. Commenced feeding both on April 2nd, and gave same quantity to each. Opened in a fortnight's time to examine—both doing well, but No. 1 contained considerably more brood than No. 2. Opened again in another fortnight; found No. 1 in a most flourishing state, but No. 2 was so thoroughly clogged with stored syrup, that there was not a single cell for the queen to lay. This is a hint to beginners to be very careful to see that the bees do not store any of the syrup, as if they do it shows that there is a deficiency either in the supply of pollen or in the laying powers of the queen. If it is that of pollen, it should be given to them; if it is that of the laying powers of the queen, the remedy for the time being is to lessen their feed, but I need not say that this queen should be superseded at the earliest possible convenience.

3. Do not be in too much of a hurry about spreading the brood. A beginner should never early in the spring attempt to introduce an empty comb into the centre of the brood nest. This, perhaps, would be all very well with an experienced bee-keeper, but in the hands of a beginner might be harmful. All that is necessary is to exchange the combs already in the brood-nest, *i.e.* take the comb containing the least brood in the place of the one containing the most.

4. Do not open the hives too often, and only on a fine warm day.

5. Do not cut off their feed all at once, but gradually lessen it; and, as far as my experience goes, if the foregoing rules shall be kept the bees will amply repay you for all the trouble and expense in the extra amount of honey which will be obtained from them.—H. P. JONES, *Llanerch, Dinas Mawddwy*.

HOW TO PREVENT AFTER-SWARMS.

[229.] Seven days after the first swarm has issued (I do not care for artificial swarming) I listen very attentively

for the 'piping' of the queen. It may not be heard very clearly until the eighth, ninth, or tenth day; but when two queens are heard distinctly 'piping' to each other (and this can invariably be heard in every hive where there are queen-cells) I open the hive and take out each frame carefully, and cut out all the queen-cells I can find, placing the bars back as I do this in the same order as before. I always find that the day after this manipulation the bees that were idle ascend into the super and work away in right good earnest, giving up all thought of swarming. If I do not want to keep any swarms I return my *first* swarms to the parent stock again just before sunset on the day they have issued, killing the queen, and manipulating on the parent hive as before mentioned to prevent further swarming. This has been my practice for more than six years, and has answered admirably; I have never as yet had a mishap. It may be a novel way, and perhaps an absurd way, to more advanced bee-keepers and 'bee-masters,' but to me, a *very humble bee-keeper*, it is less trouble, and the easiest way to prevent after-swarms and obtaining more honey. On the average I obtain 56 lbs. of the very best honey from each of my stocks, leaving sufficient to carry them safely through the winter.—THE MANAGER, *North Cornwall Apiary, Rowe, Bodmin, Cornwall.*

PREVENTION OF SWARMING.

[230.] The late vicar of a neighbouring parish was devoted to bee-keeping. He had two sons who were not. During his absence the bees were left to the inattention of these two boys, and as above all things they hated living a swarm, but dare not lose one, they adopted the following effective method of prevention:—When the bees showed signs of swarming, they took it in turns to watch, provided with a chair, jug of beer, tobacco, a bucket of water, and a good syringe: as soon as the bees came pouring out they were met with a discharge from the syringe, and required no more for that day, probably thinking the weather not suitable for a change of quarters.—VICTOR.

QUEEN-RAISING IN SMALL APIARIES.

[231.] 'Always have young queens' in full profit' in your hives.' This we know as one of the most important rules for successful bee-keeping. And to obtain these young queens, and of the best strain, in an apiary of some size, no directions can possibly be clearer or better than those Mr. Cowan gives in the *Bee-keeper's Guide Book*.

But in a small apiary—say, one of four stocks—a very common number for amateurs who merely want honey for their families and friends, what is the best process? I would invite answers to this query.

If I had that number of hives I should certainly grudge devoting, even for a time, the best of them to the raising of queen-cells, and another good one to the raising of drones. At the most I should only want two queens a-year, but at the same time I should object to buy them. I should want them home-grown. The question then is, how these are to be obtained and substituted for old queens with the least possible loss of valuable time in the honey season?—F. G. JENYNS, *Knebworth.*

EARLY QUEEN REARING.

[232.] *March 17th.* This being a glorious day, an unclouded sun, raising temperature to 60°, and bees flying after their long imprisonment as merrily as in June, I took the opportunity of examining my seventy-five colonies. Blacks have stood the past severe weather without a single failure and are still well provisioned. Ligurian nuclei, five have succumbed, although autumn-reared bees were plentiful, to crowd five and six frames

each hive. These were headed by home-reared and purely fertilised queens. Strange, other stocks headed by last autumn-imported Ligurian queens are flourishing, having eggs sealed and hatching brood. I may here say half my hives are single and half double walled, and the fatality of the nuclei was 3 to 2 in the latter.

Those who are interested, single walls v. double in point of economy, may have satisfaction to know I found the single walls containing Ligurians and blacks far ahead in point of brood; one especially so.

This has a queen now heading about $\frac{3}{4}$ lb. of bees which queen was introduced so late as the middle of September last. Finding these bees had consumed nearly all their stores, and wonderfully active (I was manipulating without smoke), I looked still further to see in what measure I should replenish, when I beheld a queen-cell, well and truly sealed, amid other brood. Judging robbers might have killed her lawful majesty, I took the queen-cell as a case of emergency, this causing me to be more fully satisfied concerning her fate. No sooner the thought than I espied her highness taking her usual quiet walk amid her company; concluding, therefore, the queen-cell was tenacious, I proceeded to remove it, first carefully lifting the capping, when, to my astonishment, I found the larva (I now enclose) well matured and developed, leaving when withdrawn a good supply of royal jelly, pointing most conclusively that in a few days another queen would have been within that home. What her mission I know not, for at least four or five weeks would elapse ere in the course of nature she could be fertilised. Maybe her mother would have found her a job, drone-producing.

Two years having elapsed since Mr. Simmins gave his Economic hive in *B. B. J.*, of January 15th, 1884, which then was most adversely criticised, it is but fair to say my single-wall hives are his pattern, and the forward state of bee life (after the past long, long cold spell) in same, proves all Mr. Simmins then claimed. The shape of roof was pronounced unsafe against weather, damp, &c. My experience has been otherwise proving no better weather-resisting and damp-proof roof exists. When properly made, such would bring comfort to the many who corresponded upon dryness of hives.—ROBIN HOOD.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[212.] *Boiling.* (J. C. B.)—Syrup for spring stimulation can be made without boiling, thus:—Put the water into a deep vessel, such as a jug, tie the sugar in a muslin bag and suspend it to a stick laid across the jug, so that it is just under the surface of the water. If arranged overnight the syrup will be ready in the morning. It will require stirring, as the lower part will be denser than the upper.—F. LYON.

[212.] *Boiling.* (J. C. B.)—Yes, by pouring boiling water on the sugar and stirring until the sugar is dissolved. If you have a cylinder extractor make a good stock at one mixing and use the extractor for the purpose. You can 'stir' it so famously; I confess I prefer boiling.—AMATEUR EXPERT.

[212.] *Boiling.* (J. C. B.)—Yes, by suspending the sugar in a cheese-cloth in the water, it will gradually dissolve, or by using the sugar in a feeder constructed for such a purpose; these feeders are to be obtained of most dealers in apiarian supplies.—W. B. WEBSTER.

[213.] *Curing Dysentery.* (Young Bee-keeper.)—Now that we have got some fine and warm weather your skeps will become free from dysentery, if you will remove floor-boards and give them nice clean dry ones. See that the skeps are not damp, if so uncover and let the sun dry them.—W. B. WEBSTER.

[213.] *Curing Dysentery.* (Young Bee-keeper.)—Mr.

Cheshire has something to say presently as to the cause; this will probably lead to a remedy. Doubtless your bees are already better, although probably the effects are seen in undue mortality. Use salicylic acid in your food.—AMATEUR EXPERT.

[213.] *Dysentery.*—If the weather in Young Bee-keeper's district has been anything like the glorious change we have had here during the past week, I expect his bees are nearly cured of the dysentery ere this; if not, feed with thin syrup with a little salicylic acid added. It will help them and cannot harm them. Be careful in feeding and not expose any food, or you may start them robbing.—WOODLEIGH.

[213.] *Curing Dysentery.*—Having had a stock of bees suffering from dysentery this spring, which I transferred to clean hive and fed with syrup, made as follows:—1 lb. of sugar to half pint of water, and scrape into it a small quantity of the inner bark of the oak and let it boil a few minutes. I have tried this, and my bees soon got quite healthy and are now breeding well.—A. J. BROWN.

[214.] (Young Beginner) and [221.] (Villager).—*Disinfecting after Dysentery.*—Expose the combs to the fumes of burning sulphur, and then freely to the air.—F. LYON.

[214.] *Dysenteric Bees.* (Young Bee-keeper).—Clean them with carbolic soap and dry them perfectly. If the combs are in a very bad state I should melt them down; but if not, clean them as much as possible and the bees will finish the rest.—W. B. WEBSTER.

[214.] *Dysenteric Bees.* (Young Bee-keeper). Thoroughly disinfect the hives with carbolic acid, and try and air them well before placing bees into them again.—AMATEUR EXPERT.

[214.] *Foul Hives.*—Thoroughly cleanse them with carbolic soap and water and stiff fibre brush à la housemaid, rinse with clean water, and when dry return your bees on as many frames as they will cover. Feed gently, and give extra frames as required.—WOODLEIGH.

[215.] *Skeps.* (Young Bee-keeper).—Yes; place your super of shallow frames on the top of skep, in the same manner as done with rack of sections when working them on skeps. Make as large a hole as possible in bottom of super and top of skep; the bees will go up with more despatch if such is made larger than the size usually found in straw hives.—W. B. WEBSTER.

[215.] *Skeps.* (Young Bee-keeper).—It would not be very profitable, as you would enlarge the hive so considerably at one stroke, cut your nine-inch boxes in half and try four-inch frames instead.—AMATEUR EXPERT.

[215.] *Skeps.*—It may be possible, but I don't think practicable, unless over Baldwin's low skeps.—WOODLEIGH.

[216.] *Ligurianising.* (F. A. W.).—If you care to go to the expense of purchasing mothers for all your hives and introducing one to each (not forgetting that you will sure to have some failure when introducing) that will be the quickest and earliest way of Ligurianising all your stocks; if such an expense is an object you will have to start nuclei and rear your mothers from two or three purchased and introduced. See answer to Query 159, March 11th.—W. B. WEBSTER.

[216.] *Ligurianising.* (F. A. W.).—By ordering fifty queens at once for earliest safe delivery and introducing them to your stocks, and after you have succeeded be rewarded by a fit of remorse, 'Vanity of vanities—all is vanity.'—A. E.

[216.] *Ligurianising.*—Order your Ligurian queens and introduce them direct, first depositing your reigning queens. I should advise doing so in batches of say ten hives at a time.—WOODLEIGH.

[217.] *Stinging Gloves.* (Rector).—I have just had a pair sent to me by the manufacturer for my inspection and opinion, which no doubt would suit your purpose exceedingly well. The bees cannot fix their stings into the leather, being prevented from doing so by the wool which has been left on the leather and made up with same outside. I can inform you where to get them.—W. B. WEBSTER, *Wokingham, Berks.*

[217.] *Stinging Gloves.* (Rector).—The best way of preventing bees stinging gloves is to wear none. They are worse than useless, being great hindrances to manipulation, and when once stung retaining the smell of the poison and inviting further attacks.—F. LYON.

[217.] *Stinging Gloves.* (Rector).—Use two pairs of gloves, the outer pair of very fine smooth cotton texture, and keep them well wetted with water. You have a feeling heart as well as tender-skinned hands. Throw away your gloves, turn up your shirt-sleeves and secure them with an elastic band to prevent the bees from crawling underneath and save the lives of your poor bees.—AMATEUR EXPERT.

[217.] *Stinging Gloves.*—Has 'Rector' tried a little carbolic acid to scent his gloves with? perhaps that may induce the bees to run rather than flight. I think bees are more prone to stinging gloves than the naked hand. I examined all my hives the other day without gloves or veil, and I did not get a sting. Move your hands slowly and deliberately among your bees, avoid jarring as much as possible, and with steady hand and good nerve you will soon relegate your gloves to the tool-house for occasional use in training the rose-trees over the verandah or harbour.—WOODLEIGH.

[218.] *Drones, Ligurianising.* (Victor).—(1) After the swarming season is over, usually the latter end of July, that is presuming the hive to be in a normal condition; (2) Do not understand this query; if you purchase two fertilised mothers they will not mate again, this only taking place once in a life. (3) Yes, the progeny of a Ligurian, crossed with a black drone, are the best for honey gathering.—W. B. WEBSTER.

[218.] *Drones, Ligurianising.* (Victor).—(1) When they cease to require their services; (2) purchased Ligurian queens should be fertile, and consequently would not require the services of a drone; (3) Yes, yes.—AMATEUR EXPERT.

[218.] *Drones, Ligurianising.* (Victor).—1. When the influx of honey is at an end, generally first or second week in August. 2. Yes, if you are content to wait until the following season to possess Ligurian stocks. 3. Yes. And to second part, Yes, again. A first cross is fully equal, or even superior to the pure race. F. LYON.

[219.] *Obtaining Honey.*—A two-storied hive would be far better for obtaining extracted honey; for section honey, a hive containing ten, twelve, or fourteen standard frames (according to size of colony), with room to use two crates of sections one above the other, would be best.—WOODLEIGH.

[219.] *Obtaining Honey.* (M. C. H.).—Your query was answered in last week's *Journal* (Selected Query 183) by eight of the best (?) bee-keepers the kingdom has produced. Happy bee-keepers to be so well cared for!—A. E.

[220.] *Honey Comb Designs.* (Apis).—The first one I saw was three years ago, but who produced it I cannot say, I believe it emanated first from Scotland.—W. B. WEBSTER.

[220.] *Honey Comb Design.* (Apis).—As these fancy combs were exhibited at Rutherglen, Aberdeen, and other parts of Scotland, perhaps they were first designed by some ingenious member of the McNally family.—MELISSA.

[220.] *Honey Comb Designs.* (Apis).—Honey comb designs have been in vogue for many years on a small scale, but only within the last five years have they developed to any extent. To Messrs. William and Richard McNally, of Glenluce, N.B., is due the honour of the invention, the former of whom was the first to bring out the idea of letter-printing and other artistic designs. These gentlemen have won during the past five years, under the name of W. and R. McNally, all the leading prizes offered for that work and still continue to make designs a special feature in the hobby of bee-keeping. It is believed, however, the idea was first brought out by our American consins.—W. SMITH.

[221.] *Disinfecting Skep.* (Villager).—I suppose that you are uncertain what caused the death of the bees, as there was a sufficiency of stores. If from cold consequent on depopulation, you would be quite safe in putting a swarm in, but there is the possibility of its being from some description of disease of an infectious character; if so, it would be folly to do so. I should melt the combs down and spring feed my other bees with the honey; after diluting and boiling it wash skep with carbolic soap.—W. B. WEBSTER.

[221.] *Disinfecting Hives.*—Brush all the dead bees out with a feather from between the combs, then put a lump of camphor in and tie the hive in a piece of canvas, hanging it up in a dry room till June. Then before you put your swarm in, cut a good sized hole in crown ready for supering, put in your swarm, and next day put on your super.—WOODLEIGH.

Queries.

[233.] Can a summer drinking beverage be made from honey, and how? What is mead?—EAST CUMBERLAND.

[234.] Will some practical painter kindly give full directions how to mix paint suitable for hives, the proportions of oil, turps, lead or other colouring?—W.

[235.] Can some one give price and size of Willesden cards, recommended as a covering for hives?—W.

[236.] *Lovely Queen*.—On March 23rd I visited a neighbour's apiary, and there I found one of his hives containing a very fine young queen, a few combs, a thimbleful of honey, but not a *single worker*. The queen was rather weak, but she ate well of honey that was given her, and in about one hour she regained her strength. Can any one give a reason for this? Is it not a rare occurrence for a queen to be left by herself in this way at this season of the year?—OLD DRONE.

[237.] *Placing Crates*.—Which is the best way to place crates on the hives? that is, Is it better to take off all coverings and place the crate on the bars, or place a piece of ticking, or some such material, on the bars, with holes cut in it, and place the crate on it?—F. J.

[238.] *Bacon Boxes*.—Could any reader inform me of a simple way to remove the salt from the wood of bacon boxes, so that it would be fit for hive-making?—W. F. A.

[239.] *Circular Saws*.—How are circular saws set to wobble for cutting grooves, &c.? Professor Cook says handles may be cut in crates in an instant by having the saw set to wobble.—W. F. A.

[240.] *Perforated Zinc for Separators*.—If strips of perforated zinc be used for separators in section crates, would the sight of each other through the perforations stimulate the bees to better exertion? If so, would not perforated zinc be a better article than either wood or sheet zinc for this purpose?—A. B. JOHNSTON.

[241.] *Second Entrance*.—Would a second entrance made in a hive, working in supers, be any advantage if it were made on a level with top of frames and under the lower crate of sections, as the bees would have a much shorter distance to travel from the entrance of the hive to the sections.—A. B. JOHNSTON.

[242.] '*Starter*' in *Bell-glass Super*.—What is the best way of fixing 'starter' for bees in bell-glass super?—A. B. J.

Echoes from the Hives.

World's End, Newbury.—We have had a beautiful change in the weather since I wrote last, and the bees have made the most of the opportunity to clear out any debris and dead bees, while others have gone off to the woods in quest of pollen. The few crocus and snowdrop flowers have been crowded all day with bees, also two or three straw skeps half filled with clean shavings with peafleur and corn-flour (mixed) shook over them. I saw them working the artificial pollen at 6.45 p.m., long after the crocus blossoms had closed for the day.—W. WOODLEY.

South Derbyshire, March 24th.—To-day the bees are carrying big loads of pollen from crocus, snowdrop, hazel, red alder, and the pea-flour skep. In December I had a skep blown over and all the combs—which only reached halfway down—broken short off. It remained upside down from middle of December to the middle of February. The bees survived the severe frosts of that period, and are now doing well—so much for inversion. (The above was a cast bought for a few shillings last autumn.) My best spring flower (not open yet) is the *Petasites vulgaris*, or common butterburr. Usually, about the 20th of March it puts up heads six to eight inches high, consisting of thousands of small pink flowers, yielding honey and a great quantity of pearly white pollen. An island in the middle of Wilne Weir is covered with this plant. It would not be suitable for cultivation, as it is a most noxious weed, the leaves being two to three feet diameter, and smothering everything underneath. Wasps never molest my bees to any serious extent, though nests abound in the river banks

during the season. I ascribe this immunity to the quantity of 'water-figwort' which grows by the river side. I have 'great expectations' of an excellent season.—M. J. ASTLE.

Oxford, March 24th.—After a long spell of cold weather we have at last had a bright day to examine our hives. Crocuses and snowdrops are also just peeping above the ground, and a merry hum continues during the warm sunshine amongst them. Pollen is being carried in in large quantities, and there is a prospect now of having a good supply of the golden syrup before another season closes. I am sorry to say I hear of much fatality in the apiaries. This is disappointing to many, but let us hope that better times are coming.—E. F. H.

North Cornwall Apiary, March 26th.—My diary for the last four weeks states that from February 22nd to March 18th the weather was very severe, snow lying on the ground, very hard frost, and biting east winds. No bees moving except on March 12th and 13th, when one or two were seen about for an hour in the middle of the day, when the sun was bright, although the wind was still very keen. The morning of March 18th brought a thorough change, the snow and frost had disappeared during the night like magic, it was quite warm, the wind having gone round to the south; the bees came out in large numbers, and the air was full of the merry hum of the little creatures rejoicing in good flight. I examined all my stocks and gave them all clean floor-boards, which were much needed. One stock had dysentery badly, but I set that right; the rest were free and healthy. The very severe weather since January 11th (when I was last able to examine my apiary) had sadly lessened the numbers in my stocks, and I found a quantity of dead on the boards. Since March 18th the weather has continued mild and warm, and the bees have been able to have a flight more or less every day, although on some days the wind has been high and the rain falling in heavy showers. Pollen also has been gathered freely at times.—THE MANAGER, *Roue, Bodmin*.

NOTICES TO CORRESPONDENTS & INQUIRERS.

AFRICANDER.—*Self-management*.—No; your plan would not answer. Excluder-zinc would prevent the egress of drones as well as the queens, the entrance would be blocked, and the bees would perish from suffocation. If the bees must be left to themselves, place the supers on the hives at the proper time, allowing room enough in the lower hive and leave the bees to their own devices. Twenty years ago we followed this plan with a dozen hives, and had no cause to regret it, our supers being well filled and no swarms were lost. The hives should occupy a cool and sheltered position where the sun's rays are excluded. Ours were placed in a cool out-house, with wide entrances through the walls. Use no excluder-zinc anywhere.

FIFER.—*Moths in Comb*.—Probably the comb contains both eggs and larvæ of the honey moth. The application of sulphur fumes to destroy the moth will have no injurious after effect when given to the bees.

J. P.—*Spraying Dysenteric Combs*.—Either salicylic acid or carbolic will answer the purpose. If the former, use Mr. Cowan's receipt, p. 151 of his *Guide Book*. If the latter, use one part carbolic acid to nine parts of water. Glycerine will cause the acid to mix with the water.

BEE SWING.—1. *Honey Confectionary*.—You will find receipts for confectionary in our back numbers; also see pamphlets by Mr. Cheshire and T. G. Newman, *Honey as Food and Medicine*, the latter an American, and sold by Mr. Neighbour, 149 Regent Street. 2. *Mouldy Combs*.—Reserve the mouldy combs in a dry place without spraying, and give them to full colonies or to swarms, which will soon polish and make use of them. 3. *Two-year-old Combs*.—The only use you can make of the two-year-old combs is to melt them down at a temperature of 200° Fahr., when the wax will set in a cake on the top and the honey will remain in a liquid state below, and may be used for bees, &c.

A BEGINNER.—*Two-storey Hive*.—We advise you to leave the hive as it now stands. As the bees increase in numbers they will descend and build out the combs in the lower storey, which the queen will use for extending

the brood-nest. When the lower compartment is partly filled, sectional or other supers may be placed above the two divisions, or another storey may be used for obtaining extracted or super honey.

A. K. B.—*Bees perished. Recommencing.*—You can only purchase, at the present time, 'stocks' or 'colonies' which have passed through the winter, and for these you would pay a high price. We advise you to wait and purchase 'swarms,' which may be obtained reasonably in the early part of June, and introduce them to your hives of comb from which the bees have perished, hives, frames, and combs having been cleansed and disinfected.

J. W. R.—*Proposed transfer of Bees by inversion of Skep.*—We should prefer to drive the bees and transfer to a bar-frame hive now, and then by stimulation get them forward to gather the harvest when it comes. Refer to subject of transferring on p. 3.

W. G. S.—*I. Foul-broody Stocks and Combs.*—As you have had foul brood in your apidary you would do well to feed the other stocks, although apparently healthy, with food containing the 'Cheshire cure.' 2. We should melt all combs which are not in use which have been affected by foul brood.

A. B. JOHNSTON.—*I. Candy.*—No; the hard stony candy sold by grocers is totally unsuitable for food. Bee candy should resemble the cocoa-nut candy sold by confectioners, without the cocoa-nut. 2. *Boiling old Combs.*—If you have no wax extractor, tie them in a canvas bag with a weight to make them sink and boil them in the copper, crushing and squeezing them while boiling. You cannot get out all the wax, the dross will always contain a little. 3. *Bumping Bees for Transferring.*—No, you will find in practice that the bees are none of them crushed by the combs. You do not need to use such violence as to dash the combs against each other, as you express it. 4. A three-pound swarm contains 15,000 bees.

J. J. S.—*Expenses incurred by a Beginner.*—The firm you name have the reputation for supplying good articles, and although the sum you name for a hive and a stock of Ligurian bees together with 'etc.' which may cover many expensive items, seems high to you, we fancy you got value for money. The charge for the articles you now require is not unreasonable, nor is that for man's time if you are at present unable to attend to your own bees. The cheapest way to commence bee-keeping is to get a stock in a skep, and when you are sufficiently experienced in handling bees get a hive such as you now purpose buying, transfer the bees to it yourself. As to advice, our columns are always open to inquirers, and if you will consult us in your difficulties we will try and help you. No doubt there are other bee-keepers in your neighbourhood, and all bee-keepers are ready to help one another. Failing friendly help you had better engage an expert for a day, or, better still, learn yourself.

J. B. S.—*Dead Bees.*—The bees forwarded when they reached us were actively alive; the purloins of the Seven Dials seem to have a revivifying effect on apparently dead bees. The bees are not pure blacks; they are hybrids, having a slight strain of Italians. 2. *Clover.*—If the clover is, as you state, *Trifolium pratense*, it is valueless to common hive-bees, though producing a large quantity of honey. The proboscides of these bees are too short to reach the nectary. It is said that the Ligurians and the Eastern races of bees (see 'Useful Hints,' p. 137) are able to work upon it, as also humble bees.

A. WÖJNER.—*Bees in a Trance.*—Your 'bees that had been dead some time,' and which were restored to vitality by being placed in a warm room, were only in a trance, caused by a sharp nip of cold. It is a case that frequently occurs.

ENGLISH MULBERRY.—Please forward name and address.

H. K.—*I. Mulberries.*—The flowers of the mulberry do not secrete honey in any quantity. The little that is produced is secreted by the female blooms. The flowers are also open at a time (in June) when other plants of better honey value are in blossom. It is not a desirable bee-plant. 2. Take a bee up by the wings. 3. No.

F. L.—*Two-year-old Combs.*—It depends very much upon

the state of the combs as to whether they are worth keeping. If tough, clean, and free from moth, they may be used in colonies which are being worked for extracted honey, and for wintering bees upon. Bees winter much better upon tough old combs, if not too full of pollen, than upon new ones. These combs should be placed in, or near, the brood-nest about the end of August, or early in September.

TYNO.—*Feeding.*—Lacking combs, feed your bees with syrup, rather thick, of about the consistency of ripe honey. Any of the bottle-feeders, of which we consider the 'Raynor' one of the best, will answer your purpose. Turn on all the holes, thus allowing the bees to take the syrup in quantity, and keep the bottle replenished daily—feeding at evening—with warm syrup, until the bees have stored sufficient—say from 8 to 10 lbs.—for their wants until honey comes in from the fields. By thus acting you will save your colony.

M., *Rathelmound.*—The specimen enclosed is a dwarf, slow-growing shrub called *Daphne mezereum*. The flowers are delightfully scented and appear in March. The light-coloured species referred to is an albino form of the above. The berries are ripened in the autumn, assuming a bright coral colour. It is propagated from seed sown in spring.

A KENT BEE-KEEPER.—You have been very successful in your treatment of your condemned bees, and should reap a good harvest for your pains. You may well get honey from the fruit blossoms, as your stocks seem from your description to be strong. As you have no ready-built combs to give to your bees, as the brood-nest enlarges uncap the outside combs one at a time, and as a comb becomes emptied place it in the centre of the brood-nest to be filled with eggs; do not give foundation until the weather is warmer. You need not feed while you are uncapping stores, but do not forget the great consumption of stores when breeding is going on, and feed before they are exhausted. The stock in which you found the stings is suffering from dysentery. Feed it with syrup containing salicylic acid. The flight of a queen when examining a stock is unusual. Your method of packing for winter is good, as is proved by the present state of your bees, with the exception of the dysenteric one, the cause of that being probably unsealed stores when wintering up.

F. M. K.—*Queenless Stock in Skep.*—Drive the bees, and unite with one of your bar-frame hives.

EAST DELWICH.—*1. Winter Passages.*—It is very important that bees should have the means of passing from one comb to another, either through holes or by the means you have used, sticks laid across the frames to give access under the quilt. In skeps the combs are not attached to the sides all the way down, but only as far as they are used for honey storage. 2. *Combs behind dummies become mouldy.*—Uncap the remainder of the cells, and the bees will soon clear the honey out. The mouldiness will not matter. 3. *Altering Frames for Metal Ends.*—You have only to cut off the shoulders with a penknife, and they are ready to receive the metal ends. Hives on the 'cold system' are frequently made with broad-shouldered frames. There is no reason against it.

W. J. R.—*Dysenteric Bees.*—Your bees have died of true dysentery; not that distension of the intestinal canal with pollen residue, which is called dysentery by bee-keepers generally, because the question has not been studied. The substance in the comb which excites your suspicion is simply pollen with a slight coating of honey over it. The disease seems only to be developed when surrounding circumstances are favourable, and the hive will not be injurious for other bees. The combs may, in my opinion, be used without risk. The honey, if the combs are not soiled, is not damaged.—F. C.

R. J. SLACK.—*Dead Queen and Bees.*—The queen which, with many other bees, you found dead outside the hive was filled with an organism now under culture and investigation. I suppose it to be the *Mucor melittophorus* of Lichtheim, but cannot yet make any statement. The organism may have developed in the tissues after the queen's death, and not have been the cause of it. The

same organism was found in three of the accompanying bees. The bees in this case, as in all others, have not died without a reason, but from causes which, because obscure, have too long remained unrecognised. Time will be required for getting the very involved question of apistical diseases into something like system, but I can now see that progress of a solid kind is being made.—F. C.

Col.—*Not the Queen*.—1. The bee encorked was a worker-bee, not the queen. 2. *Index*.—The index of the volume will be given at the end of the twelve months. 3. *Section Racks for 1½ × 4 Sections*.—If you have any of that size sections in stock by all means use them up. If you intend to adopt the size 4½ × 4½, which is likely to come into general use, the plan you propose to alter the racks is a good one.

We have received from Mr. W. P. Meadows, of Syston, near Leicester, several articles serviceable in the apiary, among which we may mention Locke's Feeder, the principle of which was mentioned in last week's *Journal*, its shape differs from that of the engraving, being circular; Simmins's Champion Frame Feeder, the principle of this was given in preceding volume, p. 360, and is applicable to all Mr. Simmins's feeders; Simmins's new dry sugar-feeder, used at top of bars for hole in quilt (see p. 188, vol. 12); also a shilling feeder. All these articles are strongly made, and reflect credit on the manufacturer.

We have also received, from Mr. S. Simmins, Rottingdean, near Brighton, *A New Era in Modern Bee-keeping: Simmins's Original Non-Swarming System as adapted to Hives in Present Use*. A notice of which will appear shortly.

Information is desired by a correspondent on bees and bee-keeping in South Brazil.

The Second Part of Mr. Blow's 'Among the Queen-Raisers in the North of Italy' will be given in our next Number with Illustrations.

Business Directory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

BRITISH BEE-KEEPERS' ASSOCIATION.

EXHIBITION AT SOUTH KENSINGTON.

It is hoped that satisfactory arrangements will shortly be made for holding a thoroughly representative exhibition of English bee-keeping in the Conservatory adjoining the Albert Hall at South Kensington. It now remains for his Royal Highness the Prince of Wales as executive President of the Indian and Colonial Exhibition to confirm the proposal.

The sources of income which can arise from the exhibition are very insignificant. No charge can be made for admission. The exhibition can, therefore, only be rendered possible by a very liberal response to the appeal now being made for donations and subscriptions to the Guarantee Fund. These funds now amount to about 85*l*. This amount must be considerably increased before the Committee can arrange such an exhibition as will be creditable to the British bee-keeping industry.—
JOHN HUCKLE, *Sec.*, April 6*th*.

DOUBLING FOR EXTRACTED HONEY AND PREVENTION OF SWARMING.

(Continued from p. 136.)

In working three or four storeys we proceed at first as already described, and when the stock hive is crowded with bees and brood we place on it a similar hive full of empty combs, the frames being placed one and a quarter inches from centre to centre. It may be thought that this is giving the bees too much space at one time, but if the weather be warm, and there are plenty of bees, we shall not find it any too much. Still, should the weather be cold, we need not give them all the combs at once, but only five or six, closing the space with a division board, and pushing down a quilt on to the tops of the frames in the lower hive. In this way the capacity can be adjusted to the requirements of the colony, and, as the bees want more room, the division-board can be removed and more empty combs given. A frame of brood taken from the lower hive and placed in second storey will entice the bees up more readily, but we have rarely found this necessary, more especially if no queen excluder be used.

As soon as these two storeys are pretty well filled

with bees add a third, but in this place your frames at $1\frac{1}{2}$ to $1\frac{3}{4}$ inches from centre to centre, as these combs will only be used for extracting, the two lower storeys, giving the queen ample room for egg-laying. It will not be long before the bees will be ready for a fourth storey, which is filled with empty combs and put between the second and third, bringing this last to the top.

The top hive will be filled and finished first and when all the combs are nicely sealed over the hive with its full combs is removed and another with empty combs placed between the second and third storeys. The combs can be extracted at once, or if we have plenty of these empty in stock the extracting can be left until later in the season. Some may imagine that it would be impossible for bees to fill such large hives, containing as they do about forty standard frames, but it is not so. These hives are after all not so very much larger than those so extensively used in some parts of Switzerland and France, and known as the Layens hives, which are not found too large. In these the queen has full liberty to lay to her utmost capability, the bees are never cramped for want of room, and swarming is entirely prevented.

It is true that all queens are not so prolific, and are not all able to keep such a large hive supplied with brood, but we do not tolerate such queens. We raise our queens only from the best stocks that have proved themselves most prolific, and all those not up to our proper standard are replaced by them. In hives with young queens bees are not so inclined to swarm, and this is one of the reasons why we have been able to work our apiary year after year without getting any natural swarms.

When we have left it to others swarms were not prevented, and we have a curious instance of this. In 1884, when we were away during the whole summer, we left instructions that no swarms should be allowed. Our man did not give the bees room in time, and the consequence was that we had a very large number of swarms, which he said he could not prevent. In 1885 we were at home during the swarming season, and by giving the bees plenty of room in advance of their requirements we had not a single swarm, and the bees never once showed any inclination to swarm.

We do not know in what the 'original non-swarming system' advertised in our columns consists, and how it differs from the plan we employ, but we may say that with our system there is no desire to swarm, and that not only, as the advertiser says, 'no other bee-master has yet succeeded in so managing that the bees actually have no desire to swarm,' but there are and have been for a number of years bee-masters who have not only succeeded in preventing this desire, but have also worked with this object in view.

To prevent swarming we must have young and vigorous queens, and these must have sufficient room to lay to their utmost. The bees must not feel cramped for room

when honey is coming in, but must have as many empty combs as they are likely to require for storage; and if these requirements are complied with, they will not only not swarm, but, what is much more important, will have no desire to swarm. Much valuable time is frequently lost in preparations for swarming, which also unsettles the bees, and this at the most valuable season of the year, when perhaps they might be collecting 15 or 20 lbs. of honey a-day.

To work this system to the best advantage it is necessary to have a large number of frames of empty comb. We have several hundreds of these which we use over and over again, and all the storeys consist of the same sort of hive. We have used shallow supers (Neighbour's frame supers with straw sides), 6 in. and some $4\frac{1}{2}$ in. deep, because we had them, also Carr Stewarton body boxes; but we found that ordinary hives did just as well, and there was the great advantage of using only one size of hive and one sized frame, which can be used either for brood or super. The ordinary entrance would be much too small for these hives, we therefore raise them one inch in front by means of two wooden wedges, and this allows the bees to go in and out on three sides of the hive. The illustration, taken from the seventh edition of the *British Bee-keeper's Guide Book*, shows the arrangement of these hives, and also the way they are raised from the floor-board.

To protect the bees from the heat, we have outer cases also, all the same size, which must also be raised so as to allow a current of air to enter at the bottom and have free circulation between them and the hives. The cover can also be raised for the same purpose. One advantage of this system is that, with the exception of the first hive taken from the top, all the extracting can be done at the end of the season, and the honey left to ripen in the hives. Another is, that we need not trouble about swarms. Our hives may be of the simplest construction, all of one size, and no special supers to trouble ourselves about.

When we remove our hives, we get them cleared of bees automatically, in the following way:—

When we insert the hive of empty combs between the second and third storeys, the third storey becomes the fourth, and the fourth, which we intend to remove, is raised one storey higher, making it five storeys. This is done early in the morning; and between the fourth and fifth storeys we lay a piece of American oil-cloth. The

bees in the fifth storey are now entirely shut off from those below them. On the top we place a board, having a hole six inches square, communicating with a box the same size; and this is fitted with a trap constructed in such a way that the bees can get out, but cannot get back. Over this we put the cover, but in such a way that daylight is not excluded from the front of the trap. As soon as the bees find themselves cut off from their companions below they rush to the trap, and by degrees the top hive is emptied of bees, which return to the hive by the entrance below. In this way there is no exposure of sweets, and, consequently, no robbing. The hive is removed in the evening without a single bee in it. At the end of the honey-season, the top storey is removed in the same way, the combs extracted in the early evening, and the next morning the hive with the empty combs is put in the place of the third storey, and this is raised to clear it of bees as described, and the honey is again extracted in the evening.

When all our hives have been treated in this way there will remain the two body hives, which have not been interfered with, and the third storey which has been extracted. We can then either place the hives with the extracted combs on them for the bees to clean, or give two or three boxes to one hive. The two lower boxes are left until we prepare our bees for winter, when we shall be able to get all the brood into one hive, and probably find a lot of honey in the second storey, which we can either extract and feed up the bees with syrup, or give them enough sealed comb for winter stores. If properly managed our colonies will contain a large population, and if breeding has been kept up a large number of young bees, which will enable them to winter well. The empty combs are fumigated with brimstone, and put away for use in the following spring. Hives managed in this way will give the maximum of honey with the least amount of labour.

PREPARING FOR WORK.

Once more winter is over and spring has made its appearance, and with the genial weather the song of the birds is heard from early morning, and, what is even more pleasurable to the bee-keeper, his bees are contentedly humming all day while they hasten to and fro in search of pollen and honey.

With the bee-keeper winter should not have been an entirely idle time, and at any rate some portion of it ought to have been devoted to preparing hives, supers, &c., and getting appliances in order for the coming season's work. The prudent bee-keeper would have done so and would also have purchased all he required during this period. It is a time when manufacturers can supply goods very quickly and are glad to do so, as they have very little to do as a rule besides preparing for the summer demand. But how many bee-keepers never think of ordering anything they may want until they actually require it, and then either send the dealer a note or telegram to send it on at once. This is hardly fair, because dealers may not be prepared to supply the article at once, and is then blamed when it is really the fault of the bee-keeper. To those who have not given their orders for what they may want we should say, Do so without delay, as it may save you a great deal of trouble later on. A stock of comb foundation and sections should be laid in at once.

If it is determined to go in for only extracted honey on the doubling principle see that sufficient hives and frames of empty comb are on hand. The hive need be of the simplest kind, provided it be of the right size and rabbets cut on two sides for frames to hang, is all that is needed. At least, one division-board must be supplied to every three boxes, but two would be better, also one floor-board with entrance passage cut in it and alighting-board to reach nearly to the ground. This we consider saves the lives of a large number of bees. Outer cases and a roof

can be used for protecting the bees from the heat of the sun. One set of quilts is required for each hive. If the bee-keeper be short of combs he must prepare a number of frames with comb-foundation of a proper thickness, that from six to seven square feet to the pound being the best for this purpose, and great care taken that it is obtained perfectly pure. The wired foundation is much stronger and is used with less risk for extracting. The only other requirements besides hives for working for extracted honey are a smoker, extractor, uncapping knife, and a can for extracted honey. To these may be added, but are not absolutely necessary, a box for carrying combs, and a comb-stand for placing combs whilst manipulating; and nervous bee-keepers should provide themselves with veils and gloves.

Those who intend to work for section honey will not want so many hives and frames, but, on the other hand, they must have ready in addition to all the other things mentioned racks of sections. There should be enough racks prepared to work at least three tiers of 1-lb. and two tiers of 2-lb. sections. Each section must be folded and fitted with a piece of thin foundation, which must not be heavier than twelve feet to the pound. Many sections are completely spoiled by the manner of fixing this foundation, putting so much molten wax on each side as to quite unfit it for eating. The best way of fixing the foundation is with the Parker machine, as this instead of adding wax thins the sheet out just where it comes in contact with the wood. When thin foundation is fixed in this way there is not that 'fish-bone' often complained about. The sections we prefer are $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ for 1 lb. and $5\frac{1}{2} \times 6\frac{1}{2} \times 2$ for 2 lbs., and travelling crates to hold one dozen each must be provided. Do not forget tin separators; we have tried wood and other substances, but find sheet tin the best, and be sure they are the proper width.

We have not mentioned feeders, as all that are likely to be needed are most probably in use at the present moment. Be sure to have spare hives for swarms if you are not working on the storifying principle, as it is very annoying to find that there is no hive into which to put the bees when a swarm comes out. All should be done without delay and everything purchased before there is a great demand. If the bee-keeper makes his own hives and appliances let him do so now before the to him busy season arrives. *Semper paratus* should be the bee-keeper's motto.

LANGSTROTH'S NEW BOOK.

It is now nearly thirty years since the Rev. L. L. Langstroth, the celebrated American author, wrote his book called *A Practical Treatise on the Hive and Honey Bee*, which revolutionised bee-keeping, and made it a pursuit no longer a matter of chance, but as certain as any other rural industry. It was at that time and still remains the best written, most complete and practical treatise on the subject. Although it has passed through several editions, improvements in bee-keeping and discoveries have been made so rapidly that Langstroth has long cherished the idea of re-writing it, embodying all our later acquired knowledge, but has always, owing to bad health and advancing age, been hindered from doing so. We are sure our readers will be as pleased to hear, as we are to be able to inform them, that at last this idea is about to be realised, and that Mr. Langstroth has secured the assistance of Mr. C. Dadant, one of the leading and most advanced bee-keepers in America. Mr. Dadant has shown himself, by his writings and work, to be, like Langstroth, a profound thinker, a careful observer, and a pleasant writer; and we have every reason to believe the great experience of these two men will enable them not only to treat the subject exhaustively, but also to give us a work far in advance of anything we have at present on bee-keeping. We remember with what interest we read and studied

Langstroth's book in our earlier bee-keeping days, and how we admired his clear and facile style of writing.

We were at that time using the Woodbury hive, but we were so fascinated by the simplicity of the Langstroth hive, which has a frame without broad shoulders, distance-pins, or anything of the sort, that we adopted it, and after using it so convinced were we of its superiority over those we were using that we removed the racks from all our Woodbury hives and have ever since done without them. This style of hive is at present more generally used in America than any other: and, although a few alterations have been made in the details of construction, the great principles so lucidly propounded by Langstroth thirty years ago are still the same.

The cost of the work has hitherto in a great measure restricted its sale, and we hope that it may be rather reduced in price, so as to bring it within the reach of a larger number. For the amount of matter it contains it cannot be called a dear book, as it is closely printed and has not the large print, wide margins, and broad spaces between the lines so common in works got up for the purpose of increasing the publisher's profits, when the information given in two or three volumes could be easily and advantageously put into one. Nor is it, like works merely written to gratify the vanity and ambition of their authors, verbose, spun out to an unreasonable length, in which other people's discoveries are unscrupulously appropriated, and theories tending rather to bewilder the bee-keeper than to assist him are advanced. Knowing as we do the character of the two men now engaged in re-writing this work, we are certain that it will be done honestly, that it will be clear and concise like the former edition, free from verbiage, and clearly point out the way to success with the sole object of advancing bee-keeping. We understand that the work is also to be brought out in French soon after the appearance of the English edition.

GLEANINGS.

In the *Bee-keepers' Guide* Rev. Dr. M. Mahin says: 'Syrian bees are much more prone to have laying workers than Italians or Germans, but fortunately they are much less troublesome. I have had more than half-a-dozen cases this season, but in no case have they given me any trouble. They have not interfered with the hatching of young queens, nor with the queens after they were hatched. As soon as the queen was hatched, or if not, as soon as she began to lay, they ceased operations, and the only damage done was the occupying of a few cells with worthless drones.'

In the *Bee-keepers' Magazine* G. W. Demaree describes his new frame, which does away with the necessity of a honey board. It has a wide top-bar with a longitudinal slot in it, and underneath this another bar to carry the foundation. Between the two bars there is sufficient space for the bees to pass up into the sections. Mr. Demaree says if the opening is in this position the queen will not go up above the top-bar. He also insists that in practical honey-producing there is no necessity for opening the brood department of hives every few days, after the fashion of novices, who mistake manipulation for practical work. A practised eye is all that is needed to know when it is necessary to open the brood department.

The *Rural World* says, 'Bee-keeping is, strictly speaking, a branch of agriculture, and many a farmer is to-day getting a greater return from his investment in bees than that received from any other stock; but might I here say that bee-keeping as a pursuit has to-day become a "speciality"? The man who enters upon this pursuit (leaving the question of capital aside) must be one endowed with a physical and mental ability—a man with open eyes and ears, and a man for emergencies.'

prompt to do what is necessary at once, and who is not easily discouraged.

In the *Bulletin d'Apiculture de la Suisse Romande* Frère Henri describes the manner in which he cured foul brood by means of thyme. He uses the common herb as grown in gardens. This is dried and put into an ordinary smoker, is set alight, and the dense smoke blown into the hive by the entrance. After doing this eight evenings he found the larvæ which had died from the disease before the fumigation now quite dry, and the new brood in a perfectly healthy condition. He continued the fumigations for another eight days, which ended in a complete cure of disease.

In the *American Bee Journal* W. M. Woodward says: 'Young bees are free commoners, whether of any kind or race, so long at least as there is need or use for them in the hive. In Italianising some of my colonies this year I have had a good opportunity for observing the bees change from one hive to another and have seen both drones and young workers pass directly from one hive to another and enter either hive equally unmolested. After observing this, I felt sure that young bees might easily steal eggs from any hive to build queen-cells, as from three colonies of Albinos nearly all of my black colonies received more or less yellow bees.'

In *Gleanings* Professor A. J. Cook says, that plant-lice (family Aphidæ) are very common, and there are few specimens of plants that do not harbour or nourish some species. Their presence is often denoted by ants running up and down the plants in quest of the nectar they secrete. These plant-lice are always active, and in almost all colonies some, usually but few, have wings. What a wise provision! The development of wings is ever at the cost of nourishing material, and so, unless needed, had better be absent. They are only wanted in a few, which may fly away and so prepare to distribute and the better propagate the species. Bee-keepers, he says, wisely copy from such examples given by nature, and as soon as queens have done with their wings—after mating is over—they are cut off. This is not against nature. Plant-lice work almost wholly on the leaves or green tender twigs. It is not uncommon for the leaves to curl up. Sometimes, as on the elm and poplar, galls are formed. The curling leaves and galls serve as both food and house for the lice. Such plants obey literally the beautiful commandment 'If thine enemy hunger, feed him,' for such plants bestow both shelter and food upon their most hurtful enemies. Nearly all these plant-lice secrete nectar, some from two tubes (nectaries) protruding obliquely from the back of the abdomen; others from the general surface of the body. This is a secretion, and if experience proves it to be always wholesome it should not be denounced or regarded with disfavour any more than milk, which is wholly analogous in its origin. This nectar serves the lice in attracting bees, ants, and wasps, which act as sentinels and keep birds and parasitic insects from destroying the lice, while at the same time the nectar serves the bees and ourselves as food. Professor Cook says he has often called attention to the difference between this plant-louse (Aphides) nectar, and that from the bark-lice (family Coccidæ). While the former is pleasant and wholesome, in all cases as far as he has examined it, the latter (which comes from the flat scale-like motionless bark-lice) is bitter, strong, dark, and unwholesome. It is certainly unfit for table use, and he should not deem it fit food for bees.

The *Indiana Farmer*, speaking of the depression in the honey trade, says,—'Style of package has much to do with selling honey. With many the idea prevails that there is an over-production of honey, hence the depressed prices. Comb honey now sells at from 14 to 18 cents (*7d.* to *9d.*) per pound wholesale, whereas a year or two since it readily brought 20 to 25 cents (*10d.* to *12½d.*) But sales are slow in almost every department of trade.'

AMONG THE QUEEN-RAISERS IN NORTHERN ITALY.

By THOMAS B. BLOW, F.L.S.,

Author of *A Bee-keepers' Experience in the East, &c.*

(Continued from p. 96.)

Leaving Bellinzona I went on to Locarno, and visited many country apiaries among the mountains around, and, from the statements made by the bee-keepers, it would seem that the average per stock for honey was fairly high: this result would be probably due to the united qualities of the district and the bees, the country being very fertile indeed. Then taking the steamer down the lovely lake of Maggiore, with its vine and tree clad hills, past the Borromean Islands—a most delightful journey, with lovely views of the distant Alps, and with weather most perfect though so late in the season—to Arona, and thence per rail to Milan.

Though bees were principally the object of my journey I could not forbear taking a day to see the sights of Milan, foremost amongst which is the lovely cathedral of white marble, with its delicate tracery and fine statuary: the Milanese, too, are justly proud of their electric lighting, which is certainly very perfect, and the effect at night in the Grand Square, with the cathedral in the background, is very striking. Most of the very fine shops, too, in the square and its arcades are lighted with the small incandescent lamps. Dr. Angelo Dubini was here, of course, the first man to see, his name being known far and wide. I found that he had been taking a very active part in the bee show held a few days before I arrived, and that he had now gone to his country residence to rest: he lives at Cassano Mognogo, near Gallarate, about an hour's journey by rail from the city; and on arriving at the station, his mansion, called the Villa Dubini, was pointed out to me on the top of the hill about a mile distant. A pleasant walk along a road, crowded with country people in their best clothes looking very picturesque—it was Sunday, their holiday day—soon brought me there, and a most cordial reception I received from the Doctor. His house commands most charming views, being on a hill in the midst of flat country, and is surrounded with beautiful gardens and terraces. Though not a raiser of queens, he had so much to show me in other things that the best had to be made of the time, as I could not stay longer than the evening. By far the most clever theorist in bee-keeping that I had met abroad, yet Dr. Dubini is still sufficiently

practical; his great forte is the invention of appliances, the number that I saw being Legion. A swarm-catcher (Fig. 1) struck me as being a most useful invention; and as, in this country nothing of the sort is ever used, and swarms are frequently lost, a description may not be out of place. It is a bag made of enamelled cloth, with the shining side inside, and is carried on a long pole; the hoop around the top of the bag is jointed, and after the swarm is shaken in, by means of a pulley and a string running down the pole, the hoop is closed;

Fig. 1.

the inside being shining and slippery there is no difficulty in shaking every bee out into the hive, or wherever they are to be put. One or two little pieces of wire cloth are

fixed about it for ventilation, though the swarms should not be kept in it longer than needful.

A dry sugar-feeder (Fig. 2) next calls for attention,

Fig. 2.

and for simplicity it is certainly unsurpassed. It consists of nothing more than an ordinary bar-frame, having 1-inch laths with bevelled edges nailed on each side; the sugar is shot in from the top, the affair is placed in the hive, and the bees stand on the bevelled edges and take the sugar. I was assured that it was most effective, and I think it is a great advantage on the clumsy tin dry sugar-feeders, so many of which have been brought out in this country. Dr. Dubini is an advocate of dry sugar feeding at certain times of the year. We have heard so much, too, of late about the ways of introducing queens to stocks in this country that I was glad to see a little of how it was done in Italy. Dr. Dubini does not introduce queens direct, and without eaging; nor does he put a bar of comb on which are bees and queen into the middle of the stock requiring a new queen without due precaution. For a queen alone a pipe-covered cage, with an arrangement to liberate the queen without disturbing the bees, is used (Fig. 3). I found that he agreed with me that the most important thing was not to disturb the bees at the time of liberation of queen, which, if done, was generally a source of trouble, the queen either being killed or encased. Then, if a bar of comb, queen, and bees be introduced, a wire cage to take the whole is used with an arrangement for uniting them together quietly. (Fig. 4.) I may say that I met no one in the course of my journey who had, with any degree of success, practised direct introduction.

Fig. 3.

A good idea for grafting in queen-cells is here shown (Fig. 5). We often spoil a nice sheet of comb by cutting out a piece containing a queen-cell from one comb, and grafting it into another. By using this contrivance the piece coming out of one comb fits into the other, and so both combs are kept in good condition. It is simply a piece of tin with the edges filed sharp.

Fig. 4.

Fig. 5.

The getting rid of bees from supers has always been a matter of some little difficulty to beginners here, and this device (Fig. 6) is certainly very simple and effective. A plain box with a door at one end is taken, and at the top a long wire gauze tube is fixed. The supers to be rid of bees are

put inside the box, and, of course, the bees fly to the light, and escape at the top of the tube. This box may be placed in the open air, as there is no danger of other bees

Fig. 6.

entering; they may try to do so, but always try to enter at the base of the tube, and, of course, cannot: they have not the sense to go to the top of the tube and down. The simplicity and cheapness of this should cause it to come into general use here. Dr. Dubini keeps his bees in hives that are an invention of his own, which are a kind of cross between the ordinary upright Italian hive and the English bar-frame hive. (Fig. 7.) The frames

Fig. 7.

can be taken out from the back by means of tongs, (Fig. 8), (these tongs are in universal use in Italy, Austria, and Germany), or the top can be removed, and the frames lifted out in the same way as an ordinary bar-frame hive. Double-walled hives are not in use, as the climate does not seem to necessitate them. The supering arrangements are of a very

Fig. 8.

Fig. 9.

primitive kind, simply a rough box with bars in it; the small opening F in Fig. 7 shows where bees enter into the super, and though I saw a few sections they were certainly far from our standard in point of quality. In the art of obtaining honey in comb the Italians are far behind us, and I believe much surprise was caused at the Milan Exhibition by the sight of some sections which Mr. Cowan took.

Dr. Dubini had but few bees, having lost heavily through foul brood; as a remedy for this he believes in the fumigation with salicylic acid, and uses a machine of this kind (Fig. 9) which, so long as the temperature is not

too high, is probably effective. E lamp, D jacket, in which C (the receptacle for the acid) is placed, and which prevents acid from overheating. We took a walk through the village to call on the local expert, who keeps a large number of stocks; unfortunately he was from home. The village priest, too, close by, keeps a very large number.

Dr. Dubini has another, and usually much larger apiary at his farm close by, and this we next visited; the bee-hives were in a very fine bee-house, and one of his farm men seemed to take great interest in looking after these stocks.

All around here are quantities of lime and chestnut trees; these latter the Italians object to very much on account of the bad quality of honey. This farm apiary Dr. Dubini is going to replenish, as he assured me 'He could not live without his bees.' There was much more to see and hear, but the evening was drawing on, and after a most pleasant talk over dinner, the Doctor drove me down to the station, and I returned to Milan, after a most pleasant day spent in the company of one of the most genial and hospitable men I ever met.

On the outskirts of Milan—and just far enough out to keep bees—I found the establishment of Mr. Luigi Sartori, and he a most enterprising and business-like man; his dépôt for hives, bees, and every sort of appliance, is, I believe, by far the largest in Italy. There were piles of hives of every sort, most of them modifications of the upright hives, some having the fronts most artistically painted and decorated. Barrel honey-extractors were, too, a great feature here, and very good ones they were, though the material used was zinc, to which Mr. Sartori thought there was no objection. The apiary, too, in the midst of the works was a very large one, and the way that some hundredweights of old comb were scattered about in heaps for the bees to clean certainly surprised me, and would have ruined any English apiary. The bees were doing their cleaning work well, and did not appear to get angry, or to rob. Mr. Sartori said that he always did that thing with his old comb, and that no harm came of it. Besides his appliance business he was a large dealer in honey and wax, and the quantity in hand was very great, and the quality of some of the samples that I tasted very fine indeed. The apiary at the works was not, of course, used for queen-rearing, but there was a larger apiary in the country kept for that purpose, and Mr. Sartori ships a great quantity of queens—to America principally, though this year a lot have been sent to India. The bees were very bright yellow indeed, so much so that I really thought that some Eastern blood must have been introduced among them; and some of the queens shown to me were very fine—the largest by far that I had ever seen. Mr. Sartori had been making a great display at the late exhibition in Milan, and I was much interested in seeing some of his exhibits, more especially his collection of bees in spirit. The number of prizes he had taken was very large.

With regard to the merits of Mr. Sartori as a queen-raiser, not having seen his queen-raising apiary, I am unable to say much. However, as a manufacturer he is evidently an advanced man, who keeps well abreast with the needs of the time.

On my way to Bologna I saw many country apiaries, some of them having the hives ranged on shelves on the fronts of the farm-houses. Bologna is a kind of centre of queen-raising, at least from advertisements I had always thought so; but on inquiry I had some difficulty in finding some of the so-called queen-raisers, and ascertained that, in some instances, they were merely agents, who knew nothing about queen-rearing, and that their sole business was to sell queens.

However, in Lucio Paglia and Josephine Chinni I found two conscientious queen-raisers, though, perhaps, their methods were not so scientific and advanced as in the apiary I described in my last. Mr. Paglia is a

queen-raiser on quite a large scale, the largest concern of the sort I had seen; he has two apiaries, one at Castel St. Pietro d'Emilia quite in the country, this being devoted entirely to queen-raising; and another, an imposing affair in the Public Gardens, just outside Bologna, which is devoted principally to honey-raising.

I took train to Castel St. Pietro, and was very kindly received by Mr. Paglia, who is also a wine-grower and large farmer, owning his own land, quite a large estate. He showed me over his apiary, consisting of a large number of hives scattered over the grounds round the house, and apologised for the apiary not being in such good order as he could wish, as he was just rebuilding his residence, and remodelling the whole place.

His system of queen-raising was very good, and he uses a great number of rather large nucleus hives for the raising and fertilising of his queens. Though very careful in the selection of his stocks for rearing queens from, he does not go in for the elaborate system of getting the accurately built rows of queen-cells, like Mr. Pometta; nor does he consider it so needful to take all larval brood out of the hive, while queens are being reared.

Mr. Paglia went back to Bologna to show me his apiary there in the public gardens; and he had the largest and prettiest bee-house I ever saw; it was fully 150 feet long, with a fair-sized room at each end for packing and storing honey, &c., with rows of hives standing in the space between. There were nearly 100 hives in the bee-house, and they had been run chiefly for honey during the past season; and he told me that he obtained 1400 kilogrammes from these hives, and had left over twelve kilogrammes in each hive for winter use. The wind from the hills being cold here in the winter, necessitates the packing of straw in the spaces between the hives for protection. All these hives—and in nearly all the Italian hives which I saw—had glass dummies, and are left in the hives all the winter. Mr. Paglia may be considered as a most practical, enterprising, and reliable queen-raiser.

A lovely drive of fourteen miles through a charming hilly country, all well cultivated, brought me to Praduro-e-Sasso, where Madame Josephine Chinni has her apiary. All of us know, that in England a good many members of the scholastic profession go in for bee-keeping, and here we have a queen-raiser in the shape of the village schoolmistress assisted by her daughter. Madame Chinni, with whom I had dealt for some years, was delighted to see one of her English customers; and many inquiries I had to answer, relating to others in England who dealt with her, for she supposed I knew them all.

This concern is not a very extensive one, as Madame Chinni likes to manage the affair herself, rather than to employ labour to do it; as the result of personal management is, she thinks, far better. A good system of rearing prevails, carried on by a greater extent, by the subdivision of large hives, and further by the use of large nucleus-boxes. There were three apiaries—one at the house close to the school, and two on the hills—and the total turn-out of queens would be, probably, not more than between three and four hundred; sent principally to England, as Madame Chinni prefers to turn out a small quantity of a good article, rather than raise them wholesale. The home apiary was rather small, Madame Chinni having had the misfortune to get nearly the whole apiary of eighty stocks burnt last year. Praduro-e-Sasso is a most remote country place, far away from town or rail, and I here saw Italian country life in its primitive rustic simplicity.

Leaving Bologna, my only other call in Italy was on Mr. Fiorini at Montselice. Mr. Fiorini is a well-known man in the town, being a large builder; and I had no difficulty in finding him; and I knew that my visit to him would be of more than ordinary interest, from the fact that he was the only man in Italy, who had been to

the East to investigate the merits of the Syrian and Cyprian races of bees. Though he raises a few queens, yet he does not make the queen-raising a business, to the extent of the others upon whom I had called. He has a comparatively small apiary, and we went through several stocks together, and also examined the original stocks that he had from the East. The savageness of the Eastern races is not so apparent in Italy as in England; and Mr. Fiorini stated that he usually handles Eastern bees with about the same degree of ease as Italians; but he cannot see that, at least, in Italy they have any advantages over the native race. He was not desirous, he said, of doing much trade with England, as his dealings had not been satisfactory; and he complained bitterly of one firm who had obtained queens from him, and from whom he had not been able to get the money.

My experiences with Italian bee-keepers here come to an end; and though I remained in Italy for two or three days longer, yet it was at Venice; and in that silent city, with its watery highways, no bees were to be seen, and no bee-keepers were to be met with.

My next article will relate to bee-keeping in Carniola.

Selected Query.

[243.] *Is there any advantage in caging the queen during a honey glut, and thus preventing her from laying, and preventing the bees from swarming?*

We do not think there is, and the bees certainly do not work so assiduously when their queen is caged, and although bees are prevented from swarming we prefer to give the queen more room for laying and prevent swarming in this way.—EDITOR.

I think there is no advantage, and, with a proper system of management, there is no necessity for it, while it has many disadvantages, and in a large apiary would cause endless labour. A judicious system of doubling, on the storifying plan for extracted honey, and of tiering up for sections, will do away with all necessity for caging the queen in order to prevent breeding and swarming.—G. RAYNOR.

There is no advantage in caging a queen belonging to a stock during a honey glut, to prevent her producing brood, as the more bees in a hive the greater the weight of the honey collected. Very much more honey is collected by a strong stock that is not allowed to swarm, than if weakened by sending out a swarm.—WILLIAM CARR.

I do not consider there is any real advantage in caging the queen during a glut of honey. If we could be sure of a continuance of fine settled weather we may increase our harvest by so doing; but it must be at the expense of the future population of the hive, and also a loss of nearly a day caused by the disturbance in capturing the queen.—W. WOODLEY.

Caging the queen in this manner will induce the worst kind of swarming—namely, with young queens raised in her stead—while no present advantage in surplus will, as a rule, be obtained. But, of a certainty, the future prosperity of the colony is thereby impaired—in some cases, altogether ruined. A queen must be kept breeding the whole time, though with a brood-nest decreasing in size towards the latter end of the harvest. No other course will give permanently good results.—S. SIMMINS.

I should not recommend it, and do not think it necessary if additional space is given in tiering up racks of sections from time to time as the increase would warrant—or storifying with additional hives if working for extracted honey.—JOHN M. HOOKER.

This is a funny query!—very funny query indeed! and he would be a very funny clever fellow who could answer it in a way to be of benefit to the craft save that he advised *non-interference* with her majesty and her loyal subjects at such time and the giving of ample room for storing at top of hives.—R. R. GODFREY.

I do not approve of interfering in such a degree with the

natural functions of the queen, nor do I deem it necessary or desirable to curtail the raising of brood at the period named, my experience showing me that in normal, *i.e.* strong, colonies, the workers are more than a match for the queen in securing possession of the cells. The preventative to swarming lies in the direction of giving ample space for both queen and workers.—J. GARRATT

I cannot say as I have never tried the plan.—C. N. WHITE.

ASSOCIATION.

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

A meeting of the Committee was held at Worcester on the 3rd instant, when there were present the Rev. E. Whitmore Isaac (chairman), the Rev. W. M. Kingsmill, the Rev. S. Latham, the Rev. R. T. W. Brayne, Mrs. Swinden, Messrs. C. H. Haynes, E. A. Dimmock, II. Goldingham, E. T. Footman, S. Tombs, and A. H. Martin, hon. sec.

The hon. sec. read a letter that he had received from Mr. C. Brown, resigning the appointment of expert to the Association; and it was proposed by the Chairman, seconded by the Rev. W. M. Kingsmill, and carried unanimously, 'That the Committee receive with regret the resignation of Mr. C. Brown, and beg to express to him their appreciation of the services that he has rendered to the Association during the time that he has been their expert.'

A sub-committee, consisting of the Chairman, Mr. Kingsmill, Mr. C. H. Haynes, and Mr. A. H. Martin, was appointed to take into consideration the election of an expert to the Association, and Mr. E. Davenport, of Stourport, late expert to the Hants and Isle of Wight Bee-keepers' Association was unanimously chosen and will enter upon his duties as soon as the state of the weather will permit.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not accessibly for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangersways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Lane, Herts (see 2nd page of Advertisements).

In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

SIMMINS' UNCAPPING MACHINE.

[244.] The first principle of this machine consists in its having two oscillating knives, which, driven by foot power, have a reverse motion, while the comb is passed down between them by the operator, and the cappings are removed from both sides at once, in the quickest manner possible. These drop into the upper can, which has a strainer at bottom, through which the honey drains into the lower vessel, where it can be drawn off by a treacle valve. An invaluable feature in connexion with the knives is that at the recommendation of the manufacturer, Mr. Meadows, of Syston, the edges are serrated, thus making them absolutely perfect for this particular purpose. Between the knives, at either end, are guides arranged to take the end rails of the frame, keeping such in position while passed through by the operator.

The lower and upper cans are readily parted for the purpose of cleaning; and all the parts can be renewed, if necessary. The knives should be returned to the manu-

facturer for sharpening when needed, though this will be seldom, as their peculiar construction enables them to stand a large amount of work.

It is not intended that the machine may be of use for odd combs from the stock chamber. I do without such unnecessary disturbance, but where any

number of colonies are run for extracted honey, the upper combs should all be finished between dividers, and then they may be rapidly passed through the uncapper before going into the extractor; and even where the uncapping knife will still be used, the rapidity of manipulation will amply repay any extra cost in furnishing upper storeys with dividers.—S. SIMMINS, *Rottingdean*.

FOUNDATION FOR SUPERS.

[245.] I am, as Mr. Simmins says might have been expected, quite 'aware of the fact that no comb honey can be obtained unless the state of the atmosphere is such as to cause the secretion of nectar;' but what I meant by the honey glut was the time when beans, clover, limes, wheat, &c., &c., are in full bloom: when honey abounds in every direction, so to speak, and everybody's bees are gathering a surplus—that is what I have always understood to be the general meaning of the term 'honey glut,' or, as it is sometimes called, the honey harvest, and which, as I have previously stated, commences in this district about the middle of June. But before this *principal* honey-glut comes, I very encouragingly hope to get as many sections completed as I am likely to require; and if we are favoured with fine, warm weather during the fruit-blossom season, I am quite sure that with my specially prepared stocks that what Mr. Simmins is pleased to call a 'forlorn hope' will be a realised fact, that is, if my experience as a honey-producer in this district during the last ten years is anything to go by.

In spite of what others as well as myself have written respecting the easily distinguished difference in combs built with *versus* without foundation, Mr. Simmins still persists that all is 'simply imaginary.' Does he mean to say that I have never had any complaints of the hard substance which is found in the centre of every comb that is raised from foundation? that I have never known the honey to be cut away from the hard 'middle bit' by the consumer, or its presence even distinguished? and that I have never taken foundation out of fine-looking combs as perfect as the day it was stuck in the section, but only imagine that such has been the case? If so, I

beg to inform him that he is labouring under a very great mistake, and instead of what I have said being 'simply imaginary,' Mr. Simmins only *imagines* that such is the case. I know a great many honey-producers, and honey-consumers too, all of whom agree with me in condemning the use of foundation in supers except one, and he being a maker and a vendor of the article, the position he takes is quite excusable.

Mr. Simmins says that if sections naturally filled are absolutely pure, so also are those built upon natural wax remoulded by man. Perhaps so; but pure as they may be there still remains the objectionable backbone; and when I call to mind the fact that I have had foundation offered me at *less* than what I make of wax, and that London dentists came to me for beeswax which they say must be absolutely pure, and add that the bulk of that in the market is not pure; and remembering too that it is not so very long ago since a very interesting article appeared in the *British Bee Journal* pointing out that large quantities of so-called beeswax is made of paraffine. There is to my mind a doubt as to whether man is content to simply 'remould' pure wax, even for use in supers; but there, anything does for some people, and Mr. Simmins and his customers are quite welcome to his fine-looking sections, with an undue proportion of 'remoulded' wax, but I, my friends, and my customers prefer the genuine and delicate work of Miss Apis; and when such an article cannot be profitably produced I will devote my whole apiary to the production of run honey.

As regards the incalculable injury which Mr. Simmins still fears will be the result of the remarks I have made, I repeat that the trade that will suffer through honest statements has no sympathy of mine; and in conclusion I do hope that the next time Mr. Simmins points out one's wrongs he will not, with the same stroke of the pen as it were, commit greater sins himself, for surely the reference I made to extracted honey has as much to do with the subject under discussion as the definition of terms, the influence of the atmosphere, &c., has.—A. SHARP, *Huntingdon*.

'SIMPLICITY' SPRING FEEDER.

[246.] There are so many 'Perfection' feeders in the market that, with Mr. A. I. Root's permission, I should like to call this the 'Simplicity,' and for stimulating purposes it seems to me on the road to 'perfection' as well. It is *simply* a piece of lead pipe (1 in. bore), widened out at one end with a plumber's 'turnpin,' and narrowed down at the other end by tapping with a mallet until the requisite dimensions are reached, viz.:—length 4 inches, diameter of cap $2\frac{1}{2}$ inches, length of nozzle 2 inches, aperture at bottom $1\frac{1}{8}'' \times \frac{1}{8}''$.

Preparation and use.—*Simply* stuff the nozzle with cotton wool, gently ramming with a thin strip of wood to within $\frac{3}{8}''$ of lower end, so that the bees cannot reach

it with their mandibles. When you can suck the air through without much effort the job is done. Test with water first. If too tightly rammed pass a thick worsted needle between wool and one *end* of nozzle. *Simply* cut a slit in the quilt next to frames and press feeder hard down; cover with the lid of a half-pound coffee tin, or anything that will fit loosely and not push off. A cushion filled with cork-dust settles nicely down round and about

the feeder. Fit your thick worsted needle into an old bradawl handle, or bit of stick, and carry it round with your syrup can when you fill the feeders, just before dusk. If you find any clogged, press down needle, always in same place, and leave the pricker in the last hive, beginning at that hive next feeding time.

Advantages.—1. The food is delivered right into the cluster. 2. The weight (1 lb.) keeps it perfectly secure while adjusting cushion or coverings. 3. Quantity always the same—about a wineglassful. 4. Cost, if made by self, 2d. each, by plumber 3½d. each. 5. *Simplicity itself.*

For the *principle* of the thing I am indebted to Mr. Simmins, who at one time described a tin feeder with hole in bottom, plugged with a roll of linen. It is possible also that Mr. Locke's idea of the sponge (page 124) is a modification of the same.—W. HOLLIER, *Dorking.*

NORFOLK AND NORWICH BEE-KEEPERS' ASSOCIATION.

[247.] Although I am not likely to take any active part in Bee Shows for the future in consequence of serious illness, I am a great reader of everything touching on apiculture. Looking over the last report of the Norfolk and Norwich B. K. A., I see a Rule '9' interpolated lately. This is 'A' 9, 'That whenever the Bee Tent is sent out it shall be entirely under the charge of the expert, no person but the expert shall be allowed to lecture unless by special permission of the Committee, the Hon. Secretary, or the expert.' What does it mean? Is there such a rule in any other Association? Fancy at one of those shows I meet my friend Cheshire, who is accidentally at Norwich; I say, 'Come along, Cheshire: let's go and stir up that solemn affair of the bee-tent. Have you a bacillus with you?' Oh, no! That won't do—you must have *special permission* from the expert (2nd Class), or the Secretary (who is busy selling his hives), or the sixteen Committee men! Fancy our old friends Abbott and Blow and Baldwin turning back and preventing Mr. Raynor, or Mr. Hooker, or Mr. Booker Hill, and a host of others who know much more than second-class experts of both practical and theoretical bee-keeping.

Who are the advisers of the Norfolk and Norwich B. K. A.? At the last show at Norwich, they gave no prizes for hives and appliances, though they paid 4l. 5s., for hire of Implement Tent, and 4l. 16s. 5d. for defraying half expense of advertising Norfolk and Norwich Horticultural Society. Examined carefully, their last report is a queer sort of thing.—J. LAWSON Sisson.

IMPROVED QUEEN AND DRONE EXCLUDER.

[248.] When we place a zinc-excluder frame in a hive, or use it in the fixed division to be found in front of three or four frames on some hives, does it not occur to us how difficult it must be for the worker-bee to get through? It cannot fly through. It must either alight on the zinc edge, seize it with the legs, poise itself for an instant, and spring off to the comb or section beyond; or, what is more, creep up and turn a sharp right angle; this process to be repeated going and coming on so many thousands of journeys. Mentally imagine these myriads of instants added together, and then see what a great loss of time there must be to the bees, and this, too, in the very midst of their busiest season when 'time is honey' if not money. No wonder they don't like excluder! Then again, how are they to drag forth the dead bees through holes just deep enough for their own bodies only? Fancy pigeon-holes the height of the bird's body when extended, and without alighting-boards on either side, said pigeons being engaged on express carrying work like the bees! The remedy for all this is to glue, or with patent cement fasten, long strips of wood a quarter inch square, the length of the

frame, and flush with the line of holes on each side. These will give us an alighting platform over half an inch wide under each hole, which will undoubtedly much facilitate honey storing and gathering. Besides, the bees would not require to touch the objectionable, cold, magnetic zinc.

If makers in future send out excluders as at present, it will be a simple matter to fasten the woods on as I say; this can also be done to those already in use. In default of square wood, headless matches, or even strips of glued cord, may be used. I scarcely need say that this principle is not applicable to excluder-zinc used on the tops of frames.—R. A. H. GRIMSHAW, *Horsforth, near Leeds.*

[We hope the time will come when makers will send out hives without excluder zinc; we have long considered it a hindrance to the work of the bees, and there is absolutely no necessity for it.—Ed.]

THE SECTION OF THE FUTURE.

[249.] It seems to me that a 'burning question' for bee-keepers will be the introduction of some new pattern of section which shall be more easily glazed, and stronger and more secure when packed, than the American one-piece sections at present in use. To such of us bee-keepers as reside at a distance from honey companies and merchants to whom we can dispose of our surplus stock, the possibility of such an improvement is very important. If we are to compete with foreign honey producers, we ought to be relieved from the painful uncertainty, and disappointments that now attend the carriage of honey. I have had far more than ordinary experience in packing fragile and valuable things, but I find the exercise of my utmost skill will not ensure my honey travelling safely. Last summer I sent thirty-two sections to North Wales in a box packed with great trouble and minute care, and they arrived almost uninjured. The other day I sent six sections in a strong wooden box half the distance and packed with equal care, but three arrived in a 'mash.'

Even if improved, strong sections could not be produced at less cost than 5s., or even 6s. a hundred, instead of the 2s. 6d. per hundred we now give, it would pay us to use them.

It is a good deal of trouble to put glass windows into packing boxes, containing perhaps only six sections. When, moreover, one has to glaze the honey also, and pack with as much care as one uses for old china, and I cannot but think that a stronger section capable of being quickly glazed or faced with thin wood, and which would not give at the corners if jarred, which the present sections do, would be gladly tried by many of us. Of course, they would take more room, but they could be put on two tiers at a time. Will not the appliance-makers give some help in the matter?

When the time comes round, some hints as to the best methods of preparing sections for sale, glazing, &c., would be very welcome; also, how best to bottle the run honey and clear it from all scraps of wax, &c., so that it may look perfect in the glass jars.—IRISU NOVICE.

BEEES AND CHOLERA.

[250.] The inclosed appeared as an article in a leading Queensland paper.

The *Dorrinda* spoken of was supposed to have cholera on board, and the editor of the paper evidently fears that choleraic germs may have been stored by the bees in their combs. The matter has excited great interest in the Colony; and if the theory is correct that bees convey germs of disease from place to place, it is not to be wondered at that great caution should be exercised. These bees were imported by Messrs. Spry, of Brisbane, whose name and fame as large apiarists are not unknown

to your readers. I shall be happy to let you know how this matter eventuated, and meanwhile, Mr. Editor, I hope some of your readers will give their views on the subject.—T. I., *March 19th.*

'We are informed that among the passengers by the *Dorunda*, and placed in quarantine with them, were a number of bees. Now, it is pretty well known that bees are about as indefatigable in the collection and distribution of germs of all kinds as any known agents. It is, therefore, by no means unlikely that these industrious insects, while foraging about Peel Island, may have managed to convey back to their hives, along with their store of pollen, whatever of these dangerous germs they may have encountered on their way. Besides, though it may not be generally known, bees are great scavengers, and frequently infest sewage, and all kinds of refuse, for the sake of obtaining saline particles, which particles the curious may observe on the comb by means of a microscope. Under these circumstances, it is evidently advisable, in the interests of the public health, that the hives and combs should be destroyed. With regard to the bees themselves, it seems a pity to adopt such a summary measure, when the trouble and expense that have been bestowed upon them are taken into consideration; but if the queens are saved, that will probably satisfy the owner.'

[Our views as to the effect of bacteria may be gathered from our reply to A. Rendell, p. 158.—Ed.]

REV. F. G. JENYNS' WORK ON BEE-KEEPING.

[251.] I am under the impression that the work on bees, recently published by the Rev. F. G. Jenyns, was intended for use in rural elementary schools. Perhaps I am wrong. But I should like, with your kind permission, to point out that the price forbids its introduction into such schools, where it might be used as a supplementary reader, and which are attended by the children of the very class who need to have their attention directed to the advantages of the modern system of bee-keeping. Could not the author see his way to publish a cheaper edition? Surely some enterprising educational publisher would publish it for 1s. 6d., in a binding suitable for school wear. As a rule, the managers of country schools are obliged to draw the purse-strings tight. I should think that many of our bee-keeping schoolmasters would adopt it as a reader if the price were moderate.—PEDAGOGUE.

HAS THE BEE-STING EVER BEEN AN OVIPOSITOR?

[252.] I append a quotation from 'Langstroth on the Honey Bee,' which seems to bear on this subject, page 39. 'Considerable doubt seemed to rest on the accuracy of Dzierzon's statements on this subject'—(that queens do not need impregnation to lay the eggs of males)—'chiefly because of his having hazarded the unfortunate conjecture that the place of the poison-bag in the worker is occupied in the queen by the spermatheca. Now this is completely contrary to fact.'—W. G. CAMPBELL.

THINGS IN GENERAL. [168.]

[253.] I think if our friend who is in trouble about 1-lb. sections will procure the one that holds nearest one pound of comb honey, that will be the right one; and in my humble opinion there is only one size likely to accomplish it—namely, $4\frac{1}{2} \times 4\frac{1}{4} \times 2$. The next difficulty our friend is in, regarding Standard frames, as the worthy editor has already explained it, I can quite endorse what has been said about manipulating being so much easier accomplished without either broad shoulders or metal ends; I have tried both, and have come to the conclusion that we are better without either. If hives are rightly constructed, and you let your frame-ends rest on tin or zinc runners, there will be little to fear, as you can either have your frames close together or apart without the bees getting out.—CHEQUERS.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[203.] *Nucleus*.—Is the croaking of bees peculiar to Cornwall and the county of 'Nucleus?' W. B. Webster pronounces that 'bees do not croak.' Well, if he insists that only frogs may be said to do so, let it be; but he may rest assured that bees do on occasions make a noise very like croaking. That my cousin 'A. E.' has never heard it I am surprised. I thought he had twigged everything. I most distinctly heard this noise last summer, and my bee-man well remembers my calling his attention to it, and certainly neither of us leant against the hive. He says it was like a bee in a bottle, or what is known in Cornwall as a 'dumbledory in a pop-dock,' but it was a distinct creak, if not croak. May I ask my other cousin of North Cornwall to say how he found out that a drone made the noise and how the drone did it?—SOUTH CORNWALL.

[217.] *Stinging Gloves*.—If 'Rector' would buy a pair of tan-leather gloves and turn them inside out, so that the smooth side is *outside*, he would not find the bees sting either gloves or hand. I had a pair made of gaiter-leather with smooth side out, and find them better than any others. I have tried all kinds as I have not the strong nerves of the 'Lords of Creation.' I put a long gauntlet on to go up the arm.—LADY BEE-KEEPER.

[233.] *Honey Beverages*. (East Cumberland.)—There are a few summer beverages made with honey; among the chief being Blatch's Honey Lemonade, Beckett's Honey Fruit Syrups. The recipes for making same are the property of the manufacturers. Any ordinary summer drink in which sugar is used is greatly improved if in place of the sugar, honey is substituted. The Rev. V. H. Moyle, Vicar of Ashampstead, Berks, was the pioneer in the advances made towards utilising honey in the manufacture of food and drinks; he would, I know, give you every information as to the means of procuring same. Mead is honey brought to a certain gravity by the addition of water, then boiled and fermented. It is justly celebrated for its peculiar effects on the brain of the human subject, a diagnosis of such could be summed up in two words,—unsteady gait.—W. B. WEBSTER.

[234.] *Paint for Hives*.—Molesworth's *Engineering Formulae* gives the following among 'Workshop Recipes':—*Painting*.—A gallon of mixture, or 6 pints of linseed-oil, 1 pint of boiled oil, 1 pint of turpentine, requires from 12 to 14 lbs. of dry paint. These proportions vary according to circumstances. A gallon will cover from 450 to 630 feet on wood. Proportion of colours for ordinary paints:—

Colours.	Ingredients by Weight.						
	White Lead.	Lamp-black.	Red Lead.	Red Ochre.	Verdigris.	Burnt Umber.	Spanish Brown.
White	100						
Black		100					
Green	25				75		
Stone	99					1	
Lead	98	2					
Red			50	50			
Chocolate ...		4					96

Priming.—White lead (sometimes mixed with chalk) diluted with linseed-oil.

Knotting.—Red lead and size.

Putty.—Spanish whiting and linseed-oil well beaten and kneaded into a stiff paste.—A. T. WILMOT.

[236.] *Lonely Queen*. (Old Drone.)—The hive in which the queen was found had probably been robbed; her subjects uniting with the marauders, and, having emptied the combs, deserted *en bloc*. See *Langstroth on the Honey Bee*, chapter on Robbing, page 263, and note.—HORNEFIELD.

[236.] *Lonely Queen*. (Old Drone.)—This is a very unusual occurrence, and no doubt arose from the colony vacating the hive on account of the shortness of stores. This is frequently done by starving bees at this season of the year,

when they endeavour to enter other hives; the mother bee usually goes with them, and is killed. Perhaps in your case, finding a not very welcome reception, she flew back to her old residence.—W. B. WEBSTER.

[236.] I remember some years ago I was called in to look at some bees and found one stock with all the bees dead and gone except the queen, and she was running in and out of hive on floor-board and about the combs in all directions, and she was as fine healthy queen to look at as I ever saw; it was about this time of year. In those days we had no use for her. We should not treat her so now.—H. TRICK.

[237.] *Placing Crates.* (F. J.)—Place the crate on the bars without quilt, excluder zinc, or anything between them; there is not the slightest necessity for anything to be placed between crate and frames. Of course your crate has spacing rails.—W. B. WEBSTER.

[238.] *Bacon Boxes.* (W. F. A.)—Purchase new well-seasoned wood; you cannot get all the salt out, and this will cause dampness in wet weather. Such boxes at the best are but sorry rubbish to waste your time on in converting them into hives.—W. B. WEBSTER.

Another correspondent suggests submerging the boxes for a week in a running stream.

[239.] *'Wobbling' Circular Saw.* (W. F. A.)—By means of two washers (one on each side of saw) having their inner faces made diagonally, according to the angle required, to the spindle.—W. B. WEBSTER.

[240.] *Perforated Zinc Separators.* (A. B. Johnson.)—The sight of each other, which must be very doubtful in a perfectly dark hive, will not stimulate the bees to greater exertions. The advantages claimed are, the bees can walk on this zinc with greater ease than on plain, and so do not traverse the face of the sections and so soil them; they also allow a freer circulation of the warm air through the rack. I should not go to the expense of them myself.—W. B. WEBSTER.

[241.] *Second Entrance.* (A. B. Johnson.)—I much prefer only one entrance. Hives are used with two as you describe, the advantage gained by such I have failed to see, and few others have done differently. I consider them a detriment.—W. B. WEBSTER.

[241.] *Second Entrance.*—I have found a second entrance very useful in working the large glass super or the straw skep as was used years ago. The bees would all enter at bottom for first few days and super workers leave at top. In a few days they would enter and leave at top and bottom entrance.—H. TRICK.

[242.] *Starter in Bell-glass Super.* (A. B. J.)—The best way is to have a small pedestal 4 inches square at bottom and round at top to fit the hole in glass. If it is a 2-inch hole I use a piece of perforated zinc and fasten it to the pedestal with a tin tack; cut a groove in each square and fasten a piece of super foundation comb in each, about an inch wide and two or three deep. It will not disfigure the glass if you want it for a show glass.—H. TRICK.

[242.] *'Starter' in Bell Glass.* (A. B. J.)—Immerse the outside of bell glass in hot water (not too hot), and place starter cut out to shape of glass, then dip it into cold water to fix it. It is a rather 'ticklish' operation.—W. B. W.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[254.] *Carniolan Hybrids.*—What is the opinion as to the working capabilities of Carniolan hybrids (black)? Are they as vindictive as Lignrians crossed with the blacks are said to be?—M. J. A.

[255.] *Dry-sugar Feeders.*—Is the dry-sugar feeder a less troublesome mode of supplying food to bees than the old syrup feeders?—G. S. F., *Epsom.*

[256.] *Two Queens in one Hive.*—Would it be possible, by dividing a long hive into two or three divisions by means

of excluder zinc or frames of sections, to obtain two or three laying queens in the same hive?—TREVOR SAXSON.

[257.]—Would it not be a good plan to fasten a sheet of foundation to a division-board with a half-inch rim all round at the edges of the division board, so that the bees could draw out half a comb on it? This, when filled with sealed honey, would keep the bees far warmer and more comfortable in winter, and would economise space at all seasons.—F. L.

[258.] *Drone Foundation in Sections.*—Is it a fact that in any comb bees require less time and material to work out and seal over drone than worker cells? If so, would it not be an advantage if drone foundation were used in all sections? Of course if there be little or no drone comb in body of hive the queen may ascend and deposit drone eggs above, but this may be prevented by using queen-excluder over frames.—A. B. JOHNSTON.

[259.] About what weight of comb would be in a well-filled and finished one-pound section?—A. B. JOHNSTON.

[260.] *Artificial Queen.*—Is an artificial queen likely to turn out as productive as a natural one?—A. B. JOHNSTON.

[261.] *Honey Receptacle.*—Can some one inform me if I can safely use an empty brandy or sherry cask for maturing honey; so cleanse it as to not in the least damage honey? or will it be wisest and cheapest in the long run to purchase a tin or tinned iron one?—EAST CUMBERLAND.

[262.] *Painting Hives, &c.*—I have twelve bar-frame hives which want cleaning inside, cleaning and painting outside. I propose to do them in the following manner:—To get four make-shift hives and stand them in the place of four originals, transfer the combs from one to the other, take away the hives, clean and paint, and, say in two or three days, restore them to their former position, and so on with the rest. Do you agree with the plan? Would there be any danger of losing queens? (2) If I find any hive without brood or eggs may I conclude it is queenless?—W. G.

[263.] *Syrup and Honey.*—How can we keep syrup from being stored with honey? For instance, I extracted all honey in the autumn, and fed up with syrup. Now, will the syrup be appropriated by the bees before the honey-flow comes? If not, how can we extract with safety the combs thus used.—BR. W.

[264.] *How to Dislodge Bees from a House.*—A gentleman earnestly desires good advice on this subject. Wishing to make alteration in his house, he has had some weather-timings removed, about ten feet from the ground, and over the bow-window of a sitting-room. Now that the warm weather has set in, the bees seem to be in full activity, and the work of building cannot be safely undertaken until they are dislodged. For several years past, bees had been noticed to affect the house, but until they took possession of this spot last autumn their presence had never in any way been inconvenient. If any reader of this will kindly correspond with the Rev. — Crofts, Mountfield Vicarage, Robertsbridge, he will be most grateful.

Echoes from the Hives.

North Leicestershire, April 5th.—Since I last wrote (22nd ult.) a change to wet and windy weather has kept the bees pretty well at home. During the fine week preceding the bad weather, the bees were constantly on the wing, but did very little else but attempt robbing. Forage was, and still is, very scarce.

Bee Vagaries. Early Swarms.—On the 24th a strong stock of hybrids swarmed out and clustered on a stone wall. After remaining quiet a few minutes, the bees began to run into the crevices, as though searching for the queen. In a short time this activity ceased, and the bees commenced returning to the hive, a few at a time. On examination in the evening, the bees covered eight bars, stores were plentiful, and there were eggs and brood in all stages. Another stock (a skep) bunched out for a time, and then took to wing. After a time the bees returned, and for half an hour were running very wildly about the exterior of the hive, when all of a sudden every bee disappeared within the hive. As I had a week before given this stock

a good supply of coarse honey, it could not be an attempt to make a starvation swarm. Dr. Emmerson reports that he saw a young queen disporting herself in front of hive No. 2, *vide* 'Echo' for March 18th.—E. B.

Keswick, April 3rd.—Since the frost and snow disappeared we have not been favoured with much suitable bee weather in this district. During the past few days it has never ceased from raining. Snow has fallen several times during the week, and it still continues very cold.—R. P.

Evesham, April 5th.—I write from the centre of a district which is known as the 'Garden of England,' in the fertile Vale of Evesham. We have passed through the longest and most trying winter that has been experienced for many years. The first snow fell on September 26th, 1885, and we had a snowstorm here on the last day of March. The bees went early into their winter quarters, and for as long as six weeks at a time were unable to get even a 'health flight.' Seven of my stocks have survived out of eight. One died through dysentery, which is extremely prevalent in this neighbourhood, and I hear of many of our members having lost three and four stocks from this cause. All my bees are now in a healthy state. I have cleaned floor-boards thoroughly, and swept out all dead bees; they are breeding fast, pollen carrying from the crocuses, and busy on the apricot blossom, which is coming out the last few days. We are quite a month later in every way than we were this time last year, but there is every promise of a most abundant bloom on all the fruit-trees in the market-gardens, which surround the town for a radius of three miles.—A. H. MARTIN, Hon. Sec. Worcester-shire B. K. A., Evesham.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

EDWARD J. GIBBINS.—*Depth of the Cowan Hives.*—The dimensions given in the *Guide Book* are quite correct. The total depth of our hive is 8½ inches. The rabbets are cut out similar to the illustration shown on page 26 of *Guide Book*. The top bar, ¾ of an inch thick, then comes level with the top of the hive, the depth of the frame being 8½ inches, leaves a space of ¾ of an inch under the frames. The frames do not hang on the top of the hive, but level with the top in the rabbets prepared for them, and the depth of 8½ must not be reckoned from the under side of top bar but from the top of it.

A. RENDELL.—1. *Dysentery.*—We have examined the brown spots you have scraped off the front of your hive and alighting board, and find they consist principally of digested pollen, with a good many pollen-grains, entire and undigested. This is different to the thinner watery fluid ejected by the bees earlier in the season. We have for some time been making observations with regard to dysentery, which we hope shortly to be able to communicate, all we can at present say is, that it seems to be a fermentation produced by a micro-fungus belonging to the family *Saccharomyces*, a fungus similar to that known as the yeast fungus, and capable, under certain favourable conditions, of decomposing the saccharine matter of the fluid consumed into carbonic acid and alcohol. Want of proper ventilation, if it does not produce the disease, at any rate aggravates it. 2. No, we do not know what experiments Mr. Cheshire is carrying on, or when he will be prepared to say anything about a remedy. 3. Nothing can be simpler than the remedy we employ. Provide clean warm hives, exchange soiled combs for clean ones, feed with candy or good warm syrup, or give a frame of sealed stores. The combs can be syringed, and when dry used again, and are just as good for breeding in as any others. You need not be alarmed about the number of different sorts of *bacilli* found in bees. We have ourselves found five

or six apparently different species, but there is no more danger to be apprehended for all that. The air is full of *bacteria*, and at every breath we are inhaling thousands, and our bodies are full of them, but we are none the worse for it. So it is with bees, they may also contain *bacilli* in numbers, and be in no way affected by them. 4. We do not consider dysentery a dangerous disease, nor is it infectious like foul-brood.

W. G. S.—If your search for the queen resulted in discovering that the hive was queenless it is possible that the bees, discovering her inability to fulfil her duties as mother-bee, have dethroned her in their own summary fashion.

W. MITCHELL.—Please consult previous numbers as to the best mode of trapping blue-tits and other enemies of bees.

BEESWING.—The bees forwarded were hybrids.

A. R.—1. *Firing Foundation.*—Put two screws or nails through the top bar after inserting the foundation, so as to pinch in the cleft. 2. Uncap the cells and also feed with thin syrup.—The honey as evaporated for storage must be thinned before it is suitable for food for brood. Hence the necessity for water, which may be conveniently supplied in the form of thin syrup. 3. *Exposure of Brood.*—The less time you expose brood the better, especially in a wind. Five minutes should not injure it, unless the weather is totally unsuitable for opening a hive at all.

T. B.—*Time to Stock a Nucleus.*—When you have ripe queen-cells with which to furnish it.

NOVICE.—1. *Number of folds of Flannel for a Quilt.*—Four or five. 2. *Uniting.*—If you know one of the queens to be young, or otherwise desirable to preserve, destroy the others. If you have no preference let them fight it out.

3. *Keeping Syrup.*—If properly made it may be kept indefinitely in a dry place. 4. You may buy feeders to regulate supply at any dealers, or you may take the lid of a round tin box and punch one or two holes with the point of a French nail, place it over the mouth of a pickle bottle filled with syrup, invert the whole and place over the feed-hole; this is the simplest and cheapest feeder and one which we constantly use. Cover the bottle bee-tight to prevent robbing.

J. W. B.—*Combs from Hive infected with Foul Brood.*—Do not on any account give them to other stocks. You may extract the honey, thin it out, add Mr. Cheshire's cure to it, and use it for feeding the infected stock; or if you do not extract, you may uncap the cells and give the combs to the infected stock, feeding at same time thin medicated food.

HORACE.—1. *Removal of Quilts.*—The winter quilts may be gradually reduced as the weather gets warmer. 2. *Time for Supers.*—When the honey begins to flow freely, and when the hive is full of bees.

LADY BEE-KEEPER.—*Moving Bees in Skeps.*—The skep should be carried bottom upwards, with a piece of cheesecloth tied over to allow of sufficient ventilation and to confine the bees. To make the combs secure, two or three wooden skewers should be pushed into the sides of the hive through combs to the other side a day or two before moving. It is desirable that, if the skep is to travel by rail, it should have old and tough combs.

J. FORD.—There is every probability that the bees have superseded and ejected their queen.

J. W. PATRISON.—*Space around Frames.*—The space between the frames and the sides of the hive should be one-fourth of an inch; the passages under the frames, three-eighths.

SRY.—*Separators.*—The most suitable width for separators for 4½ × 1½ × 2 sections is 3½ inches.

COL.—*Stimulating.*—In the circumstances mentioned we should recommend you to build up your stocks by stimulating them. You would be able to graduate your stimulating better by syrup bottles than by dry-sugar feeders.—We prefer No. 2 sample of American cloth.

BENJ.—1. The bees forwarded are hybrids distinguished by a good portion of Ligurian strain.—2. The great requirement of a candidate for a third-class certificate is that he should be able to prove to the judges that he has a fair acquaintance with bee-keeping, but it is not necessary that he should give any evidence, either orally or in writing, of this.

ARTHUR T. PLATT.—*Drones.*—1. The appearance of drones

at this time of the year indicates the presence of a fertile worker, or of an unfertilised or drone-breeding queen.
 2. *Third Class Certificate.* — Inability to capture the queen is not an absolute disqualification to a candidate for a third-class certificate. The judges would, of course, take note of this, but they look to a candidate showing a general acquaintance with bee-keeping.

* * *Several other queries are postponed to next issue, or replies will be forwarded to the correspondents.*

We have received from Mr. J. Howard, of Holme, Peterborough, and Mr. W. P. Meadows, their joint catalogue (61 pp.). This contains a very extensive list of all the supplies required by bee-keepers. We note in it various specialities, such as the Guinea extractor, the Raynor extractor, Mr. Simmins' dry-sugar feeders, uncapping machine, Raitt's honey-press, honey-ripeners, &c. Received, the price-list of Messrs. Aspinwall and Treadwell, of Barrytown-on-Hudson, New York.

We have received a letter from Mr. John McNally, in which he states that his brother, Mr. William McNally, was the first to commence bee-keeping in the family, and is the inventor of honey designs, &c., which he exhibited in the season 1882. We shall be pleased to receive from Mr. W. McNally some description of these designs.

A Kentish Bee-keeper would be obliged if 'J. T. D.' (vol. 13, p. 322) would state the cost per ounce of thymol and menthol; also the quantity of menthol required in syrup for uniting purposes, and whether he should use methylated spirits or wine, or whether it should be alcohol in the formula given.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 12-16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Entries close May 12th. Secretary, J. Huckle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

Business Directory.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

Somerset Agricultural Association Meeting

At WELLS, May 11th, 12th, and 13th, 1886.

THE SOMERSET BEE-KEEPERS' ASSOCIATION will give PRIZES for HIVES, SECTION-CRATES, SKEP COVERS, &c., at the above Show. For Entry Forms and full particulars apply to the Rev. CHARLES G. ANDERSON, Otterhampton Rectory, Bridgwater.

By the kind permission of the Council of the Somerset Agricultural Association, the BEE TENT of the S. B. K. A. will be on the Ground. LECTURES and MANIPULATIONS will be given each day.

CHARLES G. ANDERSON, *Hon. Sec.* (135)

Seventh Edition. Twelfth Thousand.

BEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By THOS. WY. COWAN, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of HOULSTON & SONS, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. HUCKLE, *British Bee Journal* Office, Kings Langley, Herts.

The best Journal of its kind, edited and published by the renowned C. F. H. GRAVENHORST, Brunswick.

DEUTSCHE ILLUSTRIRTE BIENZENZEITUNG.

Organ for the united interests of Bee-culture. By its contributions from the principal Bee-keepers, and its brilliant illustrations, this publication has already had an extraordinary circulation. Sample copies sent on request.

Also, 'DER PRAKTIISCHE IMKER.' Compendium of Rational Bee-culture, by C. F. H. Gravenhorst. Third enlarged and improved edition, with fifty-two new original Pictures, and a frontispiece. Price 1 mark (4s.), stitched; well bound, 5 marks.

C. A. SCHWETSCHKE & SON (M. BRUNN), Brunswick.

THE 'CHESHIRE CURE'

FOR

FOUL BROOD.

Accompanied by full directions for use.

Prepared by Mr. F. LYON, Who procured for Mr. CHESHIRE the Stock of Diseased Bees on which he carried out his Experiments, and which was shown cured at the Conference, Health Exhibition, July 1884.

Price 1s. 8d. per Bottle, post free.

PHENOLATED SOAP.

15 per cent pure Phenol.

For CLEANING HIVES (also a delightful Toilet Soap).

PRICE 8d. PER TABLET, POST FREE.

F. LYON,

94 Harleyford Road, London, S.E. (4)

WALTON, MUSKHAM, NEWARK.

Bar-Frame Hive.

Price 10s. complete.

Double walled back and front, Tongued and Grooved Floor-board moveable, Plinths, Porch, Entrance-contractors, Legs, Hinged Roof, Ten Frames, with E. C. WALTON'S Improved METAL ENDS (these Ends are interchangeable with those of Blow, Pine, Edey, or Harrison),

and saw-curf down the middle of bar for foundation. Moveable top sides for filling with chaff, cork-dust, &c.; two Spring Dummies, two Quilts, and Crate of 21 1-lb. Sections, with Glass at each end and Separators.

This HIVE has taken First and other Prizes at Lichfield, Doncaster, Oxford, Coventry, Stone, Ledbury, &c., the past two years.

SECTIONS.

Foundation. Smokers. Sections.

Feeders. Hives. Veils.

Bottles. Reversible Frames.

Extractors. Knives.

Diffusers.

And everything for the successful management of the Honey Bee.

FOUNDATION

SMOKERS.

METAL ENDS,

8s. gross.

Write for CATALOGUE of 48 Pages and 80 Illustrations.

Half-a-Million SECTIONS,

Best quality, 24s. per 1000.

100 SWARMS FOR SALE.

TRADE supplied with every requisite. Send for WHOLESALE RATES.

WALTON, MUSKHAM, NEWARK.

Agents for Madrid: Messrs. OUTRAM & KESSLER, Old Broad St., London.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

EXHIBITION AT SOUTH KENSINGTON.

His Royal Highness the Prince of Wales, President of the Indian and Colonial Exhibition, has been pleased to grant the use of the Conservatory adjoining the Albert Hall, at South Kensington, for the purpose of holding a National Exhibition of Bee-keeping Appliances and Products. Arrangements have been made for the Exhibition to open on Friday, July 30th, and close on Thursday evening, August 5th. An appeal is now made for donations and subscriptions to the Guarantee Fund in order that the Exhibition may be made thoroughly representative of the British Bee-keeping Industry. The under-mentioned amounts have already been announced.—J. HUCKLE, *Sec.*, April 12th.

EXAMINATIONS.

The annual first-class examination will be held at South Kensington on Saturday, May 15th, commencing at 10 a.m. First and second-class certificates will be awarded at this examination. Candidates already having gained a third-class certificate are entitled to compete at this examination. Candidates intending to compete must give notice to the Secretary, J. Huckle, Kings Langley, Herts, not later than Wednesday, May 5th. Such notice must be accompanied by an entrance fee of five shillings.

MODEL APIARIES.

Though we agree to a great extent with the views expressed by a correspondent in a former number of the *Journal* with respect to the formation of model apiaries, we do not think that if established they would fill the place of the bee tent at flower and other shows. It often unfortunately happens that the expenses of the bee tent are not covered by the receipts, and some are too apt to lose sight of the ultimate benefit to the cause of bee-keeping when the immediate deficiency is so painfully visible. Again, a large number of people present at shows know little or nothing of advanced bee-keeping; and being attracted to the bee tent, the seed, though sown on the waters, is certain sooner or later to bring forth fruit, and we could point out many an enthusiastic bee-keeper who caught the infection after seeing the dexterous manipulations of our experts.

We confess we do not see how model apiaries could be established. Those bee-keepers who make it a business recognise that it is of advantage to their trade to show visitors over their apiaries and explain any details that are required with respect to the management of an apiary. It acts as an advertisement, and that is now the sort of business, and by the sale of bee appliances and the subsequent custom they are repaid for the trouble they take. Sometimes, of course, a hive-maker may have to waste some hours, when time is invaluable to him, and the visitor departs after having made some insignificant purchase. But on the whole, taking one with another, visitors are always welcome, and though sometimes a whale has to be thrown to catch a sprat, as a rule the reverse more often holds good.

Those of us who are amateurs, only selling honey and occasionally bees, know by the bitter experience that the young bee-keeper is very exacting, and too often irrational. He seems to labour under the hallucination that your whole duty is to help him in season and out of season. We have again and again received letters from our correspondents stating the time which would be most suitable to them for us to come and visit their apiaries, and they seem to take it as a personal affront if we plead press of work, bee or otherwise. Some years ago we received an urgent note when in church requesting us to come at once: it was to take a swarm, which was beyond the power of our young bee friend.

In practice there are hundreds of model apiaries scattered all over the country. Those of us who take any interest in bee-keeping, and more especially in educating others, are only too pleased to show our apiaries and explain any knotty points, and in all well-managed County Associations there are experts who will visit apiaries for a small fee. The B. B. K. A., by their fostering care of the County Associations, has striven, and

that successfully, to cover England and Wales with a net-work of such model apiaries by helping any new associations, and providing them with lecturers, pamphlets, &c. The freemasonry of bee-keeping is such that one bee-keeper is always ready to help another, and we shall always be only too willing to help by giving introductions to well-known and skilful bee-keepers in the neighbourhood where our correspondents live.

WHAT NEXT?

In our article a few weeks since on the 'Present and Future Prospects of Apiculture,' we pointed out how necessary it was to educate the public to the benefit of honey, and what a useful article of food it would be found. When a genuine article is brought forward it generally takes some time to be appreciated; but anything doubtful that is puffed up, people are somehow attracted to it; a pamphlet setting forth in glowing terms the management of some mythical bee farm, either in California or Central Africa, goes down, and the public are thus tempted to purchase the apparent delicious nectar, ignorant that the contents of the pretty bottle was simply *pure glucose*. Well do we remember, when in Cornwall a few years since, we saw some of our Cornish 'cousins' partaking of some of this compound, and when enlightened as to its source replied, 'Well if it does not do us much harm it is far cheaper than pure honey.'

This state of affairs is passing away. We have honey companies and honey depôts, and are prepared to compete with the Yankees on open ground, provided they send nothing but pure honey. They are, however, not trying in their own land to find channels for their honey; but now have actually come over and started a company on our shores, and in our very midst, under the title, 'The Honey Company.' The following is a copy of an advertisement which has appeared in a local paper:—

'Read this! Special news for this issue. Waterbury watches given away! Delicious Californian honey direct from the Apiaries of the finest districts of California. We take this means of offering direct to the consumer this delightful article in tins of about 60lbs., securely packed and carriage paid to any address, at 30s. per tin, or only 6d. per lb. More nourishing than butter, this delicate luxury is now offered at half the price of butterine. Parents, heads of households and institutions, make an immediate trial of this delicious honey. Note.—As an inducement we offer to every purchaser, for a short time only, a present gratis of a splendid Waterbury watch, value 10s. 6d., safely packed by post.'

Now we have always known that any article that was sold by the attraction of a present of any description, could not be very good. Do we not constantly see tea advertised, and a present given away with a certain quantity? and if we are wise we would never touch such. Honey that is pure and good cannot require the temptation of a watch, a clock, or even 'three acres and a cow.' 'Wine that is good requires no bush,' and equally does the proverb apply to honey.

USEFUL HINTS.

Scarcely a day fit for the examination of hives has occurred since our last Hints. Thus far April has proved a cold and boisterous March. As we write a Report from Scotland comes to hand that—'On Tuesday night (6th inst.) the cold was nearly as intense as it has been all winter. Snow, to the depth of a foot, fell in the Western Highlands, and in Forfar and Perth shires; and showers of sleet and snow are reported up to noon of the 8th.' All over England heavy rains, sleet, and

storms,—with intervals of sunshine most dangerous to the bees by enticing them forth never to return,—have prevailed.

There can be no doubt now as to the lateness of the season and the backwardness of the bees—some report a month later than last year. It is too early, however, to despair of a honey-yield and plenty of bees to gather it. The latter becomes a still greater necessity under present circumstances. We cannot, therefore, be too urgent in our advice to 'feed, feed, feed.'

FEEDING strong colonies is of more importance than nursing weak ones. Seeing that honey is not to be procured from garden or field, the income is simply a little pollen, and populous colonies lacking food quickly perish. We have known this to happen after supers have been given. Let all apiarists, then, keep a sharp eye on food stores, remembering that any small quantity of syrup, stored in the body of the hive now, will serve as food for larvæ, even while honey, later on, is being conveyed in quantity into the sections above.

We have found Duncan's Pearl Sugar one of the best for syrup, but are sorry to learn that the firm has closed its premises in consequences of the great depression in the sugar trade. We can only hope that better days are coming.

WASPS.—Do not forget the queen-wasps. Brile village boys to destroy them, and keep a garden syringe handy, with which to shoot them down. Every queen destroyed now will cause one nest less to worry the bees in the autumn.

WATER AND MEAL.—Continue to supply these, as previously directed, until flowers become more plentiful. In olden times it was considered that when gooseberries and currants came into bloom there was no further occasion to feed the bees. That time, with us, has not yet arrived. Indeed, we scarcely remember a season in which, in the middle of April, so little food from natural sources was available for the bees. The careful observant apiarist, who never leaves anything to chance, will reap his reward in the 'good time coming.'

PREVENTING AFTER-SWARMS.—There are many who desire a moderate increase of colonies by natural swarming, while working for comb-honey, but object to the worry and annoyance of after-swarms, as well as to the loss caused by such, since neither these swarms, nor the depleted colonies from which they come, can be depended upon for passing safely through the winter, nor can surplus honey in any form be expected from them. To such we recommend a system, based upon Haddon's plan, but differing in varied degrees, which we have successfully practised.

Strong colonies, in ten or twelve framed hives, are brought up to the full amount of population, by the time the honey-flow commences, when sections are placed over them. If work is carried on briskly, a second rack is soon placed beneath the first. Before these are completed, we will suppose the swarming fever to have seized upon the bees, and, one fine day, a large swarm issues, the sections and brood-hive being well-nigh deserted. Let us suppose that our hive faces southward. The first step is to secure the swarm, which is shaken into a zinc pail, and poured down in front of a newly-prepared hive filled with sheets of foundation, which has been placed on the stand of the old stock. When the swarm has entered its new abode, the section racks are removed from the parent stock and placed upon the swarm. The old stock is now set close beside, and on the east side of the swarm, with its entrance facing due east, forming an angle of ninety degrees with the entrance of the swarm. This angle is gradually reduced daily, until on the fourth and fifth day the entrance of the parent stock faces south—the same as the swarm. On the seventh day the old stock is removed to a new stand, at some distance from the swarm, and in five

cases out of six no second swarm will issue, the number of bees being so reduced by desertion of the swarm, that the young queen, as soon as hatched, is allowed to destroy her younger sisters by tearing them from their cells. If, however, a second swarm should issue it will suffice to cut away any queen-cells remaining in the hive and to return the swarm. The following autumn, if desired, the old stock, with its young queen, may be united to the swarm, the surplus honey being removed from both colonies.

By this plan the mass of bees goes to the swarm, enabling it to complete its supers at the same time that the foundation is being drawn out and filled with brood in the hive below. The old stock recuperated with hatching brood, and headed by a young and prolific queen, will again become strong by the autumn, and may be kept as a separate colony if increase is desired. In a good season the swarm will often require one or more additional section racks, and the parent colony may also afford a surplus. Those who practise this plan, with the intention of uniting the two colonies in the autumn, often allow the parent stock to retain its original position beside the swarm, with its entrance at an angle of ninety degrees.

QUEEN INTRODUCTION.—When it is desired to *change* the queen of any colony, let it be remembered that bees never receive kindly a strange queen while they are in possession of queen-cells, or even rudimentary cells. Their first impulse on discovering the loss or removal of their queen, is to raise cells over larvae or eggs. The safest plan, therefore, is not to attempt to introduce the new queens until the mania for building cells is somewhat subdued—say in three or four days—when every cell, or commencement of a cell, should be clean cut out and a drop of carbolic solution applied to the spot. The new queen should then be placed under a pipe-cover cage between brood and sealed honey, a cell or two of honey being broken in pushing the cage up to the septum (or midrib). After twenty-four hours she may be quietly released, and will generally be received with every mark of pleasure. Our own practice is to change the queens at one and the same operation, but we are careful, before liberating the new queen, to ascertain that there are no queen-cells in course of construction, or, if there are, to destroy them, and to delay the release until the mania has subsided. In the case of colonies which have been queenless for some time it is not to attempt introduction, but to unite them to other colonies. As a rule, English bees receive a strange queen with far less trouble than any other variety. Hybrids, perhaps, are the worst of all.

SECTION-RACKS AND CASES should now be either in readiness or at once prepared. We see no objection to sections being filled with foundation if only it be sufficiently light and fine in quality. We have found none equal to the thinnest flat-bottomed American. Sections worked upon full sheets of this are perfectly transparent, have no 'fish-bone,' and we defy any one to distinguish such from those built without foundation at all. Passing a long, fine needle through the section forms a good test as well as transparency. If any impediment to the passage of the needle is felt at the centre of the section, 'fish-bone' is the cause. Our own practice is to insert a triangular piece, about half filling the section-box, and thus primed we find the sections filled as rapidly as when full sheets were used, which was our former plan. Indeed, so small is the amount of wax required for a one-pound section that we are not prepared to assert that these small boxes would not be as rapidly completed without foundation as with it during the best part of the honey season. Two-pound sections we rarely use, finding them as un-saleable as extracted honey. For fixing foundation in section-boxes, we still continue to use 'Parker's Foundation-fixer,' which is an admirable implement, does its work rapidly and well, occupies

small space, and its price is low, viz., 1s. Messrs. Neighbour, and no doubt other purveyors, keep abundance of these machines, of American manufacture, in stock. It is fully described, with engraving, on page 64 of Mr. Cowan's *Bee-keeper's Guide*.

MANIPULATION.—During the present inclement weather no examination of hives should be permitted. Scarcely anything can be more injurious to colonies than to uncover and separate the brood-nest in such weather as we are now experiencing. The heat thus lost is not recovered for days, to the great injury of the brood especially and of the entire colony generally.

THINGS-IN-GENERAL.—'Piping' of Queens.—For the prevention of after-swarms, where natural swarming is practised, we have often heard it recommended to listen at night from the seventh to the tenth day after the issue of the first swarm for the piping of the queen. Now, that this piping invariably or generally takes place, we beg leave to doubt. Although we have occasionally heard it, yet in our experience it has been the exception and not the rule. On one day last season it was our good (or bad?) fortune to have twenty-three first swarms. What a task, from the seventh to the tenth day afterwards to have spent all our evenings for the purpose of listening at the parent hive for the 'piping' of the young queen, and, when heard, of manipulating their combs one by one and cutting out the queen-cell. Pace our friends of the 'piping system,' we prefer by far the plan recommended above.

RAISING YOUNG QUEENS.—The question—'How shall we keep up in a small apiary of, say, three or four hives, a succession of young queens to supersede the old ones, with the least possible loss of time and honey?'—is often asked. We answer, (1) Follow the above plan of preventing after-swarms, taking the extra precaution of placing a super upon the hives containing your best queens after preparation for swarming has begun, or do not super at all until after the swarm has issued. (2) Instead of placing the parent hive beside the swarm, return the latter, having first removed its queen. By either of these plans young queens from the best mothers may be obtained—from populous colonies in the natural way—and with the minimum of loss in the storage of honey. Under any ordinary system the mating with drones is a matter of chance.

REVERSIBLE HIVE.—In a criticism of the 'Heddon Hive,' noticed in last 'Hints,' Mr. Alves asks the inventor to answer the following questions:—'1. Have you any trouble in making and keeping the frames of the precise width? 2. Have you not been troubled with expansion and contraction? 3. Has not the accumulation of propolis given you trouble at the tops of the frames where they touch, or nearly touch, the front and rear of the case, and also at the joints made by the frame, on the thumb-screw's side, with the front and rear of the case?—It is to be understood that an impediment longitudinally of only $\frac{1}{8}$ of an inch will prevent the replacing of a frame, and that an expansion of or an accretion to each frame of $\frac{1}{8}$ of an inch, will take up all of his spare room.' We shall be rather curious to see Mr. Heddon's answers to the above questions. Further, we are told that this new hive was ushered into bee literature with such a flourish of trumpets, and at the same time Mr. Heddon had so wonderfully crossed his old records, that some of us could not but laugh for the fun of the thing. Mr. Jones, the noted Canadian bee-keeper, being appointed agent for the hive in Canada, will, we trust, send a specimen to our Colonial Exhibition at South Kensington.

JOTTINGS BY AMATEUR EXPERT.

Mel sapit omnia.

Croaking.—So bees do really croak—Cornish bees at least. 'Like bees like masters.' I have never twigged them at it 'up a-long.' If 'South Cornwall' is surprised,

'A. E.' is not; perhaps, after all, it was only the *pikies* they heard 'down long we,' especially as the sound emitted was like a 'dumbledory.' I await 'Manager's' reply with bated breath.

Experts and Bee-tents.—So Time has laid its relentless hand on our old friend 'the Sir Wilfrid Lawson of bee-keepers.' How we shall miss him at the coming Colonial! I hope he can still watch his bees at home, as I feel assured time will then not lay dull on his hands. Wonder if his old hen has hatched out that pumpkin yet? But he is having a fling at Rule 9. Well, now, I am not going to defend the N. and N. B. K. A., but I do agree with Rule 9. Not because, if I was in charge of a beentent, I should ever use it to keep out any of the 'fathers of bee-keeping' he enumerates, or Mr. Sisson either. Keep him out? I should think not! His jokes are more interesting to many than the bees, without the bacillus thrown in. But it will keep out a host of people who are a positive nuisance to the expert, who will throng the internal arena to show how courageous they are, but who dare not show into their own gardens the day after 'their man' has taken the last honey for the season. They crowd the expert so that he has not elbow room; they block the sight from the audience, give erroneous answers, chatter amongst themselves; and if poor 'second-class' happens to be a little nervous under the eyes of so many 'lights' and does not happen to find the queen to a moment, will get her pointed out by one of these gentlemen with a huge walking-stick, and when poor flurried 'second-class' says he cannot see her majesty will get for answer, 'She has joined the cluster again now, but I am sure she was there.' How nice for such an expert to be able to keep out such gentry by Rule 9, who, like too many 'stickelers' in a wrestling-ring, are neither use nor ornament.

Sections.—Irish Novice may strengthen his sections at the corners with glue as he folds them, but he will probably prefer them made stronger; and he is only one of many. I have hitherto escaped a 'mash' with sections, but not with bottles. Corrugated card-board is a good thing for packing, but all adds to the expense. I have just seen a new thing in sections, it is a departure from all I have ever seen before; the 'craft' will have an early opportunity of judging of its merits, so I will say no more at present about it. I also hope Mr. Editor will give us the 'hints' asked for about putting up sections and honey in bottles for market at an early date.

The *Indiana Farmer* is right about 'style of packing having much to do with selling honey.' We shall find our Colonial brothers will 'lick us into fits' at the coming exhibition in 'style of packing' and the art of 'captivating purchasers,' especially if the B. B. K. A.'s new exhibition rules are strictly enforced.

Bacilli. Oh, horrors! how I shuddered when I read what you had to say to A. Rendell. 'The air is full of *bacilli*, and at every breath we are inhaling thousands, and our bodies are full of them, but we are none the worse for it.' Comforting, very! *Bacilli* Cholera! *Bacilli* *absei*! *Bacilli* *Gaytoni*! (yes, I declare I get more bald daily) *Bacilli* . . . but it is bed-time—'to sleep, perchance to dream,' *Bacilli*!—AMATEUR EXPERT.

Rebiew.

A New Era in Modern Bee-keeping. Simmins's Original Non-swarming System as applied to Hives in Present Use.—This is a pamphlet of nearly sixty pages by Mr. Simmins, of Rottingdean, near Brighton. The author is known as a contributor to our columns, and as a producer of bees and honey, and has one of the largest apiaries in this country. In this pamphlet Mr. Simmins explains how it is possible to get from 60 to 100 pounds of honey per colony, and says the principle consists in giving the bees more room than they require

in the shape of *unfinished stock combs adjoining or next to the entrance*. Only starters are used instead of full stocks of comb foundation for brood-frames, and he limits the number of his 'brood-combs just before the season commences or before any drone-cells are capped,' then inserts 'below, or in front of such brood-combs, several frames with $\frac{1}{4}$ -inch starters only.' In this way he says the bees 'having more room than they require in the nursery the desire for swarming does not exist, while, for all practical purposes, the bees can be at once crowded into the sections; the latter all being first filled with newly-built combs.' The use of this he considers will represent a saving of 30 lbs. at least over foundation. Pelham foundation is recommended for drawing out into comb, which is then cut up and put into sections used for surplus. It is not quite clear which way Mr. Simmins places his frames, as the illustration shows them at right angles, whereas the author speaks of filling up in front of brood-combs with frames containing starters, which would imply combs parallel to entrance. The sections are worked in two tiers on the 'back of the hive just over the brood-nest, which should be limited to eight or nine frames by about May 10th.' The space in front is to be filled up (with no division-board intervening) with as many frames with $\frac{1}{4}$ -inch starters as will reach the entrance. Hives holding more than fifteen frames are not recommended. The author says very little comb will be built in the empty frames at front if the bees are kept busy in the sections, and it should not on any account be allowed to be fully worked out. 'As comb appears in them cut it out and fit it into sections quite tight all round; but should any contain eggs, hang such in the comb-rack for a day or two before using, that their vitality may be destroyed, when they will be removed by the bees as the combs are returned in sections. Any with larvæ may remain, if not interfering with work in supers; otherwise give such to nuclei.' Drone-comb can be melted and is considered a clear gain in wax.

Another way is to crowd the bees on eight or nine combs about 10th of May, at the same time placing another box, with starters only, under the first. As the weather becomes favourable put on sections filled with comb, remove as fast as completed, and the lower comb will not be completed all the season. The combs in these should be run down and the frames used the following year. For producing the combs for sections Porto Rico sugar is recommended, and on the third day they are sufficiently drawn out to cut up to fit into the sections. No separators are used. For obtaining extracted honey the hive is divided by wooden separators into eight compartments, and into these eight brood-combs are placed from stock hive, which is filled up with frames having starters only. The divided hive is placed on this, and as the brood is hatched out and honey stored they are removed and the process repeated. If necessary, another set of eight can be placed under the second. Straw hives are recommended to be worked in the same way, always giving the empty space at the bottom.

This in a few words is the system which, in the words of its author, 'has reduced the whole question to the finest limit, and all availing themselves of it will have no difficulty in producing honey profitably at the present low prices, and, if needful, at even lower rates.' Mr. Simmins claims it as his *Original non-swarming system, based upon rational principles and a thorough knowledge of the economy of the bee-hive*. How true the old adage, that *there is nothing new under the sun*. There have been many devices invented to prevent swarming and systems introduced during the last 200 years with this object. John Gedde, in 1675, propounded his system, based on exactly the same principle. Gedde says:—'1. It is natural for all bees to begin at the top, and to work downwards. 2. That bees swarm for want of

crate of sections. Excluder zinc interferes but little with the work of the bees when placed close on top of frames and supers, be it glass, wood, or straw, closely fixed upon it, and well covered. The result would be pure honey and plenty, and free from brood.—R. R. GODFREY.

I find no advantage gained by the use of excluder zinc between hive and sections. I have discontinued its use for four years now, and have never yet had brood put into sections. With supers, such as Lee's, Crystal Palace, &c., it is necessary. I am strongly of opinion that it very much interferes with the working of the bees. Since giving up the use of it I have had crates more readily entered, but I have never tested this matter by having two hives working side by side, one with it and one without it.—P. H. PHILLIPS.

In working for section honey it is an advantage to use excluders, unless the stock hive is very large, so that the queen has always plenty of empty cells in which to deposit

her eggs. If there is always plenty of empty cells in the stock hive the bees will store in the sections a little more honey without the excluders.—WILLIAM CARR.

With crates of 1-lb. sections I consider the use of excluder zinc a positive disadvantage. If hives are properly manipulated the queen will rarely enter the super; but I would much rather, if it were a necessary condition, have a spoilt section or two and allow the bees greater freedom. I have seldom had a spoilt 1-lb. section, except in the Anglo-Cyprian hive, about the supering of which I wrote vol. 12, p. 349. I have not, however, been uniformly successful with crates of 2-lb. sections, having frequently one or more spoilt in a crate, and I should therefore favour, where those sections or large supers generally are used, either a queen-excluding adapting-board, or a sheet of excluder zinc with bee-space above and below. The excluder so placed interferes with the passage of the bees to and from the super far less than when it is placed flat upon the frames.—C. N. WHITE.

COUNT ZORZI'S UNCAPPING MACHINE.

During our visit to the Apicultural Exhibition held at Milan amongst other things there were two machines which were brought to our notice and particularly attracted our attention. These were an uncapping machine and a press for making comb foundation. The uncapping machine, the first of the kind we believe ever made, is the invention of Count R. Zorzi, of Bologna, who deservedly received a gold medal for it at the Exhibition.

It will be seen by the illustration that it consists of wooden stand, to which is attached a large wheel worked by a handle. This, by means of a strap, actuates a pulley fixed to a shaft, having an eccentric slot cut, which in turn gives a horizontal motion to a sharp steel blade. This is set at an angle and is fixed by means of thumb-screws. The frame containing the comb is placed into a frame-work, which is slightly inclined, and has a rack at the loose end, which is worked by pinions attached to the shaft, on which the driving-wheel is fixed. In front and between the two standards of the stand is placed a trough to catch the cappings, and below the frame is another trough to take any honey that may run out of the comb. On the left-hand side is a small vessel to hold water and a sponge or cloth. In this machine, whilst the cutting blade has a horizontal motion, the frame-work which carries the comb has a nearly vertical motion. It is placed at a slight inclination, so as to enable the comb to lay in it without movement.

For uncapping the framework is raised as high as it will go, the frame of comb placed in the recess prepared for it, and on which the edges of the frame rest, kept in its place by means of two buttons seen at the two upper corners. The knife is then adjusted by means of the thumb-screw. A turn of the handle on the driving-wheel causes the knife to move backwards and forwards at an enormous speed, at the same time that the frame moves down and the whole frame of comb is uncapped in the twinkling of an eye, the cappings like a sheet of paper falling into the trough in front. The knife is then pulled forward, and the reversal-wheel will bring the frame up to its original position, when the comb is reversed and the other side done in the same

way. After every cut the knife is wiped with the damp cloth to free it from any particles of honey or wax. With this machine the combs are always cut perfectly even, leaving which is a great advantage, as the bees have less work, and when they are perfectly flat the bees will retain them so and preserve an even space between them. After the combs have once been cut by this machine the cappings will come off with very little honey adhering to them. Where a large number of combs have to be uncapped this machine would be invaluable, and would very soon save its cost, the rapidity with which the work is accomplished being marvellous.

GUAZZONI'S COMB-FOUNDATION MACHINE.

Another machine which interested us at the Exhibition in Milan was a comb-foundation machine, the invention of M. Guazzoni's, of Golasecca, to whom a gold medal was awarded. This machine, which resembles the Fari's and that described and illustrated in the *British Bee Journal* in May 1883, but differs from these in that the plates instead of being

of plaster of Paris are made of metal, and are somewhat like the plates used before rollers were introduced. M. Guazzoni's plates in his hands produce comb-foundation with walls as good as the roller machines, and would be useful to amateurs and those bee-keepers who would like to

make their own foundations; but knowing as we do the care that is needed in properly manipulating wax to get uniform sheets, we do not think that these plates will replace rollers. Two metal plates are fixed to each other by hinges, and have two handles, as shown in the illustration. When in use the plates are covered with very thin starch paste, and are then plunged, partially open, into the molten wax, closed, and then withdrawn. Then the superfluous wax is taken off, the machine A opened, and the sheet of foundation (F) removed. The wax has to be kept at an equal temperature; and for this purpose the tank C containing the wax is placed into an outer vessel A filled with water, the temperature being kept up by the lamp B. This way of making foundation necessitates a large vessel into which to plunge the plates, and consequently the use of a large quantity of wax, and not within the pecuniary means of every small bee-keeper who can make foundation in the following manner:—Under one of the plates place a board a little larger than the plate well saturated with water; the wax can be melted in a small saucepan placed into a larger one containing water. The plates are moistened with honey diluted with water, and a small quantity of molten wax is then poured on to the lower plate, the other is immediately lowered, and the excess of wax is pressed out on to the board, from which it is easily detached. A little practice will soon teach how much to pour on without causing much to overflow. The plates are made the size of comb-foundation required, and by cutting round the edges with a knife the sheet is removed ready for immediate use.

A DANGEROUS INSECT.—We extract the following from Major-General E. F. Burton's *Reminiscences of Sport in India*, a highly interesting book, published by Messrs. W. H. Allen & Co. The dangerous insect is a large wild bee, presumably *Apis dorsata*, which builds its nest something of the shape and size of a small cart-wheel on horizontal branches of trees, and under shelves of high rocks:—

'These bees are most irascible, and, if disturbed, will fly out in swarms on the intruders, whether man or beast, and follow them for miles. I once found my tent pitched under a tree upon which was one of these great nests, and very uneasy did I feel during that day; fortunately no fire had been lighted, or the swarm would infallibly have turned out, and we might have been chased away for miles, leaving the tent and equipage to their pleasure. Several fatal accidents have happened to

sportsmen and others who have been so unfortunate as to disturb these insects. The case of two officers is well known, who, at the "marble rocks" of the Nerbudda River, were attacked and driven into the river, where they were drowned. Many a camp has been attacked, and the horses and bullocks stung to death. Animals, when picketed or tethered, of course fall easy victims. The only way to escape serious injury or death is to wrap one's self up in a blanket, or anything of the kind which may be at hand, or to plunge into water and splash violently to save such part of the head as may remain exposed; failing the possibility of either of these expedients, the only chance is to lie down, with face, neck, and hands as much covered as possible, and to remain perfectly still; the bees then may leave the sufferer, thinking that they have finished him.'

top and bottom, are three deep in cases, standing across the frames, and differ from the Rev. (J. Maynor's, which bottom of racks, and are in our opinion more suitable for these very reasons. The bee space at top and bottom we consider injurious when turning up sections, because it leaves a double space much too large between the two towers, neither can these sections with four projecting ends have such a neat appearance as those at present in general use.

The pamphlet also contains useful hints on obtaining strong colonies, care and sale of honey (although the use of galvanised tanks is not advisable), queen introduction, and dry-sugar feeding. The mactapping machine as a labour-saving implement, if effective, should be useful, but we should have preferred it constituted in such a way that the combs could be lowered by means of a frame like the Zorzi machine, instead of trusting it to one's hands. The author does not appear to be reversible frames, and says 'that a simple and substantial movable frame gives us all and more than all the advantages claimed for the reversible frame, which in whatever form used is always insecure.' Whether the production of wax will pay, or whether this system will supersede any and every other, time alone can decide. In the meantime no doubt there will be some who will try the method and give us the results of their experience.

Selected Query.

[265.] In working for section honey, is there any advantage in using excluder zinc between hive and racks of sections? Does it interfere with the work of the bees, or reduce the possible honey harvest?

We never use excluder-zinc, and believe that it interferes very much with the work of the bees. We would rather have a few sections spoiled by the queen breeding in them, knowing that we are more than compensated by the extra quantity produced.—*EDITOR.*

There is no advantage. It interferes with the work of the bees, reduces the honey harvest, and encourages swarming. Sufficient room for breeding below and turning up sections above, with ordinary care will enable any one to dispense with excluder zinc, and to reap a larger harvest of sections of better quality, than by its use. It used at all it should cover the live or six central frames only, leaving the sides of the lower hive clear for the bees to ascend and descend.—*G. MAYNOR.*

I say no advantage, but much otherwise would result from its use. Obviously it is an impediment, and must cause a loss of time in gathering and storing honey.—*J. GARBATT.*

No; the excluder zinc is not required. It is a great disadvantage, and interferes very much with the production of comb-honey. I believe it makes as much as one-third difference in the quantity produced. I speak from my own experience, having tried it a year or two since with two hives side by side, one with and one without the zinc.—*W. WOOLLEY.*

I never now use excluder zinc under the section crate. It only bothers the bees, and, being a good conductor of heat, is detrimental to keeping the brood nest warm. If the crate is properly made and is not kept too warm the queen will never, or hardly ever, lay eggs in the sections, unless the brood space is too small.—*G. WALKER.*

If there is a space of $\frac{1}{8}$ ths of an inch left between the top of the brood-frames and the bottom of the sections, excluder zinc is not necessary. I never use it. To a small extent only does it interfere with the work of the bees if of the correct size.—*JOHN M. HOOKER.*

There is no advantage whatever, neither is there any necessity for zinc excluders with a properly constructed

room.' His hives were octagon boxes, an empty one being always placed under the brood, and the top ones, having an empty space near the entrance. We would also refer to Bromwich, who, more than a hundred years ago wrote his book on *Management of Bees in Colonies* in a hive worked exactly on the same principle. He also says, 'Bees kept in colonies require no attendance, as they never swarm unless forced to it by not raising them. During the last two centuries, the same principle has been advocated repeatedly, both in England and the Continent; and even to this day it is extensively practiced in some countries. Now is the system new as applied to straw hives. We had a straw hive in four stores, the invention of M. Santia, in 1845, which was fitted with bars, and worked on exactly the same principle. It might interest some of our readers to know that the collection of hives, &c., we gave to the British Beekeepers' Association, contains a set of Godde's and Bromwich's hives, as well as the straw hive above alluded to; and we hope before long room elsewhere may be found to exhibit them. None of these hives proved satisfactory, and have by degrees been given up; and those using them now on the Continent are looked upon as far behind the times, and are certainly not amongst the successful honey-producers. This is the principle applied to frame-hives which Mr. Stimmus claims as original. The destruction of the eggs in the comb we cannot look upon with favour, as being wasteful. The last feature in the system, we think, consists in giving bees ready-made combs in the sections instead of foundation; this we have tried ourselves, and we know that any sections not finished and extracted in the autumn are taken to much more readily than foundation. We cannot see the utility of dividing a hive into compartments, and separating the brood by separators, when working for extracted honey, as it is perfectly possible to get combs sufficiently flat to uncup even with the machine recommended by Mr. Stimmus. The author does not use dividers for sections and yet recommends them for extracted honey. The amount of labour in working on this plan seems to be so considerably increased that it is doubtful if it can replace the more simple storying principle. In his advertisement in our columns it was stated that 'No other bee-master has yet succeeded in so managing, that the bees actually have no desire to swarm, and the knowledge of this system alone will prove invaluable to all who intend to make a business of bee-keeping, as it is well understood that the act of swarming during the height of the season is a loss of at least fifty per cent to the apiarist.' Does Mr. Stimmus really not know that not only have bee-masters for years worked on the non-swarming plan, but that they have also succeeded in so managing that the bees actually have no desire to swarm? We could mention many apiaries where this has been carried out, and also state that although last season was a prolific one in swarms, we did not have one, nor was there any attempt at swarming. In the instructions on preventing swarming in *Bee-keepers' Guide Book* these principles are insisted upon, and amongst the methods advocated is the one of supplying empty comb or comb-foundation to give the space needed. There is much useful information to be gathered in the pamphlet, and on some points we can quite agree with the author, although we should never think of using the sections by recommendations or adopting his method, because we are able by much simpler means to work our bees both for comb and extracted honey. Mr. Stimmus illustrates his sections and 'crate' (which he thinks should be the name of the racks into which the sections are placed). These sections, which have a bee space at

be aware, our honey is only rivalled by that of Mount Hymettus; and your George Armstrong tells us, in his *History of Minorca*, published in 1750, when he was Military Governor of the island, that owing to the great abundance of aromatic herbs our honey is unsurpassed. Considerable quantities of the nectar were at that time exported to England *via* Gibraltar.

Now, as to our race of bees. I am informed it is unknown in England; but they must be of a superior kind, for they work and breed tremendously, and not only do they wear the three classic gold bands, but when ventilating they put out a fourth and thicker line on their posteriors, which occasionally resembles a triangle in shape. And they wear grey jackets that are golden in the sun, when seen through a magnifying glass.

I regret I am unable to ascertain whether our bees really gather pollen from *Clematis Vitalba*, it having ceased to bloom. But as in November and December I knew of no flowers then blossoming bearing white pollen, I concluded it came from the *Vitalba*, which they visited extensively. Shall look into the matter next season.

Our almond trees are again in blossom, and a pretty sight it is to see in mid-winter trees in full bloom with not a green leaf visible. I can only compare it to our trees in America after a snowstorm. The crop will be short owing to a succession of gales from the north.

I see the Rev. Mr. Stroud writes from Africa that he has hives with three and four queens working harmoniously. How is this to be understood?

In looking over my populous hive, I found the inner blanket, which was thickly enamelled with propolis, pretty badly eaten up. Is it the bees? Also a place on it, nearly over the entrance, quite mouldy-like. Did the bees want ventilation? I have since found the wool thus gnawed from the blanket under the hive entrance, together with two or three large larvæ, and therefore conclude the bees did it to get rid of their enemy, the mothworm.—F. C. ANDREW, *Minorca*.

P. S.—Would some of your readers have the goodness to send us a queen-wasp in a newspaper? It need not be alive.

[It is probable that the moth-larvæ have utilised the blanket in constructing their passages.—ED.]

'NORFOLK AND NORWICH BEE-KEEPERS' ASSOCIATION.—REPORT.

[271.] I am not aware if you have seen the report of the above Association. There are one or two points in it to which I should like to call the attention of our county members. Originally there were nine rules, now we have ten. I know, sir, that you are not a Norfolk man, but to us it looks very much like wishing to exclude such men as the Rev. J. Lawson Sisson and others from attempting to make the tent what it should be, and what it *must* be, if it is to pay, *popularly interesting*. I will give two quotations from editorial articles from the *Eastern Daily Press*:—'The labours of our facetious and untiring correspondent, the Rev. Lawson Sisson, are not likely to go unrewarded.' And again:—'When we sit in our parlours eating bread and honey, we may thank the Rev. J. Sisson for the vigour with which he has promulgated in these districts the gospel of the bee.' Since 1881 this veteran bee-keeper has written nearly one hundred letters to the various papers upon apiculture, and I assure you that it is men of ability like this that this new rule is aimed against. Then, again, what atrocious spelling we get: amongst the advantages of membership, 'The *principle* advantage,' &c.; and further on, 'Bees suffering from *dysentery*,' '*priviledged*.'

The committee decided not to offer prizes for bee-furniture, feeling that a large amount had hitherto gone to those who did not interest themselves in the Association.' In spite of this they fooled away 4*l.* 5*s.*

as *hire* for an implement tent. Again, we have the addition of seventy-four new subscribers, and yet in the balance-sheet subscriptions only amount to 54*l.* 15*s.*, while in 1882 the subscriptions were 62*l.* 10*s.* 6*d.* Then, again, as assets, they put down 'Bee-tent and appliances, 25*l.*' Nonsense! 10*l.* is nearer the mark. 'Skep, 6*s.* 6*d.*' What a wonderful skep! Then, again, they say 'The manipulating tent was well patronised during the afternoon, 8*l.* 13*s.* 6*d.*, having been taken.' Now, by report of 1882, when well-known and tried bee-keepers were allowed within the holy precincts of the inner circle *without any special* permission of expert or secretary, the receipts were 31*l.* 11*s.* Yes, and if our tents were only made more attractive by amusing lecturers, even more might and *would* be taken even in our county of Norfolk.

It is very painful for me to have to pen this criticism upon our county Bee Association. I *do*, and I ever shall look back with the greatest feeling of pleasure to the days when Mr. Sisson and myself first started an Association for this county. I grieve to think that those in authority should have allowed 'private jealousies and animosities to prevail over a regard for the general good,' &c. (these are the late Mr. Peel's own words, though not written of our Association), and should have ventured to issue a report which, to say the least, is grossly misleading.—ALFRED E. BOOKER HILL, *The Chase, King's Lynn*.

EPITAPH ON THE ZULU QUEEN.

Within this glass there lies, alas!

The body of a queen,

Of princely birth, of priceless worth,

With bands of golden sheen.

Why did she die? Ah! tell me why,

From Afric's sunny clime,

Through ocean's roar, to England's shore

She travell'd in her prime.

But common bees (no judges these

Of excellence of birth,)

Refus'd to take, for Walker's sake,

Her, at her sov'reign worth.

So did she die, and outstretched lie,

Her royal heart was burst,

Bereft of breath, still fair in death,

His last love, and his first.—R. S. ROUTH.

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[203.] *Croaking Noise*.—I know my cousin 'South Cornwall' well, and as he is such an intelligent bee-master my answer need only be this—You have no doubt often heard a queen 'piping,' and seen the movement of her body when doing so. Well, just in the same way does the drone act, which I found out by very careful observation.—THE MANAGER, *North Cornwall Apiary, Rowe, Bodmin*.

[254.] *Carniolan Hybrids*. (M. J. A.)—Very good; they are less irritable than Ligurian and black hybrids.—W. B. WEBSTER.

[255.] *Dry-sugar Feeders*. (G. S. F.)—There are various makes of dry-sugar feeders. Having found 'trouble' in inserting the wooden frames in interior of frames, let me suggest that you would find one of Mr. Meadows' round tin sugar-feeders placed over hole in quilt at top of frames of great service.—MELISSA.

[256.] *Two Queens in one Hive*. (Trevor Saynor.)—Such a thing is possible, using excluder zinc, but would be of no practical utility, in fact very much the reverse. The whole of the internal arrangements of the hive would be turned upside down. Fancy the poor bees struggling through two or three sheets of zinc loaded with pollen for the larva in the end division; how much would they have on their legs by the time they had arrived at their destination? and how about the drones worrying to get outside, stopping up the

holes, and so preventing ventilation? the queens fighting through the bars: it would be a mess. Do not think of doing such a thing.—W. B. WEBSTER.

[256.] *Two Queens in One Hive.*—It may be done if perforated zinc be used instead of excluder-zinc and give two entrances, that, of course, would make it practically a twin-hive.—WOODLEIGH.

[257.] *Division Board.* (F. L.)—It is very seldom bees leave much honey in the last comb by the time winter commences, when your plan of a division board would be as cold as an ordinary one. If you want a warm dummy make it double and fill it with cork dust.—W. B. WEBSTER.

[257.] 'F. L.'s' proposal is feasible, but to do so he must place his division-board or dummy farther from the last frame to give room for his half-comb so that the economy of space would be nil.—WOODLEIGH.

[258.] *Drone Foundation.* (A. B. Johnston.)—Bees build, fill, and seal over drone comb quicker than worker. Drone foundation is frequently placed in sections where whole sheets are used. I used a few whole sheets last season; the midribs, when eating the sections, were 'a caution' to any one having carious teeth. Do not use excluder zinc under racks; it is a nuisance.—W. B. WEBSTER.

[258.] 'A. B. J.' answers the first part of his query by his suggestions at the end, *re* the excluder-zinc over frames—sections filled with drone-size comb do not present such a nice flat even surface as those filled with worker-size.—WOODLEIGH.

[259.] *Weight of Combs in 1-lb. Sections.* (A. B. Johnston.)—Five drachms, forty-six grains, troy, or just under one ounce avoirdupois. This is rather heavy. They vary considerably.—W. B. WEBSTER.

[259.] 'A. B. J.'—Not more than one-eighth of an ounce.—WOODLEIGH.

[260.] *Artificial Queen.* (A. B. Johnston.)—Queens reared artificially, or rather through the intervention of a skillful apiarian, are quite as prolific as those reared without such aid. The above is, I presume, your meaning of an artificial queen; but such a thing as an artificial queen I never saw, except in the shape of a humble-bee at the end of a line when trying to entice Mr. Chubb from the mill-stream.—W. B. WEBSTER.

[261.] *Honey Receptacle.* (East Cumberland.)—It would be the wisest and cheapest plan to procure a properly made honey-drum. You would have to wax the inside of your barrel in order to prevent the honey soaking in.—W. B. WEBSTER.

[261.] I think it would be to the advantage of 'E. C.' to purchase a cylinder at once with strainer, and tap at bottom, as the specific gravity of ripe honey would cause it to sink below the thin watery unripe honey, where it could be drawn off at the tap and the other left to ripen; but if 'E. C.' leaves his combs in hive to be sealed his honey will be ripe when extracted, and will not require maturing in bulk.—WOODLEIGH.

[262.] *Painting Hives, &c.* (W. G.)—Your plan would answer admirably. Endeavour to take the frames out *en bloc* by placing strips of wood under the ends of the frames, especially if the weather is at all cold; there is no fear of losing queen if done carefully and observantly. (2.) At this time of year, yes.—W. B. WEBSTER.

[263.] *Syrup and Honey.* (Br. W.)—You need be under no apprehension of such an event occurring; bees will want all the stores they can get for rearing their brood before the honey-flow comes. Uncap the syrup a little at a time and place such frames close to outside of brood-nest; they will be emptied speedily.—W. B. WEBSTER.

[263.] (Br. W.)—The stored syrup will most probably be all required for food ere the honey season, unless 'Br. W.' overfed in the autumn and clogged the combs with a large surplus. I would advise uncapping some of it and thereby induce breeding, and of course a larger consumption of stores.—WOODLEIGH.

ERRATUM.—In reply to Query 215, page 143, for Baldwin's low skeps read bar skeps.

Will 'W.' who advertised appliances for sale in our two previous issues, kindly send us his address? Letters addressed to initials are not taken in at the Post Office.

Queries.

[272.] *Cleaning Extractor.*—I have a honey extractor made of tin, which, through want of proper cleaning after use by borrowers, has got slightly rusted. What can I do to it? Is there any varnish or paint I can apply after thoroughly cleaning that would not affect the honey when in use?—J. I. S.

[273.] What is the best material for section dividers, and what is the best arrangement for same?—F. McK.

[274.] What is the probable amount of honey a super, size 18 x 13 x 4 $\frac{1}{2}$, would contain?—it is made to contain six combs with glass dividers.—R. CAIRNS.

[275.] *Lovely Queen.*—Since I last wrote, I found in another apiary a fine healthy young queen deserted by her subjects, but the hive was full of stores in capital condition, and had a feeder on for 'spring stimulation.' Can any one give me a reason for this, as the kind replies to my former question do not quite meet the case?—OLD DRONE.

Echoes from the Hives.

Nyon, April 9th.—Colonies in my apiary are strong for the season. Many have bees covering eight frames (thirty-two litres), and have three, four, and five frames of brood; others cover seven frames, and one only six frames.—E. B. [Our correspondent uses the Dadant hive, the frames being nearly double the size of our Standard frames.—ED.]

Geneva, Switzerland, April 2nd.—I recently visited M. Fusay. He was examining the hives in his pavilion, which is constructed on a new principle. He opened a hive which had not been touched since last autumn; this was, however, easily seen. It contained eleven or twelve very large frames of comb (a little larger than the Dadant);* the colony occupied not quite completely five combs (in his note book he put down four covered). We reckoned, I think, 65 lbs. of honey (at any rate not less); and not a single comb was mouldy. He said he had not found one mouldy comb in all the hives in the pavilion.—ED. BERTRAND.

Oxford, April 1st.—The past week has been characterised with cold and furious winds, and heavy storms, which has been successful in keeping the bees inside the hives and stopping pollen gathering, which had been carried on extensively during the previous fortnight. The occasional bright sunshine has worked much harm amongst stocks, as the insects have been drawn forth to a cruel death; owing to the clouds covering the sun while the bees are flying, and the cold overpowering them. We still hope for better times, and, as hope is spoken of by an old writer as 'the beautiful sun, which colours all it shines upon,' better times may come. But, on any account, we in this part of the kingdom cannot be so forward as we have been on previous occasions.

South Derbyshire, April 8th.—For the last fortnight the weather has been quite disheartening—cold, gusty winds, with showers of rain and sleet, have kept the bees in every day. Have not touched a hive since first examination. Out of my seventeen hives, one only has come to grief, dysentery and subsequent dwindling being the cause. This hive was the only one on which I left the old propolised quilt through the winter.—M. J. ASTLE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

ZERO.—*Doubling.*—The space bees usually respect is between $\frac{1}{4}$ to $\frac{3}{8}$ of an inch. Our frames reach to within $\frac{3}{8}$ of an inch of the bottom, and as the top of the frames are level with the top of the hive there is generally the $\frac{3}{8}$ inch space between them.

E. T.—*Vignole System of Swarming.*—1. The book you require is *La Ruche*, by A. Vignole, 2 $\frac{1}{2}$ francs, published at the Bureau de l'Apiculture, 59 Rue Monge, Paris. There is no English translation of it. 2. This depends upon the strength of the colony and the prolificness of the queen. Vignole says from twenty to twenty-five days. 3. No; the manipulations are performed on the thirteenth

* About double the size of our Standard frames.

and eighth days, that is twelve and seven *clear* days between. 4. A.'s first swarm retains stand No. 1, the place A occupied.

FLORIST.—*Melilotus leucantha*.—*Melilotus leucantha* is a biennial native of Britain, and other parts of Europe, also Siberia and Northern India; it is an introduction into North America. It grows to the height of two to three feet, and produces its flowers in July or August, on long racemes, or spikes. They are small, white, and sweetly scented with a honey-like odour; hence its name *melilotus*. It is not very showy, but is sometimes met with in gardens, grown for the scent the flowers emit. It is quite hardy, and a most excellent honey-secreting plant. It is known under the names of *Melilotus vulgaris* and *M. alba*.

C. 1. *Cleansing Hives*.—This should be done twice a-year—once in spring (now), and again when packing for winter. Take a spare hive, lift out the combs from No. 1 hive into it, clean and use No. 1 to put the combs of No. 2 in, and so on. 2. *Foundation for Sections*.—The less you put the better, as it frequently leaves a thickening of the midrib, which is unpleasant when eaten. A three-cornered piece is better than a square one. 3. *Last Year's Sections*.—Yes. If only bruised or chipped they will soon be repaired. 4. *Second Crate of Sections*.—If your colony is working well in the sections, and honey coming in abundantly, as soon as the sections are about half filled, raise the crate of sections and place the second beneath it. The bees will not desert the first, but will finish it off, carrying on the work in both crates. 5. *Removing Sections*.—It is better to leave them on until thickly sealed; they do not look so nice, but for commercial purposes thin seals are unsuitable, as they weep after being kept a little while.

NUCLEUS.—*Tin Separators*.—Unless you are expert at cutting tin straight you had better have them cut for you.

B.—*Artificial Pollen neglected by some Stocks*.—Probably they have a sufficient supply in their hives to serve the wants of the brood. The Mediterranean heath is not, we think, generally known; we shall be glad to hear more about it from you.

MISS M.—*Bar-frame Hive undisturbed for eight Years*.—The combs must be getting too old for use unless they have been rebuilt, which may be the case. At any rate, it is high time the hive was overhauled. It can be done at any time now, choosing a warm day. Having thoroughly cleaned the hive, insert frame of foundation in the centre of brood nest, and as the bees increase another. By this means the old combs will get to the sides of the hive without brood in them. They can then be extracted and melted down.

J. W. P.—*Bottle Feeders running Syrup*.—The cause is their not standing level, or the caps not fitting air-tight. If air can enter it will displace the syrup.

ANXIOUS.—1. The cause of variation in colour is that the bees are hybrids. No doubt they swarmed last year, the Ligurian queen went with the swarm, her successor mated with a black drone. 2. *Moors*.—You can only expect heather honey from those localities, and being within 1½ miles from them you will certainly get some.—3. You can get fruit-blossom honey if your bees are strong enough to gather it, and a harvest from clover and lime-trees (if any) later on.

ST. BERNARD, PENZANCE.—*Doubling*.—In working hives in the ordinary way for comb honey, our experience has been similar to yours, although we have sometimes had five frames covered if the stocks were extra strong in the autumn. On the doubling principle it is very different, as when there are three or four hives worked one on the top of the other, and the queen has full scope to lay, the populations are so large that it is not until quite late in the season that all the bees can be got down into one body box. We have had so many bees in a hive that we could only remove the frames from the second storey, and leave the box so as to give the bees sufficient room until the cold weather caused them to cluster more closely. With such colonies, it is not extraordinary to find in the middle of March enough bees to spread over eight combs. We did not mean it to be understood that at this time we expect the bees to be crowded on eight combs,

although we like to see enough to cover them thinly, and we then reduce the combs to as many as will crowd the bees, probably to six. Of course, if we could get sufficient bees to crowd eight combs, we should like it better, and we should not require to stimulate so much, but we generally find we can easily crowd the bees spread over eight on to six. If young and prolific queens are only kept, and breeding kept up late, the bees ought to go into winter quarters crowded to overflowing on ten combs with sufficient stores, which ought not to be exhausted when they are first examined. With large populations working in four storeys, there is not much difficulty in having sufficient bees to fill one body-box and if most of these are young, as they would be if the queen were kept breeding late, and all the brood from second storey brought down into this, they would come out strong in the spring. With Cyprian and Syrian bees, the queens generally lay later in the season, and commence breeding earlier in the spring. Black bees and Italians do not do so to the same extent. Our frames are not so large as the Dadant, being nearly half the size, but we received a letter from a friend who saw a hive opened in which the bees occupied five combs, and he estimated that they would completely cover four. These frames are larger than the Dadant, so quite double the size of our standard frame. They would be equal to from eight to ten of our frames, so that you see our experience of large hives does not differ very much from those who have been in the habit of using them for some time (see 'Echoes.') You do very well if you are able to work up your combs of bees to produce 100 pounds a stock and leave abundant stores for the longest winter.

C. W. R.—The sample of American cloth forwarded is not suitable on account of the smell attaching to it, otherwise it would answer the purpose.

NOVICE, C. R.—Your bees died solely from starvation. You should have given more winter food of sealed store to so strong a stock of bees. You may use the old comb again, but cut and melt down the drone-comb and those parts which are clogged with pollen. Leave the sealed honey in the hive for the present, and occasionally uncap a little. Suppers should be put on when the hives are full of bees, and when honey begins to come in freely, generally from the middle of May to the beginning of June, according to the season. They should be taken off when filled and the combs nicely sealed over. A hive which has no brood or eggs at this date is queenless, and should be united to another. It is useless to rob another hive of brood to give to it.

A. ROCHER.—You can get good enough hives to begin with for about 12s. 6d. We prefer them without legs, and the alighting board to reach the ground. Certainly have the frame at right angles to the entrance. If you wish to go in for extracted honey only, you will not want any special supers, and all the hives can be made to pack flat when not wanted for use. The pamphlet you allude to is quite out of date, besides, we do not recommend the system, and we consider feeding syrup to produce so-called comb honey fraudulent. The sugar is not converted into honey. Get *Modern Bee-keeping*; it only costs 6d.; is a most reliable guide.

MRS. A.—*Carniolans crossed with Ligurians*.—The cross would not differ much from one with black bees. Possibly the tendency to swarm existing in Carniolans might be perpetuated.

C. C. M.—*Mouldiness of Combs*.—The cause is undoubtedly damp. Remove the combs, dry them in front of a fire, and brush off the mould. Uncap the honey in one, and give it to the bees, and the others as they can take them. Lose no time in shifting your bees into a dry hive with proper roof to it, and thoroughly dry all the quilts and coverings.

NORTH COUNTRY NOVICE.—1. *Proposed Shed*.—From your description of your premises you had better not erect any shed, but place your hives facing the south and west, keeping out of the shadow of the house. The house will not interfere with the flight of the bees. 2. *Feeding*.—Yes; feed gently at once, about a gill each evening to each hive. The proportions you name are correct for spring feeding.

ASH.—*Reducing size of Hive.*—You should brush or shake the few bees off the combs before putting behind the dummy. If you were so careless as to put the queen behind it, she might perish, or the bees might join her there. 2. *Zinc for Frame Ends.*—This is very seldom used now, metal ends to the frames having rendered it unnecessary. It should be stout, one sixteenth inch base, and screwed firmly on. 3. Mr. Simmins' frames are same outside size as Association, but being of stouter wood, the inside size is less. 4. *Quilt for Storeyed Hive for Extracting.*—One thickness of felt with a board on it. 5. Of Mr. Huckle, Kings Langley. Dates, January 15th, June 1st, and October 15th, 1884.

A YOUNG BEGINNER.—*Separators.*—You would find tin separators serve your purpose best: they can be cut to size by any ironmonger: wood separators are also very suitable, and more easily to be obtained. Zinc excluders are objectionable: with a little degree of care the queen will remain in the body-hive.

SURREY BEE-KEEPER.—*Red Clover.*—Ligurians and Eastern bees can obtain honey from red clover (*Trifolium pratense*). It is probable also that Ligurians crossed with Carniolans might be able to take advantage of its presence; but to the ordinary black honey-bee red clover is valueless.

S. T. T., JUN.—The present position of your stocks enables us to say that your mode of procedure so far has been successful. It is desirable that you should continue to stimulate by gentle and regular feeding. The evidences that you mention would induce us to believe that if you could inspect the interior of the hive you would find the bees in all stages, from the egg upward. The blackthorn will be found of great service to the bees. The gorse affords the bees pollen, and some honey, but not in a very great degree.

AMATEUR.—It is practicable, if you so wish, to super skeps by putting on glass jars of the size mentioned; it would be of some assistance to the bees to give them some kind of starters.

WEST CORNWALL.—1. With bees healthy, and with queen breeding, you have every prospect, by gently and regularly feeding, to build up your stock by the beginning of June. 2. The mother-bee goes off with the first swarm, consequently the hive from which the swarm has issued will have the following year a young queen. In the event of the first swarm re-swarming it would be headed by the mother-bee. All the after-swarms would in time, if fertilised, have young queens. Have you rightly apprehended Mr. Simmins' statement?

J. C. I.—The temperature of the parent stock at the time of swarming rises very suddenly. The average temperature of the hive is from 90 to 95 degrees, at swarming time, rather over 100.

Received from Mr. J. R. W. Hole, of Tarrington, Ledbury, Herefordshire, his Illustrated and Descriptive Catalogue of Bee-keeping Appliances. This catalogue contains much useful information for amateurs and practical bee-keepers. With it he has forwarded one of his 'Herefordshire Simplicity Supers.' It contains twelve 1lb. sections, constructed so as to be placed on the frames of a standard hive without crushing the bees, and to be removed, when filled, without the jarring so irritating to bees. The sample received is well put together.

From Mr. Redshaw, of South Wigston, near Leicester, his 'Illustrated and Descriptive Catalogue of Hives and Bee-keepers' Appliances for Taking Honey without Destroying the Bees.' This is a very ample and well-arranged catalogue.

From Mr. A. Hutchings, a sample syrup bottle-feeder. This has various merits: the stand is made of all wood, which, being a non-conductor of heat, renders it very suitable for the bees; then the grains of the wood crossing each other there is no fear of buckling or sagging. The amount of food given can be easily regulated. It will be found a very handy, practical feeder.

From Mr. Kinnaird Jenkins, of East Horsley, Leatherhead, models of a frame-holder and frame-carrier. These we retain until such time as a place can be provided for the inventions of ingenious bee-keepers,

Somerset Agricultural Association Meeting

At WELLS, May 11th, 12th, and 13th, 1886.

THE SOMERSET BEE-KEEPERS' ASSOCIATION will give PRIZES for HIVES, SECTION-CRATES, SKEP COVERS, &c., at the above Show. For Entry Forms and full particulars apply to the Rev. CHARLES G. ANDERSON, Otterhampton Rectory, Bridgwater.

By the kind permission of the Council of the Somerset Agricultural Association, the BEE TENT of the S. B. K. A. will be on the Ground. LECTURES and MANIPULATIONS will be given each day.

CHARLES G. ANDERSON, Hon. Sec. (135)

NOTICE.—For late Pollen grow SUNFLOWERS. SEEDS from Best Varieties, 3d. per Packet. Address W. HOLLINS, 9 Tillington Avenue, Stafford. 128

Seventh Edition. Twelfth Thousand.

BEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By THOS. WM. COWAN, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of HOLLISTON & SONS, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. HUCKLE, British Bee Journal Office, Kings Langley, Herts.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 12-16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Entries close May 12th. Secretary, J. Huckle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE APIARIAN EXHIBITION AT SOUTH KENSINGTON.

It is with feelings of great pleasure that we refer our readers to the report of the Exhibition's Sub-committee on their negotiations with the authorities of the Indian and Colonial Exhibition and the Royal Horticultural Society, and beg to congratulate the Association on their having secured so excellent a place for their proposed exhibition as the Royal Conservatory, and in having obtained the co-operation of the Royal Horticultural Society in their undertaking. The Committee have shown much promptitude and tact in having in so short a time overcome the seeming obstacles in their path, and in having brought the preliminary business to such a practical conclusion. The Committee having so far successfully performed their part, it lies with the bee-keepers of the United Kingdom to do theirs. The success of the Exhibition now depends upon the support given by the several affiliated Associations and by the manufacturers of bee-appliances who will chiefly be benefited by the Exhibition, and the amount of the subscriptions to the fund now being raised to guarantee the Association from any possible loss. The grand design of the Exhibition is to demonstrate to the world, and especially to those who may exhibit honey in the Colonial Exhibition, that Great Britain is a honey-producing country; that since the establishment of the B.B.K.A. there has been a remarkable increase in the number of those who have devoted themselves to this new industry; and that in the future there is a capability of further development, so that the demand of the British public for honey can be supplied by their own countrymen without having recourse to extraneous sources.

The Committee suggest that the principal feature of the show should consist of a general exhibition of British honey, the produce of all parts of the United Kingdom; and to carry out this purpose they request that each affiliated County Association in England and Wales should exhibit a carefully-selected display of honey produced in its own county, and from the apiaries of its own members; and that their displays should be competitive for special prizes to be awarded to the Associa-

tions. They also desire that there should be a similar competition among the recognised associations of Scotland and Ireland. This competition among the respective Associations we consider to be an excellent suggestion, and one that should commend itself to the several County Associations. It is very desirable that good and attractive prizes should be offered for the competition, and that such prizes should be divided into two parts: (1) for the honey itself, and (2) for the taste displayed in the mode in which it is staged. A county may be able to produce good honey, but unless it is accompanied by style in presenting it to the public eye it is not easily disposed of. Whatever progress has been made in former exhibitions in taste and display, we would urge that on this occasion every pains should be taken to make a distinct and visible advance, so that this exhibition may prove more attractive than those of former years. A good impression is always left on the mind when the eye beholds a show arranged in a pleasing and artistic manner.

The Central Committee have commenced the work well, and will, doubtless, carry forward their plans and preparations in the same spirit, and they confidently look to the Associations for their earnest co-operation. The results of the Exhibition will depend on the mutual support furnished by the Central and affiliated Associations; and it is hoped that both will combine to employ their experience and their best energies to ensure a success which will be gratifying to all concerned in it.

CERTIFICATES FOR USEFUL INVENTIONS.

We are glad to notice that the Committee of the B.B.K.A. have a desire to render the Quarterly Conversations more practical in their results. Besides the papers that may be read on these occasions they propose to invite bee-keepers to forward for exhibition and criticism inventions and improvements that may be useful to those engaged in apiculture; and should any

of those be found worthy of commendation to award certificates to the exhibitors. Such certificates coming from so competent a body and so able to judge of the merits of the article and its utility to bee-keepers would be appreciated and eagerly sought for—at the same time certificates so given would be a safeguard to the public, who would thus know that the article they purchase was one that would be serviceable.

GLEANINGS.

In the *American Bee Journal*, J. B. Mason says, 'It was but a few years ago that the bee-keepers of Maine looked with distrust upon the reports of 100 lbs. of honey from a colony, that was occasionally reported by eastern bee-keepers; but, with improved implements and modern management, to-day many Maine bee-keepers can report 100, and even more, pounds of comb honey from a single colony.'

In *L'Apiculteur*, M. Bellot says, that in September he takes the honey from a certain number of hives. The driven bees are then united to other hives, which are not so strong. In one of these unions at the end of September, he did not notice a dead queen thrown out, as usual. Fifteen days later, when he had got some Italian queens he wished to introduce, he searched for the queen of this united colony, and found a very aged one, which he at once destroyed. His astonishment, however, was great when in returning the bees to the hive he found another queen, equally aged and of little value. His explanation is that the bees, whose instinct is wonderfully developed, finding themselves in the presence of two queens equally worn out, or very nearly so, and foreseeing the death of one at no distant date, did not destroy one for fear of the other perishing before she could be replaced; they therefore wished to preserve both.

In the *Illustrierte Bienenzeitung*, C. F. H. Gravenhorst calls attention to an article by Dr. Hess on a bee-louse, which, besides giving much new information on the subject, also shows the reason why the remedies M. Gravenhorst has for so many years advocated and applied have been so efficacious. The louse (*Braula cava*) principally attacks queens, and is difficult to catch, being so swift in its movements. The eggs, according to Dr. Hess, hatch inside the insect, and the young larvæ are nourished by the secretion of a gland; but when they arrive at maturity they are deposited on the floor-board of the hive, when they take the chrysalis form, from which they emerge at the end of fifteen days. The young lice remain on the brood until they have a chance of climbing on to a passing bee. Strong fumigations with tobacco dislodge the lice, and the floor-boards are cleansed several times with a mixture of water and carbolic acid. It is important to keep the floor-boards clean.

In *Gleanings* A. I. Root says, 'For some years samples of comb foundation have been sent out with very deep walls, even so deep that the queen might lay eggs in this foundation, or the bees might store a little honey in it without working over it at all. The walls are much thicker than those of foundation with shallow walls. He has been carrying on experiments with a view to testing which the bees work on most easily. To test the matter he placed pieces of both kinds of foundation in empty frames in the centre of strong colonies. The result is, the bees take hold of one foundation just as quickly as the other, and they draw it out into comb at the same rate of speed. But when the finished comb is held up to light there is a very remarkable difference. The deep-cell heavy foundation has the bottom just about as it was made by the foundation rolls—the deep walls are also about the same—while the other is thinned down in both walls and base of cell, so near to the natural comb that it is difficult to distinguish the difference. The

foundation he recommends is seven square feet to the pound for brood-combs. Some manufacturers make it as heavy as from four to six feet to the pound, and some specimens have been made that only gave $3\frac{1}{2}$ square feet to the pound. Such foundation is extravagant, being very expensive, and has no merit except that it is handsome to look at.'

In the *American Bee Journal*, W. L. Hutchinson says, in preparing bees for a journey in frame hives, he does not put sticks down between the combs, as usually recommended, but has had better success without. He fastens the frames by merely nailing their ends with $1\frac{1}{2}$ in. nails to the rabbet of the hives, leaving the heads to project a quarter of an inch, so as to easily withdraw them. When fastened in this manner, the frames cannot slide about, neither can they swing together close enough to injure the bees, while their not being fastened at the bottom allows the frames to move slightly under the influence of a sudden jolt, which assists the combs materially in sustaining the shock without injury.

Foreign.

ITALY.

Although rather cold and changeable, the weather of last month has not been worse than is generally expected to be in March. No general harm seems, moreover, to have been done to apicultural interests during the last month, and bee-keepers will be satisfied if April is, comparatively speaking, equally favourable to brood-rearing.

The Library of the Association has just been re-organized by Signor Fumagalli. From his report, it appears that it now consists of over 600 volumes, and that it is constantly receiving fresh additions, one of the latest of which being a book by Signor A. Ricci, of Empoli.

That well-known work upon *The Anatomy of the Bee* published by Signor Clerici under the auspices of the Central Bee Association, and favourably noticed in the *British Bee Journal* of February 1876, is exhausted, and no more applications for the work can now be entertained.

A stock of that famous bee, the *Apis dorsata*, has left the East Indies for Milan *via* Venice, and will be consigned to the apiary of Chevalier Luigi Sartori, of that city. Its results will be watched with considerable interest by the Italian bee community.

The Minister of Agriculture has given orders to the Central Association for a number of hives and swarms to be sent to several schoolmasters throughout the kingdom. The order is being executed, and the interest for bee-keeping on the part of the Government has been favourably received by all interested in bee industry.—From the *Apicoltore* of Milan.

FRANCE.

According to our contemporary *L'Apiculteur* of France, the severe cold experienced during the first two weeks of last month has had the effect of preventing the spreading of brood, but, generally speaking, apiaries do not appear to have been otherwise affected beyond the delay which such a check must of necessity involve. It is evident, however, that damage, although in an indirect form, has been caused in those districts where rape and colza are grown on a large scale, the late severe cold weather having nipped the plants. The red trefoil has also been seriously affected in numerous localities.

As regards honey, the cold weather of the last two months has been very favourable to its consumption, and several holders have been enabled to dispose of their stocks at prices varying from 70 to 100 francs per 100 kilos for the ordinary kinds, extra fine having found buyers even at from 100 to 130 francs. Although stocks

are yet far from being exhausted, yet there is every reason to believe that by the time the new crop can be placed upon the market very little honey of last year's harvest will remain unsold.

The wax market has been very active in best qualities, some of which have found buyers at 315 and 320 francs per 100 kilos in bond. From Marseilles it is reported that owing to large arrivals the stock has increased rather than decreased within the last month, but with an active market a great deal will be disposed of in a very short time.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Committee Meeting held at 105 Jermyu Street on Wednesday, April 14. Present: the Hon. and Rev. H. Bligh (in the Chair), Rev. Dr. Bartrum, Rev. F. S. Selater, Rev. F. T. Scott, Rev. F. G. Jenyns, Captain Bash, Captain Campbell, J. M. Hooker, H. Jonas, D. Stewart, G. Walker, and the Secretary. Letters were read from W. O. B. Glennie (Treasurer), Rev. G. Raynor, and Rev. J. L. Seager, regretting their inability to be present.

The Examinations Committee reported that the necessary arrangements for the first-class examination to take place at South Kensington on May 15th were in progress. The Exhibition's Sub-Committee reported as follows:—

'After an active negotiation with the authorities of the Indian and Colonial Exhibition and the Royal Horticultural Society, in which the prompt and business-like action of Mr. Huckle and the energetic influence of the Baroness Burdett-Coutts were very useful, the question of our having leave to hold the Show, as desired by us, in the large Conservatory was referred for the decision of the Prince of Wales; and His Royal Highness has directed that we shall have the desired permission, subject to a conditional reservation, which will not seriously incommode us. The Show is therefore practicable, and we have commenced the preparation of plans.

'The extent of the Show and the completeness of the details will be reported on when we know more certainly what assistance will be given by the several affiliated County Associations, and the amount of subscriptions to the Donation and Guarantee Funds. These subscriptions at present amount to 911.; but we consider that a full and sufficient show ought to be supported by a fund of not less than 2000.

'We desire that a principal feature of the Show shall consist of a general exhibition of British honey, the produce of all parts of the United Kingdom, and that for this purpose each affiliated County Association in England and Wales be requested to exhibit—in form and manner, and under conditions as to quantity, &c., which shall be common to all—a carefully selected display of honey produced in its own county, and from the apiaries of its own members, these several displays to be competitive for special prizes to be awarded to the Associations.

'We desire also to arrange a similar competition, if possible, for recognised Associations of Scotland and of Ireland. We further propose to have an exhibition consisting of all the different kinds of honey obtainable in this country, and such other exhibits as shall be found possible to show the importance and extent of the honey industries of the United Kingdom.

'Exhibits of hives, and of apian appliances, and of any other matters interesting to bee-keepers, will also be provided for.

'The question of a Conversazione, to which colonial exhibitors may be invited, or as to any other social recognition of such exhibitors pending the Indian and Colonial Exhibition, must be reserved for a later stage of the proceedings.

'We have directed communications to be made to the County Associations, asking for their co-operation.'

'LIVERPOOL EXHIBITION.

'Arrangements are being made with the Royal Horticultural Society as to this Exhibition, and we hope to obtain a grant from them which with other receipts will protect us against loss. This is the first of the series of annual Provincial Shows of the Royal Horticultural Society; and we have reason to believe that they welcome our desire to contribute to the interest of their shows by placing the apian department under our management.'

The Sub-Committee's report was discussed at some length; the proposal for a county competition was generally approved. It was considered that an attractive appearance, combined with taste in staging the honey, should form a leading feature in such a competition.

It was resolved that in future the committee would receive newly-invented or improved articles relating to bee-culture for examination and discussion at the quarterly meetings; and in the event of such articles being found of special merit, the Association's certificate should be awarded.

NORTH-EAST OF IRELAND BEE-KEEPERS' ASSOCIATION.—CONVERSAZIONE.

On March 25th, a highly interesting conversazione was held in the Museum, College Square North, under the auspices of the above Association. The hon. treasurer (Mr. S. Cunningham) and the hon. secretaries (Messrs. A. Crawford and Paul McHenry) deserve well of the friends of the Association for the arrangements made for the evening entertainment.

Messrs. McKenzie and Co. kindly lent for exhibition all the modern appliances in the most improved methods of bee-keeping; and these, being described by Mr. McHenry, became quite a special centre of attraction. There were also scientific instruments, particularly microscopes, under which was to be viewed much that concerned the structure of the bee. The gentlemen who kindly furnished the table with these instruments and supplemented the gift with the advantage of their explanations, were Messrs. W. S. McKee, Joseph Wright, W. Swanson, A. J. Firth, Rev. H. W. Lett, Rev. J. Andrew, S. Wylie, and W. Welch.

Mr. C. W. Henderson, Norwood Tower, sent for exhibition some specimen sections of honey, the quality of which was highly complimented by several of the more skilful judges present. Mr. McHenry also lent exhibits of honey.

The Chairman, Mr. J. K. McCausland, J.P., Vice-President, stated that the object of that meeting was to give information so as to assist some of their friends who had recently become bee-keepers. As they were now approaching the honey season, they wanted to instruct them, and to induce others to become bee-keepers. They would endeavour to point out to them the right kind of bees to commence with and the best hives to use. The Association was not yet two years in existence, but they had been very successful in consequence of the energy of some of the members.

Rev. H. W. Lett said he must congratulate the North-East of Ireland Bee-keepers' Association on the success which had attended their first conversazione, and he hoped it would give an impetus to bee-keeping. They had done a great deal during the past two years in promoting bee-keeping, but, in spite of that great deal, of which they were not a little proud, he was sorry to say that in many cases bee-keeping had made no improvement. He held in his hand a survey of the County Down, which gave an account of bee-keeping eighty years ago, and illustrations of the improved hives then used. From that he found that the beehive of which they had heard so much lately was in use at the commencement

of the present century. In organizing that Association for the improvement of bee-keeping, they were only taking up the work which had been more or less carried on many years ago. The reverend gentleman then gave some practical suggestions to those about to commence bee-keeping. He advised them on no account to buy badly-made hives, as the price of them was only money thrown away. Let them get the best hive in the market, and the result would be most satisfactory. He had seen many failures arising from the use of ill-constructed hives.

Rev. J. Andrew referred to Canon Tristram's description of how bee-keeping was carried on in Palestine, where he had been travelling for the purpose of surveying the country, and Dr. Tristram stated that among the inhabitants at the present day the barbarous practice of destroying the swarms to obtain the honey was unknown. Mr. Andrew concluded by reading some extracts from Canon Tristram on the subject.

Not the least important part of the programme was the answers given to queries that were put in writing on the subject of the habits, &c., of bees.

The conversation was brought to a conclusion shortly before ten o'clock.

WARWICKSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of the above Association will take place on May 6th, at the Grand Hotel, Birmingham, at 7 p.m.; the Right Hon. Lord Leigh presiding, to be followed by a short lecture by the Rev. K. Suart, and afterwards a general discussion on bee-keeping.

BERKSHIRE BEE-KEEPERS' ASSOCIATION.

A branch of this Association has been formed for Wallingford and district, and it is hoped that all those who are interested in bee-keeping will join, through the honorary district secretary, Mr. Geo. F. Reely, of Brightwell, who has kindly undertaken the duties of the office, and from whom all information can be obtained.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

**.* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

LONDON APIARIAN SHOW, 1886.

[276.] All County Secretaries have been asked for assistance from the counties towards meeting the cost of the South Kensington Show. I am sure that the vital importance to British bee-keeping of holding such a show at a time when a large colonial one is being held in London has only to be understood in the counties to insure a ready response. On all sides it seems agreed that the show is only possible provided that its cost can be met without drawing on the already fully employed funds of the B.B.K.A. It seems also absolutely necessary that not a moment should be lost in raising the required money, and making the arrangements. So, may I be allowed to suggest to my brother county secretaries that they will probably be easily able to find amongst their most prominent members several willing to pledge themselves to collect a certain sum from the other

members in their neighbourhood? Each collector could name the sum he will guarantee, and the county secretary will then be able at once to tell the show managers what sum can be counted upon from his county.

In this way, in a few days, a guarantee could be raised amongst the affiliated County Associations which would insure a successful show being held, and this without taxing the ordinary income of each Association. The circumstances under which this show is to be held are very special ones, and seem to require special donations to meet them, without crippling the work of the County Associations at home.—COUNTY SECRETARY.

BEST SIZE SECTIONS FOR GENERAL USE.

[277.] I should be glad to hear from your correspondents the objections to the 4" x 4½" sections, as would, I venture to think, many others of your readers. My own objections to the 4½" x 4½" sections are the following:—

1. Because they will not suit the standard frame, or rather a hive 9" x 14½" (inside measurement), thereby discouraging all such hives for valuable and interesting observation as Neighbour's Kilburn hive, &c., unless these hives were made with a deeper frame, which is not desirable for raising honey in sections—besides the increase in cost of hive.

2. Because, when a super of sections is placed over a standard hive, it does not cover the sides of the frames so much as desirable.

3. The lifts for 4½" x 4½" sections must exceed 4½" in height, and therefore two widths cannot be cut out of a 9" plank.

Whereas, in my opinion, the 4" x 4½" sections possess the following advantages over the 4½" x 4½" sections:—

1. Besides economy in cost of hive and super, they economise the heat better than the 4½" x 4½" (as in the Stewarton hive).

2. The sections being different in width and height do not require such extreme care in packing. Maxim—'Time is money.'

3. An oblong block of honey has a better appearance in a dish than a square block, and would therefore be more saleable, weight for weight.

If the B. B. K. A. adopt the suggestion of the Rev. G. Raynor, and make the standard sections 4½" x 4½" should not the standard frame be altered to 8½" x 12¼" inside measurement?

It is true that the 4½" x 4½" sections are the most generally used; but that is probably because there was no other section in the market which held 1 lb., until the 4" x 4½" section came up of late.

My object in writing this letter is not to prevent others from using the 4½" x 4½" sections, but that before I give up using the 9" x 14½" hives, to ascertain whether the 4" x 4½" sections are to be given up entirely.

In the event of other bee-keepers besides myself desiring to use these latter, possibly some bee appliance manufacturers would be willing to guarantee to supply them in future years at equal cost and quality to the 4½" x 4½" sections.—A. T. WILMOT.

THE STING.

[278.] In the paper on the sting as an ovipositor, and discussions thereon in your columns, two opinions are advanced that appear to me to be erroneous. The first, as to serratures (barbs). These are described as natural to the hymenopterous ovipositor, and a state of perfection in development would consist in their being improved out of existence. I regard the matter in entirely the reverse aspect. The ovipositors of insects are naturally and originally smooth and polished; but in the hymenoptera

there is a capacity for developing on them serratures where they would be an advantage, and this occurs accordingly, to a marked degree, in the phytophagous divisions. It occurs slightly (as barbs) on the sting of the honey bee, not, I hold, as an imperfection to be removed by further development, but because the degree to which it exists is that which is precisely the most advantageous to the bee.

This brings me to the second point, namely, that these barbs *are* an advantage to the bee, and not the contrary. Half my argument may be briefly expressed by saying that this is one of those cases that has given rise to the observation or aphorism, that nature is most careful of the race, most enreless and lavish of the individual. It is everything that the hive should be protected, it is nothing that a few worker bees should perish. If, therefore, the sting can be made more effective, that its use should lead to the death of its owner is immaterial in comparison. Whether the assailant be man, bear, or other honey-lover, he will instantly rub off any bee that stings him; and, since it is necessary that the sting be very sharp and slender so that the force at the command of the bee shall cause it to penetrate, a very trifling amount of poison would be injected, and the pain of the sting would almost instantly cease. But not so, the barbed sting remains behind, with its poison-sac, and continues injecting poison and penetrating more deeply, and the pain caused is thus much greater and more lasting.—T. A. CHAPMAN, *Hereford*.

UNFERTILISED QUEENS.

[279.] I find, in reference to this subject, professional bee-masters from time to time through the *B. B. J.* saying, and even so recently as in the first issue of March of this year, that unfertilised queens are drone-breeders, that is, if we introduce an unfertilised queen to a colony of bees she will commence egg-laying, and these eggs, if attended to by the bees, will ultimately hatch out drones. Now are we, at the close of the nineteenth century to accept these statements as sufficiently demonstrated facts, or are we to say they are wrong, and cannot but be wrong, because they contradict every other sentence in the great volume of Nature? Now the question is not in reference to drone-breeding, but simply this: can there be progeny at all of any kind without fertilisation? If so, how? Perhaps some of your more advanced correspondents will take the matter up and give us the benefit of their views and experiments on this great question, which will, I have no doubt, interest many of your readers.—A PUPIL.

[We would recommend 'A Pupil' to procure and study Professor C. T. E. Siebold's book *On a True Parthenogenesis in Moths and Bees* (London, 1857).—Ed.]

QUEEN-RAISING IN SMALL APIARIES. [231.]

[280.] Perhaps relating my experience may be of a little value as an answer to Mr. F. G. Jenyns' query. I commenced bee-keeping in 1880 with one stock in a straw skep. At the commencement of 1883 I had five stocks in bar-frame hives and one in straw-skep, which number I have not yet added to. In 1884, wishing to re-queen three of my frame-hives, I removed the old queens about three weeks before the honey-harvest might be expected to end, so that the hatching brood might keep up the strength of the stock for that time. In this district the honey-harvest usually ends with July, so I removed the old queens on 7th July; there were no queen-cells in the hives at the time. On the 24th they all had young queens hatched out and they were all laying about the middle of August. Neither my own nor my neighbour's bees stored any honey after the middle of July that year. The three stocks from which I removed the old queens gave me that year

39 lbs., 46 lbs., and 66 lbs. respectively of extracted honey, the average from my six stocks being 51½ lbs. Last year the same three stocks with their young queens, and a honey-harvest lasting three weeks longer than in 1884 gave me 111½ lbs., 107½ lbs., and 104 lbs. respectively of extracted honey. I also re-queened one stock successfully in the same manner last year, and intend to follow the same plan again this year.—GEO. FRANKLIN.

PACKING SECTIONS FOR TRAVELLING.

[281.] A query was inserted some time back, but I do not remember to have seen any reply to it. Perhaps a few words would not be out of place, although the season for despatching small parcels of section honey has gone past for the present. I sent a rather large consignment to one of the shows in the South of England last year, and did not get a single section damaged, although when I went to the railway station for it I found it in divers positions. One large case containing eight dozen was on its end, another bottom upwards, another on its side, while two travelling crates containing three dozen each, with glass sides, or rather showing the glazed sections, was deposited out of harm's way. I told my man to bring his cart; and then to see the way the careful servant of the railway company began to turn over and over again the large case. I said, 'Gently, friend, look at the label please.' 'I hadn't noticed that this was honey,' he said, 'but I could see that was across there.' I put that out of the way, referring to the glazed sections in the open-sided crates. Now every one of the cases had conspicuous labels on the top with the direction, 'This side up,' &c., but after all the pitching and tumbling about, as I said before, not a single section was damaged on either journey. How was it packed? The sections were tied up in dozens, then some straw or hay or shavings were put at bottom, then the sections of honey each glazed and tied in parcels, then the packing stuffed in tightly all round and over the top, thus forming an envelope of packing that breaks all the jars and knocks on the railway; and notwithstanding the advantages that may accrue from the visibility of the honey in the ordinary travelling crates, I prefer a common starch box or anything that will take the quantity required with some packing all round. In closing I may say I have sent honey in the comb to *India*, and it has reached its destination safely packed as above, only using sifted cork-dust instead of other packing.—WOODLEIGH.

SPRING STIMULATION AND THE BLIGH COMPETITION.

[282.] I cannot but think that a great deal of good might be done through your valuable *Journal* by experts and practical bee-keepers giving their experience on the merits and demerits of the system of spring stimulation. Mr. Lingen Seager, the Rector of Buckland-Sedleigh, and Mr. W. N. Griffin, have written strongly on the subject, but there must be a large number of experienced bee-keepers who could enlighten us on so important a question.

I was much struck on reading through the diaries of the Bligh Competitors (as given in last October *Journal*) to find that Mr. T. Owen, who did so grandly and carried off the first prize, and left off with five good stocks, makes no mention whatever of having fed or stimulated his bees during any part of the competition. Was his success in any way attributable to his not doing so, or was it merely an omission on his part to record the fact in his diary? All the other competitors who took prizes make mention of having adopted the system of feeding. Mr. W. Woodley, who did well, and took second prize, states that he fed slowly from the 11th April to the 25th May. Mr. Sealbrook, who took third

honours, states that he fed from one hole from 28th February to 3rd May. Each of the other competitors fed for longer or shorter periods, all apparently with good results. I do not wish to bring about a controversy between the competitors on this question, but to obtain the opinion of other experienced bee-keepers on the utility of spring stimulation.—W. A. WARRILOW, *Chippenham*.

DO BEES HEAR?—A CRUCIAL EXPERIMENT.

[283.] It has struck me that a crucial experiment may be tried in the coming season as to the powers of hearing possessed by bees. It is well known that if hived bees are brought near to a moping batch and if the bees in the hive set up the wonted hum of contentment, the batch of listless bees will suddenly change their demeanour and turning towards the hive, some fanning, will all run gladly towards and into the entrance of the hive. Now, in such a case, it can never be proved that smell is not a coefficient.

I propose to store up the contented hum of a hived lot by means of a phonograph, and to experiment with this stored-up sound, subsequently, upon a discontented batch of bees. The experiment might be made by any or all bee-masters who either possess or can borrow a phonograph.—FRED. STOCK, *Burton Bank, Mill Hill, N.W.*

BEE TREES.

[284.] I noticed in a recent number of your valuable and interesting *Journal* some comment on the above subject. I have been fortunate enough to come across several of these natural 'hives,' and they are, I think, more common than most people think. I have cut out three in one locality, viz., Broadwas, near Worcester; and among others I have seen, one was within a quarter of a mile of my own apiary, in the stem of a broken and dead poplar, quite twenty feet from the ground. Bees in this wild state sometimes grow immensely rich in store; one that I cut out at Broadwas, assisted by my friend who keeps the Post Office there (Mr. Wormington), who is just beginning bee-keeping, was in the stem of a willow-tree growing almost in the hedge. The bees had an entrance right into the hedge, which shows how diligently they search for these homes. No doubt a well-organized reconnoitre is made by a large number of bees, told off for the service, as I cannot think they meet with these places by chance. The stem of the tree was about thirty inches in diameter, and we bored with a three-inch American augur several holes, cutting them with a chisel into one large opening. We cut through about three inches of green wood, and then about as much more of decayed, soft wood, making a very warm lining to the hive, which was a sight to please the eye of an enthusiast. The combs were about thirty-six inches long, fifteen inches wide, and two inches thick, the lower ends to about nine or ten inches had been used for brood, the other was perfectly clear virgin honey, 80 pounds, which we divided with the owner of the field. The combs were beautifully straight except at the lower part, where I found a mass of comb all and every shape, evidently the soft wood had given way when the first attempt was made to build their comb at the top, and from the appearance, I should say the combs were afterwards built upwards. The combs were a light straw colour, so that, I think, they were a swarm of the previous year only. We inverted a cheese-box near the tree, and shook off all the bees we could in front of it, and left them at mid-day amidst thousands of robbers, including wasps and hornets; and at night we found all the bees in the box and the tree deserted. Seven pounds nett we estimated the weight of the bees, but I am sorry to say I have just heard they have succumbed to the cold, and probably want of food. This district seems very rich in honey, all the hives I drove were simply

full; and one lady told me her bees always swarm early in May, and this on the 'let-alone principle.' Perhaps this accounts for there being so many wild bees there. I have heard of others there, and a gentleman told me a short time since, that near a village in Cheshire, among some very large trees, there were scores of these 'wild swarms,' and had been for years.—C. H. BICKLEY, *3 Fern Villas, Green Lane, Smallheath, Birmingham*.

QUEEN ODOUR.

[285.] In the issue of the 11th February, 1886, the following paragraph appears in Mr. Benton's method of queen introducing: 'The strange queen is caged long enough to acquire the peculiar odour of the hive to which she is to be given.' I think, Mr. Editor, that the foregoing is somewhat at variance with the general opinion on this subject; at least, if I am wrong I shall be very pleased to be corrected in a following issue of the *Journal*.

A very interesting discussion took place at the Conversation of the B.B.K.A., held on 20th January, but the full report was, no doubt, omitted for want of space, in which the question of the queen's peculiar scent was debated; and it was, I think, unanimously agreed that the bees ascertain the presence or absence of their queen by a strong odour emitted from her, to which the bees are accustomed. Mr. Baldwin said, and was corroborated by other members present, that the reason of bees swarming on a certain branch of a tree or bush consecutively in a season was in consequence of the smell left there by a previous queen; but that the preference for that particular alighting spot only lasted for one season, the odour being dispelled by the ensuing winter. He also went on to say that if a queen be taken out of a hive and handled for some length of time, she will lose her scent, and if returned to her hive her life will in consequence be endangered. Mr. Hooker suggested that the reason was, that the queen would lose the odour of the hive from which she was taken, in which opinion he appears to be supported by Mr. Benton in the paragraph above quoted.

Now, if it is a fact that the queen, when inserted in a new hive, loses her former and obtains a new odour, it would, to a great extent, upset the fact that the bees in a hive are aware of the existence or not of the queen by the power of scent; for if it were the peculiar odour of the hive, and not of the queen, that is the important point, then how is it possible that the loss of the queen is ascertained by the faculty of scent?—WALTER G. CAMPBELL, *Hornefield, Tottenham*.

PLANTING FOR BEES.

[286.] In a previous issue of the *B. B. J.* in the spring of last year, I promised to make known to bee-keepers through the *Journal*, my experience and the results of some 250 different kinds of seeds, the merits of which I was then testing with a view of bringing before the notice of bee-keepers generally such kinds of bee-forage as might be worth profitable cultivation. As a large percentage of the seeds I sowed were annuals, I regret to say that owing to the unfavourable dry season, most of them perished. Some perennials that were of a harder nature managed to survive; but, of course, it will require another season before they can be tested. I shall not be daunted by this failure, as I am convinced that there is still a number of good bee-plants to be discovered and added to the already valuable list familiar to most bee-keepers.

The raising of plants from seeds is always an interesting occupation, but much more so when there is some other object in view than the mere endeavour to obtain certain plants. Two years ago I saved a few stock seeds, as I am very fond of that favourite flower for

the garden. When the seeds began to make their appearance I was surprised to find among the young stocks a plant quite different from any of which I have ever seen; and which I have since asked the opinion of two gardeners, and neither could inform me what the plant was, as they could not remember having seen a plant like it before. I was very envious about this plant, and thought I would test its merits as a bee-plant. It came into bloom early last May, being covered with millions of small yellow blooms, and continued to bloom on until cut down by a hard frost that came last September. The bees worked well upon it from the commencement of its blooming period until it was cut down by the frost alluded to, and in fact even after shrivelled up by the frost, the bees endeavoured to get something from it. The bees obtained nectar from it, but pollen was the chief thing sought after, and it was surprising to see what large pellets they could collect in a very short time. Whatever this plant may be, I claim for it to be one of the best pollen-producing plants ever brought before the notice of bee-keepers, and one that should be grown by every possessor of bees. And now that I am speaking of pollen plants, *Helianthus* (sunflower) should not be overlooked. When I say sunflower, I do not mean that old-fashioned single yellow-eyed variety, grown by almost everybody, but that grand double dark-eyed variety of recent cultivation known, I believe, as *H. globosus fistulosus*. It bears grand double flowers of immense size, producing honey and a fine quantity of pollen very valuable for late breeding.

It is the collection of this late pollen and the storing of the same that enable the bees at this early part of the season to produce good batches of brood, which by a little stimulation can now be turned to good account.

The recent severe winter has proved the necessity for planting a good stock of early forage for our bees to work upon on the first opportunity. Large batches of snowdrops, crocus, and arabis, in close vicinity to the hives at this part of the season, are very valuable to the bees, and I propose to give to bee-keepers very shortly my views on the subject of planting forbees.—W. HOLLINS, *Tillington Avenue, Stafford.*

[Will our correspondent, when he has the opportunity, take the trouble to forward us a specimen of the nameless plant, and we will endeavour to procure its name. Being as valuable as he states, it is desirable that it should be generally known.—ED.]

UPWARD VENTILATION. (35.)

[287.] Before long, I presume, we shall learn the result of the experiment by the author of 'Useful Hints,'* on wintering bees without upward ventilation. The weather this winter has been such as to give the experiment a fair trial, which will make the result very interesting.

In ordinary winter weather, I have no doubt that bees would do just as well, if not better, without upward ventilation, but can they stand a sudden rise of temperature succeeding continued cold?

I believe it is generally agreed that bees can withstand cold far better than damp, and upon this is based the theory of upward ventilation.

The bees clustering together in cold weather leave the ends of the frames and sides of the hive comparatively cold, and when there is a sudden rise in temperature, the warm moist air condenses on these cold surfaces—as on a window in frosty weather. Upward ventilation is useful in evaporating this moisture. It is a cure for dampness in a hive, and the question is, can we do without it? Without upward ventilation the warm air outside would not have such free access to the hive. Moreover, the hive would not be so cold, and I think that with a strong colony crowded on a small number of frames, we should without upward ventilation entirely,

or almost entirely, prevent the condensation of moisture and prevention is better than cure.

I should, myself, have tried wintering this season without upward ventilation, but I was deterred by the account in Root's *A B C* book (edition, 1883) of his experiments with chaff packing, the success of which was most striking, nevertheless that the cold seems to have been more intense as well as more prolonged than in England. He even speaks of a 'zero temperature.' Root's experience would be almost conclusive, but for a fact that he does not appear to have previously reduced the number of frames for wintering, and his success may be due to the reduction of the number of frames, and not to the upward ventilation, and, perhaps, he did not before use sufficiently warm coverings.

It must be borne in mind with regard to upward ventilation, that the lower the temperature in the hive as compared with that outside, the less will be the upward ventilation, so that the loss of heat is greatest when it is least wanted. Also, that when the warm air passes upwards, the heat is to a very great extent retained by the quilts or chaff packing, and by radiation returned to the hive—as in the case of a fire at the back of a grate, or blankets on a bed. It is quite possible also, that on a sudden rise of temperature the air in the hive may be colder than the outside air, and in that case a *downward* current of air would pass through the quilts or chaff packing, but this would be so temporary that it would, I fancy, make no practical difference.

Again, if we do away with upward ventilation a certain quantity of heated air could escape through the entrance, being replaced by cold air from outside, and the hive would be ventilated in that manner. Root noticed a bit of chaff blown out of the entrance of a hive as if impelled by a draught of wind, and this although the hive had upward ventilation. It will be observed that the opponents of upward ventilation advocate the enlargement of the entrance to summer width.

The mode of ventilation through the entrance is, I take it, as follows—Heated air ascends from the cluster, the air below taking its place, and drawing in cold air from the entrance. The heated air spreading along the top of the hive loses its temperature as it reaches its sides, and descending as it does so, escapes at the entrance, so that there is constantly a current of cold air passing in at the entrance, and a current of warmer air passing out. This would be more marked if the bees cluster towards one end of the frames, or if the sun shines on (and warms) one side of the hive, and it is possible that the cluster of bees moves so as to increase, or decrease, the ventilation as necessity may require. Ventilation through the entrance resembles the experiment described in the *Boy's Own Book* of burning a lighted candle under a bell jar with a small aperture at the top, and a piece of cardboard edge down in the aperture. The candle does not go out, as at one side of the card there is a down current of air, and at the other side an up current, thus preserving the necessary ventilation.

In one place in Root's book, he speaks of a current of warm air from the entrance of a hive melting the snow in front of it.

I cannot conclude without expressing my appreciation of Root's admirable article on ventilation in relation to damp. It is a subject on which there is a great deal of misconception.—F. L.

BEEES AND DROUTH.—A singular circumstance is reported from a hot, dry valley in New South Wales. The previous year the drouth was of long duration, and the denizens of the apiaries suffered much from it. The next year the bees made provision against a similar emergency. They filled a number of the external cells in every hive with pure water instead of honey. It is thought that the instinct of the little creatures led them to anticipate a hot summer.

* See 'Useful Hints,' p. 136, 'Enamel Cloth.'

Reviews.

GESCHICHTE DER BIENZUCHT. By J. G. Beszler, Ludwigshurg, Germany.—This work which consists of 270 pages of ably written matter, is a history of bee-keeping from the earliest to the present times. It does not pretend in any way to be a practical book on bee-keeping, but it is hoped that there may be a great many whose sole object is not one of £ s. d., who may desire to know besides the practical part of the business something about the origin and history of its development. For such this book is written, and we promise them if they will only read it that they will not be disappointed. The author, in a very happy manner, describes the mythical stories of ancient times which are in any way connected with bees. The bee has been known to exist in Egypt for upwards of 4000 years, because it is found on hieroglyphics dating before this period, and has always been looked upon by the Egyptians as a symbol of monarchy. Amongst the Jews both bees and honey are repeatedly referred to, and all the texts from the Bible relating to them are here collected. Then there is their history in Arabia, India, and Assyria, amongst the Greeks and Romans, and other people, up to the present time. A chapter is devoted to the various superstitions connected with them. Also one on bees and poetry collected from various European poets, and even the proverbs are not forgotten. There are a number of pages devoted to anecdotes connected with the employment of bees in war and self-defence. Being a German book it is natural that most of it is devoted to the history of bee-keeping connected with Germany and the German States, although casual allusion is made to other countries. All the laws relating to the ownership in bees are set out in detail, and a number of statistics given which are most interesting, and to which we shall occasionally refer in our *Journal*. The countries to which allusion is made besides Germany are Servia, Poland, Austria, Hungary, Switzerland, Italy, and America: we suppose that according to the author's judgment bee-keeping is not of sufficient importance in England, as it is nowhere mentioned. One very interesting feature is the photograph containing the portraits in miniature of 109 of the principal European bee-keepers,—Dzierzon occupying the centre place and being surrounded by others whose names are equally well known. There are also over 180 short biographical sketches of well-known living and deceased Continental bee-keepers; and amongst them are found those of Berlepsch, Bertrand, Blatt, Boutlerof, Dathé, Dennler, Dr. Dönhoff, Dzierzon, Gravenhorst, Huber, Hilbert, Hruschka, Jacob, Jeker, Langstroth, Dr. Lenekart, Dr. Mullenhof, Dr. de Planta, Dr. Pollmann, Dr. Preuss, Schönfeld, Schultz, Siebold, Vogel, and Zwilling. We heartily recommend the book to those of our readers who know the German language, feeling sure that they will derive much interesting information respecting the history of bee-keeping from its perusal.

We have received from Mr. T. G. Newman, the editor of the *American Bee Journal*, a pamphlet entitled *Brief History of the North American Bee-keepers' Society*, in which twelve pages are devoted to the first fifteen conventions, and the remainder to a reprint from the *American Bee Journal* of the report of the Proceedings of the last Convention held at Detroit on December 8th, 1885.

We find the North American Bee Association was founded on the 21st December, 1870, and the Rev. L. L. Langstroth was elected its first president. About the same time the American Bee-keepers' Association was also started, with Mr. Langstroth as president. Both these Associations were dissolved the following year, and a new Association formed called the 'North American

Bee-keepers' Society.' A digest of its proceedings is given, and from it we find that this Society has also had its dark days, and at the Convention at Toledo in 1875 'none of its officers were present except the Treasurer, and after much discussion the general opinion was that the Society hold one more meeting at the Centennial Exhibition in Philadelphia and cease to exist.' Gloomy, indeed, is the history of the Society about this time, and very little is said about it, but it was not dissolved. The Convention was held, although the attendance was small, but, little by little, more interest was taken in it, until we find in 1885 the Society records upwards of 100 members.

Although we have nothing to learn from the Americans as to Associations or shows, our own organizations of both these being far in advance of anything of the sort in America, yet we should be glad if our British bee-keepers would emulate the spirit of communicativeness displayed by American bee-keepers, and like them impart to us at the quarterly conversaciones of the British Bee-keepers' Association more of their experiences. We are sorry that we cannot agree with Mr. Newman who, in his prefatory remarks, points out that there is an opening in England and the Continent of Europe for American honey. There are evidences clear and distinct that this importation has already been overdone. We do not think it will pay to send over American honey; and although our importation of foreign honey is still very great it is chiefly confined to the inferior and cheaper qualities, which find their way also in equally large quantities into the United States, and after paying a duty of twenty cents per gallon are even sold at a lower price than American honey.

Mr. A. Todd, in speaking of this honey in the *American Apiculturist*, says, 'I know factories using hundreds of barrels of honey per annum, and they won't use American honey because the price has not been right as compared with the equivalent saccharine matter and flavouring power obtained from the foreign article.' We ourselves know that the importers of American honey have, even during the last year, not been so successful in disposing of it, and that still a large quantity is lying unsold in docks. This state of things has been brought about by British bee-keepers being able to supply the demand, and at prices which, while being sufficiently remunerative to themselves, are practically excluding American honey. Mr. Newman is also, we think, misleading when he quotes the amount of honey imported in Hamburg from 1877 to 1880 (taken from a German paper) without stating the importations since that date. The information would not be palatable, for we find by Messrs. Schacht & Lerneke's circular that exports to Europe during the last nine months of 1885 were very small, and since 1st of July last, as far as regards Germany, entirely ceased, owing, it is stated, to an alteration in the tariff. But we could point to the fact there are now more bee-keepers engaged in the production of honey, and that with improved appliances and more economical methods it is rapidly becoming a staple product all over Europe. From about 200 the number of members of the British Bee-keepers' Association and its affiliated County Associations has in less than twelve years risen to upwards of 10,000; so we again counsel foreign importers to 'pause' before they send us further consignments of their superabundant honey.

These facts should be placed before American bee-keepers, and they should not be buoyed up with the false hope of a European market which, as the number of bee-keepers increases, must, sooner or later, be closed to them.

Apidae Europææ. By Dr. H. L. Otto Schmiedeknecht.—We wish to call our readers' attention to the above work, which is at the present moment coming out

in parts. It is a history and description of every known genus, species, and variety of bee in Europe. It is the most exhaustive and complete work we know of on the subject. To give an idea of the extent of the work, we will mention that in the genus *Nomada* no less than ninety-six species are described; there are six plates of engravings containing sixty-one figures, the description occupying 249 pages (imperial 8vo.); genus, *Andrena* occupies 439 pages, and there are 186 species described. The first volume is complete in 866 pages, and describes the genera *Nomada*, *Bombus*, *Psithyrus* and *Andrena*. The work comes out quarterly, and the annual subscription is 14 marks. As a book of reference it is invaluable, and the excellent illustrations are a great help in determining species. Eleven parts have already appeared.

Replies to Queries.

* * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[203.] *Croaking Noise in Hive.*—Having kept bees twenty years or more I don't remember ever hearing the croaking noise before last year, and several times in the same hive. It sounded too hoarse to be a queen piping, which makes me think it might be a drone.—J. WILSON.

[262.] *Painting Hives, &c.* (W. G.)—(1.) The plan proposed would answer very well, but instead of makeshift hives I would recommend new hives of the same kind you now have in use (that is, if you wish to increase your number of stocks) and paint them the desired colour, and transfer the combs into them as quickly as possible, at same time leaving out the outside combs, if only for a day or two, and so crowd the bees so that they will the sooner raise the heat of hive to proper temperature. You need not fear of losing the queen if you do the work carefully and keep both hives close together during the operation of moving the combs, when what few bees remain in the hive may be allowed to fly home at their leisure, or be gently brushed up with a feather after hive has been removed a little distance. Then proceed with the cleaning of the insides, which should be well scraped with a spatula to remove all dirt and propolis, and well scrubbed out with a good stiff brush, carbolic soap and boiling hot water; then rinsed with clean cold water, allowed to drain, place in sun or before a fire to dry, well sandpaper the outsides, and stop up all nail-holes, sun-cracks, &c., with putty, and give two coats of paint, when they may be taken (when dry) to the next four and exchanged, and so on until all twelve have been finished, this will save you the trouble of transferring the same hives twice, and leave you four hives, which may be cleaned, painted, and prepared ready for your swarms. In case you do not wish to increase your number of stocks, leave the 'makeshift' hives in the place you first put them until all the hives have been attended to, when the last four finished will take their places. I have been doing my hives in the above manner, and after having given them two coats of paint I stain them with a stain made of burnt sienna three parts and yellow ochre one part, well ground in water or beer, which should be well rubbed on with a stiff brush and laid on same way as grain of wood; then, with a 'grainer's softener,' or painter's duster brush, lightly figure it over, then, when dry, give one or two coats of varnish. This is a little more expensive in the first place, but when the same operation of cleaning is required next year the hives will only require well washing all dirt off outside and revarnishing. I have several hives now in use that I have not painted these last ten years, but have regularly varnished them. I never find the water running all over insides of roofs. (2.) Absence of brood and eggs at this season of the year is almost a certain sign of queenlessness, but if the hive is well filled with bees do not trouble about finding the queen amongst them, but go on with your transferring and examine them again in four or five days to see if any eggs or brood is in the cells, when you may be sure the queen is all right. It should not be much difficulty to find a queen this time of year as I have seen no drones as yet, which sometimes are apt to deceive a novice, but any one owning twelve hives

should make a point of being able to find a queen.—W. SILVER.

[272.] *Cleaning Extractor.* (J. I. S.)—If your extractor is only slightly rusty it will not affect the honey, providing you draw it off at once after extracting, and thoroughly wash the extractor both before and after using. There is no paint or varnish I know of that is odourless; honey will become flavoured directly if placed in contact with such.—W. B. WEBSTER.

[272.] *Cleaning Extractor.*—I should think 'J. I. S.' had better get his extractor retinned. I don't think paint will prove a satisfactory solution of his difficulty.—WOODLEIGH.

[273.] *Dividers.* (F. McK.)—Opinions are very varied upon this subject. Wood dividers are cheaper than metal, but they easily break and frequently warp, so spoiling the shape of the sections; I have given them up, and now only use plain zinc of the thinnest description and find they are as near perfect as possible. The arrangement of some entirely depends upon the description of rack used; I use long ones, right across the three rows of sections; in dividable racks they must be less than height of one section, but same width, having legs to rest on side bars in order to give bee space underneath.—W. B. WEBSTER.

[273.] I prefer zinc, as it does not rust; is unbreakable and thinner than any other suitable substance cut out strip, leaving two ends as feet to rest on, strips giving bee room between tops of frames and bottom of sections.—WOODLEIGH.

[274.] *Capacity of Super.* (R. Cairns.)—A super having a capacity of 1176 inches with six combs contained 43 lbs. of honey, comb included; yours in rough figures would contain about 40 lbs.—W. B. WEBSTER.

[274.] From 30 to 36 lbs.—WOODLEIGH.

[275.] *Lovely Queen.*—'O. D.' does not tell us if there was any brood or eggs in the hive in which the queen was left 'monarch of all she surveyed' (in the dark). It is probable she may have been a late queen, as 'O. D.' says she was a young one, and not fecundated, and in this case it is probable that it was a survival of the fittest—the condition of the hive points to a small number of consumers during the winter.—WOODLEIGH.

[259.] *Erratum.*—For troy read apothecaries.—W. B. W.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[288.] *Sweetening Hives.*—Can any reader inform me what is best to sweeten bee hives with that have been destroyed by mice? Most of the frames are full of comb.—G. C.

[289.] *Extra Queens.*—In uniting to make up stocks for wintering does it not seem a pity to destroy the extra queens, some of which would be so useful, and in their prime the next season? Could they be successfully preserved indoors with a few attendants, or by any other means?—HONEY-SUCKLE.

[290.] *Swarming and Non-swarming.*—Would the honey-yield from one stock in spring, covering eight frames and allowed to swarm once, be equal to that of two stocks in spring covering four frames each, and not allowed to swarm?—HONEY-SUCKLE.

[291.] *Raising Queens.*—Can good queens be started and raised in nuclei if we take the precaution to give them but little brood, and that from our best queens, and perhaps limiting the number of cells they start?—HONEY-SUCKLE.

Echoes from the Hives.

North Notts.—March 19th and a few following days were grand, since when weather has been cold and wet. My stocks in good condition; better, if anything, than this time last year. A dozen hives through winter under enamel quilts have come through better than six under porous; as

many bees or more, and combs drier. Most of them have bees on from eight to ten frames, cold as it is. Several have brood in four or five frames. No natural food outside yet.—**FRIAR TUCK.**

Alfriston, Sussex, April 12th.—The weather to-day has been lovely and warm; bees busy gathering pollen from the elms and buttercup. Bees have been at work on gooseberries to-day, but I don't think there is much honey yet.—**YOUNG BEE-KEEPER.**

Hexham, April 14th.—I commenced the year 1885 with six stocks, five bar-frame and one straw hive, and as I did not want much increase, I worked three, for honey alone, and let the other three swarm. The amount of honey I got exceeded my expectations very much, but I must say that the weather was almost all I could desire. We have two large nurseries and lots of market gardens here; hawthorn, sycamore, and lime trees in abundance; this is, in fact, a beautifully wooded district, being a clean, healthy market town. We have a good few bee-keepers here, and I may say that a number of them are changing their skeps and box hives for bar frames, the chief complaint against frame-hives being their costliness, the extra weight and size being against them in taking them to the moors, which are about six miles from here, over very hilly and bad roads. As I am a carpenter I make nearly all my own hives, the frames of which hang parallel to entrance and hold fourteen standard frames; the hive body is double walled on each side; loose floor-boards, as I think they are more handy than nailed ones. All are made of the best pine, and well painted. Nos. 1, 2, and 4 I worked for honey alone; No. 3, 5, and 9 for swarms as well. No. 1 swarmed twice, but I threw them both back. The first weighed 6 lbs. and the second 9½ lbs.; I never saw such a large swarm. Nos. 3, 5, and 9 all swarmed, which were put into bar-frame hives. The following table shows how far behind the blacks are in comparison with hybrids and Ligurians; although the first year I had the Ligurians I was rather disappointed in them, as they did not do very much, but each succeeding year they have done better. I now give you the results:—

	Clover.		Heather.		Total.
	lbs.	...	lbs.	...	
No. 1. Ligurians	50	...	15	...	105
" 2. Blacks	28	...	9	...	37
" 8. Hybrids	24	...	21	...	45
" 4. Blacks	30	...	8	...	38
" 5. "	29	...	7	...	36
" 6. Swarm from Blacks	18	...	—	...	18
" 7. Swarm from Hybrids	49	...	—	...	49
" 8. " Blacks	29	...	—	...	29
" 9. Straw Skep	—	...	—	...	—
	297		60		357

The above is all comb honey. I use only the 4¼ × 4¼ size sections. I also took 40 lbs. of heather honey from the bottom frames, which sold for 1s. 3d. per lb., and left plenty to winter on. The section honey I sold as follows:—Clover, from 1s. to 1s. 4d. per lb., and the heather at 2s.—**T. HEDLEY, Woodbine House.**

South Cornwall, April 17th.—We have had but few days when anything could be done with bees. A fortnight ago I examined four lots and found them in good condition, and on Thursday last I looked through five or six frame-hives and one skep. In the case of the former I found brood on (generally) three frames, though in one instance on two only, and bees very numerous with abundant supplies of food. In fact, I have removed two well-filled frames of honey. I have heard of only one loss among my neighbours, and I fancy this lot was left weak. The queen and the last score of bees died last week. Other stocks are reported strong, but the wind is blowing from the east again, and everything is at a standstill. We are, however, placing great reliance on a statement made a month ago in *B. B. J.* that the fine weather 'must come!'—**C. R. S.**

Norwich, April 18.—We are having very cold stormy weather here; bees are prevented from even taking an airing. Willow has and is flowering, but very little pollen has been gathered on account of the adverse weather. Myrobella plum, whin, red flowering currant, Iberis aubrieta and wallflowers, are flowering profusely, and not a bee can get out to visit this valuable forage.—**HENRY DORRIS.**

Ballyskeagh, Dumurry, April 3rd.—We are having bad bee weather here just now; high winds, with heavy, cold

showers, and temperature very low. An occasional fine day allows bees to get flying, when they are very busy on crocuses and inverted skep, with shavings and pea-meal. Hope to send you a note soon of state of various apiaries in North of Ireland, and how bees have wintered. This would be premature just now, as winter does not seem away yet.—**P. McH.**

Killarney, 13th April.—This is the first mild day that has come since the beginning of the year. Though still the mountains are covered down to their base, what between snow, sleet, cold easterly winds, and rain, my bees have not been out more than six or seven days since the 1st of February. I got a fine hour a few days ago to have a peep at them, and found brood in different stages in all, and also discovered stores running dangerously short in three hives; yet the weather has been such since then I have not been able to do anything for them, lest I may do more harm than good. To-day, however, I begin stimulating in all my hives; though it is rather late, as the honey flow begins here about the middle of May, with white clover, and continuous until the 1st of July, when the bees finish off the surplus storing of the hives. Many thanks for the valuable 'tips' you give us from week to week under the head of 'Useful Hints' in *Bee Journal*.—**MAUGERTON.**

Minorea, April 4th.—My big hive has for some days been working in the sections. I have now added a second case of 21 sections to it, and think I shall have to add 21 more within a week, as it is very crowded on eight frames, nearly all brood; it had 12 frames, but I crowded it on to 8. Its first 21 sections and excluder behind are more than half finished. We generally manage our hives without smoke or gloves; bees very gentle.—**F. C. ANDREW.**

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column. Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

J. H. JENKINS.—Doubling.—You can if you like do as you propose, and put the hive of empty combs or foundation at the bottom. If the bees are strong and there is plenty of brood you will not find a whole box too much. You can also work your eighteen and twenty frame hives in the same way, only using two storeys, but in this case, when the whole of the twenty frames are occupied, we would only give ten above to begin with and add the other frames as they are needed on either side.

T. HILL, JUN.—I. Simmins' Original Non-swarming System is published by S. Simmins, Rottingdean, near Brighton. It may be procured from most dealers in bee-appliances. You will find our review of it in Number for April 15.—**2.** We may arrive at the development in the *Bee Journal* suggested at some future time.

W. H. R.—Transferring.—The combs in transferring had evidently not been carefully tied into the frames; they gradually fell from the top bar. They require to be cut and trimmed so that they should fit into the frame. If not deep enough to reach the bottom bar place a lath beneath it and wedge up with corks. If this is done properly the bees, if fed a little, will repair the combs, and in two days the tapes may be removed.

R. L. NEWMAN.—Wax-moth.—The maggots seen are the larvae of the wax-moth (*Galleria cereana*). Cleanliness and prompt destruction of every moth and larva will keep them in check. The most efficient safeguards are, however, strong stocks and Ligurian bees.

P. KEENE and E. TULLEY.—Same reply as preceding.

E. J. BROOKE.—Bacillus depilis (Gaytoni).—Your bees are evidently suffering from the above disease, which was formerly known by the name of 'drosy.' It has been prevalent in America of late, where it is considered a new disease. The young bees are affected chiefly, but in all probability the queen is infested by the bacilli. We refer you to the *British Bee Journal* of December 1st,

1885, 'Useful Hints,' p. 383, where the disease is fully described, together with the remedy, viz., phenol, as prescribed by Mr. Cheshire. We believe it is not contagious.

- LIGUSTICA.**—1. *Pea-flour.*—You cannot induce bees to take more or less pea-flour than suits their taste, or their needs. Supply plenty, and they will take all they require. Probably at this advanced season they will not take any, since pollen in abundance is to be obtained from natural sources, which the bees much prefer. 2. *Mating.*—An Italian queen has been known to mate with an English drone, when the two hives were seven miles distant. Practically about three miles distance will be sufficient to ensure good results.
- A. T.**—The British Bee-keepers' Association have not adopted a standard hive, though they have a standard frame, the outside dimensions of which are fourteen inches long by eight and a half deep, the top bar being seventeen inches long.
- R. K.**—*Nadiring.*—Nadiring is the opposite of supering. A nadir is an addition to a hive below the floor-board. Some bee-keepers obtain very good results from this method of management. An eke is an addition to the walls of a skep above the floor-board.
- T. HARPER.**—The oil-cloth you have forwarded will be found suitable.
- BEE-SWING.**—The honey advertised is that alluded to by us in our editorial, 'What Next?' of last week. It will be desirable to have its purity tested.
- C. HUG.**—*Uniting.*—Drive the colonies out of both skeps. Remove the oldest queen, and shake down both lots of bees together on a sheet in front of that skep which contains most sealed brood. The skep must be wedged up about three inches in front, and the bees will run in quietly and unite without any fighting. The brood in the deserted skep should be cut out and placed over the feed-hole of the other skep, and covered by a small cap (super). The bees will hatch out the brood, and there will be no loss. Any sealed honey may also be placed with the brood. When the brood is hatched—say in ten or twelve days—feed with syrup. You may thus obtain a very good swarm from the skep, and twenty-one days afterwards may transfer the parent stock to a frame-hive. We advise you to keep the frame-hives as they are for the present, feeding them when necessary, and—say in a month's time—unite the weakest colonies to the stronger ones before putting on sections or doubling for extracted honey. By following this plan you may obtain half-a-dozen strong colonies, any two of which would collect more honey than the ten together if left as they are. For doubling use a ten-frame standard; for sections a twelve-frame standard. Metal ends we advise.
- BZZ.**—*Old Combs, Dry Sugar, &c.*—(1.) You may safely use the old combs for other colonies, and for extracting when filled. (2.) Dry them before the fire and brush off any mould. Spray them slightly with salicylic acid solution, and hang them in a dry room until required for use. (3.) Dry sugar poured in behind a dummy, raised a little from the floor-board, is a very undesirable method of feeding bees. The sugar would deliquesce at the bottom of the hive and cause a dreadful mess. Syrup-feeding from a bottle-feeder is far preferable, occupies less time, and is more advantageous to the bees, being less expensive in the end. (4.) The storeys required by a strong colony during the season will depend entirely upon the honey yield. In an average season and country, if each storey contains fifteen Standard frames, one will be quite sufficient. Ten frames for each storey will be found better than fifteen. (5.) Enamel cloth, with metal binding, of a suitable texture, and very easy to manipulate, is sold by most dealers at from 6d. to 1s. each quilt, and is advertised in our columns.
- E. K. ELLIOT.**—*Abnormal Egg-laying.*—You do not give sufficient details of the colony to enable us to decide the cause of the deposition of several eggs in a cell. The age of the queen, the population of the hive, and the size of brood-nest, are important elements in the question. Judging, however, from your statement, we think the brood-nest is too circumscribed, that is to say,

a paucity of cells for receiving eggs causes a prolific queen to deposit several in one cell. Or a reduced population able to cover a small amount of brood only may be the cause. In the former case—which may arise from too much sealed honey, or from combs clogged with pollen—the remedy is to insert an empty comb of worker cells in the brood-nest, and to uncap the honey cells on both sides of the nest, removing any comb clogged with old and dried pollen. If the population is small, the addition of a weak colony, or of a brood-comb or two, with adhering bees, would be found of great advantage. At all events, we advise you not to condemn the queen, since the fault, in all probability, has arisen from her fecundity.

YOUNG BEE-KEEPER.—*Excluder Zinc.*—We do not advocate the use of excluder zinc when working sections, either on bar-frames or skeps.

J. C.—Be pleased to put yourself in communication with E. H. Bellairs, Esq., Wingfield, Christchurch, Hon. Sec. of the Hampshire and Isle of Wight B. K. A., who will be happy to inform you if there are any experts in your locality.

A YOUNG BEGINNER WILLING TO LEARN.—*Section and Extracted Honey.*—There is no doubt that if so disposed you can work for both section and extracted honey. The plan you propose is quite feasible. The sectional supers you mention, in consequence of the cheapness of American sections, are not so much in vogue as in former years. But still they are great favourites with many bee-keepers, and will serve your purpose.

MELLOR.—*Bees refusing Syrup.*—If your bees have refused to accept your syrup you may rest assured that you have made some mistake in its manufacture,—possibly in compounding it; the water or the sugar may have been bad, or it may have been burnt. Somehow their instinct has told them it was unwholesome. If being your first attempt, we can only say, 'Try, try again.'

SUSSEX AND H. C.—Queries forwarded to the writer.

A. L. PLATT.—We are pleased to hear that your stock is now progressing satisfactorily.

E. C. KERR.—The bees are infected, but since they did not reach me alive it is impossible to pronounce dogmatically upon the case.—F. C.

E. W. P.—*Drone-breeding Queen.*—The drone-breeder I do not think was bred last year in the sense you intend it. She was raised (the other queen being probably lost) too late to mate, and hence the difficulty; certainly, she had never mated. You may find a cut-down queen-cell in the hive.—F. C.

F. G.—*Bees diseased.*—The bees reached me in good condition. I find the muscles of the thorax loaded with small bacilli in dense patches. The bacillus is about the same size as Gaytoni, but is differently clustered and seems to have a different effect upon the bees. The case, I believe, to be new in character. The history of the stock would be very useful if we succeed in cultivating this bacillus. I am making the attempt both at home and in conjunction with Dr. Crookshank. Should the stock not have a chance of pulling through, so that it becomes valueless, I should esteem the queen alive as a great favour: as she would, if placed in a nucleus, give me an opportunity of tracing the case.—F. C.

H. J. L.—*Transferring and Moring fifteen yards.*—Move your skep by one yard at a time until in the place where you wish the stock to remain, then transfer to your frame-hive. You can transfer on any warm day, but let the brood be separated from the bees as short a time as possible.

J. B. S.—1. *Transferring.*—See reply to 'H. J. L.' 2. Yes, if your skep is strong and you are careful not to chill any brood and to feed gently. 3. As Sir Roger de Coverley says, 'Much may be said on both sides,' but we prefer the frames parallel with the sides. 4. Golden Syrup is unsuitable for food. 5. *Vinegar.*—The small proportion of vinegar mixed in the syrup to prevent granulation, would not have an appreciably injurious effect on the bees, or on tin or zinc.

J. L.—*Enamelled Quilts*.—Many bee-keepers have tested the use of enamelled quilts during the winter, and have had good reason to be satisfied with them. The bees have been more comfortable and the hives drier than usual. The ventilation required has been obtained through the hive entrance. The firm mentioned being respectable dealers their goods may be depended on, though we have not had any experience with the article mentioned.

A. N. MONTAGU.—1. *Comb debris*.—The powder is pollen, excrementitious matter, wax debris, &c. The bees were most probably starved, and tore down the cells to get at the small amount of honey which is mixed with the pollen. As dead bees were found on the top of the hive under the cover, there must have been a hole, consequently loss of heat and greater consumption of food. The comb forwarded was old, but otherwise sound.—2. *Getting honey from roof of house*.—The best plan would be to place a frame-hive with some empty combs or foundation, and a frame or two of brood, and place this against the wall where the bees come out, making, of course, a hole in the hive to fit the hole in the wall, and thus compel all the bees to pass through the hive. Then, two or three days after, you must break open the ceiling, smoke the bees well, and remove them, the brood, and the honey, and put them in another hive. After you have cleared out all the bees, &c., shut up the back entrance of the hive by a piece of board or slate, and the bees that are flying will collect in the frame-hive, and can be removed at night and placed in your apiary. The hole must then be stopped up with plaster, cement, &c. If you wish any further directions, we shall be pleased to give them.

ERNEST H.—*Races of Bees*.—There is every probability, as your apiary consists of various races of bees, that your queens will not mate with those of their own race; nor should this be regretted, as in-and-in breeding is objected to not only by the queens themselves, but by all bee-keepers. If you are anxious to keep your queens to drones of their own race we suggest that you should try what is called 'Kohler's process,' a description of which will be found in the *Bee Journal*, Vol. VII., p. 197.

R. J. BROOK.—We should be obliged by your forwarding to us some of your bees which you describe as 'white and fluffy,' with a view to their more minute examination.

W. L., *Mortock*.—The combs and honey may be utilised for the benefit of your other stocks.

MISS BOLTON.—1. *Tits*.—Not desiring to kill tom-tits, which are so destructive to your bees, they may be prevented from doing mischief by fixing a piece of wire-netting a few inches about the hive entrance, so that the bird cannot pick up the bees from the floor-board. 2. Fumigate the hives with sulphur, wash with carbolic-acid solution or phenolated soap.

E. DAVIS.—*Carniolans*.—The address of the Austrian firm who advertise Carniolan queens is given in the advertisement. We are not in a position to say that we have a personal knowledge of the queens sent out by them, but as the advertisers are near the habitat of those bees, they have a favourable opportunity of vouching for their purity.

A SUBSCRIBER.—*Granulated Honey*.—Granulated honey can be given to the bees; it is desirable to melt it over a fire, keeping it a little below boiling point, and to thin it to the consistency of feeding syrup by mixing with it hot water.

A CORRESPONDENT wishes to know if any bee-keeper has tried Locke's Perfection Feeder, and with what results.

Received, Leslie Tait's 'Supplementary Price List of Bee Hives and Apiarian Appliances for 1886.'

MENTHOL AND THYMOL.—I have only just noticed the questions of a 'Kentish Bee-keeper' addressed, I infer, to me (page 159). Cost, per ounce, of menthol is 1s. 3d., of which put five grains to twenty ounces of syrup for uniting purposes. Thymol is 1s. 9d. per ounce. I always use spirits of wine. Being a dispenser I am in possession of all

articles mentioned—the prices I quote are from a price list. If a 'Kentish Bee-keeper' will communicate with me and pay postage, I will give any other information required that I have found useful in regard to bee disinfection.—THOS. J. DAVIS, 12 *Palace Road, Bromley, Kent*.

We have received from Mr. H. Dobbie, of Cringleford, Norwich, a sample parcel of bee-forage seeds, and we may say that for quantity and quality those who may patronise him would have good reason to be satisfied with them. Mr. Dobbie appears to be determined to make this branch of bee-keeping a speciality, and is hunting up all plants which have any reputation as honey-secreting flowers with a view of testing their merits in this direction. We may also state that Mr. Dobbie has in the press a work on Bee-forage and cognate subjects, which will we trust fill up a void which has been long felt by bee-keepers.

MR. MEADOWS, of Syston, near Leicester, writes:—'I notice in a review on *A New Era in Bee-keeping*, a few remarks on uncapping machines. Simmins' machine, of which I am the maker, can have the feature which you recommend attached, by which the combs are lowered in a very simple manner, and the whole arrangement is a complete success.'

In the illustrated catalogue received from Messrs. Aspinwall and Treadwell of New York we note, amongst other things they illustrate and describe, an extractor almost identical with the 'Rapid Honey Extractor,' which we introduced in 1875, and which has since that time been in extensive use in this country. Our extractor is, however, more compact, as we do without the centre rod, and in this way reduce the diameter of the can and simplify the machine. Our 'Rapid Extractor' has been illustrated in most books published since 1875, and has also appeared in all the principal dealers' catalogues. This is the machine which is ten years later brought out as something new, and for which Messrs. Aspinwall and Treadwell have obtained a patent.

Editorial, Notices, &c.

DOUBLING FOR EXTRACTED AND COMB HONEY.

Those who do not desire to work entirely for either extracted or comb honey, but would like to have some of both, can do so on the doubling principle. In the first place, we must get all our colonies strong in the way already described on page 135, and as soon as the bees are ready for it, or the honey harvest commences, we put on a rack of sections. When these are full of bees, work begun in them, and honey coming in plentifully, we either put a hive filled with empty combs under the stock hive, or else put it on the top of this, and between it and the sections. If this is done at the right time swarming is entirely prevented, and the work in the sections continued without any interruption. When one-pound sections are used, three tiers of them can be worked at one time, or if the two-pound sections are preferred, only two tiers should be worked. When we wish to put on a second set of sections, these are placed under the first, and the third set is placed under the second. It will be found that these will give the bees ample room, but when the top sections are removed if we find that the honey harvest is not yet over, another whole set of sections can be given. We do not mind if they are not all completed, because the unfinished ones can have the honey extracted from them, and be put away for future use. At the close of the season when all sections are removed, the second storey will be found to contain a quantity of honey, and this can be extracted.

We may not get quite as many sections working on this plan as we might with only one body box, but we have this advantage that there is no swarming, and if the bees are properly managed there is no desire to swarm. We do not use excluder zinc or honey boards of any description, but place the sections right on to the top of the frames. The bees must also have plenty of room to go in and out freely, we therefore raise the hives in front by means of wedges, so that there are three sides which they can use for this purpose, and these at the height of the honey season will not be found too much. Outer cases, as described on page 148, to protect the hives from the heat of the sun, and allowing plenty of ventilation, should also be provided. Those who have hives on legs will find that they can easily work them in the

way we managed the Alexandra hive, brought out by Mr. Hooker in 1879. It has two body boxes, and his method of working it was to put a rack of sections on the lower hive, and if the bees swarmed, to hive them in the upper hive, and place a board between the two. The sections were then put on the second storey, the swarming fever checked, then the communication between the two hives was opened, the parent and swarm reunited of themselves, formed one colony, and work in the supers went on briskly.

We worked our hive somewhat differently, and instead of allowing the stock to swarm, or running any risk of its doing so, as soon as the frames were full of brood and the hive full of bees, we put on our sections. All the frames were then removed from the lower body-box and put into the upper one, the lower box being filled with frames of empty comb and comb foundation, and the sections put on the top. We used no board or excluder-zinc between the boxes. As the brood was hatched out the cells became filled with honey, and as fast as the sections were completed they were removed and empty ones put in their places. This being a hive on legs, and the legs fixed to the lower body-box, it was impossible to work it otherwise than by managing in this way: we induced the bees to continue work uninterruptedly in the supers, and were also able to get extracted honey without any attempt on their part at swarming. Hives on legs can easily be worked in this way, and if the tops are hinged the hinges should be removed so as to allow them to be raised above the three tiers of supers. The floor-boards must be lowered to enlarge the entrance. We must again impress upon our readers the important fact that if they wish to work without swarming, they must have young and prolific queens, and the bees must have more than sufficient combs to store their honey in. We say more than sufficient because, when they are collecting honey rapidly and it is thin, they require plenty of room to distribute it before it is properly evaporated to seal over. If they have not this room they waste their time or are induced to swarm, therefore always give them plenty of room during the honey-flow in advance of their requirements.

'A BOOK ABOUT BEES.'

One of H. M.'s Inspectors of Schools has given the following valuable testimony to Mr. Jenyns' *Book about Bees* as a Reading-book for Schools. His cordial approval

of it is all the more valuable as he is not himself a bee-keeper:—

'A most interesting book. I think it is very well adapted for a school reading-book. To begin with, it is a subject that is in itself most interesting, as well as instructive: the necessary technicalities are put as simply and clearly as possible, and the book itself is full of interesting illustrations and stories which would catch a child's attention, and is written in an easy, readable style, which, for a child in one of our schools, is the happy mean between over-difficulty and over-simplicity; it is not hard enough to repel, but hard enough to add to the child's vocabulary and stock of ideas. Of course I am speaking of it simply from a literary point of view as a reading-book; and though I am, as a rule, opposed to books which deal throughout with one subject as being likely to weary a child, I should have no hesitation in approving this book if submitted to me for use in a school.'

USEFUL HINTS.

Up to the present time the weather still continues unfavourable to the bees, one day only having occurred on which they could work in force since our last Monday, the 19th inst., was a brilliant, cloudless day, on which pollen was carried into the hives in great abundance, and weak and queenless colonies were conspicuous by their sluggishness. The really prosperous colonies, however, are becoming daily stronger, and we have ten frame-hives crowded with brood and bees in anticipation of the future in-gathering.

SWARMING.—A couple of days hence the 'merry month' will again make its *entrée*, and—always weather permitting—swarms from over-crowded hives will soon issue forth, with the usual accompaniment on the cymbals of Mother Cybele,—at least in the benighted and remote county districts. And what more delightful sound on a balmy and bright May day than the merry hum of the circling swarm, with its attendant 'tinkling' performed by the good house-wife with her wondering bairns all around her? For ourselves we should almost as soon think of laying aside the all-absorbing pursuit of bee-keeping as of preventing natural swarming altogether in our apiary. For this great event—the issuing of swarms—all things must be in readiness, such as hives for the permanent holding of the swarms, skeps for receiving them from the bough, sheets for spreading underneath, a pail of water and a garden syringe, and a clean zinc pail into which to shake the swarm (when preferred to a skep). The pail is preferable when the swarm is at once to be set upon its future stand and in its permanent hive, which should be placed upon a sheet or board and wedged up in front when the swarm is poured from the pail close to the hive, into which every bee, sliding out from the pail, will quickly disappear, when the new colony is at once set upon its stand with every prospect of success. Before hiving the swarm, a slight sprinkling of the cluster with cold water from the syringe will render it less disposed to fly away, and more amenable to the process of 'hiving.'

ARTIFICIAL SWARMING, in its various aspects and methods, need not be recapitulated here. Let it suffice to refer our readers to *Modern Bee-keeping* and to Cowan's *Bee-keeper's Guide*, where the instructions given cannot be improved. One word of warning only will we add: 'Do not resort to artificial swarming until the colony is nearly ready for natural swarming;' that is to say, do not divide a colony until at least ten frames are well crowded with bees having abundance of brood.

UNIONS AND WEAK COLONIES.—For profit by surplus honey, do not attempt to build up weak colonies by the addition of brood or bees taken from stronger ones. It is far better to add the weak to the strong, thus reducing the number of hives, but greatly strengthening

the apiary as to its honey-collecting powers. The only exception to the rule is where a weak colony possesses a young and prolific queen, which is worth saving; it may then be advisable to build up by an additional frame of brood covered with young bees, and by stimulation. By robbing good colonies to strengthen weak ones, it is possible to bring all up to a medium standard, but any two of these will collect less honey than one really good colony. Our object should be to obtain as many *first-class* colonies as possible, and this can never be accomplished if we rob them of brood and bees.

FEEDING.—So long as the cold weather continues, and while little or no food is to be had from the fields, feeding must be by no means neglected. The strong colonies require it more than the weak. When giving combs of honey, it is best to uncap one side of the comb only, and to place that side next to the brood-nest—not in its centre—having first cut a hole of about an inch in diameter in the centre of the comb, as a passage-way for the bees. Pollen is now procured in sufficient quantity from the fields to enable us to dispense with the artificial.

PUTTING ON SUPERS.—This should not be done until the hive is crowded with bees; neither in cold weather, nor until honey is coming in freely. Injury very often results from supering too early, such as reducing the temperature of the hive, chilling brood, disheartening the bees, and other evils following on these. We are often asked when supers should be put on; just as if seasons were always alike—never early and never late—the population of all hives equal—queens equally prolific, &c. In that case, we might fix a date which should last for all time without varying. Until the millennium of bee-keepers arrives, we can only offer the above suggestions. As a general rule, hives full of bees, fruit trees in bloom, weather warm, are the three conditions which must be our guide.

SEPARATORS.—These we always use in our section-racks and cases, and we prefer tin to wood, on account of its cleanliness, and being less liable to propolisation. Supers, especially in the early part of the season, must be well wrapped up in warm material, and should rarely be uncovered, or loss of warmth will follow. There should be one bee-space only at the *bottom* of all section-racks—but not at the top—so that when 'tiering up,' *i.e.* placing an empty rack beneath one filled, or partially filled, there may be a single bee-space, and not a double one between the separate divisions of the whole super. This is important, otherwise comb will be built between the several racks, to the spoiling of sections, and increasing the difficulty of removal and separation. After a trial of various kinds and sizes of sections, we much prefer the one-piece V-sections $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ in. as the 1-lb., and $5\frac{1}{4} \times 6\frac{1}{4} \times 2$ in. for the 2-lb. Those dovetailed at the four corners are less stable, and do not keep their shape so well.

BEE-FLOWERS now in bloom, or due, are blackthorn, furze, coltsfoot, plums, apples, pears, arabis alpina, &c. Soon the hedges will be white with the hawthorn, or may bloom, than which no flower yields a finer quality of honey. We have several beds of *Aubrietia greeca*, covered with its pretty purple bloom, on which in fine weather the bees disport themselves in such numbers as we never saw on other flowers. Wallflowers, too, obtain special notice.

DOUBLING HIVE.—The prize offered for a hive of this description, at the Royal Show at Norwich in July next, is, we think, a step in the right direction, but, in our view, limiting the price to 15s. is a mistake. A complete, and really good hive, should consist of stand, two body or brood boxes (interchangeable), two racks or cases of sections (also interchangeable), and ample roof or cover. Is it possible that all these parts can be supplied of sound material and good workmanship for 15s.? We trow not, and should have suggested 18s. as

the lowest limit. We apprehend that the above-named parts may be exhibited as two hives, each priced at 15s., but should be glad of an authorised statement on this point, as opinions vary and many are in doubt. Supposing two hives permissible, then No. 1 should consist of stand, two body boxes (for doubling), and roof; No. 2, of stand, one body box, two section cases, and roof, the separate parts belonging to each hive being interchangeable with those of the other hive. Is this the intention of those who drew the schedules? Is it also allowable that the body boxes and section cases shall be *invertible*, or *reversible*, as well as interchangeable? We know that enlightenment on these points is anxiously desired by several well-known firms of hive-builders, and hope soon to see in our columns a solution of the difficulty.

ENAMEL CLOTH AS WINTER COVERING.—We notice in last issue 'F. L.'s letter on 'Upward Ventilation.' If he will refer to pages 3 and 136 of the *B. B. J.* for the present year, he will find that we have reported favourably of the use of enamel cloth during the late winter. 'F. L.'s remarks are very much in accordance with our own views on this subject. In our experiments, hives with the largest populations, and confined to about as many frames as they covered, wintered best under enamel cloth. The smaller colonies with more space showed dampness on the outside combs. But all came safely through. The few losses we have sustained have been of colonies wintered under pervious quilts. All our best stocks—now crowded with bees and full of brood, on ten frames larger than standards, and ready for supers when the weather changes—have been wintered under the enamel cloth. Their hives continued throughout the winter perfectly dry, and none were attacked by dysentery. These colonies were wintered on separate stands, well protected by outer cases and roofs, in a sheltered position with a southern aspect, and with entrances open as in summer.

THE LATE DR. F. STOCK, M.A.

In our last week's number there is an interesting communication from Dr. Stock of Mill Hill, respecting the hearing of bees and experiments with the phonograph. He did not live to see his note in print. We extract the following from the *Nonconformist* newspaper:—

'We deeply regret to announce the untimely death of Dr. Frederick Stock, of Mill Hill, which occurred on Monday, April 19, after a brief illness of only some ten or twelve days' duration. He had been at Mill Hill but a few years, having succeeded Professor Harley in 1881 as master of Burton Bank Boarding House at Mill Hill School, and during his too brief tenure of office there he has won the love and esteem both of his colleagues and his pupils. He was born in 1854 at Longwood, near Huddersfield, where his father, the late Rev. J. Stock, LL.D., was pastor of Salendine Nook. He received his first education at the Devonport and Stoke Grammar School, proceeding after a brief interval to University College, London, where his career was one of long and brilliant success. He graduated as B.A. at London Uni-

versity in 1872, taking honours in moral and mental science. In 1875 he took his M.A., after which he became a student at Heidelberg University and at Paris. In 1879 he obtained the highest honour his university had to offer, by graduating as D.Lit. In recognition of these distinguished successes he was elected Fellow and Member of the Council by his College. In 1884 he married Miss Elizabeth McDougall of Banbury. By the members of his own family he was almost idolised, and by a large circle of friends was admired and loved. But now he has left wife and child, mother, brother and sisters, to rejoice his sainted father.

'Dr. Stock was baptized by his father, and received into the church at Morice Square, Devonport, from which his membership was transferred to Salendine Nook, and finally to the Congregational church at Mill Hill. He will leave behind him the memory of a short life of thirty-one years, but one of stainless purity, of honourable work, of noble purpose, and unflinching rectitude of aim and of action.'

FRANCE.

The Central Apicultural and Entomological Society held a meeting in Paris on the 17th March. The Abbé Delépine read a report upon the apicultural exhibits at the last general exhibition. The report stated that the general appearance of the exhibition was satisfactory, and the samples presented in an attractive manner. The report points out also that the lots exhibited were eighty-four in number, made up as follows:—Run honey, 30; honey in the comb, 25; and wax, 29. The run honey was sent from the various districts of France, but in some instances it was deficient in purity and flavour, which might be attributed to the lateness of the season, and the unsatisfactory mode of extracting. The centrifugal slinger is little known as yet, and in many parts of the country the honey is not taken until the month of September, while in many instances it is left in the hive until the following spring. In France, the report continues, the greatest attraction in a bee-show is always the honey-comb. In this instance the combs exhibited by M. Assot were the most admired, as were also a number of American sections tastefully put up in coloured paper. The commissioners therefore recommend that still greater attention should be given by bee-keepers to the question of taste in the putting up of their honey. In conclusion, the commissioners finished their report by recommending that 'in future all apicultural exhibits be examined by thoroughly competent bee-keepers and honey and wax merchants.' This, the commissioners believe, is what the exhibitor is bound to wish, and it is anticipated that if the duty of judging be vested in competent men and becomes an established rule, the number of exhibits may be expected to double itself.

JOTTINGS BY AMATEUR EXPERT.

'Mel' sapit omnia.

Snubbing.—So 'Nucleus' felt somewhat snubbed by my reply to his query: I am deeply pained to know it; it was farthest from my thoughts to so treat any self-constituted 'novice.' We may all learn from the youngest; and this subject of 'Drones croaking' is certainly new to many of us. For the sake of readers who are not 'cousins,' I may interpret 'Dumbledory in a pop-dock'—'cockchafer in a ginger-beer bottle.'

Croaking.—What a pity 'South Cornwall,' 'Manager,' 'Nucleus,' and Mr. T. A. Chapman, were not at the last quarterly *Conversazione* of the B.B.K.A., when the 'piping of queens' was being discussed; what light they could have thrown upon the subject! 'Manager' alludes 'to the movement of the queen's body when piping,' and says the 'croaking' drones behave in a similar manner. Perhaps, like an obliging 'Cousin,' he will give the

readers of the *Journal* a more detailed account of the whole proceedings.

'Piping' of Queens.—The writer of 'Useful Hints' refuses to defend his 'Hints' by controversy. I do not wish to beguile him from his usual course, but to give my experience. I never had an after-swarm from a bar-frame hive, always having taken means to prevent it. But, on the other hand, I never had an after-swarm from a straw skep if the queens did not 'pipe' late at eve and early in the morning of coming off. I am not above learning from one of the old grandmothers of bee-keeping. I have one, a near neighbour—a widow. I took her in hand some years ago, drove her condemned bees for her, showed her how to get three first prizes in one season for her honey, and, what is far more important, got into her favour. She still sticks to her old method of 'taking-up,' but allowing her bees to be 'drove' instead of 'burnt.' She often gets her five stocks increased to fifteen or sixteen in one season, and has called me into her garden, when passing, at 5 a.m., to listen to her 'casts' piping, and she will tell me constantly when they will come out, always making a point of listening early and late. The method recommended in 'Useful Hints' for 'preventing after-swarms' is quite right for bar-frame hives, but the question with this old woman and the 'novices' who ask the queries in these columns is, 'How are they to know when after-swarms are likely to issue?' and to such I answer, 'Piping' is a good, although not an infallible guide.

Raising young Queens.—'Useful Hints' has attempted to answer the question put by the Rev. F. G. Jenyns, as to how we shall best keep a succession of young queens in an apiary of, say, three or four hives, with the least possible amount of loss of time and honey. The answer given is good, if you have the (bad) luck to get a swarm, but I have not had the happiness to get but one swarm from my bar-frame hives for three years. Will Mr. Simmins please note? Query: How am I to keep my hives replete with young queens without purchasing from dealers? 'A Surreyshire Bee-keeper' in *Journal of Horticulture* says that is the best method. Yes! in the face of some of the revelations Mr. Blow has just made to us in these columns. How it pleased me to see that exposed; one half of our troubles in the shape of Bacillus and furious bees may be there traced to its source. But I shall get into hot water with the dealers.

Excluder Zinc.—We must prepare to do the last sad office for this article; a few gave it a bad name and all have joined in the chorus. I do not like the look of this; that it has kept many queens out of sections I do not doubt. If people throw it away—and I hope they will—without taking other precautions they will fare the same fate as a 'leading light' in my present adopted county. Said he to a friend, 'Come and look at my super, the bees have filled it and sealed it over in no time. Splendid! it is fit for the show!' 'Yes,' said the friend, 'it is the handsomest specimen of drone-brood I ever saw; all the sections are complete; I hope you will get first prize, you deserve it.'

'Devonshire Rector' is responsible for more than getting the 'cloth' abused over 'them darned gnats.' Writes a hon. sec. to me: 'Ay! that's an A1 yarn! I laughed till I cried, and then laughed again: poor old countryman!' I hope 'Rector' got him to go to church and preached to him from 'The second is like unto it.'—AMATEUR EXPERT.

HONEY IN THE HIVE.—Ascertain by actual weight the amount of honey which a comb of an average thickness will contain, and from that estimate the amount in each hive. Allow for the weight of the combs, especially if old, and also the amount of pollen they may contain. For out-door wintering each hive should contain at least 25 lbs.; for in-door wintering, or where the hives are well protected, 20 lbs. will do.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

SOUTH AFRICAN BEES.

[202.] In these days of keen competition it has always appeared to me that one of the first objects of the bee-master should be, while he is studying how best to facilitate every operation in connexion with bee-culture, and to procure honey in its purest form, to raise his stocks to the highest state of excellence, by improving the breed of his bees. In this way, and in no other, is it possible to concentrate in one strain all those characteristics which commend themselves to the bee-keeper as most desirable.

There exists at present a good variety of material to work upon in order to accomplish this, and with judicious selection and careful attention the best results should accrue. There are 'Eastern' bees and 'Western' bees, most of them probably the outcome of admixtures in the past, and differing more or less from each other in intrinsic qualities, yet if the aim is, as I think it must be, to obtain by proper management a bee, hardy, vigorous, and active, prolific, home-loving, and honey-crazed, yet gentle and submissive withal, a kind of typical bee, I am of opinion that the best of factors will not be complete until the 'Southern' bee—the indigenous 'African'—has received its share of consideration. To this race I have already more than once referred in your valuable *Journal*, strongly recommending it a place in the apiaries of Europe and America, and meanwhile have left no stone unturned to facilitate its exportation and ensure its safe introduction. The chief obstacles to these are, I am happy to say, in the way of being overcome, and I live in hopes of seeing 'Africans' figure ere long in the *B. B. J.* in the category of established foreigners.

As to the race itself, I regard it as the outcome mainly of the old Egyptian bee (*A. luteofasciata*), crossed by some greyer variety, probably the Cyprian, and finally by the black bee. The special features and characteristics of all these, the 'Africans' in a more or less degree retain. In this their native country they undoubtedly exhibit all the fine traits and reputed excellences of the much-lauded 'Ligurian' and 'Carniolan,' with none, or traces only, of their recorded drawbacks. After fifteen years' experience of 'Africans,' against ten years of closest intimacy with ordinary European bees, I can safely say that under existing conditions their excellence is of a very much higher order, and this without disparagement of my older friends.

In reference to the bees specially under notice, I may remark, by the way, that by close observation and unflagging attention in the matter of breeding, I have myself educed most promising features, though upon principles which may perhaps be at variance with the notion of some of your readers, but which are practically successful nevertheless, viz. in the case of a superior stock once obtained keeping to the one same family blood alone, branches of which are at remote distances, from which alone 'crosses' are made: but more of this in the future should occasion require.

The 'Africans' have the advantage of being perfectly healthy, being constantly recruited from wild stock

reduced to domestication. They are very prolific, the bees of a single stock weighing from ten to twelve pounds. They are very tractable, and under ordinary treatment very manageable, and though possessed of strong offensive instinct, rarely require any smoke. Their working capabilities when honey is to be had are remarkable, early and late in all seasons, and even by moonlight, while their staying power under extreme drought is scarcely credible. These few observations will not I hope be considered out of place, but act I trust as a fresh stimulus to well-directed efforts.—J. W. SROOD, M.D., *Port Elizabeth, Cape Colony.*

A CURE FOR DYSENTERY.

[293.] During the past season I had a few hives badly affected with this disease. I followed the generally adopted plan of clean hives and dry coverings. In addition to this I placed the hives in a dark room, and warmed the bees with hot bricks for several consecutive hours, keeping the empty part of the hive at a temperature of between sixty and seventy degrees. The effect on those treated this way was most successful. I took some of the bees in my hands, one at a time, and in each instance their swollen bodies deposited a dry, powdery substance of the colour of their excrement, after which they appeared relieved. I tried some other bees in my hand that had not been previously artificially heated, and though their abdomens were much swollen they made no deposit. I remember some time ago some one suggesting in the *Journal* (I believe it was 'Useful Hints') that bees probably during long, unhealthy confinement deposited excreta in a powdery form, and my observations go a long way towards confirming this idea. After this heating process the bees were removed to the garden, but were unable to fly for a month, weather being against them. At the time I changed them to the clean, dry hives they were dying by hundreds and lying in heaps on the hive-floor. My boy assisted me, and he was continually pointing out what he believed were queens—the bodies of the workers were so swollen. When the time for flying came I watched with anxiety to see, if they were alive, what quantity of dead they would carry out. I was amazed that no dead were delivered at the entrance, and concluded that the stocks had so far weakened that they were incapable of performing the task. It was a delightful sensation, however, on uncovering them to find that there were scarcely any to carry out, and that the abnormal conditions previously noticed had all disappeared. I am strongly of opinion that bees do not suffer from long confinement, provided the temperature is not very low and too exacting on their energies. If we notice the excrement of bees at this season, it does not partake of the watery character of that which is observable in cases of dysentery. This is not on account of confinement. I have had some bees enclosed for the last month, and on liberating them a few days ago their faeces had all the appearance of that of bees that had been flying the previous day. I may say my bees now do not fly when they wish, but when I wish, and that shortly I hope to exhibit at our shows a hive for the prevention of the most destructive scourge in bee-keeping—spring dwindling—and at an early date I will endeavour to write you on the subject.—JOHN RUDGE, *The Bee-Hive, Dursley.*

A NEW FUMIGATOR.

[294.] I have sent with this note a fumigator I have invented to take the place of the ordinary smoker. You will see that carbolic acid is the agent used. I have been in the habit in taking away sections of using a feather dipped in diluted acid, to which you have referred on several occasions in the *B.B.J.* This manner of

applying the vapours of the acid is very unsatisfactory when placed in the hands of novices or careless bee-keepers; if the sections are touched with the feather, it leaves an unmistakable odour for some considerable time; in fact, I have tasted it distinctly on eating a section. I therefore conceived the idea of using the vapour of the acid only as a means of quieting the bees when manipulating; in this I have been eminently successful. All manipulations this season I have performed with the aid of this fumigator. The bees act in the same manner as with smoke, rushing to their cells and gorging, and allowing as great a freedom to be taken with them.

My first attempts were rendered rather dangerous, on account of the acid dropping, or being blown, into the hive, which made a great commotion, and would cause a general exodus of the stock, which I found to be the case last summer. I therefore produced the accompanying appliance, which would entirely prevent anything but the vapour from the acid entering the hive. I have to-day overhauled fifteen stocks with it very satisfactorily. Its advantages are:—

1. Always being ready for use.
2. No lighting required, which, you know, is such a nuisance.
3. Will last without recharging for a week with ordinary work.
4. Its simplicity in recharging not taking more than fifteen seconds.
5. Its portability, as it can be carried—after separating—in the pocket.
6. Its handiness in driving a swarm from any inaccessible place, or from flowering shrubs, rose-trees, &c., without the danger of breaking same.
7. Does not matter how you lay it down, there not being any fuel to keep alight.

The air is drawn in through and around sponge, and is expelled in same manner; so gets thoroughly impregnated.

- S. Shield preventing acid being blown into hive.
- A.R. Receptacles for any acid escaping from sponge. This ought to be shaken from superfluous acid before putting in cylinder.
- P. Sponge.
- H. Hooks (4) to hold sponge in position.
- C. Cap fitted to prevent acid getting on hands of manipulator, the sponge being drawn out at the time of removing same.

I have an idea that the use of this, instead of smoke, would prevent, to a certain extent, the ravages of Bacilli, but of that I am not in a position to state. Of course, the application of carbolic acid is not my idea; simply the manner of applying it.—W. B. WEBSTER, *Wokingham, Berks.*

HIVE-PORCHES. [202.]

[295.] Having given a considerable amount of attention to this subject, followed by actual experiment, I should like to offer a few remarks giving the result of my observations. I think I have copied and tried nearly every kind of porch I have seen, and have at last decided to use only the one I shall now describe.

First, as to the *Landing Board*. This should project from the hive about nine or ten inches, and its free edge should measure eleven or twelve inches. Its attached edge need not be so much. This liberal size is necessary when honey is abundant at a distance, and the weather at all cold. I have seen the bees returning home from the heather tired and heavy, and throw themselves on to the board like an intoxicated or exhausted man,

frequently resting a while before crawling up to the entrance. Sometimes they will alight on a bush, or your clothes if you are near the hive, and after a little rest enter the hive—this especially if the porch is not all that is to be desired. Should the board be small, they sometimes miss it and fall to the ground, and are chilled before they rise. Again, the board should have a good slope, making an angle of about 120° (the third of a circle) with the hive front. This only prevents wet and dead bees, and other *débris* not remaining on it, but facilitates the landing of the bees. It is more adapted to the slope of the bee's body as it lands, and thus it gets hold with all its six feet at once. I have often seen bees skid on a level board and strike the hive front. Sometimes it prefers instead to land on the vertical hive-front above the entrance. When a bee is out for an airing, after being confined, you will see it always prefers to land on a sloping or vertical surface before a horizontal one to rest. The slope prevents departing and returning bees meeting in collision, too. The board should never be painted, and I prefer it *not* planed, unless too rough. I do not like it to reach down to the ground, because of earwigs, snails, mice, &c.

As to the *roof* of the porch, I consider this the least important part. It is only useful to prevent driving rains or snow from striking the hive entrance, and in winter to shade it. Indeed, it is rather in the way of the bees than otherwise, as they prefer to alight as close to the entrance as possible. I therefore make mine project only three inches, and level so as not to drip on to the landing-board; and by making a saw-cut across the under surface, it inclines slightly to the sides.

Then as to the *sides*. These are of more importance than, I think, is generally accorded to them. They are undoubtedly necessary for saving bee life if wind is blowing (as it often is) during the honey-season. I make the upper edge three inches, same as the top, the lower edge four inches, or more, to project along the landing-board. There is no reason why the sides should be further apart than the whole width of the entrance, say, six or eight inches. On the contrary, for many reasons, the porch should *not* be larger than is necessary.

Rain and snow drive into the larger porches, or the wind sweeps the bees out of them when landing. Again, bees often have more difficulty in finding the entrance in a wide porch, particularly if the entrance is

narrowed or partly closed. I have seen bees seeking the entrance in the corners of the wide porch. Then the *sides* pass between the sides and the hive-front, and can be moved from the *outside* of the porch—a desirable feature when robbing is noticed and the bees irritable. The height of the sides need not be more than two and a half inches at the edge touching the hive, and should be put at right angles to the hive-front.

Thus we have every facility given to enable the bees to land readily and safely: they fly into the porch and are at once sheltered and safe. I have seen it urged that when the wind is blowing in front that this kind of porch encourages it to enter the hive. This would hold good if there was another opening in the hive for the exit of the wind, which there is not; but even should this be the case, by making the entrance in a certain way I minimise the effect of this. These remarks are already too long, but with the Editor's permission I may explain this again. I may here remark, however, that the smaller the mouth of the porch in proportion to the entrance, the less this objection holds good. In this

case, the size of the porch matters more than the shape. I have noticed, too, that wasps and robbers like a large porch better than a small one.—DOCTOR CRAIGS, *Dumfries, N.B.*

REVERSIBLE FRAMES.

[296.] For some time past I have thought that the 'coming frame' must be a reversible one. I do not say that mine is the coming frame, but I *do* say that it is simpler and cheaper than any that I have hitherto seen or heard of. It seems to me that if bees are to have their combs reversed it must be done quickly, and with as little annoyance to the bees as possible. If the frame has to be altered in any way whatever, in order to reverse it, I consider it imperfect. I have invented a frame which is *exactly* the same top and bottom, and, therefore, it can be reversed in a moment, and by a very simple contrivance the proper distance is kept. It consists of only *four* pieces of wood. This is accomplished by the frame *standing* on a little strip quarter of an inch high, *each* side of the bottom of the hive. I can supply them singly or in numbers, but the right of manufacture is mine.—W. CHITTY, *Pewsey, Wiltshire.*

HAS THE BEE-STING EVER BEEN AN OVIPOSITOR?

[297.] I must apologise to Mr. Grimshaw for not having ere this thanked him for so kindly and fully answering my queries on the above subject. Useless or rudimentary jaws may be seen in the perfect insect of the common mayfly, consolidated wing-cases on the common purple ground beetle, useless wings on the vapourer moth (female), and as every one knows the female glowworm is without wings at all. By the way, why should the female glowworm be luminous more than other beetles with apterous females? That the unimpregnated queen of *Apis mellifica* should be able to lay fertile eggs (even though drones only result from them) is, I suppose, an example of parthenogenesis, although not such a satisfactory one as that shown by experiments with aphides or the gipsy moth.

I was looking at a queen-wasp's sting under the microscope yesterday and was surprised to find that the inner sheath of the sting (or what is generally taken for the sting proper) had not a perfectly even surface, for at a nearer distance to its point than one-third of the entire length of the sting-case there rose a sort of hump sufficiently abrupt to prevent the sting case (which is left behind together with the sting proper and poison-bag, when the honey-bee stings anything) from entering any object beyond it. The sting proper is only just visible to the naked eye. The two plates covering the sting case are lovely under the microscope, and so well adapted for keeping the sting-sheath clear and bright. If the sting was once an ovipositor, as there seems to be no doubt it was, the channel through which the ova used to pass is now diverted, as it does not now end in the point of the sting-case. Can any of your readers tell me what is the supposed use of the claw on the wing of the nestling moorhen?—MAURICE C. H. BIRD, *April 17th.*

STINGS AND GLOVES.

[298.] It has been repeatedly remarked that the experience recorded from time to time in the *Journal* is nearly always of a favourable character. Disappointments and losses are mostly kept in the background. Now, I think

it probable that many amateurs have, like myself, found that it is not so easy to handle bees without protection, as they had been led to suppose. I began bee-keeping in 1882, through reading Mr. Cowan's *Guide Book*. I commenced by the purchase of a stock hive—a skep—in the autumn of that year, and from the directions given in the above book I made a frame-hive to put the swarm in the next summer. This was done successfully, and a second swarm put into a skep. Never having seen a frame-hive before, I was very fond of manipulating, as I suppose most novices are; but, strange to say, though I wore no gloves, I did not get stung, in fact, I could do almost anything with that hive of bees without their molesting me. The next summer I increased to six bar-frame hives, and got through the early part of the season in the same happy manner; but, at last, when removing sections from one of them, I received two stings. I took no notice of it at the time, but my hand subsequently swelled to a great size, and was so stiff and painful that during the remainder of the day and half the following one, I was incapacitated from my work, as that work required the employment of the full force of the muscles of the hands. Later on I received other two stings with a like effect. Well, I thought this would never do, as, being a working man, I could not afford to lose my situation, which I feared would be the case if this was often repeated, and therefore, although reluctantly, I purchased a pair of gloves, and have since made it a rule to wear them when dealing with the bees. Now, my bees, which were originally blacks, have become hybridised, and I have often found that they attack my gloved hands most furiously, but whether it is because I wear gloves, or because they are hybrids, I cannot say. Last autumn, when preparing the bees for wintering, the inmates of one of the hives attacked me as soon as it was opened so furiously and so pertinaciously, that, in pity for them, I closed it up without removing surplus combs, or doing anything beyond seeing they had sufficient stores. In this case they literally covered my gloves and parts of my clothing, and scores, if not hundreds, perished from the loss of their stings. It seemed, indeed, as if every bee in the hive was eager to commit suicide in that manner. Now, I should like to ask what, in the opinion of more experienced hands, was the cause of this? They were not queenless, as I found brood in the hive when examining it this spring, at which examination they showed none of their previous pugnacity. Neither was it that they were not carefully handled. Has any fellow reader experienced the like? Also, I would like to know what an old hand without gloves would have done in such a case? I have noticed on many occasions, even when the hands have been moved most slowly and deliberately, that bees have darted straight off the combs on to my gloves, and stung instantly without reference as to whether the hands were naked or not; and, therefore, I find it hard to believe that any less stings would have been given had the hands been really naked. I sincerely wish to take the advice given to 'Rector' in a late issue, and to do without gloves, as they are clumsy things; but is there a reasonable probability that I should soon get so inured to it as to be able to stand stinging with impunity? Could an old bee-master thus with impunity stand forty or fifty stings? If some of our expert friends who kindly give advice on many points would be so good as to give their experience and opinions on the questions I have ventured to ask, I have no doubt they will be giving both pleasure and profit to many others in addition to—A. COTTAGER.

[Your bees at first were easily handled. Having become hybridised they gave evidence of their new blood. The gloves, saturated with bee-poison, roused the bees to fury. 'A Cottager' does not state whether he employed smoke or carbolic acid solution to dominate the bees; an old bee-keeper would have adopted some such means.]

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[203.] *Bees Croaking.* I sometimes hear a croaking noise somewhat similar to that produced by the stretching of a cable round a pillar, and have come to the conclusion that it is caused by the tips of the wings vibrating and striking the smooth surface of enamel cloth. I should be delighted to think we had got hold of a portion, an alpha, of bee-language.—R. A. H. GRIMSIAW.

[256.] *Two Queens in one Hive.* (Trevor Saynor).—Yes, it is quite possible, but requires some skill, judgment, and knowledge of habit. I have had as many as six queens in one hive divided by excluder, each division having its own small entrance. When I required a queen I took one out, and when I had one for which I had no immediate use I put her in until I wanted her. I have even wintered bees in this way. I have done the same in a large twin hive, so that if one queen got lost it did not much matter. I have found this a capital way of uniting; but, as said before, it requires some judgment. For instance, towards the spring, when the bees begin to diminish, the lot may go over to one side, leaving one queen with too few to keep up sufficient heat. No division should contain less than three frames, but then they may be very small frames.—M.

[277.] *Best Size Sections.*—I am of the same opinion as your correspondent in last issue, that the $4 \times 4\frac{1}{2}$ sections would be an improvement on the $1\frac{1}{2} \times 4\frac{1}{2}$. I am of his opinion, that an oblong block of honey has a better appearance in a dish than a square block, and would, I believe, be more saleable. I have never used any but the $4\frac{1}{2} \times 4\frac{1}{2}$, but would change if I could get the others.—F. C. THOMPSON.

[281.] *Packing Sections for Travelling.*—I think chaff would be better than hay, or straw, or shavings, in packing sections for travelling by rail.—F. C. THOMPSON.

[287.] *Upward Ventilation.*—I always cover my hives down so as to prevent upward ventilation, but I also make hives warm by means of sawdust, &c. at the sides. Three or four thicknesses of woollen material (flannel, carpet, cloth, &c.) intermingled with sheets of brown paper and earboard, over which I lay a slab of wood, and a brick for pressure, forms the general run of top coverings I use.—E. B.

[288.] *Sweetening Hives.* (G. C.)—Remove combs, and wash inside of hive thoroughly with carbolic soap, exposing it afterwards to a current of air; clear the combs as much as possible from dead bees and hang them up in some covered place, where the bees cannot get to them, in a current of fresh air, spraying them with salicylic acid solution. If the foregoing is done thoroughly, a good job will be made of it, so that a swarm can then be placed in, and supers put on at once.—W. B. WEBSTER.

[289.] *Extra Queens.* (Honeysuckle).—They can, with a little attention—which with ordinary blacks is not worth the trouble—be preserved in three or four framed nuclei.—W. B. WEBSTER.

[290.] *Swarming and Non-swarming.* (Honeysuckle).—This would entirely depend upon the respective merits of the mother-bees; if they were of equal quality, and the two four-frame lots being in such condition early in the spring, they would beat the eight-frame lot in the honey yield; that is not allowing for any surplus from the swarm after it has left the parent stock, which I presume you mean.—W. B. WEBSTER.

[291.] *Raising Queens.* (Honeysuckle).—These must be started and the larvae reared in good full colonies having plenty of young bees; this is imperative if it is wished to rear healthy and prolific mothers.—W. B. WEBSTER.

Queries.

[299.] *Unfertilised Queens.*—Did ever any bee-master in the United Kingdom rear a queen-bee either naturally or artificially, and, as soon as hatched, make her a life prisoner, at the same time exclude every drone from the hive? If so, did the queen become a drone breeder? Has

ever any such experiment *been* made? Like your correspondent, 'A Pupil,' in your last issue, page 177, I have a deep interest in the subject.—A. COCKBURN.

[300.] *Worker and Drone Eggs.*—I have a pure Ligurian queen who is now laying drone eggs in worker cells; at the same time there is sealed worker brood. What is the reason of this? Is it possible for the spermatheca to have become exhausted, the result being drone eggs?—E. W. P.

[301.] *Sting Antidote.*—What is the best antidote for stings?—MELISSA.

[302.] *Wax-discoloration.*—What is the cause of the discoloration of wax?—MELISSA.

Echoes from the Hives.

North Leicestershire.—Only four good days for the bees between 24th ult. and 24th inst. Good Friday was a splendid day, and so is to-day (Easter Eve). The bees are well at work on willow, gooseberry, currant, arabis, ribes, plum, and coltsfoot. Stocks are many of them still weak, from the effects of the heavy losses sustained in the snow last month. There are a good many reports of queenlessness. A stock supplied with dry sugar a-top was in full flight on Sunday, the 18th inst., but on Monday died: little of the sugar had been taken.—E. B.

Honey Cott, Weston, Leamington.—Glorious weather now, the cuckoo and swallows are come, plum-trees as white as snow with blossoms, bees roaring at work, hive entrances crowded with young bees sunning themselves. Have been sparingly spreading brood where stocks could stand it without risk, as perhaps in a few days we may get a sudden chill. The blackthorn is out in places, and buds ready to burst in others; and generally when that is in bloom we have a touch of what is called round here *blackthorn winter*.—JOHN WALTON, April 26th.

South Derbyshire, April 26th.—Since the 8th inst. east and south-east winds, with occasional sunshine, have prevailed. Good Friday was a perfect bee-day, work in full swing from 8 a.m. to 5 p.m. Examined hives after 5 o'clock. Find cold wind has finished off nearly all last year's bees, and hives are now rapidly becoming stronger. In hives which have last year's queens, brood-spreading is quite unnecessary, for every available cell that the bees can cover is tenanted.—M. J. ASTLE.

Revlín House, Donegal, April 23rd.—The weather here is very unfavourable for the poor bees. On the 9th inst. had a good fall of snow and piercing cold: it has been dry from about the 13th, but cold east winds prevailing. Bees flying very little, but when favourable gathering any amount of pellen. I gave them meal on shavings about a fortnight ago, but only the Italians worked on it, and then only for a few days. Have been stimulating for the last month. I transferred one straw skep on the 1st, and two more on the 16th, into frame-hives, of which I have twenty. The honey season here is always late; hope it may turn out a good year.—GEO. TURNER.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

OXONIENSIS.—*Carniolans.*—We have not actually proved that Carniolans collect honey from red clover, but we are inclined to think, from their length of tongue, and the large size of the bee, that they do.

W. C. E.—*Removing Bees.*—By removing your bees half a mile to a field of white clover you would lose more than you would gain by the loss of returning bees. Half a mile is a short distance for bees to fly, and at that distance we are not at all certain that they would not gather as much honey as if set down in the field itself.

H. W. D.—1. *Feeding.*—It is not necessary to feed every night. A large bottle-feeder, with two or three holes turned on, will not require refilling more than once a week. 2. You will not find one hole sufficient. Much, however, depends upon what feeder you use. 3. There must have been some fault in replacing the bottle. If the feeder was accurately made there would be no leakage, whatever the consistency of the syrup. A good bottle-feeder will retain water as well as syrup. The bottle should always be full when first placed upon the hive. There is not much fear of robbing now, since the bees obtain all they require from natural sources. 4. The tin feeder you mention acts very well, but it allows the escape of warm air from the hive, and in cold weather the bees become chilled in the feeder. There is no objection to its use in warm weather. 5. *Spreading Brood.*—If there is brood in all the six frames remove the outside frames (from each side) to the centre, and place a comb of sealed honey on each side of the nest, having first uncap the cells on the sides next the brood. If only three or four frames contain brood, do not spread at present. 6. We recommend enamel cloth, *decidedly*, for summer use. Its use in winter is a moot point. We ourselves wintered a number of colonies under the enamel cloth during the late winter most successfully. Your sample is rather thick, not sufficiently pliable. Try Neighbour's. 7, 8. *Transferring.*—It is better to transfer in a warm room. In a temperature lower than 70° Fahr. the brood is liable to chill. From skeps the bees should be driven and confined in an empty skep, when their hive may be taken indoors, and the transferring may there be performed with ease and at leisure. This should be done in the morning before the bees begin to fly. When the transferring is complete place the new hive on the old stand, and shake out the bees on a board in front, when they will at once enter their new abode. The operation must only be performed in warm weather, when bees are flying freely. Care must be taken to obtain a sight of the queen when driving. The Woodbury frame, being of nearly the same size as the Standard, combs and brood may be readily transferred from the former to the latter. About mid-day, on a fine warm day, remove your Woodbury hive a few yards from its stand, and in its place set an empty skep, wedged up, on a large board. Take each frame from the 'Woodbury' and shake off the bees in front of the skep, brushing off with a feather the few stragglers remaining. Take the combs indoors, transfer, and proceed as in the former case. All transferring should be completed *immediately*.

F. J.—Enamelled cloth during the past severe winter has been well tested, and has been proved to be suitable for preserving the warmth of bees. It will also be found of service for summer use.

WEST CORNWALL.—1. Enamelled cloth should have the shiny side placed on the frames. 2. Observatory hives with glass sides are not suitable for wintering bees; such hives are very desirable for exhibition purposes.

TORMOHAM.—*Aspect of Hives.*—It is not very material in which direction the entrances of hives are, but to have them face south or east is preferable.

A. T. WILMOT.—The comb forwarded was not infested with foul brood, but was a bad case of chilled brood.

BADENOCH.—*Crooked Combs.*—You will find in previous volumes directions for straightening crooked combs.

E. M.—*Tin Feeder.*—See reply to H. W. D.

F. C. T.—Your bees dying of starvation while there was sealed honey in the hives was owing to the absence of winter passages and the distance between the cluster and the honey.

W. G. C.—*Metal Ends.*—These can be easily fitted to frames when filled with brood. All that is necessary is to cut off the wooden shoulders with a pen-knife and push the ends on. The slight raising of the frames is no detriment.

W. J. K.—*Treatment of Stocks with Fertile Workers, &c.*—Unite 1 and 2. Unite the contents of tree to No. 3. Saw the hollow containing the bees in half lengthways. Cut out the combs, tie them into frames and place in a hive, preserve the brood, add the bees from No. 3, and any combs containing brood.

W. W. (Brinklow).—*Preventing Loss of Swarms from Skeps.*—If you give room by ekes beneath and supers at the same time, you may safely leave them from week to week.

W. W.—*Inversion of Skep.*—Place an alighting board at the old entrance, which will of course be above the old level, unless you remove the old stand and lower the skeps.

F. H.—1. *Bees perishing in Brewing Vat.*—The sweet smell of the wort was the attraction. 2. *Weak Stocks.*—Stocks containing only three frames covered with bees and brood in only one, at this season, are too weak to be of service, and had better be united as you propose.

SUSSEX.—*Doubling.*—1. By having outer eases as shown on page 148, or by fastening strips of wood bevelled on the top. 2. Yes; if you are going in for section honey, work on the plan given in our article in this number. 3. No; we have tried the plan, but do not find it any material advantage, and have found less pollen carried into the upper chambers with the entrance at the bottom. This should be large enough, as described.

W. H. HUGHES, *Marazion.*—You can clear supers of bees in the way described on page 148, *B. B. J.*, or into a box fitted with a tube of perforated zinc, as shown in Fig. 6, page 151. We shall be pleased to give articles on requeening hives, and in the meantime we would refer you to the chapters on queen-rearing and introducing queens in *British Bee-keeper's Guide-Book.*

H. C.—*Galvanized Tanks.*—Our reasons for objecting to galvanized tanks is that the galvanising consists of coating iron with zinc, and this, in connexion with honey, we have long since learnt by experience, was objectionable, because the acid in the honey acts upon the zinc to the detriment of the honey. Extractors and honey-tanks should be tinned. See page 71, *British Bee-keeper's Guide-Book.*

* * *Through pressure on our space several replies will be forwarded privately to the Querists.*

J. WILSON.—Received with thanks three queen-wasps. Received from Mr. E. C. Walton, of Muskham, Newark, Notts, his *Illustrated and Descriptive Price List of Moveable Comb Bee-hives and Apicultural Appliances* (48 pp.)

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

July 12-16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Entries close May 12th. Secretary, J. Hückle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

July 30-August 5.—Great National Show at South Kensington. Secretary, J. Hückle, Kings Langley.

NOTICE.—For late Pollen-grow **SUNFLOWERS.** SEEDS from Best Varieties, 3d. per Packet. Address W. HOLLINS, 9 Tillington Avenue, Stafford. 128

WILL BE READY SHORTLY.

A WORK ON 'BEE PASTURAGE,' dealing with the Propagation and Successful Cultivation of nearly 100 of the best Honey and Pollen-producing Trees, Shrubs, and Plants, giving the Time of Flowering, Soil best adapted for Growth, average length of time in Flower, Honey and Pollen Values, &c. &c.; also Chapters on Honey, Pollen, and on Sowing and Raising Plants from Seed.

HENRY DOBBIE, Thickborn, Cringleford, Norwich.

SEEDS of the BEST HONEY-PRODUCING PLANTS known, for Garden and Field cultivation, in 3d., 6d., and 1s. Packets. One Shillingsworth free, with cultural directions if required. Plants of Figwort (2 years old), 5s. per 100; Myrobella Plum (2½ feet high), 6s. 6d. per 100; Thyme, Marjoram, 5s. per 100; Golden Rod, well rooted, 6s. per 100. Half quantity half price. Address H. DOBBIE, Cringleford, Norwich.

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HÜCKLE, Kings Langley.

DR. PINE'S BEE-KEEPERS' LOTION

Is now the acknowledged remedy for Stings, not only of Bees and Wasps, but of all Insects.

THE FOLLOWING ARE AMONG THE TESTIMONIALS RECEIVED:

'I have found Dr. PINE'S Bee-keepers' Lotion most efficacious. I have been stung twice lately, and instead of having the annoyance and pain for a couple of hours, all ill effects went away in a few minutes, leaving no inflammation whatever. I have found it equally useful when applied to the bites of the very annoying "harvest bugs," from which we suffer much on chalk soils.'—D., *Doct.*

'On Sunday last a little boy visitor was teasing the bees in my garden, and received seven stings on the face and head. You kindly gave me some of Dr. PINE'S Bee-keepers' Lotion, which acted like a charm. Soon after applying it the pain ceased, and in less than one hour there was no swelling or sign of inflammation to be seen. You are at liberty to make any use you please of this testimony to its effects.'—I remain, Sir, yours obediently, H. CARTER, Vestry Clerk, Hanwell.

'A man in the employ of a friend of mine, whilst trying to dislodge a nest of hornets, was badly stung. After having applied various remedies without success, and becoming seriously ill, your Bee Lotion was applied, and relief was soon obtained. I shall continue to recommend it to the Members of our Association and others.'—Yours faithfully, R. R. GODFREY, Hon. Sec., Lincolnshire Bee-keepers' Association.

'I enclose 1s. 8d. for another bottle of that excellent Bee Lotion and the carriage of it. This Lotion enables me to laugh at my little friends and their stings.'—C. H. H., in letter in *British Bee Journal*, Vol. V., p. 54.

Price 1s. 8d. per Bottle, post free.

From the Proprietor, F. LYON, 94 Harleyford Road, London, S.E.

WALTON, MUSKHAM, NEWARK.

Bar-Frame Hive.

Price 10s. complete.

Double walled back and front, Tongued and Grooved Floor-board moveable, Plinths, Porch, Entrance-contractors, Legs, Hinged Roof, Ten Frames, with E. C. WALTON'S Improved METAL ENDS (these Ends are interchangeable with those of low, Pine, Edey, or Harrison),

and saw-curf down the middle of bar for foundation. Moveable top sides for filling with chaff, cork-dust, &c.; two Spring Dummies, two Quilts, and Crate of 21 1-lb. Sections, with Glass at each end and Separators.

This HIVE has taken First and other Prizes at Lichfield, Doncaster, Oxford, Coventry, Stone, Ledbury, &c., the past two years.

SECTIONS.

Foundation. Smokers. Sections.

CLOSING OF ENTRIES FOR THE BEE DEPARTMENT AT THE ROYAL AGRICULTURAL SHOW.

Intending exhibitors are reminded that the entries for this Show close on May 12th. The Exhibition this year will be held at Norwich (see advertisement).

FOUL BROOD AND CAMPHOR.

When this disease has visited a district, its eradication is extremely difficult. The germs being scattered far and wide, it is not wonderful that we frequently hear of the disease breaking out again, more especially if we bear in mind, than any one germ, under favourable conditions in a hive, can grow and multiply at such a rate as very soon to completely destroy it. Those who have had foul brood in their hives during the past season, we would recommend them to be on their guard, and take such measures as will ensure the disease not breaking out again.

It is generally in spring that foul brood first shows itself, and then much more difficult to recognise. This is why so many allow it to get to a more advanced stage before they are really aware that they have it in their

hives. When foul brood is tolerably advanced it is easily recognised, as the caps of the sealed brood appear pierced or partly removed, as seen in illustration, and the cells contain a putrid, sticky, coffee-coloured substance, which is all that remains of the sealed larvæ.

If the head of a pin be inserted into this substance, it can be drawn out into long threads, and in this respect it differs from chilled brood, in which the remains of the decayed larvæ are watery and not tenacious. Frequently foul-brood may be recognised even without opening a hive. Numbers of bees will be seen at the hive entrance vigorously fanning, and at the same time the air drawn from the hive will have a putrid, nauseating odour, which can be perceived several feet from the hive. The disease should not be allowed to get to this stage, but attacked when it first shows any signs of being present. It requires a careful scrutiny of the combs to recognise foul-brood in its earliest stages, and even then the novice may fail to do so.

On examining the brood, notice must be taken of the larvæ. If diseased, instead of lying curled round at the bottom of the cell, they are generally turned in such a way as to show their backs and move about in an unnatural way. These larvæ, instead of being white, have a slight yellowish tint, which deepens as the disease advances. Those cells containing larvæ, sealed over before they had been attacked by the disease, will be slightly darker in appearance than the surrounding brood, and whereas the capping of this is raised, the diseased cells will be found to be depressed. We must caution the bee-keeper not to expose brood too much in spring. For a minute examination a warm day should be chosen, otherwise the brood may become chilled, and in this way form an active medium for the propagation of foul-brood. The treatment we should recommend is, that by means of camphor, discovered by M. D. Ossipow, a Russian bee-keeper of great experience. This remedy, which we have on several occasions alluded to, and which we described in the *British Bee Journal*, in 1874, is so simple, and from reports we receive from all parts of Europe so efficacious, that it must commend itself to all bee-keepers. It consists in simply placing one or two pieces of camphor, about the size of a walnut, wrapped up in rag on to the floor-board inside the hive. The camphor evaporates slowly, and can be renewed when it has entirely disappeared.

Mr. Cheshire, at page 71, states M. Durand directs attention to camphor as yielding admirable results if the diseased brood be removed. There is, however, not the slightest necessity to remove any brood at all, and it is because of its extreme simplicity that this treatment commends itself in preference to such processes as Boutlerow's phenol treatment (lately advocated by Mr. Cheshire), or the simpler treatment by salicylic and fumigation of Hilbert. Mr. Charles Seren, in the January number of the *Bulletin d'Agriculture de la Suisse Romande*, describes how often other remedies had failed, and in a very short time cured with camphor foul-brood in hives where breeding was being carried on, and without the removal of any of the brood. To those who have not foul-brood, or any signs of it, we should still recommend them the use of camphor as a preventative, or

even to do as we do, and never give bees any syrup without the addition of salicylic acid. It has been also recommended by M. Jarie to give bees camphorated syrup, but camphor is not readily dissolved in water, the proportions being one in thirteen, although a little more is dissolved if the water be kept warm.

There is another remedy which was first introduced by M. Klempin, which also appears simple, namely, fumigation with common thyme. No special fumigator is required, but an ordinary smoker can be used. The simple herb as grown in the garden is dried, lighted, and the smoker filled with it. The nozzle of the smoker is then placed in the entrance, and the smoke blown into the hive. This is done every evening for eight days to a fortnight without disturbing bees or brood, after which it is said the disease entirely disappears. Both these remedies, either used by themselves or in conjunction with each other, are simple, inexpensive, and easy of application, and we hope bee-keepers will give them a fair trial. The camphor remedy has already been before the public for some years, and is so simple in its application that the merest novice can do no harm by its use. We therefore recommend all those who have had foul-brood, or suspect foul-brood in their districts, to put a lump or two of camphor into their hives at once, and prevent what they might find much more difficult to eradicate if they allowed the disease to attain its full development.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Committee Meeting held at 105 Jernyn Street on Wednesday, April 28th. Present: The Rev. G. Raynor (in the chair), the Rev. F. S. Sclater, Rev. L. Seager, Captain Campbell, H. Jonas, J. M. Hooker, D. Stewart, G. Walker, and the Secretary.

It was resolved that the Association should be entered in the guarantee list of the South Kensington Show for the sum of 20*l*. The appointment of Judges to act at the St. Ives and Aylesbury Shows was considered, and other formal business transacted.

The usual meeting of County Representatives was held at four o'clock. There were present: C. H. Haynes, Worcestershire; A. P. Lipscombe and J. P. Sambels, Herts; W. de Lacy Atherne, Surrey; J. Bowley, Berks; J. L. McClure, Lancashire and Cheshire; J. Kino, Bucks; Rev. W. E. Burkitt, Wilts; J. Garratt, Kent; F. Kenworthy, Middlesex.

The Rev. F. S. Sclater moved, according to notice, that the following be added to the conditions of affiliation:—

'That the affiliation of each County Association is granted on the understanding that the affiliation fee is punctually paid, and the general organization and conduct of business is approved by the Committee of the B. B. K. A., the Committee of the B. B. K. A. having at all times the power to withdraw the privileges of affiliation.'

Mr. Sclater, in introducing his motion, said that he brought forward this motion as the Secretary of a County Association, and his object was to make the affiliation of the counties to the Central Society of more value to the counties themselves; his resolution was intended to enable the B. B. K. A. to take steps when necessary to improve the organization of any county society which could not be said to be doing its work efficiently. The motion having been seconded, Captain Campbell rose to move the following amendment:—

'That the affiliation of each County Association is granted on the understanding that the affiliation fee is punctually paid, and that the general organization is

such as may be approved by the B. B. K. A., who have the power to withdraw the privileges of affiliation.'

He said he did so in no hostile spirit to Mr. Sclater, who he was quite sure was actuated by an earnest desire to further the cause which every one present was desirous of promoting. He (Captain Campbell) fully recognised that legislation in the way indicated might be necessary, but he was of opinion that the Central Society should not have the right or power to dictate to any County Association the methods by which it should conduct its business.

The amendment was seconded by Mr. McClure.

The question was discussed at some length. Mr. Garratt was of opinion that the rules of affiliation already gave the Central Society sufficient power to take steps when necessary to improve the organizations of any County Society, and he considered that the resolution was rather, as it were, tightening the hand and giving power for the exercise of parental authority.

The Rev. J. L. Seager supported the resolution. He considered it would enable the Central Society to exercise parental care, and not 'parental authority,' as indicated by Mr. Garratt; and speaking as a County Secretary he felt sure that if the Central Society were called upon to use its powers under this rule considerable benefit would accrue to the county on whose behalf it was exercised.

Mr. Sambels was opposed to the resolution.

Mr. Stewart, in supporting the resolution, considered that the discussion had wandered somewhat wide of the mark and that in the discussion the policy of the Central Society and the results of that policy had been overlooked. It must be remembered that it was the aim of the B. B. K. A. to establish in every county a well-organised County Association and to impress upon the Counties the necessity of arranging a good district system of working those counties. All this was done at considerable expense to the Central Society; not only were funds expended to carry out this work, but the B. B. K. A. lost many of its members who became members of the County Associations. Under these circumstances it was not at all probable that the Central Society would take any steps under this rule, which would tend to injure the bee-keeping cause in any county.

Mr. Walker also supported the resolution. A letter was read from the Secretary of the Essex Association, who was unable to be present, in favour of the resolution.

On a division the amendment was carried by six votes against two.

THE GREAT NATIONAL SHOW AT SOUTH KENSINGTON.

The Secretary reported that assistance had been promised from the counties of Herts, Berks, and Bucks, the two former counties had promised a donation of 2*l*. 2*s*. each.

Mr. Sclater reported that the Bucks Association had taken steps to collect individual subscriptions amongst its members, and at present nearly five pounds had been realised.

Captain Campbell reported that a similar plan was being adopted in Surrey, and he was in hopes of being able to realise nearly 20*l*. towards the fund.

Mr. Garratt considered that the prize list should be published as early as possible in order that the County Associations and individual exhibitors might be enabled to make the necessary arrangements to enter into the respective competitions.

The second quarterly *Conversazione* of the year was held at 6 p.m., when amongst the company assembled were Dr. Walker, Mr. Stewart, Captain Bush, the Rev. W. E. Burkitt, Mr. Sambels, Mr. Garratt, Captain Campbell, Mr. Hooker, Mr. Haviland, Mr. Andrews, Mr. Daintree, Mr. Kenworthy, Mr. Henderson, &c.

Mr. Sambels, on being called to the chair, said that several new inventions relative to bee-keeping would be exhibited and submitted to the meeting, whose opinion would be invited thereon. First of all he would call on Dr. Walker to give some account of his Zulu Queen.

Dr. Walker exhibited a crate in which rather more than a pint and a half of bees had been conveyed from South Africa to this country. He stated that they had borne the journey very well, and arrived in England in a satisfactory condition. There was nothing new to bee-keepers in the formation of the crate, and nothing worthy of special mention except that there was a good contrivance for giving the bees water. That was a most important matter, for the greatest obstacle to be encountered in sending bees on a voyage was the difficulty of supplying them with water. A very good system had been adopted in the crate before them. An ordinary sponge was fixed outside, which could be saturated from time to time, and the crate had been so built that the moisture therefrom would run inside, and if there was any excess arrangements had been made to carry it off. He had been very unsuccessful as regarded the queen, and he hoped for a different result if Dr. Stroud should send him another. It was a difficult matter to introduce a queen in the early part of the year. This one he had introduced by caging in the ordinary way, but he ultimately found her dead. Probably he would have been more successful if she had arrived about the end of May, for the young bees took to a queen much more readily than bees which had been hibernating during the winter.

In reply to Mr. Stewart, Dr. Walker said that all the apparatus for supplying water could be manipulated from outside, and that the only improvement he could suggest in the crate would be that at the bottom of the hive there should be a sliding drawer, so that there would be greater facility for removing dead bees and *débris*. The drawer might be made of perforated zinc. He was sorry he did not bring the African bees with him, but on a future occasion he would be happy to exhibit them. They were something like Ligurians, having fine gold bands, but were a much smaller species. A full description of them would be found at page 188 of the *British Bee Journal* for the 29th April. They were regarded as prolific bees, very good honey gatherers, and he would be glad to see them introduced into England.

The Chairman was glad to see the contrivance, and invited the company to examine it, as they would not fail to learn something in regard to the proper formation of a travelling hive.

Mr. Hooker, Mr. Garratt, and others commented favourably on the exhibit; and in answer to questions, Dr. Walker explained that there were proper arrangements for ventilation by a slide at the bottom, and that no doubt the hive was slung during the voyage.

The Chairman said he noticed that handles were provided, which was most important in the case of a travelling hive, and was a matter of detail which was often forgotten. The members present were exceedingly obliged to Dr. Walker for the trouble he had taken to show them the hive, and he hoped that he would be more successful on a future occasion with his African queens, which might lead to the introduction of the Colonial bees into English apiaries.

Mr. Septimus Allen produced samples of glass sections, the advantages of which, he thought, must be apparent to most bee-keepers. They were blown as experimental sections, but in the case of a quantity being wanted, a block would be made, so that they would be pressed. The opening in the top for putting in the foundation was sawn out or ground out, but in the case of the glasses which were pressed, the hole would be formed in the pressing. He was aware it was occasionally said that there was a probability that the

bees would not work up into the sections on account of the smooth surface of the glass. He, however, contested this dictum, and was quite prepared to have a few more made and put in use, when he prophesied they would be filled as fast as could be desired. The advantages of these sections were that they could be easily packed, and there was far less chance of honey being lost than in the ordinary wood sections. Besides that, they would make an attractive object on the breakfast-table, and for that reason would ensure a higher market value than the wood section.

Mr. Garratt and Mr. Hooker believed that the glass sections never could replace wooden ones, because of the extra cost in producing them.

Mr. Allen pointed out that they could be filled over and over again.

Mr. Stewart thought they were a repetition of the principle of the old bell glass, and were defective in ventilation, owing to which the confined heat would very likely cause suffocation to a good many bees, or the moisture resulting therefrom would in some sections cause mouldiness, and deter the bees from working therein. He was decidedly of opinion that the bees would lose a great deal of time in climbing over a smooth surface. Besides, in those glasses, the bees could not pass from section to section as in the case of the wooden ones, and some time would be lost in going in and out.

Mr. Garratt quite agreed in Mr. Stewart's remarks with regard to the isolation of the bees in each section. He would like to know how the bees could finish off their work at the bottom. Mr. Allen had not shown that there was any provision for attaching it to the bottom. In these practical days of bee-keeping they found it was desirable that the sections should be attached all round to give greater firmness in travelling. Then, again, it seemed to him that the method of taking the honey from the glass was a very awkward one—only by digging at the contents with a spoon.

Mr. Hooker did not think there was much ground for complaint against the glass on the score of ventilation. He had used bell-glasses with the zinc tube, and had always found that the bees stopped up the holes in the tube. With regard to foothold, he thought a line of wax would give them a ladder way up at all events, and if there was no other difficulty to encounter than the mode of taking the honey out of the sections, that was a matter that could be easily got over.

The Chairman was of opinion that these sections would suit a class of fancy consumers, who would be led to purchase by attractive appearances. There were many disadvantages connected with glass sections. Glass afforded the worst kind of foothold, and the matter of moisture would also give trouble no doubt. Then the loss of time in getting from one section to another was a matter of great moment to the producers. Still, as practical men, they must not lose sight of the fact that there would be a market for those sections probably at increased prices, owing to their prepossessing appearance, and if they were placed on wooden bars he had no doubt the bees would finish them off quite as well as they did the ordinary wood sections. He could call to mind customers in his own neighbourhood who would be likely purchasers. There was also the advantage that after being emptied they could be returned for refilling. He wished Mr. Allen could bring a crate with twenty-one of them nicely filled, the bees performing this work in about eight or nine days, when the members would be better able to form a judgment of the merits of the glass section. He thought that a manufacturer having made his moulds and started in the manufacture of the glasses, would not charge much more than the price of 1-lb bottles. He invited the meeting to express its opinion on the section, which no doubt would have great weight with the Committee of the B.B.K.A. The question was whether they really

thought the article one of practical utility to bee-keepers?

Mr. Meadows (Leicestershire), Mr. Hooker, and Mr. Stewart, offered further suggestions and comments on the exhibit.

Mr. Andrews said his experience was to the effect that bees could stick their combs to sides of glass just as well as to wood.

Mr. Allen having replied, a show of hands was called for, and the meeting declared by a majority of six its opinion against the utility of Mr. Allen's exhibit.

The Chairman said he trusted, in spite of the adverse vote of the meeting, that Mr. Allen would not be deterred from pushing his project in the market.

Mr. Meadows (Leicestershire) exhibited an improved extractor invented by Mr. Raynor. He said that the principal features of this contrivance were that the comb was very easily reversed, that it was impossible for it to bulge, that the whole apparatus came to pieces without any trouble, and was very easily cleaned. It was strong and well made, and would extract two combs at once.

The Chairman, Mr. Hooker, and Mr. Garratt, commented favourably on the apparatus, and ultimately the meeting expressed its opinion by a large majority in commendation of the extractor.

Mr. Meadows then exhibited Dr. Ray's 'Melpel,' which he said had been before the public for some time. The great drawback in articles of that sort was their complication, as they usually consisted of too many parts. The one before them was an exception to the rule, and would extract three 1-lb. sections or two 2-lb. sections.

Messrs. Garratt, Hooker, Stewart, the Chairman, Andrews and Haviland, were generally of opinion that no objection could be offered to the instrument, except that it was unnecessary, for where extractors for frames were in use by bee-keepers there would be no occasion for the Melpel, because the large extractor could always be so manipulated as to extract sections; and therefore it would not be wise to incur expense in multiplying useless beagar.

Mr. Meadows said that the cost of the apparatus was only 5s. 6d.

On a vote being called for, the meeting expressed disapproval of the Melpel, not of its merits, but of the desirability of recommending bee-keepers to purchase it.

Mr. Meadows then exhibited a feeder. He did not claim any credit for novelty in regard to it, but only put it before the meeting as a very cheap and serviceable article. It could be supplied with a bottle at one shilling.

After a few remarks from Messrs. Garratt, Hooker, Andrews, and Bush, the meeting unanimously expressed approval of the feeder.

Mr. Meadows then exhibited two improved queen-cages which he contended were well and cheaply made. There was nothing new in their design, and he only wished to show them to the meeting without specially seeking for an expression of opinion in regard to them.

Mr. Henderson exhibited a new fumigator, which had been invented by Mr. Webster, a frequent correspondent of the *Bee Journal*. A full account of the instrument and its action appeared at p. 189 of the last number of the *Journal*. He (Mr. Henderson) had asked Mr. Webster whether the fumigator would quell those bees which were not susceptible to the effect of smoke. Mr. Webster had replied: 'I am more than satisfied of its efficacy, and have, since writing, tried its effects upon some exceedingly vicious lots with results far superior to smoke.'

Mr. Garratt would like to know whether carbolic would have any effect on the honey-comb.

Mr. Meadows stated that he in conjunction with another gentleman had considered the matter of fumigation, and were about to introduce a system,

Mr. Andrews asked whether bees would get rid of the fumes of carbolic as quickly as of brown paper or tobacco.

Mr. Haviland thought it would be premature for the meeting to express an opinion on the fumigator while so little was known of the effect of carbolic fumes.

The Chairman, Captain Bush, and Mr. Stewart thought that if carbolic were used, it should be carefully diluted.

Mr. Henderson said that it would not be desirable at the present time to express any decided opinion on the subject. He had brought the fumigator to the meeting as a novelty in bee appliances. He could have wished that Mr. Webster had been present to describe his own invention.

Mr. Stewart moved and Mr. Hooker seconded a vote of thanks to each of the exhibitors, which was carried unanimously.

Mr. Meadows thanked the meeting, and said he was always glad to have the opinion of practical bee-keepers, whether for or against his appliances, and quite apart from commercial considerations.

Mr. Allen also responded to the resolution.

Mr. Garratt proposed and Captain Bush seconded a vote of thanks to the Chairman, who briefly acknowledged the compliment, and the proceedings terminated.

A SOMERSETSHIRE B.K.A.

A local branch of this Association has been formed at Taunton. A meeting of bee-keepers was recently held in that town, when Mr. Searlett, Mr. H. Maynard, and Mr. B. Maynard were elected local Committee, with Mr. C. Lewis, Fore Street, Taunton, as local Secretary.

Permission was obtained to hold a show in connexion with the Horticultural Exhibition on August 12th, and a prize list was drawn up and a fund started.

SOUTH KENSINGTON EXHIBITION.

ITALY.

Our Italian contemporary, the *Apicoltore* of Milan, publishes the list of the exhibitors to whom prizes were awarded in the 'Products' section of the Bee Show lately held in that city. The following are a few of the most familiar names appearing in the list, with particulars of their respective exhibits:—The Very Rev. Don Cirillo Girotti exhibited an interesting collection of beautiful honey obtained by his bees from various kinds of blossoms, several samples of beverages and articles preserved in vinegar made from honey. Prize: the large silver-plated medal. Signor Giovanni Grammatica: Besides his thirty pots of honey and other sundry exhibits, his *pièce de resistance* was a coat of the royal arms worked in wax. Prize: the large silver medal. Signor Giacomo Bertoli of Varallo, Sesia, whose well-noted Ligurian bees were so much admired a few years ago at South Kensington Bee Show, exhibited his well-known honey from Monte Rosa, and an Alpine flora. Andrea Tartuferi of Falbriano, was honoured with the gold medal for his unsurpassed display of honey, wax, liqueurs, and wines flavoured with honey. Signor Eusebio Pin contributed a large quantity of Alpine honey of exquisite quality, and was awarded a large silver medal. Altogether the number of prizes distributed in this section was twenty-five.

PROPERTIES AND CHARACTER OF HONEY AND TABLE HONEY.

The present day has been rightly called the 'age of adulteration.' In fact, we can hardly consume any article but we find it adulterated. Is it therefore wonderful that analysts become indispensable functionaries in cantons and towns? Soon, even the smallest villages and hamlets will also have their own analysts. How do we stand in this respect with regard to honey, which is one of our most valuable and remunerative agricultural products? No breeding of cattle realises a profit of 60 to 70 per cent, as do bees to their intelligent cultivator.

First we ask: What is honey? Whence is it derived? What is artificial honey?

Honey is far from being only the simple nectar collected by bees from innumerable flowers, it is rather a delicate and complicated production of the body of the bee. So far as conscientious chemical analysis has shown, honey deposited in the cells by bees consists of no less than twelve substances, namely, water, cane-sugar, grape-sugar, fruit-sugar, gummy substances, albumen (digested and capable of coagulation), fat, formic acid, lecithin, volatile oils, ashes, and saliva. This last is secreted by the salivary glands, and mixes, first in the mouth, then in the oesophagus and honey stomach with the nectar collected by the bees, which is thus converted into honey. In this laboratory of the honey-stomach the cane-sugar and the gummy substances are transformed into invert sugar (a mixture of grape and fruit-sugar), as well as the albumen is digested. The beneficial action of this ferment continues in the honey cell; and this is the reason why old honey, having an equal proportion of water, is richer in sugar than new honey. The honey receives the albumen in the stomach of the bee. This substance is not found in the nectar collected from the flowers, at any rate if it does exist, it is not in so suitable a form for nourishment. The formic acid, represented in so minute a quantity, plays an important part in the preservation of honey. According to the observations of Dr. Müllenhof, of Berlin, before sealing the cells the bee turns round and by means of its sting injects a minute drop of poison, which is formic acid. Other bee-keepers maintain that the formic acid present in the hive in the form of vapour is absorbed by the honey, and is thus introduced before the sealing over of the cells. It is a proven fact, that formic acid is always found in pure honey. This abundance of nourishing substances explains the usefulness of honey for the nourishment of the queen, who, doubtless, lives principally on honey, and lays on an average 300,000 eggs a-year. It is for the same reason that workers can live notwithstanding the enormous waste of their bodies, and that honey is of such value even to man.

Respecting the physiological and medicinal properties of honey, in an article by M. Theiler in the special catalogue of the National Exhibition, the following extract from Dr. Hurlimann appears:—'Honey is not a universal food like milk and meat; it is nevertheless an important nutritive substance. Honey is especially distinguished for its easy digestibility, for it passes directly into the blood without any change or transformation, and becomes a powerful producer of heat.' This important property justifies its use for the table as well as in the treatment of invalids.

Pure honey gathered in the plains and mountains of Switzerland is of an exquisite quality; this is why it has up to the present time enjoyed a good reputation and realises high prices. It is therefore not strange that attempts have been made to imitate this article by artificial means, and to manufacture and adulterate it in every way. America stands at the head of this in-

dustry, France and Germany worthily follow, and even Switzerland is not far behind.

TABLE-HONEY.

This is the grand word to which the following remarks apply, and against which we declare war to the knife, the more so because our petition with upwards of 200 signatures, which made the modest request for the substitution of the name *artificial honey* for *table-honey*, failed in its object. But now we do not wish to have even this name. Neither table nor artificial honey has any right to be called honey. We know only one honey and that the produce of the bee. All the imitations do not merit any other name than syrups. In this respect we share the views of the courageous and valiant champion of honey, Dr. Stautner, the editor of the Munich *Bee Journal*.

WHAT IS TABLE-HONEY?

Table-honey, synonymous in Germany with artificial honey or Swiss honey, is an artificial product, in the manufacture of which enter, in varying proportions, honey (mostly derived from abroad and of inferior quality), glucose, and treacle. This mixture is manufactured in factories to which admission is generally excluded to all except those interested. But how are we to distinguish honey from artificial honey? It can be done both chemically and mechanically.

1.—CHEMICAL PROCESS.

We determine the quantity of grape-sugar contained in the honey, first in its ordinary state, then after having boiled it with a small quantity of sulphuric acid or hydrochloric acid. After this process we shall discover a great difference between natural and artificial honey. It is thus that the amount of grape-sugar in honey before boiling, compared to the amount of this sugar after boiling with one or the other of these acids, only gave a difference of 8.33 per cent of grape-sugar, whereas the difference in the manufactured article rose to 45.28 per cent. The difference of grape-sugar therefore contained in pure honey and artificial honey is 36.95 per cent. These figures are significant. The increase observed in artificial honey is due to dextrine and cane or beetroot sugar (saccharose). Naturally such a process of analysis does not give the exact quantitative determination of all the different constituents of the mixture, it is, however, sufficient to enable us to judge of the substance with which we have to deal. The only method by which we can make an exact quantitative analysis is given in the excellent work of Dr. Sieben of the Sohlet Laboratory, in Munich, in 1884. (*Zeitschrift des Vereins für die Rübenzucker Industrie des deutschen Reiches*, August, 1884.)

2.—MECHANICAL PROCESS.

This process is exceedingly simple, and can be carried out at any time and anywhere by any housewife. Mix in a flask about two tablespoonfuls of honey which is to be examined with six of alcohol (failing which, brandy or spirits of wine will do). Shake the mixture well. After allowing it to rest a short time, we find in table-honey a thick white precipitate, which is not found in pure honey. This will dissolve in spirits of wine. If the honey is granulated or thick, it should be dissolved by heating and adding an equal quantity of water to it. Another method of analysis recommended by Dr. Ambühl of St. Gall, is based upon the reaction of colours by means of tincture of iodine on dextrine, a constituent part of glucose in artificial honey. (See the *Schweizerische Bienenzeitung*, October, 1885).—The PRESIDENT of the Swiss Bee-keepers' Association.

(To be continued.)

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements)

* * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

PLANTS FLOWERING IN MAY.

[303.] The following bee flowers will bloom this month:—Broom, bird cherry, hawthorn, and holly; fruit trees, viz., apples, pears, plums, cherries, raspberries, limnathes, wallflower, barbary, furze, horse-chestnut, maple, &c.—H. DOBBIE, *April 26th, 1886.*

WEBSTER'S NEW FUMIGATOR.

[304.] Owing to the numerous applications I have received as to the manner of using and agent used in my invention, the above appliance, perhaps you, Mr. Editor, will kindly grant me space for a description of the same. For two seasons I had observed the effect of carbolic acid upon ordinary blacks and Ligurians, and had used the same, as many others had, when removing sections; it occurred to me that the acid could be utilised in every description of manipulation; in the end I succeeded quite beyond my expectations. Up to this time I had been experimenting with ordinary English blacks only, and found that the mixture of one part carbolic (Calvert's No. 5) to four parts of water and a little glycerine was superior in its effects to smoke, while the great advantages of the fumigator over the smoker was a continued source of satisfaction to me, and I used it in its perfected condition on all occasions this season, which were very frequent. I then sent one to Mr. Cheshire; my spirits being rather damped when I received a communication from him that it was very effective with ordinary colonies, but with very vicious ones it was of little use. He at the same time advised me to try another agent. This I did; and scouring the country for exceptionally irritable lots, I found the effects upon them was astonishing. While emptying a hive, the gentleman who had charge of them said, 'If you had used smoke they would have been round you stinging you wholesale.' They packed themselves like herrings in a barrel, with their heads in the cells gorging. I had at this time no Eastern bees, only blacks and Ligurians; but Mr. Cheshire having plenty of Syrians and Cyprians, he made further experiments, and found that by an alteration in the agent these were, using his own words, utterly subdued. To Mr. Cheshire alone belongs the honour of discovering an agent for subduing the irascible temper of these little 'savages.'—W. B. WEBSTER, *Wokingham, Berks.*

SIMMINS' UNCAPPING MACHINE.

[305.] Referring to Mr. Meadows' communication, I must say he appears to have lost sight of both the efficiency and simplicity of this machine. The additional frame suggested by the editor as being desirable, is not needed, because the implement as completed last autumn meets every requirement. A frame-work to hold the comb is absolutely necessary in a machine with only a single knife like Zorzi's, but with my own having a double action, and uncapping both sides of a comb at

one operation, such a complication is not only unnecessary, but superfluous, as the guides arranged between the knives at either end to take the end rails of the frame are all that are needed. With a forefinger and thumb on each projecting ear of the frame of comb such can be passed through more quickly than it will take to fasten the comb into any additional frame-work before proceeding, without considering the removal and reversing of the same.

By referring to the illustration given on p. 154, it will be seen that the guides could not very well be shown in photo taken to obtain same, though the engraver made some attempt to bring them into view. The accompanying sketch will explain their position.

Another advantage in my machine is, that no damp cloth is needed, because of the peculiar construction of the knives which only require cleaning when finished with for the day. With regard to obtaining perfectly even combs, I did not, like the editor, come to the conclusion that such would always remain so. As a matter of fact, experience has taught me that they will not continue sufficiently even to work with double knives, and therefore, to enable one to take the fullest advantage of this, the more rapid process, the combs must be built out between dividers, for which the first cost is trifling, compared with the rapidity of manipulation given ever after.

I may say that the machine was first put in hand in the spring of 1885, and brought to its present state during the autumn of that year, when it was used successfully. I have recently been somewhat surprised to find (*American Bee Journal* for March 24th last, and fuller illustrated description lately given in *B. B. Journal*) that another bee-keeper had been working upon almost the same principle; but for simplicity and rapidity, I believe my own machine will be found more serviceable than that of Count Zorzi's.—S. SIMMINS.

BEST SIZE SECTIONS FOR GENERAL USE.

[306.] Although knowing that most bee-keepers prefer, or rather use, $4\frac{1}{2} \times 4\frac{1}{2}$ one-pound sections, I am very glad to see the remarks of A. T. Wilmot in favour of $4 \times 4\frac{1}{2}$. No doubt it is a pity that a standard size cannot be agreed upon to suit all bee-keepers; but from the fact that a standard-sized frame has already been adopted, and that the $4 \times 4\frac{1}{2}$ section exactly suits that frame—whether in super crates on top, or in section frames in the body of the hive, or both—a way very much advocated when working chiefly for section honey—I think it would be a still greater pity for the British Bee-keepers' Association to adopt a Standard section which would not suit their Standard frame.

When the Standard frame was agreed upon, some few years ago, I altered all my hives to suit it, and any new ones I have since got were not only the same, but provided with section supers and section frames to suit the $4 \times 4\frac{1}{2}$ size. I am now wanting a lot more new hives, and feel A. T. Wilmot's dilemma to be my own; not knowing whether to have supers made to suit the sections I now use or to alter those I have in use—discard section frames altogether from the body of the hive and go in for the $4\frac{1}{2} \times 4\frac{1}{2}$ sections now so generally in use. I would not think of using two sizes of sections in the same apiary, no more than I would two sizes of

brood-frames; but if I thought that I could continue to be able to get $4 \times 4\frac{1}{2}$ sections in future years, at an equal cost, I would most certainly continue to use them.—W. J. TURTLE, *Tandragee*.

SIZE OF SECTIONS.

[307.] In answer to the numbered objections (277, page 176) raised by Mr. A. T. Wilmot against the adoption of $4\frac{1}{4} \times 4\frac{1}{4}$ sections, I beg to submit the following replies:—1. The $4\frac{1}{4} \times 4\frac{1}{4}$ will fit the standard size hive by adopting a broad frame as always used; this is absolutely necessary if you desire to keep your sections clean.

2. A rack holding twenty-one $4\frac{1}{4} \times 4\frac{1}{4}$ sections will cover the standard frames if placed with the rows of sections running across, even when placed the reverse two strips of wood or quilting will prevent the bees ascending into the roof of hive.

3. By having a lift cut from a 9-inch plank sufficient room will be found, as in all hives there is a certain amount of spare space in the roof for packing, &c.

In reply to the presumed advantages of the $4 \times 4\frac{1}{2}$ sections of Mr. A. T. W.:

1. There being no alteration required in hive there is no expenditure; as to economising the heat can it be possible for a quarter of an inch to make any perceptible difference?

2. There is no advantage whatever here, as you can see at once which is top and bottom of any section, $4 \times 4\frac{1}{2}$ will require as much examination to see which is the top or which is the bottom as the $4\frac{1}{4} \times 4\frac{1}{4}$, and as a matter of course will take as long packing as each other.

3. Quite a matter of individual opinion; a square block of honey will fit a round dish I should say better than an oblong one, and most tea or breakfast dishes are made round.

I am strongly of opinion that the $4\frac{1}{4} \times 4\frac{1}{4}$ section ought at once to be adopted as the standard section, ninety-nine out of every hundred bee-keepers at the present time use that size for pound sections, and have their racks made for that size. We must move with the majority, and those very few bee-keepers who use the $4 \times 4\frac{1}{2}$ by a very slight expenditure could gradually introduce the $4\frac{1}{4} \times 4\frac{1}{4}$ into their apiaries.

There is no doubt in my own mind that back supering will become before long a thing of the past. I am quite certain that if any bee-keeper desires to make a big return at the end of the honey season—and who doesn't?—he will have to double; if he makes a commencement there will be no going back to the now rapidly becoming obsolete back supering.—W. B. WEBSTER, *Wokingham, Berks*.

SIZE OF SECTIONS.

[308.] In your last issue A. T. Wilmot wishes to know the objections to $4 \times 4\frac{1}{2}$ sections. There is only one—they are not quite so generally used as the $4\frac{1}{4} \times 4\frac{1}{4}$. There is not one advantage the $4\frac{1}{4}$ section possesses which the $4 \times 4\frac{1}{2}$ does not, but there are several the latter possesses over the former, as your correspondent shows. If the British Bee-keepers' Association should adopt one as a standard, surely it will be the one to fit their Standard frame. I cannot conceive of them doing otherwise, considering what they adopt now will probably be for future generations. The *Bee Journal* used to recommend the $4 \times 4\frac{1}{2}$ section; now they appear to recommend the $4\frac{1}{4} \times 4\frac{1}{4}$. Why is it? Nearly all the bee-keepers in my district use the $4 \times 4\frac{1}{2}$. I have started between twenty and thirty with them this last two or three years. A. T. Wilmot will always be able to get them from Abbott Brothers, Southall.—JOHN BELL.

STINGS AND GLOVES. [298.]

[309.] 'A Cottager' asks for the experience of other bee-keepers, and, as one who can sympathise with your correspondent, I would beg to offer a few remarks. I have had one skep in my possession which contained hybrids, and whenever I meddled with them they attacked me furiously; while I have a bar-frame containing blacks which rarely ever show their temper in such a manner. Without a doubt I suppose we may conclude that hybrids are more fierce than blacks. To come to the subject-matter as to when 'Cottager' would become so inured to stand any amount of stings with impunity, I would say that is a difficult question to answer. Some—and I am one of them—never would be inoculated to such an extent as to make them what one person once told me he was, 'bee-proof.' Why it is I do not know. I know a bee-keeper of some twenty years' experience, I know another of some five or six years' experience, and another of three years' experience. Now these three will tell you that, though they are not timid when manipulating their hives, they would much rather not get stung. And why? For the simple reason that they swell up so dreadfully as to make the pain of a sting almost unbearable. As to the oldest of the three he tells me that one out of about every nine stings causes a swelling. Why is this? Is it because the ninth bee happens to sting his flesh close to an artery? As to myself only a fortnight ago I was stung very badly, I had just finished wrapping my bees up—it has been very cold here—when one little rascal thought 'he had had enough of this world,' I suppose, and would not work for such a monster as me, and so gave me a taste of his fury by stinging me in the centre of the forehead. I took no notice of it that night, but, lo and behold! the next morning my forehead was swollen and very painful. Nothing daunted I went out, but it gradually got worse, and by mid-day it was so bad, and had descended into my eyes, that I was obliged to lay down the rest of the day. I may say the night previously I applied the old remedy of putting some blue over the sting.

Well, to continue my tale. My head got very hot, and the whole of that afternoon I was nearly distracted. I was advised all sorts of remedies, and I may tell your correspondent confidentially, I tried most of them, but with little effect. At last, my eyes being nearly black, my friends induced me to have a bread poultice on, and this cooled my temples wonderfully; it gave me much relief, though it did not reduce the swelling. On the following day the swelling had not decreased, though it was less painful, and I could tell I had borne the worst of it. To end briefly, I would inform 'Cottager' that in three more days I was myself again. My work lying out and about the town, I was asked by more than one, 'who the fellow was that gave me such a dressing?' and this, perhaps, was a little the worst, as it was put down by many friends that I had fallen out with 'the brewer.' As a rule I wear gloves and veil. I didn't in the earlier part of my bee-keeping, but, as I have explained above, I swell so much when I do get stung that I am obliged to. As to my being inoculated, I do not believe I ever should be sufficiently to stop all swelling. I had eight stings in about two months last year, and the eighth, which was on my leg, paid me out as much as the first.—E. F. II., *Oxford, May 1st*.

STINGS.

[310.] 'A Cottager' asks, 'Could an old bee-master with impunity stand forty or fifty stings?'—Yes, ten times the number. Last autumn I had taken a lot of bees and left them on their stands. Being detained, it was dark when I got to the last place to remove them. I had been working during the day with my coat off, and my shirt-sleeves rolled up, and had put on my coat without troubling to turn them down. When I poured

one lot of bees into my box, before I could close them in they boiled up and ran up my hands and arms, inside my coat stinging all the time. As I had to drive two miles, groom my horse and bed him down, have supper and a long chat with my host, a bee-keeper, it was three hours before I got to bed, and all that time the stings were in my arms. I can truly say that there was not a single square inch from my knuckles to my shoulder-blades without a sting or more. *Moral: Never (if you can avoid it) handle bees after dark.* The next morning I was frightfully stiff. But as I was bound to finish my round of bee-taking, I set to work, and in the course of a few hours the stiffness went off, and I felt no ill effects.

I am quite sure bees, in general, are more irritable than ten years ago. In 1875, 6, 7, I used to go bee-driving and never took a veil with me. I should be sorry to do so now. In remote country places, far removed from any advanced bee-keepers, I seldom see a stock which does not show signs of a remote cross with yellow blood. These hybrids arising from black queens mating with Ligurian drones are far more irritable than those arising from Ligurian queens mating with black drones.

'A Cottager' asks what an old hand would have done when attacked as he was. I should have thrown the quilt over the bees, smoked them freely, and sprinkled them with thin syrup. The cause was probably that all their stores were sealed, and so they had no opportunity of gorging.—F. LYON.

HIVE DESERTION.

[311.] That the desertion of a hive by bees at this time of year, as stated by one of your correspondents, being due to shortness of stores, I think there can be no doubt. A case has just occurred in my apiary of which I was witness. The stock was weak, but it was being regularly fed, yet about midday it left the hive, and entered another weak hive at the other end of the apiary. Curiously enough the queen at the head of this invalid stock I had just discovered to be a drone-breeder. Is it in the least possible that scents from the first hive would have discovered the condition of affairs in the second hive?—E. W. P.

DOG AND BEES.

[312.] I beg to tell 'Amateur Expert' that my old hen hatched that pumpkin into what is called a 'squash,' and that she did so in spite of sundry dippings meant to stop her 'incubatory proclivities.' As 'A. E.' has read my letters in Norwich papers, I may also tell him that my dog 'Rough,' who so hated the hum of a bee, died of extreme old age: I trust 'A. E.' may do the same. 'Rough' has been followed by a dog of other tastes. He's as bad as the idiot bee-boy at Selborne, only he's not an idiot: he's a most intelligent dog. Sometimes he carries hay from one stall to that in which his favourite 'Angelina' (my pony's name) lives. He pulls down her halter from a hook high up on the wall and tries to put it on her. But bees! oh dear! I quite fear about him at swarming time. He takes them with a fly-shot. How he avoids the stings I don't know. He seems to me to know that the insects *have* stings. Those bees crawling on my hearth he touches gently with his lips, and then, raising his lips, he seizes them with his teeth only. I think of getting him 'special permission' to enter the bee tent, 'just to show 'em how it's done.' He has one dodge I never saw in any dog before—I throw a stick high up into the air; he cannot tell rightly which way it is going, so he spins round like a wheel on its axis, and in a second of time surveys the surrounding space and marks the direction. The dog is a thorough-bred Irish terrier, born last July. I've just told him what I've said, and he takes it quietly.—J. LAWSON SISSON.

WASPS.

[313.] May I have the use of your *Journal* to ask if your readers find the wasps in extraordinary numbers this year? I have never known them so numerous. I killed to-day, April 28th, 8; 27th, 22; 26th, 17; and on the previous week, about 30. They were all found feeding on thirty-six gooseberry-trees in my garden.—JOHN B. RIXY, *Bagborough Rectory, Taunton.*

QUEEN WASPS.—A CAUTION.

[314.] The other day I observed several wasps flying around and settling on one of the pear-trees in my garden. I knocked down a few, but finding that they increased in numbers I had a net made similar to a naturalist's butterfly net, and on Friday evening last in about two hours had caught sixteen of them. On Saturday I caught fourteen more, thus making thirty queens destroyed in less than twenty-four hours. If every bee-keeper will keep a look-out *now* and destroy as many of the pests as possible, we shall be freer from their attacks on our hives in the summer and autumn.—H. COLEBY, *The School House, Wargrave, Henley-on-Thames.*

REVERSIBLE FRAMES.

[315.] There is an air of refreshing simplicity about the letter of your correspondent, 'W. Chitty,' in this week's issue. He has invented a reversible frame, which is to eclipse all others! But it violates one of the elementary principles on which bar-frame hives are constructed, viz., that *the combs shall be supported from the top, and shall not touch either sides or bottom of hive*, lest in replacing, bees, or perhaps even the queen herself, should be crushed. I imagine 'W. Chitty' has had no experience with his own frames. He claims the 'sole right of their manufacture,' and I venture to say that 'his right there is none will dispute.'—ROBERT S. LATIMER, *The Manse, Willingham, R. S. O., Cambs.*

FLOWERING HEATH.

[316.] Some of your readers may not know of a very useful spring flowering heath, which I am told is the *Amenia carnea*. I have large quantities of it here, so I can speak of it from experience. It grows very freely, and yields large quantities of pollen just when that is most wanted.—E. J. BROOK, *Ecclefechan.*

HOLIDAY NOTES AT A WELSH WATERING-PLACE.

BEE PASTURAGE.—MR. SIMMINS' NEW BOOK.

[317.] Coming from the Midlands only a fortnight ago, where a few pear and plum-trees showed a venturesome promise of bloom, the hum of bees among orchards of apple in full blossom is a delightful change. The business-like work of the bees is infectious, and induces a sturdy application of pen, or in this case pencil, to paper, with a determination to have a regular good bee-shot. The three-volume novel and the Home Rule scheme, with its surroundings of magnificent speeches, alike pall, and one turns with delight to the charm of the season, which at this early date, 29th April, has produced the note of the cuckoo and the cornerake, and the twitter of the swallow, and, above all, the happy *honey hum* of the bee. The buzz round the pea-flour skep, which this year, owing to the total absence of flowers, had to be resorted to once more rather against the grain, for pollen-bound combs are a nuisance; the buzz round such an artificial arrangement has a different sound from the pure honey song. And the banks in the lovely district near Aberystwyth are in places covered with primroses within a hundred yards of the water's

edge on the seashore. The resident bee-keeper here is a happy man. The somewhat rugged and bleak appearance of the mountains is lit up on closer inspection with numerous spring flowers. Wild strawberry is plentiful, and banks and ridges of golden gorse abound everywhere. In fact, the latter has to be kept in bounds by being set on fire, and one evening lately one side of a mountain looked like a volcano might do, hidden in fire and smoke. But the valleys are the charm. Wild cherry, wild apple—crab, I suppose,—and blackthorn, make the hillsides white. There ought to be more bees kept in this neighbourhood to reap the wasted harvest. That is the fact which strikes one after search and inquiry, 'Do you keep bees, and why not?' After that philosophical reflection I turn to the bee literature I have with me on this pleasant hill-side, the sun as warm as July. I am told that in spite of the hard winter, which has swallowed up some 30,000 sheep, and which is remembered in the price of mutton, snow never lives more than a day or two in this locality. The 'Useful Hints' are always eagerly scanned by me, and I should imagine, by all bee-keepers, for the man who cannot be told anything new is often left in the cold. But this time it is not in the *B. B. J.* that the best tips occur, but in the new book of Mr. Simmins. New?—well, a month old. Having skimmed it through I lent it, but only had time to study it now. And it is study it wants to get the full good out of it. This reminds me it is to Mr. Simmins that I owe peace of mind in leaving a score of stocks at this critical time, for the honey harvest battle is fought *now*, and not in July. The dry-sugar feeders, stored with 6 lbs. each, and one at each end of hive, will keep stimulation going till an inspection can be made next week. But the literature and the study of it, apart from *the* plan, the system of working for extracted honey, is most worth careful reading. Mr. Simmins might know the difficulty under which I have invariably found myself, in spite of a greedy devouring of all things appertaining to bee-culture in the English language, whether in English or American Bee Journals. Doubling was successfully accomplished, and fair yields of honey obtained (say 40 to 80 lbs.), but the queen was often crowded out below. The fault, the cause, and the cure, are each dealt with in a few concise words. There is one little difficulty still not cleared up by the writer, namely, what is to be done with the large quantity of empty combs which he apparently collects? They must not be put back again into the top storey, as is usual, and they must not be put below, as fully-drawn-out comb induces too much breeding, and to cut them up for the wax-pot I consider wasteful. Should Mr. Simmins have time perhaps he would explain his method of dealing with them.

The many other tips, such as the single-walled hive, the aspect for hives, the enamel quilt, all mentioned incidentally, afford much food for reflection: but, wheugh! the wind has touched a rheumatic joint, and I must bring this yarn to an end,—to be concluded in our next.—E., *Aberystwyth*.

EXHIBITORS AT SHOWS.

[318.] Are we poor would-be exhibitors to understand that to have a chance of winning a prize at the B.B.K.A.'s show we must glaze each separate section on both sides, and then put it into a show-crate having glass on each side as well, or (what a boon!) that we can get out of the difficulty by first putting each section into a small box having glass sides, and then place box in show-crate? Why this double doing it? What does uniformity gain by it? Would not a plain show-crate showing through glass sides each side of every section please the eye and keep robber bees at bay as well? Or, if I may be so bold, that each separate section must be glazed on both sides if not shown in (glass-sided) crate that shows each side of every section without unpacking? The quarter-inch paper edging is not much certainly,

but just enough to hide many defects or pop-holes in what may otherwise be a perfect section, and would lead to sections taking prizes before those which perhaps were not quite so good in centre of visible surface, but which might have no other defect, and would therefore be better sections than those taking prizes before them. Then the expense. I have always understood that one of the rules of our glorious B.B.K.A. is that bee-keeping was to be taught more especially for the good of the poorer or cottager class, yet we have here a rule which will put our cottagers outside the exhibition altogether, and, in a sense, others besides cottagers too. For one cannot afford to keep bees unless at a profit. I got only an average of ninepence for my sections last season, and shall never get more, and most likely less; then why should we go in for unecessaries? As to bottled honey, does the rule mean that the bottles must be corked and capped in addition, or will the cork inside the screw-caps meet the rule, and that the bottles should only be corked when parchment, &c., are used for covering instead of screw-caps?—FRIAR TUCK, *Mansfield, Woodhouse Notts.*

A MATTER REQUIRING AMENDMENT.

[319.] As one that takes a lively interest in the industry of bee-keeping, I am surprised to think that such a practice has been allowed to go on so long without being condemned, as that which I am about to bring under the notice of the bee-keeping community. The facts I refer to are as follow, and I can vouch for the truth of the statement, several instances having come under my own personal notice. In the honey classes of some of our Scotch competitions, several parties well known to the bee-keeping world make it a practice of going about the country and buying up all the poor cottagers' honey at a ridiculous small price. This is put aside until the first annual honey show comes round, is then staged as the exhibitor's own produce, and in many cases wins the best prize, and is sold at a good figure.

This, I think, is a very unfair practice, and should not be allowed at any competition in the honey classes. Some are not even satisfied with what they lift in the country under false pretences, but drop into the shops of some of our honey dealers and make a selection from their stock, which is also shown as their own produce. This practice being allowed does not give the honest bee-keeper a fair chance in competition. If exhibitors cannot produce honey from their own bees, they should not be allowed to compete with the exhibitor that has; for it is a very discouraging thing to see a man winning many of the leading prizes, and not one pound of the honey his own produce, and I would suggest the following clause be added to the rules of every Association:—

'That all honey staged for competition must be the sole produce of the exhibitors' own bees, gathered in the natural way during the current year.'

The rule in many competitions is: 'That the honey staged must be the *bona fide* property of the exhibitor.' The swindlers I refer to take the benefit of the last-named rule, and have the idea they have acted fair. I urge these remarks to the consideration of every Association when framing rules, and will be happy to see some of our advanced friends take up the subject, and give their opinions regarding it. Meanwhile I wait with patience in hopes that bee-keepers generally will respond to these remarks, and by doing so put an end to this most obnoxious system.—JOHN D. McNALLY, *Springburn, Glasgow.*

[The practice is a most reprehensible one, and should be stopped. There need be no difficulty about this. The compilers of the Schedule can insert a sufficiently stringent clause to prevent it.—Ed.]

Replies to Queries.

* * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[203.] *Croaking Noise*.—So far as my experience teaches me, there are two kinds of croak among bees. Firstly, when, upon the putting on of the quilt, a bee is fixed between it and the frame top-bar; this is, evidently, produced by the wings, and ceases upon the release of the bee. Secondly, a croak peculiar to the queen. This I have many times heard, and when, as in late autumn or early spring, drones are non-existent. 'Nucleus' properly describes it as a distinct croak. I have heard it both when a hive is closed and when open, and so frequently, that the sound not only assures me of the presence of a queen, but I have even been enabled by it, more than twice or thrice this season, to take out the particular frame upon which was the queen at the period of examination. Up to this present, there is not a drone egg, much less a drone bee, in my apiary.—**APIARIST.**

[272.] *Cleaning Extractor*. (J. I. S.)—Thoroughly scour with whiting and oil, and, if very bad, rub with very fine emery cloth; when clean, keep a little oil on when not in use. You cannot have it re-tinned. You can have a new cylinder fitted to inside cage-work, if desired.—**W. P. MEADOWS.**

[299.] *Unfertilised Queens*.—(A Cockburn.)—Most bee-keepers have unintentionally tried the experiment. When a queen is lost late in autumn her successor becomes practically a prisoner, or at any rate her liberty, in the absence of drones, is of no service. Within the last fortnight I have met with a case to the point. On examining a friend's bees I found a stock full of drone brood in worker cells, and found the young queen. I had seen a queen in this stock late in September. She must have been lost, therefore, and replaced after that date. The young queen having had no opportunity of working was a drone-breeder.—**F. LYON.**

[299.] *Unfertilised Queen*. (A. Cockburn.)—Parthenogenesis is not confined to the genus *Apis* alone, but is known to exist in many other insects, especially so is it observable in the Aphides; there is not the remotest doubt but that such is a fact. I have reared mother-bees after all the drones in the apiary have been killed, and on every such occasion they have proved drone breeders; this is not only my experience, but anyone who has so reared them will give the same facts. Only two weeks ago I found a drone-breeder in a hive; this hive had on the 13th February a properly fertilised mother and worker brood and eggs in the combs; this mother-bee was killed by imprudent manipulations, a fresh one was reared, which I saw, but there being no drones at the time she could not be fertilised, and as a consequence is now a drone-breeder. Dissection will also prove the above facts; for instance, on examining a drone-breeder except in very isolated instances, the spermatheca does not contain any spermatozoa, which conclusively proves that effectual connexion with the male has not taken place.—**W. B. WEBSTER.**

[299.] *Unfertilised Queens*. (A. Cockburn.)—I think any bee-keeper would experience a great difficulty in confining a young queen recently hatched, as where the ordinary workers could obtain an exit, she would manage to squeeze through. I have never heard of such an experiment being made; and if it was, what would it prove as any advantage to bee culture?—**G. H. G.**

[300.] *Worker and Drone Eggs*. (E. W. P.)—Querist does not give age of queen. Young queens just mated will often for a little time lay some drone-eggs in worker-cells. Old queens that are nearly spent do the same, and I have known queens do it that have got injured by pressure, when they have rather a 'canny' appearance, with their wings most likely not even and symmetrical. Imported queens often do this for some little time after being liberated.—**G. H. G.**

[300.] *Worker and Drone Eggs*. (E. W. P.)—There is a possibility of the spermatheca becoming emptied of spermatozoa, but when such an event happens a very visible diminution in the strength of the colony is observable before such an event occurs. Are you sure that they are drones in the worker cells? I was myself surprised on opening one of my hives about a fortnight ago at seeing what at first sight

appeared to be drone brood, but on releasing a few of the inmates who were on the point of emerging I found they were workers. In order to account for this phenomenon I found that the cells in this part of the comb were exceptionally shallow. The weather being too cold for wax to be used the bees had elongated the cells with the substance they use for capping brood and so formed what appeared to be drone capping; this may be so in your case. Another explanation may be found in the fact that being short of drone-cells they have used worker-cells that have become enlarged by the foundation stretching, which is often the case when adulterated or been subjected to a very high temperature. If the original mother has been killed and a fresh one reared, she, not having been fertilised, would lay drone eggs.—**W. B. WEBSTER.**

[301.] *Sting Antidote*. (Melissa.)—The application of carbolic acid directly the sting is inflicted was recommended in this *Journal* last season; I think the remedy is almost as bad as the disease. My advice is to get used to it. A very highly recommended antidote is advertised frequently in this *Journal*.—**W. B. WEBSTER.**

[301.] *Sting Antidote*. (Melissa.)—Best antidote is to get blood inoculated with the poison (formic acid); and, second, apply alkali, of which I always found ammonia most successful.—**G. H. G.**

[302.] *Wax Discoloration*. (Melissa.)—This takes place in that part of the comb where brood has been reared, the portion where honey only is stored; keeps its colour for a very considerable time; pollen stains the comb. Your own table-cloth does not retain its pristine whiteness after having been much used, and so it is with the bees' combs.—**W. B. WEBSTER.**

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[319.] *Drones*.—Has it ever been proved beyond a doubt whether drones produced by unfertilised queens are or are not capable of fertilising queens?—**F. LYON.**

[320.] *Foul Brood*.—Can any bee-keeper having had practical experience of foul brood state his method of cure, and the respective merits of salicylic acid and phenol?—**G. H. G.**

[321.] *Bees Flying from the Hive*.—Could any of your readers explain how my bees are flying from the hive never to return? I have a bar-frame hive, which I examined last week, and found some of the combs a little mouldy. I cut the mouldy pieces away, and gave them the best of the comb in a new hive. Now the bees began to come reeling out, and next morning I found the half of my bees dead in front of the hive.—**R. JONES.**

Echoes from the Hives.

Ectefechan, April 30th.—The past winter has tried any colonies poorly wintered very severely. I have found hybrids to have stood the winter best. The stock I asked you about (and for which you gave me two answers the week before last) is doing well, and as full of bees as the hive will possibly hold, they are even round the entrance on very cold nights.—**E. J. BROOK.**

North Cornwall Apiary, May 1.—The last month has been very unpropitious for bees in this immediate neighbourhood. The air has been very cold, and the winds high and boisterous. My diary only records six days out of the thirty as being of real use and benefit to bees in this apiary. Thousands of bees have been dashed to the ground laden with pollen, and destroyed by the cruel east winds, thus weakening the stocks to a great extent. It has been the most trying winter and spring I have experienced during my fourteen years of bee-keeping.—**THE MANAGER, Rowe, Bodmin.**

South Cornwall, May 3.—It really seems as if fine weather were—if not come, yet coming at last. The wind still blows from the east, but there is only a little of it, and I have ventured to transfer from a badly made hive of local manufacturers to one of Abbott's. Only on one other day could I have done so, or on two at the most. Quantities of old stores still remain, but they will not last long, though I fear we can look for but little spring or early summer honey, as blossom will be scarce. I hear of no unhealthy bees in this neighbourhood.—C. R. S.

Oxford, May 1st.—After a short spell of cold weather, and a rather longer one of warm weather, we have had still one more change. For the past three or four days a strong easterly wind has been blowing, and consequently the bees have done less work. Plum and apricot trees remind one of winter, when they were covered with white snow; and the currant and gooseberry bushes supply a large quantity of pollen. At last things begin to look brighter, and our hearts are glad. Hives nearly full of brood, the hawthorn in bloom, may budding, the fields studded with flowers, and the flower-gardens containing an abundance of bee-flora, are sufficient to give us an impetus and wish each other success. We are moving in Oxford at last; though we cannot get every bee-keeper to join the Association, we may hope to reach 'the country flowing with milk and honey' some not far distant day. Even the Mayor has promised to assist us in any possible way. Surely we have cause to work and be happy, and trust that soon foreign honey will be excluded from our market. May it be so.—E. F. H.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

K. K.—*Living Swarms.*—As soon as your bees have clustered, shake them into a straw skep, and take them to the spot they will eventually occupy; towards dusk, spread a sheet before the entrance of the hive, then take away the skep, and place in its stead the bar-frame hive. Then shake the bees out of the straw hive on the sheet, and they will at once enter the hive. The frames should be filled either with comb or foundation. The quilts should be on the frames and a bottle of syrup ready before the bees enter. There are other ways of living swarms, but the above will answer your purpose.

J. B.—The sample of wax appears to us to be pure.

A CHATTON APIARIAN.—The bee forwarded was the queen. We recommend that you should let the hive alone, there being every probability that the bees will reproduce a queen.

COL.—1. *Uniting.*—The queen which you desire to retain having been secured, bring the skeps close together by daily gradations, and drive the bees from both skeps. They should be made to bear the same odour, and should be caused to gorge themselves with honey or syrup; they should then be mingled together, and placed in the skep they are to occupy. 2. *Sugar.*—The sugar will be found suitable for dry-sugar feeding, though not the best for the purpose. It is of the kind known in the trade as 'Demerara Syrups.' 3. *Separators.*—The tin separators are the best, being cleaner; the zinc and wood are cheaper. 4. *Honey Confectionery.*—Communicate with the Rev. V. H. Moyle, Ashhamstead Rectory, Berks, who will be pleased to furnish you with the information desired.

C. C. J.—*Wax, Propolis, &c. on alighting board.*—The substance enclosed in your letter consists of wax, propolis, and the excrement of bees. The explanation is this:—Beneath the cluster of bees the small particles of wax, from the unsealing of the honey cells, were scattered. The bees, from long confinement were compelled, to some extent, to discharge their faces, which, being mixed with the refuse wax, formed a glutinous substance they

were unable to remove from the hive. When spring advanced they were enabled to collect it into masses, but were still unable to extrude it from the hive; and in order to prevent ill effects, certain to arise from the effluvia of the fetid ordure, they encased it under a covering of propolis, just as they will glue down and cover up with propolis a snail or a mouse which may have gained access to the hive and which they are unable to expel. We have often noticed the same proceeding in our own hives. Your bees were evidently dysenteric.

J. STRADLING.—*Bees Dwindling.*—Your bees, being reduced in number—from dysentery, spring dwindling, or effete queen,—succumbed to an attack of robbers, and were driven from their hive, queen and all. The queen had ceased breeding, either from old age, or because she had an insufficient number of bees to cover a brood nest—probably from both causes combined. We fear the bees will not survive.

SCOTY.—The names of the flowers forwarded for identification are:—1. *Erophila verna*—Vernal whitlow grass. 2. *Stellaria holostea*. 3. *Mercurialis perennis*—Dog's mercury. The last plant does not bear a very good reputation as it possesses poisonous properties.

BEGINNER.—*Swarm from Skep.*—By returning the swarm, having removed the queen, at the same time supering, you will most likely avoid any further attempts to swarm. We should advise you to transfer your bees from their present skeps to bar-frame hives, you can then control swarming by giving more room at your pleasure.

D.—*Fertility of Queen.*—The mere fact of acceptance by the bees taken alone does not prove fertility. You will know in a few days by the presence of eggs, and whether she is fertilised (quite a different thing), by whether the eggs laid in worker-cells produce workers or drones. If the latter she is unfertilised.

IN A FIX.—*Loss of Queen.*—By the time young queens are raised and ready for flight, drones will also probably be flying, and if so all will go well. You can see if you have sealed drone brood, even in a skep, by the domed cap-pings.

R. S. R.—*Suspected queenlessness.*—Search again for eggs. As pollen is carried in it seems that breeding must have commenced, although you failed to see any brood. As all were swarms last year, the queens would, of course, be old and might have died.

BEE-STING.—1. *Stings.*—You will find advertised in our columns a remedy which is highly spoken of. 2. *Robbing.*—Cover up your feeder so that no bees but those of the fed stock can get at the food. To allow strange bees to get at a feeder is the best way to set up robbing, which is far more easily prevented than cured.

NIGGER-JACK.—1. *Doubling in a Hive with high outside Walls.*—Make a plain box without bottom, 14½ wide, 8½ in. deep, and long enough to take 10 frames, 14½ or 15 in. Use this as the top hive to contain the brood combs of the second stock. Place it directly on the frames of the lower hive. Raise the roof by a lift, as shown at E, p. 59. 2. *Working on the Doubling System.*—One hive remains on its stand; the combs of the second hive are taken from the bees and placed on top of the first, the bees of the second being placed upon their own stand and treated as a swarm. 3. *Distance Guides.*—Metal ends are the best, but some experienced bee-keepers use none at all. If none are used, the ends of the top bars should touch the inside of the outer walls. 4. *Finding the Queen.*—You will find this become easy by practice. If you do not excite the bees much, you may often see a batch of bees, as represented on the title-page of the *Journal*, the queen being in the centre. If they are excited, by running over the combs, the difficulty of catching sight of her majesty is greatly increased. Try the centre combs first.

J. S.—1. *Ligurianising.*—We should recommend an imported queen in preference to a home-raised one. If you introduce her at swarming time, do not wait for natural swarming, but when about to take place divide the stock and give the queen to the old stock. 2. *Excluder.*—You must use a sheet of excluder the whole size, vertically, of the hive; the plan you propose would not answer.

MAUGERTON.—1. *Names of Flowers.*—The flowers enclosed are

produced by the Norway maple (*Acer platanoides*), and like the sycamore is a valuable tree for bee forage. If the bark of this maple is bruised or cut at this season, the juice or sap will flow out in little streams, and bees will sometimes collect this saccharine fluid. 2. *Bees on Paint*.—Bees are often attracted by the smell of turpentine, especially as existing in pitch pine or yellow deal. Being attracted to the neighbourhood of the wet paint, they were blown on to it by the wind.

SIMPLICITY.—1 and 2.—You had better obtain a good bee-book and read it up. You will soon learn to distinguish the queen when you have once seen her. See reply to 'Nigger Jack.' You cannot make an artificial swarm until you can find the queen. 3. *Smoking Bees*.—Give a puff at the entrance, then with one hand raise the quilt, beginning at one corner, while you gently puff smoke under it with the other hand. You can then lift out the frames.

DUMBLEDOREY—'A. E.' has most strangely forgotten his Cornish. That a 'dumbledorey in a pop-dock' means a 'cockchafer in a ginger-beer bottle' is a suggestion which has caused more than one smile. It is simply a humble bee in a foxglove, and the noise produced by struggling wings and legs is pretty well known. After all, it hardly represents the peculiar croaking spoken of. I wish I for one could have been at the Quarterly Conversazione. I have a lively recollection of one three or four years ago, but we in these parts are too far removed from the great centre to do more than correspond with it.—SOUTH CORNWALL.

RECEIVED from Alfred Withinshaw, The Apiary, Nantwich, Cheshire, his *Illustrated and Descriptive Price-list of Bee-hives* (32 pages).

Also several numbers of *The Housewife*, containing a series of practical papers on 'Bee-keeping,' by Edward York.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

THE RAITT FUME CHAMBER,

Adaptable to ordinary Smoker barrel, will shortly be ready. Await further notice before purchasing, and so get a perfect article, or apply direct to

W. P. MEADOWS, } or { J. H. HOWARD,
Syston, Leicester. } Holme, Peterborough.

SUPERIOR BEE VEILS, Wire Gauze Fronts, 1s. 2d. each; 3 for 3s. Splendid BEE TRAPS, for Clearing Supers, 6d. each; 3 for 1s. No Bee-keeper should be without them. Address W. CRISP, Halstead, Essex. A 520

WHITE FLINT HONEY JARS, Feeding Glasses, &c. Send for List; prices low.

FREDK. PEARSON,
STOCKTON HEATH, WARRINGTON. A 593

MANIPULATE WITHOUT SMOKE.

WEBSTER'S FUMIGATOR

ENTIRELY supersedes the Smoker, both in simplicity and effectiveness. No 'going out,' as no fire is used. Always ready for use, no matter how laid down, without any extensive preparation. No tainting of honey. No dirty liquid dropping from it to soil combs. Quite portable, can be carried in pocket. Will subdue the most vicious of bees. Can be fitted to any smoker-bellows.

Mr. F. CHESHIRE writes: 'I find—by experiment—that the most vicious Eastern Bees are utterly beaten at once.'

Price 4s. 6d. complete with Bellows.
3s. without Bellows.

BOTTLES OF AGENT FOR USE WITH VICIOUS BEES, 6d. EACH.

W. B. WEBSTER, Wokingham, Berks. A 596

NOTICE.

AMERICAN ONE-PIECE SECTIONS, $4\frac{1}{4} \times 4\frac{1}{4}$, will be to hand in a few days.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

ARE BACTERIA IN BEES HARMLESS?

At page 156 of the *British Bee Journal*, issued on the 8th ult., I find an editorial note referring to 'our reply to A. Rendell,' the reading of which has, in one respect, surprised me, as it quietly ignores the previous references I have made to my discoveries as to the cause of dysentery, and which have continued for about twelve months. I do not doubt the observations cited in the reply, but the fact that the discovery is mine is self-evident, and needs no comment. But later on a point of general interest and primal importance in understanding the question of germ diseases is so very erroneously stated that for the sake of a subject I have much at heart I must venture to absolutely dispute the position taken. The reply runs thus:—'We have ourselves found five or six apparently different species, but there is no more danger to be apprehended for all that. The air is full of bacteria, and at every breath we are inhaling thousands, and our bodies are full of them, but we are none the worse for it. So it is with bees, they may also contain bacilli in numbers and be in no way affected by them.'

With regard to the number of species discovered, it is enough for the moment to say that I have a slide of the blood taken from a living queen sent me by the Rev. Lawson Sisson, in which there are no less than eight distinct species at least, and I am convinced that twenty species existing in bees is a modest estimate of the number with which I am fairly well conversant; so that here I am fully in agreement with the reply, but its next statement is diametrically opposed to the conclusions of scientists: of which more presently. To rebut the assertion that '*the air is full of bacteria*, and that at every breath we are inhaling thousands,' it is only necessary to ask the proofs. None certainly can be given, while experiment and experience alike show the notion to be a simple delusion. Illustrations could be given in number, but two will suffice: Miquel found at Montsouris an average of one bacterium in 650 cubic inches of air; and since an inspiration of an adult may be taken at 36 cubic inches, it gives one bacterium in eighteen inspirations. In the Rue du Rivoli, Paris, he discovered a very unusually large number, amounting to one bacterium in 12 cubic inches, or three bacteria per inspiration. 'At every breath we are inhaling thousands' would hardly do even if we spent our lives in the healthful exercise of carpet-beating.

Again, the statement that 'our bodies are full of them, but we are none the worse,' is most astonishing. Where could such an idea have originated? an idea which no one acquainted with the outlines of bacteriology could for a moment entertain. In health the blood, the muscles, the brain, the nerves, &c., are absolutely devoid

of any bacterial trace, and any existing would at once be noted by a bacteriologist as an evidence of disease. They are found in the digestive tube throughout its length it is true, but even there they often point to conditions of trivial or serious disturbance. In the bee certain bacterial forms in the bowels point to disease at once, while no bacteria *can* exist in the blood or tissues unless as a cause or concomitant of disease.

The statement then that 'bees may also contain bacilli in number and be in no way affected by them' is as misleading as it is possible to make it. Bacilli in the bowels may have no *serious* import, but if existent in the tissues they indicate a definite and diseased condition which demands careful and scientific investigation.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

[Mr. Cheshire has not taken us into his confidence, and we are ignorant of the discovery he has made and what he really claims, as we have seen no description or particulars of it. We know he has stated that he was making observations, but that surely is no reason why others should be precluded from doing so too. The field of research is open to all, and Mr. Cheshire surely does not claim the exclusive right of investigating any matter connected with bees or their diseases. However, though exercising the full right of making any observations we like, we do not lay claim to any discovery, and they have been carried out with the primary object of verifying the published discoveries as to dysentery of Prof. Leuckart in 1856, and Dr. Dönhoff (*Bienenzeitung* for 1857, p. 66); also Prof. Hoffman (*Notizblatt für Kryptogamische Studien*, Vol. I., p. 117; see also *Bienenzeitung*, Vol. XIII., p. 67, Vol. XV., p. 151; Vogel's *Handbuch der Bienenzucht* 1879, p. 203; Dr. Assmuss' *Die Parasiten der Honigbiene und die durch dieselben bedingten Krankheiten dieses Insects*, 1865, p. 55. We could give many other references to show that our observations were nothing new, and until Mr. Cheshire makes public what he really does claim to have discovered within the last twelve months, it is not at all *self-evident* to us that our observations can be his discoveries. When his observations are made known we shall be only too pleased to give Mr. Cheshire credit for any original discoveries. We have, however, a lively recollection that in the case of foul brood Mr. Cheshire claimed the discovery of bacillus as being the cause of the disease, entirely ignoring that Dr. Cohn had made this discovery in 1874 (see *Pestluft und Foulbrut* by P. F. Liska, 1876), and that it was subsequently confirmed by Schönfeld and others. Mr. Cheshire must pardon us for calling attention to this, and excuse us if we decline to admit any claim to discoveries not made public. We are tolerably well acquainted with Continental bee literature, what has been written to the present time and the discoveries made, and we should only make ourselves the laughing-stock of foreign scientists were we to entirely ignore all that has been

done by them. Nowadays it is absolutely necessary for a scientist to be also a linguist, for, as De Candolle points out, 'What is thought new in one country is found to be already known in another by those who read different languages.'

With regard to our statement that the air we breathe is full of bacteria, as Mr. Cheshire has cited Miquel we will also refer to the same observer. Will Mr. Cheshire be surprised to learn that Dr. P. Miquel, in a paper on the *Hourly Variations in Aerial Bacteria*, published in *La Semaine Médicale*, for 6th Nov. 1884, states that the number of bacteria varies from hour to hour, and have approximately regular maxima and minima in the course of the entire day. At 8 a.m. the number of bacteria is high, and decreases up to midday. From midday to 1 p.m. there is a remarkable minimum and then a gradual increase. At 8 p.m. the air is strongly infected. From 10 to 11 p.m. the air is very impure, the number decreasing from 1 to 3 a.m., and again increasing towards morning. Taking the number at 50 per cubic centimetre of air at midday, Miquel says the rise may be up to 1000 in the same quantity of air at 8 p.m. The number of bacteria we inhale is a simple matter of calculation. A cubic centimetre is 0.061 of a cubic inch, or in round numbers about $16\frac{1}{2}$ cubic centimetres go to a cubic inch. This would give us 825 bacteria per cubic inch at midday, and 16,500 in the same quantity of air at 8 p.m. By multiplying the above by 36 cubic inches for each inspiration it will be seen that it is no exaggeration to say that at every breath we are inhaling thousands. Miquel has made 'bacteriology' a study for upwards of ten years, is no novice, and is admitted to be an authority. Besides this there are the experiments of Pasteur and Tyndall, who proved that germs existed in large quantities in the air, but decreased in the higher altitudes until a point was reached when they were no longer present. We have ourselves seen animals preserved on the summit of the Simplon by merely being hung up and dried in the air, and in which no decomposition had taken place owing to the total absence of bacteria, and these animals can be kept in the fresh state at this altitude for an indefinite time. At the lower level of the Rhone Valley such meat could not be kept for a day without decomposition commencing.

Yes; our bodies are full of bacteria and 'we are none the worse.' We said nothing about their being present in the blood, muscles, brain, or nerves, and will allow competent authorities to speak respecting these, but they are only a portion of our bodies. Our correspondent admits that they are found in the digestive tube throughout its length, and they *may* point to conditions of trivial or serious disturbance, but they do not always do so, and when they do it is the exception and not the rule.

Now let us for a moment see what our leading authorities have to say on the subject, those who have been and are in the thick of the work. Speaking of micrococci Dr. Klein says, 'They are widely distributed in the air. They also occur in the body of man and animals wherever there is dead tissue' (not necessarily from disease). They are 'found in ordinary pus, in the normal oral cavity (on the filiform papillæ of the tongue and on mucous membrane), in the bronchial secretion of ordinary catarrhal exudations (nasal cavity, bronchi, &c.), 'and in the cavity of the small and large intestines.' He further says that in the dead tissues within the living body micrococci may be found in colonies, *i.e.*, as zooglæa in the blood-vessels and in parts around. Bacilli, he says, are found on the surface of the mucous membrane lining the cavity of the tongue and mouth. Dr. Cameron says microbes (bacteria) 'are to be found everywhere, and carried by the air into putrescible matter'; also, 'microbes of various species may be found in the saliva and in the secretions of the bronchi and intestines even when there is no disease.' 'It is not enough, therefore, to find bacteria, or vibrios, or other

microbes, in the fluids of the body, to enable you to say that they had anything to do with a disease.' Professor E. Ray Lancaster says in *Nature*, 'Who can say that much is known as yet about these organisms when even so earnest a student of them as Dr. Robert Koch did not know that his so-called "cholera comma bacillus" occurs in the mouths of nearly every healthy man, woman, and child?' Dr. Koch himself admits that he has found bacilli somewhat resembling the cholera bacillus in saliva, and curiously also in a bee, although he considers them different.

In their cholera report, Drs. Klein and Gibbs draw attention to the fact that comma-shaped bacilli, similar in appearance to those found in cholera, 'are ordinarily present in certain parts of the alimentary tract in health, and there is reason to assume that these comma-shaped organisms present themselves under two, if not three, forms in the mouth alone.' In the report a remarkable case is stated of a tank surrounded by huts in which 200 families were living. One case of cholera had occurred the first week in November, and in the middle of December this tank was examined. It was very dirty and contained quantities of bacilli, and this water, although contaminated with choleraic evacuations and extensively used by these inhabitants for many weeks for all purposes, including drinking, had not produced another case of cholera.

We could easily multiply such statements to show that bacteria do exist in our bodies even in health, but we will conclude by quoting Dr. Lionel Beale, who says in *Disease Germs*, page 64, 1870, 'that there does not probably exist a single tissue without these germs, and the blood of not a single man is exempt from them.' (As we have translated this passage from the French the words may not be exact, but the meaning is correctly conveyed.)

What are we to say in the face of all these statements? Bacteriology is still in its infancy, and those who have made it their study are by no means unanimous on all points, and we are not surprised to find our correspondent's views differing from the authorities we have mentioned. It has as yet to be proved that the various bacilli found in bees have anything to do with particular diseases in these insects,—and surely Mr. Cheshire will not wish us to believe without such proof that the twenty species with which he is 'fairly well conversant' represent so many different diseases. It is evident that Mr. Cheshire clings to the idea that the different species or genera breed true. Has he not found ample evidence of the transformation of one form into another, as micrococci into bacteria, and of these into bacilli, and vibrios and spirillæ, and of each of these directly, or indirectly, into the other forms? Careful observation would have revealed this fact. Professor E. Ray Lancaster says, 'The instability of the forms of schizophytes merely implies that the range of presently observable specific characters taken as a whole (which forms the true limits of what mankind at the moment calls a "species") is *not* simply and directly coincident with the range of one particular and readily observed set of characters, namely, those of form. A great deal more depends upon the question of transmutability of the form of schizophytes than is admitted at present by pathologists. We would merely warn them that the doctrine of fixity of the forms of pathogenic schizophytes is as much an *assumption* and as much to be received with caution as is the contrary doctrine of universal transmutability of such forms. One great fact is certain, namely, that *some* schizophytes do exhibit the positive evidence of change of form in the course of growth under varying conditions.'

In face of such evidence, we stated, admittedly, that 'we have ourselves found five or six *apparently* different species.' It is not enough to find bacteria in the fluids of the body to enable you to say that they have anything to do with the disease. And Dr. Cameron further

states, 'To prove the relation of cause and effect between a specific microbe and a specific disease, a much more vigorous method of demonstration must be adopted. You must not only show that the microbe is found associated with the disease, but that it is always associated with it. You must not content yourself with showing that by the inoculation of blood or serum containing the microbe the disease can be produced, but you must show that if the microbe be destroyed or removed the fluids are rendered harmless; and to complete the case you should be able to free the microbe by artificial cultivation from all contamination with the fluids of the disease, to grow it as a simple ferment outside the body, and to show that, thus purified, when introduced once more into the animal economy, it gives rise once more to the particular disease.' Drs. Klein and Koch also insist on four conditions, and that in no instance can it be *satisfactorily proved* that a disease is due to a particular micro-organism if any one of these conditions remains unfulfilled. The more one knows about bacteria the less one is inclined to speak dogmatically on the subject, and Professor Lancaster says, 'The fact is that the proportion of what we know by careful experiment and observation in reference to bacteria and their allies, as compared with what we must soon know, is so small that conclusions and generalisations are not useful except as suggestions to those who are in the thick of the work.'

Those who take up a new branch of science frequently speak more positively than those who have made it the study of a lifetime, and who have found by experience that the more they know of the subject the more they have to learn. It being admitted by competent authorities that we do contain bacteria, how is it that we do not suffer from them? Simply because, as is well known, they cannot multiply except under particular favourable conditions, and temperature, the medium in which they grow, presence or absence of certain chemical compounds, are capable of materially affecting them. Bacteria, which are, under ordinary conditions, associated with putrefactive changes in dead organic material, cannot, under these ordinary conditions, grow and multiply within the living body. Dr. Klein says: 'The cavity of the alimentary canal, small and large intestine, especially the latter, contain under normal conditions innumerable masses of putrefactive micro-organisms. These being much smaller than chyle-globules, must of necessity become as easily absorbed as the latter by the lacteals, and by these are carried into the general circulation; but being putrefactive, they are unable to exist in the normal blood and normal tissues, and therefore, in a healthy condition, perish.'

We know we must have tried the patience of some of our readers by discussing the germ theory, but we could not allow Mr. Cheshire's letter to go unanswered, more particularly as some of our correspondents seemed to be rather alarmed at the number of different bacilli stated to exist in bees, and we have deemed it absolutely necessary to give the opinions of recognised authorities, and to show that, although bacteria may play an important part in, they are not necessarily only associated with, diseases. Too little is still known of the subject to enable even the most experienced to speak positively; and when such an authority as Dr. Koch has been shown to have been wrong, we must receive with caution the assumption of those not having the same experience; and we think we have been able to show that instead of our statements being *'diametrically opposed to the conclusions of scientists'*, they are fully supported by the views of the highest authorities on the subject. We must apologise to our readers for thus fully going into a subject of little interest to them generally (although we have by no means exhausted it); and having, we hope, removed the cause for unnecessary alarm, we will now close the discussion, feeling sure that as it can serve no useful purpose, our readers will

have had enough of it, and will not wish it continued in our columns.—Ed.]

NORWICH EXHIBITION.

Referring to the inquiry made by the writer of 'Useful Hints' in our issue of April 29, we are desired to state that it is intended that the hive should, in addition to the roof, have a second body-box, in which either racks of sections could be placed, or frames, as in the lower hive; only one set of frames and one rack of sections are required to show its capability.

USEFUL HINTS.

We are now experiencing glorious weather for our bees. The high temperature, brilliant sun-shine, with gentle westerly winds, and fruit trees in full and plentiful bloom, ought to gladden the hearts of all apiarists.

Before these lines are in print many of our friends will have heard the joyful cry, 'A swarm is out,' and many will be watching with pleasure the busy little insects at work in their section-boxes. In our fruit-growing districts honey is now coming in fast, and no opportunity of securing the precious nectar should be lost, since of all the honey collected none surpasses that obtained from fruit and May bloom in colour, quality, and freedom from granulation.

We have section honey collected in May and June of last year as transparent, bright, and fine-flavoured as on the day it was removed from the hive.

FEED ALL SWARMS until their combs are built. This is positively necessary, at this early period, to push them forward so as to have all in readiness for the white clover bloom. The syrup given will be used in the elaboration of wax, and breeding will be induced thereby. No system can be more 'penny wise and pound foolish' than that of starving swarms, especially if unfavourable weather supervenes.

WIRED FOUNDATION we have found superior to all others. Upon it the bees build straighter combs, and work with a better will than upon wired frames with the foundation pressed upon the wire. In the latter case a stronger wire must be used, and sometimes the bees will cut away the foundation around the wires, leaving gaps in the comb.

The frames should be filled to within a quarter of an inch of the bottom bar and an eighth of the side bars. The top bar should have a saw-cut, and the frame being inverted, with the slit placed over a couple of studs—driven into a bench—the foundation is quickly and easily inserted by giving the frame a slight turn, pushing in the foundation, and allowing the frame to recede to its former position. With a little practice the operation

is so speedily and neatly performed, and the foundation held so tightly in the frame, that we have found no other plan at all equal to this.

FRAMES OF COMB should now be given in an upper storey where doubling with a view to extracted honey is practised. If such are not in stock frames of foundation must be used. The exhaustive articles on storifying, lately given by our Editor, render further remarks on this subject unnecessary here.

DIVIDING.—As a rule the end of the present month will be found early enough for dividing, and, indeed, natural swarms, in late May or early June, generally surpass those of an earlier date in the energy with which they work. Such swarms, placed on foundation and fed, will send forth adult young towards the end of June, the time of the clover honey flow, when their activity and working energy will be at its highest point. These swarms will often fill their hives with comb and brood in ten or twelve days, and may be supered in the very nick of time for the great honey harvest.

COMB AND FOUNDATION ALTERNATELY.—Such is constantly recommended upon which to place swarms. We doubt, however, its advisability for this reason. When a frame of foundation is placed between two fully worked-out frames of comb, if honey is coming in fast, the combs will be filled and their cells lengthened before the foundation is drawn out. Consequently the new combs will be narrowed for want of room. Experience has proved to us that this is almost invariably the case, and we can show hives now, of two years' standing, where the alternate combs are twice the thickness of the adjoining ones, an unevenness which has arisen entirely from following this plan. It is best, therefore, to confine the swarm to six or eight frames of foundation, according to its size, in the centre of the hive, by division boards, for the first three or four days, and then to place frames of comb with worker cells on the outsides of the newly drawn-out and brooded combs, at the same time giving a super as well. This may be safely done if the swarm occupies the stand of the colony from which it came, and the weather is at all propitious.

PUTTING ON SUPERS.—Whenever the object of the apiarist is comb-honey and prevention of swarming, supers should be given early, that is to say, when the hives are getting full of brood and bees, and before preparations are made for swarming. If drones are plentiful, and rudimentary queen-cells are once commenced, no amount of supering will prevent the issue of swarms. But if, when the hive has a full population, say about the middle of May, a case of sections is placed above, and ventilation given below, according to temperature, and a judicious system of tiering up section frames, swarming may, in a great measure, be prevented. Still much depends upon the season. The honey yield being poor, and the weather moist but warm, swarms will be plentiful and honey *nil*, no matter what system is followed; and such seasons occur sometimes. When the bees have taken full possession of the supers, and are storing honey bottom ventilation must not be neglected. It may be accomplished by wedging up the hive $\frac{3}{8}$ -inch in front, and $\frac{1}{4}$ -inch at back, thus causing an under-current throughout, and allowing entrance and departure for the bees on all sides. This is a very important item in prevention of swarming.

ARTIFICIAL SWARMS.—Where fertile queens can be obtained at reasonable prices, the following plan of dividing is, perhaps, the least objectionable and the most profitable, when increase, with a fair amount of surplus honey, is desired. Let A be the hive it is proposed to divide. About mid-day, when bees are flying, remove from A one frame of brood, with the queen, and place it in the centre of a new hive B, filling up both sides with frames of foundation or empty reserved combs, or both.

Place B upon the stand of A. Take combs from A, and shake into B about half the bees from A, returning the combs to their place in A. Cage, under a pipe-cover cage, in the centre of A, the new and fertile queen, and close up the frames, removing A to a new stand. On the following morning the queen may be released, and, in a good season, both hives may be worked for extracted, or comb honey, with fair prospect of success, provided the division is made sufficiently early, say not later than the first week in June. This system must only be applied to hives with large population and abundance of brood.

NATURAL SWARMING may be best accomplished with a fair yield of surplus honey on the plan given in 'Useful Hints' on page 162 of our issue of April 15, 1886, in which case careful watching for swarms is necessary.

CARBOLIC ACID as a bee-quieter requires great care in its application, or great loss may ensue. Let the novice, therefore, act with caution in its use. In our early days of experimenting with this powerful acid, we had the misfortune to destroy one of our best colonies. On a fine evening in early May, having uncapped one side of a comb of sealed honey, and placed it next to the brood-nest, the floor-board was removed, scraped clean, and sponged over with a strong solution of carbolic acid, and again placed under the colony. On passing the hive an hour afterwards we were surprised to find a number of dead and dying bees beneath the flight-board; and on reopening the hive our chagrin and dismay may be imagined, on finding the whole population of the hive, queen, aged bees, drones, and young bees just emerging from the cells—totally demoralised, rushing over the combs as fast as their clammy condition would permit, and out of the hive to die—glued, as to their wings, by the uncapped honey, and thus unable to fly, and redolent of the scent of carbolic. The result was that the whole population, terrified beyond measure by the carbolic fumes, rushed madly about the hive, over the unsealed honey—in their fright, filled their sacs, disgorged the contents upon their companions; and finally perished miserably in their own sweets, those which were able running out of the hive to die, others perishing within the hive. We were unable even to save the queen, which was a fine prolific Italian in her prime. The brood combs were sprayed with warm water, dried near the fire and given to another colony.

In consequence of this mishap, we never use a stronger solution than one ounce of Calvert's No. 5 carbolic acid to one quart of warm water, and we apply this when manipulating, at the top of the hive rarely at its base.

Mr. Webster's invention of a fumigator for injecting the fumes of carbolic acid into hives with a view to intimidation, is most ingenious, and will no doubt prove a powerful 'intimidant'—if we may be allowed to coin a word; but we would decidedly utter a note of warning to the inexperienced, advising all to use it tentatively and sparingly.

A piece of old calico, steeped in the above solution, wrung out and spread over the tops of the frames, will enable anyone to manipulate a hive without annoyance from the bees, and it will quickly rid a case of sections of its inmates, without causing the general exodus or stampee described above; but we again say, be very careful how you apply it below, since it has a tenfold more terrifying effect upon bees than injected smoke.

QUEEN WASPS, keep a sharp look-out for. They are very numerous.

WEAK COLONIES should be manipulated as little as possible. By giving them an additional comb at the side, when more room or food is required, they will increase faster than by constantly pulling to pieces the brood-nest.

REVERSIBLE FRAMES.—We are not very favourably

impressed by the latest novelty in this direction, which has been portrayed and described in our columns as that of Mr. Chitty. We think these frames would quickly become fixtures; but that if their withdrawal sometimes were made a *sine qua non*, the bottom bars would remain fixed to the 'little strip, quarter of an inch high, each side of the bottom of the hive,' much to the annoyance of the operator. But if, on the other hand, the withdrawal of the rectangle, complete, were accomplished, we should dread replacing it in the hive, from fear of subjecting our pets—and perhaps their highly prized queen—to a cruel and crushing death. We seem to have some recollection of a bottom rack many a long year ago, invented—and discarded for a similar reason—in the Woodbury hive of the dear old friend whose name it bears. But we live in days of progress and inventions, ranging from hive appliances to Home Rule, and we must not throw cold water on good intentions. Notwithstanding the justice and expediency of this sentiment, we are afraid that we cannot dance to the 'piping' of 'Amateur Experts' queens; or rather, perhaps, we should say to the 'piping queens' of the dear old grandmother, who still sticks to the old methods of 'listening' and 'taking up.' All honour be to her. Our conservative proclivities lead us to sympathise most thoroughly with her and all her class. We once possessed an imported Syrian queen, which was so determined to propagate her own sex, that she, or her undeveloped sisters, filled the hive and a rack of sections too with queen-cells. The ends of every comb, the sides of every section, were fringed with queen-cells; and, what is more, almost every cell produced a lively queen. Swarm after swarm issued, each accompanied by a number of queens; until, after the departure of several, we had the curiosity to inspect the interior of the parent hive, when on its ten combs we found seventy odd young queens—very odd no doubt—running about most amicably over the combs, and exhibiting no signs of ill-will towards each other. Altogether not less than 120 young queens were hatched in this hive within a week; and the thought naturally comes into our mind, that if our old 'grandmother's' few queens kept up such a 'piping,' what a chorus there must have been in our hive! Why, dear Mr. Editor, it must have been equal to the most powerful 'hurdy-gurdy!' BUT, alas! we did not 'listen,' and so missed the treat. No doubt our friend, 'Amateur,' would have prevented all this, since his frame-hives do not cast swarms; and we too, perhaps, might have attempted prevention, but we indulged our curiosity to see what would happen, and so left nature to follow her own course. 'Amateur' has only had one swarm in three years from his frame-hives; but he does not state their number, neither the race of bees he cultivates, nor his method of prevention.

Our experience differs materially from his. Last season, although our hives are large and well shaded, many swarms issued without leaving behind them even a rudimentary queen-cell, or making any preparation for swarming, except a few drones; and our bees are hybrids, blacks, and of other races. Nevertheless, we are aware that much of this swarming might have been prevented by proper precautions. Since, however, it is quite possible to procure swarms from hives of large population, and having good queens, it is an easy matter to keep up a succession of young queens—by such means as we ventured to recommend—together with a fair return of surplus honey. If natural swarming is not desired, it is an easy matter to remove a queen, and to compel the bees to raise another in her place without much loss of time, when preparation for swarming has begun. Although we do not consider ourselves bound to answer all objections to any plans advocated under our heading, still, so far as time and opportunity permit, we are always happy to defend, or to give a reason for, statements here put forth.

ASSOCIATIONS.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

A meeting of this Association was held at the Old Town Hall on Saturday, the Mayor (I. Hart, Esq.) presiding. Among those present were Messrs. T. Carter, C. Foxon, T. Walker, W. Ingram (Belvoir), W. P. Meadows (Syston), W. S. Pridmore (Hinckley), Isaac Saunders, G. W. Smith, G. Bryan, L. Fosbrooke, J. W. Bickley, Johnson, C. Redshaw, Bird, and E. Ball, Secretary.

The Mayor said the object of the meeting was the interchange of ideas regarding bees generally.

Mr. Pridmore read a paper on 'The History of Bee-keeping,' in which he said that bee-keeping had occupied the attention of mankind from very early ages. On the Continent and in America bee-keeping was conducted on a more extensive scale, and in a more scientific manner, than in England; and when they considered the enormous import of honey into this country from the United States, Australia, New Zealand, and Russia, they would see that bee-keeping was of more importance to them than most people are aware of. The value of the honey imported into England in 1883 amounted to 33,778*l.*; in 1884 to 62,357*l.*; and in February, 1885, alone to 5385*l.*, so that for England to be anything like equal to those countries in honey production, they must to an enormous extent extend the business of bee-keeping.

Mr. Ingram submitted a paper on 'Bees and Bee-flowers.' Bee-keeping, he said, was advanced from a pursuit of amusement occasionally indulged in by residents in the country, and often in a rude, barbarous fashion, to an industry of recognised economical importance, and the proof of that was the existence of a British Bee-keepers' Association, well supported and numbering several hundred members; county Associations, embracing nearly every district in England, and the publication of two journals devoted exclusively to the interests of bee-keepers. The flora, so important to bee-hiving, had been greatly interfered with by the cultivation of the land; and as the bee-keeping industry was largely increasing, it was necessary to extend the cultivation of suitable flowers to replace the native flora by the systematic introduction and growth of plants known to afford the food required by bees. Success in bee-keeping depended on the natural or artificial advantages of the district in which the hives were situated. Mr. Ingram mentioned and produced specimens of a few plants which bee-keepers would do well to cultivate.

A third paper was read by Mr. Meadows on 'The Structure of the Wing of the Bee.'

On the motion of Mr. Bird, seconded by Mr. Carter, a vote of thanks was accorded to the Mayor for presiding.

IRISH BEE-KEEPERS' ASSOCIATION.

The annual general meeting was held on Thursday, April 29th, in the rooms of the Society for the Prevention of Cruelty to Animals, 36 Westmoreland Street, Dublin. Henry Chenevix, Esq., J.P., in the chair. Present: Hon. Richard Bellew, Vice-President, Miss Knight, Messrs. Henry Chenevix, Robert Spronle, Violet Thomas Smith, John P. Allen, John Edmondson, John S. B. Vauston, S. K. Twigg, W. J. Bramley, Walter J. Stanford, E. D'Olier, jun., Charles Frederick Knight, M.D., Hon. Sec. The minutes of the last annual general meeting were read and confirmed. The report and balance-sheet issued for the year 1885 were received and adopted, and a vote of thanks passed to the auditors. A vote of thanks to the Society for the Prevention of Cruelty to Animals for the gratuitous use of their rooms for committee and other meetings was passed unanimously. Lord Ardilaun was re-elected President of the

Association; The Hon. Richard Bellew and the Rev. Canon G. A. Proctor were re-elected Vice-Presidents; W. Jenning Bramley, Esq., was unanimously elected a Vice-President; Sir James Mackay having resigned, Mr. Edmondson was elected Hon. Treasurer; Messrs. Allen and Twigg were elected auditors for 1886. Dr. Knight stated that he did not wish to be re-elected Hon. Secretary. Mr. Sproule moved a vote of thanks to Dr. Knight for the amount of work done by him on behalf of the Association since the last general meeting. Mr. Stanford said he found that the Hon. Secretary had during that time delivered over fifty lectures on bee-keeping. Mr. Edmondson considered that it would be impossible to expect an Hon. Secretary to do this work in addition to his other duties. The vote of thanks was passed by acclamation. On the motion of Dr. Knight, seconded by Mr. D'Olier, Mr. Walter J. Stanford was elected Honorary Secretary for 1886. The Hon. Richard Bellew suggested that a subscription list should be started to pay off the outstanding accounts amounting to 3*l.* 2*s.* 9*d.*, and that circulars should be sent to members asking them to contribute. The meeting adopted this suggestion, and the following subscriptions were announced by the Chairman:—The Hon. Richard Bellew, Vice-President, 5*l.*; Rev. Canon G. A. Proctor, Vice-President, 3*l.*; John Edmondson, Esq., 2*l.*; W. J. Bramley, Esq., 1*l.*; Henry Chevenix, Esq., 1*l.*; W. J. Stanford, Esq., 1*l.*; Hon. Mrs. C. B. Bellew, 10*s.*; R. Sproule, Esq., 10*s.*; Dr. Allen, 10*s.*; S. K. Twigg, Esq., 10*s.*; E. D'Olier, Esq., jun., 10*s.* Mr. Duffin moved 'That it is most desirable that the Irish Bee-keepers' Association should take steps to have Ireland adequately represented at the forthcoming Grand National Apiarian Exhibition in London.' Mr. Sproule moved and Mr. Twigg seconded the following amendment, which was carried, 'That the Hon. Secretary be requested to communicate with the Hon. Secretary of the British Bee-keepers' Association, respecting the forthcoming Grand National Apiarian Exhibition, London, stating the grounds which prevent our co-operation, and that he be empowered to call a special meeting of the committee to take steps in the matter on receipt of the reply.' Dr. Knight moved, 'That the annual general meeting be held in future in the second week of the month of February in each year.' After some discussion the motion was agreed to.

The Hon. Richard Bellew opened a discussion as to whether the Association is advocating the right system of bee-keeping to induce the small farmers and labourers to keep bees. He was very sorry to find that the Association had been so badly supported, but if people could be shown that they would derive pecuniary advantages from bee-keeping they would be more liberal with their contributions. The change from straw hives to bar-frame hives was generally too abrupt; it would be better at first to advocate the use of improved straw hives for bees, especially those which can be fitted with frames of sections. The Pettigrew skeps were, he thought, well adapted for bee-keepers, and it was possible to manage the hives so that when the honey season was over two stocks could be united after the honey had been removed from them, winter supplies being provided by feeding up to weight. Bee literature was more valuable in his opinion than a bee-tent.

Mr. Edmondson said the bee-shows had been of great advantage to bee-keeping in Ireland. Honey was now put up tastefully for sale. One reason why the spring show was always a financial failure was that it was held at a time of year unsuitable for manipulations, and also that members had to pay for admission to the show at Ball's Bridge to get to the bee-tent.

Mr. Stanford suggested an independent show in June or July. To become a bee-keeper one should catch the bee-fever at a tent, and once a man gets the bee-fever he keeps it.

The Chairman would like to know if bee-keeping really

paid, and thought the lecturer might with advantage point out to people that they had an alternative to the bar-frame hive in the improved forms of straw hives.

Mr. D'Olier remarked that sections were not seen in Dublin before the establishment of this Association.

The Hon. Richard Bellew in reply said that he had been a bee-keeper for over fourteen years, and had investigated many matters relating to apiculture. He had, by causing a strict account of expenditure and income to be kept from twelve hives, found that bee-keeping did pay. Foul brood he had banished by transferring all stocks to straw hives. Bees required, if they were to be a source of profit, an immense amount of time and personal attention; it was a mistake to ask cottiers to keep bees in too expensive a manner. At present he was engaged in working out a non-swarming system.

The following officers were appointed for 1886:—President, Lord Ardilaun; Vice-Presidents, Hon. Richard Bellew, Rev. Canon G. A. Proctor, and W. Jenning Bramley; Hon. Treasurer, John Edmondson, 10 Dame Street, Dublin; Hon. Secretary, Walter J. Stanford, Onnavarra, Lucan; Committee, Rev. J. M. Aldridge, Dr. J. Purser Allen, Rev. Canon Bagot, Frank Collins, W. E. Duffin, L. C. Gavacan, J. Malcolm Gillies, Captain Hefferman, Rev. P. Kavanagh, Charles Frederick Knight, M.D.; Rev. Thomas Lindsay, J. K. Millner, J. R. O'Reilly, D.L., S. K. Twigg. On the motion of Dr. Knight, seconded by Mr. Sproule, a vote of thanks was passed to the press for opening their columns for the report of meeting and the discussion of matters relating to bee-culture, and also for much editorial assistance given during the year 1885.

The Hon. R. Bellew having been moved to the chair, a cordial vote of thanks was passed to Mr. Chevenix for presiding.

MONTGOMERYSHIRE BEE-KEEPERS' ASSOCIATION.

We are pleased that a bee-keepers' Association has been inaugurated in the county of Montgomery under very favourable auspices. Stuart Rendel, M.P., has been elected President; E. Jones, Esq., Trewythen, Llandinam, Treasurer; and Mr. J. Francis, Caersws, Secretary. Will bee-keepers in the county place themselves in communication with Mr. Francis, and render him all the assistance they can in building up this Association?

FRANCE.

It appears that the difficulty of finding means of disposing of honey surplus is one which, of late, has been agitating the mind of French bee-keepers not less than their brethren's on this side of the Channel. Our contemporary, the *Apiculteur* of Paris, in discussing this question in one of its recent numbers, expressed itself in the following terms:—'But the question of sales remains in the same precarious state that it was. Will our bee-keepers take the initiative of forming an association to further this object as the one which already exists in England, and which is on the point of being commenced in Switzerland? A few adhesions to the appeal addressed to them to that effect in December last have reached our editor. Some of these adherents throw out suggestions which appear to be entitled to every consideration. If nothing can be formulated sooner, those interested in the movement might arrange for a meeting in Paris during the Exhibition which is to be held in that month, and then discuss the whole project as embodied in a draft. In the meantime, it would be well to see what can be done at the forthcoming shows. We would recommend, however, that greater attention be paid to taste and attractiveness in presenting their honey to the public eye in an inviting form; this remark applies not only to honey but also to the various appliances used for obtaining it.'

Correspondence.

CARBOLIC ACID.

[322.] I carefully stated in the *Journal* last year, that only a very small quantity of the strong acid had to be used. If, immediately a sting is received, the end of a wooden match or a piece of wood sharpened to a point is dipped into the acid, and allowed to touch the sides of the bottle, to take off the superfluous acid, and then placed on the part stung, and the same amount of water applied with the same piece of wood, the scar left is very small; if the acid, however, is applied with a large pole I quite agree with Mr. Webster, that the remedy is worse than the disease. Ammonia only acts as a cooling lotion, the idea that it neutralises the acid of the bee-poison is a relic of the old chemical theory of medicine. In no case that I know of has carbolic acid, properly applied, failed to take away the pain and swelling, and I shall be very glad to hear any testimony to the contrary, either through the *Journal* or privately, as it is not a patent, and any one can use it. Has any one known Dr. Pine's lotion to fail in its effect? I have not analysed it, so cannot say what its contents are.

With regard to 'E. F. H.' he must have been stung by a drone, as he talks ('tis passing strange') of 'he' and 'his.' If he had been stung in or near an artery, and the poison had formed a clot in it he would most likely have had to be fitted for his wooden surtout, which would have been a sad loss to us bee-keepers, as we should miss his amusing letters.

The bee-poison is taken up by the lymphatics and may get into the smaller veins, but I have never known a case of inflamed veins from a bee-sting.—GEO. WALKER, *Wimbledon.*

STINGS AND GLOVES.

[323.] 'Cottager's' inquiry (No. 297) as to stings and gloves received two answers in this week's *Journal*. They give him, however, poor encouragement and little help—are truly 'Job's comforters.'

Allow me to say a word. Like 'Cottager' and some others, stings formerly rather seriously affected me, but I can assure him that I am now gradually becoming much more indifferent to them; they affect me less and less every year. I cannot, however, even now, altogether on some occasions dispense with gloves. But now for my advice. After long experience of gloves, and having tried many, I give my decided vote against all the woollen gloves generally recommended. They are cumbersome, and, worst of all, entangle the bees, and provoke them to sting. And then, when one bee stings, others follow as a matter of course; india-rubber gloves are unbearable, and the worst of all. Contrary to custom, I recommend leather gloves, but you must take especial care what kind of leather you get. Some kinds make the bees furious. Ordinary 'garden gloves' do this. I always use a good pair of thick ordinary driving-gloves, the great thing being to take care that they have a smooth, shining surface. To these I attach short gauntlets made of white American cloth. This is the best material, because it is smooth, and so the bees are never get caught by their little claws, and, being stiff, it never gets into creases, which are so many traps to hold bees, and make them begin to sting, and so provoke a storm. I find that such gloves very seldom get a sting.

But further—and this is a most important point—have at hand a little weak carbolic acid; and, before you begin to manipulate, wet your gloves slightly with this, and if by chance you receive a sting on the gloves or clothes instantly apply a drop of the mixture to the spot. It removes the smell of the poison and prevents mischief. Wetting the gloves with water is a great preservative, but carbolic acid is much better. I use a little on my hands when without gloves.

And now, as another 'useful hint' in the same direction, let me say that I generally remove coat and waistcoat, and substitute a waistcoat with sleeves buttoning at the wrist, made of smooth holland. This is cool and comfortable, and presents a surface which is very seldom stung—much less so than a flannel shirt—and then there is nothing to entangle the bees like coat-tails. Have the collar of the waistcoat cut *very low*, and the veil, which goes under it, is kept well away from the face.—E. G. JENYNS, *Knebworth Rectory, May 7th.*

STINGS AND GLOVES.

[324.] I fear 'A Cottager' will be more alarmed than ever when he reads 'E. F. H.'s' sad tale. As a novice may I be allowed to report my experience, which I hope he will find encouraging? I began bee-keeping only last year, and during the season received about thirty stings, occasionally three or four at one time. The first few I found painful, and although I used liquid ammonia freely my flesh 'puffed' up, and the irritation after swelling had subsided was almost unbearable; but, I am glad to say, I at last became inoculated, so at the latter part of the season the stings caused me little or no suffering or even inconvenience by swelling. I left off ammonia, and my only remedy was the extraction of the sting as soon as possible. This year I have been stung once; for a few hours my hand was swollen a little, but nothing like last year's first experience. For the bees' sake I prefer not to be stung, still I do not entertain the slightest dread of very serious effects of their animosity or spite. I use a veil and smoker, but have never worn gloves.—ERNEST.

BEE-STINGS.

[325.] In reply to 'Cottager's' question, 'Can he get injured to bee-stings?' I answer, 'Yes.' Like him I found it inconvenient to have a swollen face. On one occasion when driving from a shop I inverted it without smoke (it having gone out) with the result that I received a great number of stings in the face and head, since that I have not, to any extent, been affected by stings.

Last summer while getting a swarm, the box which I was standing on, went over, and all the whole swarm over me, some forty, or more, stings were taken out of me, and am happy to say that I did not swell in the least, although the pain was dreadful. This season I have had several stings in the face, without any bad results.—THOS. J. DAVIS, *Bromley, Kent.*

THE NEW FUMIGATOR.

[326.] There is no doubt that Mr. Webster's fumigator is a step in the right direction, and as I did not observe in his remarks any appearance of an intention to patent the invention, but to give the idea to the bee-keeping fraternity, as has been so frequently done in the past, perhaps he will forgive me for suggesting a simplification of his method of applying phenolised air (neither 'fumes' nor 'vapour' is a strictly correct term) in subjugating bees.

If we use a sponge of just sufficient size to squeeze into the furnace part of the ordinary smoker now in use, and dip this sponge into water; then after wringing it out, add one teaspoonful of phenol (*i.e.* carbolic acid, alcohol, and water in equal parts), I do not think we need fear the acid being blown out of the chimney, as there is the perforated tin protector to prevent it. The expense of using carbolic acid for the purpose, and in the way suggested, is, too, a matter for consideration as against the old rags of the smoker, costing nothing. At present, having only too frequently recurring opportunities of purchasing suits for certain young bee-

hunters, who test said clothing in the adjoining woods, on the trees, and the branches thereof, I find an old corduroy garment clipped into strips and tied in small rolls, provide any amount of smoking stuff, which is so good that to get it extinguished, not to keep it alight, is the difficulty.

I have tried carbolic acid, and this certainly disgusts the bees into retreat, but I do not find it quieten them; and if used at the mouth of a hive before manipulating wood, I believe, have a tendency to irritate them, instead of alarming them into gorging a skiful of honey, as is done by smoking, the signal of the 'hive on fire.'

I only draw attention to this for the purpose of ventilating the question (not the hive), my experience of using phenol being very limited.—R. A. H. GUMSHAW, *Horsforth, near Leeds.*

PREVENTION OF SWARMING.

[327.] In his review of my book the editor endeavoured to prove that the 'principle' upon which my system is founded is not new. By referring to page 9 he should have seen that I do not claim that the principle itself is new; but inasmuch as the same is *applied* as a *system* to modern hives to meet present requirements, I am justified in claiming that a new method of management has been instituted. On the said page the opening chapter begins thus: 'Simmins' original non-swarming process is based upon purely natural principles; and is founded upon the fact that *No colony in normal condition attempts to swarm unless it has all its brood combs completed.*

Hence it is clearly shown that the 'principle' was known by me to be already existing; but for the first time it is *applied* in the form represented as a complete system.

Take a parallel case. The first great principle upon which all extractors work is that of centrifugal force, which has ever been in existence; but nevertheless the first inventor of the machine *applied* that already existing force in such a manner as to bring about an entirely new method of obtaining honey from the combs. But that is not all; even since this application different bee-keepers have brought out extractors under their own name, when any improvement only has been added by them. Thus we have the 'Cowan' Extractor, Abbott's Extractor, &c.

Again, look at the moveable comb principle first introduced in a practical form by the great Langstroth; and since whose time no actual improvement has really been made in the frame which holds the comb; yet we have different forms and methods of application of the same, as the 'Cowan' hive, 'Raynor' hive, and a host of others. Each claims originality in regard to his own peculiar form of application, and justly so.

While it is admitted that the bee-keepers' profits are greatly enhanced by the prevention of swarms we are asked to believe that the community already possessed the means of staying the issue of such. Nevertheless, we find in the issue of January 7th of the current year, p. 11, an editorial reply to this effect: 'There is no certain method of preventing swarming;' also in the *British Bee-keepers' Guide Book*, while showing why it is desirable that no swarms should be allowed, the author goes on to say that 'this is *frequently very difficult to do.*' As a matter of fact, too, because no reliable, or definite system of prevention has hitherto been established, especially while working for comb-honey, the vast majority of bee-keepers candidly admit that they could not as a rule prevent the issue of swarms, and among these we have some of the first and largest producers of the day.—S. SIMMINS.

[In our review of Mr. Simmins' pamphlet we stated that many systems had been introduced based upon this principle, and that it was not new. We did not say that Mr. Simmins claimed the 'principle,' but that this

principle applied to frame-hives was what he claimed as original; we, therefore, fail to see in what way we have misunderstood him, or not given him credit for applying the principle in his own particular manner. Gedde's system was, however, founded on the same facts, although he states it in other words. We cannot admit that the system as *adapted to straw skeps*, page 20 of our correspondent's pamphlet, is new in any respect.

We cannot see that the cases he cites are at all parallel. Neither the extractors nor hives are claimed as *original*, but as improvements; and we think our correspondent would have done better and avoided much criticism if he had called his the 'Improved Non-swarming System' instead of the 'Original Non-swarming System.'

With regard to the reply alluded to, we would state that when once the bees have got the swarming fever there is no certain method of preventing swarming, and not even the system advocated by Mr. Simmins would do it. We have known bees to swarm in such cases even after half the combs had been removed and empty ones put in their places. By quoting a portion of a paragraph from our *Guide Book* our views, as there clearly stated, are not expressed. The paragraph reads thus on page 15: 'Those who desire a harvest of honey and not an increase of stocks, should endeavour to prevent bees swarming. This is frequently very difficult to do, *because when bees have once got the swarming fever every device of the bee-keeper will not check it.* If, however, steps are taken in time, swarming can generally be prevented by giving room in the hive and supers a little *in advance of the requirements of the colony.* Keeping the hive cool and giving plenty of ventilation also assists in checking swarming. Another way is to give room for the queen to deposit her eggs by removing combs containing brood and giving *empty combs or comb foundation.* Should the combs be filled with honey, additional breeding space can be given by extracting it. *Whatever plan may be adopted, the bees should never feel cramped for want of room.*' Also, on page 56, in describing the doubling system we state 'Colonies thus treated are effectually prevented from swarming.' We know that those who do not give bees the required room admit that they could not as a rule prevent swarming. We are acquainted with most of the leading bee-keepers and largest producers both here and on the Continent, and know that those of them who do give the necessary space are able to work their apiaries and entirely prevent any desire to swarm. We recently visited one of the leading bee-keepers in Geneva, the owner of upwards of 200 hives, who has not had a natural swarm for many years, and entirely prevents swarming by giving abundance of room in advance of the requirements of the bees, and this is the whole secret of the non-swarming system as practised on the Continent. This gentleman has three apiaries at some distance from his residence, and yet he is certain of his bees not swarming during his absence, and he could not give the attention required for the constant manipulations required by Mr. Simmins's method. Once the bees have acquired the desire to swarm no method of preventing them is certain.—ED.]

Replies to Queries.

* * * In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[319.] *Drones.* (F. Lyon).—Rather a difficult matter to prove, and I doubt very much whether it has or ever will be. Why should they be unfertile? They never partake of the outward or inward form, colour, or variety of the drone which fertilised the mother, which, I think, conclusively proves that the drone plays no part whatever in the formation of the male progeny.—W. B. WEBSTER.

[320.] *Foul Brood.* (G. H. G.)—I have cured four brood with phenol, acting strictly according to the directions of Mr. Cheshire, and changing the mother bee. It has never reappeared in the same apiary. I have not used salicylic acid for that purpose.—W. B. WEBSTER.

[320.] *Foul Brood.*—See our answer to R. J. Collisson in 'Notices to Correspondents.'—EDITOR.

[321.] *Bees Flying from Hive.*—R. Jones's bees, I have no doubt, succumbed to the cold; transferring bees from one hive to another requires great judgment, especially if part of the combs have been destroyed. In his case I should only have allowed the bees two combs, placing them in the centre of the hive, with two boards on each side to keep the heat in till they got stronger, then adding only one bar at a time.—CHARLES E. CUTHELL.

[321.] *Bees Flying from the Hive.* (R. Jones.)—Simply changing bees from old to new hive would not have the effect you describe. When combs are only a little mouldy you need not cut it away, the bees will clean it when they want to use that portion. The only inference that I can draw from your description is that there must be something deleterious in the wood of the new hive. Turpentine is very pernicious. Examine hive, &c., and note whether the wood is saturated with anything of such a nature.—W. B. WEBSTER.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[328.] *Untimely Drones.*—Drones were flying in large numbers six weeks ago from a bar-frame hive that contained a strong swarm of last year. I find them now all gone, brood on seven frames, and drones just hatching out. What was the cause of their presence at that time, as they had unquestionably wintered in the hive, and the queen was perfect?—G. H. G.

[329.] *Hiving Swarms.*—Will some practical bee-keeper inform me if, after the swarm has clustered on tree and been shaken into skep, I shall be doing right in shaking them out in front of bar-frame hive at once, or let them stop in skep until the evening?—FARMER.

[330.] *Thinning Foundation.*—Can any of your readers tell me why my bees neglected to thin the foundation-comb I gave them last year? It was the thin sort, and I inserted the whole sheets, filling nearly up the frame. In one instance I have an odd-looking bar built upon one side and not the other.—CHARLES E. CUTHELL.

[331.] 1. *Honey.*—How am I to know when the honey harvest commences, and when it terminates; also when there is a honey 'glut'? 2. *Comb Designs.*—How can I induce my bees to form the comb in the shape of letters, &c.?—J. D.

[332.] *Firing Foundation.*—Wanted to know the best means of fixing foundation in frames that have waxed guides, as the frames would have to be taken in pieces for a saw cut. Can this be avoided?—INQUIRER, Yorks.

[333.] *Queen Fertilisation.*—Is it possible for the spermatozoa in a queen-bee to become exhausted, and the queen to be fertilised a second time? I have a queen that is hybrid, the progeny of which are gradually becoming more and more to resemble the black, though they still retain their hard-working (and stinging) superiority. The hive has not swarmed to my knowledge for two years, nor have I seen any queen-cells or absence of eggs, as would have been the case had the original queen been superseded.—DOCTOR CRAIGS, Dumfries.

[334.] *Dry Comb Foundation.*—I have a quantity of sections over from last year, ready fitted with comb foundation. The wax has become dry and brittle, and along the edge a little mouldy. Please say how I can make the wax fresh, as bees do not take readily to foundation in this condition.—A SUBSCRIBER, Kircubbin.

Echoes from the Hives.

Sunningdale, Berks.—I find that auriculars are a capital flower for pollen for the honey-bee. There is a good-sized bed of these flowers in full bloom near my hives and the bees go home from them laden with pollen every day just now. The flowers are quite hardy.—F. G.

Dumfries.—On April 12th, after manipulating one of my hives, I saw a bee on the landing-board struggling with another, which I caught, and saw it was a drone, not quite up to usual size. This had been turned out of a hive containing nine frames of bees, four of which contained brood, some hatching—none drone-brood, so that it must have remained all winter.—DOCTOR CRAIGS.

Carlisle.—The children of the village brought me 703 queen-wasps between April 29th and May 8th, all caught in their gardens, or close to the village. The wasps are very large creatures.—BEESSWING.

Swineshead, May 3.—Only had a few good days for bees. The sharp frosts lately, especially on the 28th, 29th, and 30th ult., have impeded the secretion of honey from flowers which are now abundant. In this district many of the stocks are still weak from losses during snow, &c., also in skeps from queenlessness. Clovers are growing luxuriously.—R. THORPE.

Stretton Heath, Yockleton, Salop, May 5th.—Perhaps you may find the following interesting. In the first place I am a shoemaker, I started to keep bees on June 9th, 1883, by purchasing one stock of bees in a bar-frame hive. At that time I had never seen a drone or a queen. I am now in possession of eighteen stocks of bees, all in bar-frame hives. The hives are all my own make with the exception of three. I enclose one of my circulars, and you will be able to judge by that whether I have had success in bee-keeping or not. I wish the *British Bee Journal* every success, for I cannot find words to tell you how much I have learned from reading its pages. We are having some most beautiful weather for the bees this week.—JOHN BRADLEY.

Somerton.—First swarm in this district came out of a bar-frame hive, the property of W. Snow, Somerton, on Sunday, the 9th of May. All stocks seem to have wintered well here, and several late swarms which were unlikely to hold through the winter have done so, and, though weak, are likely to build up now. Weather yesterday, very close and warm; this morning, cloudy, and much cooler.—J. I. S.

Scrafton Lodge, Middleham, York-shire.—*Queen Wasps.*—I quite agree with Mr. Riky about wasps being numerous this year. I killed on May 4th, 42; 5th, 18; 6th, 140; and 7th, 119; these were all killed on gooseberry bushes with a piece of elastic, than which nothing can be better or quicker.—A. W. CUNYTON.

Thickthorn, Norwich, May 6th.—For the last week or ten days the weather has been very fine, but still cold nights continue. Cherries, pears, and plums are flowering freely, but the secretion of honey is but little. The common bay laurel and the bird cherry have been much frequented lately by bees, collecting a saccharine secretion produced by small glands situated at the base of the leaf blades. In the bay laurel the glands are level with the surface, but in the bird cherry they are raised a little, and are about the size of a pin's head. My twelve stocks that were wintered on aphidian honey have got through all right, and at the present are strong and healthy.—MEXBY DOBBIE.

North Leicestershire, May 8th.—Nearly a fortnight of splendid weather has set the bees going in fine style. Fortunately, too, there has been plenty for them to 'go' at; gooseberries, currants, plums, pears, dandelion, and gilliflowers, are in full bloom, and the sycamore and maple are just bursting into bloom. Stocks are improving fast, but there seems little likelihood of May swarms. Queen-wasps are frightfully numerous.—E. B.

Chippenham, May 8th.—Up to the middle of April the weather was not favourable for the bees; they, however, made good use of genial opportunities, and I believe great activity has prevailed within the hives. May has commenced gloriously, the bees working splendidly for the last

ten days without a check. The young bees are coming out strong to gather forage, which is now plentiful in every direction. The apple bloom, which is late, is just bursting forth. Drones made their first appearance to-day. Prospects are certainly improving, but let us not boast, as there are no doubt drawbacks to come.—W. A. WARRILOW.

Hartley Vicarage, near Sittingbourne, May 8th.—*Early Swarming.*—It may interest some of your readers to know that in the 'Sunny South' not only has the honey season commenced, but the swarming season as well, for in this immediate neighbourhood I have heard of two swarms in this week, one at Sittingbourne on Wednesday, the 5th, and another at Lower Halston on Thursday, the 6th. The former was secured, but the latter was lost, flying straight away from the hive without settling; and I have this day seen two stocks in this parish which, with weather like to-day, may swarm to-morrow. Our cherry orchards are now in full beauty of flower, honey is abundant, and about half the stocks in my own apiary have required supering.—P. T. SCOTT.

Brecon, April 28.—To-day, upon uncapping some stores for a stock, I noticed coagulated honey in some of the cells; while others, side by side when uncapped, showed it in a liquid form. It afforded evidence of how much the 'condition' of honey is affected by its source among the bee flora.—T. P. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

O.—*Vignole System.*—There is no danger of the bees of A and B fighting, because when A is put in place of B the bees from this hive will return laden with honey, and will be cheerfully received in a depopulated hive. You should cage the queen if you carry out the modification you propose, because there would be a risk of the bees fighting. In doubling, as recommended on page 148, the bees are not prevented from getting between hive and outer cases, which are also raised, and there would be no object in doing so as these only act as protection against the heat of the sun, and in giving free ventilation round the hives.

BEE-SWING.—We do not apprehend that the disease will reappear this season, but it will be prudent to disinfect the combs with salicylic acid. We believe that Webster's fumigator might have the desired effect.

R. L. RICHARDSON.—*Heather Honey.*—Heather honey twelve months old cannot be extracted by the ordinary extractors; in fact, unless it is extracted immediately after it is gathered by the bees, it cannot be extracted by such extractors. There is an extractor called 'Raitt's Honey Press,' which forces it out; or it can be cut up into cubes, placed in a conical bag, and exposed to heat, when it will exude. We are pleased to hear that your bees are now progressing favourably.

W. H.—A reply will be forwarded.

J. W. G.—*Stafford.*—1. Let the bees be moved a yard a-day to the desired position. 2. Yes; the artificial swarm having been made can be removed in the same manner as a natural swarm. 3. Portions of comb fixed to tops of frames will serve your purpose as guides. 4. 'The white grubs with red heads' are the larvæ of the wax-moth; they should be destroyed as promptly as possible. 5. Tied or enamel cloth should be placed next the frames. Old bagging can be placed above it.

J. E. ROSOMAN.—Discretion should be exercised in the selection of American cloth. There should be no offensive smell in that placed on the top of frames. We have not heard of any case, when care had been exercised, of American cloth being injurious to the bees.

R. S. ROUTH.—The bees forwarded were burrowing bees of

the genus *Andrenide*—species, *A. Trimmerana*. See reply to 'E. C. D.'

R. S. COLLISSON.—*Foul Brood and Camphor.*—We do not think the camphor which you have placed in the hive will affect the honey, as it rapidly evaporates. As you have only a few cells affected, camphor should be sufficient to check the progress of the disease. We cannot say if it is an absolutely certain remedy, but it has been very much used on the Continent with excellent results. We are not surprised at your not liking to try the phenol treatment again. It has been used with more or less success on the Continent since 1874, but is gradually getting into disuse, principally from the trouble attending its application and from the fact that it is only at certain times of the season that it is efficacious. Most of those who have tried it have gone back to the simpler method of fumigation with salicylic acid by the Hilbert method. With this method there is no disturbance of colonies, frames, or supers, and if persevered in is certain to cure. The fumigations are done in the evening when all the bees are at home, at intervals of six days, and should be continued until a cure is effected. From four to six times is usually sufficient. One of the most important advantages of this system is that every bee, larva, and every part of the hive, is penetrated by the fumes of the acid. As you can have only your mornings and evenings at your disposal, we should recommend this plan if camphor should fail. A partial failure by a reappearance of the disease must not be attributed, as is too frequently the case, to the non-elicacy of the agent employed. Salicylic acid, thymol, eucalyptol, camphor, phenol, menthol, and other disinfectants, have the power of preventing the development of *bacteria*, but they do not destroy the spores of *bacilli*, therefore if these are present, as soon as the disinfectant is exhausted the hive having returned to its normal state, and the conditions favourable to the development of the spores, they start afresh and have to be destroyed again. It is by destroying the hatches of *bacteria* as they start into growth that at last a cure is effected. Should, however, any of the spores remain in the hive, the disease may break out at any time. For this reason we have always maintained the advisability of putting salicylic acid in the syrup given as food to bees. It is perfectly harmless to bees, and if spores start into growth at any time, they are at once destroyed. Some years ago we had foul brood extensively in our apiary and cured it with salicylic acid, and we have not hesitated to receive infected hives and place them amongst our own for the purpose of curing them. We have, however, not had a single case of foul blood in our hives since, and we trace this immunity from disease entirely to the use of salicylic acid in the food. There is no reason why camphor should not have the same effect, but the proportion of camphor which can be dissolved in water is one in thirteen hundred. Where a large number of hives are kept, we think the only practicable and sure method of cure is Hilbert's fumigation with salicylic acid.

EAST KENT.—The best advice we can give you under the circumstances is to remove your bees on a hand-barrow into some friend's garden some distance away, say one mile, and in a fortnight bring them back to their proposed new site on the house. Their well-being there depends on the aspect and to how far it is sheltered from north and north-east winds.

L. W.—*Wheatley, Oron.*—We will look at the substance under a microscope and see what we can make of it. Knowing the action of all acids on zinc, we should not care to pour very hot bee food such as you describe into a galvanised vessel and give it to our bees as you confess you have. Why not put it into a stone bottle, or at least wait until it had got cold?

E. C. D.—*Andrena.*—The '*Andrena* mining bee' belongs to the great division of the family of bees called *Andrenide*. One of the great distinctions between these and the *Apide* is that while the latter live in societies with a regnant queen, the former live solitarily. These solitary bees do not lay up stores for their winter subsistence, but display a wonderful instinct in the provision they make for their young. There are males and perfect females, no neuters. The work of preparing nests and procuring food appears in all of the species to

devolve on the females. The *Andrena* commonly make their nests in the earth; their cells are thimble-shaped, and composed of sand-grains compacted together by a glutinous liquid secreted by the insect. There are eighty different kinds of *Andrena*; probably those noted by you were of the species *Andrena Trimmerana* or *Colletes succinea*, both very common in Britain.

W. S. PRIDMORE.—The dipterous insect forwarded was a pure fly, though somewhat resembling a bee: its specific name is *Eristalis fossarum*. The *Eristalis tenax*, which feeds on the vilest garbage, is frequently called 'the hee-fly.'

SUBSCRIBER.—I have covered many of my sections with paper after being glazed for the three past seasons, and find it pays me to do so for the better class of customers. The paper can be got any colour, on one side only, and with a glazed surface, and will resist a very fair amount of damp and handling. Most stationers keep it, but your better plan would be to get the address of some firm who make a speciality of such labels, and get them to print you some with a special device that would be a guarantee to purchasers in future, and you would soon find a demand for your special 'brand' that would pay both you and your agent. The paper should be cut like the en-

closed sketch, and the overlap would keep in the glass and give the section a neat appearance as well.—A. E.

J. S. WEBB.—There is no symptom of foul-brood in the small piece of comb forwarded.

D. W. D.—*Carbolic Acid Solution.*—Carbolic acid solution is applied by a feather or brush to the tops of the frames, and has the same effect on the bees as smoke. The carbolic acid solution may consist of four table-spoonfuls of the acid to one quart of water, to be well shaken before using. Other contrivances, such as Webster's Fumigator and Raitt's Fume-chamber, have recently been brought before the public. Mr. Webster recommends a mixture of one part carbolic (Calvert's No. 5) to four parts of water and a little glycerine.

GLENSK.—*Defunct Queens.*—From your description we do not understand how the dead queen, outside the quilt, could have got there, since the hive, we suppose, had a roof or cover. If she escaped from beneath the quilt, and another queen was cast out from the entrance, it is probable that two queens were wintered in the same hive, which occurs sometimes. Examine the hive, and if you find no queen, but queen-cells in progress, you may conclude that the hive is queenless either from both queens having perished in battle, or one being driven out and the other superseded. If you find eggs and young larvae you may rest assured that the hive possesses a queen. In either case we advise you not to interfere, but allow the bees to take their own course.

T. P. C.—*Old Combs.*—You may safely give the combs containing pollen to the bees. They will either make use of it or cast it out, and afterwards will clean and polish the combs for breeding.

ETA.—*Frame-hive under Skep.*—Neither of your proposed plans would answer. There are two methods you may pursue with fair chance of success:—(1) Drive the bees from the skep. Having cut out the worst combs from the frame-hive, cut the skep in two between the two centre combs; cut out all the brood comb and tie into the frames; arrange these in the centre of the frame-hive; fill up the hive with the remaining frames; place it upon the stand of the skep, and shake out the bees on the top of the frames. See answer to H. W. D., 'Transferring,' page 192 of our issue of April 29th. (2) Swarm your skep either naturally or artificially, and put the swarm into your frame-hive. In twenty-one days afterwards, transfer bees and combs from skep to another frame-hive. We advise you to join your County Associ-

ation, but shall be very glad to receive you as a member of the B. B. K. A.

EXTRACTOR.—*Finding Queens.*—We advise you to manipulate your hives less frequently. The injury done by cooling the brood nest under frequent examination is great. Black queens are not easily found, especially by a beginner, being very shy, and quick in their movements; they often desert the combs, running along the bottom or sides of the hive. In such case it is next to impossible to catch sight of them, as they are surrounded by bees constantly in motion. When examining a hive, do not smoke at the entrance. Remove the cover *very quietly*, without any shaking of the hive. Raise the quilt gently from one side (throwing in a little smoke) until you get it clear off. Take out the dummy and a side comb, draw half the combs from the centre to the side. Examine each comb, working from centre to sides; and if the examination is carefully performed, without jarring or alarming the bees, you will soon find the queen. The colony whose brood had diminished was probably about to supersede its queen, from age, or other defect, hence the raising of drone brood; a careful examination would have discovered one or more queen-cells. You would have done better to unite 6 and 7. Your colonies are decidedly weak. If the case were our own we should reduce the number of hives by one half, reserving the best queens. According to your own account, by this plan each colony, when doubled, would contain ten frames, six of which would have brood—no very great strength for this time of year.

A. T.—Through a printer's error we said last issue that 'camphor was soluble in water one in thirteen,' it should have been one in thirteen hundred.

C.—1. *Queen Wasps.*—We hear from all quarters of the abundance of queen-wasps this spring. There is little doubt that the wasps you have killed were queens. The cry of all bee-keepers should be, *Delenda sunt vespe*. 2. The bee forwarded by you was a black one.

MISS M.—*Hiving.*—There should be no difficulty in living the swarm the same evening at the short distance mentioned. Either pour in the bees at the top, having removed some of the frames, or let them run in at the entrance. 2. *Age of Queens.*—A careful register should be kept of the age of queens; a young queen is more sprightly and nimble than an old one. The old queens go with swarms, therefore stocks which have swarmed and casts have young queens.

J. B. writes:—The flower I send you is grown extensively around here. I don't know the name of it. I find it is the best plant grown for early spring flowering; it remains in bloom so long. I can highly recommend it to all bee-keepers.

[The name of the flower enclosed is white Iberis or perennial candytuft (*Iberis sempervirens*). It is a most useful plant to grow for early bee pasturage; it is easily cultivated and flowers for some weeks in early spring.—E.B.]

QUEEN WASPS. (313.)—Like other correspondents, I have noticed queen-wasps about this year. On April 30th I caught over two dozen on my gooseberries, on May 1st sixteen. I had a pair of forceps about a foot long shaped like scissors. I have seen lots more in the neighbourhood. A farmer tells me they won't be so numerous in autumn as last year, though I scarcely saw any last spring. Let us hope his experience may have him to a correct conclusion.—**DOCTOR CRAIGS, Dumfries.**

MANIPULATING BEE-HOUSE.—A rejected army bell-tent is bee-proof, roomy, portable, and picturesque for this purpose, and can be got for 25s., and 1s. 6d. for bag and mallet, and will last many years.—**DOCTOR CRAIGS, Dumfries.**

We have received from Mr. J. A. Woiblet, Sanges, a simple and ingenious apparatus for embedding the wires in comb-foundation, which we hope to be able to exhibit in operation at the next *Conversazione* of the B.B.K.A.

Also *The Hive-bees Indigenous to India*, by J. C. Douglas.

From A. G. Hill, Kendallville, Indiana, their *Illustrated Circular of Bee-keepers' Supplies and Bees*.

From Abbott Bros. a sample of their patent tin section-holders. This will be found to serve the purpose admir-

ably of sending sections safely from one part of the kingdom to another. When lined with a wooden section-box it would form a useful Parcels Post box. It is clean, and not subject to breakage or wearing out. A number of them could be conveniently packed into a very small space.

From Abbott Brothers, their tool list for carpenters, gardeners, painters, &c., and the supplement to their trade catalogue of 1885.

Received from Mr. W. H. Dolan a specimen of his 'Leaf Show Case.' This is, we consider, an improvement on

previous show-cases, as it occupies less space, and the sections are more easily handled. It opens with a hinge, enabling the judge to inspect both sides of the sections with case, and when sent out are fitted with four sheets of glass, and hold twelve $4\frac{1}{2} \times 4\frac{1}{2}$ sections.

We have received from Mr. Webster, Wokingham, Berks, two sections of honey, one of which had been fumigated by him with the preparation which he describes as of more efficacy in dominating vicious bees than carbolic acid, the other had not been subjected to the same operation, with a request for us to state if any perceptible difference could be detected between them. We tested the sections by smell and taste, and are able to say that the effects of the fumigation had quite passed away before they reached us. It would, however, be desirable that bee-keepers should have some intimation of the nature of the preparation which is employed for the subduing of the bees on whom smoke and carbolic acid have but slight effect. We desire, moreover, to direct the attention of any of our readers who may employ this new 'intimidant' to the cautions contained in the 'Useful Hints' in this issue, p. 210.

By some misadventure in the transmission of proofs from abroad, some mistakes occurred in our last issue, in the paper on Foul Brood and Camphor which ought to have been corrected:—

P. 195, col. 2, seven lines from bottom, *for* salicylic and *read* salicylic acid; in following line, *for* Seren *read* Serex; five lines from bottom, *for* often *read* after.

P. 196, col. 1, line five from top, *for* one in thirteen *read* one in thirteen hundred.

*** Several communications are unavoidably postponed to our next issue.*

Show Announcements.

June 29–July 5.—Hives, Honey, &c., Royal Horticultural Show at Liverpool. Secretary, J. Huckle, Kings Langley.

July 12–16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Entries close May 12th. Secretary, J. Huckle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Granttham.

July 30–August 5.—Great National Show at South Kensington. Secretary, J. Huckle, Kings Langley.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

EXHIBITION AT LIVERPOOL.

We beg to call attention to the arrangements made for an Exhibition of appliances and honey in connexion with the large Horticultural Show at Liverpool, to commence on June 29th. The Lancashire and Cheshire Association are giving active support to this department of the Show by contributing the sum of 10*l.*, and otherwise rendering efficient aid in the arrangements. If the weather is favourable, it is calculated that not less than 100,000 people will visit the Exhibition. Prize lists for honey, &c., may be obtained upon application to J. Huckle, Kings Langley. The entries close on June 10th.

SOUTH KENSINGTON EXHIBITION.

The following donations have been added since our last issue:—

Neighbour & Son	£2	0	0
Warwickshire Association ...	1	1	0
C. H. Hodgson	1	1	0
Gloucester Association	1	1	0
J. R. Truss	0	2	6
G. Brett	0	2	6
Previously acknowledged ...	136	7	0

£141 15 0

The Kent Association has formed a special Committee for their county, to carry out the proposals of the Committee of the B. B. K. A. in reference to the County Competition at this Exhibition.

FEMALE WASPS.

Although the *British Bee Journal* may not be the most proper medium for noting the habits and peculiarities of wasps, yet as these insects are in many of their habits very similar to bees, and at various times of the year—in spring and in autumn—the attention of bee-keepers is specially directed towards them, we feel that we are justified in pointing the attention of our readers to a remarkable incident in their natural history, which we think is well worthy of being chronicled in our pages.

For some time past we have been receiving daily intimations of the extraordinary prevalence of female wasps, which most of our correspondents have designated (perhaps prematurely) 'queen-wasps.' This intelligence has

been forwarded to us from all parts of England. From Carlisle a lady correspondent tells us that the children of her village have brought her 703, while from the south, in Lymington, Hampshire, another has informed us that they have brought her 203. Our first information of this surplusage of vitality was the reception of a box containing 150 live wasps; these, so far as size, appeared fully developed. They allowed us to handle them with impunity, and they might have been pronounced non-accute; but they had been prematurely roused from their winter torpidity, having been discovered under the thatch of a house and forwarded to us before their powers had been brought to maturity. About four weeks after we received some others; these had been revived in the natural way by the warm beams of the spring sun, and when we endeavoured to handle them they soon gave us evidence of their stinging powers, and made us exclaim with Cicero, '*Vespas videmus uti aculeis.*'

The extraordinary number of these wasps this spring has perplexed the minds of bee-keepers. It would appear that this super-abundance is contrary to their usual experience. Kirby and Spence inform us: 'The number of females in a populous vespiary is considerable, amounting to several hundred; they emerge from the pupa about the latter end of August, at the same time with the males, and fly in September and October, when they pair. Of this large number of females *very few survive the winter.* Those that are so fortunate remain torpid till the vernal sun recalls them to life and action. They then fly forth, collect provision for their young brood, and are engaged in the other labours necessary for the foundation of their empire.' In this year, however, the contrary has occurred; the few have died, the many have survived. And this is the more to be remarked when we bear in remembrance the great length and extreme rigour of the past winter.

Notwithstanding the extermination of so many hundreds by lynx-eyed children and adult bee-keepers, we feel assured that wasp-life has not altogether been destroyed. We shall find that many have survived and that the life-work of these wasps is being continued. They are, even now, making progress with the object of their creation, excavating their habitations, and making preparation for their brood. When we think of the amount of work which devolves on the mother-wasps we cannot but be struck with their ingenuity, industry, and perseverance. About the first week in June the young worker-wasps appear, and then they assist and relieve their mothers in their work of building cells and nursing the young wasps. In the summer months the queen-wasps are never seen out of their nests.

We as bee-keepers are, however, concerned more particularly with the wasps in autumn. It is then that we find them well-nigh ubiquitous; they boldly enter our dwell-

lings, they peer inquisitively into every corner, they visit our receptacles of sweets, they sip at our breakfast tables, they rob the grocers' shops, they annoy our bees and purloin their honey, they harass and destroy the weak hives, and their continual buzzing and hovering about are a constant source of distraction.

These questions then arise:—Shall we in the coming autumn have these pests in the same extraordinary abundance that we have had them during this spring? Are these female wasps queen-wasps? Mr. Knight, of Elton, in a paper on 'The Economy of Bees,' which appeared in the *Philosophical Transactions* of 1807, mentions that in the previous year, 1806, there was an extraordinary number of female wasps throughout the kingdom, which circumstance, he says, 'has not been satisfactorily accounted for.' He proceeds:—'A greater number of female wasps were observed in different parts of the kingdom in the spring and early part of the summer of 1806 than at almost any former period; yet scarcely any nests or labouring wasps were seen in the following autumn, the cause of which I believe I can explain. Attending to some peach-trees in my garden late in the autumn of the year 1805 on which I had been making experiments, I noticed during many successive days a vast number of female wasps which appeared to have been attracted by the warmth and shelter of a south wall, but I did not observe any males. At length, during a warm gleam in the middle of one of the days, a single male appeared, and selected a female, close to me; and this was the only male I saw in that season. The male wasp, which is distinguishable from the female and labourer by his long antennæ and shining wings, and by a blacker and more slender body, is rarely seen out of the nest, except in very warm days, like the drone-bee; and the nests of wasps, though very abundant in the year 1805, were not formed till remarkably late in the season; and then I conclude that the males had not acquired maturity till the weather had ceased to be warm, and that the females in consequence retired to their long winter sleep without having had any intercourse with them.'

Kirby and Spence noticed the same abnormal amount of female wasps in the spring of 1815 and the paucity of their numbers in the following autumn; and others have remarked the same circumstance. Might we then request our readers to make observations on the condition of wasps at the close of the season and enable us to chronicle the result in our pages?

Foreign.

FRANCE.

According to our contemporary, the *Apiculteur* of Paris, the weather in France has not been all that could be wished for our favourites, for it has been very changeable and rather cold. Not so, however, in the southern districts, in some of which they have had some beautiful days, which have permitted the bees to work on almond, plum, cherry, and other early flowering trees. Generally speaking, in those parts of the country where the weather has been more or less favourable, bee-keepers seem to be satisfied with the state of their apiaries. It is evident, however, that in the less favoured provinces the mortality has been great where feeding has not been resorted to, but even the latter have not been able to make much progress with brood-rearing. It appears, moreover, that many apiaries have suffered from dysentery. In summarising the events of last month, the *Journal* above named states that bees were enabled to regain some of the ground they had lost in consequence of the cold winds of March, but swarming will nevertheless be retarded this year by a couple of weeks.

Owing to the continued illness of M. Hamet, Professor of Apiculture at the Luxembourg Gardens of

Paris, the lessons to be given at the opening of the season have been delivered by M. E. Beuve, Professor to the Apicultural Society of the Aube. Pending the complete recovery of M. Hamet, the practical lessons at the Luxembourg Gardens will be conducted by M. Bourgeois, a member of the Central Society. M. Asset, a bee-keeper of Sèvres, has been decorated with the order of the 'Mérite agricole.' M. Asset is the first bee-keeper who has received this distinction.

CANADA.

Writing to-day, April 24th, from Canada, the prospects for the season are remarkable. Colonies of bees are fully three weeks in advance of last season. They have wintered well, and even those who, from their feeble condition, were expected to succumb, have under existing favourable conditions built up wonderfully. Having just visited the apiaries of some of our most successful bee-keepers, a brief sketch might be of interest, especially those apiarists who intend visiting England during the Colonial and Indian Exhibition.

Arriving at Woodstock, a walk of a mile and a half brings us to the outskirts of the town, and the handsome residence of Mr. J. B. Hall, one of the Commissioners appointed by the Ontario Bee-keepers' Association to visit England. Mr. Hall was hard at work preparing to get his bees out of winter quarters (19th); over 200 stands were marked by cover—half storey and sawdust cushions—and the neatness of the apiary was pleasing to the eye. Mr. Hall has had the reputation for years, and justly, of being not only one of the most successful honey-producers in Canada, but he is also *very* successful in wintering his bees. The gentleman has also the reputation of keeping the information which he possesses to himself most jealously. It is safe to say that, whilst Mr. Hall cannot be induced to transfer the result of his large practical experience to paper, and is not anxious to buttonhole any one and press his views upon them, he will be found ever ready to answer the inquiries of any one who is desirous of availing himself practically of his (Mr. Hall's) experience. The winter repository is underneath a portion of the residence—the floor is mother earth, the walls brick; ventilators are two in number. Colonies are placed about ten inches above the ground, and piled four high and two hives back to back, and about four abreast. The temperature at time of taking from cellar was 62° Fahr. He seeks to keep his bees at a temperature not lower than 55°, and as spring approaches, still higher. This stimulates brood-rearing; and as a result, colonies on ten frames, besides having many young bees, have five and even seven cards of almost solid brood when leaving winter quarters; and as we would expect—they are in splendid condition for the honey-harvest. Clover gives the first surplus. Out of about 220 colonies, only one was affected with dysentery. It appeared strong in bees. Some six or eight were starved, and the balance, which were taken out during the night, had a beautiful flight in the morning.

Mr. Hall uses the Quinby hive; the brood-chamber is seldom manipulated; the extracted honey is secured from the upper storey; also, the comb and a perforated metal honey-board is used to keep the queen in the lower storey. Mr. Hall has extracted 2000 lbs. of honey from the upper storey with the assistance of one person in four hours. The Caucasian bees have here been experimented with and discarded; the Carniolans are being experimented with. The Cyprian and Palestine have been found wanting in many necessary qualities, and the bees are bred according to the actual results in wintering, honey-producing, &c., irrespective of colour and breed, and a record is kept of every colony; queens are only used after a year's record or more has been obtained.

Taking the morning train, Belmont is reached, and a three-mile drive brings us to the farms and residence of Mr. S. T. Pettit, of Belmont, President of the Ontario

Bee-keepers' Association, who, ever since Doctor Thom, of Streetsville, suggested an exhibition of honey at the Colonial and Indian Exhibition in his retiring address as President of the Association, has spared no labour to bring the suggestion to a successful issue. Mr. Pettit has also been very successful as an apiarist for the last five or six years. He winters outside, packing his bees in chaff, and linging clamps upon their summer stand. Commencing on a small scale, and with little knowledge, some eight or nine years ago, he relates, he obtained his information through often dearly-purchased experience. Good literature was rare, journals published were not as comprehensive to the beginner as now; but success has crowned his efforts for some years. Mr. Pettit has lost only two colonies out of about eighty, and they had been at work gathering honey and pollen for nine days. The combs and manner of alighting of bees showed that not alone was pollen gathered in abundance, but also honey. Soft maple, willow, and elm were in bloom.

Honey is secured, as with Mr. Hall, from top storey. There are two farms of Mr. Pettit's within easy range of the bees, and in a ramble through the woods many fine linden-trees were pointed out, for which room had been carefully made by cutting down trees of less value to the honey-bee. Alsike clover-fields also will probably yield a fine flow of honey, besides a paying seed crop. A cellar and extracting room is in the course of erection; and in future, owing to climatic disadvantages, intensified as timber is being cleared away and shelter diminished, the bees will be wintered in the cellar. The ungainly clamps of all shades and cuts certainly lend no charm to the apiary.

Mr. Pettit has relinquished the management of his farms to one of his sons, and, unless it be during election campaigns, devotes most of his time to apiculture and a flock of very fine South Down sheep. Like Mr. Hall and the owner of the next apiary we visit, Mr. Pettit can seldom be induced to give the result of his long and financially successful experience on paper.

We next visit Mr. M. Emigh, of Holbrook. He is reported to have made a small fortune from his apiary. His mode of wintering and rearing honey is much as Mr. Hall's: 170 have wintered, and are in excellent condition, out of 173. Mr. Emigh has also a fine residence and farm, but his time and energies are largely given to the apiary. He has abundance of Alsike clover in the vicinity, and himself pays but little attention to bee-pasture.—R. F. HOLLERMANX, *Brantford, Canada, April 23rd.*

ASSOCIATION.

WARWICKSHIRE BEE-KEEPERS' ASSOCIATION.

The sixth annual general meeting of the members of this Association, held at the Grand Hotel, Birmingham, was well attended. In the absence of Lord Leigh, the President of the Association, Mr. R. Ramsden, of Knowle, presided. There were also among those present the Rev. W. K. Stuart, and Messrs. W. Madeley, C. Barwell, Jacob Rowlands, J. Blackham, J. L. Hawkes, Dugard, Pearson, T. Cox, Walton, Ward, J. N. Bower (hon. sec.), Ingerthorp (assistant secretary), C. W. Summer-skill (expert), and a number of ladies.

The Chairman, in opening the proceedings, spoke of the importance of bee-keeping to cottagers and others as a means of eking out their incomes.

The Committee, in their report, stated that they were glad to be able to record the steady progress of the Association. The receipts from all sources, including a balance from the previous year of 30*l.* 1*s.* 2*d.*, amounted to 15*l.* 6*s.* 3*d.*, and the expenses to 14*l.* 17*s.*, leaving a balance of 9*l.* 9*s.* 3*d.* in hand. The number of members on the books at the close of the year was 412. During

the year two tours had been made by the expert and much appreciated; lectures in connexion with this Association had been delivered at various places, and the bee-tent had been exhibited at a number of horticultural shows. The quantity of honey sold at the honey depot had been three times greater than in any previous year.

On the motion of the Chairman, seconded by Mr. W. Madeley, the report and accompanying balance-sheet were adopted.

Lord Leigh was unanimously re-elected President, and the Lord Bishop of Worcester, the Earl of Denbigh, Lord Newport, Lord Windsor, the Hon. H. A. Adderley, the Hon. C. L. Adderley, the Hon. A. C. G. Calthorpe, Colonel the Hon. C. G. Scott, Sir R. N. C. Hamilton, and Sir Charles Mordaunt, were re-elected Vice-presidents. The Committee and Honorary Treasurer and Auditor were thanked for their past services and re-appointed; and Mr. Bower was unanimously re-appointed honorary secretary, and the assistant-secretary and expert were also re-appointed.

Subsequently, a most interesting lecture, followed by a discussion, was delivered by the Rev. W. K. Stuart, on 'Modern Methods of Bee-keeping.' The lecture was illustrated by a series of admirably executed crayon drawings, the result of original research into the subject by Mr. T. Prince, of Bradford. Also an interesting collection of nests, &c., was exhibited by Mr. Hiam, of Astwood Bank.

Votes of thanks to Mr. Stuart for his lecture, and to Mr. Ramsden for presiding, brought the meeting to a close.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Stanger's and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of April, 1886, amounted to 113*l.* [From the Statistical Office Returns, supplied through E. H. Bellairs, Esq., Wingfield House, Christchurch.]

SCOTCH HONEY COMPETITORS.

[35.] I can assure you that, notwithstanding the unfounded accusations brought against us Scotch bee-keepers and honey dealers by John D. McNally, we all the same heartily reciprocate your opinion, that if such practices did exist they are most reprehensible ones, and would certainly meet with the utmost condemnation of every honest exhibitor. But I am pleased to think that if such statements were made by the same writer on this side the border they would certainly be treated with silent contempt. Inexperienced youths who, for the sake perhaps of a little notoriety, persist in scribbling fictitious nonsense, are easily disposed of amongst intelligent bee-keepers; it is only a pity that those tactics oftentimes stir up warm discussions, when, if the personal objects in view were really known, such writings would at once pass into oblivion. Misunderstandings and differences of opinion may exist amongst us, but I hope, Sir, you will always find it the rule in Scotland that we

value honour too highly to condescend to such contemptible resources as are brought forward by John D. McNally. Let him produce the name of any such individual from the many he knows, let the charges be manfully put forward, and let the schedules and rules of the associations so imposed upon be submitted to the verdict of the public, and then I have no fear of the final issue.—SCOTCH BEE-KEEPER.

For several years I have taken a deep interest in apian exhibitions throughout Scotland, and am much surprised to find one (who has no practical knowledge of such Exhibitions, and whom I have every reason to believe is not even the happy possessor of a single swarm of bees) bringing forth such glaring charges regarding the honesty of our Scotch exhibitors. It is evident that our champion has seen very few of the schedules regularly issued in connexion with all our district shows, because, unless in the case of open classes and for competitions, rules are inserted even more stringent than those J. D. McNally would have us all to adopt. In this matter, therefore, he is only copying the rules laid down by one of our largest district Shows, viz., the East of Scotland. Even the Caledonian, which is distinctly an exhibition open to the world, has strictly confined classes; and it is rather noteworthy in connection with this open competition that J. D. McNally's own brothers have for several years taken full advantage of its open provisions, and have carried off leading honours with entries simply bought in the open market for the occasion. No one, however, can call this an infringement of rules, seeing that it is the 'exhibit only' which is judged. It is wise, therefore, in all county and district Shows to have confined rules, so that the 'exhibitor' is also rewarded according to his merits.

I presume that J. D. McNally must know that whatever rules and restrictions are made, it is the duty of the judge and committee to see that no one is allowed to exhibit fraudulently. I therefore maintain, Mr. Editor, that your views are those generally held by every prominent bee-keeper in this country, and from the close intimacy which I have had for years with many of our leading Scotch apianians, I can, without hesitation, challenge the statement which J. D. McNally has thus publicly brought forward, and demand a single proof that such a system is prevalent amongst us. This proof has been publicly offered in order to get up an argument, let it now be forthcoming, and then the subject will be fully and fairly discussed.—J. H.

OUR LITTLE DIFFICULTIES.

[336.] Bee-keeping is not always a bed of roses. Have none of my readers ever realised the utter disgust one feels when one's smoker goes out in the midst of opening a hive whose temper, one knows to be, to say the least of it, rather uncertain; or when some tool or other that should have been in one's tray-barrow is not there; or when one's frame-rest has been left in the bee-house; or the lid not on one's frame-box, or a hundred other little *contratemps* only known to bee-keepers. To shut down the hive, or to leave it and go fetch—well—is a cross between fire and fryingpan.

Two or three seasons ago I had been bothered a good deal in this way, and every time I muttered to myself, 'What a nuisance it is; I must have help.' I sounded the representative of my stable: he looked glum. I gave gentle hints to my crabbed old gardener, who views all modern ways of bee-keeping rank heresy, and all I got was,—in words, 'Don't ye see, maister, us be mortal busy just now;' in manner, 'Us hates them there new-fangled ways of yours.' To which one's riling reply did not go for much, 'No, you prefer a brimstone cushion.'

Well, things went on that year for some weeks, the weather got muggy, one's temper and the bees' temper were in like ratio, when all at once a change came for

the better—or the worse, I leave to my bee-keeping brothers and sisters, bee-keepers, or bee-encouragers.

One morning I was reading my letters and papers at the open breakfast-room window—we have but one in-and-out post in these remote parts of north-west Devon—and I heard a step on the gravel, and a respectable, motherly-looking widow crossed the front and came up, and with a very low bob and in broadest Devonshire, 'Does your honour want a handy boy?' I immediately bethought myself of 'my little difficulties,' and jumped at the idea like a trout at a fly in the big stream which runs through the park. 'What can he do, my good woman? Can he clean a horse?' 'Lor a-bless 'e, he clean our donkey fine.' That was something,—but not bees. Leading up I said, 'Can he clean boots?' 'O yes, your honour, till he sees his *praty* face in 'em.' On thoms, I mildly asked, 'Do you keep bees?' The hit was unlucky. 'No; us don't.' 'Do you like honey?' This was better. 'Oh, us do; and so does John and the little uns.' A few more questions and a couple of one-pound sections for the little ones and for John to improve his taste with an eye to the future, and the lad was hired, and the sections were placed in her basket—not in her umbrella, which looked as if it were capable, and was made a receptacle for—well, presents, veils, perquisites, &c., and away she went, and I flung up my paper and said to my better half, 'Now I have got a bee boy.' Man proposes, God disposes.

On the following Monday morning, on going into the garden, I saw, already monopolised by gardener, as unlikely-looking, ugly young lout as you would see in a day's march. However, his looks belied him, and he turned out a ready help in the bee-garden, and generally had his wits about him, and the right thing in the right place, and my temper improved and all went merry as a wedding-bell for some weeks to come. When all at once something happened in the bee-garden. I forgot what it was—sheep, or cattle, or colts, or something, got into it, and a hive was upset, and we both rushed out to put things straight 'without our armour on,'—unveiled in fact. Bees furious. We, too, hasty and hurried. The bees thought we had capsized them. The end of it was we suffered considerably about the face, the carriage was just coming round, and I went out and saw no more of 'John,'—my hopeful John, that evening. And I came home and went to bed, and dreamt of the pretty little rosebuds I had seen playing lawn-tennis, and what not, and awoke to our little difficulties with a vengeance. John's mother appeared at the open window once more, not this time with 'front serene' (it was at least an inch off her forehead), and there was something about her bonnet ribbons which gave me a pain somewhere, and a surmise that all was not as before.

'Praise, your honour, us be coombe to say as our John's beauty be aal agone, and he ca'nt see out of his head; and neighbours do asay it be a dratted shame to treat a poor body's son so.' 'Passons ought to know a better—and not go to keep no savage bees to stang people.' 'That her beautiful boy'—oh dear, how much does a mother's view err—'was a spilt for ever,' &c. Memory fails me to tell all her rancorous words. I was dumfounded and thought of the future and all it boded.

Well, I lost my help, and have had to do my bee-work alone ever since; but that was easier than my old gardener's 'told-you-so' kind of look for many a day after. Oh, how the old sinner chuckled some time after when the bay horse (he hates the sound of a bee) would not suffer himself to be put to because the bees smelt the fresh compo on his harness, and buzzed about his ears, till all had to be taken some distance down the road ere they could be tackled, and then the stage-whisper as one started: 'Baes didna use to be like this, till they was a put into stange houses.'

Let me end my not an A I yearn I hope, by a tale Charles Lever tells of a little disaster, illustrating the relations

between an improving landlord and an untutored tenant. The agent is presenting the tenants to the worthy innovator, who inquires into the condition of the grumbling and dissatisfied recipients of his favours.

At length on a tenant presenting himself—whom the agent fails to recognise—the worthy Baronet turns to the figure before him, which, with face and head swollen out of all proportions, awaits his address with sullen silence.

'Who are you, my good man? What has happened to you?'

'Faix, and it's well you be axing that same, my own mother wouldn't know me—'tis all your own doing entirely.'

'My doing,' replied the astonished landlord, 'what can I have to do with the state you are in, my good man?'

'Yes, it be all your own doing, and may ye be proud of the same. 'Twas them blessed bees you giv me. We brought the divils into the house last night. And where did we put them? Out into the pig's corner. Well, after Katty and the children an' myself was awhile in bid, the pig goes rootin' about the house, an' he wasn't aisy till he hooked his nose in the hive and spilt the bees about the flure, and then, when I got out of bid to let out the pig that was a-roarin' through the house, the bees settled down on me and began stingin' me, an' I jumped into bid again wid the whole of them afther me, to Katty and the childer, and there, what with the bees abuzzing and astingin' us under the clothes, out we all jumped agin, an' divil such a night was ever spint in Ireblin as we spint last night. What wid Katty an' the childer aroarin' an' aballin', an' the pig atarin' up an' down like mad, an' Katty wid the besom, an' myself with the fryin'-pan, flattenin' the bees agin the wall, till mornin', and then the sight we wor in the mornin', begor! it is ashamed of yourself, ye ought to be.—Rector, *Buckland Filleigh, North Devon.*

ON THE BEE'S STING. [252.]

[337.] Mr. Chapman takes exception to two opinions said to have been offered on this subject, (1) that barbs are natural to the hymenopterous ovipositor, and (2) that they are disadvantages to the bee. I cannot find that I made an assertion that barbs were a distinguishing characteristic of the hymenoptera; yet even were I guilty of raising this ghost, your correspondent himself lays it by stating that 'on the ovipositors of the hymenoptera there is a capacity for developing on their serratures.' Admit development and abortion may with logical propriety be claimed.

By instancing various insects (Hymenoptera, Hemiptera or Diptera, Cynips or Cicads, Wasps or Bees, it mattered not) I endeavoured to show the identity of the sting with the ovipositor in anatomical construction, and argued that the ovipositor was being adapted to another purpose, for offence or defence, seeing that there are races of stingless bees, and races of varying grades of pacific disposition, of elusiveness, or ignorance, up to our own irascible, half-bred demon, perhaps apicing the pyramid with *Apis dorsata*, which is said to attack almost any living thing without cause. Again, I urged that the sting, as we find it used, is imperfect, confined as it is to imperfect females, and only used by them on forfeiture of their own lives.

Your correspondent must, I think, admit that if the barbs were 'improved out of existence,' as he puts it, the whole genus *Apis* would have cause to be grateful; and I am sure the enemies of the honey-bee would not dread its weapon the less were Providence in its good time to permit the barbs to become rudimentary, and the sting consequently extractible, any more than the present enemies of the wasp can afford to leave out of reckoning its barbless sting.

The bee who stung and flew away,
Would live to sting another day,

all the better for that teaching which experience gives.

At present, some races of bees when much irritated will sting posts and rails, or anything they can get their weapons into; and on the other hand, some insects with smooth ovipositors will use 'a bare bodkin' in the same way. How cruel it seems that, when alarmed by our smoke into filling its pouch with salvage store, the bee is almost unable to punish the robber incendiary!

Watch a bee trying to sting when well filled, and its sting will be seen to protrude from a straight abdomen in the most insensate fashion. We call it taming, subduing, and quietening them. The honey-sac is under the abdomen just in the most awkward place to allow the bee to bend its body (after seizing hold of the object with six pairs of pincers, as purchase or leverage), sufficiently for it to inflict the wound. Such painful muscular effort would in all probability cause regurgitation of the honey. I am surprised to find Mr. Chapman advancing (*Mors janua vite*) that the barbs are a positive advantage to the bee. Nature is too skilful a general to say, 'So long as the city be saved (i.e.) the lives of my soldiers matter not; she is constantly enabling her subjects to economise their forces, and waste as little life as possible, just as our generals are careful of the units of an army. As for the quantity of poison left in the wound, in the case of the wasp and nettle, it must be conceded that sufficient is used to produce the desired effect, viz.—future avoidance. If the barbs in bees' stings became aborted, some eighteen or twenty apertures behind the rudiments would still remain to pour out as many drops of poison on insertion and withdrawal.

A month ago appeared the first volume of Mr. Cheshire's new work on bees and bee-keeping, far and away the finest work on the scientific aspect in the English language, and I find on p. 184 the following, which I am tempted to quote as conclusive corroboration of my assertions. 'Automatically the bee's sting is analogous to the boring ovipositor of the saw, gall, and ichneumon flies. When we call to mind the strange piercing power of the sting, and its venomous effect, we shall have no difficulty in accepting the statement that the difference between the sting and the ovipositor is rather that of function than of structure.'—R. A. H. GRIMSHAW, *Crag Hill, Horsforth, nr. Leeds.*

CARBOLIC ACID VAPOUR VS. SMOKE.

[338.] The several references made in last issue of *Bee Journal*, as to the effects produced on bees by the use of carbolic acid, are, in my opinion, quite in accordance with the experiences of those who have expressed them: without doubt great care should be exercised in the use of same. The acid itself should on no account enter the hive, as well might you allow your burning fuel from smoker to enter as well as the smoke: the acid is the generator of the vapour, the burning fuel the generator of the smoke.

The writer of 'Useful Hints' gives one special experience in support of this, which, without doubt, is what any one might expect under such circumstances:—The floor-board of a hive was washed with a strong solution of carbolic acid, and then placed in its position at bottom of hive; this being saturated was a continued source of uprising vapour, and would continue to give off such for several hours, and very likely days; this was quite sufficient to kill or stupefy any bees. What would any one suppose would be the result of injecting smoke into a hive in a continuous stream for an hour? Why in less than five minutes the inmates would be killed, and yet this continued stream of carbolic acid vapour did not kill all the bees in that time; is not this a fair proof that the carbolic acid vapour is of less deadly a nature than smoke?

I do not advocate the use of carbolic acid *in* the hive; in my letter of the 29th April, page 189, I distinctly mentioned a mishap I had last summer; it occurred in this way: I had used my smoker in precisely the same manner as Mr. R. A. H. Grimshaw advises; everything went well until I had finished several hives; by this time some of the acid had escaped from the sponge, no doubt in infinitesimal portions, and collected round the perforated diaphragm, giving this an extra tilt, it was run into the hive, the consequence being most of the bees 'cleared out quick!' Having seen the result of my accident, I at once removed floor-board and a comb which had a small quantity on it; in doing this I removed the source of the supply of vapour, and in a short time the bees all settled down comfortably. Every bee-keeper, no doubt, has had the misfortune to give a straw skep an extra puff or two of smoke, and found the bees in a state of stupefaction when he turned it up. The cause of this is not far to seek, he has injected the smoke for so long a time that the air inside has become displaced by the smoke; the same would happen if carbolic acid had been placed *in* the hive, it would keep giving off vapour, until this had displaced nearly all the air, and the results would be the same.

It is only the vapour that must enter, and this being so volatile quickly escapes again, or is fanned out by the bees, but there having been only vapour injected, there is no source from which more can be formed, and the hive is clear at once. Let any one, for experiment, take his smoker and fit it up in the same manner as Mr. R. A. H. Grimshaw, and inject some of the vapour into a hive and try how long the hive retains the smell of it, but be very careful not to let any acid even touch the frames or combs, it will be gone in less than two minutes.

A cloth saturated with carbolic acid solution, as recommended in 'Useful Hints,' laid over the frames, no matter how effectually it is wrung out again, will leave a source of carbolic acid vapour on the frames wherever it touches, and will act in the same manner as if you were gradually injecting smoke, no doubt, in this instance, in a very mild form, and not sufficient to make it dangerous.

With a fumigator the vapour only is injected, and quickly leaves the hive after it has accomplished its work—frightening the bees.

If Mr. R. A. H. Grimshaw had practically tested his method of fumigation he would not have asserted what he does in his third paragraph. As my and many others' experiences are directly opposed to it, I will guarantee to make an ordinary colony gorge by means of carbolic acid quicker than by smoke.

As the introducer of this system in a fairly perfected condition, I may be biassed in its favour, but having received so many flattering testimonies as to its efficiency has made me feel that I ought strongly to advocate it for the benefit of my brother bee-keepers.

I have not protected the fumigator in any way, so that any one who is practical enough can make them. It is not a very difficult job, the illustration in the *Bee Journal* of the 29th April is correct in all details, with the exception of a stop on each wire to prevent the sponge shifting over the inlet,—added since.—W. B. WEBSTER, *Wokingham, Berks.*

DRIVING.

[339.] In my capacity of local secretary for our County Association, I met with a method of bee-driving quite new to me and which I thought might interest some of your readers. I was riding along a country road in a district where the bee-keepers were unknown to me when I espied in a garden some straw skeps. I at once dismounted, and on entering was fortunate enough to find the owner smoking his evening pipe before his cottage

door. I introduced myself to him, and in answer to my query as to how the bees were doing he told me that 'one was a good strong lot, but t'other were a lot he took the honey from last year.' 'Then you understand how to drive them?' said I. 'Well,' he said, 'I've got a fashion of my own which I reckon is a deal better than some o' the plans I've seen tried. A neighbour o' mine here wanted some bees last autumn, and I told him he could have mine if he'd take the trouble to fetch 'em. Well, he were about here more than an hour with one lot a-smoking of 'em out, and I reckon I do it all according to my plan in about ten minutes.' Of course I was anxious to know what his plan was, so I asked him to explain. In order to make the story short, I will not attempt to give it in his words, but his method was as follows. Proceeding just in the way of close-driving, putting an empty skep rim to rim with a full one and a towel round to keep in the bees, he places them in an empty tub with the full skep under and then slowly filling the tub with water until the full skep is covered. The top one is then removed, when the bees are found clustered in it. He said, 'I've done it that way many a time without killing a dozen bees and not half the fuss or bother like there was with that smokin' and beatin' the hive wi' sticks, and the honey quite as good, because it is all sealed over and the water don't hurt it a bit.'—SOUTH GLOS.

HONEY-COMB LETTERS AND DESIGNS.

[340.] Press of work has hitherto prevented me from advertising the articles written on the above subject in the *B. B. Journal*, of dates 1st and 8th April last. Honey-comb designs have been in vogue for a number of years, such as stars, circles, &c.; but these are very simply done, and it is only in regard to comb letters and figures that I claim the honour of being the inventor. Permit me to describe how it is done.

Take a super made of $\frac{3}{4}$ wood, say $16 \times 8 \times 3$, outside measure, and you want the year 1886 built in it; get strips of foundation about one inch deep, draw out the shape of the figures in super; then fix the strips of foundation with a smelter in centre where the figures are to be built. Thus fixed, get thin pieces of wood separators about $\frac{3}{8}$ less in depth than the inside of the super, so as to allow the bees free access under; on these separators fix little corner-pieces to form the circles and bends in such a way as to prevent the bees from misshaping the figures. These blocks are then fixed in the super with fine brads, to draw out easily when the super is finished. Any letters or figures can be done by putting the foundation in the shape wanted, and filling up the interstices in the same way as already stated. My first attempt at letter-building was in 1882. I then tried the word HONEY. The super was too long, and the bees only finished out ONE in the centre—H and Y were unfinished; these I cut off, leaving ONE complete, which I exhibited at Stranraer Flower Show that year. Every year since I have done more or less at letter-building.

The late Mr. Pettigrew also tried the letter-making. His method was to take pieces of wood, 6 in. square by $\frac{1}{2}$ in. thick, and fix a strip of foundation on each piece of wood in the shape of the letter wanted. This was let into a large hole in the crown of his skeps, and the bees drew out the foundation. When taken off he then cut off parts of the letters where too thick with a knife, and thus shaped each letter to his mind. There was never any honey in his letters by this method, and therefore they could not be called 'honey-comb letters.' His handiwork was shown at the Oldham Exhibition in 1883. In *Gleanings* of May or June 1884, Root describes another way of building letters in frames, by getting two letters made in each frame and filling up the corners and spaces with blocks. I have never seen Root's method worked out, and therefore I cannot say how it does. As usual, our American friends brought it out in 1884 as

something new. Stars, circles, and suchlike, are more easily done than letters. It is only necessary to fix the foundation in whatever way you want the bees to build, and almost invariably you will get it. The idea only requires a little taste and ingenuity, and once known is very simple. Lastly, the making of letters and designs is not a paying 'spec,' unless a large sum can be got for them. Several bee-keepers to whom I have shown the idea have sold at exorbitant prices.—WM. McNALLY, *Glenluce, Scotland.*

FOUL BROOD.

[341.] I was hoping to find more answers to my query *re* the above from bee-keepers who have experienced it, and was somewhat disappointed at only the reply of Mr. W. B. Webster, and he having only used phenol in its cure. As it seems to me that this is a subject that will affect us bee-keepers more and more in the years to come, through the purchase of foreign queens and the exchanges of bees and hives, it would be very interesting, I think, if apiarists who have experienced this scourge would state how their hives became contaminated with the germs of bacilli, as I think it would be shown that in the majority of cases it was imported through the purchase of strange bees or second-hand hives; and also the means they took to eradicate it, and with what success, so that we might see which was the more efficacious remedy,—salicylic acid or phenol!

It was through the purchase of about a dozen hives from a bee-keeper who was giving up bee-keeping that I first got foul brood among my bees; and unquestionably the party knew of it, as he had cut the combs from all the frames most neatly, leaving no signs of any diseased cells. Other bee-keepers had purchased from him a few days before, and in these cases also, I afterwards discovered, foul brood had appeared; and in several cases where the owner had but just commenced bee-keeping, he lost all his bees, his hopes were blighted, and he gave up the thing in despair. I had all my frames boiled in a furnace, and the hives scrubbed with soda, soft soap, and boiling water; but I suppose there was some crevice not properly cleansed of the germs, for, anyway, in the course of a few weeks, foul brood broke out in one hive, and then in another, until I had about six affected with the disease. This was at the time so much was being written and said about 'Cheshire's cure,' and I suppose I had from his agents quite a dozen bottles of the 'cure'; but, alas! it didn't cure them a bit, as it was in mid-summer, and the bees would not take the medicated food. I poured it into the combs, but, no, I could not get the bees any better; in fact, the complaint rather increased. I spoke to one county expert, who 'knew nothing about it, and didn't want to.' When a few days after, Mr. Summerskill, of the Warwickshire, called in, and he at once said, 'Fumigate them with salicylic acid;' and he gave me a sketch of a fumigator, which I had made at the tinman's, and which is almost exactly the same as figures in your useful little manual, Mr. Editor (although this was before the last edition came out). I fumigated them at evening every three or four days for about three weeks, and these stocks are now some of the strongest in my apiary. I found another, that was all right last season, a few days ago with a few diseased cells, and at once adopted Hilbert's method, and I do not fear of the consequences. I also have placed in every hive a small piece of camphor, as I strongly believe in the old adage that 'Prevention is better than cure.'—G. H. G.

FOUL-BROOD.—A TEST OF DISEASE IN THE QUEEN.

[342.] A short narrative of my experience with foul-brood, and of my endeavours to establish a test as to the healthiness of the queen, may be of interest to your readers, especially after your 'Editorial' of the 7th

inst., and the request of one of your correspondents for advice.

Last year I tried in vain throughout the whole summer to cure a stock infected with *Bacillus alvei*. The stock (a very strong one in June) dwindled right away in spite of constant efforts with phenol, clean hive and fresh frames. Two other stocks slightly affected during the same period yielded to treatment in ten days. Why not this one? In September I sent the queen to Mr. Cheshire, and he was good enough to inform me that 'though a fine-looking queen both her ovaries were very badly diseased with *Bacillus alvei*.' How I wished I had dethroned her three months earlier, but I had no idea she was diseased, and I was a comparative novice—how was I to know? This spring I have *Bacillus alvei* in three stocks (the same three). In two of them the disease is disappearing under phenol, but in the third the disease is obstinate, and my last year's experience rising before me like a nightmare, I thought perhaps the queen was diseased. How could I test it? As the queen was a young one and a good layer, I was loth to lose her, so I placed in the centre of the brood-nest a fresh comb quite empty and continued the treatment. I wanted to establish this test:—If nothing undesirable manifests itself in that comb the queen is all right, if anything *does* show itself she is diseased. In ten days 50 per cent of the cells in that comb contained rotting grubs. This seemed to me to be decisive, so I took her majesty away and sent her to Mr. Cheshire, who very kindly examined her, and pronounced her to be diseased. Thus my test seems to be established, but only in a solitary instance; and I trust I may never be in a position to repeat it: but some of your readers, doubtless, who are troubled with this pest may like to try it, and to recount their experience in the *Journal*. In cases of *Bacillus alvei*, the question of the healthiness of the queen seems to me to be the all-important one, especially as Mr. Cheshire tells me that he very much doubts whether his treatment will cure *any* adult bee. This being so, the only safe thing to do whenever the disease does not begin immediately to yield to treatment, is to re-queen. There are two other points of interest upon which Mr. Cheshire has expressed his opinion to me. One is that a diseased queen *can* lay healthy eggs, for the ovaries are only locally affected so far as his observations go; and the other is that it is possible for a diseased egg to hatch, and (under treatment of course) to develop into a perfect and healthy bee.—WM. GEO. SMITH, *Caistor Cottage, East Finchley, May 13th.*

FOUL BROOD.

[343.] I beg to say that I have had three years' practical experience of foul brood, and having used both salicylic acid and phenol I can speak of them with some confidence. For more than a year previous to the appearance of the disease I invariably used the solution of salicylic acid and borax when feeding, but notwithstanding this precaution my bees got foul brood in 1880, from which date to the end of 1882 I had salicylic acid in constant use, according to Cowan's and Hilbert's formulae. I also used it by sublimation, and in fact I did not spare time, trouble, or expense, but without producing the least appreciable results. In the beginning of 1883 I used phenol with success by melting the contents of an ounce bottle of Calvert's carbolic crystals No. 1 and pouring it into a quart of cold water, about a teaspoonful of this solution being mixed with a pint of syrup and given to the bees. When honey was very scarce they would take it in even stronger doses, and the result was that the bees cured themselves without my taking any trouble, as by that time I had almost despaired of getting rid of the disease. My bees are now in perfect health, and I have never been obliged to destroy a hive or even a frame.

I am aware that salicylic acid has been successfully used as a remedy for foul brood, but I wish to express my thorough conviction that it would not have cured my bees, even supposing that I continued using it to the present time. In my opinion the substance used to eradicate foul brood should be disinfectant in action, readily soluble in water, and volatile at ordinary temperatures, and of these properties salicylic acid only possesses the first, while carbolic acid possesses all three.

I think I have discovered another remedy for foul brood equal in every respect to carbolic acid, and superior to it in being inodorous, but, pending the result of experiments, I am unable to say anything positive about it at present. When I am it shall become public property.—ROBERT SPROULE, *Fairview, Co. Dublin.*

[We have also had practical experience of foul brood, and succeeded effectually in eradicating it with salicylic acid, in the same way as a great number of large apiaries have been cured. If our correspondent failed, it is probably owing to the reasons given on page 216 in our answer to R. T. Collisson, and not any fault of the agent employed. We should be glad to welcome any simple and effective remedy for foul brood, and one that will not be so objectionable to the bees as carbolic acid, and that can be used at any time, like salicylic acid, without injury to them or the honey.—Ed.]

BACTERIA.

[341.] I for one am pleased to see that you have at last put down your foot upon bacteria. We have heard enough about them of late. I never take up the *Journal* without anticipating the discovery of another species, and I am rarely disappointed. I would respectfully ask,—nay, *entreat* Mr. Cheshire to pause in his headlong career. I don't mind a few, although I did hope our little friends were free from the nuisance. I don't object to the *Bacillus Gaytoni*, and I could bear, though with increasing reluctance, a *Bacillus Cowani*, *Hookeri*, *Hucklei*, and other well-known names, including, for the sake of auld lang syne, a *Bacillus Bartrunii* (pardon my ignorance if I have not correctly Latinised the names); and if an extra prolific or virulent one should be discovered, then let it be known to the scientific and the bee world as the *Bacillus Cheshirei*. But I would have the bacteria end there. We have had too much of them already, and when, in your issue of May 13th, Mr. Cheshire declares that there are no less than eight species in a slide of Mr. Sissons' queen's blood—awful thought!—I instantly cry, and I am sure the bee world would join in loud chorus, 'Enough! enough! No more bacteria! Let them rest in peace where they were before you disturbed and unearthed them by your scientific probing!'

I am glad, therefore, Mr. Editor, you have put your foot down upon the accused bacteria, although I personally wish it could have been done with less than four columns of the *Journal*—space too precious to be wasted upon bacteria this time of the year. It would perhaps have been nice wholesome reading about Christmas, when, practical bee-keeping having ceased, theories of all kinds may be legitimately discussed. I therefore skipped most of the four columns, and shall all future columns on bacteriology, only agreeing most heartily with the concluding sentence, in which you, Mr. Editor, surmised, very correctly, that your 'readers had had enough of it, and would not wish it continued.'—JOHN PEEL.

P.S.—I am keen on a *Huckle bacillus*. The bee-world owes him much.

NOTINGS.

[345.] *Size of Sections.*—Mr. Turtle (306) thinks it a pity a standard size section cannot be decided on. I myself consider it has. According to Mr. Turtle's own words, at

the opening of his letter, he says *knowing that most bee-keepers use the 4½ × 4½ sections*. Then, sir, we four-and-a-quarters are in the majority, and the 4 × 4½ size section users in a hopeless minority; and as things in general from the Government downwards are decided by the majority, the thing is as good as settled, only requiring adoption by the parent Bee-keepers' Association. This subject was fairly thrashed out some time back in the *B. B. Journal*, and one of your Selected Queries answered by a selected few of the vanguard of British bee-keepers ought to have carried some weight. Unless some valid reasons had been discovered in the oblong section the square does not possess, those among us who have visited the shows held under the auspices of the various Associations during, say the last six years, know very well that in no single instance has a prize been awarded to any crate or rack of sections otherwise than the 4½ × 4½ size. So that, speaking on behalf of a large number of working men, who I know are using the ordinary sized section, and also in favour of uniformity of size which has been fostered and developed by the compilers of show schedules everywhere for several years past, I appeal to the committee of the British Bee-keepers' Association to settle the matter by the votes of the majority.

Our friend, 'J. B.' (308), has initiated the bee-keepers of his district with the wrong pass-word to the craft—re-sections. Would 'J. B.', on consideration, wish the thousands of crates made and sold during the past decade, and also the large number held by the various dealers and manufacturers of bee-appliances ready for the coming season, relegated to the lumber room of obsolete beegear; also the hundreds of thousands of sections, aye I think I may say millions of sections, at present on hand of the ordinary size, consigned to the flames, to suit the caprices of a few, when those few crates in use made to hold 4 × 4½ can easily be made to hold the ordinary size by putting a piece of ¾ inch board inside. But if 'J. B.', 'A. T. W.', 'W. J. T.', and others, prefer the size they have adopted let them stick to their first love. As regards the argument that the sections ought to be of a size to fit the standard frame, who, I ask, is there among advanced bee-keepers that toys with fixing sections into ordinary frames? Those few that still work on the back supering system use frames the width of sections. Experience has proved to me that bees will work in sections over the brood nest when they will not look into sections at back (with excluder zinc between). The little difficulty about the crate of 21 sections not covering the frames will I opine be shortly removed by the makers of broad-ended frames, who, by a little alteration of their machinery, leaving the distance pieces a little longer, and 'presto' the job is done, the crate will cover the openings and also conserve the heat of the hive.

Wasps.—Queen wasps everywhere; have never known such numbers as this spring; day after day I have been waging a war of extermination, but still they come. Early in the morning I have hunted for them among the wraps of my few straw skeps, and in the heat of the day I have been in search of the yellow-jacket brigade around the fruit trees.

Glazing Sections for Show.—'Friar Tuck' need only glaze his sections and not his crates also, but I may tell him if he glazes his sections he will be far more likely to find a customer for them at the show than if he sends them in a glazed crate. Then again, unless 'F. T.' has his crates made to take glazed sections, he will find a difficulty in getting them in after they are glazed (let him see to that matter in time). The screw tops he mentions with cork inside will be sufficient, and a word as to bee-keeping for cottagers; there is not the slightest doubt of the *bona fides* of the intentions of the pioneers of Bee-keeping Associations working for the good and benefit of cottage bee-keepers, but there is nothing that can confine any particular occupation to one class, and so others, seeing

the possibility of making a profit by keeping bees, have embarked in the industry, and in many instances, I fear, to the disadvantage of the *bond fide* cottager, who finds himself outmatched in honey production both in quantity and quality by his more intelligent and painstaking neighbour. The only hope for him is to move with the times; in fact, keep abreast of the times, and I maintain, if the labourer takes an interest in his bees, with the machinery of the County Association at his command, he can keep to the fore. Our friend 'F. T.' speaks of his prices of honey; it was certainly a low price if the quality was good, but if he got forty to fifty sections off each hive, I guess he realised a total his father and his grandfather never dreamt of.

Mr. Dobbie omits two good bee-plants, viz., the dandelion and the sycamore-tree.—WOODBLEIGH.

POLLEN GATHERING—QUICK WORK.

[346.] Many of your readers may not be aware of the incredibly short space of time in which a bee will gather a large quantity of pollen and return with it. Most of the following records were taken on Easter Monday between the hours of one and three. The time at which each hive was opened, was recorded, and the numbers indicate the number of minutes which elapsed before the entrance of the first bee with a *good quantity* of pollen. Where they carried but little they were not counted. To gather it the bees had to fly over about three acres of land with intervening trees, buildings, and hedges.

Those of the highest number were in a bad temper and much disposed to sting.—J. RUDGE, *Dursley*.

STINGS AND GLOVES.

[347.] I am quite pleased to see 'A Cottager's' experience, which quite agrees with mine. I have stocks which are quite a pleasure to work with, others which at times are ungovernable (and these latter are the ones, by the way, which led me to abandon the smoker—when they are at their worst it is of no use, when at their best it is not needed). Now, given these two facts, irritable bees and the pain and inconvenience of stings, why should gloves not be worn? Granted that they are clumsy—one gets accustomed to work with them, and as for their causing loss of bee life I don't admit this. If I manipulate carefully it is not often that a bee leaves its sting in my gloves, but should it try give it time and it will usually withdraw its sting by a rotatory motion, except it be one that is determined on death, when it stretches itself flat on its chest in intense anger and draws itself away from its sting. But this would occur just the same on the bare skin. Again, I have often seen bees prick the gloves slightly with the sting and repeatedly, till a vulnerable part was reached—say the wrist when the under gloves are too short, and then in goes the sting deeply. In this case the gloves I should say prevented the destruction of the bee. With all deference to those that are bee-proof, I must still conclude that if I were compelled to manipulate my hybrids without gloves or veil I should prefer to place myself on the retired list of bee-keepers. While on the subject of stings, I have

observed two things not so far as I know mentioned. First that after the sting has become separated from the bee it continues to eject the poison by intermittent and visible contractions of the poison-sac; second, if the nearest tip of the newly detached sting be slightly inserted in the skin the motions of the sting cause it to penetrate more deeply. Can anyone inform me from experience whether indiarubber gloves are efficacious or not? They would be less clumsy.—PAIN NO PLEASURE.

Replies to Queries.

* In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[297.] *Bee Stings.* (Melissa.)—No remedy that I have yet tried is as efficacious as tincture of amica; it takes away the pain at once, and generally prevents any swelling or after-irritation.—F. D.

[298.] *Bee Stings.* (A Cottager.)—I would like to say a few words and give my experience respecting stings. In the first place, I think it depends a great deal on how bees are handled, for if they are manipulated clumsily, they will assuredly sting. The movements of manipulators should be slow and evenly, and I am afraid gloves would add considerably to the clumsy handling of frames; and, in the next place, the odour of a sting remains longer, I should think, in a glove, than anywhere else, but the proper thing to do is to blow some smoke on the place stung; and then again a great deal depends on how a sting is taken out of the flesh—rub it off, not pull it out with finger and thumb. I use a smoker and veil, but no gloves for me; and I feel confident I could manipulate even without a veil and not get stung, unless a bee would run up my sleeve and get squeezed there or with my fingers. I drove fourteen straw skeps last year, and five this year, and I did not get more than half a dozen stings doing the lot, or my manipulations during last year and up to date. I use dried rotten wood in my smoker, which is the best if obtainable.—G. T.

[298.] *Bee Stings.*—Some of your correspondents make inquiries concerning inoculation for bee-stings. Why, if they cannot summon up courage to allow the bees to in, oculate them, or if the bee-sting is too virulent at first should they not try nettle stings at first, for the action of both bee and nettle stings is due to formic acid? I, for my part, suffer nothing from the sting of the nettle, though of course I feel the original prick, but then I am proof against bee-stings, their stings producing no greater result than that of a flea-bite.—E.

[328.] *Untimely Drones.* (E. H. G.)—Your query is not sufficiently explicit to give any decided opinion. Did you see the drones in the hive during winter, as you say they were unquestionably there? Again, where have they gone to? Have you seen them turned out, or noticed any dead ones lying about since? Such an event as drones six weeks ago is not in itself a very extraordinary event; it would be more so to find them in a stock having a fertile mother during the winter.—W. B. WEBSTER.

[329.] *Living Swarms.* (Farmer.)—It is not imperative that you leave them in the skep until evening. After they have settled down quietly in the skep, remove it to where your frame-hive is to stand; you can shake them down in front of same, after tilting it up from floor-board, any time afterwards; but I prefer the evening, as they do not then fly about so much.—W. B. WEBSTER.

[329.] *Living Swarms.* (Farmer.)—I usually get my swarm into its permanent dwelling as soon as I can, and shake the bees into a bar-frame hive among the combs or in front, and let them run in. They seem more likely to settle down quicker this way, owing to the presence of comb or foundation, than if left in empty skep. It is also a saving of several hours' work and loss of time to the bees.—G. H. G.

[329.] *Living Swarms.*—I adopt either plan successfully. Shade the hive in both cases.—A. C. S.

[329.] *Living Swarms.*—Farmer should at once shake out his bees in front of bar-framed hive. I carefully fasten a sheet all along the front, under the entrance, and having

thrown the bees upon it, tilt them towards the entrance by holding up the corners of the sheet. With me they have always drawn in very rapidly, and I have sometimes taken the hive to its allotted place within half an hour of swarming.—CHARLES E. CUTHELL.

[330.] *Thinning Foundation.* (C. E. Cuthell.)—The cause was either the sheets of foundation, not being fixed exactly correct in frame, so that midrib was not in centre; or else combs adjoining had been built with cells longer owing to frames not being correct distances apart. This would compel the bees to lessen the depth of cells on the new frame of foundation.—G. H. G.

[330.] *Drawing out Foundation.*—The foundation was perhaps given when the bees had too much room in the hive or too late in the season.—A. C. S.

[330.] *Thinning Foundation.* (Charles E. Cuthell.)—Your hive was not sufficiently populated to cover both sides of foundation. This often occurs late in the season, when no more storage or breeding space is wanted by the bees. You should not put thin foundation in body of hive; this is only intended for the supers.—W. B. WEBSTER.

[331.] *Honey.* (J. D.)—By your own observations, you may reckon that when there is an abundance of honey-producing flowers in bloom, such as clover, and bees working hard, there is a 'glut' on; when the flowers die off, and bees hang listlessly about the entrance, or try to rob other hives, honey is not coming in.—W. B. WEBSTER.

[331.] 1. *The Honey Harvest* may be said to commence when the honey is beginning to be sealed over. 'J. D.' will easily find out when the harvest is over. The term 'honey glut' merely means that honey is coming in very fast. 2. *Comb Designs.*—Better leave fancy work alone till a little experience in ordinary management is gained.—A. C. S.

[See W. McNally's letter, p. 224.—ED.]

[331.] *Honey Glut.* (J. D.)—The time this occurs differs considerably all over the country, and some years there is scarcely any. In this part of Worcestershire we get ours at the time of the white Dutch clover being in blossom.—G. H. G.

[332.] *Fixing Foundation.* (Dr. Craigs.)—Bar-frames are always a nuisance in an apiary unless the top bar is saw-cut, and unless this is the case the foundation must be fixed as you would do it in supers or large sections, viz., with melted wax.—G. H. G.

[332.] *Fixing Foundation.*—Have a small gluepot (or a make-shift for one) with wax in the inner vessel and water in the outer one. Let the wax be quite melted, hammer an old teaspoon to a narrow point and let it stand in the wax till hot, hold the foundation in position and run a stream of hot wax along the edge of the foundation (which must be cut quite straight to lie close to the top bar) by pouring from the spoon held at one end, that end being tilted up. The hot wax will melt the edge of the foundation as so make a firm joint. Treat the other side similarly. Fuller instructions in a back number by Mr. Hewitt; I cannot give the number as it is lent out. I am breaking up all my saw-cut frames.—A. C. S.

[332.] *Fixing Foundation.* (Inquirer.)—I should purchase fresh frames, they are cheap enough. If you do not do this, and do not care to have a saw-cut made, run some molten wax from a spoon—having its point pinched—along the top of foundation, at its junction with frame; then wire it with three wires, and press wires into foundation with a button-hook.—W. B. WEBSTER.

[333.] *Queen Fertilisation.* (Doctor Craigs.)—No; it is directly opposed to all theories, observations, and experiences of all entomologists and bee-keepers. I should be of opinion that your bees had swarmed without your knowledge; is there any possibility of such an event?—W. B. WEBSTER.

[333.] *Queen Fertilisation.* (Dr. Craigs.)—I do not think a queen-bee is fertilised more than once in her life; but I believe it quite possible and likely for the bees to supersede one when she becomes worn out or injured. How often do we find a Ligurian stock of bees become hybrids in the course of a season or two, proving the superseding of the old queen for a young one of their own rearing. There is a great deal of difference in the egg-laying powers of different queens. I have one now five years old, the head of a most prosperous stock.—G. H. G.

[331.] *Dry Comb-foundation.* (Subscriber.)—The bees will clear away all mould from the foundation; if you wish to bend or alter the wax, by placing the sections in a warm place you will soon be able to put them right.—G. H. G.

[331.] *Dry Comb-Foundation.* (A Subscriber.)—The foundation will become soft on exposure to warmth; bees do not take as readily to old foundation as to new. I should put fresh starters in the sections.—W. B. WEBSTER.

[331.] *Last Year's Foundation.*—Hold it before the fire for a few moments, both sides, till it assumes its former appearance.—A. C. S.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[348.] *French Work on Bees.*—Will any one kindly give me the name of a French work corresponding in character to *Modern Bee-keeping*; clear and simple, and such as an educated person could easily understand?—F. D.

[349.] *Dead Bees.*—On examining my hives on the 12th inst. (it had been raining all day) I found there were about 100 dead bees on the alighting-board and inside about a pint of dead and dying bees. Can any of your readers tell me what is the cause of it?—J. W. S.

[350.] *Spreading Brood.*—If, although one has been careful to keep dummies crowded with bees when spreading brood in spring, hot sun and cold winds suddenly kill so many bees that two or three frames of brood are left without bees, is it better to remove these frames, brood, and all, or allow it, chilled as it is, to remain, in hope some of it may hatch out?—O. W.

[351.] *Rearing Young Queens.*—I found in a second swarm (cast) last year, three weeks after swarming, twenty-seven young queens in all stages. The skep was about half filled with comb, and worker brood also laid symmetrically and in all stages, but no drones. The queen was found and to all appearance was all right. Has any bee-keeper had a similar experience, and to what reason does he condescend for the rearing of the young queens by the bees? Several were running about the combs mixed with the ordinary workers.—G. H. G.

[352.] When supering a hive containing six frames with a twenty-one 1-lb. rack of sections, what is the best way of stopping up the open space where the rack does not cover the frames to keep the bees from getting into the space behind the dummy board?—YOUNG BEE-KEEPER.

[353.] *Sections containing Brood.*—What would be the effect of placing sections containing brood (having been hung in the hive) in the section racks? Would the queen be more likely to visit the other sections in the racks? Would the bees take to the sections more readily?—J. C. T.

[354.] *Finding Queens.*—I have as yet only kept black bees, and find, in manipulating them, the less smoke used the better, especially in finding a queen; the chances of speedy success are greater if no smoke is used at all. I should like to know if these views coincide with those of your other readers.—CHARLES E. CUTHELL.

[355.] *Early Destruction of Drones.*—In one of my hives drones are being hatched daily, but no sooner do they appear than the worker-bees kill and turn them out of hive. Can any of your numerous readers tell me the reason of this, and what, if anything, should be done? I have been and am still feeding with syrup.—HUMBLE BEE.

Echoes from the Hives.

Alfriston, May 15th.—I have not heard of any swarming yet. We have had very little good honey weather as yet. Weather is cold and rainy, and to-day we had a small shower of snow. Apples and other fruit-trees are nearly in

full bloom, rape the same. Rillk is just beginning to open; this is one of our best honey plants, although the farmers do not like it among the corn.—YOUNG BEE-KEEPER.

Fromspore, Worcester, May 16th.—We have been experiencing here the last five days most miserable weather for the bees; rain, rain incessantly from morning to night, and in many parts of the country nothing to be seen but water for miles. The barometer is now rising, and when the fine weather appears, our bees will have a right glad-some time of it. First swarms in this district I have heard of occurred at Goosehill Farm, Hanbury, on Friday and Saturday, May 7th and 8th. Queen-wasps are more plentiful than I ever remember seeing before. Large numbers have been destroyed round here.—G. H. G.

Dublin, May 13th.—We had splendid weather up to Sunday, the 9th instant, but ever since it has rained without ceasing, accompanied by cold east winds, more like December than May.—C. A. J.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

TREF EGLWYS.—*Fooling Queen.*—See 'Extractor,' p. 217.

DURBELL.—We should suggest, if you desire to have a swarm, that you should make it artificially after one of the usual methods: this would be preferable to your hazarding a failure, which would probably be the result of the plan you propose to adopt.

A YOUNG BEGINNER.—As you appear to have failed in driving, we should recommend you to wait until the bees swarm, and then put the swarm into a frame-hive and leave the stock until twenty-one days, when all the young bees will be hatched out. The honey may then be taken and the bees put into a second frame-hive.

RENWOOD.—1. *Securing Foundation.*—If the foundation when inserted in the sawcut should prove loose, it might be securely fixed by a few French nails passing through the wood and wax. 2. *Early Swarm.*—May 5th was an early date for a swarm, but we should not attribute this to your having unduly spread the brood.

J. M. P.—The comb forwarded has an unpleasant smell, betokening incipient foul brood. The interiors of the capped cells have dried up.

G. LEDGER.—The two bees forwarded are Ligurians; but this does not determine that the bees in the hive are pure; they may be hybrids.

G. H.—1. *Sections.*—The rack of sections may be placed on twelve frames. 2. *Sealed Stores.*—The sealed stores should be uncapped, as required by the bees.

A. E. A. E.—We should not extract the frames. Continue building up your hive, and you will be prepared for the honey harvest when it comes.

J. MASON.—*Bacillus depilis.*—Your bees are suffering from the above disease. Use phenol according to Mr. Cheshire's directions. All dealers in appliances supply it in bottles at 1s. each. See 'Useful Hints,' p. 383, vol. xiii. *B. B. J.*, for description and cure of disease.

ALLISON.—*Pollen-Combs.*—Do not put the combs containing old and hard pollen in the centre of the brood-nest, or you will seriously retard the work of the colony. Place them on the outsides of the nest, and the bees will soon remove the pollen and prepare them for receiving brood.

J. D. MORRIS.—*Hive, Bees, &c.*—1. The 15-frame size is best, as the whole number of frames need not be used except when required. 2. The Italians. They are most gentle and good workers, and queens very prolific. Obtain good imported queens. 3, 4. Cyprians, or Syrians, next, but they are not so gentle. The crosses of these races with Italians are best of all, both as regards temper and work.

AMATEUR, Herham.—1. *Beer in Syrup.*—No harm will be caused. The reason of acceptance when refusing plain syrup is that the smell attracted them, while the slight smell of the plain did not reach them. 2. The appearance you mention does not indicate dysentery, which would be shown by dark brown smears inside the hive and on the alighting-board. It is unusual, although not a sign of disease.

A. F.—*Parker's Foundation Fixer.*—Fasten the fixer to a table or bench; put a little honey or thin starch where it is to touch the foundation. Slide the section under the lever against the stop; put the foundation under, one-eighth of an inch, raise the back end of lever and turn up the foundation at right angles against the point, and with a sliding motion draw back the lever. If the wax is not very hard, the foundation will be found to be very firmly fixed.—*Cowan's Guide-Book* (p. 64).

G. CLARK.—The bees forwarded are evidently affected with the bee-disease which goes under the name of *Bacillus Gaytoni*, or *depilis*. This is evident from the hairlessness and the shiny surface of the abdomen. See reply to J. Mason.

ENQUIRER.—1. *Hive with bad Smell.*—As you do not describe the smell, it is impossible to say the cause, as you say you found no visible symptoms of foul brood. The camphor can do no harm, unless sections are being filled, when it might possibly communicate a flavour. 2. *Solution of salicylic acid.*—This is nearly insoluble in water. Add 1 ounce borax and 1 ounce salicylic acid to 4 pints of water, and add of this solution 1 ounce to nearly a gallon of syrup. 3. *Ligurianising.*—You can hardly Ligurianise your apiary from one stock of Ligurians, as the young queens will almost certainly mate with black drones, and their progeny will be hybrids. The method of queen-raising has been frequently described in our columns, and you will find it also in any good text-book. It is certainly very unusual to find black bees still existing in a stock which received a Ligurian queen last August. Possibly a weak stock of blacks has united itself to the Ligurian stock.

ERSON.—*Swarming artificial, &c.*—1. Your proposed plan will do, but the operation must be performed at midday, when bees are flying, and you must fill up the new hive with frames of foundation or comb. The stock to be divided must also be full of bees and brood. 2. Sawdust will do, but cork-dust is better. 3. Decayed apples, &c., are visited by the bees on account of the saccharine matter they contain. 4. Piling up one hive upon another, or super upon super, to any number which the bees can occupy is usually termed 'storifying.' *Doubling* is working with two hives only, of precisely the same dimensions, and interchangeable in all their parts. The frames of upper hive are extracted and returned as often as filled. 5. A sixteen-frame hive is too large for storifying. One containing twelve standard frames is quite large enough. 6. The number of supers required will depend upon the colony, the honey yield, and the size of the supers. Two or three racks of twenty-one 1 lb. sections, given as required, will usually be found sufficient in a fairly good season. If body-frames are used for storifying, one or two, according to bees and season. 7. No. The additional box must be given above, not below. 8. Ten or twelve standard frames.

A. W. C.—*Preventing Swarms.*—You may prevent the issuing of swarms by giving room in the hive by the frequent insertion of sheets of foundation. Your question is rather obscurely worded, but we presume that this replies to it. 2. *Inserting Frames in Hives.*—The frequency depends upon the strength of the stock. Unless the seven frames are all filled with brood, and a large population hatching daily, one frame a-week at present would be too often.

F. J.—*Camphor in hive when sections are being filled.*—It is probable that the honey may acquire the taste and smell. Extract a little from the stock hive and test it. If that has no taste or smell, the sections are still less likely to be affected. It would certainly be safer to discontinue the use of camphor while sections are being filled.

INQUIRER.—The comb with bees thrust into cells was not affected with foul brood. The bees had died of starvation.

INQUIRER.—The three larger wasps were, as you presumed, female or queen wasps. The fourth was a wasp that is found in all parts of the world. It delights in making its nest in old posts and rotten wood, but has no objection to take advantage of a ready-made excavation. Its specific name is *Odoneris quadratus*. It has very pretty markings.

CUMBRIAN.—1. *Effects of Cold Weather.*—Your bees have ceased to carry in pollen and the queen to lay eggs on account of the cold weather. You may have also chilled them by undue examination. 2. *Foundation.*—The sample of foundation sent is too dark for sections; none but the finest quality should be used for them.

THOROUGHNESS OF BEES.—The feverish anxiety, the intense eagerness, the earnest individual effort, the unceasing perseverance, the seeming (only seeming) recklessness, the unwearied diligence, the strong desire, the single intention to make hay while the sun shines, to gather honey and pollen when the opportunity offers, with the immediate seizure of every such opportunity; the haste to be rich, but in a perfectly legitimate way, by its own unaided labour; the evident full enjoyment of work for its own sake and for the community, the steady application, the undivided attention, the untiring earnestness, which is not diverted for one instant from the great work in hand; the immediate and unwearied attention to details as part of a whole grand scheme, though the end may be unknown to the worker. The doing with the whole might, and force of mind, and power of intellect, and strength of body and soul, and help of conscience, the little, or much, brought to our hand to be done, are some of the true lessons to be read, studied, pondered over, learnt, made our very own, and incorporated with our daily life, from the little busy bee, of which Dr. Watts said—

'How doth the little busy bee
Improve each shining hour,
And gather honey all the day
From every opening flower.'

APIS.

BEE GLOVES.—There have been many inquirers as to the best bee gloves. The best and cheapest I know are the smooth white leather ones made by Reynolds, High Street, Andover, to which gauntlets of net or holland to extend over the elbows, with elastic run in, must be attached. These do not aggravate the bees as any kind of tanned leather does, which they seem to sting for the mere fun of it, even if hung upon the hedge. Of course I hardly ever wear gloves myself, but with very vicious bees I always find these efficient.—W. E. BURKITT.

WASPS.—About a week ago I killed over an hundred, and there are hundreds more. I find them plentiful about the gooseberries and pears. They seem to me to get larger in size than they were when I first noticed them.—JAMES HOLME, *Ambleside, Windermere.*

QUEEN-WASPS I find wonderfully numerous this year, though I destroyed all neighbouring nests last year. I killed fifty-seven last week on our gooseberry-trees with my finger and thumb (they will not sting if you do not tickle them), but since Sunday, May 9th, I have not seen one.—W. E. BURKITT.

QUEEN WASPS.—I never saw such an extraordinary number of the above as there are this year. They seem to feed especially on the blossom of the black-currant, which is out here in abundance. One day last week my gardener and myself killed more than twenty in my small vinery, and on several occasions we have killed as many as five or six in a day.—A. H. MARTIN, *Eresham.*

J. I., F. D., and others, write to the same effect respecting the prevalence of female wasps.

STINGS.—Seeing the answers in *Bee Journal* to 'A Cottager,' perhaps my experience of Sunday evening last would not be out of place. When at about 5.30 p.m., I was in the garden, and got stung in the forehead above my left eyebrow. The sting was immediately taken out, and carbolic acid applied with a drop of water after, as advised in *B.B.J.* I need hardly say that it burnt and tingled for

about an hour afterwards, but this I would not mind, it is the dreadful way I swell that makes me wear veil and gloves when manipulating, and run from the approach of a bee when unprotected. Well, to give an idea of what a solitary sting can do for me, I must explain that I am writing this on Tuesday morning with one eye only, my left one being closed up, as it has been since a quarter to eight on Sunday evening, and my left cheek stands out with fatness, and would, I am sure, compare with the fattest prize baby ever seen; my forehead, too, has developed most marvellously. I must add that this is far from my first sting, and that I always swell dreadfully. My doctor says that is owing to the softness of the tissues of the skin.—ALBION.

BEE-HOUSES.—For some time past our eyes have been attracted by the neat appearance and the interior arrangement presented by the engraving in our advertisement columns of a bee-house manufactured by Messrs. Boulton & Paul, of Norwich. Some bee-keepers do not hold in high esteem these houses, but many who are cramped for garden-room find them an advantage. The Rev. G. Raynor and Mr. A. I. Root, of Medina, Ohio, have had much to say in their favour. Those advertised are very portable, and can be easily put together. They have, as all manipulating rooms should have, revolving windows for turning the bees out. The roofs are of corrugated iron, and the sides and lining to roof are bee-proof. The manufacturers may be depended on for their workmanship.

Received from Messrs. Howard and Meadows a Raitt Fume Chamber, with a spray diffusing brush, a description of which will be given next week.

A match-box has been received containing, according to a correspondent, a red insect which had been troubling him. The box had been broken in transmission through the post-office, and the insect had escaped.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANOEWAYS' PRINTING OFFICE, Tower Street, St. Martin's Lane, w.c.

[No. 205. VOL. XIV.]

MAY 27, 1886.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

Special attention is called to the following arrangements:—

Prize-lists for the Bee Department at the Royal Horticultural Show at Liverpool are now ready. Entries close June 10th.

Prize-lists for the great National Show at South Kensington, to commence on July 30th, will be issued in the course of the present week. Entries close June 30th.

The pamphlet on the management of Straw Skeps has been translated into Welsh, and is now ready for sale.

SOUTH KENSINGTON EXHIBITION.

The following donations have been added since our last issue:—

D. A. Thomas	£2	0	0
Collected by Miss Collins, Essex					
District Secretary	0	10	0
Miss Eytton	0	10	0
Previously acknowledged	141	15	0
			£144	15	0

PARENTAL AUTHORITY.

The discussion at the last Quarterly Conference of the motion moved by the Rev. F. S. Selater was very opportune, though some of the delegates seemed to think that it was unwise on the part of the parent Association to make any more stringent regulations than at present exist, because of the probability of some of the children turning restive and kicking over the traces altogether.

It is a point we are constantly insisting upon, though too often forgotten, or at least misunderstood, and that is, that the affiliated Associations, not only collectively but individually, get back from the parent Society much more than the value of the affiliation fee. In a former number we discussed the advantages of having some central authority, and so now we would the rather consider its judicial power.

The need of some court of appeal is obvious to any one, and that this naturally should be the B. B. K. A. is still more obvious; though, of course, the final court of appeal is the general body of bee-keepers, who are members of one or more of the Associations.

For instance, it is quite possible that the B. B. K. A.

might lose touch of the general (bee) feeling on some matter. If it was on some matter of vital importance, at the next annual election of the Committee only those would be returned who promised to rescind the obnoxious edict, and again the B. B. K. A. would represent, as we believe it does now, the true feeling of British bee-keepers.

The rule that every affiliated Association should send in its annual report and balance-sheet is not only for the chance perusal of bee-keepers, but that the Central Committee might be able to judge how each and all were progressing.

It might occur that some or more were not worthy of being affiliated, or that there was evidently a strong party in opposition to the existing county authority. It would be then the duty of the B. B. K. A. to establish some *modus vivendi*, or, if that were impossible, to consider whether the erring Association should be allowed to continue in affiliation, or whether it would not be better to recognise the opposition.

This, of course, would be an extreme measure and only to be used with great caution, for if it were not approved by the general body of bee-keepers, the B. B. K. A. would be inevitably wrecked and without benefit of clergy.

If the B. B. K. A. were to have no control whatever over the acts of its children, it would be simply on a level with the County Associations, and not the fostering parent of each and all.

BRITISH BEE JOURNAL.

To a great extent the departure of an enterprise from its ordinary course is an experiment. In the history of the *British Bee Journal* there have been several of these departures. These have scarcely been the outcome of any disposition of our own will, but have been in a measure forced upon us by the development of the industry of which the *Journal* has attempted to be the faithful exponent. Perhaps it may not be possible to separate these two—the rise and progress of the honey industry in the country and the continued expansions of the *Journal*—from each other. It would be more in accordance with facts to say that the two have proceeded *pari passu*,—both mutually helpful of each other in their onward march. The honey industry has advanced by leaps and bounds to its present position, while the *Journal* has during the same time passed through diverse transitions.

We are not now desirous of stating the increase of bee-keeping, or of quoting statistics in support of our statement, the fact is patent to all; suffice it for the present to say that bee-keeping and honey-producing is rapidly becoming one of the most important 'minor' industries of the country, of the extent of the future of which we have at present but a faint idea. The numerous county Associations; the large and increasing numbers comprised in these societies; the publications which treat of the economy of the bee, either wholly or in part; the Honey Companies, established for the sale of pure British honey; the interest taken in bee-culture by every village and hamlet, all proclaim the truth of our assertion. We have rather at present to note the continued progress of the *Journal*, and we feel it is our just duty and our grateful privilege to state to our numerous supporters, subscribers, contributors, and last, not least, our advertising friends, that our last departure—its production as a weekly *Journal*—has eventuated in a success. Our circulation has been maintained, our advertising connexion has been increased. The *Journal*, like the bee it illustrates, has now passed through various stages. In the bee we have, first, the egg, then the larva, then the pupa, then the imago, or the perfect insect. The *Journal* had its beginning as a monthly; it was launched forth on the world with much diffidence and many tremblings; but, fortified by the encouragement given to, and the interest taken in, the adventure, it in course of time developed into a bi-monthly; and, increasing in strength, we took heart of grace, and advanced to a weekly. Can we consider our work yet to be complete? Have we no more changes to pass through? Have we arrived at the imago or perfect form of publication? We cannot assert that we have; our full purpose cannot be said to be accomplished, or our aspirations realised, till the *British Bee Journal* is published weekly at the price of one penny. For this, however, we are content to hope and wait; and we struggle and press forward to this goal, being assured that if we continue true to the trust reposed in us,—if we prove increasingly anxious to merit the support which has been so generously accorded us, the time will soon come when we shall be able to take the position to which we aspire, and that time will be shortened in proportion to the assistance which our friends will give us.

In the meantime its present weekly publication has brought us into closer communion with our readers; it has given us a wider scope for our operations; it has enabled us to reply to our subscribers with greater facility; and its special features of Selected Queries and Replies to Queries have elicited much interest.

We are pleased to say that we are daily gaining new subscribers. The *Journal* has many friends in Scotland and in Ireland; it finds its way to New Zealand, Australia, Cape Colony, Canada, the West Indies, to the United States—in fact, we may say without exaggeration that it is read wherever the Anglo-Saxon language is spoken. It is our desire and our ambition to maintain the position we have achieved, and with gathered experience to continue to progress in the future.

We again thank our friends and contributors for their kindly countenance, and trust that they will continue to render to us their welcome assistance and patronage.

USEFUL HINTS.

As an Englishman is known, all the world over, by the interest he takes in the weather, our usual opening remarks will at least assure our friends of our nationality if they serve no other purpose. Since our last, then, the bright anticipations of 'glorious summer' having at last arrived have been sadly nipped in the bud. An Essex gentleman, writing from Barnard Castle on the 13th inst., states that—'The moors of North Yorkshire and Durham are entirely covered with snow,' and accounts of storms, floods, and cold ungenial weather, are the rule and not the exception. So sudden has been the change from summer heat 'to winter's cold' that supers have been removed by many, and feeding recommenced. But again we have a pleasant change, which, let us hope, may be more lasting, and that we may yet obtain the wished-for harvest from our bees.

THE NORWICH SNOW, for which we are happy to learn that there is a large entry in all classes of the Apianian Department, is likely to prove a great success. The paragraph of explanation respecting the requirements of the 'hive for doubling and sectional purposes'—that is to say, the best hive for general purposes—in our issue of May 13th is entirely satisfactory, and has conferred a boon on all who intend to exhibit in this class, as there can now be no shadow of doubt as to what the Association requires.

SMOKING SWARMS.—On more than one occasion we have known swarms to be destroyed by injecting smoke. The novice, anxious to see 'how the swarm is getting on,' armed with his smoker, in fear of stings, injects puff after puff into the newly hived swarm, on the second or third day's occupation of its new domicile, forgetful that the honey-sac of every bee is gorged, and the small amount of comb built most fragile; when, as a natural consequence, the poor bees, alarmed and excited, disgorge their honey, the whole population becomes a clammy mass, and perishes in the midst of its fallen combs. We are cognisant of cases where smoke has been administered to a swarm, with the view of *quieting it*, before despatching it by railway, or otherwise, to a friend or purchaser, and the swarm on its arrival has been found defunct from the above-named result. Since our 'Hints' are intended to warn the inexperienced against 'how not to do it' as well as to teach them 'how to do it,' let such make a note never to use smoke, carbolic acid, or other 'intimidant' in the case of swarms. Indeed, during the summer months, while the honey-flow is on, it is best to dispense with all irritants and intimidants whatever, and simply to manipulate 'with quietness and confidence' whenever manipulation is necessary. We must, however, except such operations as removing a super, or introducing a queen.

WATCHING FOR SWARMS.—June, the great swarming and honey month of the year, is close upon us, and all apiaries should now be closely watched or swarms will be lost. Many a new beginner loses swarms without being aware of his loss. Often and often have we, on returning home after a day or two's absence in June, found swarms on the neighbouring bushes or trees around our apiary, notwithstanding the fact that our gardener and his boy have always *strict charge* 'to watch the bees.' Lawn-mowing, or some other gardening operation, requires attention, the bees are left for *just ten minutes* (half an hour?) and the swarm departs! 'Most sure to go, sir, when we isn't looking!'

REVENING SECTIONS.—Bees finish the tops of their combs more perfectly than the bottoms, and this remark applies to sections, as well as to brood-combs. When a case of sections is half completed, by inverting the whole we may, therefore, get our sections better and more evenly filled. By looking down between the rows of sections we can see when the tops are finished. If at that time the honey-flow continues unabated, and our colony is strong, let the section-case be inverted, and

another empty one be placed beneath it. The inversion, and giving room below, will cause the bees to work with renewed energy, and the sections will be finished alike at top and bottom. But failing invertible cases, the system of tiering up should not be neglected, since bees will often swarm when a case of sections is only half filled, while if more room had been given swarming would have been prevented. As soon as the brood-chamber is crowded with bees, and the tops of the combs are becoming white, from the addition of new wax in lengthening the cells, is the proper time to put on sections. Too much attention cannot be paid to conserving the heat around the section-case. So changeable is our climate that if 'super coverings' be neglected and a cold or frosty night, or a stormy period of a few days occurs, the sections will be deserted, and the work delayed. The best sections are invariably those which are most quickly completed.

FOUNDATION for sections should be the thinnest and lightest that can be procured, and it is immaterial whether the sections be filled, or merely the V-shaped pieces be used. Not so, however, with brood frames. If these be only half filled the lower half will be built out with drone comb—a most serious disadvantage, leading to the production of an excess of drones, and ruining the colony in many cases. If you do not wish for drones, let your brood-frames be filled as nearly as possible with worker-celled-foundation.

CROWDING INTO SECTIONS.—It is a common practice with many apiarists to reduce the size of the hive by removing the outside frames when putting on supers, thus confining the bees to the central, or brood, frames, when, from want of room, they are more easily induced to take possession of the upper storey. The chief difficulty in effecting this is the exclusion of the bees from the vacant spaces, caused by removal of frames, at the sides of the hive. Unfortunately few division-boards are made sufficiently close-fitting to prevent the passage of bees, which, obtaining an entrance, soon fill up the spaces in preference to working above. Before giving the supers, therefore, the close-fitting of the division-boards must be ensured, and strips of wood to cover the spaces from front to back of hive must be provided. These are always useful in manipulation when removing frames for extracting or otherwise, and should be of the length and thickness of the top bars of frames, varying in width from one to three inches and a few of $\frac{1}{4}$ inch only to fill up gaps.

DIRECT INTRODUCTION OF QUEENS.—Mr. Alley, an American apiarist of note, and author of a book on queen-raising, gives the following directions for immediate introduction of fertile queens:—'Subdue the bees by tobacco smoke at evening, and remove the queen of the hive. After closing the hive give more tobacco smoke, but not sufficient to cause the bees to fall from the combs. Next, allow the new queen to run in at the feeding-hole or at the entrance, and continue to give more or less smoke for a period of fifteen minutes, being careful not to stupefy the bees.' Mr. Alley successfully introduced eight queens in this way in two hours, and the bees were at work again the following morning as if nothing had happened.

CHANGING PLACES.—When the bees of a colony—from whatever cause—have dwindled, but have a prolific queen depositing from two to six eggs in each cell—an occurrence by no means uncommon at this period—we have found the old plan of changing stands with a strong colony answer remarkably well. On a fine day, when bees are in full flight and honey is coming in rapidly, cage the queen of the weak colony on a brood-comb, and remove the hive to the stand of one of your strongest colonies, taking the latter to the stand of the former. On the following morning the queen may be released, and the weak hive will soon become strong. It is not necessary to cage the other queen, there being no danger to her

from the few stranger bees returning from the fields. If the above directions are strictly followed fighting will rarely ensue; but if there is any disposition to rebel a few puffs of smoke will soon quell it. Where it is desired to equalise stocks, in preference to obtaining a large honey yield, there are few methods superior to this.

QUEEN WASPS.—*Apropos* of the conclusion arrived at on this subject in the closing paragraph of the interesting article on 'female wasps' in our last issue, we give the following, written some twenty years ago: 'There need be no alarm at the number of queen wasps which have made their appearance, as it by no means follows that they will produce a nest a-piece. For several years I have noticed their abundance or scarcity, and certainly for six in succession the numbers in spring and autumn bore an inverse ratio to one another. The first year I noticed it was in 1847, but I believe it was in 1852 or 1853 that some articles appeared in the *Zoologist* on the subject; and it was shown that out of some hundreds of queen wasps dissected in a year when they were exceptionally abundant none showed signs of impregnation. A friend of mine has sometimes paid as much as 5l. or 6l. a-year for the destruction of queen wasps, but I never found his fruit (or bees?) less damaged than my own. ALIQUIS.' In our own experience by this time the fecund female wasp may readily be distinguished from her unfertilised sister by the size of the abdomen, and the leisurely mode of flight. Earlier in the season it is, of course, mere difficult.

THE KOHLER PROCESS.—As we are often asked for an explanation of this method we give it concisely below. It is a method of procuring the fecundation of young queens by selected drones, and, therefore, of breeding any race of bees—as Italians, or Syrians, for instance—pure, and was first practised by Herr Kohler, a noted German apiarist, whose name it bears:—When a young queen is hatched out in a nucleus-box (or in any other hive) pure drones of her own race are selected and confined with her in the same box for two or three days. Then on the afternoon of a fine day, when all other drones in the apiary have gone to rest, and the queen is judged ready to take her wedding flight, the hive is opened. As might be expected, the queen and her companions immediately avail themselves of their liberty and a pure breed is secured. Should the first tour prove unsuccessful the hive is again shut up and not opened until the following afternoon. The closed hive should be removed to a dark and cool room, while the bees are under confinement, and removed to its accustomed stand before the bees are set at liberty. Feeding with a little warm syrup before the flight takes place will expedite the process. Baron von Berlepsch, writing of this method in the year 1867—when it was first introduced—says: 'I have tested the discovery at six different times, and on every occasion it has proved successful.' With ourselves it has rarely failed. Sufficient ventilation must be afforded to the hive while the bees are confined, or serious consequences may ensue. Since the Baron's time most prominent apiarists have proved and approved this method.

Correspondence.

THE 'RAITT' FUMIGATOR.

[356.] Before describing the above it is well to apologise to Mr. Raitt for using his name in connexion therewith, Mr. Raitt giving his practical experience with carbolic acid in numbers of May and October *Record* for 1885. It is only just to say that he pointed to the advisability of using carbolic-acid vapour, and I determined that all smoker-barrels for the next season should be so prepared, and the appliance bear Mr. Raitt's name. Such was carried out so far as the smoker-barrels were concerned,

but, from want of time and my co-worker, Mr. Meadows, being at a distance, the opportunity did not occur till now to complete our work. I send you the smoker and carbol-holder, which in its simplicity explains itself, yet it may be well for those who have not the appliance at hand to describe it. It will fit any smoker-barrel which is not less than $1\frac{1}{4}$ inches diameter inside by $4\frac{1}{2}$ inches deep. Smoker nozzles having grate attached, such grate must be removed. The original smoker-barrel has grating at bottom which in practical work I have found far before those placed in nozzle.

A is a funnel which, when rapidly filled, holds sufficient carbolic acid to charge wadding in B; when so charged the diaphragm at C prevents any acid being thrown out of nozzle. D is draught space where carbolised air passes by action of the bellows. E shows position of carbolic charge in original smoker. The holder is made of tinned wire $\frac{1}{2}$ -inch mesh, giving but small resistance to draught in comparison with brown paper or other smoke agent used in ordinary way. For fumigating the crude or black acid is preferable. As many persons will still prefer to use smoke, it is a matter of importance that a choice of utilising the present smoker for fumigation at a small outlay should be given. This the 'Raitt' effects.

To save bee-keepers' expense (in these hard times) it may be worth describing how I have applied carbolic in spring and autumn manipulations, using saturated calico for my surplus honey gathering. Take a quart of water, and add thereto one ounce of Calvert's No. 5, at the same time add five or six drops of glycerine (this has no effect beyond the more effectual uniting of the acid and water). In a corked or capped vessel place the mixture, exposed to sun or warmth of room prior to using. Apply the same in spray form, so soon as quilt is removed, from a 2-inch or 2 $\frac{1}{2}$ -inch flat brush (sample enclosed), of course allowing time for filling of honey sacs, and re-application of spray, if necessary, before handling. This method will quiet *any* race or colony, and is far more effective and time-saving than any other method of subduing I have practised. I will not name it a *new* method, for in bee-keeping, as in other things, there is nothing new. A particular application only may be so.

Carbolic-acid vapour is effective, but when used in equal proportions of carbolic acid and Liq. ammonia doubly so. For making the best of one's time on expert tours, and in a large apiary, I prefer spray treatment beyond any. The carbolised water not only prevents loss of bee-life in manipulating when properly used, but is a healthful disinfectant to the colony. It can also be applied to any part stung, to gloves if used, or for dressing hands prior to handling another colony, thus destroying the scent which may remain of last colony handled. From recent experiments I have proved carbolic spray will not affect or injure sectional honey, especially such sections as are left to bleach, as recommended by Mr. Simmins. Still, carbolic vapour, either injected by fumigator or allowed to act from calico sheet (originated and recommended by our old friend the Rev. G. Raynor) would be preferable to many, no doubt. I write with no view of defending anything herein given, from want of time, still I shall be happy to answer any queries through the *Journal*.—JOHN H. HOWARD, *The Apiary, Holme, near Peterborough.*

DRIVING, &c., (339.)

[357.]—The way of driving spoken of by 'South Glos' is not new. At Louth (September 8, 1881), at a *conversazione* held in the Town Hall, I gave a description of same thing, told me by an old cottager whom I met in a railway carriage.—(See *B. B. J.* October 1, 1881.)

PARKER'S FOUNDATION FIXER.—(P. 229.) I take it I must be getting very clumsy in my old age, for I cannot find that that fixer is at all equal to the one of young Abbott's. I want nothing better, I have filled many hundreds of sections with the little roller. I don't like Parker's. My bees have taken three dozen of the twopenny packets of Symington's pea-flour. I don't trouble meself with making artificial flowers,—thank you. I have an oak table in my garden, where I picnic my bees (neighbours' too, I daresay). They (my bees, not my neighbours') rush at the yellow packets before I open them. Sir John Lubbock is right, they understand colour.—J. LAWSON SISSON.

THE WELSH SKEP PAMPHLET.

[358.] Here we have got at last the long-promised 'Skep' pamphlet, the first Welsh publication from the British Bee-keepers' Association, but translated very carelessly, and by some one that knew nothing about bees. There is much difference between a stock and a swarm, but in this pamphlet they are both called 'swarms;' and the floor-board called 'wood-floor,' and that it should be 'hard' instead of 'sound;' that 'a piece of timber should be provided by the entrance for the bees to alight upon;' For 'the space between the sides of rack and the outer casing can be filled in with chaff, and a small chaff cushion pushed in at the end will keep the sections close together;' we have 'The notches between the edges of the box and the outer side can be filled with bags of fine chaff, which will keep the sections safe together.' Not a word is said about the cheese-box, which the English pamphlet says would answer very well as a stand to place the skep upon. We are here told that bees, when swarming, will leave the hive in 'constant multitudes.' For 'upon the floor-board on the ground,' we have 'upon the ready wood floor.' For 'after-swarms or casts,' we get 'after swarming;' and for, 'If these be lived, however, all the queens but one will be destroyed,' we have, 'But if they are got into a hive, all the queens except one should be killed.' Under the head of 'Driving,' or 'Driving out,' as our translator puts it, we are told that 'false swarms must often be made;' and he is very misleading in describing the mode of driving, that the bees, after a minute or two, will begin to 'fly up;' and if the weather be chilly, that they will drive much more easily if, after smoking, we 'pour between each comb about half a pint of warmed syrup, and allowing them about a quarter of an hour for licking it'—very short allowance, we should think. And what next? Well, we are told that bee-keepers now-a-days have a mechanical way of making swarms, called 'mechanical swarming;' and in describing this sort of swarming, for 'During driving keep a sharp look-out for the queen, and if she is seen to go up drive out about half the bees in the hive,' we have, 'Whilst driving them out keep a sharp look-out for the queen, and if she is seen taking her wing send half the bees out after her,' to fetch her back likely. Then we are told to 'put the swarms on both ends of the old stand;' 'That sections holding two or three pounds are now generally used; for 'rising young bees,' we have 'feeding young bees;' for 'flour-candy,' we have 'ground-candy.' After filling the feeding-bottle, we are told to 'place over its mouth a small fire-shovel;' with many other misstatements. We feel very sorry that the first Welsh publication from the Association is marred by so many errors. We do not think that it will be of any good to give it circulation in its present condition, because it contains

so many ridiculous statements: it will only produce greater suspicion in the old Welsh bee-keepers against the 'new-fangled notion' of the modern system. The sooner the better to have a revised version of it adapted for the Welsh. But we hope that the Association will be more careful of it next time. We understand that they intend to bring out a Welsh translation of *Modern Bee-keeping*; we would suggest to them a better plan to get it done—that is, to give a prize, say of two or three pounds, for the best translation of it, or for the best treatise in Welsh on modern bee-keeping, including the subjects treated of in *Modern Bee-keeping* and the 'Skep' pamphlet at the National Eisteddfod, which will be held next year in London. Very likely they would get half a dozen or more compositions, and select the best and get it published, which would be a great boon to the Welsh bee-keepers.—CELFOFYDD CYFARWYDD.

LARGE-SIZE WORKER FOUNDATION.

[359.] I cannot induce my bees just now to build worker-comb. I have placed several whole sheets of Abbott's large-size worker-foundation in two or three strong stocks, and in each case, I am sorry to say, they have worked out *drone-comb*, which is so much waste of time. Kindly inform me through the *B. B. J.* my best plan to stop this.—J. J. CHINICK.

[The queen could do no otherwise than she has done. Possibly, she was puzzled when she came athwart some cells which were neither worker nor drone size, which you describe as 'Abbott's large-size worker-foundation;' but being larger than worker she naturally dropped a drone-egg into them. The mistake was your having placed such foundation in the brood-nest. The comb should either have been placed behind the excluder or in the supers. We presume the foundation is that described as No. 4 in Abbott's catalogue, the cells of which are four and a quarter to the inch. The catalogue clearly describes the purpose of this special manufacture as 'being strongly recommended for combs intended for the extractor.' We can only suggest that these combs should be removed, and true worker-celled foundation substituted in their place.—Ed.]

WEBSTER'S FUMIGATOR.

[360.] When I made my remarks on a simplification of Mr. Webster's fumigator, I did not suppose that gentleman intended to manufacture or deal in the article, or I would have left it to sink or swim, according to its merits, in the medium of public opinion on which it has now been launched. Having thus (according to your advertising columns) become a commercial venture, I will wish it 'bon voyage,' and feel sure your readers will join me in thanking the inventor for giving us the idea of more perfectly vaporizing anything which will assist us in manipulating. The public spirit of your frequent contributor is to be admired, yet he did not increase our obligations by hearkening to 'the voice of the charmer' when you, Mr. Editor, invited him to disclose the name of his, or rather Mr. Cheshire's, new agent.

Mr. Webster is wrong when he suggests that I did not practically test the ordinary smoker in the way I pointed out, and that too without any acid itself being blown into the hive, as I had the sponge well wrung out, not saturated, and when not in use, let the smoker stand on the usual end—uppermost position. Phenolised air must, under such circumstances, have been produced equal to that by the Webster process.

I have not had to wait long for a justification in my condemnation of carbolic acid, and that from the inventor himself, for Mr. Webster stated that he had sent one of his fumigators to Mr. Cheshire, whose remarks showed disapproval of the agent used (carbolic acid), and suggested another found to be successful. I cannot

give exact quotation, as I have not your file with me.—R. A. H. GRIMSHAW, *Crag Hill, Horsforth.*

[In previous communication, p. 223, col. 2, line 39, for Automatically, read Anatomically.]

CHEAP HIVES.

[361.] I have just come upon the following statement in an old number of the *B. B. J.*: 'Letters have appeared from time to time in this *Journal*, showing how useful hives could be made out of the rubbish of a grocer's shop, but we have no records how these hives answered.' Perhaps you will allow me space to give a short description of how mine serve. My hives are made after the plan given by Mr. Hewitt in the *B. B. J.* for 14th March, 1884. They hold fifteen of Abbott's frames (Abbott's new method of fixing foundation is, I think, unequalled), and are deep enough to hold another box of fifteen frames for doubling, or else two racks for sections, total cost for hive and set of frames about 5s. I have only had these hives in use for two seasons, but although they were buried in a snow-drift for above a week, not a particle of wet had got in. For a makeshift I use 'coffee-with-ehicory' boxes; they measure $18 \times 14\frac{1}{2} \times 8\frac{1}{2}$ inside, just the size for standard frames. About five minutes' work is all that is required to make as good as new be. For section racks I get empty Oswego corn-flour boxes, they measure $14\frac{1}{2} \times 12\frac{3}{4} \times 8$ ins. inside. I take bottom out of them, and reduce the height from 8 ins. to $4\frac{1}{2}$ ins., then put in the pieces of wood for the sections to stand on, and I then have a section-rack, after fifteen minutes' work, equal to the best, as it is dovetailed and made of some very fine American wood. I always use $4\frac{1}{2} \times 4\frac{1}{2}$ sections, as they are much more in demand than any other. The boxes for the hive, makeshift, and rack only cost 6d. each from a grocer, and altogether I think my apiary is fitted out more cheaply and better than any other near here, more especially I would contrast it with some friends, who have got their hives from Perth, or near it. Their hives are single-walled, and have frames rather larger than standard size, and to pack the quilt properly is a task indeed. I have fitted some of these hives with Pine's metal ends, and have found it a great improvement; also I have made the dummy so that it can be used to contract the hives. Before this was done these hives were bringing a bad repute on bar-frame hives in general, as every one thought them inferior to a good straw-skep, and yet these hives cost 21s. The Stewarton is the coming hive for this county, however, because it gives as much if not more honey, and is a great deal easier to send to the heather. Last year I simply fastened the section-racks firmly down upon the broad-shouldered frames, and put cheesecloth over the top and perforated zinc over the entrance, and they travelled safely; but this year I intend to get the floor-board spaced to hold the frames more firmly. Hives with fixed floor-boards should have the entrance extend along the whole front of the hive, as I find that when the hive is doubled nothing less will do. I have lots of feeders, but the only kind I now use are the 'Simplicity,' as described by Root in his *A B C of Bee Culture*. They only cost 4d. each from Messrs. Edey & Sons, and will serve either for bar-frame or Stewarton hives. I sometimes make use of my Raynor feeder and also covered 'Simplicity' or Gray's feeder, but not often, as they are more bother. I use the 'Simplicity' feeders behind the dummy. For spring stimulation Simmins' dry-sugar feeder is splendid. Last October I packed several hives so as to prevent upward ventilation, making them very warm all round with chaff; other hives were packed with the ordinary tray of cork-dust with upward ventilation, but I cannot say that there was the slightest odds either way. They all wintered safe and well, those contracted to as many combs as they could cover, either upward ventilation or not, did fully the best. You will be pleased, Mr. Editor,

to hear that there are a great many bee-keepers about here who are changing from the skep to the bar-frame system. My *B. B. J.* goes through a good few friends' hands every week, and they all unite in praising it, and saying that they could not do without it, more especially the 'Useful Hints,' which come very handy, as we are always three weeks behind the South.—GEORGE D. CLARK, *Kirklandhill, Dunbar, May 19th.*

PROPERTIES AND CHARACTER OF HONEY AND TABLE HONEY.

(Continued from p. 199.)

The polariscope is a very sure means of detecting artificial honey. But as a means simple, expeditious, and at the command of every housewife, the spirit process seems to us for the present to be most recommended. In fact spirits of wine are to be found everywhere, whereas chemical laboratories supplied with polariscope, and chemical reagents, are much less accessible to the public. However, the object of the spirits of wine test is to give us an approximate analysis.

In the face of the above results let us ask ourselves the question: is this article manufactured with honey, glucose, and treacle, in varying proportions, legitimately and honestly the right to the title of honey, which is properly applied to a substance, the produce of bees? No, we are obliged to answer that the manufactured article is not honey; consequently the word should not even be used in connexion with it. The name of syrup is the only one suitable, and for such a designation we will give ample reasons. Scientific analysis clearly supports us in our views. The manufactured article can no more be called honey than a mixture of flax and cotton be called linen, or wool and flax pass as woollen material.

In Germany the justice of these principles is acknowledged, for the custom-house authorities of Prussia have abolished the pernicious, reprehensible, and deceptive terms of table and Suisse honey, and have decided, it not being honey but syrup, to tax it at fifteen marks the one hundred kilos, instead of three marks as real honey.

The terms *table-honey, pure table-honey, Suisse honey,* are only fraudulent expressions, the meanings of which many persons in Germany, and with us, do not understand, and therefore with too much confidence look upon this as an article of superior quality, and even pay a higher price for it than for ordinary honey. The same thing happens with salt, which the public thinks is of better quality when it is called *table salt,* instead simply *salt.* We find the utmost confusion of the term to exist in the statements of the chief agent of one of the principal manufactories of honey in Switzerland, which were given in the pharmaceutical *Centralhalle* in Leipzig. Speaking of adulterated Swiss honey (table-honey), he says: 'All Swiss honey contains an admixture of starch-syrup, because the public desires, and considers as a sign of good quality, honey which will not *granulate,* but remain liquid.' 'Moreover,' he adds, 'that this honey is not sold as pure honey from bees, but as pure Swiss honey.'

The President of the Swiss Bee-keepers' Association has protested and given a correct interpretation of the terms. He points out that the important difference between pure and adulterated honey consists in the first always, and the second never granulating. In Germany honey manufacturers are being attacked on all sides. Let us follow this example.

The following statistics collected by Mr. Ph. Ritter, late President of the Swiss Bee-keepers' Association, give an idea of the increase in the importation of syrup:—

HONEY.—Average annual importation from 1840 to	
1879	3256 cwts.
WAX AND WAX PRODUCT	2150 "
SUGAR AND SYRUP	245,070 "

The importation of golden syrup and raw treacle has rapidly increased at the following rate:—

1874	12,648 cwts.
1875	18,302 "
1876	21,096 "
1877	31,638 "
1878	40,966 "
Annual average	26,726 " *

Then comes the importation of colourless syrup or glucose (starch-syrup):—

1877	8304 cwts.
1878	8842 "
1879	8734 "
Annual average	8627 " †

From the above figures we come to the following conclusions:—1. That the bee-keeping in Switzerland is not sufficient to supply the demand for honey. 2. That the importation of the constituents of table-honey (treacle and glucose) is increasing rapidly; it is therefore easy to understand why the manufacture of this article increases so rapidly.—The PRESIDENT of the Swiss Bee-keepers' Association in *Schweizerische Bienenzeitung.*

(To be continued.)

Replies to Queries.

[329.] *Hiving Swarms.* (Farmer).—Swarms are best hived as soon as possible after they are settled down, if 'Farmer' will take every other bar out of his hive, and after shaking or brushing with a wing (which I find is the best thing to manipulate with) according to the position of the swarm, all the bees into a skep, then give the skep a sudden firm shake, he will find nearly all the bees will fall to the bottom of the frame-hive, then cover them up with a cloth; when they get settled down, draw the bars together and dummy them up to the required space, when they will at once commence to build up their comb.—JOHN DIXON, *Great Ayton.*

[331.] *Honey Glut.*—If 'J. D.' has such a thing as a hive with a hinged back or side he can place a frame of sections there with a sheet of glass at back, and will then be able to see pretty well what is going on in the hive without disturbing it. This is a very pretty sight at the commencement of the honey glut if the bees are strong. To do this nicely with the standard frame-hive the 4 x 4½ sections should be used.—A. T. WILMOT.

[332.] *Firing Foundation.*—I used formerly to fix my foundation in the frames by cutting the sheets into strips two to three inches wide, and fastening the ends on to the under side of the frame by pressure, in the same way that the foundation is fixed in the sections. In this way I was always able to get nice straight combs. I have a wax smelter, but never use it.—A. T. WILMOT.

[334.] *Dry Comb Foundation.* (A Subscriber).—If you warm your sections well either at a fire, paraffin stove, or gas, you will find it will look like fresh, and lose any fusty smell. It has the same effect on last year's comb-foundation.—JOHN DIXON, *Great Ayton.*

[348.] *French Works on Bees.* (F. D.).—Mr. Cowan's *Bee-keeper's Guide Book* has been translated into French. V. Rendu: *Les Abeilles*, third edition, with seventeen engravings. This work is approved by the Société pour l'Instruction Élémentaire (fifty centimes). Published by M. Hachette, 18 King William Street, Strand.—MELISSA.

[349.] *Dead Bees.*—(J. W. S.).—The 12th was wet with cutting east winds. Bees were blown on to cold, wet ground or on alighting-beard and chilled. I picked up a good handful apparently dead, put them in a box and warmed them in front of fire; in a short time there was a joyful hum. Between the showers, and while the sun was out for a few minutes, I relieved the bees. In front of hive they made a 'bee line' for the entrance. 'J. W. S.'s' bees would probably have done the same if similarly treated.—NUCLEUS.

* This is the principal ingredient of table honey.
 † This is the other companion of table honey.

[349.] *Dead Bees.* (J. W. S.)—To all appearances, one would suppose that your bees were starving; but with no other particulars but the very meagre ones you give, it is impossible to give a definite opinion.—W. B. WEBSTER.

[349.] *Dead Bees.* (J. W. S.)—I experienced in many of my hives a similar occurrence about this date, and I put it down to the bees becoming chilled on their return to the hive after a journey, and, the alighting-board being wet, they had not sufficient strength left to carry on into the hive proper, where it was warm. It was at this time a continual rain, with sunshine for a few minutes, and then followed a snap of cold wind and rain.—G. H. G.

[350.] *Spreading Brood.*—I think a great mistake is often made by spreading brood prematurely, and I never do it until the season is fairly advanced. The common cottagers' skeps we see around us on all sides are not interfered with, and yet invariably it is these which swarm first. I should never leave frames of brood in a hive unless the combs were well covered with bees, on chance any of it hatching out, as I think there is every fear of the dead brood decaying, and eventually being the means of propagating foul brood.—G. H. G.

[350.] *Spreading Brood.* (O. W.)—It is very exceptional for hot sun and cold winds to kill so many bees suddenly as would cover three frames. Allow the frames to remain for a time, and note how they go on. The bees will clear the dead out; but if there are very large patches of dead brood, it is a very good plan to carefully uncap, and syringe the brood out with water, afterwards putting them in the extractor to expel any left, as well as the water; then spray them with solution of salicylic acid solution and dry.—W. B. WEBSTER.

[351.] *Rearing Young Queens.* (G. H. G.)—Your swarm was preparing for a maiden swarm with a vengeance. A number of virgin queens in a hive is not an unusual occurrence; they are not taken any notice of by the workers until after they are fertilised; but such an event as yours is very rare. I have never had such an experience myself.—W. B. WEBSTER.

[352.] *Escape of Bees.* (Young Bee-keeper.)—I understand this query that his section-rack does not fit exactly over all the frames; if so, it is what generally is the case in all apiaries, and is usually overcome by cramming pieces of quilting, &c., into the spaces. If the bees get out into roof they usually soon find their way back again; the only thing is to see that outside bees cannot get in, or robbing will soon occur to some tune.—G. H. G.

[352.] (Young Bee-keeper.)—Do not super a hive with only six frames. Increase them gradually to ten, then super.—W. B. WEBSTER.

[353.] *Sections containing Brood.* (J. C. T.)—The bees would go up in the sections at once, as their affection for the brood seems as great as the affection of a mother to her child; I don't mean the genus *homo*. The mother-bee is more inclined also to visit the sections. All the sections that have had the brood in them will be discoloured. Cut the brood out, especially if it is drone, and let the bees finish them; if you have many, you can transfer them into a frame and place in hive.—W. B. WEBSTER.

[353.] *Sections containing Brood.* (J. C. T.)—The bees would all the sooner commence work in the supers. I do not think queen would be any more likely to go up, and the brood when matured would hatch out. The combs of these sections would not be quite so eyeable, being slightly darker, owing to their having had brood hatched in them.—G. H. G.

[354.] *Finding Queens.* (C. E. Cuthell.)—The querist, I presume, refers to ordinary manipulations with a frame-hive, and not to open driving from a skep. If so, I agree with him, and, as a rule, find the queen near eggs recently laid, or by empty cells from which the young bees have but recently emerged.—G. H. G.

[354.] *Finding Queen.* (Chas. E. Cuthell.)—Most certainly; bee-keepers, as a rule, are too fond of fairly choking the bee, and ply the bellows with as much vigour as they would to a forge. If too much smoke is used, the mother rushes about 'all over the shop.'—W. B. WEBSTER.

[355.] *Early Destruction of Drones.* (Humble Bee.)—I have noticed a little of this; it is owing to the demand of

food being greater than supply, and the workers consequently turn out the drones first. It is all through the recent prolonged rains, when the bees could do nothing day after day.—G. H. G.

[355.] *Early Destruction of Drones.* (Humble Bee.)—A very frequent occurrence in early spring. Honey is very slowly coming in, on account of the bad weather, which the bees are quite cognisant of; they can hardly get enough to rear the brood, and do not want a lot of lazy drones to eat it, and so drive them out.—W. B. WEBSTER.

Queries.

[362.] *Doubling.*—Can any of your readers give me the full dimensions for making a good hive for 'doubling,' also for extracted honey?—NOVICE.

[363.] What makes workers telescope their abdomens in and out when alighting and resting after a flight?—RARE SIGNS.

[364.] *Supers and Sections.*—I propose working one of my stocks with a Woodbury 'super,' which I have fitted with frames instead of bars. There are eight of them, 12 x 5½ in. If the season should be a good one could I get some sections as well, placing a crate between the hive and supers? or is it best to keep to extracted honey and give more space as needed by slinging the combs in the super?—RARE SIGNS.

[365.] *Sections and Extracting.*—Or could I with advantage work a stock in a long hive with one crate of sections on the top, and besides extract from two or three back frames? The fact is I want only a small amount of extracted honey.—RARE SIGNS.

Echoes from the Hives.

Holme, near Peterborough, May 19.—Bees three weeks behind. Fruit blossom lost, still a few days' sunshine will set us upon our feet again.—JOHN H. HOWARD.

Sompting, near Worthing, May 21st.—When shall we see a cloudless sky? The weather here is something horrid, and we have experienced such a winter that has made the best of us tremble. I hear little else here but 'Bees all or most of them dead,' 'Hives for sale,' 'Going to give up bee-keeping,' 'Want to buy a lot cheap?'—A. P. BERRY.

Gresham House, Corbridge, May 22.—We have had three weeks of nearly constant rain, but as this is a fine day and the glass is going up, I hope the fine weather is coming.—R. L. RICHARDSON.

Honey Cott, Weston, Leamington, May 22nd.—At the beginning of this month things looked very promising, but about the 10th a change came o'er the spirit of our dream about swarms and honey, for it rained four or five days with scarcely any intermission, being at the same time very cold, which necessitated continuous feeding to keep bees in good heat. There have not been more than two fine days since, but the rain has brought the beans and clover along finely, so that if we get nice weather by-and-by there will be a good chance for some honey.—JOHN WALTON.

Somerton, May 24th.—W. Snow, New Street, had another first swarm from straw skep on Sunday, the 23rd, the one reported for the 9th should have been from 'straw skep,' not *bar-frame* hive. Weather has been fine, but is now wet and cold again. Swarms are scarce as yet.—J. J. S.

North Leicestershire.—Fourteen consecutive rainy days, yielding 4.48 in. of rain, have not been favourable for bees, and some stocks have shown the straits they are in by evicting both young drones and immature brood. Today (May 24th) is warm, cloudy, and hazy, and the bees are apparently endeavouring to make up for lost time, for the sycamores and apple-trees are alive with them. No swarms in this neighbourhood at present.—E. B.

South Derbyshire, May 24th.—The last month has shown us all kinds of weather. May opened with a magnificent week for the bees, but on the 10th, 11th, and 12th, rain simply poured down incessantly. A tremendous flood in the Derwent Valley was the result, and my apiary was under water for thirty-six hours. My hives were all raised nearly four feet from the ground in readiness, and at

its highest point, the water just missed them by $\frac{3}{4}$ of an inch. Very luckily for me a very strong, cold, north wind blew whilst the water was up, or my prospects for this year would have been utterly ruined. I only lost about 1 per cent of bees through drowning. The hive I spoke of in a former 'Echo' as having 'come to grief' is pulling round nicely. About thirty or forty bees and the queen survived till the middle of April, having a patch of brood as big as half-a-crown. I gave them a frame of hatching brood and young bees from another hive, and now they are coming on remarkably well. The bees are working well to-day; it is cloudy but calm and very warm, over 60 degrees.—M. J. ASTLE.

Caerleon, Mon., May 25th.—We are having a bad time of it just now down in South Monmouthshire, nothing but rain since the 12th inst. The fruit-blossom has come and gone, but my bees have not been able to gather owing to the wet. We must now wait for the clover, which mostly blooms down here the first or second week in June.—ISCA SILURIUM.

NOTICES TO CORRESPONDENTS & INQUIRERS.

A. T. WILMOT.—*Supposed Diseased Brood.*—1. Chilled brood is not likely to become diseased, but since the date of your last letter it may have become decayed. 2. If disease does exist, it would not, of course, show itself in winter when there was no brood. The dead bees had most likely died naturally when too cold for the others to turn them out. 3. *Hilbert's Fumigation Process.* This is fully described in Cowan's *Guide-book*, p. 138.

JOHN MACV.—*Burrowing Bees.*—The bees reached us safely, but the cells were pulverised out of all shape and form. The bees are burrowing bees of the family Andrenidae. These are solitary, not social, bees; they show great industry and ingenuity in the construction of their nests, and in the provision that they make for their young. They are very frequently to be seen at this time of the year collecting food and carrying to their nests pollen for their brood. See reference to them on page 216; and on consulting indices of previous volumes you will be able to ascertain many particulars of their natural history.

R. L. RICHARDSON.—1. Great care should be taken in inserting foundation that it should hang perpendicularly, we are inclined to say that the bees have worked irregularly from this cause. Wired foundation is a preventive of this occurrence. 2. If you desire to supersede the present queen the bees would rear another. This should not be postponed too late; the beginning of the second week of July would be a suitable time. This would be preferable to permitting the bees to do so, as they might be disposed to continue her presence for a length of time. 3. No. 1 sample of enamelled cloth would answer your purpose.

WALTER C. A.—*Skeps.*—If your neighbourhood furnish rushes, skeps might be made of them, bound with brambles; but it is desirable that they should be made of stronger materials than are generally employed by cottagers. The best skeps are made of rye-straw, bound with cane. The size of skeps depends on the honey-yielding qualities of the district. A suitable size would be 15 in. in diameter and 7 to 9 in. deep, or 16½ in. in diameter and 10 in. deep; this latter would hold 50 lbs. of honey. The hole in the crown should be 3 or 4 in. in diameter.

L. WREN.—*Honey.*—The honey forwarded is pure, but of rather inferior quality.

H. M. F.—*Wax-moth.*—The 'caterpillars' forwarded were the larvae of the wax-moth, their existence in hives is detrimental to bees.

W. W. D.—*Placing Sections.*—Feeding must be discontinued before you place the sections on frames. The time for putting sections on is when the hive is full of bees and brood, and honey coming in plentifully from the fields.

A. WORKING BEE.—*Sparrows and Swallows.*—There is no doubt that sparrows are very destructive to bees, more especially when they are rearing their callow brood. Swallows are not so partial to bees, they prefer smaller insects; they are, however, not altogether innocent of apicide, having occasionally been discovered in the act. (See Vol. 13, p. 325.)

EXTRACTOR.—*Unfertilised Queens.*—From the absence of worker and the abundance of drone-brood, there is no doubt that your queen was of last year, and unfertilised; she therefore became a drone-breeder. The patch of drone-brood, found afterwards in the brood-frame, which you inserted, was raised from this queen's eggs, and is proof positive of her not having mated. Probably you pinched the queen in catching her; or she might have been chilled. It is always best to place a few workers with the queen in the box, and to keep them warm.

J. M. B.—*Drone Brood cast out.*—The cold weather caused the bees to condense the drone brood, being at the edges of the combs, became chilled, and was therefore cast out. RARE SIPS.—F. Cheshire's work is published by L. U. Gill, 170 Strand.

R. Y.—The comb bears symptoms of incipient foul-brood.

A. P. B.—Worker bees do not store any thing in their cells but honey.

NOVICE.—It is very desirable that bee-keepers should be brought into a mutual knowledge of each other. We conceive there is no better mode of attaining this object than by joining the district Association in your neighbourhood. By frequent meetings in which an interchange of thought would take place, a sympathy of feelings, a fraternity of spirit, and a co-operation of energy, would be evoked.

ANOTHER NOVICE.—Among bee-keepers there is no recognised standard size for hives, neither is there any uniform mode of making the ends of frames or of measuring the distances between them. The British B. K. A. have adopted a standard frame, and the hive can be made—according to the will of the hive-maker or the honey-producing qualities of the district—to take any number of frames, but ten or eleven are generally used. There is a great diversity of opinion among bee-keepers respecting distance-keepers; broad-shoulders, distance-pins, metal-ends have all their supporters; whilst some contend that frames can be manipulated with greater ease and rapidity by not having any distance-guides at all. We do not think that bee-keepers will ever arrive at an unanimity on these minor points. The distance from centre to centre of comb is 1½ inches, or, to be more exact, 1½⁹/₁₆.

BEE STINGS.—There is a remedy for bee-stings given by a physician which to me is new. He states that the wax of the ear is secreted to prevent insects from entering, and destroy them if they attempt such a lark. The wax is a remedy for all such poison, and we carry with us nature's own antidote for poison from the bee. Let it be applied at once to the wound, and none more effectual can be obtained, and the substance is always applicable and effectual for the system of the individual by which it is secreted. It costs nothing to try it.—R. F. HÖLTERMANN (*Canadian B. J.*)

STINGS AND REMEDIES.—Mr. G. Walker asks if any one has known Dr. Pine's lotion to fail? Well, I tried it two years ago, and although I applied the lotion liberally directly after being stung, I swelled frightfully; in fact, as bad as when I used nothing. I have tried ammonia until my face blistered with the like result. But I think the worst is over, as the last two stings did not trouble me, and I tried no remedy. The poison used to affect me thus:—Painful for a few minutes; then feel no more of it for about twenty-four hours; then it would commence to irritate and swell for twenty-four hours; then gradually go down.—C. BARNETT, *Godalming.*

HIVE WITH A BAD SMELL.—'Inquirer' asks the cause of his hives having a bad smell when there are no visible symptoms of foul brood. I have observed during the last four years that hives which contain a large quantity of unsealed brood in the spring have a peculiarly raw smell, like that of uncooked meat. Later on, plenty of new honey coming into the hive covers this smell. On beginning bee-keeping this raw, and really disagreeable smell, quite alarmed me. Now I know it to be a sign of a prosperous colony.—BEE-SWING.

ENQUIRER.—Stock Lignrianised August 31, 1885. Black bees last seen May 8th, 1886.—NUGLETS.

MANIPULATING BEE-HOUSE.—Will Doctor Craigs be good enough to say where a rejected army bell-ten' can be got? —BEE-SWING.

Mr. A. Green, of Selston, Alfreton, writes:—'I have invented a top bar for frames, which I think will prove useful to bee-keepers. It is interchangeable with metal ends, and is made entirely of wood. I feel it necessary to protect the right of manufacture.'

Mr. Richard McNally writes:—'In your issue of 20th inst., under the heading "Scotch Honey Competitors" [335], a false charge is brought against me, as one of John N'ally's Brothers "having bought honey in the open market" and showed it as my own production. Without entering in any way in the debate, I give it an emphatic denial. As a member of Committee of Caledonians. I would not allow such a thing to pass without informing the other members of Committee; and it remains with "J. H." to prove such an assertion.'

[We readily insert the above, but we do not find any reference to Mr. R. McNally in the letter of 'J. H.'—Ed.]

Received from Mr. L. Wren, of Lowestoft, a very simple and cheap block for inserting foundation into the saw-cut of a frame. Two headless nails—2½ inches from each other—are inserted in a block by which the opening is increased so that the foundation is easily slipped in. There is at one end of the block a revolving piece of wood which secures the bar, and allows both hands to be used in slipping the foundation into the now gaping saw-cuts.—Also, a reversible frame, in which the ends can be cut off from the ordinary frames, and then fixed to the metal ends. These ends too easily drop off the frames, and if they fell among the bees would create an undesirable commotion. What is required in reversible frames is that the ends should be firmly fixed to the frames, and at the same time easily and quickly detached.

Show Announcements.

June 29-July 5.—Hives, Honey, &c., Royal Horticultural Show at Liverpool. Entries close June 10th. Secretary, J. Huckle, Kings Langley.

July 12-16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Post Entries to June 1st. Secretary, J. Huckle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

July 30-August 5.—Great National Show at South Kensington. Secretary, J. Huckle, Kings Langley.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

June 24, 25, 26, 28.—Royal Counties Agricultural Show, Portsmouth.

July 14.—Swanmore.

July 31, August 2.—Royal Horticultural Show, Southampton.

Aug. 18.—Farnborough.

**MANIPULATE WITHOUT SMOKE.
WEBSTER'S FUMIGATOR**

ENTIRELY supersedes the Smoker, both in simplicity and effectiveness. No 'going out,' as no fire is used. Always ready for use, no matter how laid down, without any extensive preparation. No tainting of honey. No dirty liquid dropping from it to soil combs. Quite portable, can be carried in pocket. Will subdue the most vicious of bees. Can be fitted to any smoker-bellows.

Mr. F. CHESHIRE writes: 'I find—by experiment—that the most vicious Eastern Bees are utterly beaten at once.'

Price 4s. 6d. complete with Bellows; post charge, 4½d.
3s. without Bellows; post charge, 3d.

BOTTLES OF AGENT FOR USE WITH VICIOUS BEES, 6d. EACH.

W. B. WEBSTER, Wokingham, Berks.

**BOULTON & PAUL,
Manufacturers, NORWICH.**

Manipulating or Bee House.

THESE Houses are well made, and painted three coats. The sides and lining to roof are covered with tongued boards, which are bee-proof; roof of corrugated iron. They are very portable, being jointed with bolts and nuts. Any one can put them together.

With Revolving Window for turning the Bees out, Bench for working on, or for standing Hives upon, Floor, and Door to lock, complete.

Sizes—6 ft. x 5 ft. Price £8 0 0
8 ft. x 6 ft. „ £11 0 0

10s. HIVE.

PRIZE £2 worth of Goods, to be selected from Catalogue. Limited to 300.

In order to show the efficiency of E. C. WALTON'S HIVES, and to create a further development of Bee-keeping, E. C. W. has decided to offer the above inducement to intending purchasers. The Prizes are for the largest quantity of Honey, gathered from one of the above Hives in one Season, by fair means, the producer being allowed

7s. 6d. HIVE.

PRIZE £1 worth of Goods, to be selected from Catalogue. Limited to 100.

to work for Comb, or Extracted Honey, but the quantity of Extracted must exceed the Comb by one-third.

Anyone wishing to compete, must order their Hives before May 31st, and send in their report before Sept. 30th, 1886.

The winning numbers will be published in the *B. B. Journal*.

Any Person ordering for the Competition must say they are going to compete, or they will not receive a Ticket.

E. C. WALTON will be willing to purchase the Honey produced.

E. C. WALTON, Muskham, Newark.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

FROM CREATION TO 384 B.C.

My purpose is to give a brief account of the early history of bees; to show the knowledge which was possessed by man in the primitive ages, when wonderful inventions and long study had not drawn aside the veil which so effectually concealed for hundreds of years some of the greater mysteries of the hive; to give to those who think but little on the subject some inkling of what was known before the production of honey became a widely recognised industry; to ask them to consider which is the most wonderful exploit, the knowledge of Aristotle—culled from the ancestors of the modern bee-keeper, without those aids to research so commonly now possessed, with but few early writings to which he could refer; without treating the subject as one sufficient to engage his whole attention—or the knowledge of a modern bee-keeper, gained by the direct aid of books of his own day and of the earlier ages, and assisted by all the mechanism and inventions which can assist the curious eyes of an industrious, painstaking searcher after knowledge?

At present it is impossible to think of attempting more than giving a brief survey of the period from the creation of the world to the time of Aristotle, which may be roughly stated to embrace all time until 384 B.C.; and before going further it may well be stated that such facts as are here given are entirely derived from the *Natural History of Animals*. It is, of course, recognised that some few sentences are still extant of a far earlier date, in which mention of these busy insects is made, but none of them are of great importance; and we may also remember that although the works of earlier years have not come down to us, the great author of the *Natural History* had in all probability access to them, and incorporated in his own work such parts as he thought were either, by reason of their still being facts which had not then been dispersed, or being of general interest from an historical point of view, worthy of his notice. An instance is probably now before us when we read that some thought the young of bees were gathered from the flowers; others that the rulers of the hive produced them.

Of bees then, wrote Aristotle, there were four kinds:—1. Two sorts of kings; 2. Two sorts of

workers; 3. Thief bees; 4. Drones. The better sort of ruler was of a red colour; the inferior, black and variegated, of a size double that of a good bee. The workers also were of two kinds and the best of these was 'small, round and variegated,' the other long like the wild-bee. The thief bees were black and had a broad abdomen. The drones, the largest of all, had no sting and were stupid. At the time of which we write it had been noticed that the progeny of the ruler was different to that of the subject bee. The progeny of the king was red, and of the consistency of thick honey, and was in bulk as large as the perfect insect. Moreover, the cells for these rulers were placed at the bottom of the comb. The king was known to possess a sting which, however, he seldom used, and it is added that in every hive there were several rulers. Even the minutest particulars seem not to have escaped the eager eye of the earliest pioneer of bee-keeping—of whose work we have written record—for he tells us that to the king belonged a peculiar scent, sufficient to attract his subjects from a distance; and also that the rulers never left the hive even for food or any purpose other than swarming. Then comes what to me seems a great proof of accurate observation, for he writes, that if the kings died—and in every hive there were several—it was a fatal misfortune to the rest, being indeed the sure precursor of ruin; for after such death the drones, instead of being produced in one part of the comb only, were reared promiscuously in all parts of the hive—accurate observations in so far, that although not being aware of the ability of the bees themselves to raise another ruler, the presence of an abnormal king or a fertile worker has been detected. The king, being the chief of the hive, has engrossed so much space that it will be impossible to say more upon the subject, although it is one of great interest; but what is there in all the subject not of an interest equally great to an intelligent man? Of the two sorts of workers it may be said they did all comb construction, food collecting, and other necessary work of the hive, and to them there will be occasion to refer again. Thief bees were black, and most injurious to all the rest; and of our friend the drone, Aristotle had perceived that he did no work and had no sting, and says that by some he was supposed to be the male; he was also stupid, and was destroyed at the close of the season. Some thought

the ruler was indeed a perfect female; the drone a perfect male. The average life of a bee was six years.

The chief work of the hive, after rearing young, was to collect wax, honey, bee-bread, and mitys; and of these four, which correspond to what we consider the four principal substances used by the bee, a very erroneous and imperfect idea evidently prevailed. Wax was, we are told, collected from the flowers; and a most curious instance of close observation is given, for it is written that the bees collected wax by climbing on the flowers with their fore-feet. These they then cleansed upon the middle pair of legs; these again were cleansed on the curved part of the hind legs, and after this third movement the load was safely stowed away. In these wax-collecting journeys the bees were not capricious, for if they first paid their court to the violet, to the violet they remained faithful, and did not flit from one species of plant to another as their mere whims might influence them. From this wax the combs were made and on these the cells, which were constructed with two mouths; two cells on each base, the one on the inside, the other on the outside, and those cells which contained most wax contained most honey.

In comb construction the bees observed an order, for first they built cells for their own kind; next cells for the rulers, which were of a smaller size than the first; and, lastly, cells for the drones, and these were smaller still. How did, it may well be asked, these curious ideas gain credence?—The bigger the bee the smaller the cell!

Honey was not a secretion of the flowers at all—at anyrate, not in the way which we believe that it is—for at certain times of the year the most lovely flowers gave no honey, and this was accounted for by the fact that honey fell from the skies, and the chief fall was at the time of the rising of the stars, and when the rainbow touched the earth. And from this it was concluded, it may be supposed, that cup-shaped flowers yielded most honey, for, as it fell in drops from the skies, it was the more easily retained until collected by the bees.

Bee-bread was a substance carried on the legs, like wax, of an inferior quality to the other food, and sweet, like figs. Mitys was the perfection of wax.

In this account of the productions of the hive, little remains now of which it can be said that it is borne out by facts. The whole is proved by modern research to be of a fanciful nature, and, for the most part, essentially a false description.

Each bee had its appointed task, for in every hive there were the honey-gatherers and the wax-collectors, the bringers of bee-bread and the carriers of water; and it was also remarked by even this early writer, that of all insects the bee was the most cleanly, for it never settled upon flesh nor yet did it like anything seasoned. In all journeys, when the wind was high, a stone was carried by the bees to preserve their balance. The bee began, he says, to work when it had attained the age of three days; of its earlier existence, whether sprung from an egg which hatched and from which issued a worm, it

seems difficult to tell from the history; but this is clear that the progeny of the worker-bee was a little white worm, which was placed at the side of the cells and rose to be fed; that after a certain time the cell was covered up, and the worm got wings and feet, while a worm it evacuated an excrement, but not afterwards. The wings were four in number and membranaceous, and by beating these and causing a friction of the air within the 'Buzz' was made.

(To be continued.)

GLEANINGS.

In the *Bulletin d'Apiculture de la Suisse Romande*, M. G. de Layens compares the swarming with the non-swarming methods of bee-keeping. Those compared are the natural swarming, the artificial swarming, and the total prevention of swarming methods. In his district the season has not been a good one, and those of his neighbours' hives which gave natural swarms did not collect sufficient honey for their winter's provision, and only those which did not swarm gave some surplus honey. In swarming artificially, the swarm can be made some time before natural swarms appear, and by placing the swarm on the stand of the parent stock, and removing this to the stand of another strong stock (as described by us in the *Vignole* system), time is saved, and the swarm is sufficiently recovered by the time of the great honey-flow to take advantage of it. In this way the hives would give an average of 5 kilog. (almost 10 lbs.) M. de Layens has worked his apiary for eight years on the non-swarming plan, which, with his large hives, he is able to do easily, and only makes artificial swarms when he requires them; and by this method he obtained an average of 14 kilogs. (almost 29 lbs.). From these results he comes to the conclusion that in bad or indifferent seasons natural swarming gives a very bad return, artificial swarming allows the bee-keeper to get a better result, and that the non-swarming system yields results far superior to the others. Therefore, as indifferent and bad seasons are more frequent than good ones, the bee-keeper, by adopting the non-swarming system, has a better chance of getting honey than by any other method. During the eight years that M. de Layens has practised this system, he has seen more bad years than good ones, and has always not only got enough honey to pay for the trouble and expenses attending the keeping of bees, but has also derived a good profit from them. Whilst in 1879 his bees were storing up sufficient provisions for winter, hives in the neighbourhood were perishing by hundreds, not only for lack of honey, but principally from the excessive natural swarming.

In *Gleanings*, we find A. C. Hamilton, writing from Oxford, England, says: 'There has been an immense increase in the production of honey in England during the last two years, and a vast improvement in the methods used. The result is that there is now a very large supply of first-class clover-honey raised in England. It can be got wholesale at 5*d.* and 6*d.* per lb. here, just half what it was two years ago. This is cheaper than first-class American honey, with cost of transport added. The stores with which I am connected find that at present they can get first-class honey cheaper from English producers; and while this continues we shall not require honey from America. It is said that there is a vast importation of first-class California honey. I cannot see how it can pay a man who can get 5 cents or 6 cents a lb. for honey in America, to transport it to England, where it will fetch about the same price. But I have since been told that high-class California honey is sold in Liverpool and London at 35*s.* per cwt, or 3*d.* per lb., or 7½ cents per lb. I got a specimen, but it was not first-class clover-

honey. But although not first-class, I am surprised that it should pay any one to import and sell it at that price.

In the *Bee-keepers' Guide*, the Rev. M. Mahin, D.D., suggests the probable use of fertile workers, which he says are most frequently found in those races of bees which are natives of countries where the summers are long and dry. In such countries there are long periods of hot weather, in which there are no flowers, or so few as not to afford bees a living. At such a time drones are killed, that there may be no non-productive consumers in the hive. The rearing of brood almost entirely ceases. Suppose by accident a queen is lost. There are a few eggs in the hive from which a queen may be raised, but not a drone within a hundred miles, it may be, for her fecundation. If, about the time queen-cells are built, drone-eggs are laid by some of the workers, they may produce drones in time to mate with the queen, and thus avert the destruction of the colony, for when there is little or no honey gathered, and there is little activity among the bees, queens mature slowly, and may be fertilised when several weeks old, as Dr. Mahin has more than once had the opportunity to observe.

L'Apiculteur announces that its editor, M. H. Hamet, is preparing a book, entitled, *Dictionnaire d'Apiculture ou Glossaire Apicole*, which is to appear about the middle of the year.

In *Gleanings*, James B. Mason says, in handling Carniolans, that they remain quiet on the combs, although they can be shaken off as easily as any other bees. Although when you are handling them they take no notice of robbers flying about, they will not allow a robber to get in at the entrance, and are in this respect equal to Cyprians. Another peculiarity is that they gather no propolis, but fill up all cracks with wax.

In the *American Bee Journal*, Professor Cook says he finds, by actual observation, that single flowers are sometimes visited by bees fifty times a-day, and he has seen bees visit over twenty flowers a minute.

PROPERTIES AND CHARACTER OF HONEY AND TABLE HONEY.

(Continued from p. 236.)

If pure honey found a readier sale here bee-keeping would be carried on without doubt more extensively. Nature supplies us with ample honeyed treasures. We are firmly convinced that it is not wise economy to import from abroad at a great monetary sacrifice an article which nature supplies us with gratuitously. We even here put aside all the other advantages to be derived from bee-keeping (for instance, the most important work the bees perform in the fertilisation of flowers, and consequently in the production of fruit, &c.) The pecuniary loss inflicted on our country by the importation of honey and wax is greatly increased when our own producers have to compete for an article which is required by us with imported goods (treacle and glucose), by means of which an article is manufactured and sold which not only destroys all the profits of the bee-keeper, but also sends the money out of the country. 'Already,' say some of our principal bee-keepers, 'we feel the falling off in the demand abroad for pure honey, owing to the bad reputation acquired by table-honey in Leipzig and Berlin.' Have not our bee-keepers the right of the protection of the law as well as other producers? They certainly have.

The ease with which this honey can be made is seen from the number of recipes offered to anyone wishing to purchase them. For instance, one advertisement states: 'Any person wishing to learn to manufacture honey (an industry which yields a profit of fifty per cent wholesale and 100 per cent retail) can send his address to E—, chemist, H— Street, Zürich. Fee thirty francs. Time required for learning half day.' Then for twenty to

thirty francs one gets the following printed instructions: Recipe for table-honey: Take . . . kilog. crystal-syrup and . . . kilog. of pure foreign honey, mix well and the table honey is ready, &c., &c. Crystal-syrup (glucose) made from potato starch by means of sulphuric acid, is, according to medical opinion, absolutely detrimental to health, more particularly if badly made and taken frequently. This accounts for the remark one often hears that 'honey does not agree with me.' Bees will not even touch glucose unless it is largely mixed with honey. The police have therefore weighty sanitary reasons for waging war against the manufacture of table-honey. Therefore we again repeat, there exists the absolute necessity to remove from the manufactured article the least appearance of its relation to honey, and therefore cry, 'Down with the words *table-honey* and *artificial honey*, and allow it no other name but that of *syrup*!'

Granulated honey can be easily rendered liquid without its losing its aroma or impairing its quality. The jar has simply to be placed in a tin vessel of water kept at a temperature of 40° Réaumur until the honey becomes liquid.

We have said all this for the purpose of properly determining the terms *honey* and *syrup*. And now bee-keepers, authorities, and all the public in Switzerland, unite and shout with one accord, 'Down with *table-honey*!'—The PRESIDENT of the Swiss Bee-keepers' Association in *Schweizerische Bienenzeitung*.

Selected Query.

[366.]—*What is the best system on which to work an apiary, say, of twelve hives, for the production of comb-honey only, without increasing the number of hives, either by natural or artificial swarming?*

I should work the apiary on the storifying system, and if a swarm issued return same, giving two extra frames and an extra crate of sections, thus satisfying their natural instinct for comb-building after swarming, and also store-room for honey in the sections.—W. WOODLEY.

Having the hives fully prepared for the honey-glut when it comes, I would put on crates of supers, and when nearly finished lift these up and put empty ones below next brood-nest. Give the supers in good time, and plenty of them, and keep entrance at full width. If hive can be lifted up from bottom board one-eighth of an inch, it would greatly help to keep the temperature down in hive; thus in a good measure swarming can be prevented. Should a swarm issue, I would return it back *minus* the queen, watching on the tenth day afterwards; and do same again should another come off.—R. McNALLY.

No certain method of preventing swarming altogether has yet been discovered when working for comb-honey, although most apiarists have turned their attention to the subject. The chief points of prevention are (1), allowing plenty of room in the brood compartment, particularly on the front side of the hive, keeping several combs unfinished where frames are ranged parallel to the entrance, (2), keeping the bees well at work in supers on the 'tiering-up' system; (3), ventilation between floor-board and hive; and shading hives. In the case put above, I should endeavour to carry out these points. If a swarm were cast from any hive, I would place it in a new hive upon the old stand, upon frames of foundation, and the surplus cases upon it. Above these I would place the old hive—brood-combs and all—having first removed its floor-board, and cut out all queen-cells. When the brood was all hatched in the old hive, I would shake out all the bees in front of the new hive, and, removing the former, would give another case of sections below the other surplus cases. If thought necessary, a sheet of excluder-zinc might be placed between the old hive and surplus cases.—GEORGE RAYNOR.

Stimulate the twelve stocks by feeding, spreading the brood &c., as described by me in my reply to Query 22, p. 16, of this volume, so as to get all as strong as possible by the first honey glut. To obtain the largest harvest of comb-honey, I would

then select from the twelve stocks the eight strongest (instead of equalising the whole by robbing the strongest to build up the weakest, as is generally advised), and still further increase their strength by exchanging the frames having the least brood with frames taken from the four remaining stocks having the largest amount of sealed and hatching brood, and leaving each of the eight selected stocks eight or nine frames filled with ripe brood. For obtaining comb-honey not more than nine standard frames should be used, and with a judicious tiering up of racks of sections, furnished with foundation, well in advance of the requirements of the bees, so that they are not overcrowded, swarming will in most cases be prevented. In 'tiering' up or 'stori-fying' sections, always put the additional rack immediately above the brood and under the racks already on. On p. 16 above referred to I have described more fully the mode of tiering up I recommend. In a short time the strongest of the four stocks not supered can be built up and treated exactly as the other eight have been. Much more comb-honey can be obtained by this system than any other that I am acquainted with.—JOHN M. HOOKER.

It would simplify matters considerably to be able to refer to the Cowan, Simmins, or other system; we should then know the hives and exact method of management recommended by the gentlemen whose names the systems bore. As far as I am aware there is only one detailed system named as above for the prevention of swarming, while producing comb-honey and that is the system recently made public by Mr. Simmins. A reply to be really useful to those who look to this column for guidance would take up more space than you are able to allow. I would therefore refer such to the replies by Mr. Hooker and myself on p. 16 in present volume, and only add that super room should be given slightly in advance of the requirements by tiering.—C. N. WHITE.

SOUTH KENSINGTON EXHIBITION.

The following donations have been added since our last issue:—

Wilts Association	£1	1	0
G. D. Haviland	0	10	0
Previously acknowledged	144	15	0
	£146	6	0

It is to be hoped that persons who are willing to contribute to this fund will send in their names as early as possible to the Secretary. Not less than 200*l.* should be guaranteed. Prize Lists are now ready.

ASSOCIATIONS.

SOMERSETSHIRE BEE-KEEPERS' ASSOCIATION.

This Association held its first Exhibition for the season on May the 11th and two following days at Wells in connexion with the Somerset Agricultural Society's Show. The show-yard was prettily situated in the Bishop's park, and the route to it lay through a quaint old gateway and along a very fine avenue of trees, which were looking their best with the fresh, spring foliage. The bee-tent was well situated a short distance from the entrance. The bee appliances were staged in a shed close by. The various classes were well represented, and some good hives shown by Mr. S. J. Baldwin, Bromley, Kent; Mr. T. F. Fluise, Barnstaple, Devon; Mr. C. E. Pyne, Yeovil, Somerset; Mr. A. F. Hutchings, St. Mary Cray, Kent; Mr. Perry, of Banbury; Mr. Hole, of Tarrington.

Through some unfortunate delay in the railway the hives of Mr. A. F. Hutchings did not arrive on the ground in time for competition, but we were particularly struck with their make, and they would probably have stood well in their respective classes.

We noticed that the first prize for crate of sections was awarded to one of the Benthall type, which is certainly the easiest kind to work. The arrangements of the Show were ably carried out by the indefatigable hon. sec. the Rev. Charles G. Anderson. The weather the first day was all that could be desired, and the bee-tent was fairly well patronised. The manipulations were entirely conducted by Mr. Anderson, who also delivered short lectures, in which he was assisted by Mr. Wm. N. Griffin. On the second day constant heavy showers rather checked the proceedings, but Mr. Anderson, ever at his post, was not to be daunted, and in spite of the elements succeeded in having several bee drivings. Very great interest was shown, and we hope that the Wells meeting may bring many new members to the ranks of the Bee Association. The judges were Wm. N. Griffin, Esq., Freshford, and F. Clark, Esq., and appended is the list of awards:—

- 1.—The best and cheapest hive on the moveable-comb system, with arrangements for summer use } Equal 1st { S. J. Baldwin.
2nd, T. F. Fluise.
3rd, C. E. Pyne.
- 2.—The best and cheapest hive on the moveable-comb system with arrangements for summer use } 1st, S. J. Baldwin.
2nd, C. E. Pyne.
3rd, E. J. Butt.
- 3.—The best skep-cover containing crate of sections } 1st, S. J. Baldwin.
2nd, T. F. Fluise.
- 4.—The best crate of sections } 1st, S. J. Baldwin.
2nd, A. F. Hutchings.
- 5.—The best sample of thick foundation, manufactured in the United Kingdom, from pure bees' wax, not less than 2½ lbs. for worker cells, with price per lb. attached } 1st, S. J. Baldwin.
2nd, E. J. Butt.
- 6.—The best sample of thin foundation, same condition as above } 1st, S. J. Baldwin.
2nd, E. J. Butt.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

At a Meeting of the Committee of the above Association, held at Leicester, on Saturday May 29th, the following resolution was put and carried unanimously:—

'That the Association decline to show at the Colonial and Indian Exhibition at Kensington, owing to the date clashing with that of the Leicestershire Show, and to the low state of the funds of the Association.'—E. B.

IRISH BEE-KEEPERS' ASSOCIATION.

A committee meeting was held at 36 Westmoreland Street, Tuesday, May 18th, Dr. O'Farrell in the chair. Present: Dr. Knight, Dr. Allen, the Rev. P. Cavanagh, Messrs. Edmondson, Read, Vanston, Sproule, Gillies, and Walter J. Stanford, Ounavarra, Lucan, Hon. Sec. Considerable formal business was transacted. A letter was read from the Society for Prevention of Cruelty to Animals regretting that they would be unable for the future to lend their rooms to the Association for committee and other meetings. It was decided, after some discussion, not to hold an independent show this year. A sub-committee was appointed to try and make arrangements to have Irish bee-keeping represented at the coming Grand National Apian Exhibition, and to report to the general committee.

A WASP AND BEE FIGHT.—A Worcester Correspondent writes to a contemporary: 'Noticing a cluster of bees at the entrance of one of my hives, I examined it for the cause, when I found a large green wasp (*Vespa Germanica*) and bee united in a death-struggle. The wasp had attempted to enter the hive, when the bee attacked it and stung it in the mouth, from which it was unable to withdraw its barbed sting; and the wasp in return had gnawed away the lower part of the abdomen of the bee, when both were killed in this position.'

Foreign.

FRANCE.

Weather and other circumstances have, within the past few weeks, favoured the wholesale honey trade. Considerable lots of 'whites' have found purchasers in barrels, and 'extras fine' in half barrels as well as in pots. A good stock, however, of 'whites' in pots remains unsold. This is probably owing to the inferior foreign honeys, notably Hungarians and Americans, which have of late been offered to grocers at from 70 to 80 francs per 100 kilos, and which are being unscrupulously retailed by them at 1.40 francs and 1.60 francs per kilo, or, say, 50 per cent profit. It is a pity that our retail trade does not encourage the consumption of our own French honeys, which are now offered at from 85 to 90 francs per 100 kilos, and would leave a considerable margin of profit, although not quite so great as is derived from the imported ones. This probably explains why our English brothers, finding their market glutted with inferior foreign honeys, have united themselves in the form of a league for the direct sale of their home-produced honey to the exclusion of the imported ones. The success obtained in London cannot fail to take root. Shall we be able to follow our neighbours' example?

Now, as regards the actual quantities on hand, it is probable that there will be less on June 1st next than there has been for considerable time past. Paris dealers have profited by the lessons they have learned of late, and no longer believe in overloading themselves with too heavy a stock; but as a natural consequence, the honey remains unsold in the provinces, where it cannot find a buyer at almost any price. Their presence cannot improve the chance of the new harvest, and if the latter is an average one, it is difficult to see how better prices than last year's are to be obtained. In fact, the prices at which bees for the provinces of the Gâtinais and the Beauce are bought show that producers of honey are basing their purchases upon this calculation. They, like all other producers, are becoming more and more prudent.

As the English market has closed its doors against inferior American honeys, these are now trying their luck farther north, or come to Havre, where a fair consignment of Chili was lately disposed of at 45 francs per 100 kilos, in bond. It is reported that another lot of over five hundred cases from California is soon to be offered at ridiculous prices. These will probably find a sale among makers of 'pain d'épice,' because Brittany honeys command much higher figures. The manufacture of these 'pains d'épice' is becoming quite a regular trade both in Paris itself and in its environs. The sale of this article is, it appears, daily increasing and extending itself all round.—*From the Apiculteur of Paris for April, 1886.*

ITALY.

According to the *Apicultore*, of Milan, April has not been for Italian bee-keepers of a nature likely to raise their spirits. Generally speaking, it has been dull, cold, and inclined to rain, thus leaving but few favourable intervals for the bees to be out on profitable expeditions, and to provide the necessary food for their brood. As, however, April is not, from an apicultural point of view, the harvest month, the Editor advises his readers not to be discouraged, as a spell of fine, bright weather, of the Italian pattern, will enable bees to make up for time lost.

A new Bee Association has been started at Puos d'Alpago (Belluno), of which Signor Silvio Fontanive, of Sospitolo, is the moving spirit.

A month or two ago Signor Francesco Ghezzi, a certificated bee-keeper, residing at Albuzzano, advertised that he would be prepared to assume the management

and responsibility, either of established apiaries as going concerns or to be started, guaranteeing to their proprietors, upon certain conditions, a fixed annual revenue therefrom, taking upon himself the risk of a loss, or the benefit of any excess profit. As a moral guarantee to those who would avail themselves of his overtures, Signor Ghezzi and his wife submitted themselves a few weeks ago to a severe test or examination, presided over by the President of the Association, Count Barbo, Vice-President, Prof. Barbieri, and Councillor Stefano Fumagalli, who expressed themselves fully satisfied with their theoretical and practical knowledge of bee-keeping. The result has been that Ghezzi's proposal has been accepted by so many bee-proprietors that he can accept no more offers. In commenting upon this new departure in the mode of speculating in bee-keeping, the *Apicultore* expresses the hope that many others may soon follow Mr. and Mrs. Ghezzi's example, as the presence in the country districts of individuals willing to stand or fall by the success they are confident of achieving, will go a long way to help the hesitating to make up their mind to embark in bee-keeping in a business-like manner.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the "British Bee Journal," c/o Messrs. Straungeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C." All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

** * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

REVERSIBLE FRAMES.

[367.] I do not know whether the reversible craze is having such a boom your side of the water as on this, but I do know that the theory on which it is based is wholly unscientific, and that the results claimed to follow its adoption can be far more easily and cheaply obtained, and with far less labour and trouble.

I have experimented to some extent in the matter, and my views are based on the results of those experiments. It is a conceded fact that bees will not seal up brood in cells more than regulation depth, namely, in those that are built in comb more than $\frac{3}{4}$ inch thick. It is also a conceded fact that they dislike to store honey in cells that are not deeper than those built in such comb; in fact, the more space given for depth of store cells the better they are liked and the more freely used. Keeping these points constantly in view, it is easy to work out a theory in regard to the matter, and if in practice that theory proves tenable, we may consider the matter fully proved. I have worked up such a theory, and four years' experiments have fully tested it to my own satisfaction. Premising that the main object of reversing is to rear brood in the brood-chamber and force surplus honey into sections, and, knowing the method even if practicable is clumsy and difficult, I assume that a method that is compatible with the natural habits of the bees, and that possesses the virtue of being cheap and easy, is far superior, particularly when it requires no change from the particular style of frame-hives in common use.

The method I have adopted and, as I think, fully tested is as follows:—In early spring, when I make my first examination, I extract the honey from the brood-chamber, shave all the combs to just $\frac{3}{4}$ inch thick, and then replace them just bee space apart, filling in with a dummy if needed. As soon as the honey season opens I place as many sections as is desirable on the frames,

and remove them as fast as they are filled. The result invariably is that brood only is reared in the brood-chamber, while honey is at once stored in the sections. The reason of this is obvious, and follows legitimately and naturally from the well-known habits of the bees, described in the beginning of this communication.

When the season is near its close I remove sections entirely, space the frames in the brood-chamber a little wider apart, and allow the bees to store up their winter supply.

The above plan can be used with any frame-hive in existence, and thus avoids any extra expense, and is preferable to reversing on this point alone; but when we take into consideration the further point that reversing is unscientific as well as expensive, we have the strongest possible argument in favour of the method I have explained, even if viewed merely as theoretical: when in practice it is found, as I have found it, to produce invariable results, then we have the strongest possible claims in its favour.

You can make such use of the above as you may choose, as I give it wholly in the interest of bee-keepers the world over, and desire to have the matter fully tested by every bee-keeper in the civilised world. Where there is so much assumption, I desire to do what little I can to enable the brotherhood to work in accordance with law, and at the least possible expense and trouble. A subscriber for years to your valuable *Journal*, I appreciate your labours, and trust you will succeed in the noble work you are striving to perform, namely, that of bettering the condition of bee-keepers in your country, particularly 'Hodge,' and thus bee-keepers the world over.—J. E. POND, jun., *Fairboro', Norfolk Co., Mass., U. S. A., May 17.*

LECTURING IN NORTH WALES.

Roc Wen, North Wales.

[368.] Having been asked to conduct a lecturing tour through the mountainous districts of North Wales, I have availed myself of the opportunity of casting abroad the seeds for the growth of modern bee-cultivation in these far-away and wild regions. During last week I took the coast line, delivering lectures at Colwyn Bay, Rhyl, Llandulas, Abergelle, Conway, and Llandudno. Next week we are going 'up into the mountains.' Such an expedition, I am told by the residents here, has never before been attempted. It will chiefly have to be done in carts, as baggage is rather too heavy to carry with you with any degree of comfort along such mountainous roads; it also necessitates an interpreter going with you, as it is quite the exception to hear anyone speak English; even the better-class farmers are backward in this respect. A Welsh-speaking gentleman has volunteered his services, and accompanies the expedition. I find very little bee-keeping going on in the parts I have visited. These districts at one time were very celebrated for the production of honey, a large honey fair being held every September in the town of Conway. Some of the inhabitants told me that very large quantities of honey and wax changed hands, but that during the last ten years it has gradually dropped off, so that now it is not worth the name of a market. I have succeeded in awakening the interests of a few, and they seem to have caught the bar-frame fever rather strongly. There is no doubt that, now it has been placed in the hands of such men as Mr. E. W. Davies, Hon. Sec., and Mr. Squires, great good will come of it, as these gentlemen evidently mean business, and do not intend to allow the old industry—bee-keeping—of North Wales to decline. I have come across about six bar-frame hives, with the exception of one gentleman at Conway, who has five; four of these were in excellent condition, but very much in want of extra space, the fifth being motherless. I provided them with means of obtaining another. Here they feel very

little the effects of winter, camellias, veronicas, and such like delicate shrubs growing in the open. Great interest was evinced by many, but superstition is very rife, and stands very much in the way of the extension of the knowledge of modern apiculture. At one village, the lecture being given in the schoolroom, I had an audience of over 200; I stayed until midday next day, and was busily engaged most of this time answering questions to those who had attended the lecture the preceding evening.

Bees seem very backward, and it will require some two or three weeks of fine weather to bring them up to the proper standard.

I will give you an account of our mountain expedition next week.—W. B. WEBSTER, *Wokingham, Berks.*

JAPANESE HONEY.

[369.] As already reported, a parcel of honey was included in a trial consignment of Japanese drugs which were sold in Mincing Lane two weeks ago. As far as we are aware, honey from Japan has not previously appeared in our markets, and for this reason it may be well to place on record its more prominent characteristics. It possesses a coffee-brown colour; the odour is similar to Californian honey, but is somewhat offensive; and the taste is slightly bitter, though otherwise honey-like. On standing it separates into two layers, the upper granular and of firm consistence, the lower syrupy and less viscous than simple syrup. On separation from the granular portion the syrup was found to have a specific gravity of 1.350. On treating the honey with water the greater portion of it dissolved, and there floated on the surface a large quantity of yellow pulverulent matter, which dyed the filtering paper, as well as remains of insects, pollen-grains, and other suspended impurities. On examination this pulverulent matter, which makes up, along with crystallised grape sugar, the bulk of the granular portion was found to consist of wax. This exists to an unusually large extent, and should make the substance an efficient basis for boot-blackening, which we understand from a correspondent is the purpose to which it is to be put. The product is never likely to be used in pharmacy, but as it is unique in some respects it would be of interest to trace its origin, and if possible to have information regarding the food of the bees and the source of the yellow colouring matter, which is the principal characteristic of the sample.—*The Chemist and Druggist.*

BEEES AND BEANS, &c.

[370.] I have seen it stated in bee books that it is doubtful whether bees are able to extract honey from the flower of the bean, except when the base had been pierced by the humble-bee. Is this the case? I watched last evening the bees on a field of winter beans where they were very busy, and upon examination I found most of the tubes were pierced at the bottom, but I cannot think this could have been the work of the humble-bee alone, for the whole field of about ten acres was being worked by bees, and this after five o'clock. I enclose a few of the flowers I gathered. I have never seen my bees at work on the common broad bean which grows in gardens.

There was some discussion in the *B. B. J.* on the subject of red clover as pasturage. I never saw any quantity working on the first crop, but I remember in 1884, when pasturage was scarce, seeing the bees vigorously at work on a second crop in August.

I should like to mention that I had a swarm from a skep on the 18th May this year, nine days earlier than last, and eight days later than 1883. I should like to know what has been the experience of others.

I have been using American cloth over my bees, but I find they bite it, and especially round the feeding-stage.—EASTERN COUNTIES.

PLANTS FLOWERING IN JUNE.

[371.] The undermentioned bee flora will flower this month (June):—Birdsfoot-trefoil, bugloss, borage, buttercups, charlocks, clover (white, red, alsike), comfrey, corn-flower, hawthorn, holly, limnantes, lucerne, melilotus, mignonette, motherwort, phacelia, rape, raspberry, sainfoin, snowberry, strawberry, sweet scabious, veronicas, dog-rose, &c.—H. DOBBIE.

BEES AT LAUREL LEAVES.

[372.] What do bees get out of the common laurel? This spring I observed my bees busy at the leaves. They make one or two perforations on the back, near the base, where the first and second pairs of ribs or veins branch off from the mid-rib, and every laurel leaf bears the marks. I enclose a few of the leaves. Now that they are feeding on cabbage, apple, and sycamore blossoms, I have not noticed any at the laurel leaves. If this question has been asked and answered before, I will be glad of the reference.—H. W. LETT.

[The above has been frequently noted by bee-keepers. From the glands, which are the objects of the search of the bees, is distilled and gathered a nectar, or honeydew. References in previous *Journals* will be found in Vol. V., pp. 34, 72, 74; Vol. IX., two letters on pp. 190, 210; Vol. XI., p. 74, &c.—Ed.]

TEST OF FOUL BROOD.

[373.] I am glad to find that one by one our less fortunate brethren are sending in their experiences with our dread enemy 'foul brood' for publication in your valuable columns. By a letter in your issue of to-day I am sorry to see that my friend, W. G. Smith has not yet eradicated the disease from his apiary. What I wish to know is whether his 'test of disease in the queen' is really any test at all. He commences by placing an empty frame of comb in the centre of an infected brood nest: if the brood in that comb had turned out healthy I presume it would have proved that the queen was not diseased, but 'in ten days fifty per cent of the cells contained rotting grubs.' Does this prove disease in the queen? Suppose the queen to have deposited healthy eggs, would not the brood become diseased in that time? As far as I can see many might be led to de throne healthy queens if they applied this 'test.'—Wm. H. COLDWELLS, *Balkam, 20th May.*

FOUL BROOD.—EAT OR STARVE.

[374.] On my return home after a month's absence I found my nine stocks wonderfully improved. Three had been supered in my absence, and I found them all at work upstairs, two fairly actively, and the third with the sections crowded. Three other hives place me in a dilemma. They are swarms of last year, perfectly crammed with bees, and yet so short of stores that though room is urgently needed, I dare not super them; the weather is so bad, showers of rain and hail, and very cold nights. Apple-bloom yielded little or nothing. My bees seem to have wonderful queens to judge by the great quantities of pollen going into the hives. My three remaining stocks are formed from condemned bees, and they cover seven bars each, and have quantities of brood. I put two colonies driven from skeps in each hive, and they wintered very well. It is very pleasant to see my bees thriving. It seems only the other day when I had only to look at a hive to put it all wrong, and exterminate the unfortunate inmates. I had one hive affected with foul brood last year, and, as some of your readers complain of not being able to make their bees take the phenol in summer, perhaps they may be disposed to follow my example. My hive at end of July was very full of honey, so I extracted it all,

and burnt the combs and bars. I put the bees into a new hive on fresh combs of foundation, and with the door shut up with perforated zinc, and a sheet of the same over the bars, I placed the hive in a dark tool-house facing north, and fed with phenol. As it was a case of eat or starve, they ate, and for thirty-six hours I kept them in. For ten days or so they continued to take the phenol, and I am thankful to say I have seen no foul brood since. I got a cast and requeened with it, removing the queen, who was sickly. The colony gave me more extracted honey, but did little in supers. They are now a very fine hive. A neighbour who had foul brood has been giving phenol all the winter, and there is no trace of disease, and the hive is very strong. Your correspondent's bees who take Symington's pea-flour have different tastes to mine. In vain I have offered it—even spoon-feeding the expanded crocuses with it—but my disgusted bees will not approach a manipulated flower, and utterly scorn my attempts to feed them in that way.—IRISH NOVICE.

BEST SIZE SECTIONS FOR GENERAL USE.

[375.] Replying to Mr. Webster's answers (307) to my letter on above (277), he says, in answer to my objection No. 1, that 'the 4 $\frac{1}{4}$ " x 4 $\frac{1}{4}$ " sections will fit the Standard sized hive by adopting a broad frame as always used; this is absolutely necessary if you desire to keep your sections clean.' Mr. Webster has evidently never tried it, or his bees are very different to mine. I admit that it *can be done* if one does not mind the expense and extra trouble, although even then there is a waste of side space; but it *cannot be done satisfactorily* unless the frame covers the sections all round, for otherwise the sections will get out of place, and consequently get badly propolised. I have tried the experiment, and am not likely to repeat it.

No. 2. His answer admits the evil, as he suggests a remedy, which, however, is only applicable when a twenty-one crate is used.

No. 3. Here Mr. Webster makes the roof supply the deficiency in height, but what would he do in the case of a flat roof? Say, for example, an inverted tea-tray. (Of course, I mean the principle, not the tea-tray.)

And now as regards his replies to what I have stated to be advantages.

No. 1. As regards the first part of his reply; if he is right, I am wrong. In regard to the second part, I say, Yes. In three tiers of sections this is $\frac{1}{3}$ "; in fact, it is six per cent,—not much, perhaps, but it's some.

No. 2. Mr. Webster may be able to 'see at once,' but I can't; indeed, I've even seen *judges* at shows apparently unable to do so. I have something further to say below as regards packing.

No. 3. Here is the exception, in which he has given me a *quid pro quo*, but, in reply, I can, I think, say that with the exception of bread-and-butter dishes, &c., nine out of ten are neither round nor square.

Neither do I agree with Mr. Webster when he says we must move with the majority. Surely not when we think the latter are wrong.

Certainly bee-keepers can with a 'slight expenditure introduce the 4 $\frac{1}{4}$ " x 4 $\frac{1}{4}$ " sections into their apiaries' if they wish to, but so also can I by a 'slight sacrifice' weed them out of mine. At the time I wrote my letter I supposed that there must be some tangible objection to the 4" x 4 $\frac{1}{2}$ " section of which I was unaware, but since then I have two other reasons, which would alone determine me to use these latter. First, Because it will be distinct from that used in America, viz. 4 $\frac{1}{4}$ " x 4 $\frac{1}{4}$ " (which, by the by, they use because it suits their Langstroth frame), and would therefore be to some extent a guarantee to the 'British public' that it was home produce, and not 'maize' honey. Second, Because by using the 4" x 4 $\frac{1}{2}$ " sections I can make a market

packing-case to hold twenty-eight ($\frac{1}{2}$ cwt.) sections (first to hold the empty ones, to be afterwards replaced by filled ones) very simply and cheaply.

In conclusion, I would remind Mr. Webster that I did not say anything about 'back supering' (?), or doubling either. He is very sure, but bee-keepers always have been sure, and sometimes wrong. My motto is, 'Chacun à son goût.'

May I ask 'John Bull' whether he guarantees his statement, that Messrs. Abbott Bros. will always supply the $\frac{1}{2}$ " x $4\frac{1}{2}$ " sections, of course at same price as the $\frac{1}{4}$ " x $4\frac{1}{2}$ "?—A. T. WILMOT.

PORCH.

[376.] I enclose a section of a porch and alighting-board with 'zigzag' slide. I make all my hives in this way now, and like none so well. (a) is the porch roof

a Porch roof extending all across the front.

b Porch and entrance (the entrance extends the whole width of hive). Dotted line marks entrance $\frac{3}{8}$ in. high.

grooved to throw off water, and (like the entrance) extending all across the front. As regards the entrance, I

Ground plan of slide for doorway as in page 71 of *Modern Bee-keeping*.

think this of great importance; it is often useful in hot weather, and gives great facility for removing dead bees and debris from the whole floor, including the front corners (which otherwise escape), with bent wire.

If closed ends are desired, they can be added on them

by dotted lines on section; and of course the alighting board should be much wider than the section shows.

In putting my hives together, I nail the front on to the sides, instead of the sides on to the front, to avoid cutting away for door-slide. I paint all joints with thick paint just before nailing up, and drive all my nails 'dovetail' fashion.—W. E. BURKITT, *Hon. Sec. and Expert, Wilt's Bee-keepers' Association, May 12th.*

A QUEEN INTRODUCTION.—A NOVEL METHOD.

[377.] One fine day in March last I examined a hive, satisfied myself of the presence of brood, and was closing it again when I found a dead queen on the floor-board. I was so shocked that I had not presence of mind to look again for eggs or another queen, and had to wait in uncertainty for another fine day, trying meanwhile to account for her death, and wondering if the brood was hers, and were the bees raising another, &c. To my surprise on my next examination I saw eggs and a splendid queen—I think the largest I ever saw—but she was hybrid, and the bees (which I had bought) were black. I was puzzled until turning up my diary I found that last year in June I had some spare queen-cells, and thinking the queen of this hive was somewhat slow in her movements, and past her second year, I put the finest queen-cell just within the super, simply laid on the bottom of it. In a few days I removed the empty cell—hatched. Thus the puzzle was solved, and the benefit of a diary proved. But I should like to ask your readers would you recommend me to try this plan again? It would be so simple for those who keep skeps, and they could easily get queen-cells after a swarm.—R. B. P.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

[348.] *French Books* (F. D.)—I desire to add to the books I mentioned last week *Elevage des Abeilles*, by M. Georges de Layens (two francs).—MELISSA.

[349.] *Dead Bees*.—Like 'J. W. S.', a few days ago seeing about fifty young bees laden with pollen nearly dead within a few feet of the hive, I collected them, and placed them on the top, removing zinc from feeding-hole, and covering them with a bell-glass. The bees quickly surrounded them, and seemed to treat them as friends, relieving them of their burdens, and drawing them into the hive, apparently revived by their attentions.—CHARLES E. CUTHRELL.

[353.] *Sections containing Brood*.—I do not think placing brood in supers would attract the queen into them. I think it is most probable the brood would be deserted by the bees, and so perish. I regard every square inch of brood as too valuable to trifle with, but should like to hear how 'J. C. T.' succeeds, as I think any experiment to induce bees into the supers is praiseworthy.—CHARLES E. CUTHRELL.

[362.] *Doubling*. (Novice).—Make stock on body-hive of sufficient size to take ten Association Standard frames, and each doubling-box of the same dimensions so that they will fit one on each other.—W. B. WEBSTER.

[362.] *Doubling*. (Novice).—The British B. K. A. have offered prizes at the Show at Norwich on the 12th to 16th of July, and at the great National Show at South Kensington, July 30 till August 5, for the best hive for general purposes suitable for doubling to obtain extracted honey, or for tiering up racks of sections for comb honey. Could you not wait till after this and see what improvements the prize hives have, and what they are like?—J. M. H.

[363.] *Bees Telescoping their Abdomens*. (Rare Sips).—This action of bees, like the wagging of the tails by dogs, is an outward sign of an inward feeling; and that feeling is one of self-complacency or joy, which the bee, if left to

itself, has so many reasons for possessing. Christopher North (Professor Wilson), in his *Noctes Ambrosianae*, puts into the mouth of the Ettrick Shepherd (James Hogg) words which indicate the same idea: 'The bees are clinging silently to the flowers, sook, sooking out the honey-dew till their verra doupes (*Anglicè*, abdomens) diln wi' delight.'—MELISSA.

[363.] (Rare Sips.)—The same that makes your chest heave after violent exertions.—W. B. WEBSTER.

[364.] *Supers and Sections.* (Rare Sips.)—It is possible; but your hive will have to be very strong, and plenty of honey coming in. I should confine myself to extracting, and use another hive for sections.—W. B. WEBSTER.

[364.] *Supers and Sections.* (Rare Sips.)—I would advise you to put on the rack of sections first, and when they are about half filled raise the rack and put the Woodbury super between it and the hive. If your bees are strong you would get both filled in this way.—JOHN M. HOOKER.

[365.] *Sections and Extracting.* (Rare Sips.)—If you do not want extracted honey adopt the plan recommended in my answer to 364. A ten-frame hive is large enough for all purposes of storifying, whether doubling or tiering up sections.—JOHN M. HOOKER.

[365.] *Sections and Extracting.* (Rare Sips.)—You can do as you propose very well; of course, you will only get a small quantity of extracted honey.—W. B. WEBSTER.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries unanswered in this way will be answered by the Editor and others.

[378.] *Driving.*—How can I drive the whole of the bees from straw skeps, to make a clean, quick job of it? When I drive some score, or from that to 200, it takes a long time to get them out. I have had a too-large number to finish between my thumb and finger, as they make their appearance on the top of the combs when I have turned the hives up to take the combs out.—CORDWAINER.

[379.] I should be pleased to receive any hints as to the simplest method of raising three or four queens to supersede present ones, as I would like to try the easiest plan for my first attempt. I find the *Journal* a real guide, philosopher, and friend.—IRISH NOTICE.

[380.] *Figwort.*—What is the experience of practical bee-keepers of the value of *Scrophularia nodosa*, or figwort, as a bee-plant?

BEEs AT A LAWYER'S OFFICE.—Not long since, in a famous little town of West Herts, a colony of humble bees settled on the ground, just at the entrance of a lawyer's office. Many were the jokes and gibes occasioned by their presence. 'He that entereth here,' said one wag, 'is certain to be stung!' 'Nay,' said another, 'these bees are non-aeuleated; they cannot sting, but they can and do gather honey, so that the motto should be, "He that entereth here is sure of a harvest!"' 'Are you sure,' said a third, 'that these bees are non-aeuleated?' They are mason bees, and I advise you to test your theory on your own person.' While the discussion was raging, an action of ejectment was brought against the intruders, and immediately executed, so that the dispute was left undecided.

EARLY BEES.—If, as the old adage has it,

A swarm of bees in May
Is worth a load of hay,

good weather prospects should be argued from a still earlier departure from a hive. On Tuesday, April 27th, we hear, Mr. Charity, baker, St. Peter's Street, secured a fine swarm of bees from his apiary. The new colony appear to be strong and well.—*Stamford Mercury*.

THE BEES' PETITION.—O ye bee-keepers! our dear masters, we pray you do have a little pity on us, your humble, hard-working servants. Why should you seek to make our little lives shorter still by giving us slippery-

sided boxes and cold receptacles, in which we are condemned to waste our time, energies, and shoe-leather, to get in and out of them; and also will not be satisfied with our best endeavours on your behalf, but you must urge us to harder work with your extractors and mell-pells. Are we to be improved entirely off the face of the earth? or only suffered to exist just to show what we once were? Give us, we pray you, fair play, and we will do our very best; only do leave us alone to do it in our own way.—Your humble servants, APES.

Echoes from the Hives.

South Cornwall, May 29th.—As your next number will be dated in another month, it seems fitting to report progress. There is with many people an impression that this county is a very early one, forward in vegetables, fruits, bees, and what not. It is a most erroneous idea. In certain favoured localities near the coast, and literally on the coast, there is early produce; but on high ground quite near, we are not in advance of what is reported from counties in the east and south of England. We have had the unfavourable weather you write of in your last, with only a few fine days interjected, and there is no mistake about the result which this produces on our hives. Some stocks in skeps have swarmed—one did so last week. On Monday last one departed and returned, and yesterday another took its flight and was captured. Well, I wish it luck! The weather is fine by day, and honey in small quantities is coming in; but the nights are bitterly cold, and two days ago there was a shower of hail. I am satisfied, from inspection of my own hives, how much the weather has to do with the increase of the family. A considerable store of old honey in the hive does not stimulate the queen in cold weather. Perhaps she feels, as I do, that I might as well not have left it; but I thought to save time and trouble—an important consideration. I fear there will not be much honey of this year for early shows. Our annual exhibition is to be held at St. Austell, in connexion with the County Agricultural Show, on June 23rd and 24th.—C. R. S.

North Cornwall Apiary, May 29th.—A few bees have been on the wing more or less every day during the month with the exception of three days, when they were kept in altogether, but very little work has been done, as the weather has not been so propitious for bees in this neighbourhood as was at first anticipated. The air has been for the most part very chilly, the winds boisterous, storms of cold rain falling frequently. I have only been able to record nine really warm days on which the bees could work freely without interruption.—THE MANAGER, Rowe, Bodmin.

Lismore, Ireland.—Bees wintered well here. I know of a few losses from neglecting spring feeding. The storm on Monday week last destroyed masses of bloom of all sorts, and the hail-showers since have done much harm. This time last year I had lots of honey in the hives.—IRISH NOTICE.

Intheorseay, Cork, May 27.—The outlook is, I fear, poor for honey; no apple blossom. Shocking weather since 15th. Has retarded stocks that have bred but slowly this year.—JOHN P. SMYTH.

Pallanza, Italy, May 29.—The bee weather about here has been lovely, and a fortnight's uninterrupted fine weather has enabled bees to store plenty of honey from acacias, and quantities have already been extracted.—T. W. C.

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

W. K. R.—Enamel cloth has been proved to be a suitable covering for frames. Both samples of enamel cloth forwarded are suitable; No. 2 is the better of the two.

- A COTTAGER.—*Excluder-zinc*.—There is no necessity for excluder-zinc between frames and sections, the distance between the sections prevents the ascent of the queen.
- A. B.—*Carniolans*.—The Carniolan is a large bee, and is distinguished from other bees by its silvery appearance, caused by the abdominal rings of white hairs. See Vol. xii. pp. 110, 123.
- P.—When the honey-glut comes, the bees will then most probably draw out the remainder of the foundation.
- S. R.—Please consult previous numbers, in which you will be able to derive the information how to get bees out of trees.
- R. I. S.—The bees arrived in a sad plight. The honey from the piece of comb had exuded, and the bees were drenched, drowned, and distended. It was not possible to say what had affected them.
- R. J. COLLISON.—I. M. Bertram's fumigator may be procured from C. T. Overton, Lowfield Apiary, Crawley, Sussex. It should be used in accordance with directions in Cowan's *Guide-book*, p. 138. 2. The queen having been forwarded to Mr. Cheshire for his examination, he writes, 'The queen I have carefully dissected, but found no evidence of disease.—F. C.'
- ADVANCE.—We are obliged to you for your note. We shall have much pleasure in giving insertion to Mr. Clowes' mode of queen-introduction.
- H. W. L.—*Old Combs*.—Combs may be used with advantage eight or nine years. After this the cells become reduced in size through the accumulation of cocoons so that the young bees do not attain to their normal size. It has not, however, been proved that they are permanently smaller in size.
- J. P.—*Salicylic Acid Solution*.—You will find a full reply to your question by referring to answer to 'Woodland.' Reply to your second question will be given next week.
- VIRTUOSO.—1. *Glazing Sections*.—See reply to 'Subscriber' in our number for May 13th. As several have made inquiries about glazing sections recently, we have requested 'Amateur Expert' to write us more fully on the question, and he has promised to do so next week. 2. The piece of American cloth forwarded will be found suitable.
- L. W. *Wheatley, Oxon*.—In further answer, we say that the two bees sent being in such a smashed-up state we found it next to impossible to detect anything foreign upon them; any extraneous matter appeared to consist of crystals of sugar, salicylic acid, or some other salt, with here and there pollen-grains of a composite flower, most likely of coltsfoot or daisy. The surface of the body where denuded of hairs appeared whitish, but nothing that we could detect to indicate disease. Here and there upon the wings, and upon a wing sent subsequently, we have found in but a very few places, and very sparsely scattered, what at first appeared to be a compressed hair; but on further examination we found its size and manner of branching very different, and we should think it some kind of fungus which would produce disease and have never seen anything like it before upon a bee—its structure or method of fruiting would enable us to determine its species; and these we are not able to ascertain, and would be glad if our correspondent would forward us further specimens for examination, and also describe, as minutely as possible, what means he took to winter the hive and what with, so that more light may be thrown upon this interesting subject.
- F. D. M.—1. *Layens' Hive*.—You will find a description of the Layens' hive in the *Elevage des Abeilles*, by Georges de Layens, the first edition of which was published in 1874; since which time it has passed through several editions. 2. *Flat-topped Hives*.—The Greeian is a very good flat-topped straw hive. 'Pettigrew's hive,' though too large for many districts, is another good one. In fact any well-made flat-topped hive, of medium size, will answer the purpose. 3. *Storifying Hives*.—Storifying hives must necessarily be flat-topped. The Stewarton, and Carr-Stewarton, are among the best. 4. *Bee-Books*.—Most bee-books, both ancient and modern, give engravings of the different kinds of hives in use in their own times, with description. See Bevan, Dzierzon, Cowan, &c.
- WOODLAND.—*Salicylic acid*.—Given in the manner you state, viz., 4 lbs. of sugar syrup, boiled half-an-hour, and $\frac{1}{2}$ oz. of salicylic acid stirred into it while boiling—was quite enough to have killed all your bees. No wonder that you succeeded in killing about half of them. The wonder is that the bees took the syrup at all. They must have been perishing from want of food, or they would not have taken it. In our answers to queries, respecting the application of salicylic acid, we always refer to the recipes given in Mr. Cowan's *British Bee-keepers' Guide Book*, page 151, which book we strongly advise you to purchase. The price is 1s. 6d., and by consulting it you would have saved the bees you have destroyed. For your benefit we give the recipe: salicylic acid, 1 oz.; soda borax, 1 oz.; water, 4 pints. The acid and borax to be well rubbed together and dissolved in the four pints of warm water. Of this mixture, or solution, 1 oz. only (about half a wine-glassful) is to be added to the whole quantity of syrup, made from 10 lbs. of sugar and 7 pints of water. You will readily perceive, therefore, how strong a poison you have administered to your poor bees, since the quantity of salicylic acid, prescribed in the above recipe, is quite as much as can be given with safety.
- A KENT BEE-KEEPER.—1. *Introducing Italian Queens*.—Introduce the Italian queens to your colonies of medium strength. 2. *Artificial Swarm*.—If the skep is full of bees, and preparing to cast a natural swarm, drive out about two-thirds of the bees to form your swarm, and place this swarm on the stand of the old stock. If not in the place you wish it to occupy, move it two or three feet every fine day until you have it where you wish. The old stock may be moved to its new stand at once. 3. *Transferring*.—It is better to allow the skep to remain *in statu quo* for three weeks before you transfer it to frame-hive.
- AMATEUR, *Durham*.—*Skeps versus Frame-hives*.—The general consensus of opinion is in favour of bar-frames. In the absence of any details, we can only suggest that over-manipulation may be the cause of your bar-frame hives not giving so good results as your skeps. The temptation to be constantly opening them to see how they are going on is often too great.
- E. V.—*Storifying*.—If your stocks are strong they will no doubt accept an upper storey of eight or ten empty combs when there is sufficient honey coming in to cause them to require storage room. By placing a frame or two of brood in the upper storey, you will be likely to attract the bees to accept it.
- X. Y. Z.—*Large Number of Drones in a Stock*.—As you appear to have transferred your stock from a skep to a frame-hive, we presume that you rejected the drone-combs. If not, remove them from the hive, and in those combs containing both worker and drone-brood, destroy the latter. This will prevent any further undue production of drones, but do not seek to remove those already existing.
- R. G.—*Increasing Strength of Stock now covering Six Frames*.—Place the frames partially filled with brood between those wholly filled with it. Keep warm, and if the weather is cold, and no honey coming in, feed gently, not rapidly. As the combs become filled with sealed brood, give another comb in the centre.
- II. C.—*Preventing After-swarms*.—It is not necessary that the hive containing the swarm should be similar in appearance to the parent hive; but, the choice being given, we should prefer the two hives to be like.
- S. R. H. G.—*Bees Deserting*.—It is impossible to say what caused the bees to desert their hive and brood. The angry mood of the colony, a few days previous to their desertion, would seem to point to robbing as the cause. Or it might have been want of food. The late inclement weather, during which no honey has been obtainable, has caused speedy consumption of stores and a good deal of robbing. We presume you have no pests—such as ants, or mice—to disturb and annoy your bees.
- A. A. H.—*Artificial Swarming*.—If the frames of your hives are of the same size and pattern—i.e., are interchangeable—you cannot follow a better plan than that advised by Mr. Cowan, on page 84 of his book, given under the heading, 'To make two colonies for one.' If the frames are not interchangeable, the queen should be removed

from the Cheshire hive, and the Abbott hive, fitted with foundation, being placed on the stand of the Cheshire, about half the bees should be shaken from the frames of the latter on to a board, or sheet, in the front of the former, and as they run in the queen should be placed amongst them. The Cheshire hive must then be removed to a new stand. These operations must be performed at midday, on a fine day only, and the swarm must be fed.

W. MITCHELL.—*Moving Hive.*—If the weather continues cool you may remove the colony in the skep to a distance of a quarter of a mile without losing many bees—perhaps none. Let the entrance be closed, late in the evening, when all the bees are at home, and the skep carried carefully to its new stand, when the entrance must be opened and a board set up in front of it, so as to shade the entrance. This will cause the bees, when flying out, to mark their new location, and few will fail to return to it. After two or three days the board may be removed. Remove from the old stand all marks of the former domicile, and disguise the place as much as possible.

CHRS.—*Rack of Sections for a Skep.*—Unless your skep is a very large one, a rack of twenty-one sections would be too large. The usual size of rack contains eighteen (see *Modern Bee-keeping*, p. 52). For this a case is provided which fits over the hive, and contains the sections; it is 15 inches square inside and 9 inches deep. If the rack is properly constructed, no excluder is required, the spaces between the sections themselves excluding the queen.

SOMETHING NEW AND NOT PATENTED.—*How to insert foundation in supers.*—Take a flat-iron, such as is used for smoothing linen; place it near the fire to hot; place sections on a board; cut foundation; when hot set it across sections. Be careful not to scorch; remove iron; press starter quarter of an inch with thumb or finger; turn up at right angles; then fold.—**A COTTAGER.**

BEE-SWING.—'Inquirer' (Dublin) tenders his sincere thanks to 'Beeswing' for encouraging explanation of raw smell. The uncooked-meat smell is already wearing away. Hives prosperous. 'Nucleus's' remark noted. Blacks all dead now. There was no uniting, as suggested by the Editor.

BEE-KEEPING IN SUFFOLK.—A correspondent writes: 'I find that bee-keeping in Suffolk has been much neglected. I am desirous of stirring up the cottagers to take more interest in their bees, and to keep them on better principles.' What has the Suffolk Association been doing since its formation to leave grounds for such a statement? Our correspondent has already made one county to go, and we feel sure that we shall shortly hear of better doings in Suffolk.

MANUFACTURING BEE-HOUSE.—If 'Beeswing' will send to Pope & Sons, Downham, Norfolk, they will forward him a list of rejected army tents and marquees, with engravings of same. They are low in price, and well adapted for supplementary tents at bee-shows, &c.—**J. LAWSON Sisson.**

A correspondent writes: 'There is no flower gives more pollen than orange gourds, pumpkins, and vegetable marrows, and all that family of gourds. I have seen them rolling in the flowers at 5 a.m. till I could see nothing but pollen all over them. I had to look sharp to get any to impregnate the female flower.'

'Novice' writes: 'Some correspondent recommended water and meal for bees; he would be obliged by his stating the proportions.'

In your reply to R. L. Richardson you say, 'great care should be taken in inserting foundation that it should hang perpendicularly.' Whatever care is taken in putting the foundation in the frames, the combs will not be properly built to fill them unless they themselves hang perpendicular. When a hive is put into the position it is intended to occupy it should be perfectly level across the frames, the weight of the bees when building out the comb would then cause it to hang true in the frame and be so built.—**JOHN M. HOOKER.**

I have tried perforated zinc for the bees to alight on instead of wood, but it does not answer. The bees never alight on it on their return home with a load, but always set themselves down on the wood if possible.—**MID CORNWALL.**

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

June 17, 18.—Essex County Show, Brentwood. Secretary, F. H. Meggy, Chelmsford.

June 29-July 5.—Hives, Honey, &c., Royal Horticultural Show at Liverpool. Entries close June 10th. Secretary, J. Huckle, Kings Langley.

July 12-16. Bees, Hives, Honey, &c., Royal Agricultural Show, Norwich. Post Entries to June 1st. Secretary, J. Huckle, Kings Langley.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

July 30-August 5.—Great National Show at South Kensington. Secretary, J. Huckle, Kings Langley.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

June 24, 25, 26, 28.—Royal Counties Agricultural Show, Portsmouth. Entries close June 17. Secretary, E. H. Bellairs, Wingfield, Christchurch.

July 14.—Swanmore.

July 31, August 2.—Royal Horticultural Show, Southampton.

Aug. 18.—Farnborough.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

THE 'DAVIES' HIVE

was Awarded the BRONZE MEDAL at the HEALTH EXHIBITION for the 'Cheapest and most Useful Hive.' It has double walls throughout, 15 Frames with Metal Ends, Crate of 33 1-lb. Sections, Dummy and Quilt, Roof, Legs, Poreh, Alighting-board and Entrance, Shutters. Price, 21s.; or painted, 24s. Small size, containing 9 Frames and 21 Sections, 15s.; painted, 17s.

STEAM-POWER HIVE FACTORY,
 BRAINTREE, ESSEX.

CHEAPEST HOUSE FOR
BAR FRAMES & SECTIONS

A. DONNELLY & CO.'s, Lurgan, Co. Armagh.

- PINE BAR FRAMES, good finish and morticed. Ardmore pattern. 1d. each; or 7s. per 100.
 - 15 $\frac{3}{4}$ PLAIN TOP BAR, Standard size, with Groove for Foundation. 1d. each; or 7s. per 100.
 - 17 in. PLAIN TOP BAR, Standard size. 1d.; 8s. per 100.
 - 17 in. BROAD-SHOULDERED BAR FRAMES, Standard size, with either Slit or Groove for Foundation. 2d. each; or 14s. per 100.
 - BASSWOOD SECTIONS, of superior quality and finish, V-joint, with either plain or curved openings. 1 lb. size is either 4 $\frac{1}{2}$ x 4 $\frac{1}{2}$ x 2, or 4 $\frac{1}{2}$ x 4 x 2, and in either one or fourpiece. 2s. 8d. per 100; or 23s. per 1000 case.
 - 2 lb. size is 5 $\frac{1}{2}$ x 6 $\frac{1}{2}$ x 2, onepiece. 3s. 3d. per 100; or 28s. 6d. for 1000 case.
 - IMPROVED SMOKERS (the best in the market), 2s. 4d. each. Sent by parcel post anywhere in the United Kingdom for 2s. 10d.
 - NEIGHBOURS' FEEDERS, plain, 10s. per doz.; improved, 11s. per doz.; or 1s. each.
- A Substantial Reduction will be made on these prices to large buyers. A 672

MANIPULATE WITHOUT SMOKE.
WEBSTER'S FUMIGATOR

ENTIRELY supersedes the Smoker, both in simplicity and effectiveness. No 'going out,' as no fire is used. Always ready for use, no matter how laid down, without any extensive preparation. No tainting of honey. No dirty liquid dropping from it to soil combs. Quite portable, can be carried in pocket. Will subdue the most vicious of bees. Can be fitted to any smoker-bellows.

Mr. F. CHESHIRE writes: 'I find—by experiment—that the most vicious Eastern Bees are utterly beaten at once.'

Price 4s. 6d. complete with Bellows; post charge, 4 $\frac{1}{2}$ d.
 3s. without Bellows; post charge, 3d.

BOTTLES OF AGENT FOR USE WITH VICIOUS BEES, 6d. EACH.

W. B. WEBSTER, Wokingham, Berks.

A 596

Bronze Medal awarded for Straw Skeps at the Great Crystal Palace Show, 1875.

Seventeenth Edition. Price One Shilling.

SEVENTY POUNDS A-YEAR:
 HOW I MADE IT BY MY BEES.

By the late J. W. PAGDEN.

Also, by the same Author, price Sixpence.

EARLY ARTIFICIAL BEE-SWARMING.
 NO WATCHING REQUIRED.

Apply to Mrs. J. W. PAGDEN, The Chestnuts, Alfriston, Sussex, by whom the same manufacturers of 'Economic Bee Furniture' are employed as formerly. (110)

THE BEST FOR SKEPS. THE 'TRIUMPH' SUPER.

A STRAW SUPER, well made, light, and warm. Combs can be removed, emptied, and replaced. Bees will take to it when Sections are left untouched. Specially adapted for Storifying. Holds 18 lbs. Easy to Manage. Covered Window for Observation. Comb Starters fixed.

Ready to put on Hive. Carriage free for 4s. 6d.

BOURNE & TAYLOR, 34 & 35 FURNIVAL STREET, E.C. A 651

DR. PINE'S BEE-KEEPERS' VEILS

Cannot be blown against the face;
 Do not obstruct the sight, nor confine the breath.

The Journal of Horticulture for April 3rd, 1879, says:—'We have seen nothing better as a protection to the bee-keeper when working among his bees, than Dr. Pine's Veils. . . . The whole upper of the body is effectually defended from the attacks of the bees, while the clearness with which the work can be observed through the wire netting is so great, that no difficulty is experienced in performing any of the operations of the apiary in perfect safety.'

Prize Medal, B. B. K. A., 1879, for the best Bee-dress.

The only Medal ever awarded for a Veil.

ENAMELLED DEAD BLACK; DO NOT RUST.

Dr. PINE'S VEIL.

Inventor and Proprietor—

Registered Trade Mark,
 No. 46,244.

F. LYON,
 94, HARLEYFORD ROAD, LONDON, N.

Every genuine Veil bears the accompanying Registered Trade Mark; others are, more or less, inferior imitations.

Price 2s. 6d., post free.

Strips of Specially Woven Wire, with selvage each edge, for making them, 1s. 2d. each, post free, of the Inventor and Proprietor—F. LYON, 94 Harleyford Rd., London, S.E. (3)

BOULTON & PAUL,

Manufacturers, NORWICH.

Manipulating or Bee House.

THESE Houses are well made, and painted three coats. The sides and lining to roof are covered with tongued boards, which are bee-proof; roof of corrugated iron. They are very portable, being jointed with bolts and nuts. Any one can put them together.

With Revolving Window for turning the Bees out, Bench for working on, or for standing Hives upon, Floor, and Door to lock, complete.

Sizes—6 ft. x 5 ft. Price £8 0 0
 8 ft. x 6 ft. „ £11 0 0

CARRIAGE PAID.

Portable BUILDINGS of all kinds made on the shortest notice.

FROM CREATION TO 384 B.C.

(Continued from p. 242.)

It was supposed, says Aristotle, that those bees which made rough and imperfect comb did so on account of their youth and inexperience, not yet having gained a perfect mastery of the art of comb-building. Such workers as these were thought to be but one year old, and then we come to a curious—and not very flattering—statement, to which a certain portion of the bee-keepers of the present day may take great exception. The historian says 'that the older bees stay at home and did the work of the hive and thus became hairy, while the young ones, going into the fields to work, became smooth; and it is added that the small bees were more industrious than the larger ones, so that their wings became worn at the edge and their colour black and burnt, but the bright and shiny bees were idle, like women.'

Swarming, of course, could not fail to attract the attention of the most primitive bee-keeper; and bees are accustomed, as many know to their cost, to be most obstinate and self-willed in this the exercise of their power of increase, and often in spite of the greatest care of their master to carry out their instinctive desire; much more so when no care to prevent was exercised. Swarms were thought, at the time of which we are writing, to be imminent when a peculiar and singular noise was made for two or three days and the bees were suspended one upon another in the hive, on seeing which the bee-master was accustomed to sprinkle them with sweet wine. The fact, too, that bees at the time of increase are little inclined to sting was also recognised, although a different

reason was assigned to account for a like result. So 'young bees do not sting so severely as old ones, for this reason the swarms are carried to the apiaries, for they are composed of young bees.'

Another curious case, and this time it is the earliest mention, I believe, of the use of smoke to quiet bees while being handled. For smoking we are told caused the bees to do what at other times they carefully refrained from doing, namely, eating their honey which they had stored for future use, and so gorging themselves with the result that they could be handled without fear. But yet, again, a tribute paid to the gratitude of bees, for 'when a swarm had been weak, strange bees had been known to come and fight with them and take away their honey,' but when the bee-keeper killed them (the robbers) 'the others came out and defended themselves, and would not injure the man.' I have not found this to be the case, in fact probably many bee-keepers have failed to receive so marked a sign of gratitude from the hives they have saved from pillage.

Again, it was said that bees delighted in noise, and accordingly at swarming time a noise was made to induce the bees to settle. This is an early mention of the past—shall I say?—custom of ringing swarms. It was also believed that insects slept—remained at rest without movement—and particularly the bee, which remained quiet and ceased to hum during the night, for there was silence in early morning until one bee aroused the rest by humming several times, when all awoke to work. At night again there was at first some little noise until the hum resounded, when all was still and silence again pervaded the hive. Of bees themselves little more can be said at present, but a little time may be given most briefly to consider bee enemies and bee diseases.

Of bee enemies the chief ones recognised were the wasps, titmouse, swallow, bee-eater, frogs and toads: and of the way the last-mentioned went to work, according to the view of the primitive bee-keeper, an amusing idea is given; for the toad, it is said, blew into the hive and then awaited the bee, which came to see the cause of the disturbance, and ate it. Wasps were trapped by setting flesh in a pan, and when the pan contained a goodly number of the thieves, the pan being placed upon the fire soon ended the lives of these

pests, which even now give no little work, if stocks are not kept strong enough to thwart their efforts by offering an obstinate resistance.

Three diseases of bees are mentioned, and two at least of these can be identified as the same with which the bee-keepers of the present day are troubled. These diseases were (1) cleros, (2) teredo, (3) wildness.

Cleros was a disease apparently our 'wax-moth,' for we are told that the form this disease took was that insects were produced in the hive which destroyed the comb, a also a little spinning worm, which did the same kind of injury. This creature produced a spider-like animal like itself, which caused sickness in the hive, and also another creature like the moth, which flitted about the candles. This again produced a creature filled with a woolly substance. It was not killed by the bees and could only be ejected by smoking.

2. Teredo, a caterpillar, was also produced in the hive, and this, too, the bees did not drive away.

3. Wildness in bees was a disease giving evidence of its presence by a strong smell, and the cure used in this case was feeding on thyme, and in close weather placing in a cool place, and in cold weather in a warm place. With this, the earliest record ceases.

Such is the history of the bee-keeping of the above period, as far as it can be given in so small a space. It is a subject of general interest, and although for practical purposes it may not be of any assistance, it will store up in the mind a sense of the past greatness of great men. If it is possible, and the needful space is at my disposal, I may endeavour during the long drear nights of the winter to give another outline of a period subsequent to the one which has been engrossing our attention, and so little by little give an idea of bee-culture as it has been from the creation onwards, until in the course of a few more columns the time is arrived at when modern literature, taking up the thread of ancient practice by careful interweaving and splicing, has brought it to its present perfection of completeness.—THOMAS MARRIOTT.

USEFUL HINTS.

At about this time last year we were experiencing tropical weather. Bees were swarming out of hives and supers, betaking themselves to the woods, and other places which seemed to strike them as more agreeable than their over-heated hives in such boiling weather. All this took place after a cold May, in which snow was constantly reported from various localities, with cold winds and frosty nights. But there was one important point of difference between May 1885 and May 1886, the latter being an exceptionally wet month, and, partly in consequence of this, but more perhaps owing to the long and severe winter, our bees are in much worse condition than they were in 1885. Then, numerous cases of sections were completed by this time. Now, we have not heard of a single case being filled. The low temperature and the excessive rainfall have prevented the secretion of nectar in the various blooms already past, and, even if the bees have been able to pay them visits, the storage of honey has been almost *nil*. Our only hope would now seem the clover-blooms, and our chief attention must be devoted to keeping up the

strength of our colonies, and, at the same time, to prevent the issue of swarms, until the hoped-for change of weather and consequent honey-flow sets in.

SWARMS, either natural or artificial, must be fed, not however too freely, lest the newly-built comb should be clogged with the stored syrup, and the queen prevented depositing her eggs from want of vacant cells.

Much depends on natural income. During a continuance of cold weather and short honey-flow, bees will consume a large amount of syrup in the elaboration of wax for comb-building. But, on the other hand, with a copious influx from the fields, little or no syrup will be required. Then again, the supply of combs or foundation, and the size of the swarm, are all factors in the amount of food required. Indeed, in bee-keeping, as in all other pursuits, upon the 'What, when, and how' to do it, success entirely depends. Half a century ago, we call to mind the dictum of a celebrated physician of our acquaintance, who, having two sons, one a clever youth, the other somewhat dull, announced—and carried out—his intention of making the former a doctor, and the latter a parson, for, says he, 'a doctor to succeed must be a clever man, but any simpleton will do for a parson!' an assertion which, as regards religion, or even morality, we are pleased to believe, has no place in our day. Nevertheless, we are disposed to think that a man to become a successful apiarist must learn to think and act for himself, under the endless varieties of circumstances for ever presenting themselves, and, to say the least, must not be a born simpleton.

EXAMINE SWARMS about once in three days, to ascertain the straightness of the new combs, and to remedy any defects. If any are built cross-wise, they must be at once set straight within the frames, and must be very carefully handled, or misfortunes will occur from the falling of combs and injury to eggs and brood. All hives should be set perfectly even, by means of a spirit-level, when the combs will be built straight. Let the manipulation be performed during the flight of the bees, and in shade, carbolic solution applied above the frames being preferable now to smoke as a bee-quieter.

SMOKE, of which most perhaps use too much, should only be applied to old-established colonies, and that in very small quantities. The evil of injecting too much smoke into hives arises from the sudden flight of the bees preventing them from filling their honey-sacs, and rendering them almost unmanageable. Under such treatment, angry beyond measure, they freely use their stings, and are most difficult to subdue. As a rule, then, use no smoke, or *very* little, at the entrance, and merely a few puffs occasionally across the tops of the frames to keep the bees below.

ARTIFICIAL SWARM. RE-QUEENING. REMOVAL.—The following proposition having been referred to us for solution, thinking it may prove generally useful, we give our answer here. *Proposition*.—Given, two strong colonies in frame-hives, A and B. It is required to form a third colony, C, to re-queen the three colonies with young queens raised from the best queen in A or B, and to remove them to a new locality, say, at a distance of one mile at least. *Solution*.—About the hour of noon, on a fine day, when bees are in full work, divide A into two equal parts, say, five frames, containing bees, eggs, and brood, in about equal numbers in each part. Place the part containing the queen on A's stand. Remove B to a new stand, distant at least twelve feet from its old one. Place the queenless part of A (which we will now call C) on B's old stand. Give to A and C each two frames of worker comb, or foundation, on the outside of their brood-combs, confining, between two division-boards, the seven frames in each hive. Close the hive until evening. Next, let A contain a better queen than B. In the evening, when bees have ceased to work, remove the queens from A and B. On the tenth day afterwards select from A or C two sealed queen-cells,

large and well developed, cutting them out carefully, and insert them in B, having first removed all its queen-cells. Two good queen-cells only should be left in each of A and B. In twelve days after the excising and insertion of the queen-cells the young queens should be laying in all the three hives, which fact being ascertained, the hives may then be removed to their permanent locality, the removal being made late in an evening, and a board set up in front of each hive to cause the bees to mark their new station. If preferred, the hives may be removed within five days after the artificial swarm was made, and the manipulation of the queen-cells may be performed in the new location, drones being in sufficient numbers.

FROM WHICH HIVE IS THE SWARM? is a question often asked and rarely answered, unless the swarm has been seen to leave the parent hive. If the hive has been supered, the desertion of the super will prove the departure of the swarm. When there is any doubt, and it is important to know from which hive the swarm has issued, after having it and placing it upon the stand it is to occupy, take a handful, or a small box full, of bees from the swarm and toss them up a short distance from the hive suspected to have cast it. These bees will return to the parent hive, and will stand fanning at the entrance.

All our old hives have a small window at the back, about 3 inches square, by means of which we are able to tell both when a hive is ready to swarm, and when a swarm has recently departed, by the crowded or diminished population. Years ago, on returning home one evening, a peep through the window of a strong hive of Italians disclosed the fact that a large swarm had departed. In vain we asserted such to be the case to the 'Guardian of the hives'—call him Priapus if you will—'Hadh't he been watchin' the blessed bees all day long? He was sure no swarm had gone from that heeve.' Despite all these asseverations we insisted upon a strict search of all the hedges and bushes in the neighbourhood, Priapus taking one direction, 'Booy' another, and ourselves a third. After an hour's search, just as the 'shades of evening were closing o'er us,' the whoo-oo of Priapus announced the joyful fact that the swarm was found. High up in an ash-tree, about 100 yards from the apiary, around an arm of the tree, was clustered the vagrant swarm—a beautiful swarm of 'yellow-jackets,' weighing over 5 lbs. Light failed us for its removal, so it remained until sunrise on the following morning, when it was secured and returned to the apiary, our Priapus exclaiming, 'Right you was arter all, sir; but hang me if I oodent a bet a pund it had'n't swarmed at all, at all.' By means of a back ventilator, Dr. Dzierzon states that he is able to make the same discovery as we through our windows.

TIERING UP.—When the auspicious change of weather comes, and the fields are redolent of the delicious scent of the white clover, do not neglect to 'tier up' section cases. Many a pound of honey is lost from not giving sufficient room for storage, and the bees either swarm or become lazy. Never allow them to hang listlessly in clusters upon the hive front, but give air below and section-cases above, always placing the empty one *below* the partially filled one. There are those who advocate the opposite plan, but, except at the close of the season, we have never found it succeed. Then, indeed, when honey comes in slowly, and sections are only partly sealed, room being required, it may be well to give it *above* by placing an empty case over the unfinished one. By doing this the sealing over is often accomplished more quickly, but—

'In the midst of the honey-flow,
Always place your "case" below.'

A good section-case, capable of being 'tiered up,' or inverted, while admitting the minimum of propolisation, and consequent discolouring of the sections, we have not

yet seen, but trust that at some of our forthcoming shows such a desideratum may be produced.

FREQUENT MANIPULATION.—Dr. Langstroth has laid it down as an axiom that 'Practical bee-keepers should remember that the less they disturb the stocks, on which they rely for honey, the better.' Hives should not be needlessly opened, and the bees should not be so much interfered with as to feel that they hold their possessions by an uncertain tenure; such an impression will often impair their zeal for accumulation. Those who, during the late inclement weather, have been careful to feed, and to economise the heat of the hive, will fare better than those who have been over-manipulating, when the honey comes at last.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Meetings of the Committee were held at 105 Jermyn Street on May 19th and June 1st. Present: Hon. and Rev. H. Blyth (in the chair), Rev. Dr. Bartrum, Rev. F. G. Jenyns, Rev. G. Raynor, Rev. F. S. Selater, Rev. F. T. Scott, Rev. J. L. Seager, Captain Bush, J. M. Hooker, H. Jonas, D. Stewart, G. Walker, W. O'B. Glennie (Treasurer), and the Secretary. The Examinations Sub-Committee reported that owing to only two candidates having entered for the first-class examination it had been resolved (with the consent of the candidates) to postpone the date of the examination to Tuesday, August 3rd, being the fourth day of the South Kensington Exhibition.

In view of the Show being fixed to open on July 30th, it was resolved to abandon the Quarterly Conversazione fixed for Wednesday, July 21st, and the Secretary was requested to write to Mr. Grimshaw (who had promised to read a paper on 'The Vocal Organs of Bees') expressing their regret at being compelled to postpone the meeting.

The Exhibition Committee presented the prize list as prepared for the South Kensington Show. It having been considered, it was resolved that the sub-committee do issue the same forthwith.

The revised copy of *Modern Bee-keeping* was submitted, and the Secretary was instructed to send a proof copy to each member of the Committee for approval.

The Rev. Geo. Raynor, the Rev. F. G. Jenyns, the Rev. J. L. Seager, and Mr. J. M. Hooker, were elected to act as judges at the Norwich Exhibition. The Rev. Dr. Bartrum, Mr. W. B. Carr, of Bebington, and Mr. W. Carr, of Manchester, were elected (jointly by the Lancashire and Cheshire Associations and the B.B.K.A.) as judges for the Liverpool Exhibition.

It was resolved that the Committee do hold their next meeting on Wednesday, June 16th, and the succeeding meeting on Wednesday, July 7th, at 3 p.m. on each day.

IRISH BEE-KEEPERS' ASSOCIATION.

A Committee meeting was held at 35 Trinity College on Tuesday, June 1st. The hon. secretary reported that Dr. Traill had kindly promised the use of his classrooms for committee and other meetings. It was decided to hold a conversazione on Thursday, June 17th, at eight p.m. Postcards to be sent to members inviting papers and exhibitions of apian subjects. Meeting open to members and their friends; also to the press. It was proposed at the next committee meeting to try and make arrangements for the sale of members' honey.

DEVON AND EXETER BEE-KEEPERS' ASSOCIATION.

The first exhibition for this season of the above Association was held in connexion with the Devon County Agricultural Society's show at Axminster on

May 18th, 19th, and 20th. The show yard was prettily situated in the grounds of Mr. Knight about half a mile from Axminster. The first day the wind and rain was so bad that the Bee tent could not be put up. The next two days were better, and though the weather was still rather against us, Mr. Baldwin managed several manipulations. There was no new honey shown owing to the late season, but some excellent specimens of 1885 were staged. The appliances were exceptionally good. A new feature in the show was various things made with honey—honey chocolate, honey and fruit liqueurs, honey lemonade, &c., &c. The judges were—W. Horton Ellis, Esq. (Exeter); Rev. J. Bartlett, J. Thacker, Esq.; and R. P. Kitson, Esq. The following were the awards:—

1. For the best exhibition of comb honey of 1885 in section. 1st, J. Thacker, Esq.
2. For the best dozen jars of run or extracted honey of 1885. Rev. J. A. Kempe.
3. For the best sample of bees-wax in cakes of not less than 1 lb. Rev. J. A. Kempe.
4. For the best straw-hive of bees not being a swarm of the present year, open to cottagers only. J. Sanders.
5. For the most perfect bar-frame hive with cover and stand. 1st, S. J. Baldwin; 2nd, E. J. Butt; 3rd, H. Moxey.
6. For best wood or straw moveable comb-hive suitable for cottagers. 1st, S. J. Baldwin; 2nd, E. J. Butt.
7. For the best straw hive for depriving purposes. S. J. Baldwin.
8. For best sample of comb foundation (part for stock and part for super) manufactured in the United Kingdom. 1st, S. J. Baldwin; 2nd, equal, H. Moxey, E. J. Butt.
9. For best collection of agricultural appliances. 1st, S. J. Baldwin; 2nd, H. Moxey; 3rd, E. J. Butt.
10. For best honey extractor. S. J. Baldwin.
11. For cheapest and best sectional super. 1st, equal, S. J. Baldwin, H. Moxey.
12. For best bee feeder. H. Moxey.
13. For any useful apparatus connected with bee management. Special prizes to Fry and Sons for 'honey chocolate'; Mr. Beckett, honey and fruit liqueurs; S. J. Baldwin, patent lever honey tin.

The County Show will be held at Lynton on August 2nd. Schedules may be had from Messrs. Godfrey, Chapel Street, Exeter.

Foreign.

CYPRUS.

While the demand for Syrian bees is less active than formerly and Palestines are only rarely wanted now, Cyprians are gaining friends in every country of the world where they have been tried. Whenever thoroughly tested in their purity side by side with any other Eastern race they invariably receive the preference. This is just what I thought years ago would be the case and what I said repeatedly. It was in deference only to the statements of many older than I, that this opinion was not brought forward with more persistency, but all who were so pronounced in advocating (under the name 'Holy Land bees') the superiority of the two races first mentioned over Cyprians have now had ample time to discover their mistake and rectify it if they wished to do so; and though, during the past season, I have been better able to execute orders for Syrians than Cyprians, I shall let nothing deter me from stating plainly my convictions founded on six years' experience, much of the time in the native lands of these races, and an extended correspondence which gives me the views of a large number of skilful bee-masters residing in every country into which these races have been introduced. And this conviction is, that Syrian and Palestine bees, though they will continue to be cultivated, some have had their best day, while the star of the Cyprians is in

the ascendancy. That it will remain when it has reached its zenith I fully believe, for the statement of Chancellor Cori of Bohemia, the discoverer of Cyprian bees, is as true to-day as twelve years ago: The race of the Island of Cyprus is the noblest and most valuable of all bees which up to this time have become publicly known.—F. BENTON (*Bees*).

JAMAICA.

Bee-keeping in Jamaica is carried on in a very primitive fashion. Wax is more sought after than honey, and large quantities of it are shipped to England. Numbers of bees are kept by the black people. I visited one apiary, owned by a 'black,' and spent some time examining his bees. The apiary was situated among the mountains about 2300 feet above the sea. His hives consisted of soap-boxes, turned upside down and resting on four stones, one at each corner. These stones raised the hive four or five inches off the ground, leaving the bottom of the hive entirely open, and in some cases the combs were hanging below the bottoms of the hives and almost touching the ground. One part of each hive would be filled with cobwebs, &c., and the other part occupied by the bees. To get the bees out of the hive when taking the wax and honey, he kindled a little fire near the hive, allowing the smoke to ascend into the hive until the bees were quieted, when he shook them on the ground and placed another box over them. He extracted the honey from the combs by cutting them up fine and straining. There are not many Italians kept in the island, most of the bees being blacks. The people are beginning to use the frame-hives, but most prefer the box hives. The yield of honey per hive is not as great as might be expected. The blossoms of the logwood, acacia, and other trees yield considerable honey. The honey is mostly of good quality, but some kinds are dark-coloured and bitter. The season for honey gathering is almost the reverse of what it is in Canada. The bees suffer a good deal from drought at times, but I am told the Italians are less affected by it than the blacks.

The wax-moth is very troublesome. The red ants are also a great pest to the bee-keeper, entering the hives, destroying the bees, and devouring the honey. In some places the hives are placed on stands about four feet high, with the legs standing in pans of water, so as to keep off the ants. Frogs and birds also destroy large numbers of bees, and a great many are drowned in the molasses troughs in times of drought. The swarms that go off to the woods, and there are many of them, sometimes build their combs beneath the horizontal branches of trees, much like the *Apis dorsata* is said to do.—A. E. GILPIN (*Canadian Bee Journal*).

NEW ZEALAND.

Amongst the several rural industries now being carried on at Matamata, there is none more generally interesting to visitors than that of apiculture. Bee-farming has now become an established industry in England, America, on the Continent of Europe, and in Australasia; and deservedly so, for very few industries connected with rural pursuits have made greater progress during the last few years, or shown better results when systematically carried out. The importance of apiculture as an industry attracted the attention of Mr. J. C. Firth, who, with his characteristic enterprise, started the nucleus of a bee-farm some three and a half years ago, with Mr. Hopkins, the well-known apiarist, as manager. The result has proved the good judgment of Mr. Firth, for instead of the whole of the honey that is secreted in the clover blossom now 'wasting its sweetness on the desert air,' as formerly, many tons are annually harvested, which find a ready market at a remunerative price. There is one thing worthy of mention, viz., the honey produced at Matamata is without doubt equal to the best produced in any part of the world.

Connected with the management of the apiaries, of which there are two at present, there are two substantial buildings—one containing a large workshop, in which the hives, frames, and other appliances are made, a honey-room for storage of honey, a fumigating room, and an office. The first thing that attracted our attention on entering was the large stacks of 2-lb. tins of honey, nearly 10,000. These had been brought from the principal apiary, and were ready for soldering, preparatory to being labelled and cased for market. At the time of our visit the season's crop of honey was nearly all in, and this will amount to about ten tons—the product of 200 hives—an average of 100 lbs. per hive. In the fumigating room, which for the nonce had been turned into a wine room, we were shown a number of casks containing fruit wines, mead, cider, and vinegar, in a state of preparation. These had been made principally with honey, and gave promise of turning out excellent in quality. The honey used in their manufacture had all been obtained by washing the cappings of the combs; the portion shaved off before extracting the honey from them, and which is useless for market.

Mr. Hopkins, the manager, is of the opinion that were mead, honey, and fruit wines, honey-vinegar, and other such-like products obtainable, an immense demand would soon spring up for them. We have no doubt that this might be made a very profitable branch of bee-keeping if bee-keepers would but turn their attention to it. It would not only be the means of utilising a vast amount of surplus honey, but a great benefit would be conferred on humanity by placing within reach some wholesome, health-giving beverages in the place of the vile compounds now sometimes sold as wines. There is no reason why we should not again revive some of those ancient beverages, such as mead and metheglin.

The other building is used for manufacturing comb-formation. Four of the latest and most improved machines for making it are in use at Matamata, and, in fact, everything that can be devised for purifying the wax and manufacturing a first-class article.

The Home Apiary, situated near to the manager's house, is a small one of about thirty colonies, principally devoted to queen-rearing. Here we saw a large number of miniature or nucleus hives, in which the young queens are reared and kept until they are required. Until quite lately none but pure Italian bees were kept and bred in this apiary, but in December last pure Cyprian queens were imported. These for the time were located here for the purpose of having the young queens reared from them mated by Italian drones, as the progeny from this cross are now considered to be the best working bees cultivated.

The 'Burwood Apiary,' situated some two and a half miles from the 'Home Apiary,' is devoted to honey production. The hives, about 200 in number, are in long rows in an enclosure of about an acre, surrounded by pine-trees, and are well sheltered. The extracting house, where the honey is extracted from the combs, stands nearly in the centre of the apiary. At the time of our visit extracting was going on. From the extractor, which stands on a platform about 4 ft. above the floor, the honey runs into a triple strainer, and from there into the honey-tank, capable of holding 3000 lbs. Here it is allowed to remain for a day or two to get thoroughly ripe, when it is skimmed and run off into tins for market.

One peculiarity about the Matamata honey is its rapid granulation and very fine grain. In the hottest weather it granulates in about three days from the time it is extracted, and in more than one instance this season it would not run from the tank thirty-six hours after being taken from the comb. When placed in a dish on the table its colour and grain give it the appearance of butter, from which it is sometimes difficult to distinguish it.

Mr. Hopkins informed us that the past season has

been a fair one throughout New Zealand for bee-keepers, and that he estimates the season's crop at over 300 tons for this colony. He thinks the Auckland province alone will have produced nearly one-half of that quantity. Altogether we look upon the industry of apiculture as one of much importance to the State, and well worthy of any direct encouragement the State can give it. We congratulate Mr. Firth on his enterprise, and the example he has set to other colonists to 'go and do likewise.'—*New Zealand Herald*, March 6, 1886.

Selected Query.

[381.]—*Are queens reared in full colonies under the natural swarming impulse better than those raised artificially either on the nucleus system or otherwise? and, if so, in what points or qualities are they superior?*

By taking care that no queens are raised from larvae not older than one day from the egg; there is no difference to be observed either as to longevity or prolificness, provided also that plenty of young bees are present to act as nurses. Queens raised carelessly, or from larvae several days old, almost invariably run out during the spring of their second year—really before they are twelve months old.—S. SIMMONS.

I consider naturally-raised queens superior to those artificially reared in nuclei; a queen raised in a full colony by natural impulse would be more prolific, more robust, and her progeny would inherit her superior qualities and prove more industrious.—W. WOODLEY.

I always raise my royal cells from eggs laid by my best selected queen in a very strong colony, and by this means I keep improving my splendid strain of Ligurian bees. When they are about a day from hatching, I cut out each royal cell separately, and insert it into another comb, and put it into an empty hive, which is placed on the stand of the stock from which I want to take a swarm, the old stock being removed to a new situation. In about two hours in one morning I have made fourteen swarms. In that case, the bees raised seventeen royal cells on one comb. Fourteen of them I was able to cut out separately to make the swarms, and each of them had their queen hatched in about twenty-four hours, and all did well. The other three royal cells I destroyed, as they were attached to the others. I never raise queens in *weak nucleus hives*, as I believe the greater amount of heat in a strong colony produces stronger, finer, and more prolific queens.—W. CARR.

I have always found queens raised under the natural swarming impulse, in large colonies—*matribus paribus*—superior to those raised in nuclei, or by other means (and by far superior to imported ones), especially in longevity, fecundity, and general hardiness of constitution. This is my chief reason for preferring natural to artificial swarming, even where frame-hives are used, and for practising the so-called 'Heddon method of preventing after-swarms,' lately described in 'Useful Hints.'—GEORGE RAYNOR.

Queens reared after natural swarming are invariably better than those reared at any other time or in any other way. May and June are the months in which *natural swarming* takes place; the colonies are in a healthy and vigorous condition, they then consist of a large population of young bees, have thoroughly recovered from their long confinement during the winter months, and plenty of honey is coming in. All the conditions are most suitable for queens having the strongest constitutions being reared, according to the natural instincts of the bees. Queens raised in the strongest and most populous colonies are always the best and the most prolific. Queens reared artificially either early or late in the winter are much more delicate, and frequently die the first winter.—JOHN M. HOOKER.

I look forward to the replies to this question with interest, as I am unable to say whether those queens reared under the swarming impulse are better than those reared by the ordinary, or what I believe is generally known as the Cowan method. For the past three seasons I have worked colonies headed by queens reared by the above methods side by side, but there has been no perceptible difference in the results.—C. N. WHITE.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

REVERSIBLE FRAMES. [367.]

[382.] When reading the article of Mr. E. Pond, of Foxboro, Norfolk Co., Mass., U. S. A. (who, I believe, is a lawyer), it occurred to me that I had before read an article of his on the same subject, and on looking over the American papers, I found one which differs in a marked degree with that above referred to. In the *Kansas Bee Paper* for July, p. 103, he writes:—'The question of reversible frames is one of no little importance; that is to say, the results said to be produced by reversing are exceedingly advantageous. The experience of all bee-keepers is that the lower part of frames are never so well filled out as the upper; reversing is said to overcome this entirely. We, however, look for far greater results therefrom. Our experience is that, when we get the brood placed to the top bars of the frames, the bees will at once begin work in the sections. In order to accomplish this in days past, we have been obliged to make use of the extractor, which causes considerable hard labour at a time when we are busy otherwise. Now, it seems we can accomplish this result simply and easily; all we need do is to reverse the frames at the time we put on the sections. The bees will rear brood close up to the top bars, and at once proceed to fill the sections. If any trouble is feared from the queen going into the sections also, it can be easily remedied by using the perforated zinc honey-board between the frames and the sections. We experienced somewhat last season in this matter, and with good results. We are again experimenting this season on this point, and so far it has proved a success. Many plans of making reversible frames have been given to the public, but the simplest one we know of is to make frames with a projection only at one end of bottom bar. The frames can be used in any hive, by simply putting a strip of tin or sheet-iron across the bottom of the hive, for the projection of the bottom bar to rest on. Then, when desired, the frame can be turned over, without trouble or change of the hive.' On the method proposed to be adopted by Mr. Pond I should like to make a few comments on a future occasion.—JOHN M. HOOKER.

REVERSIBLE FRAMES.

[383.] In your American correspondent, J. E. Pond (367) we have another illustration of that class of genius which knows without observation and understands without experience. He says, 'I do know that the theory on which reversibility is based is wholly unscientific, and that the results claimed for it can be far more easily and cheaply obtained and with far less labour and trouble.' As one who approves of reversing, allow me to take up his arguments and conclusions in your valuable *Journal*. Let me—

'Take them up tenderly,
Touch them with care;
Fashioned so slenderly,
False as they're fair.'

Although he is good enough to tell us he does know all about them, he does not even intimate that he has ever had a reversible frame, or even seen one; neither does he record the experience of any one else. This reduces very considerably the value of his statements. I do not know whether we shall agree as to the meaning of the word scientific, but I take it to apply to knowledge—not opinion—derived, *ex posteriori*, from observation or experience. In this sense reversing is scientific, as subsequent statements will show. He says, reversing, if practicable, is clumsy, and difficult, and expensive. This shows again his want of knowledge. We have amongst us reversible frames which are easier to work and less clumsy than any ordinary frame I have seen, while their cost is no more, and they abundantly repay if only for the purpose of getting the comb attached to each side of the frame, thereby increasing the breeding space and preventing breakage. Again, he says, 'It is a conceded fact that bees dislike storing honey in cells that are not deeper than those in brood combs.' This is an assumption. Unquestionably bees as a rule store their honey in deep cells, probably because they are able to store a greater quantity, but there is not an atom of proof that bees dislike storing in brood-cells on account of their depth or shallowness as he intimates. There may be a score of reasons given why they do not as a rule store in brood-cells, but the best I can think of is because they reserve them for the use of the queen and propagation of species. Everyone with experience knows that they will store in brood-cells when the others are filled without exhibiting any dislike. Then he gives us his superior method, which, I venture to say, no one in this country will fully approve. 'In early spring,' he says, 'when I make my first examination, I shave all the combs to just $\frac{3}{4}$ of an inch thick, and then replace them just bee-space apart.' I wonder how many stocks he has? How the bees must gorge on that day! What excitement! Just bee-space apart, so that the bees, fanning in their glory at the discovery of so much food, can fetch it from the cells behind with their wings while they can suck it in from within their tongues! Bees are said to be gluttonous, and to imbibe sufficient for three days; I should say most of these never want again. What inducement to robbing too, just at the beginning of the season, that is, for those that are able to fly. But there, they do all things big in America, and cutting combs, it seems, is not exempt.

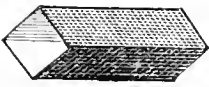

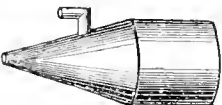

He calls his method, in contrast with reversing, labour-saving. In autumn he puts combs wide apart, so that bees shall build thick combs to store food, and for him to shave it down again on that auspicious spring day—how the bees must look forward to it!—the opening honey-glut. I may be wrong, but I make a practice of getting as little comb as possible to shave off in the spring, and I thought I was sparing of labour both for my bees and myself. At the conclusion he becomes highly philanthropic towards the bee-keeping world, and indignant towards those who reverse their combs. He says, 'I give this information wholly in the interest of bee-keepers the world over, and desire to have the matter fully tested by every bee-keeper in the civilised world. Where there is so much assumption'—save the mark—'I desire to do what little I can to enable the brotherhood to work in accordance with law, and at the least possible expense and trouble.' We shall all agree to have the matter fully tested, and hope that before Mr. Pond writes again he will try a few reversible frames of a simple character. He will not then, perhaps, be disposed to denounce that as assumption in those who differ from him when they have proved it by practical experience.

It is a common practice for some bee-keepers to argue that reversing is unscientific and unnatural. We were told by one correspondent, who was anxious to have no further discussion, that after a time we might turn our

houses upside down, which I should not object to if I thought it would improve my circumstances or increase my income. There's the rub. We say that reversing does increase the income of the bees, and that it is scientific. Bees and their hives are capable of improvement. We try to understand their habits, and under what conditions they will work best, and we employ that scientific knowledge to practical purposes. Reversing frames is never, as far as I have read, seen, or heard, objected to by the bees, while it puts them in a condition of securing a larger harvest in supers with more certainty than any other system, and by keeping the combs fairly clear of honey it promotes breeding—the very objects bees most desire. I know that putting frames close, as advocated by our able Editor and others, is a good plan, but I have tried both, and can unhesitatingly say that reversing is easiest and most certain of results. However close the frames may be, the bees will store honey in them if they do not like the supers. I have found it so, and even uncapping did not make them carry it above, but I have never found a failure with reversing. Reversing is no more unscientific than any other plan. It proceeds upon well-known lines, and is the system which takes most advantage of the natural habits of the bee.—J. RUDGE, *Bee Hive, Dursley.*

FUMIGATORS.

[384.] No doubt many bee-keepers would try the effect of carbolic acid fumes if they could do so without having to use a special appliance for the purpose. The following simple additions to the ordinary smoker will enable it to be used equally well for both purposes.

Procure a piece of perforated zinc and bend it into a square tube, thus—

 of the right size to fit the inside of smoker barrel; into this squeeze the piece of sponge that is to hold the acid; this will hold the sponge in its place and allow a free current of air all round it. Now fix a small elbow-pipe on the chimney of smoker, thus—

 and plug the nozzle of chimney. When required as a smoker, the plug must be taken out of nozzle and put in elbow-pipe. Any acid escaping from sponge will run down into nozzle, where the plug will prevent it from running into the hive. Any tinman will make this alteration for a trifle, or a handy man could do it for himself.—W. H. DOLAN, *Loose, Maidstone.*

A BAD START.

[385.] I have read somewhere that young bee-keepers generally learn something never to be forgotten on their first trip to the heather with their bees. Well, what I am going to relate did not happen on my first trip, but I was only a novice till it did happen. I had three hives out of my stock which were very strong and good, and I thought that I would take them to the heather in the gig and leave the others to follow in a cart. We had only about six miles to take them. At six o'clock in the morning my brother Willie and I got the pony into the trap and then commenced to load up. The first hive was a bar-frame. We got it safely into the gig, ditto with the second, which was a Stewarton, with three body boxes and two tops. The third and last that I was going to take was also a Stewarton, when I lifted it into the trap the pony began to get impatient and restive. The very thought of what followed makes me shiver. Well, when I had got the last hive in and was moving it about to get it to rest firmly, what did that awful pony do but start violently forward, and over I went and

the Stewarton with me, right over the back of the gig! The hive broke of course, and the bees got out, and stung, equally of course. My brother, who was trying to hold the pony, got stung, then the pony was stung about the head, and he bolted down the avenue. I got up, leaving the hive lying as it was, and ran down after the pony, who had caught the wheel of the gig into the gate, and, feeling himself held, was kicking like mad. I got round in front and got hold of the brute by the head, just as the other Stewarton was flying over the back all in pieces. I had scarcely got hold of the rein before the pony hit out with its fore feet and laid me on the flat of my back. Fortunately I was knocked a little to one side or I would not be here now. Just as he got rid of me he managed to break the east-metal pillar, and away into a grass field he went in fine style. He did not go far, however, before he wheeled sharp to the right and sent the bar-frame hive over the side. A little further and he again turned to the right, with which turn the gig turned completely upside down. Somehow the pony got the traces clear, but the reins having been fastened to the lamp-holder the poor brute came back over the track that he went, pulling the gig upside down by the reins. When he got to the place where he threw out the bar-frame hive I caught him, and my brother coming to my assistance, we got the pony loose somehow; the bees were stinging too badly all the time for me to tell how we did exactly. My brother took the pony away to the stable, and after some of the farm-men had the harness taken off, put him into a loose box, where the poor brute had to be nursed for many a day. Almost all the stings that the pony got festered, and the hair came off in patches round the stings. Three months after I counted 250 sting-marks on one side, and the worst places were a trifle too thick to be counted, the mane especially. When I went into the house my sister took a table-knife and actually shaved the stings from my face, and my brother was almost as bad. I would rather not mention what I suffered from them, but will say this, that I scarcely feel stings now.

Of course the wise ones say that I should have done this or that and prevented such a smash-up. I can assure all such that I know better now than to load a cart with hives when the horse is in the shafts. The worst of it is that if I so much as mention the profits of bee-keeping I am always told to remember the pony. Perhaps some will ask what became of the hives, so I will tell what I did. As soon as I could see a little I gathered the combs, or what was left of them, and after turning the Stewarton upside down, and fixed the combs upright with corks and bits of stick, put them on their old stands and left them so. Out of ten combs in the bar-frame seven were not very much damaged, but the bees were—I don't know where. I got a queen some days afterwards surrounded by a few bees in the grass field, but the other two queens were lost. This is all fact, and if it make some bee-keepers a little more careful I will be pleased. I daren't put my name to the end of this, and, Mr. Editor, I hope you will never tell it. I am bad enough plagued already without being hung up in the papers.—G. D. C.

LARGE-SIZED WORKER CELLS.

[386.] In thanking you for your kind reply in answer to my inquiry (359) I cannot exactly make it out, as the comb in question which worked out drone-cells is identically the same pattern I used the whole of the last season, and the early part of this too, and I had good patches of brood hatched out producing fine large worker-bees, and not a single drone until about the middle of April. Why did not the queen drop drone-eggs into these cells? or the bees work out drone-cells for their reception?

I suppose the cells are of such a size to admit of their utilising them to either.

Acting on your advice, given some few weeks ago in the *B. B. J.*, I discontinued the use of distance-pins and reduced somewhat the size $1\frac{3}{8}$ in. between the frames. I think this will have the desired effect.—J. J. CHINNICK.

[Some years ago, when experiments were being made to produce a larger-sized worker-bee by some bee-keepers, Mr. J. M. Hooker imported from America a machine for making the larger-sized worker-cells; the first year, to some extent, he succeeded: worker-bees were produced; the second year there were large patches of drone-brood, and discovering that no dependence could be placed on the ovipositing of the queen, he has discarded the use of the machine. We are of opinion that your experiments will not result in success, that you will not be able to lead Nature out of her ordinary lines, and that you will agree with Messrs. Abbott that such cells should be utilised only for the production of honey to be extracted.—Ed.]

THE SMALL TIT AND THE BEES.

[387.] I have so often pleaded for my little friend—that sprightly little bunch of feathers—the tom-tit (*Cornulus Parus minor*), and that, as he is not yet acquitted, I feel sure you will add this as still further evidence of his innocence. I placed in the winter time a number of boxes made in such a way that I could open and inspect them, and placed them in various positions in my garden. Only one of these, unfortunately, has been tenanted, but a numerous and evidently voracious family is being brought up in this my *observatory birds' nest*. Sir, not a bee do they even touch, though my hives are not twenty yards from them, and the parent birds visit their nest some hundreds of times a-day. My apiary is at the bottom of a walled garden, and having an arbour at one corner of it where I can view all my colonies, and sitting there as I do sometimes for an hour or more at a time reading or writing, I have a splendid opportunity of watching not only the friends, but the enemies and molesters of my bees. My little tit is innocent! Would that the voice of all bee-keepers would pronounce the verdict 'Not Guilty!'—ALFRED E. BOOKER HILL, *The Chase, King's Lynn*.

CAN WE MAKE THE BEE-TENT MORE ATTRACTIVE TO THE PUBLIC?

[388.] Looking over the reports of the various County Associations, one can but notice that, generally speaking, there is a deficiency in receipts of County Shows and bee-tents year by year. Now, to recover lost ground, and to make shows more serviceable, should be the aim of every one. I think the day of large takings to witness driving is gone for ever; in fact, almost everybody knows how to drive. This cannot be said of general manipulation with frame-hives. We have lingered too long in Standard 1. How few of us know anything about queen-rearing, introducing, &c.! I am not ashamed to own that I often have failed to get first-class queens. I take it as a test of competency if a person, cottager or otherwise, can rear good queens. Certainly, County Associations and organizers of shows would do well to give more attention to instructing their members in this most important branch of apiculture. This might be attained by getting up a *conversazione* in the bee-tent amongst those proficient in the art in its various systems—illustrated by the expert with a stock in frame-hive. I would venture to say this would prove more agreeable to expert and audience than the ordinary driving and transferring, with its accompanying robbing and stinging. I have a lively recollection of such a scene,—and guess our expert has, too. The Observatory hive has been a great source of attraction to the general public, and always will be; but it might be made more instructive to modern bee-keeper if some of our queen-rearers would

send a frame of sealed or hatching queen-cells; with ease they might arrange them to hatch during the show. By this means, we should acquire an insight into the system adopted by English queen-rearers. Thanks to Mr. Blow, we have learned something as to the mode adopted on the Continent. With my very limited experience, I could not see, till he gave us the information, how queens could be sold for the money at which they were offered by dealers. Our great want is better, not cheaper, queens.—PLATELAYER.

PEA-FLOUR.—[374.]

[389.] If 'Irish Novice's' bees don't like pea-flour, they are quite right in refusing to take it. I can't think that the crocus flowers like it any better. If the older Darwin's theory be true, the crocuses also must be disgusted by being spoon-fed. 'Irish Novice,' perchance, has lots of natural pollen in his neighbourhood. I have not. Hence the 'different tastes' he speaks of.—J. LAWSON SISSON.

HOW TO MAKE A CHEAP AND SIMPLE $\frac{1}{4}$ CWT MARKET PACKING - CRATE FOR 4" x 4 $\frac{1}{2}$ " SECTIONS.

[390.] Take a $\frac{1}{2}$ " x 9" board, cut four lengths $13\frac{3}{4}$ ", and three lengths 10" (or better, cut two lengths $13\frac{1}{4}$ ", two $14\frac{1}{4}$ ", two 9", and one 10"). Cut one 10" length into four strips, nail these latter on to each end of the $13\frac{3}{4}$ " boards in such a manner as to overlap the ends $\frac{1}{2}$ " all round. These are the top and bottom boards. Now these four boards, with the two 10" (or 9", as case may be), will be found to cover the twenty-eight sections exactly. All that has now to be done is to nail the bottom sides and ends together, and to screw the top. The cost for making one dozen of these crates is as follows—of course bee-keepers must not put time into consideration:—

15 feet 9" x 3" plank at 3d. per foot	3	9
Sawing same (five cuts)	2	0
1 gross $1\frac{1}{4}$ " thin screws...	0	10
1 lb. nails (say $1\frac{1}{2}$ " blue ovals)	0	5
			<u>7</u>	<u>0</u>

In the above cost I have allowed for a 10" x 3" plank, which can be cut down to 9" full. The width of sections varies. I have some in which seven placed side by side only make $13\frac{1}{4}$ ".—A. T. WILMOT.

THE IDLE MAN AND THE BUSY BEE.

Hast thou ever stood,
In the glowing month of June,
Under the garden wall,
Or the pleasant shade of the trees,
In an idle and listless mood,
Watching the 'blessed bees.'
Marking the outward dart,
The hastily plumed wing,
The eager sudden start,
The labour'd home-coming?

Hast thou ever leant,
Lazily over a hive,
Head prone and elbows bent,
Watching the toilers go and come,
All the ambient air alive
With a musical low-pitched hum.
Seen the o'erladen bee,
Panting for very breath,
Working so merrily,
Yet working to the death?

Hast thou ever quaffed
The rich ambrosial scent,
From the gather'd store within,
(By some light zephyr waft),
Speaking to your rapt sense
Of the harvest you hope to win,
Of sections pile on pile,
Extracted *mel* to boot,
A ready sale the while,
Crowning the splendid loot?

Once on a time I dreamt
Such a midsummer-day's dream
(Nor sleeping, nor quite awake,
But absorbed in reverie),
As I stood or idly leant
On the verge of the living stream,
When, sudden as lightning's flash
From a thunder-cloud'd sky,
An angry bee made a dash,
And stung me under the eye!

It hurt me I must confess,
It scattered my pleasant dream,
I felt less inclined to bless,
And thought on a different theme;
Remembered a parallel
In the words of Holy Writ,
One sent to the ant—well, well—
And the cap seem'd made to fit!

W. H., *Dorking*.

MORAL.

Don't trifle with time, but render
Due homage to industry, friend;
And though honey is sweet, remember,
Every bee has its bitter end!

BEE-STINGS.—As so much has been written in your valuable *Journal* about bee-stings, perhaps it might interest some of the readers to hear my experience. In the autumn of last year I purchased three stocks, viz., black, hybrid, and Ligurians. I had several stings from the black and hybrids in clearing the entrances of the hives in October, but they were nothing more in the way of pain or swelling than gnat-bites, so I congratulated myself that I was going to have no difficulty with bees on that score, so employed myself during the winter making hives, frames, &c., also telling my friends that bee-stings had no effect on me. But, alas! in April I had quite a different story to tell. In examining for queens (though I did it very gently, and killed no bees), two or three stung me on the hands. The pain was nothing at the time, but the next day my hands looked like boxing-gloves, and I could not use them, so I began to think of wearing gloves for manipulating, but did not like the idea, as I hate gloves at all times. In the first week of May, when spreading brood, I had several more stings, which swelled up very rapidly, and for two days I had to stop doing anything. So I started gloves, a pair of white kid, and over them thin woollen gloves, with the points of the fore-finger and thumb cut off the latter, so as to be able to pick the frames up easily; but the bees were determined to be even with me, and as I was watching them a day or two ago one fellow came straight at me, a hybrid. I kept quite quiet, having read that that was the right thing to do. But no, he was intent on stinging, first in my whiskers, then on my neck, and not liking these parts, darted into my ear. Even that he did not care about, so tried my nose, and was entering; but I really thought that too great a liberty, so put my hand up, and my friend stung me on the end of my nose. I put some ammonia on it, but it was no use, and in a couple of hours I had a bottle nose and one black eye. Now why did that bee sting me? We read that they only sting in self-defence. I had never offended it in any way; in fact, I do not think I had ever seen it before till I was brutally assailed. Somehow I cannot believe in the inoculation theory. People first going to India suffer terribly from mosquitoes, but after a time their blood becomes poor, and

the insects cause but little inconvenience. Possibly if I continue to keep bees till I become an old man, my blood may become thin, and the bee-stings have no disagreeable effect—A BEE SERVANT.

Replies to Queries.

. In their answers, Correspondents are respectfully requested to mention in each instance the number and the title of the query asked.

Requeening Stocks in a small Non-swarming Apiary.—
1. With reference to a recent query in the *British Bee Journal* asking for advice with respect to requeening stocks in a small non-swarming apiary, where it is not worth maintaining nuclei, I would suggest that the old queens are dethroned about five weeks before the drones are expelled; by this means you have brood-rearing to occupy the bees when honey gathering is at its height—a supposed advantage—and the queen, by a little judicious feeding, will settle down to her maternal duties before winter sets in. Observatory hives are interesting, and are at the same time most useful in small apiaries for replenishing queens.

2. For 'fixing foundation' Abbott's new arrangement for frames is excellent—foundation is inserted with the utmost ease and with great security.

3. I believe I was one of the first to use carbolie. I also would give a warning to those who use it. I well remember losing a fine swarm (when being thrown into a frame-hive) under the influence of this intimidant. The bees became so scared that they took wing and decamped. I do not wish in any way to depreciate the value of carbolie, which is most useful if applied with care.—G. H. G.

[362.] **Doubling.** (Novice.)—The best shape for doubling is a square hive, with one or two upper parts that are thoroughly interchangeable. It is for extracted honey that bees are worked in this method, and it is very rarely the queen ascends any of the upper frames, finding nine or ten sufficient for breeding in. I never use any excluder as some recommend, and have taken a cwt. of honey from one hive by this method, which gives, I think, a fair average: you would get twenty frames for slinging with two upper tiers, the remaining ten in body-hive being left the bees for wintering in.—G. H. G.

[361 and 365.] **Supers and Extracting.** (Rare Sips.)—If a good season, you might possibly get sections worked between top of frames and your 'Woodbury' super; but you must remember that the bees will give you better results in weight by your extracting than in comb honey. You could with advantage in a long combination hive get both, by working with about twenty-four frames, and super to cover about ten, and extracting remainder; but I am afraid we shall not get so good results this season as all would wish, both in quality and quantity of honey.—G. H. G.

[370.] I have been spending a good deal of my spare me this week in watching the bees (common blacks) at work on ordinary garden broad beans. Up to this afternoon I have not been able to catch one actually piercing the base of the flower, but a few minutes ago I saw the whole operation. The flower was certainly unpierced before, for I examined it and watched it until a bee settled and with a sort of screwing motion inserted its proboscis. The bees also gather a very dark-coloured and waxy-looking pollen in considerable quantities.—T. S.

[378.] **Driving.** (Cordwainer.)—The quickest method of driving bees is by the method called 'bumping.' After frightening the bees and removing any sticks that may be placed across the hive, give it a sharp bump on the ground in order to break the attachments of the combs, then remove the combs one by one, brushing the bees back into the hive, after placing the hive on its original stand, to collect the flying bees. When they have settled down they can be removed. You can manage about six or eight hives in an hour or less.—W. B. WEBSTER.

[378.] **Driving.** (Cordwainer.)—This querist's experience is what usually occurs when driving bees from skeps; it is very rarely indeed that every bee will leave the hive, but a few are usually found on the combs, which cause no trouble

as when the combs are taken out they are easily swept off. I hardly understand the latter part of his query, 'When I have turned the hives up to take the combs out,' as in driving the bees from a skep, they should always be driven in an inverted position, though I have heard of bees being driven through the hole at top of skep when they were in flat-topped skeps, and if 'Cordwainer' did this, no wonder at so many bees being found on combs, they being so much less inclined to move than when hive is upside down, and a lot more rapping is required.—G. H. G.

[379.] (Irish Novice.)—The simplest plan is by removing mother bee from one hive, you will then have, say, seven or eight cells formed. When nearly ripe, remove mother bees from the other hives, and about twelve hours after introduce cell to each. Reserve a couple in first hive in case of mishap.—W. B. WEBSTER.

[379.] *Raising Queens to supersede old ones.*—(Irish Novice.) Insert comb or sheet of foundation (comb is best) into centre of your selected stock. In two days examine it for eggs. If found, brush off adhering bees, put it in company with three or four empty combs into new hive in position of some other stock, which need not be the best you have.—PLATELAYER.

[379.] *Raising Queens.* (Irish Novice.)—Bees usually raise at least four queen-cells; I have found as many as twenty-seven in a hive, and for re-queening I always rear them from a hive having a prolific queen and whose bees are strong in numbers and good workers. Make an artificial swarm, and some fifteen days afterwards cut out the queen-cells you require and insert in combs of hive you wish to re-queen. I generally insert two cells for any fear of accident to one.—G. H. G.

[380.] *Figwort (Scrophularia nodosa).*—The last time I saw figwort was in the garden of a well-known bee-keeper. He had taken great pains with its cultivation; but it had been a complete failure. It possessed no attractions for his bees. It, however, bore evidence of having received the attentions of all the insects in his garden; the whole of the soft portions of the leaves had been eaten away, and it presented as perfect a specimen of the skeletonization of a plant as I ever witnessed. Wasps are said to be very partial to it. The *S. nodosa* (the noted Simpson plant) should not be confounded with the *S. aquatica* which is to be found in the neighbourhood of moist places and streams.—MELISSA.

[380.] *Figwort.* (J. P. Smyth.)—I have confidence in stating that this plant is one of the best honey-yielding plants growing wild in this country. A great quantity of the 'Water-Figwort' grows wild about here, and the small brown flowers are thronged with bees, even when white clover and limes are in their prime.—M. J. ASTLE.

Queries.

Queries and Answers are inserted free of charge to Correspondents. When more than one query is sent, each should be on a separate piece of paper.

Our readers will greatly oblige us by answering, as far as their knowledge and observations permit, the Correspondents who seek assistance. Answers should always bear the number and title placed against the query replied to. Any queries answered in this way will be answered by the Editor and others.

[391.] *Removing Wax.*—What is the best method of removing the small particles of wax, &c., from extracted honey?—EDWARD J. GIBBINS.

[392.] *Anglo-Carniolan Bees.*—Are bees that are the progeny of a Carniolan queen and an English drone as gentle and easy to manipulate as pure Carniolans or pure Ligurians? or do they resemble the Anglo-Ligurian cross in temper?—DAR.

[393.] *Turning Drones Out.*—On Sunday, June 6th, the drones were being turned out of one of my hives; what was the reason?—BLANCHE.

Echoes from the Hives.

Plymstock.—There are no signs of white clover blossom yet, but the leaves are well up. Very few swarms have yet come off; I have only heard of three, viz., two on the 23rd, and one on the 30th of last month. There is hardly a bar-frame to be seen here, all skeps, but I am trying to induce a trial of modern methods.—TREVOR SAXNOR.

Somerton, Somerset.—Weather wet and cold up to Saturday, when we had a hailstorm. Sunday beautiful warm day, summer in fact; but Monday and Tuesday is February and March again, with cold and rain.—J. I. S.

Bromsgrove, Worcestershire, June 1.—Sunday last, May 30th, only good day we have had for a fortnight. At time of writing a steady downpour. Most disheartening to beekeepers in this district.—G. H. G.

Holme, June 3.—Weather in this district far from being as one would wish. The continued unseasonable time and strain of willing to work in any weather has cleared all old bee life from my apiary. Now the baby bees are depending solely upon stores given either as syrup-filled combs, or in feeders, the former being most effectual where old stores are entirely cleared out. My thermometer giving me but little comfort for the future, I have almost decided to place it out of sight. Many distressing inquiries I receive from far and near. Hope still bids 'Be of good cheer.' Feed! feed! feed! Then when the honey morn does break, how surprised shall we be at labour done ere it closes, and after all be rewarded for our care and attention.—J. H. H.

South Derbyshire, June 4.—After nearly a month of cold, showery weather, our hearts are gladdened by a splendid morning. I have a boy-sentinel perched on the rails enclosing my apiary watching for swarms in tremendous earnest. Have been feeding frame-hives right up to now to keep breeding going, which otherwise must have almost entirely stopped, for bees have gathered next to nothing since the beginning of May.—M. J. ASTLE.

Torquay, June 5th.—What weather we have had, scarcely a fine day for a fortnight! The last three days have been fine though, and the bees are taking in some honey. They got very little from the apple-blossom, which is now over. I have heard of several swarms here, and also of foul brood, which is about in several apiaries.—R. P. KIRSON.

Bromsgrove, Worcestershire, June 6th.—The weather here seems to have improved for the better the last three days, and barometer has steadily risen. Bees are working like 'niggers,' but no honey coming in; pollen in abundance, frames full of brood and but just a shade of honey. The fruit blossoms are all over round here and nothing to signify for bee forage will be out for another week till the beans and they followed by the white clover. I have known of several swarms last two days, which their owners tell me are quite a month later than last year. I have found a case I think of foul brood brought on by chilled brood in a cottager's frame hive through spreading the brood, but will report further in a week or two.—G. H. G.

North Leicestershire, June 7th.—To-day is the fifth successive good day for bees, maple, apple, sycamore, mountain ash, rhubarb, broom, holly, hawthorn, and dandelion are each and all affording abundant supplies of nectar and pollen. The bees, however, are very backward, many stocks not so strong as they were in April. Uniting is being resorted to in order to bring the stocks up to the required strength for the main honey-flow from the white clover at the end of June and beginning of July.—E. B.

Larnaca, Cyprus.—The winter seems to have been severe all over Europe and in all Mediterranean countries. But while in more northern climates my bee-keeping friends write they were buried in snows, I was away off where the winds blow from Africa's Great Desert, and at the beginning of February was hiving swarms and extracting rosemary honey. Stocks that had not gotten short of stores during the months of December and January and were protected from rains so their hives were dry inside, were quite populous some of them occupying twenty-four frames, twelve to fifteen of them fairly filled with brood.

Feb. 15th, I counted eighteen frames of brood in one hive. Frames each having 120 square inches. Three hundred and fifty queen-cells, formed by a single stock preparing to swarm, were counted on twelve frames. Here in Cyprus the colonies are less advanced, for even Cyprians cannot get honey out of bare rocks and barren sands.—F. B. (Bees).

Notes from the 'Bavarian Apiary.'—Last Sunday morning just after breakfast, when standing with our little son Ralph by the window to view with me the appearance of the weather, we were suddenly greeted by a bevy of sea-gulls which came flying merrily down the 'Schwabinger Bach,' while Ralph clapped his chubby hands and exclaimed at their beautiful appearance. I rejoiced in the thought, 'Now a storm, then fine weather, and our dear little bees will dare to peep out once more!' And so it has proven, Sunday and Monday we had a warm rain, melting away the snow and ice which had seemingly become fixtures to us. Tuesday the sun came out and with it myself and my bees. The little fellows seemed so glad to get out after a confinement of about five months with only one flight of about two hours one day during the last week of February; the next day, however, they were as suddenly frozen up as they had been thawed out the day before, and remained so for nearly three weeks. During the past week I have looked them all through, changed some over into new hives, &c., thinking to myself they were now ready for work. This morning while I sat writing, Zoë came running up from the garden, where she had been at play, exclaiming, 'Mama, the bees are having a fine time.' I dropped my pen, feeling a little like Mahala Chaddock, though 'that husband of mine' is not here to right up. Nor I haven't the conveniences from A. I. Root's five-cent counter upwards to cheer me on in my German house-keeping or bee-keeping either, still, I felt like Mrs. Chaddock in this point, things go wrong when I am not at every corner; and the bees were having a fine time,—not only our own, but our neighbours'. They had sought around and found in the store-room several hives of combs partially filled with honey which had been intended for spring feeding. And they had been fed, for they were nearly emptied of the several pounds of honey they had contained but yesterday. I called the servant, who came running from the wash-house in fear, but I assured her they would not sting when on such an expedition, and I must say she is a right brave old German woman or she would not have ventured; while there was no danger it is often hard to convince these stupid people of the same, but she came to help me, saying, 'So! ist es wahr! Stechen sie nicht?' and with my again assuring her, she grew right brave and we soon had the wreck cleaned up and carried off to the attic, where what was left was safely deposited for future use. I found, also, upon closer examination, as the Germans say, they had been having 'An ächter Krieg' with some of their neighbours, the Cyprians and Syrians proving, however, that they were ready to protect their precious stores let them be ever so little. All this was a new experience for me, and I began collecting my ideas together on what I had seen of late in the bee journals on this subject, but I only had very indefinite ideas on the subject, when all at once I remembered one point I had heard Mr. Benton speak of in case of robber bees, and that was closing the entrances partly up. This I did, and it had the desired effect. Our fine weather has continued up to date, and I have just finished filling early orders for Great Britain and I am beginning to think seriously about our friends over in America, but you know that long sea voyage makes me delay a little; I can feel for the little fellows in their sea-sickness on a stormy sea, and I dread starting them.—MRS. FRANK BENTON, 'The Bavarian Apiary.'

NOTICES TO CORRESPONDENTS & INQUIRERS.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

P. G. SAUNDERS.—*Anbrent fulva*.—The bee forwarded is of the family of *Andrenidæ*: its specific name is *Andrena fulva* (for description of which see Vol. 13, p. 35). Its neighbourhood will not disturb your bees, and there is no possibility of your being able to turn them to any account. They, however, will prove an interesting study.

F. HUGHES.—*Injured Queen*.—Queens should be perfect and without blemish. The loss of part of one leg would not diminish her ovipositing powers, and it might not seriously affect her movements over the comb. If you watch her progress during the season you will be able to discover whether the injured limb is any impediment in the performance of her duties.

M. C. H.—We believe that good foundation for supers can be obtained from those purveyors of bee-appliances who advertise in the columns of the *Journal*; and it would not become us to say that one produces better material than another. Kindly excuse us, therefore, for not giving a more direct reply to your question.

P.—*Removing Bees from a Wall*.—Unless you can get permission to remove more than two of the planks we do not think it possible to get the bees and combs. By smoking, or injecting carbolic acid vapour, you might be able to drive the bees out, and then with a long knife you might be able to detach and remove the combs, but, judging from your description and sketches, it is rather a hopeless operation.

E. C.—*Preventing Casts*.—You did wrong to cut out all the queen-cells. Unless you saw a queen you should have left one. Unless you have a spare queen, or another hive about to swarm from which you can give a ripe queen-cell, you had better unite the stock to another or to its swarm.

S. RICHARDS.—References will be found in Vol. 13, pp. 213, 374; Vol. 12, p. 311, &c.

H. C. M. F.—*Stock Dwindling*.—1. The symptoms you describe point to an aged and worn-out queen. Hence the increasing number of drones and the decreasing number of workers. She has now died. The bees will no doubt raise a queen from the brood which you gave them, but, as this will take time, if you have another stock at swarming point, preserve a ripe queen-cell and give to the queenless lot. 2. Give only hatching-brood for strengthening, and not more often than, as bees hatch out, to cover the added frames. 3. Smoke in moderation is not detrimental to brood.

J. H.—We consider the subject mooted in your letter has been sufficiently ventilated.

M. T. K.—You will find in *Modern Bee-keeping*, and in Cowan's *Guide-book*, directions for feeding in spring and autumn, with recipes for the food then most proper to be given.

F. COCKS.—The sample of enamel cloth will be found suitable, but we prefer it not so smooth.

B. C.—The introduction of the spare queens to the queenless stocks will be a very proper mode of utilising them, and will be a great saving of precious time at this season.

IGNORAMUS.—*Bees Deserting their Hive*.—The presence of the wax-moth was not in such excess as to be the cause of the bees deserting their hives; it is rather to be attributed to the exhaustion of their stores and to their being in a state of starvation. During the past season there has been little opportunity for the bees of acquiring honey, and unless they have been continuously fed, there was great danger of their dwindling to the 'small flight' observed. There need be no apprehension of evil con.

BAR-FRAME WASP-NEST.—A bee-keeper here has had an empty bar-frame hive standing between his other hives with the doorway turned opposite towards the wall, and the other day he saw a queen-wasp about this hive, but lost her. On opening the hive he found her nest nicely fastened to one of the empty bars in the hive, below the crate of sections, which were also on the hive. I took out the bars; there was a small cake with eight or nine cells, and the queen was busy at work inside.—J. I. S.

sequences resulting from the introduction of the comb into other hives.

H. J. L.—1. *Braula cæca*.—From your description and drawing we have reason to believe that the insect you found was a *Braula cæca*, a bee parasite. These parasites frequently affect bees from Italy, Cyprus, and the East. They cling with great tenacity to the queens. In the south of Europe they are very troublesome, but in the northern part and in England they disappear, the climate not being favourable to them. 2. *Ants*.—These cluster under the quilt for the sake of warmth. If you pour some paraffin oil over the pathway of the ants you will get rid of them.

M^YLADY NOVICE.—*Ants*.—Please refer to reply to H. J. L. 2.

C. WIDDEN.—*Bligh Competition*.—This was a most interesting experiment inaugurated by the Hon. and Rev. H. Bligh. Its object was to institute a comparison between the various hives and systems of bee-keeping, and the most economical mode of conducting them; and to show cottagers what may be done in bee-keeping, the operations were conducted in their gardens. Prizes were given to the most successful competitors. On the last occasion the first prize was gained by Mr. T. Owen, of Cosham, Wilts, who proved satisfactorily to the judges that, with the two pounds allowed as capital to start with, he had, during the allotted time, realised a profit of 14l. 3s. 2d. We cannot say whether there is any probability of the competition being repeated, but we hope it may.

J. P.—*Three Queens thrown out from swarm*.—These are young queens, and there is little doubt that another remains with the swarm, perhaps the old queen died or was lost and thus the young queens went out with it. The survivor would be unfertilised and would not lay for a few days. If, when you see this, there are still no eggs or brood you may conclude that she is lost. The same applies to the young queen remaining with the stock.

F. F. G.—1. *Uniting*.—This is as good a time as any, and when plenty of honey is coming in the operation is easy. Remove the queen you do not wish to preserve, open out the frames of the strong hive and place those of the other between them, a little smoke is all you require to quiet them. Unite in the middle of a fine day and place the united stock midway between the old positions. 2. *Changing hives*.—This is best done at midday.

BALLIE.—1. *Sending bees from England to Scotland*.—Bees cannot be sent by parcel post. 2. *Feeding swarms in transit*.—If likely to be, as you say, six days on the road, a damp sponge should be securely tied in one corner of the box, and in another corner a muslin or canvas bag of Demerara sugar. 3. *Weak Stocks in Skeps*.—Transfer to a bar-frame hive and give the bees only those combs containing brood. Unite a swarm to them if you can get one and then give more combs according to the size of the swarm.

W. F. ASKEW.—An answer to your question is given in 'Useful Hints.' As you make no mention of the distance apart of the two gardens, or of the one to which the bees are to be removed, we have supposed the latter to be at least a mile, but the operation would probably succeed at a much shorter distance.

B. C. W.—*Concave Hive*.—You are mistaken in supposing the frames to be broad-shouldered. Novice's metal corners only are used, and it is specially stated (see page 34, and Fig. 16 of our *Guide-book*) that 'there are no distance-pins or broad shoulders.' When in position, the tops of the frames are 'flush' with the sides of the hive—an arrangement which is a *sine quâ non* in all doubling hives; and there can be no escape of heat when the hives are doubled.

P.—*Symptoms of Dysentery*.—When this disease exists, the combs and other parts of the inside of the hive are fouled with stains of a clayey appearance.

R. W.—*Camphor*.—You should tie the camphor in pieces of muslin, and place it in the corners of the hive. It will not cause the bees to leave the hive.

W. J. T.—*Foul Brood*.—The small piece of comb bears evidence that the hive from which it has been taken is affected with foul brood. We would suggest that you

should at once try either the Phenol cure or the Bertrand fumigator.

SOUTH DEVON.—1. Bertrand's fumigators are procurable from C. T. Overton, Crawley, Sussex. 2. The white matter has been smeared on the bee from some substance in the hive, but we are unable to say what that substance is. The bee itself appears afflicted with *Bacillus depilis*.

I am glad to see the first symptom of a bee journal at one penny. I myself could, I think, increase its sale in our small place by about eight or ten copies when it comes down. It is cheap enough at present, but is too much for each one to take alone, especially with two or three other papers as well. But let it come to a penny, and then the price will tempt instead of deterring them, and those who now club together outside the Associations will then take a copy each. I will put, say, what the effect of the changes in price and time of issue:—When the *Journal* was a monthly, ten of us took one copy. When it was a bi-monthly we continued thus, but as soon as it came to a weekly we took three copies; and when it comes to a penny paper I think we can all take one. I shall try hard to get them to do so.—J. ISHERWOOD.

RECEIVED.—*Bee Pasturage*. By Henry Dobbie. This will be noticed next issue.

Received from Messrs. Joseph Dines & Sons (Maldon, Essex) their Catalogue of Improved Hives and Bee-keepers' Appliances (16 pp.)

From Mr. C. T. Overton, Lowfield Apiary, Crawley, Sussex, his Illustrated Catalogue and Price List of Improved Bee-hives and Apiarian Appliances (32 pp.)

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for one Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

PORTSMOUTH SHOW, June 24, 25, 26, & 28,

IN CONNEXION WITH THE

ROYAL COUNTIES AGRICULTURAL SOCIETY.

NEARLY £40 is offered in PRIZES, together with the SILVER and BRONZE MEDALS of the HANTS B. K. A.; most of the Classes being open to all England. The Schedule includes Prizes for Section Honey, Extracted Honey, Honey Comb Designs, Methods of 'Putting Up,' Hives of all descriptions, Super Racks, Extractors, Observatory Hives, Imported Queens, Collections of Appliances, Inventions, &c., &c.

Send post card for full Schedule (now ready) to the Hon. County Secretary, E. H. BELLAIRS, Wingfield House, near Christchurch.

ENTRIES CLOSE JUNE 17th.

LINCOLNSHIRE AGRICULTURAL SOCIETY.

LINCOLN EXHIBITION,

JULY 21st, 22nd, and 23rd, 1886.

THE following Sums will be offered in PRIZES for BEES, HONEY, HIVES, &c., exhibited on the 22nd and 23rd of JULY:—

BEES, £4 10s. HONEY, £5 4s. 6d. HIVES, &c., £14 10s. 6d.

ENTRIES FOR THIS DEPARTMENT CLOSE 5th JULY.

For Prize Lists, &c., apply to R. R. GODFREY, Hon. Sec., Lincolnshire Bee-keepers' Association, GRANTHAM or to STEPHEN UPTON, Sec., St. Benedict's Square, LINCOLN.

WALTON, MUSKHAM, NEWARK.

Bar-Frame Hive.

Price 10s. complete.

Double walled back and front, Tongued and Grooved Floor-board moveable, Plinths, Porch, Entrance-contractors, Legs, Hinged Roof, Ten Frames, with E. C. WALTON'S Improved METAL ENDS (these Ends are interchangeable with those of How, Pine, Edey, or Harrison),

and saw-curf down the middle of bar for foundation. Moveable top sides for filling with chaff, cork-dust, &c.; two Spring Dummies, two Quilts, and Crate of 21 1-lb. Sections, with Glass at each end and Separators.

This HIVE has taken First and other Prizes at Lichfield, Doncaster, Oxford, Coventry, Stone, Ledbury, &c., the past two years.

SECTIONS.

American V-cut Sections of White Basswood,

$4\frac{1}{4} \times 4\frac{1}{4}$ SECTIONS at 12s. 500.

$4\frac{1}{2} \times 4$, same price as above, always kept in stock.

WALTON'S CYLINDER EXTRACTORS,

To take Two Combs that will not chill the Brood, 21s. each.

HONEY BOTTLES of White Flint Glass, to hold 1 lb. of honey, with

Screw Stoppers and Cork Wads to prevent leakage, 30s. gross in case.

COMB FOUNDATION.

DUNHAM FOUNDATION, so much in favour, and easily worked by the Bees, 2s. 3d. per lb.

PELHAM FOUNDATION, a great favourite, 2s. 3d. per lb.

WIRED FOUNDATION, preventing sagging, 3s. 3d. per lb.

SUPER FOUNDATION, of splendid quality, 3s. 3d. per lb.

BINGHAM SMOKERS, 4s., 6s., 7s., 8s. each.

CLARKE'S SMOKERS, 3s. each.

STRAW SKEP SUPERS, to hold Eighteen 1 lb. Sections, 5s. 6d. and 3s. 6d. each.

TRADE supplied with every requisite. Send for WHOLESALE RATES.

WALTON, MUSKHAM, NEWARK.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

QUEEN-REARING.

One of the conditions required for successful bee-keeping is the possession of strong colonies, and this can be best secured by having only young and vigorous queens. Most bee-keepers will have noticed that there is a very great difference in the progress made by neighbouring colonies, some will increase very much faster than others, although they may be about the same strength at starting. It will also have been noticed that some are more inclined to sting and are more irritable than others. Such backward or irritable colonies can be improved by the introduction of selected young queens. The ordinary way of allowing queens to be replaced naturally when the workers will no longer tolerate them, or by swarming, will not accomplish the desired end. It is necessary that we should make a selection of our best colonies and only breed from them. We also consider that the best returns are to be obtained from young queens. Queens may live four or five years, and there are bee-keepers who think they are just as good at that age as when younger; but this is quite contrary to our experience. When queens are stimulated to lay to their utmost, and as much as possible got out of them, they are very little use after the end of the second year. It is certainly to the bee-keeper's advantage to get all the work he possibly can out of them in as short a time as possible, and queen-rearing is so simple that no bee-keeper, who has a dozen or more hives, should be without a stock of young queens to replace those past work.

In selecting colonies to breed from, they should be the two very best in the apiary—one for raising the queen-cells, and the other for raising drones. This should be done early in the spring, about April, so as to ensure the hatching of selected drones before any other drones appear. But it is not yet too late, and even now it is possible to obtain the fecundation of the queen by the Kohler process, already described in 'Useful Hints,' p. 233.

For raising queens, select the best colony, whose queen has proved herself to be prolific, and whose progeny are quiet; and it is most important that they

should be good workers. If the bees are already collecting honey stimulation will not be necessary; but if they are not getting any stores they should be fed gently. Be careful to cut out all the drone-comb, and remove any frames containing such comb, and replace them with frames containing only worker-combs, because from this hive we shall raise only queens, and obtain drones from another hive, and so prevent that in-and-in breeding which is detrimental when queens and drones are constantly bred in one hive.

The hive which is to contain our selected drones is prepared by having drone-combs placed in the centre, which the queen rapidly fills with drone-eggs. When the drones commence to hatch out will be the right time to start queen-cells in the other hive, containing only worker-brood. The queen of this hive should be removed, and given to a colony having an inferior one, or can be utilised in making a swarm. After the queen is removed, examine some of the combs, and cut off the edges from one containing eggs, so as to induce the bees to start queen-cells from cells containing eggs, and not from those containing grubs. Any queen-cells already started should be destroyed. To prevent two or three cells being started close together, we remove the eggs from every other cell, and enlarge the mouth of the cells which we select with a piece of wood bevelled in the shape of a cone. This usually insures their being at once utilised for queen-cells. A large number will be started, and we select as many as may be required from those first started, and destroy all subsequent ones.

In about eight or nine days from starting the queen-cells the bee-keeper will be ready to form his nuclei. We use the ordinary hives for this purpose, and generally take three frames from some of our other hives, two of which should contain brood, and the third honey. If so many frames cannot be spared, two will do. These are taken from any of our other hives, taking care not to remove the queens with them; and as all the old bees will return to the stock when the frames are placed in the nucleus, shake or brush the young bees from one or two other combs into it, or about as many as will well cover the frames and keep up the temperature. In this way form as many nuclei as you have queen-cells to introduce. With a sharp knife cut out the queen-cells very

carefully, so as not to damage them in the slightest degree. Leave a small piece of comb attached above the queen-cell, and by this pin it on to a comb in the nucleus with its point downwards. Close up the space with two division-boards, cover to keep warm, feed with syrup, keep the nucleus well supplied with bees, and in three or four days the queen will begin to hatch. They can then be fertilised by the Kohler process, or by preventing any drones from other except the selected hive from flying out. About the time the queen is expected to fly out to meet the drones, a comb of brood should be introduced into the nucleus, and this the bees will not forsake, otherwise they might leave with the queen, and would be lost.

As soon as queens have commenced to lay in the nucleus, they are ready to be used at any time. We generally introduce our queens after the honey harvest, so that our colonies go into winter quarters with young queens, and it very rarely happens that we lose a queen during the winter. Unless we wish especially to keep a particular queen, we replace all our queens at the end of the second season of their existence. The advantages of young queens are (1), that if properly selected they are more prolific; (2) that they are less inclined to lay drone eggs; (3) that they are less inclined to swarm, and swarming is much more easily prevented; (4) that if the queens have ample space in the hives for the full development of their breeding capacities, the colonies become so strong that the amount of honey collected is enormously increased; and (5) that colonies with young queens winter better, and are not so liable to become queenless.

LIVERPOOL EXHIBITION.

We are requested to state that persons having honey on hand for sale may forward the same for exhibition in the sale class at the Liverpool Exhibition. No entrance fee charged. Application must be made at once to J. Huckle, Sec. B.B.K.A., Kings Langley, Herts.

It is proposed to hold an Examination of Third Class Candidates at the Liverpool Exhibition on Tuesday, June 29th. In order that an opportunity may be given to those residing in the Northern Counties and the Isle of Man to compete for these certificates, notice must be given to Mr. Huckle as above.

GLEANINGS.

In *Gleanings* Ernest R. Root says: 'We very much prefer wheat chaff to oat chaff for wintering, as the former seems to be a better absorbent, while the latter, possibly equally good an absorbent, does not dry out. Colonies last year that had oat chaff did not winter nearly as well; the chaff was wet and mouldy, and had become matted down. On the contrary, wheat chaff was nice and dry.'

In the *American Bee Journal*, in answer to the question, 'Is a one-storey hive as good for extracting purposes as a two-storey hive, provided it is long enough to give sufficient room?' G. W. Demaree says: 'I have tried both, and I am sure the "tiering-up" plan gives the best results.' Dadant & Son say, 'No, it places the

honey too far from the brood, and spreads the colony too much. We prefer a one and a half storey hive with additional half storeys whenever needed.' J. E. Pond, jun., says: 'Much will depend upon the locality. With me the two-storey hive is preferable, and the labour of manipulation is much less with it also.' James Heddon says: 'I have twice given this query careful and comprehensive trial. The result is, I much prefer the "tiering-up" system, and I wish to have but eight Langstroth combs in each tier.' A. J. Cook says: 'I have not been able to see any difference. I much prefer the latter, as they are so much more easily managed.'

In the *Bulletin d'Apiculture de la Suisse Romande*, M. G. de Layens says, in comparing different systems of bee-keeping, the time employed by the bee-keeper ought to be reckoned, so as to give a fair comparison of the profits. He has carefully put down every hour spent with his bees, and he finds for the last two years it has averaged thirteen days a-year. The average produce of the two years is 450 kilograms. Taking the cost of labour in his district at three francs a-day, and the price of honey at 1 fr. 30 c. a kilog., with labour costing 39 francs, he got honey worth 585 francs. Estimating his 30 hives at 30 francs each=900, and 100 francs for apparatus makes a capital of 1000 francs—the annual interest at 5 per cent would be 50 francs. This, therefore, leaves a return of 535 francs, with an expenditure of 39 francs in labour. In this calculation he has omitted the value of wax, which amply pays for any incidental expenses.

In the *Bee-keepers' Guide*, A. G. Hill, in speaking of the best size for the brood chamber, says: 'When we began bee-keeping, we learned from M. Quinby that 2000 cubic inches is the most desirable size for a brood chamber, and we have never seen anything in our experience to change this opinion. It is a safe size, and that will give the bee-keeper the least trouble, and, considering all things, the most profitable.'

In *Gleanings* J. A. Green says he thinks it quite possible for honey to become poisoned through the crushing of bees. This may also come about by the poison being wiped off from the protruded stings of angry bees. Who, he says, on opening a hive on a cool morning has not noticed the rows of upturned stings, each with its drop of poison on the tip? What becomes of this poison? It is very unlikely that it is reabsorbed by the poison-sac. 'I am familiar with the taste of this poison. I have often tasted it upon my hand, left there by a bee that had not stung me. I have also detected it on the surface of sealed honey by touching it with my tongue shortly after such a display of stings as I have mentioned.' He thinks that in this there is a reason why some people cannot eat honey, and are unpleasantly affected by it, and why with them eating large quantities of it produces such severe results.

In the *American Bee Journal* Professor Cook says it is almost certain there are no plants which secrete poisonous honey. It has been suggested that yellow jessamine (*Gelsemium sempervirens*) produced poisonous honey. It is known that the sap of this plant has peculiar tonic qualities, and so it was suggested that the honey from the flower had the same. This view is not sustained by vegetable physiology or by experience. All secretion from animals and plants is through glandular cells. These do not eliminate sap or blood elements, but secrete nectar from elements in the sap or blood. The nectar is a new substance formed by the gland. Thus there is no reason to think that nectar from a flower will contain poison because a decoction from the plant is poisonous.

In the *Organ für naturwissenschaftliche Forschungen* Dr. A. de Planta publishes his researches on the chemical composition of pollen of hazel. The pollen-grains are three-cornered with rounded sides, and are from 0.026 to 0.037 mm. The skin consists of an extine with

openings, and an intine, which at a later period is elongated through these openings. The contents of the pollen-grains consist of protoplasm and oils, which in some places appear in large drops. Starch is also found. The intine consists of cellulose, or a cellulose-like substance; the extine consists entirely of cuticle. In the natural state the pollen was found to contain 9.19 per cent of water, 4.81 per cent of nitrogen, and 3.81 per cent of ash. After thoroughly drying, by means of a sulphuric acid desiccator, and subsequently in a hot-water chamber, the residue remaining consists of 31.63 per cent of nitrogenous substances, 64.36 of non-nitrogenous substances, and 4.01 per cent of ash. From his experiments, he has found that the pollen contains globulin, peptones, of which he found 0.06 per cent in fifty grammes of pollen, hypoxanthin 0.15 per cent, and amides 0.37 per cent. The pollen, according to Fehling's test, contained no glucose. On the contrary, cane sugar was proved to be present to the extent of 14.70 per cent; starch, 5.26 per cent of which is also present. The presence of such a large quantity of cane sugar in hazel pollen is not only interesting from a physiological point of view, but also from the part pollen takes in bee food. Dr. de Planta found two kinds of colouring matter, one easily, and the other with difficulty, soluble in water. This pollen contained 2.06 per cent of colouring matters. Also cuticle 3.02 per cent, waxy substances (but these are not definitely identified), fatty acids 4.20 per cent, cholesterin, and 8.41 per cent of a resinous, bitter substance. It is evident from this that the vegetable protoplasm is rich in organic substances, most of which are in the inside of the pollen-grains, as the skin consists principally of cuticle, and a little cellulose and wax.

In the *Bee-keepers' Guide* Dr. J. P. H. Brown says that every queen-breeder who has any practical knowledge of the business knows that no first-class queens can be profitably reared unless all the conditions bearing upon the development are perfect. The colonies in the queen-rearing apiary must be strong; breeding must be rapidly progressing and the hives boiling over with young bees. Both pollen and honey must be coming in quantities to supply all the demands of a populous colony. Settled and mild weather is another factor. The nights must be sufficiently warm so that the royal larvae incur no danger of getting chilled. Unless these conditions are present queen-rearing is an up-hill business.

The *Bee-keepers' Magazine* says, 'Each apiarist learns something new every year, and it is his duty to impart this information to his fellows, through the columns of his favourite paper.'

In the *Schweizerische Bienenzeitung* J. Halter describes a method of putting a stop to robbing. After trying the usual methods to stop it, when, owing to extracting, robbing had been going on rather extensively, and these remedies failed, he succeeded in putting an end to it in a very simple manner. He placed a piece of window-glass, about 8 by 5 inches, in front of the flight-hole, the top resting against the hive and the lower end about 1½ inches from the entrance, so as to enable the bees of the hive to go in and out at the sides. The next morning the robbers made an attack on the hive in great numbers, but going straight at the entrance were stopped by the glass. They swarmed in front of the glass, but could not find the entrance at the sides, and very soon returned in disgust. To effectually put a stop to further robbing the glass should be allowed to remain for several days, until the robbers forget the spot.

In the *Canadian Bee Journal* S. Cushman says, 'With nitrogenous as well as carbonaceous food a certain amount of exercise (not perpetual however) would increase the vitality as well as the heat of the body. So if bees warm up by exercise (and I have no doubt they do if exposed to sufficient cold or with loss of heat from

top ventilation) then there is all the more need of pollen in the hives. I believe pollen to be necessary at all times as food for bees: a very slight amount may be needed when in the winter cluster and undisturbed by heat or cold, but the little then needed is just as important when needed as at any other time. I want pollen in the hives at all times. The theory that there can be no diarrhoea without pollen and that bees will winter better without it I consider a false one and against common sense.'

In the *Bulletin de la Société d'Apiculture de la Somme* J. B. Voirnot says the constant use of honey is without the slightest danger even during an epidemic of cholera. Honey prevents or cures constipation. The formic acid which honey contains makes it useful in affections of the mouth, throat, organs of respiration and chest. Professors, and all who have to speak in public, should consequently make frequent use of honey. It is also good for colds, coughs, hoarseness, quinsy, pulmonary affections, catarrh, and asthma. A little goose-grease mixed with it adds to its curative properties.

In the same paper the editors say that essence of eucalyptus has been proposed as a cheap and effective method of curing foul brood. A few drops of this essence are poured on the floor-board of a hive infected. The evaporation prevents the healthy brood from being affected and the diseased brood disinfected is removed by the bees. The vapour of this essence destroys the microbe of foul brood. A few drops of essence of eucalyptus in the food also have a salutary effect.—[We believe M. Bauerl, of Geneva, was the first to recommend this treatment.—Ed.]

In the *Bee-keepers' Guide* G. W. Demaree says in all his experience he never knew a queen to mate before her third trip from the hive, and it will be admitted that these several trips in the air in the immediate vicinity of her home give her some experience of the locality. But the young queen has advantages that workers do not have. When she leaves the hive the workers collect on the alighting-board and keep up a lively movement till the queen returns. These movements on the part of the workers at the entrance of the hive answer as a signal from the home of the returning princess. With these advantages in her favour the young queen rarely ever enters the wrong hive. In fact, he does not believe it ever occurred except in the case of two queens going out at the same time from adjoining hives.

In the *Bulletin d'Apiculture de la Suisse Romande* Charles Dadant says, frequently enough, two queens, the mother and her daughter, are found living in peace in the same colony, both laying and living side by side without interfering with each other. This takes place when the bees, having recognised the falling fecundity of the mother, have made preparations to replace her by rearing one of her daughters. But this abnormal state of two queens in one hive generally only lasts a few weeks, or at most a few months.

In *L'Apiculteur* M. Hamet says he is the oldest member of publishers of bee literature. The *Apiculteur* is in its thirtieth year, and besides this he has issued several other publications. By the end of 1886 he will have issued 70,000 volumes and pamphlets, viz., 40,000 vols. of *L'Apiculteur*, 18,000 vols. or *Cours d'Apiculture*, 8000 *Calendriers apicoles*, 4000 *Anesthesies*, and several others jointly with other authors.

IN GOOD HONEY YEARS FOUL-BROOD DISAPPEARS OF ITS OWN ACCORD.

In order to prove this truth I send you the following instances:—

1. In 1880, foul-brood broke out in three apiaries in Enzheim. For three years I cured according to Hilbert's method, destroyed several hives and kept continually the whole of the stations here under my

own careful control and care. In the summer of 1882, I was positive that foul brood had entirely disappeared. As the months May, June, and July, were good honey months, the bees were in good condition. In the bad honey years 1880 and 1881, the treatment was without success.

2. In 1881, hives affected with foul-brood appeared in a neighbouring district. It was no use thinking of a regular cure there, for the greater number of the bee-keepers had no idea of the danger, which threatened their pets and the latter were left to themselves; but in the summer of 1882, no trace of foul-brood was to be found in this neighbouring place, and the hives were full of bees and honey, as at Enzheim.

3. In the spring of 1884 foul-brood was raging at all the apiaries in the Hasel and Breusch Valleys. Mr. Vierling, a distinguished bee-keeper from Niederhaslach, effected cures in many apiaries, according to Gravenhorst's method, by means of carbolic acid, and towards the end of the summer of the same year the disease had been removed.

4. On June 10th, 1884, Mr. Vierling found the only surviving hive in the apiary belonging to the miller Siat in a high degree suffering from foul-brood, diffusing quite a pestilential odour and exceedingly weak and inactive.

The owner, however, would not follow Mr. Vierling's advice, to destroy the hive at once, but left the bees to their fate.

Mr. Vierling was not a little astonished when, in the spring 1885, Mr. Siat requested him again to look at his hives and bees, which were again busily flying in and out. He was even more astonished when he found the bees perfectly healthy. The foul-brood has, also, entirely disappeared at the present moment from all the apiaries in both the above-mentioned valleys, as well as from the skeps as from the moveable-frame hives, the half of which had undergone no cure whatever.

The summer and the autumn of 1884 were exceedingly good honey seasons in all the valleys of the Vosges, and to such an extent even, that Mr. Vierling's hives which were suffering from foul-brood in the spring produced a great quantity of slung honey in the same year.

In all the above-mentioned cases, those hives which were subjected to an artificial cure, as well as those which were left to themselves, recovered at the same time, and each time in consequence of a good, long continuing honey season. From this we must conclude, that the bees themselves possess a means of overcoming this pestilential disease effectually, and this effectual antiseptic is nothing else than formic acid, or bee-poison.

In a bad honey season the activity of the bees is reduced to a minimum. As at such a time there is no loss of working powers, little is eaten, and in consequence of this, only little formic acid produced. The evil-smelling miasma of foul-brood seems to force the bees to complete inactivity and to take from them all pleasure in the keeping clean of their dwelling. Should no great influx of honey disturb such a lazy life, an infected bee-hive is irrecoverably lost, in spite of all application of thyme, camphor, salicylic acid, and whatever other remedies there are, that have been praised by tongue and print.

It is quite different when suddenly a glut occurs. Let us then consider the life in the interior of a hive. How busily they are all running backwards and forwards, how the cells get filled, how diligently they build!

The diligent workers are no longer frightened by the decaying corpses of the dead brood: they must be removed, for there is a want of room. The soiled cells are cleaned again in a few hours, and instead of the foul-smelling, pestilential odour, the bee-keeper is greeted by

a pleasant smell of honey and wax, in which it is easy to perceive the sharp, somewhat poignant smell of formic acid.

The more honey that is brought in and carried from cell to cell, the more formic acid is brought into use, and the sooner the foul-brood disappears.

The radical cure of a hive suffering from foul-brood is, therefore, only possible in a good honey year, and without the intervention of the bee-keeper himself.

Whether the same end can be also attained in a bad honey year by artificial, uninterrupted feeding, and by allowing the bees to build freely, will be taught by the future. Instead of an addition of carbolic or salicylic acid, I would introduce with the food the bee's natural remedy—formic acid, in small doses. Formic acid is to be had in every druggist's shop.—DENNLER, *Enzheim, Nov. 11th, 1885, Elsässisch-Lothringische Bienen-Zuchter.*

[This article has appeared in several Bee papers, and we give it here because we wish our readers to know all that is being done with respect to foul brood. We would, however, point out that the theory advanced is in direct opposition to our experience, and that although a cure may be easier in abundant honey seasons, yet it is quite possible even in bad honey seasons—as we ourselves have proved—to cure foul brood. We are very glad to find others have done the same. M. Bertrand, in the *Bulletin l'Apiculture de la Suisse Romande*, points out that the seasons when he cured his hives were particularly bad, and he winds up by saying, 'Cholera, another bacillus disease, appears, rages, and ends by disappearing of itself; is it not combated from its commencement without waiting for it to finish its work and exhaust its vitality?' We would, therefore, caution our readers not to trust to this 'let-alone' principle. We would also recommend them to be careful with the proposed remedy, and not abandon those already proved to be efficacious, for one not yet tried. In the *Schweizerische Bienen Zeitung* for March, M. H. Hœusser also criticises M. Dennler's article, saying he has completely cured foul brood in his apiary by Hilbert's process, and that his experience does not at all confirm M. Dennler's theory with regard to the spontaneous disappearance of foul brood in good honey seasons.—ED.]

Foreign.

FRANCE.

It appears that in the Ministry for Commerce, a statistic of French apiculture is made up annually. The latest taken is for 1881, and has been published by our contemporary the *Apiculteur* a couple of months ago. These figures show that the number of stocked hives throughout France in the year in question was 1,669,759, and their product is represented by 8,566,542 kilos of honey and 2,644,762 kilos of wax. If the value of the honey is estimated at one franc per kilo, equivalent to about 10d. per 2 lbs. 3 oz., the market value of the whole of the honey produced in France in 1881 would be about eight millions and a half of francs, and that of the wax another eight millions, if valued at three francs per kilo. Compared with the three previous years, the above figures offer the following comparison:—

	Stocks of Bees.	Value of Honey.	Wax.
		Francs.	Kilos.
Totals for 1881 ...	1,669,579	8,566,542	2,644,762
" " 1880 ...	1,771,073	8,613,645	2,660,701
" " 1879 ...	1,808,518	8,581,678	2,472,942
" " 1878 ...	1,371,365	9,948,643	2,845,729

These statistics embrace eighty-seven Departments, of which the following are a few of the most 'populated'

from an apicultural point of view, their respective figures being as under:—

	Stocks of Bees.	Value of Honey.	Wax.
		Francs.	Kilos.
Allier	18,227	48,025	35,178
Lower Alps	25,000	106,250	45,000
Upper Alps	14,150	21,250	14,150
Ardèche	22,410	73,953	33,615
Aube	30,000	153,000	54,000
Aveyron	25,000	100,000	37,500
Corrèze	40,000	80,000	40,000
Côte-d'Or	26,106	23,495	22,190
Côte-du Nord	62,000	496,000	229,400
Fimistère	72,000	486,000	108,000
Ille-et Vilaine	70,000	367,974	137,990
Isère	28,000	168,000	42,000
Loire-Inférieure	10,000	360,000	40,000
Lot	25,000	50,000	25,000
Manche	42,350	219,865	50,820
Morbihan	68,575	411,450	137,150
Pas-de-Calais	18,473	116,860	31,404
Saône-et-Loire	35,000	218,750	47,250
Haute Savoie (Upper Savoy)	21,815	104,712	39,267
Somme	27,902	118,572	37,389

It further appears that in 1881 the actual number of stocks within Paris itself exceeded one hundred.

In commenting, however, upon the foregoing figures, the *Apiculteur* advises its readers not to put implicit faith in their correctness, for having, in the majority of cases, been taken down by wood guardians (*gardes champêtres*), it is allowed to suppose that in many instances the hives have been counted from a distance without ascertaining whether they were all stocked or not. Moreover, when the figure has been furnished by the cottager bee-keeper himself, its accuracy does not become more reliable, for this class of people are naturally of a suspicious nature, and look upon all such inquiries as the forerunner of a new burden in the shape of a fresh tax upon their limited income.

CANADA.

BEE-KEEPERS' CONVENTION IN OXFORD, CANADA.

A number of the counties in Ontario, Canada, have organized local bee-keepers' associations. These associations meet at time and place in the county appointed by its members. They are generally quarterly, and are the means not only of fostering a more friendly relationship between those interested in apiculture, but aid materially in the advancement of profitable bee-keeping.

Amongst such associations in Canada that of the County of Oxford, which met at Woodstock, May 1st, 11 a.m., claims a high place. There were present forty-four members. The president, Dr. Duncombe, of Embryo, in the chair. Reports of wintering were received, and the loss is estimated at a trifle over 10 per cent. This estimate is from about 900 colonies, only a partial report of members. The question of spring management was taken up, the Canadian climate is such that April and early May is uncertain as to degrees of heat. It was generally advocated to contract entrances during cool days and nights and put chaff cushion above the frames, making all comfortable, especially for the weaker colonies. This is the general method adopted in Canada during spring.

Introducing queens was next brought up. It was advocated to wait until cells had been capped five days if it was desirous to introduce a virgin, and then let her out of the introducing cage. The bees are then apt to take her for one of their own cell inmates emerged and leave her unmolested. Although it is difficult at times introduce queens, especially virgins, after having for

some time left the cell, much depends upon the care exercised in releasing her from the introducing cage and closing the hive.

Mr. J. B. Hall was then requested to give an account of what had transpired during his visits to Toronto in connexion with the Colonial and Indian Exhibition. Mr. Hall stated everything was progressing favourably; the Oxford county had promised to send more honey than any other county in the Dominion.

Mr. C. Malcolm, of Innerkip, in speaking of success in bee-keeping, stated he found no certain rules could be laid down, so much depended upon circumstances. He found that in his cellar for wintering colonies side by side, and apparently in equally good condition in the fall, had come out of vastly different strength in the spring. He thought the constitution of the bee was not sufficiently studied. Queens, who threw worker progeny, which proved themselves not as vigorous and capable of withstanding hardships as others, should be carefully excluded from the apiary. By closer observation these weaknesses might be noted. The general impression was bees had bred more during the winter than is customary. This had caused an unusual consumption of stores, and many of the colonies lost had starved. The question of whether feeding should be done in the fall to stimulate brood-rearing, and the almost unanimous verdict was no. He kept his cellar from 48° to 88°, and bees commenced breeding towards spring as the temperature raised. The advisability of wintering in a cellar without bottom boards was discussed. Few had tried it—those that had favoured such a method.—R. F. HOLTERMANN, Brantford, Canada.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Upper St. Martin's Lane, London, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, King's Langley, Herts (see 2nd page of Advertisements).

* * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

HONEY AND FLOWER SHOWS.

[394.] Another season has ushered upon us the usual bustle and anxiety regarding our annual exhibition. The getting up of a schedule for such may seem a light matter, but I am afraid none but those who have undertaken the duties which usually fall to the lot of a general secretary have any idea of the difficulties to be surmounted in getting everything satisfactorily wound up, and all as far as possible pleased, whether on the winning or losing sides.

From experience I know such undertakings are not always of the most pleasant nature, for in our best efforts we often find when once the work is over that there are sure to be novices and theorists making new discoveries, finding fault with everything done, and even suggesting ideas which in many cases if adopted would prove ruinous to every bee-keeper, while the actual practical issue is lost sight of, and ingratitude is too often the final result obtained from those even who have had the greatest gain. Notwithstanding these unfavourable criticisms 'Shows' must ever continue to be the only practical source of information and education on the different improvements habitually springing into existence.

'How to organize aparian exhibitions in rural districts' has taken up my attention for several years, and I purpose as briefly as possible to give a short outline of how

we were enabled to introduce the 'hobby' into this district and at the same time make it the means of re-constituting a Horticultural Society of over twenty years' standing. For several years this Society was gradually losing the confidence of the public, consequently its failure was a foregone conclusion. In 1882 matters had assumed a very gloomy aspect. The following year I felt impressed that an exhibit of bees and honey might assist in increasing the public interest, and having submitted my plans to the directors they were readily accepted, and eventually with the assistance of my two brothers the first apiarian display was inaugurated with great success. Unfortunately the horticultural department was again a failure, and at the annual meeting the directors resigned, and a vote was almost carried to wind up the Society. Some of us thought it hard to give up such an old important institution, and so willing volunteers came forward to make another effort, the writer undertaking the duties of honorary secretary.

Our first business meeting resulted in the addition of an apiarian department to our proposed schedule, and this I believe was the first amalgamation of a Horticultural and Apiarian Society in Scotland. The increased interest manifested in 1884 was most encouraging, and the result was that the annual exhibition turned out the most successful held for many years.

In the Apiarian department our Committee wisely resolved to leave every class open, as very few bee-keepers were in the district, and thus every one interested had the facilities afforded of making the first competition a success.

In the honey classes my brothers were again the principal exhibitors, while the other classes were mostly got up by myself; these included an Observatory hive at work, a model apiary, collection of honey goods from Mr. Moyle, and of natural history objects, diagrams, &c., all relating to the study and management of the bee.

The present year (which happens to be the twenty-fifth anniversary of the Society) promises to be the most successful ever held. Over 500. in cash, medals, &c., is offered and already guaranteed by the directors; we have also secured the Highland Society district medal for our honey department, and above all, we are able to confine our apiarian classes to our own district, thus fulfilling the duties of every local show, in specially providing for the individual amateur who may exhibit for the first time. You will see from the schedule, which I herewith enclose, that open and confined classes are even made among ourselves, so that a truly representative competition may be the final outcome.

I can, with every confidence, commend our experiment as a means of introducing practical bee-keeping in country districts, where apiarian shows of themselves cannot be thought of, and thus the risk and expense combined would certainly be reduced to a very trivial matter.

Unfortunately many of our local exhibitions are mismanaged alike by over-zealous directors and competitors, and I trust in a future article to describe the different classes of competitors we meet at all 'shows,' whether of flowers, honey, poultry, &c., and the different tactics many adopt to become prize winners even in the face of the most stringent rules, and also show how the rules of every association might be framed to at least partially remedy this glaring defect, and render more interesting all our public competitions.—E. McNALLY.

CUMBERLAND JOTTINGS.

[395.] I have a wish to say a word or two about bee-keeping here. I'm afraid if my bees could have read the glowing accounts of your management—for which we are so very much indebted to you—they would prefer to be similarly treated. In passing, I may say that, following the instructions given in your *Guide Book*, I worked two hives on the doubling system last year, and

was more than satisfied with the result in both cases. One hive was a large one holding seventeen frames single, or thirty-four doubled, and the other an ordinary ten-frame hive. In both cases the upper set of frames were extracted when sealed over; your explanation of the improved system of storifying (page 253, vol. XIII.) coming to hand too late for last year.

The winter in this part of Cumberland was unfavourable for both bees and bee-keepers, and the spring has been still more so. I hear many complaints of bees dying and weak stocks. The cold east winds and rains have checked breeding, and but for the assistance of the feeding bottle would have wrought serious mischief with hives full of brood, but with little stores. On Wednesday last I noticed from my windows the last patch of snow on the Caldbeck Fells—some twelve miles distant—which I am happy to say has disappeared altogether under the bright sunshine of the past few days. Since Thursday last we have had splendid weather, and the bees are working with a will on pear, apple, and sycamore blossom. Arabis is about finished; red clover is coming out—though I have not yet seen the bees working on it. They did well on the currant blossom and wallflowers, but missed the splendid show of wild cherry on the few large trees in my garden field.

My own bees (five hives) have passed through winter fairly well, and are now making good progress; two of them covering fifteen frames, with brood on all except the outside ones, and a third on ten frames. The remaining two are on seven and five frames respectively, and will be used probably as nuclei.

As an instance of the value of winter passages during a long spell of severe cold, I may mention that in closing up my hives last autumn I neglected to cut passages, and found on opening in spring a thick seam of dead bees in the centre of one of them, all the honey consumed from the combs on each side, while the bees on each side were living and had abundance of food. Fortunately the queen was safe, and is now doing well in a small way.

I tried dry sugar feeding during the spring of 1884, but could not satisfy myself of its economy as I noticed through a small window in the back of feeder that the bees were apparently unable to reduce a large portion of the sugar (Demerara) the upper surface—half inch or so—being thoroughly desiccated, and the colour changed from brown to white. Some of the bees were busy pushing their tongues down to the original brown, while others were as busy carrying out of the feeder, and no doubt out of the hive, the hard desiccated particles. Water was supplied by an ordinary feeder on the hive, and the bees seemed to make use of it for some purpose. I had not then adopted the American cloth, and probably I shall be told that therein I failed; but the Turkish bath was not then so fashionable, and that must be my excuse. I can understand that by applying moisture through contact with water the end may be attained; but I am doubtful whether the bees are sensible enough—or foolish enough, I don't know which—to carry water into the feeders to cook artificial food. It would be interesting to know the value of the food taken and rejected in this way, and also the relative value of the labour expended by the bees, profitably and unprofitably, and of the little extra labour shirked by the bee-keeper.

It was my intention to make further experiments in this line, but circumstances, &c. A friend of mine had similar experience with 'Good's food' this spring: the particles of sugar being distributed around the hive entrance.—THE COLLIER, June 7.

EXPERTS AT THE UNIVERSITIES.

[396.] May I suggest that the B.B.K.A. should send a competent lecturer to the Universities? In the gardens

stocks could be kept, and as nine-tenths of the clergy are educated at the Universities an impetus would be given to the art of bee-keeping which would be greater than any number of local Associations.—E. LIDDELL.

WASPS' NEST.

[397.] Allow me through the medium of your columns to insert a letter (which if not apiculture is very much akin to it), the purport of which relates to the wasp. Of late I have noticed in your most valuable paper small paragraphs referring to the extraordinary quantity of female wasps about this year. I think they must be making nests now as I have not seen nearly so many this last day or two, and I think I can confirm this observation by relating the progress of a nest built in a hive cover.

In turning up a cover a few days ago, in which I had noticed a female wasp going in (the perforated zinc over the hole had fallen down during the winter), I found two cells each with an egg in, enclosed in a ball of delicate tissue-paper-looking substance, in the top of

SECTION OF NEST. Full Size.

- A.—Outer wall.
- B.—Ball with cell and wasp enclosed.
- C.—Hole through which the wasp enters.
- D.—Hive roof.

Of course, this is inverted.

which there was a hole through which the wasp passed to the cells. The following day I noticed three more cells had been built during the night, but there were no eggs in them; the next day I found that the wasp had begun to build another wall about a quarter of an inch off the ball containing the cells, there were no more eggs in the other three cells. The following day between six o'clock a.m. and dinner-time the wasp raised the wall half an inch—this I consider enormous for an insect, the material it used was still wet in some places and is of a light grey colour. The nest now presents another wonder of insect architecture looking somewhat like a flower. The wasp is very tame, for when the cover is lifted up the wasp keeps at its work, but will fly off if the cover is not soon returned. I write this, not as a piece of instruction to the reader, but I thought any who have not seen one might like to know how they began their nests and how they started a colony. I shall cut the nest out and keep it among my 'curiosities.'—F. K. PRESTON, *Dudley Road, New Somerhy, Grantham.*

Review.

BEE PASTURAGE. By Henry Dobbie, Certified Expert of British Bee-keepers' Association. (Jarrod & Sons, London.)—The author of this little work is known to our readers as a contributor to our pages on bee flowers, and the results of his practical experience and cultural directions of the plants most visited by bees are here given. It is free from technicalities, plain language and simple terms being used, so as to bring it within the comprehension of the humblest cottager. In his anxiety to be plain, we think our author has sometimes erred. English names of flowers are all very well when they are

explained, but we think they should be accompanied at any rate by the botanical Latin names, so as to show what particular plant of a family is meant, and, above all, purely local names should never be used. We will take as an instance *Balm*. There are no less than eight different plants called by this name, some of which we know are of little value, and one of them is not even nectariferous. How is the uninitiated to know which of these balms he is to cultivate? Then, again, *Charlocks* is purely a local name, and a cottager in Sussex would not understand what was meant by the word, although a Norfolk one might. Now, *Sinapis arvensis*, which goes by the name of *Charlock*, in some places rejoices in no less than ten other names by which it is known in different parts of the country. These names are, *Brassica*, *Brussock*, *Carlock*, *Corn mustard*, *Field kale*, *Kedlock*, *Kerlock*, *Kelk*, *Wild kale*, and *Wild mustard*. How many Norfolk men would understand what was meant by *kelk*, the common name for this weed in Sussex?

We trust that in a second edition this confusion will be remedied, and thus enhance its usefulness. We would also suggest that a slip, pointing out the orthographical and typographical errors which sometimes it is difficult to avoid, should be pasted into the present edition. The chapter on sowing seeds, soil required, and the future treatment of the young plants, is very useful, as there is much ignorance on these points. There is also a chapter on 'Honey, Honey Dew, and Pollen,' but, as our observations, now carried on for more than twelve years, and upon upwards of five hundred species, are somewhat at variance with the author's, we hope at some future time, when we can spare the space, to enter more fully into the subject. At the end the author gives a list of bee flowers and their approximate honey and pollen values. These are expressed in per-centage figures, which we have always looked upon as a very erroneous method, and very incomprehensible. All the plants named are useful as honey or pollen producers, but what does 30 per cent of honey in, for instance, *Barberry*, mean? and how have these figures been carried out? Again, what is the meaning of the honey value of lucern being 90 and sainfoin 75? What experiments have been made to prove that the latter is inferior to the former, or that they are equal as pollen-producers? On the contrary, sainfoin is *par excellence* in the first rank as a honey plant, and, according to our observations, even better than lucern, for it yields, in addition, pollen, which the latter does not, owing to its peculiar construction. Lucern, owing to its explosive flowers, scatters the pollen as soon as an insect alights on them, and we have repeatedly noticed that the honey-bee avoids very carefully this explosion by inserting its proboscis literally close to one of the wings, so that no explosion occurs, and consequently no pollen is collected.

We have always maintained that the best arrangement of bee flowers was to place them in three classes, and in this way we prepared some years ago, at the request of the British Bee-keepers' Association, the list of flowers sought after by bees, since published by Messrs. Sutton and Sons. The plants were divided into three classes, represented by figures, 1 being *moderate*, 2 *good*, 3 *very good*.

We are also curious to know how it was ascertained that bees collected any honey at all from wild clematis. We know that bees will collect honey in some districts from certain flowers when they do not in others, but we have examined bees working on this plant in England, France, Germany, and Switzerland, but have never yet succeeded in finding that they collected anything but pollen, although Dr. Alefeld, of Germany, states that he has sometimes succeeded in finding honey in the stomach when bees were working on wild clematis. As another curious instance we will mention *Limnanthes*, which the author says with him the bees do not visit. On the con-

trary, with us in Sussex our beds of *Limnanthes* are covered with bees from morn till night.

All the plants named in the list are useful, and should be grown where possible. Although we do not think that large harvests of honey will be got from growing a few plants for bees, yet we quite agree with the author that much can be done to benefit colonies by planting for spring bloom. If every one were to sow seeds, much more could be done. Many plants are common weeds, and can be easily increased to our advantage in our hedgerows and woods. We have in this way planted thousands of plants of *Nepeta cataria* and *Scrophularia nodosa* in the forest adjoining our property, so that now these plants, formerly rarely found, are beginning to be quite plentiful, and we hope also to yield us some return for our trouble. We recommend *Bee Pasturage* to all bee-keepers, and hope that they will not only derive a pleasure from carrying out its instructions, but that they will also benefit by a greater harvest of honey.

Echoes from the Hives.

Alfriston, Sussex, June 12.—Honey has been coming in fast for this last week, but the temperature is low; wind from south-east being very cold for two or three days. All my hives have large quantities of sealed honey. On the 10th I took four or five sections from one stock; all others are at work in supers. One lot I have had to give a second crate of sections to prevent them swarming.—J. H. LEVETT.

Holme Apiary.—On the 7th inst. a decided and genial change, continuing until the 11th, when showers followed each day more or less. Rain and sudden change for cold this afternoon, to the effect of drone and drone larvæ being expelled from most colonies. During fine warm days, nuclei have been formed; Syrian and Cyprian queens successfully introduced. Super racks have been placed, but no storing commenced, not from lack of workers, but want of continued fine weather for Flora to secrete the coveted nectar.—JOHN H. HOWARD, June 14.

Lismore, Ireland.—Some improvement in weather. But the late storm has so destroyed the hawthorns' bloom and foliage, that there is not much honey coming in. The little yellow bird's foot trefoil promises to bloom abundantly. I am sending three hives to the mountain in a day or two. I send them to a cottage just at the foot of the mountain, so they get a fine double harvest, heaps of white clover and flowers in the upland pastures to the south and great stretches of mountain heather to the north. This is excellent for any hive that is backward, as the white clover is ten days or a fortnight later than in the valleys and lowlands. Hives all in splendid order, full of bees and ready for the honey—if it comes.—IRISH NOVICE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

EAST DULWICH.—Feeders.—In cutting the hole from the enamel cloth, it is required that the hole should not be too large, so that the heat of the interior of the hive should not be unduly reduced. As you request us to mention a good syrup feeder, we can recommend the Raynor feeder. When using this, it is necessary that the circular piece cut out of the quilt should correspond with the inner circle of the stage, which is dome-shaped, and the feeder is placed over it. The under side of this stage is lined with cloth, is impervious to moisture, and non-conductive of heat. When placed on the frames over the centre of the cluster, the heat ascending makes the dome the warmest part of the hive, and the bees are able to feed in the coldest weather and without any disturbance of the cluster.

E. DAVIS.—1. The queen must either have been old or out of condition from some cause. She evidently was unable to rise to the call of the bees, and to escape their not too gentle stimulation, she found refuge in flight. 2. Queens do not leave the hive for the purpose mentioned. 3. The best sugar for making syrup is Duncar's pearl, or some granulated sugar similar to it; the sugar candy from the shops is not to be recommended for making syrup.

MORNING STAR.—Langstroth Hive.—You will find in Dr. Langstroth's *Hive and Honey Bee* engravings of his hive and particulars of its dimensions. The Langstroth hive contains ten frames, 17 $\frac{3}{8}$ " \times 9 $\frac{3}{8}$ ". It is 18 $\frac{1}{2}$ " long, 14 $\frac{3}{8}$ " wide, and 9 $\frac{3}{8}$ " deep. The super case holds seven frames, each capable of holding three 5 $\frac{1}{4}$ " \times 6 $\frac{1}{4}$ " sections. Since its invention in 1851 it has undergone various modifications. Mr. Heddon prefers an eight-frame Langstroth containing about 2000 cubic inches, while the ten-frame Langstroth is the one recommended by Mr. A. I. Root, containing more than 2500 cubic inches. There is nothing special in the exterior appearance of this hive to require an engraving.

MISS CARTER.—Disease is not the cause of the bees bringing out the immature food. It is indicative of the shortness of stores; and this is the bees' mode of equalising the amount of stores and that of the number of consumers.

A. B.—Queens Mating. Queen-cells.—(1.) The proof of fecundation on the day it takes place can only be ascertained by observation. On returning to the hive, after meeting the drone, the generative organs of the latter may be seen projecting from the abdomen of the queen. This is quickly removed by the bees, but cases have been noted in which it has remained for several days, the bees apparently being unable to remove it. About the third or fourth day after mating the young queen begins to lay, depositing her eggs in a regular and orderly manner. (2.) Queen-cells are sealed over on the ninth day from the laying of the egg. The young queen leaves the cell on the sixteenth day, and takes her wedding flight about the fifth day of her age, weather permitting. (3.) The insect on the bee is the bee-parasite called the *Brula caca*. As the season progresses these insects die off. They generally accompany bees imported from the south of Europe. (4.) The distinguishing marks of the Carniolan bee are not very perceptible in the bees forwarded, the special greyish pubescence having since death almost disappeared. So far as we can determine, we are inclined to say that they are of the breed mentioned.

WILLIAM WALKER.—Transferring from a Skep.—Drive the bees from the skep; cut the skep from top to bottom between the central combs. Cut out the combs, and fit them into the frames of the bar-frame in the same position they occupied in the skep—that is, top side uppermost. Tie the tapes around them. If the comb is not deep enough to fill the frame, place a lath beneath, and tie it so as to bring the comb to the top of the frame. Comb-foundation being now so cheap, discard all crooked or imperfect comb; reject drone-comb. When the frame and sheets of foundation are placed in the new hive, place it on the old stand, and shake in the driven bees on the top of the frames, or throw them on a sheet on the front of the hive. Feed the bees, and in two days the tapes may be removed. 2. *Excluder Zinc.*—Zinc with oblong holes ($\frac{1}{16}$ " \times $\frac{1}{16}$ ") is accurately cut to exclude drones and queens; but bees laden with honey are able to pass through.

M. C. H.—Foundation Fixer.—We are in the habit of using the foundation-fixer invented by Abbott Bros., which answers our purpose very well. Some persons prefer Parker's foundation-fixer, which may be procured from most purveyors of bee-appliances.

B. A.—The enamelled cloth may be retained on the frames during the summer with two or three folds of blanket, and with a proportional number more during the rigour of the winter.

E. H.—Dried Pollen.—The contents of the box forwarded were the hardened pellets of last year's pollen. Old pollen is frequently neglected by the bees when the fresh pollen is brought in. No harm can result to the hive from its presence.

FRODSHAM.—Red Ants.—A bee-keeper recommends the following plan for preventing ants entering hives:—Take four stout nails 2 $\frac{1}{2}$ or 3 inches long, and put them into the legs of the stand endways, so that they project about 1 $\frac{1}{2}$ inches. Take four garden-pot saucers, fill them with water, and place the stand in them, and no vermin will be able to crawl up the legs into the hive, and the nails will keep the ends of the legs out of the water.'

T. S.—Your suggestion will be submitted to the proprietor, and no doubt it will receive due attention.

IRISH NOVICE.—Foul Brood.—The piece of comb forwarded

was affected with foul brood; and if as you say it was the best bit of comb in the hive the remainder must have been very bad.

R. K.—The use of $\frac{1}{2}$ starters instead of full foundation sheets is, we consider, a retrograde step, as it will impose a considerable amount of unnecessary labour on your bees. However, with feeding the plan will not materially injure your prospect of getting honey, and it will prevent the recurrence of the sheets getting sagged.

A correspondent inquires the names of some parasites on bees forwarded. When we examined the box, the lid had been stayed in, and the bees were absent. Most probably the parasites were *Braulae caeca*.

Modern Bee-keeping has now reached its forty-fourth thousand—the largest circulation attained by any work on bee-keeping. This last edition has been carefully revised, and its information has been brought up to the present time; several new engravings have been added.

Mr. Cowan's *Guide-book* has not lost its interest, and the sale of it continues to be very active. The thirteenth thousand is now on sale. The late edition has been thoroughly revised. Simmins' dry sugar feeding and the effect of carbolic acid have been described.

CRATES FOR SECTIONS.—Many of your readers may be glad to know that fancy soaps are often packed in boxes $4\frac{3}{4}'' \times 6'' \times 18''$. They can be bought for 2d. each and make capital Benthall crates when cut down.—TREVOR SAXTON.

SECTIONS.—One argument in favour of $4\frac{1}{4} \times 1\frac{1}{4}$ sections seems to have been overlooked, viz., that they contain 36 $\frac{1}{2}$ cubic inches, while $4 \times 1\frac{1}{4}$ only contain 36 cubic inches. An eighth of a cubic inch is not much, but it is something.—T. S.

Business Directory.

For the use of Manufacturers and Purchasers of Bee-keeping Appliances.

The Name and Address and Business of any Manufacturer will be inserted in this List, under one heading, for One Pound per annum. Additional headings, Five Shillings extra. Advertisers in 'THE BEE JOURNAL,' whose orders amount to Five Pounds per annum, will be inserted Free.

HIVES AND OTHER APPLIANCES.

ABBOTT BROS., Southall, London.
BALDWIN, S. J., Bromley, Kent.
BLOW, T. B., Welwyn, Herts.
BURTT, E. J., Stroud Road, Gloucester.
EDEY & SON, St. Neots.
HOLE, J. R. W., Tarrington, Ledbury.
HOWARD, J. H., Holme, Peterborough.
MEADOWS, W. P., Syston, Leicester.

Show Announcements.

Giving Name and Address of Secretary, Date and Place of Show, Date of Closing Entries. Terms: Three Insertions and under, Two Shillings and Sixpence; additional insertions, Sixpence each. No charge made to those Associations whose Shows are announced in our general Advertising Columns.

June 17, 18.—Essex County Show, Brentwood. Secretary, F. H. Meggy, Chelmsford.

July 22, 23. Lincolnshire Agricultural Society, Lincoln. Entries close July 5. Secretary, R. R. Godfrey, Grantham.

July 30—August 5.—Great National Show at South Kensington. Entries close June 30th. Secretary, J. Huckle, Kings Langley.

HANTS AND ISLE OF WIGHT BEE-KEEPERS' ASSOCIATION.

June 24, 25, 26, 28.—Royal Counties Agricultural Show, Portsmouth. Entries close June 17. Secretary, E. H. Bellairs, Wingfield, Christchurch.

July 14.—Swanmore.

July 31, August 2.—Royal Horticultural Show, Southampton.

Aug. 18.—Farnborough.

Strong Black Mosquito Net,

72 inches wide, as used for Bee Tent Screens, Bee Veils, protecting Wall Fruit, &c., &c.

Price 1s. 6d. per yard, or 1s. 4d. per yard for a piece of 12 or 20 yards. Cash with Order.

Address **R. R. GODFREY, Grantham.**

Mr. CHESHIRE'S NEW BOOK,

The most Exhaustive and Reliable Work on Bees ever published.

Vol. I. now ready, 7s. 6d. post free. Address

W. HOLLANDS, Waddon, Croydon,

Sole Maker of Appliances recommended by Mr. CHESHIRE.

See Advertisement of April 15.

Now Ready, price One Shilling, post free.

BEE PASTURAGE, by HENRY DOBBIE, dealing with the Propagation and Successful Cultivation of nearly 100 of the best Honey and Pollen-producing Trees, Shrubs, and Plants, giving the Time of Flowering, Soil best adapted for Growth, average length of time in Flower, Honey and Pollen Values, &c. &c.; also Chapters on Honey, Pollen, and on Sowing and Raising Plants from Seed.

HENRY DOBBIE, Thicketthorn, Cringleford, Norwich.

Seventh Edition. Thirteenth Thousand.

BEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By THOS. WM. COWAN, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 8vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of HOULSTON & SONS, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. HUCKLE, *British Bee Journal* Office, Kings Langley, Herts.

The oldest Weekly Bee Paper in the World.

THE AMERICAN BEE JOURNAL

Established in 1861.

Price 6s. 6d. per annum, post free.
