---	---

A **NUITY**, a yearly payment of money to a specified person or persons, for a term of years, for life or perpetually. The varieties and combinations of annuity payments are almost as numerous as the contingencies or desiderata of human life; each having figured so largely in law as to receive a specific legal title. If the annuity is for a definite term of years, it is called an annuity certain; if forever, continuing to heirs or specified successors, a perpetual annuity or perpetuity; if for a limited period, a term annuity; if during the whole of a given period, not cut short by any contingent event, a whole-term annuity; if for a short period, a short-term annuity; if it does not begin till after a certain date, a deferred annuity; if not till after the occurrence of some specified event, a contingent annuity; if its beginning or duration is based on the continuance of a life or lives, it is called a life annuity; if for the time that certain persons survive, a temporary life annuity; if on any life provided another is living, or some event happen or not, a contingent life annuity; if it begin only after some death or deaths, a reversionary annuity; if for the duration of the longest of two or more lives, a joint-life annuity; if to the survivor of two or more, a survivorship annuity. There are increasing and decreasing annuities, their nature obvious from their titles. An annuity ceasing only with the death of the annuitant, and with a proportionate part of the next payment made to the heirs, is called a complete annuity; if it ceases with the last payment made to the living, a curtate annuity. This by no means exhausts the forms or combinations possible or even actual; nor does it fully define even those mentioned. Thus, in a joint-life annuity, what is to happen on the successive deaths up to the last? The shares of the dead might return to the estate, but in practice are successively added to those of the survivors in equal portions till the last survivor receives the whole. In contingent annuities the commonest contingency which terminates it is that the annuitant shall become self-supporting, as on marriage or remarriage or the attaining of majority; as when a man provides for his widow or daughter or son by will.

In respect of object, annuities may be broadly divided into two sorts: those providing for others and those providing for one's

self. The former are probably the oldest, and are of course testamentary, taking the place of a legacy in the lump. Till modern times these were chiefly (and with great European houses are still so) charged directly on the private property of the testator in the hands of legatees or trustees. In Europe these permanent charges on property form a feature of the highest social and even political importance. The entailed estates are always incumbered with multitudes of annuities to connections or dependents of the houses, absolutely fixed, while the income from which they are to be paid may shrink indefinitely. But for a century and a half it has been gradually taken up by great incorporated companies and combined with the business of life insurance (q.v.). The insurance companies pay the annuities on contracts matured by the death of the testator, the payments beginning either then or at a specified time thereafter. In America this system has also absorbed almost entirely the old contractual annuities, in which the annuitants buy incomes for themselves by paying a lump sum to a person, company or public body for a term or life.

These contractual annuities, though based on the same calculations and mathematically identical, are historically of two distinct kinds as respects their object, the one seeking security, the other investment. The latter is the older, and resulted from conditions now obsolete; partly the paucity of investment securities, partly the laws against usury, which could be evaded by annuities, as a given sum was paid for by a return of services, and the element of interest did not formally enter into it at all. Hence the favorite method of borrowing money by the great mediæval companies and houses, and municipalities and States as well, was by annuities, sold on a rough estimate of the chances of life; in which the buyers were always keener than the sellers, and till very modern times the bargain was always against the payers of the annuity. Many shrewd investors accumulated great properties by careful selection of annuities on good lives, being allowed to propose the lives upon whose duration they laid this wager (until scientific mortality tables were constructed). The interest on government debts is a perpetual annuity; and of course any investment at interest is an annuity for its term, but such investments are not

classed among annuities as the term is currently used.

The other object, that of securing one's self against the chances of fortune, though reached by the same means, has till recently had one broad distinction,—it was done at once and usually in early life, instead of in small lots as money accumulated. It was commonly the sinking of an inherited property (rarely an acquired one), by women, or by men of quiet tastes and unsuited for the struggle of business life, to produce a sure moderate income free from care and business chances. Naturally such annuities are much commoner in the older countries than in America, though steadily growing here from the same causes. Large inherited fortunes are rare in new countries, and the desire to live in unventuring ease equally so, but as family properties increase and the struggle for life grows harder, the annuity system grows likewise. But it has been vastly extended in recent years by its junction with the insurance system, enabling even relatively poor men to buy an income for their dependents after death, or themselves in old age, in small instalments instead of an impossible lump sum; and also leaving to a widow a steady income for a term of years or life, in place of a lump sum to be invested by herself or trustees, and possibly mismanaged or lost or embezzled. Therefore, both in its ease of purchase and in its advantages of payment, it is steadily growing in favor, and becoming larger in proportion to the total of life-insurance dealings.

Historically, annuities are probably as old as the great Assyrian-Babylonian times, in the 7th and 6th centuries before Christ, when great banking houses that lasted for generations, and commercial and mercantile facilities, were well developed; but the first positive mention is brought out by the Falcidian Law of Rome, 40 B.C., which enacted that not more than three-fourths of a property should be willed away in specific legacies. As this could not be obeyed unless some method of valuing annuity legacies was devised, the following rough estimate was accepted: Up to 30, 30 years more of life; up to 60, as many as were wanting to make up 60. This extremely defective calculation—which assumed that a life over 60 was not worth even a year's purchase, and was very inaccurate for others—was replaced by the great Roman jurist Ulpian (d. 228 A.D.) with one much better, though still imperfect; but interesting as the first known table of life probabilities graduated with reference to age, and, strangely enough, revived and used by the Tuscan government in the early 19th century, long after more scientific ones were in use. It is as follows:

Birth to 20, 30 years	44 to 45, 15 years
20 to 28, 27 "	45 to 46, 14 "
25 to 30, 25 "	46 to 47, 13 "
30 to 35, 22 "	47 to 48, 12 "
35 to 40, 20 "	48 to 49, 11 "
40 to 41, 19 "	49 to 50, 10 "
41 to 42, 18 "	50 to 55, 9 "
42 to 43, 17 "	55 to 60, 7 "
43 to 44, 16 "	60 and up, 5 "

This contained no interest computation. Until the 18th century there was little advance in the scientific aspects of the business; it remained a speculation, though an extensive and recognized one, and England under William of

Orange may almost be said to have maintained her national existence by borrowing money on annuities, as the Dutch had to some extent before it. The researches of Pascal, Fermat and Huygens in the 17th century into the theory of probabilities greatly advanced the accuracy of calculations; in 1742 Mr. Thomas Simpson published his 'Doctrine of Annuities and Reversions,' one of the landmarks of the business; and in 1762 the Equitable Assurance Society, the first insurance company of the world, was started primarily to do annuity business, which is the parent of life insurance, though now but a minor incident in it. Several other companies were founded shortly after. The real foundation of modern life insurance, however, and of scientific annuities as well, was the publication in 1771, by Richard Price, of his Northampton Table of Mortality. This estimated the term of life-average too low, but it was the predecessor of the Carlisle and other tables on which modern life insurance is built, now supplanted by the actual experience for generations in numberless great offices.

It is obvious that while the rate of mortality is a determining factor in annuity rates as much as insurance rates, its incidence is exactly in reverse. That is, the higher the rate of mortality and the shorter the average term of life, the less money in gross will have to be paid on a contingent annuity contract, and consequently the less will be the sum needed to sink in it, or in current phrase, the lower the rate of annual premium. Conversely, the older the buyer is, and consequently the shorter his expectation of life, the less his annuity is worth. On the contrary, the less an individual's expectation of life under an insurance contract, the higher must his premium be to accumulate sufficient money in the assumed period to amount to the promised sum. The factor of interest is the same for both; the higher the interest, the lower the premium or the initial sum paid. In the now frequent insurance contracts, where the principal sum is paid to the beneficiary in annuity instalments, the question is one of interest complicated by the probabilities of the beneficiary dying before the payments are completed. More usually now, however, this latter element is eliminated by providing that in such case the remainder shall be paid to the legal representatives, so that it becomes an annuity certain. An interesting concrete illustration of the effect of overrating the mortality is the sale of annuities by the English government under the Northampton Table. This table had figured a correct total of deaths against an incomplete table of births in a given population, and consequently assumed too high a death rate; the government, therefore, fixed the annuity rate too low; and vast quantities of annuities were sold under Mr. Perceval's scheme of 1808 for funding the national debt. The actuaries discovered the miscalculation, and one of them in 1819 warned the government that it was losing \$40,000 a month on these contracts; the advice was unheeded; buyers continued to be shrewder than the government and purchased largely of the attractive bargain, and in 1827 another actuary publicly announced that the government was losing \$40,000 a week. The next year the sale was suspended, with a total loss to the government of not less than \$25,000,000.

ANNULATA, OR ANNELIDS

1 *Heteronereis*
 2 *Phyllocoele laminosa*
 3 *Glycera*
 4 *Arenicola*
 5 *Pontobdella muricata*

6 *Nais Proboscidea*
 7 *Terrebilla Emmalina*
 8 *Hermella*
 9 Common Earth Worm (*Lumbricus agricola*)
 10 Tubes of *Hermella Alveolata*

The calculations for annuities are a part of actuarial science. In the United States the following are the approved rates of the best-managed companies: In consideration of \$1,000 paid to a company the annuity granted to a person aged 40 would be \$52.75; 45, \$58.10; 50, \$64.70; 55, \$73.50; 60, \$86.20; 65, \$100; 70, \$123.45; 75, \$145.95; 80, \$180.15. But, as stated, the pure annuity, sinking a large sum to buy a yearly income, does not figure largely in America.

Legally the annuity, whether charged to the person of the grantor or on specific real or personal estate, is treated as personal property except for purposes of inheritance or devise-ment, when it is held to be real property. A rent-charge, however, is a charge on specific real estate only, and is held to be real property under all circumstances. Consult Blackstone, 'Commentary on the Laws of England'; Kent, 'Commentaries on American Law'; Baumgartner, 'Handwörterbuch des gesammten Versicherungswesen' (Vol. I, Strassburg 1898-); Wal-ford, 'Insurance Cyclopædia' (London 1880).

ANNULATA, or **ANNELI'DA**, a term applied to the phylum of sea-worms, comprising the most specialized worms. They are represented by the leeches, the earthworm, the naia of fresh water and the marine annelids. The phylum is divided into four classes: (1) *Chaetopoda*, (2) *Gephyrea*, (3) *Archi-annelida* and (4) *Hirudinea*. In the more typical form they are characterized by their long, bilaterally symmetrical body, which is cylindrical, consisting of numerous segments either unarmed, or more usually provided with *setæ* alone, or with *setæ* and paddle-like appendages (*rami*). The head is simple, with a few simple eyes, or provided with tentacles (*antennæ*) alone, or with tentacles and *branchiæ*. An eversible pharynx, armed with teeth, is usually present. The alimentary canal is straight, the tubular stomach sometimes sacculated; the vent is always situated in the last segment of the body. The nervous system is well developed, consisting of a brain and a ventral ganglionated cord. The circulatory system is closed, with a dorsal and ventral, and lateral vessels connected by anastomosing branches in nearly every segment. The sexes are generally separate, but many annelids are hermaphrodites. The embryo passes through a cleavage-stage (morula or blastula), gastrula, sometimes a neural stage, and after hatching, development is either direct or there is a marked metamorphosis, the larva passing through a trochosphere and cephalala stage. Consult Parker and Haswell, 'Text-book of Zoology' (New York 1897).

ANNUNCIATION, the declaration of the angel Gabriel to the Virgin Mary that she was to become the mother of our Lord (Luke i, 26-38). Annunciation or Lady Day is a feast of the Church in honor of the annunciation, celebrated in the western Churches on 25 March. The institution of this festival is generally assigned to the 7th century. The Italian, formerly Sardinian, order of Knights of the Annunciation (*Ordine Supremo dell' Annunziata*) was instituted by Amadeus VI, Duke of Savoy, in 1360. It received statutes from Amadeus VIII in 1409, was renewed in 1518 and raised to the first order of the Sardinian

monarchy in 1720. The subject of the Annun-ciation has been a favorite with artists from Fra Angelico to Dante Gabriel Rossetti.

ANNUNZIO, ān-noon'tzē-ō, Gabriel d', Italian novelist, dramatist and poet: b. Franca-villa, a small fishing village on the Adriatic, in 1864. He was educated at the Collegio Cicog-nini, Prato (Tuscany), and the University of Rome. At the age of 15, while still in the former school, he wrote 'Cincinnati,' his first story, for which the editor of the *Fanfulla della Domenica* paid him 50 francs. So struck was he with the evident talent of the boy that he visited him at college, praised his work be-fore the assembled pupils of the school and prophesied that he would make for himself one of the greatest names in Italy. This visit had much to do with shaping D'Annunzio's life. From that moment he determined to devote himself to literature. It became to him a pas-sion, the one aim of his life. He continued to write stories that were accepted by the press; and while at Prato he composed an ode, 'Lungo le Rive del Romuleo Tebro,' which he dedi-cated to King Humbert. The sovereign ac-knowledged the receipt of a copy; and the ar-rival of the Imperial letter caused a sensation among the masters and pupils of the school and raised the literary enthusiasm of the boy to fever heat. He read widely and wrote with feverish intensity. In his 'Confessiones' D'Annunzio has given a vivid account of the struggle he made to master the Italian tongue. Words were his tools, and to use them as a master he must know them intimately. So he read widely works on science, politics, litera-ture, history, philosophy; and he collected voc-abularies of scientific and technical subjects and proceeded to master the meaning of every word therein. He imitated Carducci and the Latin poets and French and German writers. Often he worked 18 out of the 24 hours, writ-ing in complete solitude, while his faithful friend Michetti "stood guard and made his rounds to keep off intruders." 'Laus Vitæ' was written under these conditions (8,000 lines) practically without interruption.

The publication of his first volume of poems in 1880 made a reputation for D'Annunzio as the most promising of the younger Italian poets. 'Terra Vergine' and 'Canto Novo' (1882) in-creased his fame. While still in his teens he added to these 'Intermezzo di rime' (1883); and 'Il Libro delle Virgini' (1884). The press of Italy received the boy with open arms and he responded with 'San Pantaleone' and 'L' Isotteo' (1886). When he left the university he became a journalist and contributed largely to the literary columns of the press of the capital. In his 'Confessiones' he states that the first 33 years of his life had passed before he had mastered the art of writing with facility and that, during this literary period of 18 years, he was never able to settle down to one certain style but was constantly vacillating between the many literary claimants upon his attention. In the midst of this active journalistic life he pro-duced 'Elegie romane' and 'Poema para-disiaco.' Then followed a period of still greater literary activity and the production of work of a still superior quality. His first novel 'Piacere,' strongly influenced by the French school of his day, appeared in 1889, and was

followed by a series of novels as remarkable for their style, vivid word painting and analysis of character as anything in Italian literature. These include 'L'innocente' (1891); 'Giovanni Episcopo' (1892); powerful but gruesome stories influenced by the Russian school then popular in Italy; 'Il Trionfo della Morte' (1894), a clever psychological study; 'Le Virgini delle rocci' (1896); and 'Fuoco' (1897). The latter, a "great success of scandal," a powerful story, in its way, brought its author more notoriety than genuine appreciation and thus, like Carducci, he acquired a reputation for literary unwholesomeness which he long failed to live down.

Tiring of novel writing and smarting under the whip of the critics, he turned again to poetry, which he had not altogether neglected, and begun the 'Laudi,' a series of lyrical poems in praise of the sky, the earth, the sea and great heroes. In these, which it was his intention to complete in seven books, his art showed such improvement that his new poetic effort was received with great enthusiasm throughout Italy and, the French reviewers singing his praise, he awoke to find himself an international character.

But D'Annunzio had other fields to conquer. Turning to the drama he produced, in rapid succession, a series of notable plays including 'La Città Morta' (1898); 'La Gioconda' (1898); 'La Gloria' (1899); 'Francesca da Rimini' (1901); 'La figlia di Jorio' (1904); 'La 'fiaccola sotto il moggio' (1905); and two tragedies, 'La Nave' (1908) and 'Fedra' (1909). The interludes between the writing of these plays he had filled in with a vast amount of journalistic and critical work, poems and short stories. A collection of the latter, 'Novelle della Pescara,' appeared in 1902. The younger literary set of Italy gathered about him, and his became a name to conjure by. 'Forse che si forseghie no' appeared 1910.

On account of the non-moral tone in the characters of many of his novels and short stories, certain critics continued to bitterly attack him; and this, combined with his incessant desire for something new, took him to the French capital where he wrote 'Le Martyre de Saint Sabastien' (1911); 'Le Canzoni della Gesta d'Oltremare' (1912); 'Le Chevrefeuille' (1913); and 'Cabiria,' a very elaborate photo play based upon historical incidents in the second Punic War. 'La Leda senza Cigno' was published in 1917.

When the European War broke out D'Annunzio volunteered as a private in the Italian army, in the aviation squad; and entered into the conflict with all the enthusiasm of his ardent nature. He was rapidly promoted and in May 1915 he was made a lieutenant. Other military honors followed. By his personal example and with his pen and his voice he stirred Italy to the actualities of the war as no other man was able to. In Rome and other cities, in the army and behind the lines, his voice carried the weight of his reputation as the national poet and the mouthpiece of the nation. As the national press representative at the front he wrote some of the most vivid and intimate descriptions of war conditions penned during the European struggle. In January he was decorated with the French Croix de guerre; and this was followed by still other recognitions of his signal service.

D'Annunzio inherited Carducci's literary mantle as the most prominent of his admirers, the most faithful of his disciples and the most ardent of his champions. As a word painter D'Annunzio is an artist of magnificent vision. His style is brilliantly perfect. In every thing he writes is the touch of the poet of plastic beauty unsurpassed in Italian literature. But most of the characters in his novels and shorter stories lack the saving sense of humanity. They rave and rant and make beautiful, poetical, touching speeches and take themselves very seriously; but they do nothing worthy of their high pretensions, nor do they, for the most part, in any way advance the ends of the story; for they are the brilliant dreams of a poet rather than the sane creations of a great novelist and painter of human nature. D'Annunzio is too much the subjective poet to be a great story teller. He misses scores of opportunities to develop his plots when the development is self-evident. The same fault is apparent in his dramas and his short stories. It is as a poet, therefore, that he must live or die. Few if any Italian writers have equalled him in his command of rhythm, his sense of music, his richness, splendor and accuracy of language, his vividness of perception and his wonderful power of reproduction. These, in their highest form, are essentially the gifts of the poet. In his novels, short stories, dramas, tragedies, poems, even in his spectacular photoplay, D'Annunzio is ever the poet; and it is the power of his poetic art that has made him popular in spite of their artistic defects and lack of moral motives. See FRANCESCA DA RIMINI; LA CITTÀ MORTE; LA GIOCONDA. Consult Borgese, 'Gabriel D'Annunzio' (Naples 1909); Collision-Morley, 'Modern Italian Literature' (Boston 1912); Gargiulo, 'D'Annunzio (Bari 1912); D'Annunzio, 'The Triumph of Death' (New York 1896); 'The Intruder' (New York 1898); 'The Victim' (London 1899); 'The Virgins of the Rocks' (London 1899); 'The Dead City' (Chicago 1902); 'Francesca da Rimini' (New York 1902); 'The Daughter of Jorio' (Boston 1907); 'La Gioconda' (London 1913); 'The Butterfly' (London 1915).

JOHN HUBERT CORNYN,
National University of Mexico.

ANNUS MIRABILIS, the year 1666, famous in English history for two decisive victories over the Dutch fleet, and for the great fire of London. Dryden's poem of this name, published in 1667, commemorates these events, and is dedicated to "the Metropolis of Great Britain, the most renown'd and late flourishing City of London."

ANNVILLE, Pa., township in Lebanon County, five miles west of Lebanon, the seat of Lebanon Valley College, an institution controlled by the United Brethren in Christ. It was founded in 1762. Pop. (1910) 2,482.

ANOVA, a genus of Malayan buffaloes, particularly the small black species, with low, erect horns, called sapi-utan (*A. depressicornis*), and found in the highlands of Celebes. The genus was once classed with the antelopes.

ANOBIUM, a genus of beetles belonging to the family *Ptinidae*. It contains the death-watch insects, *A. striatum*, *A. tessellatum*, etc.

ANODE, the name given by Faraday (in 1832) to the electrode, or terminal, at which a current of positive electricity enters a battery or other electrical apparatus in which chemical work is performed. The term has since been extended so as to include the electrode by which a positive electric current enters a vacuum tube. The other electrode, in every case, is known as the "cathode." The anode of a primary battery (see BATTERY) commonly consists of a plate or rod of zinc, while the cathode consists of a plate of carbon, or copper, or platinum. In electrolysis the anode and cathode both consist, usually, of platinum or carbon. In a vacuum tube the anode commonly consists of a wire or disk of platinum, while the cathode (which is varied in shape according to the purpose to which the tube is to be put) is usually made of aluminum or platinum.

ANODONTA, a subdivision of the freshwater mussels (q.v.), abundant in the streams and lakes of the United States and most temperate countries. They have smooth, thin shells without hinge-teeth.

ANODYNES. See ANALGESICS.

ANOINTING, an Oriental custom of applying oil to the head or unguents to the body. The Greeks and Romans, particularly the former, anointed themselves after the bath. Wrestlers used unguents in order to render it more difficult for their antagonists to get hold of them. The use of oil for ceremonial purposes is equally ancient. Its first mention is in Gen. xxviii, 18, where Jacob, in commemoration of a remarkable dream, is said to have set up a pillar and poured oil upon it. In the Mosaic law and several ancient religions a sacred character was attached to the anointing of the garments of the priests and things belonging to the ceremonial of worship. This could be done only with oil made for the purpose, and signified a consecration of the articles to the service of religion. Jewish priests and kings were anointed when inducted into office, and were called the anointed of the Lord, to show that their persons were sacred and their office from God. The Old Testament prophecies respecting the Redeemer style him, on account of his royal descent and his dignity, Messias, that is, the Anointed, which is also the meaning of his Greek name Christ. The custom of anointing still exists in the Roman Catholic and Oriental Churches (see SACRAMENTS), and is also frequently a part of the ceremony of coronation.

ANOKA, ä-nō'kă, Minn., a small city, the county-seat of Anoka County, with manufactures of lumber, flour, machinery, a sash and door factory, a motor company and a starch factory. It is 18 miles north-northwest of Minneapolis on the Great Northern, Minneapolis Northern and the Northern Pacific railways and on Rum River. The commission government chosen (1913) provides for election of mayor and four commissioners biennially. Both water works and electric light plant are owned by the municipality. Pop. (1910) 3,972.

ANOLIS, a genus of slender, long-tailed, iguanid lizards of the American tropics, which are expert climbers and seek their insect food principally in trees and bushes. They have a pouch under the throat and the ability to change color. It is not surprising, therefore, that one

of the species (*A. carolinensis*), a beautiful golden-green lizard, very common in our Southern States, and often kept as a pet, should be called the American chameleon. About 100 other species are known. See CHAMELEON.

ANOMALY, a deviation from a rule. That which deviates is called anomalous. In astronomy the true anomaly is the angle which a line drawn from a planet to the sun has passed through since the planet was last at its perihelion or nearest distance to the sun. On account of the planets not moving with the same velocity at all parts of their orbits, this angle does not increase uniformly; hence its name. The anomalistic year is the interval between two successive times at which the earth is in perihelion, or 365 days 6 hours 13 minutes 48 seconds. In consequence of the advance of the earth's perihelion among the stars in the same direction as the earth's motion and of the precession of the equinoxes, which carries the equinoxes back in the opposite direction to the earth's motion, the anomalistic year is longer than the sidereal year, measured by the sun's return to the same position among the stars, and still longer than the tropical or common year, measured by the earth's return to the same equinox. It exceeds the latter by 25 minutes.

ANONA, ä-nō'-nă, a name given in Mexico, Central America and the countries of the west coast to the chirimoya and sometimes to other members of the Anonaceæ family.

ANONYMOUS, a term applied to a work the author of which does not give his name. There are no rules about the signing of names to works in Great Britain and the United States. Consult Cushing, 'Anonyms' (Cambridge, Mass., 1890), and 'Initials and Pseudonyms' (1st series, New York 1885; 2d series, id. 1888); Halkett and Laing, 'Dictionary of Anonymous and Pseudonymous Literature' (4 vols., New York 1882-88); Hamst, O., 'Handbook of Fictitious Names' (London 1868).

ANOPHELES, a genus of *Culicidæ* (mosquitoes), embracing those species of blood-sucking mosquitoes which carry and communicate to human beings, by biting, malarial diseases. See MOSQUITO.

ANOPLOTHE'RIMUM, an extinct primitive ruminant fossil in the Upper Eocene formations of Europe. It was among the first fossil vertebrates discovered in the gypsum quarries of Montmartre in Paris and was named by Cuvier in 1822 from its defenseless character (Gr. ἀνοπλος, unarmed; θηρίον, beast), as it has neither tusks nor horns to protect itself from its carnivorous enemies. They form the type of a distinct family, in many respects intermediate between the swine and the true ruminants.

ANORTHITE, a triclinic feldspar, having the composition of a silicate of aluminum and calcium, CaAl₂Si₂O₈. It is especially interesting to the chemical mineralogist because it stands at one end of the albite-anorthite series of feldspars (see FELDSPARS). Its cleavage is in perfect parallel with the base and distinct parallel with the brachypinacoid. It is brittle, breaking with a conchoidal to uneven fracture. Its hardness is 6 to 6.5 and specific gravity about

2.75. It is usually colorless or white, sometimes grayish or inclining to brick-red. It occurs in glassy crystals in the ejected blocks at Mount Vesuvius, Italy.

ANOSMIA, the loss of the sense of smell. This may be produced by: (1) Injury to the nerves of smell as they originate in the mucous membrane of the nose, in chronic nasal catarrh, in polypi or in injury to the nose. (2) By injury to the olfactory bulbs or to the olfactory tracts. Such injuries occur in severe blows or falls, particularly in fracture of the ethmoid plate accompanying fracture of the skull. (3) By injury to the brain centres of smell, which are located in and about the uncinata gyrus. See **SMELL**.

ANSARIES. See **NOSSAIRIANS**.

ANSCHAR (ANSGAR or ANSKAR), French prelate: b. near Amiens, 801; d. Bremen, 3 Feb. 865. He was educated at the monasteries of Corbie and of Korvei. He belonged to the Frankish nobility and under the patronage of Louis le Débonnaire, together with Autbert, went to preach Christianity to the Northmen of Schleswig. Here he endured many persecutions but succeeded sufficiently to have the Pope establish an archbishopric in Hamburg. Anshar was made the first archbishop in 831. When Hamburg was overrun and plundered by the Danes in 845, Anshar was obliged to flee. Later he preached in Denmark and Sweden. A church was named after him at Bremen. He was canonized by the Roman Catholic Church. He was the author of a life of Saint Willehad. His feast is celebrated on 3 February. Consult lives by G. H. Klippel (Bremen 1845) and Tappehorn (Münster 1863); also Butler, A., 'Lives of the Saints' (London 1847).

ANSELM, Saint, a celebrated theologian, regarded by some as the founder of scholasticism: b. Aosta, in Piedmont, 1033; d. Canterbury, 21 April 1109. At 27 he became a monk at Bec in Normandy, whither he had been attracted by the celebrity of his countryman Lanfranc, then prior of the monastery there. When Lanfranc was promoted to the abbacy of Caen, Anselm was elevated to the dignity of prior and in 1078 he was made abbot, which office he retained for 15 years. During this period he wrote his first philosophical and religious works: the dialogues on 'Truth and Free-will,' 'De Veritate' and 'De Libertate Arbitrii' and the treatises 'Monologion' and 'Proslogion,' and at the same time his influence made itself so strongly felt that Bec became the chief seat of learning in Europe. In 1093 Anselm was offered the archbishopric of Canterbury, which had lain vacant since the death of Lanfranc in 1089, and accepted the offer, though with great reluctance and with the condition that the King of England, William Rufus, should acknowledge Pope Urban in opposition to the antipope Clement, which the King ultimately consented to do. In 1097, a new difficulty having arisen between Anselm and William, the former set out for Rome to consult with the Pope. Urban received him with great distinction, but did not venture to declare himself on the side of the prelate in his dispute with the King. Meanwhile William had seized on the revenues of the see of Canterbury, which he retained

till his death in 1100. Anselm accordingly remained abroad, where he wrote his celebrated treatise on the atonement, 'Cur Deus Homo.' When William Rufus was succeeded by Henry I, Anselm was recalled. His canonization seems to have taken place in 1494. All the works of Anselm are directed toward founding a reasoned system of Christian truth. Such a system he considered to be a legitimate demand of reason, although he repeats again and again the doctrine that faith is necessary to the intelligence of the Christian mysteries, that the teaching of revelation must first be accepted by faith and afterward shown to have the support of reason. His celebrated ontological proof of the existence of God is to be found in the 'Proslogion.' The 'Cur Deus Homo,' treating, as already mentioned, of the atonement, is the most important of Anselm's works. In order to satisfy the reason of the need of an atonement and of the efficacy of the particular atonement that the Christian religion represents as having been made in the death of Christ, Anselm endeavors to establish the following positions: First, that God's honor is wounded by sin and His justice therefore requires satisfaction; second, that this satisfaction can be given only through one who is at once God and man; and third, that the voluntary death of Christ actually accomplished this satisfaction. The works of Anselm have often been published. The last complete edition forms the 155th volume of Abbé Migne's 'Patrologiæ Cursus Completus.' Among the numerous separate editions of the 'Cur Deus Homo' may be mentioned those of Lämmer (Berlin 1857) and Fritzsche (Zürich 1868). Anselm's personal character, distinguished by single-mindedness, gentleness, large-heartedness and piety, makes him one of the brightest ornaments of the Christian Church. Consult Eadmer, 'Vita Anselmi'; the works of Franck (1842); Hasse (1843-52); Rémusat (1853); Church, R. W. (1870); Rigg (1896) and Welch (1900).

ANSERES (Lat. nom. plur. of *anser*, goose), an order of water-birds, chiefly marked by the series of tooth-like projections on the edges of both mandibles, so placed that those on the upper mandible fit into the spaces between those on the lower when the mandibles are closed. Ducks, geese and swans (qq.v.) belong in this order and some classifications also include the screamers. They live and breed near the water, are found in all parts of the world, and are usually of large size. As a rule, they are swimming-birds and their numerous young need but little care. About 200 species are known.

ANSON, George, LORD, a celebrated English navigator: b. Shugborough, 23 April 1697; d. Moor Park, 6 June 1762. He entered the navy at an early age and became a captain in 1724. In 1740 he was made commander of a fleet sent to the South Sea, directed against the trade and colonies of Spain. The expedition consisted of five men-of-war and three smaller vessels, which carried 1,400 men. After much suffering and many stirring adventures he reached the coast of Peru, made several prizes and captured and burned the city of Paita. His squadron was now reduced to one ship, the Centurion, but with it he took the Spanish

treasure galleon from Acapulco, arriving in England in 1744, with treasure to the amount of £500,000, after having circumnavigated the globe. His adventures and discoveries are described in the well-known Anson's 'Voyage,' compiled from materials furnished by Anson. His victory over the French admiral Jonquière, near Cape Finisterre in 1747, raised him to the peerage with the title of Lord Anson, Baron of Soberton. Four years afterward he was made First Lord of the Admiralty. In 1758 he commanded the fleet before Brest, protected the landing of the British at Saint Malo, Cherbourg, etc., and received the repulsed troops into his vessels.

ANSON, William Reynell, Rt. Hon. Sir, 3d baronet: b. 1844; d. Oxford, 4 June 1914. A famous English jurist, educated at Eton and Oxford, where he won some of the highest academical distinctions. He practised at the bar till 1873; was appointed Vinerian reader in English law at Oxford (1874); where he took an active part in promoting the foundation of a school of law. In 1880 he made a bid for parliamentary honors as a Liberal, unsuccessfully. Elected warden of All Souls' College in 1881; became a member of the Hebdomadal Council in 1884 and vice-chancellor in 1898. In 1899 he was elected M.P. for Oxford University, but as a Unionist. In 1902 he was made parliamentary secretary of the Board of Education and, as the representative of the Education Department in the House of Commons, he had much to do with defending and bringing into operation the Education Act of 1903. He established an enduring reputation by his great work, 'The Law and Custom of the Constitution' (1881), a monument of learning and lucid exposition and the most trustworthy guide to the complex machinery of British government. It is the textbook from which British statesmen have to learn their business. His other chief work, 'The Principles of the Law of Contract' (1879), has also become a standard classic. Sir William Anson was a trustee of the British Museum—an honor more difficult of attainment than a mere peerage. The future King of England received his instruction in constitutional history from him. As Anson died unmarried, the baronetcy passed to his nephew, Sir Denis Anson, a very young man, who was drowned in the Thames a month later.

ANSON, Tex., town and county-seat of Jones County, on the Wichita Valley and the Abilene Southern railroads, 150 miles west of Fort Worth. The town is located in the midst of a fine agricultural country and has extensive cotton and live stock interests. It contains cotton gins, confectioneries and a municipal waterworks, two banks with combined resources of \$140,000, a common school and a high school and five churches. The value of taxable property is \$625,000 and the municipal revenue amounts to about \$7,500. The town is under the commission form of government. Pop. 2,500.

ANSONIA, Conn., city of New Haven County, situated on the Naugatuck River, a few miles above its junction with the Housatonic, and on the New York, N. H. & H. Railroad, being also the terminus of the New

Haven and Derby branch; 12 miles northwest of New Haven. Among its public buildings are the Anson G. Phelps public library, a memorial to the founder (in 1840) of the city, and the city hall. Ansonia has extensive manufactories of brass and copper goods, clocks and clock equipments, movements, etc., electrical supplies, flour, lumber and lumber products, foundries and machine shops, etc. According to the United States census of manufactures in 1914, there were 42 establishments of factory grade employing 4,882 persons, of whom 4,312 were wage-earners, receiving annually \$2,412,000 in wages. The capital employed was \$16,535,000 and the year's output was valued at \$21,499,000; of this, \$4,287,000 was added by manufacture. Since 1909 the capital in Ansonia's industries has increased 69.4 per cent and the output has increased 7 per cent. It was formerly a part of Derby and received its city charter from the legislature in 1892. Pop. (1910) 15,152; (1916) 17,500.

ANSWER, in law, a defense in writing, made by a defendant to charges contained in a complaint filed by the plaintiff against him in a court of law. In all the code States a statute similar in its provisions to § 500 of the New York Code of Civil Procedure has been adopted. This section provides that the answer of the defendant must contain: (1) A general or specific denial of each material allegation of the complaint controverted by the defendant, or of any knowledge or information thereof sufficient to form a belief; (2) a statement of any new matter constituting a defense or counterclaim, in ordinary and concise language, without repetition.

ANT, a small social insect of the family of *Hymenoptera*, characterized by unusual distinctness of the three regions of the body, head, thorax and abdomen and by the stack or petiole of the abdomen having either one or (rarely) two "scales" or "nodes," so that the abdomen moves very freely on the trunk or thorax. The antennæ are elbowed as in wasps and bees. Ants live in societies, consisting, besides the males and females, of smaller wingless workers. In all ants, except the *Odontomachida* and *Dorylida*, the mandibles are wide apart at the base or insertion, so that they can be used without the other appendages of the mouth being opened or even moved. Both males and females are winged, but the males are much smaller than the females, while the wingless workers are smaller than the males. In these wingless forms the segments of the thorax become more or less separated, making the body much longer and slenderer and less compact than in the winged normal sexual forms, the prothorax being more developed than in the males and females. The workers often consist of two forms: one with a large cubical head, or worker major, sometimes called a soldier, and the usual small-headed form, or worker minor. In certain genera this polymorphism (q.v.) is still more marked. The legs are usually long and slender, the tarsi are five-jointed as usual in *Hymenoptera*, but the front or basal joint is disproportionately long, so that it functions as if part of the tibia; the tibiae of the fore pair of legs are furnished with comb for cleaning the antennæ and mouth

appendages. A sting is sometimes present, as in the *Poneridæ*, which sting like wasps and bees and in the *Myrmicinæ*, while in the workers of ordinary ants it is either vestigial or entirely wanting. Some ants secrete an active poison (formic acid), which they inject into the wound made by their jaws in biting. In the *Formicinæ*, whose sting is atrophied, the amount of poison secreted is "relatively enormous" (Janet). Our *Formica obscuripes* is a very ferocious species and, like the European *F. pratensis*, rises upon its hind legs, curves the abdomen and ejects its venom, while Muckermann adds that the ejection of formic acid is so copious as to enforce the observer to momentarily retire.

The larvæ of ants are uniformly maggot-like, being legless, soft-bodied, cylindrical and with a small head bent on the breast. They are helpless and are fed by the workers.

Wheeler has shown that different species of ants employ very different methods of feeding their larvæ. Some (those of *Camponotus*, *Formica*, *Lasius* and *Myrmica*) feed their young with liquid food regurgitated from their crops and possibly also with the secretion of the salivary glands. Other species, however, *Ponerinæ* and some *Myrmicina*, feed their larvæ with comminuted insects. Wheeler states that the larvæ of certain ants "are not only able to subsist on solid food, but even on food of a vegetable nature."

The larvæ of the stingless genera usually spin a delicate silken cocoon, while those of the aculeate genera do not. Within the cocoon the larva transforms into the pupa.

Nesting Habits.—The history of a formicarium, or ants' nest, is as follows: The workers only (but in some species the winged ants) hibernates and are found early in the spring taking care of the eggs and larvæ produced by the autumnal brood of females. Every ant colony is founded by a single fertilized female. In the course of the summer the adult forms are developed, swarming on a hot, sultry day. The small yellow ants, abundant in paths and about houses in New England, generally swarm on the afternoon of some hot day in the first week of September, when the air is filled toward sunset with myriads of them. The females, after their marriage flight in the air, may then be seen entering the ground to lay their eggs for new colonies, or they are often seized by the workers and retained in the old colonies. Having no more use for their wings, they pluck them off and may be seen running about wingless. The female, after laying her eggs, does not go abroad in search of food, but feeds the young larvæ with food regurgitated from her stomach and derived from her fat-bodies; thus the larvæ are poorly fed and become workers.

Nests.—The nests of some species of *Formica* are six feet in diameter and contain many thousand individuals. Ants also build nests of clay or mud and inhabit hollow trees. Ants in Europe build true mounds, sometimes three feet high, but in North America they are mostly subterranean, though in Wisconsin one ant (*F. obscuripes*) erects a true mound about 20 inches high.

Formica sanguinea is one of our most abundant species, making hillocks of sand or clay, according to the nature of the ground.

From the formicary walls and underground galleries radiate in a labyrinth in all directions; and deep down, where the soil is perpetually moist, the galleries descend to a relatively greater depth than in Europe. Packard has found a variety of this species in Labrador, where it is common. It does not throw up hillocks, but tunnels in the earth. The nest of *Cecophylla smaragdina* is formed by drawing together a number of green leaves, which are united with a fine web. Some nests are a foot in diameter. This species swarms in hilly forests in New Guinea. Its sting is not very severe.

It is in argillaceous countries especially that the *Ecodomas* build their enormous formicaries, so that one perceives them from afar by the projection which they form above the level of the soil, as well as by the absence of vegetation in their immediate neighborhood. These nests occupy a surface of many square metres and their depth varies from one to two metres. Very many openings, of a diameter of about one to three inches, are contrived from the exterior and conduct to the inner cavities which serve as storehouses for the eggs and larvæ. The central part of the nest forms a sort of funnel, designed for the drainage of water, from which, in a country where the rains are often abundant, they could hardly escape without being entirely submerged if they did not provide some outlet for it.

The "agricultural ant" myth has been exploded by Wheeler, who shows that these ants do not plant grass seeds or "ant-rice" for a harvest. It is probable that Lincecum's error was due to the fact that the sprouted seeds stored up and then cast away as inedible take root and thus form a partial circle of tall grass around the nest.

Mushroom Gardens.—Möller has described what he calls "mushroom gardens" made by several South American species of *Atta*. The ants cut and bring the large pieces of leaves into their cellars, then cut them into smaller fragments and finally comminute these still further till they form a flocculent greenish-brown pulp. This pulp is heaped up and soon becomes invaded by the mycelium of a fungus (*Rozites gongylophora*). The mycelium is kept aseptically clean—that is, free from all other species of fungi and even from bacteria—and induced to grow in an abnormal way by bringing forth minute swellings which constitute the only food of the ant colony. Möller likens these swellings to the *kohlrabi* of the German kitchen gardens.

Forel has studied the habits of two other species (*Atta cephalotes* and *A. sexdens*) in Colombia, in relation to this process of collecting and comminuting the leaves and in cultivating the mushroom. He has found that the largest workers (soldiers) triturate the leaves and defend the nest. They draw blood when they fight. The indigenes are said to use these insects for closing wounds. They induce them to bite the two lips of the wound and thereupon sever the bodies from the heads, which then serve as a suture. The medium-sized workers cut the leaves from the trees, while in the nest the workers of the *minim* caste are forever clipping the threads of the mycelium of the *Rozites*, which then develops the *kohlrabi* on which the ants feed.

Wheeler excavated a large nest of leaf-cutting ants (*Atta ferrens*) in a piece of woodland in Texas. The large burrows, nearly an inch in diameter, were found to extend down to a depth of from three to five feet, and to open into large chambers, some of which were fully 10 inches across and five to eight inches high. A few of these chambers were traversed by the roots of a large cedar, in the shade of which the ants had dug their formicary. Mushroom gardens were found heaped upon the floor, or, more rarely, enveloping, as aerial or "hanging" gardens, the roots that extended across the chambers.

The shape of a mushroom garden is that of a discoidal sponge. On its upper surface the ants pile up the flocculent vegetable debris, threaded in all directions with fungus hyphae, in the form of thin, vertical, anastomosing plates, so that as much surface as possible is exposed to the atmosphere of the chamber. This atmosphere must contain a great amount of carbon-dioxide and a very small amount of oxygen. The ants leave several tubular or funnel-shaped openings, varying in diameter, and extending down into some chambers excavated in the base of the vegetable mass. In these chambers lives the huge queen of the colony (an insect nearly an inch long), the newly-fledged males and virgin queens, together with the larvae, pupae and attendant ants. The whole mushroom garden swarms with workers representing all the different castes so characteristic of the genus *Atta*. The big-headed soldiers stalk about slowly over the surface of the comb, descending from time to time into the interior, as if to make sure that the great family is properly attending to its multifarious occupations, while thousands of *minims* keep moving about through the meshes of the mycelium, weeding the garden.

Relation of Quality and Quantity of Food to the Production of the Sexless Workers.—As is obvious, since the workers rarely lay eggs, the worker caste is not inherited either directly or collaterally from the parents. The view now suggested and supported by a considerable body of facts is that the larvae on hatching are at first all alike and that those which become workers are fed with different as well as less food than those which develop into sexual individuals. We know that the differences between the queen and the worker bees are due to differences in the nature of the food. The worker white ants have been found by Grassi to be the result of having different food and less of it than the males or females. Wasmann believes that the large workers of *Polyergus rufescens* ("ergatoid females") are produced by the slave ants (*Formica fusca*), living in the colony, through excessive care and feeding of certain larvae,—that is, that the *fusca* workers or slaves attempt to change worker larvae of *Polyergus* into queens, but succeed only in producing the wingless ergatoids. Emery also holds that the sexual polymorphism of the ant colony is the result of the development of an instinct in the workers to feed the larvae in different ways and thus the characters in which the worker differs from the corresponding sexual forms are not congenital but acquired.

As has been said, the female ant, on founding a new colony, herself lives and nourishes

the freshly-hatched larvae with food from her stomach, ultimately from the fat-body. Hence these larvae of the first brood are poorly fed and become small or dwarf workers (micro-ergates). These workers leave the nest and bring in food to their half-starved parent. Thus fed she becomes more prolific, lays another batch of eggs and the larvae become larger and finally change into larger-sized workers. The colony thus becomes more populous and, as Wheeler states, the workers of successive broods grow larger until they attain the full stature of the species. Then and not till then do the workers bring up the males and queens, which are carefully herded, fed and groomed by the workers until ready for the marriage flight. In some species of ants the males and virgin queens do not appear till the second or third year after the colony is founded. In a few American species of the huge cosmopolitan genus *Pheidole*, Wheeler and others find that the large-headed and small-headed or dwarf workers are connected by a perfect series of intermediate forms and this is due to the varying quantity of food. After an unfavorable season (autumn and winter) of drought and cold the number of *Pheidole* soldiers was unusually small. Thus Grassi's view as to the origin of the polymorphic forms in the termites being dependent on the quality and quantity is borne out by recent observations on ants.

Polymorphism and Variability of Ant Castes.—No solitary ants are known to exist, in all besides the males and females there are workers, and this is the direct result of their social mode of life. In our common species there is only one kind of worker, those in which the head is of uniform size, no big-headed ones or soldiers. But in ants collectively, though not in any one genus, there may be eight sets of individuals—that is, ordinary males and "ergatoid" males, ordinary females and ergatoid fertile females, and exceptionally (*Formica rufa*), a set intermediate between the female and the worker; there are also soldiers, worker-majors and one or more kinds of worker-minors. The adult, sexually capable, though wingless forms, are called by Forel "ergatoids" from their resemblance to workers (Εργατης, a worker), this term is applied to both sexes. The worker females differ from the normal-winged female in the lack of a *receptaculum seminis*. The greatest number of castes in any one genus is five, occurring in *Eciton*, *Cryptocerus*.

Wheeler shows that polymorphism and variability depends on the amount and nature of the food and the increase in the population of the colony, and on the care and protection afforded to the reproductive individuals of the colony. There is, on the other hand, little variation in colonies which are poorly fed and therefore unable to increase rapidly in number.

Primitive Ants.—Two primitive sub-families of ants, the *Dorylinae* and *Ponerinae*, appear to have been evolved from a still more primitive and ancestral group, the *Cerapachynae*, which Wheeler with good reason claims to be "the most archaic and generalized of existing *Formicidae*." This group, species of which occur in Africa, southeastern Asia, Australia and the southwestern United States (Texas) is represented in this country by *Cerapachys*, which mines the ground for a few inches under stones.

The colony appears to be unusually small, the queen is wingless and the workers quite blind, and its life appears to be wholly subterranean, yet possesses senses of contact, odor (judging by the thick antennæ), and of hearing (it has "a beautifully developed stridulatory apparatus, which occupies the whole of the large membrane between the postpetiolar and first gastric segment") (Wheeler). This form, as Emery points out, seems to be the nearest of any ants to the *Mutillidæ*, especially the genus *Apterogyna*, which has an ant-like pedicel to the abdomen, and also resembles the ants in other features. That this group is also a very primitive one is shown by the plastic forms of females, of which there are four kinds, significant, as Wheeler remarks, "as the phyletic source to which the different female forms of all the subfamilies of ants are to be traced."

Slavery.—This phase of social life is not infrequent among ants, and it reacts upon the slaveholders by rendering them helpless. *Formica sanguinea* has been observed in Europe by P. Huber to go on slave-hunting expeditions. They attack a "negro colony" belonging to a smaller black species, pillaging the nests and carrying off merely the larvæ and pupæ. The victors educate them in their own nests, and on arriving at maturity the negroes take the entire care of the colony. *Polyergus rufescens* is also a slave-making ant, and Latreille very justly observes that it is physically impossible for the rufescent ants (*P. rufescens*), on account of the form of their jaws, and the accessory parts of their mouths, either to prepare habitations for their family, to procure food or to feed them. *Formica sanguinea* sallies forth in immensely long columns to attack the negro ant. Huber states that only five or six of these forays are made within a period of a month, at other seasons they remain at peace. Huber found that the slave-making *Polyergus rufescens*, when left to themselves, perish from pure laziness. They are waited upon and fed by their slaves, and when they are taken away their masters perish miserably. Sometimes they are known to labor, and were once observed to carry their slaves to a spot chosen for a nest. The *Formica sanguinea* are not so helpless; they assist their negroes in the construction of their nests, they collect their sweet fluid from the *Aphides*; and one of their most usual occupations is to lie in wait for a small species of ant on which they feed; and when their nest is menaced by an enemy they show their value of these faithful servants by carrying them down into the lowest apartments, as to a place of the greatest security. Pupæ of both the slave-making species were placed in the same fornicary by Huber, where they were reared by the "negroes," and on arriving at maturity lived together under the same roof in the most perfect amity. Darwin states that in England *Formica sanguinea* does not enslave other species.

In this country forays of a colony of *Formica sanguinea* upon a colony of a black species of *Formica*, for the purpose of making slaves of them, has been not infrequently observed. Slavery (*duloris*) is known to exist only between ants belonging to the same subfamily, the species of only four genera being known to practise slavery. In Europe the "paragon of dulotic ants" is *Polyergus rufescens*, or the

"amazon" ant, as the workers are very warlike, though they are in other respects helpless and completely dependent on their slaves, dying of starvation if deprived of them. Darwin's explanation of the origin of the slave-making habits is that they were originally due to the predatory instincts of ants in general, seen in their carrying off the pupæ of other species, which, becoming stored as food, and finally developing would in their new abode do what work they could; and this habit of collecting pupæ for food might be rendered permanent for the purpose of raising slaves.

Sound Produced by Ants.—Certain species of ants are evidently not deaf, because capable of producing sounds which must be heard by others of their own kind. Thus *Myrmica rubra* has a sound-producing apparatus, a strigil, or file on the seventh abdominal segment (Janet); another ant of this group (*Sima laticeps*) is provided with a stridulating file; and in the ronerids there is a stridulating organ consisting of a band of very fine raised lines on the second segment behind the node. Other ants (*Polyrhachis*) tap on the surface of a leaf with their heads, producing a sound audible to human ears, as does an Assamese species by scraping the end of its abdomen on the dry leaves of its nest.

Senses of Ants.—While ants may be blind and deaf, none are known to be destitute of the sense of smell. The olfactory organs are little sensory pits in the antennæ. It is undoubtedly by means of their sense of smell that ants recognize the members of their own nest, and those of other species which they treat as enemies. It is probably by this means that they distinguish their friends from their enemies. Thus the cause may be the result of reflex action, rather than any special degree or kind of intelligence.

Parasitic Ants with No Workers.—Such are the ants of the genera *Anergates* and *Epæcus*; in the former the male and females are helpless, incapable of leaving the nest and dependent on the attentions of the workers of another genus (*Tetramorium*) which live with them. This strange relationship seems thus far inexplicable.

Symbiosis in Ants.—The relation between ants and plants is very intimate, and it assumes different phases. See SYMBIOSIS.

Commensalism.—Ants' nests are so many apartment or boarding hives. A vast number of beetles, aphides, cockroaches, flies and arachnids take up their abode in the nests of ants, where they are allowed by their willing or unwilling hosts to feed on the excretions of the ants themselves or their food. The fostering instincts of ants thus seem to be extended in various degrees to their guests and thus lay the foundation for this semi-parasitic community. Upward of 1,500 species of *Arthropoda* are known to live in more or less cordial relations with their hosts.

Late Professor of Zoology, Brown University.

ANTACIDS, or **ALKALIES**, drugs which correct abnormal acidity of the digestive tract or the secretions of other organs. Direct antacids are those that unite directly with acid in the stomach and intestines; the principal are ammonia, magnesia, potassium, bicarbonate, chalk and lime water. The acetates, citrates and tartrates of the alkalis act by being changed into carbonates, and increase the alkalinity of the blood, which diminishes the acidity of the urine, and are called indirect or remote antacids. Direct antacids are given after meals to neutralize an excess of the hydrochloric acid of the stomach resulting from fermentation of the food. Remote antacids are extensively used in the treatment of gout and rheumatism.

ANTÆUS, ān-tē'ūs, the giant son of Poseidon (Neptune), and Gē (the earth), who was invincible so long as he was in contact with the earth. But Heracles (Hercules), whom he challenged to combat, perceiving the secret of his strength, lifted him in the air and strangled him.

ANTALCIDAS, Spartan statesman, chiefly known by the celebrated treaty he concluded with Persia at the close of the Corinthian War in 387 B.C. The peace which followed was styled "The Peace of Antalcidas."

ANTARCTIC REGIONS, the name given to part of the earth's surface surrounding the South Pole. Its limits are variously defined by geographers; some consider it to be coextensive with the Antarctic Ocean, which in a strict sense is bounded by the Antarctic Circle, while others include also that portion of the great Southern Ocean affected by Antarctic influences. According to the latter interpretation the region is approximately defined by the northern limit of the drifting pack-ice or about lat. 50° S., although icebergs are sometimes encountered as far north as lat. 45° S. The Antarctic region is surrounded by a great expanse of shoreless water which further north is divided by the continental lands into the Atlantic, Pacific and Indian Oceans. The area comprised within the Antarctic Circle is about 8,200,000 square miles.

Exploration.—The early explorations into the region south of the equator and the discovery of numerous lands gave rise to the belief that a vast continent existed near the South Pole. The first voyage of Captain Cook in 1769 showed, however, that New Zealand, contrary to the general opinion, was an island, and in his second voyage, in 1772, it was proved that the continent, if it existed, did not extend beyond the Antarctic Circle. In 1773 Cook sailed south again and the following year reached lat. 71° 10' S. in long. 106° 54' W., where he was prevented from advancing further by enormous ice-floes. No land was seen on this voyage, although its presence was indicated by flights of birds. In 1819 Captain Smith rounded

Cape Horn and sighted the South Shetland Islands, while in the following year Alexander Land still farther south was discovered by Bellingshausen. Morrell, an English explorer, sailing in 1822, visited the Falkland Islands, Bouvet Islands and South Georgia, and reported that he found the temperature of both air and water to be milder the farther he advanced southward. Biscoe circumnavigated the southern ice region in 1831-32, penetrating beyond lat. 67° S.; he discovered Enderby Land and its southwestern extension, which he named Graham Land. Kemp sighted and marked Kemp Land in 1833. The Balleny Islands were discovered by Balleny in 1839, and D'Urville, in 1839-40, made a long voyage during which he visited many of the previously discovered lands, changing their names to make room for selections of his own. The latter also found Adélie Land, an immense tract situated far south of New Zealand and stretching for an unknown distance toward the Pole. The voyages of Wilkes (1838-42) and of Ross (1841-42) were of great importance, especially in their scientific aspects. Ross encountered land in 70° 41' S. lat., 172° 30' E. long., which had a steep, rocky coast-line; farther south in 77° 32' S. lat., he found a lofty, active volcano which he named Mount Erebus and an inactive cone called Mount Terror. He sailed for a distance of 450 miles along an unknown ice barrier rising 150 feet above the water. During the next 30 years little was added to our knowledge of the Antarctic region. Dallman in 1873-74, however, visited many of the localities marked by previous explorers and was able to confirm their reports. The Challenger expedition, which started out in 1874, returned with proof of a floating ice barrier and also accomplished a vast amount of oceanographic investigation. More recently the expedition of Gerlache, who penetrated to lat. 71° 36' S., was fruitful in scientific results and added over 100 islands to the list of those previously known. Borchgrevinck, a Norwegian, in charge of an English expedition, passed the winter of 1898-99 in the Antarctic and in the following summer reached lat. 78° 50' S., the farthest then attained. In 1900 he set out again and succeeded in locating the south magnetic pole in lat. 73° 20' S., long. 140° E.

From 1901 to 1912 Antarctic exploration was very active. Several expeditions were fitted out in 1901 and one of these under Capt. Robert F. Scott reached lat. 82° 17', long. 163°, the farthest south. A Swedish expedition under Dr. Otto Nordenskjöld, 1902-04, made many discoveries but lost its ship, the *Antarctic*. Other expeditions were under Dr. Erik von Drygalski (1902), W. S. Bruce (1904), Dr. Jean Charcot (1904), and Lieut. Ernest H. Shackleton (1907-09). In 1909-10 Dr. Jean Charcot on his vessel *Pourquoi Pas?* had a year of successful exploration, in which he found new lands, made new soundings and achieved other valuable scientific results. His work was mainly between the 69th and 71st parallels. In 1910 five expeditions were in the field: English, Capt. Robert F. Scott; Norwegian, Capt. Roald Amundsen; Australia, Dr. Douglas Mawson; Japanese, Lieutenant Shirahase; German, Lieut. William Filchner. Captain Scott sailed from New Zealand on his vessel *Terra Nova* 29 Nov. 1910, with the intention of establishing win-

ter headquarters at the foot of Mount Erebus and on King Edward VII Land. Captain Amundsen left Norway in the ship *Fram* in the summer of 1910 with the intention of rounding Cape Horn and entering upon the ice-drift across the Polar Sea which he had long contemplated. He changed his plans after sailing and when Captain Scott arrived at his proposed winter headquarters he found Amundsen already there.

Amundsen was finally successful in first locating the Pole. On his ship *Fram* he reached Hobart, Tasmania, 7 March 1912, on his return voyage and announced that he had discovered the South Pole 14 Dec. 1911. The winter of 1910-11 he spent in quarters in the Bay of Whales, 164° W., 78° 48' S. On 10 Feb. 1911, he began to prepare for his winter's work and before 11 April had built caches as far south as 80°. The lowest winter temperature which he here recorded was on 13 August, minus 59° Celsius. The mean temperature for the year was minus 26° Celsius (14.8° below zero Fahrenheit). On 8 September, with eight men, 90 dogs and seven sledges, provisioned for four months, he started for the Pole, but only got as far as the depot at 80°. There the party remained until the middle of October when a fresh start was made with five men, 52 dogs, four sledges and four months' food. Victoria Land was reached 11 November. At 85° the land joins the Ross Barrier of ice and from that point the explorers had to climb through a region of land whose heights ranged from 2,000 to 11,000 feet high. In four days over the glaciers they reached a height of 10,600 feet, and their highest altitude, 10,750 feet, was attained on 6 December at 87° 40'. On 8 December at 88° 23' they passed the farthest south record of Shackleton. From this point they found the going easy until on 14 December at 3 o'clock in the afternoon observations showed that they had attained their object. From 14 December to 17 December they remained at the Pole, taking observations and finally locating exactly 90° S. where they flew the Norwegian flag and named the land at the Pole King Haakon VII Plateau. Returning, winter quarters were reached 25 Jan. 1912. The principal results of the expedition were locating the Pole, determining the extent of the Ross Barrier, ascertaining the apparent connection of South Victoria Land and King Edward Land and the mountain ranges therein and the exploration of part of King Edward Land.

Thirty-five days after Amundsen had planted the flag of Norway at the South Pole, Capt. Robert F. Scott, R.N., unfurled the Union Jack of Great Britain, the exact points, as determined by observation, being not more than half a mile apart, and Scott took from the Amundsen tent the written message for King Haakon, which was subsequently delivered. Scott's southerly route had been practically that of his former discovery and of the Shackleton expedition and the return from the Pole was along the same track. Of the party of five, Petty Officer Edgar Evans was fatally injured soon after leaving the Pole and 11 miles from "One-ton" Camp, 155 miles from the Hut Point base in MacMurdo Sound, Scott, Dr. Edward A. Wilson, second in command, chief of the scientific staff, and Lieut. H. K. Bowers died in their tent of cold and privation. A few days before

Capt. L. E. G. Oates of the Inniskillen dragoons, in desperate straits, bade his commander and comrades goodbye, saying as he left them: "I shall be gone for some time," and upon a spot near may now be read the inscription:

"Hereabouts died a very gallant gentleman."

Not until the following spring (1913) did Surgeon Anderson succeed in reaching the tent of the dead and recovering the bodies of Captain Scott and his comrade, with records, collections and scientific data. The last entry in the journal contained:

"I do not regret this journey, which has shown that Englishmen can endure hardships, help one another and meet death with as great fortitude as ever in the past.

"These rough notes and our dead bodies must tell the tale, but surely, surely, a great rich country like ours will see that those who are dependent on us are properly provided for."

Sir Douglas Mawson, of Yorkshire birth, Australian training and education and professor in the University of Sydney, accomplished in 1911-14 a memorable Antarctic work of adventure and discovery. A member of the Shackleton expedition, he was of the party which successfully ascended the active volcano Erebus and penetrated to the floor of its crater and had demonstrated his fitness for field work and scientific research. Organizing a well-balanced party, competent in each branch of investigation, sustained by his government and contributions from scientific societies of Great Britain, the expedition on its leaving Sydney tarried for some time at Macquarie Island, upon which a party in charge of a wireless telegraph station was left, while the main body pushed on to a permanent base on Adélie Land. From this point work in every direction was diligently prosecuted, the coast line to the eastward being mapped and connected up with that of the Scott party in Ross Sea, while far to the westward a detachment under Capt. Frank Wild wintered, gathering valuable data. Sir Douglas himself at the head of an inland reconnaissance party accomplished one of the most difficult and perilous marches on record, losing in its early stages, through a crevasse, Lieutenant Ninnis, R.F., and later, through illness, Dr. Anton Merz, his two comrades, and narrowly escaping with his own life. A novel and interesting feature of the expedition was the maintenance, during a large portion of the time it was absent, of wireless communication with its Macquarie Island station, thence to Australia and the world, by means of which the news of the death of Captain Scott and disaster to his expedition was received. Sir Douglas' scientific work (in recognition of which and his exceptionally able conduct of it, and of his expedition, King George conferred upon him the order of knighthood) will require several years and a large amount of work for its complete and adequate publication.

The most ambitious and daring of all Antarctic projects was that of Sir Ernest Shackleton, launched in August 1914, after his offer of his services and that of his party to his country in the great war which had just broken out was declined. Sir Ernest's project contemplated a base on Coats Land and advance from that point directly over the ice barrier land mass and whatever might be met with to the South Pole, and thence keeping on to the familiar British Ross Sea base on the opposite side of the globe, employing for the purpose two ships,

two parties, each working in support of the other, though only that headed by himself was to make the complete transcontinental traverse. Leaving Liverpool, Sir Ernest proceeded in the *Endurance* via Buenos Aires and the Falkland Islands to South Georgia, whence the last word was that the ice conditions were so unfavorable that the attempt upon the main land must be deferred until the following season. More than a year passed when Sir Ernest again reported that though he had sighted new land he had been unable to reach it and compelled to abandon his main objective, the traverse of the great Antarctic land mass. The *Endurance* had been crushed and sunk and after a perilous journey over the pack, followed by one in boats across the open sea of nearly 1,000 miles, he had left his party of 22 marooned on Elephant Island, with a short supply of provisions. Sir Ernest himself with two comrades had crossed the distance between Elephant Island and South Georgia, landing upon it at the peril of his life, and after the loss of his boat had made his way over its interior to the Norwegian whaling station, whence his report was sent. Uruguay promptly placed a small vessel at Sir Ernest's disposal for the relief of his Elephant Island party, but the attempt was unsuccessful and at last a second and successful effort was made with a larger vessel under the Argentine flag. On the opposite side of the Antarctic continent results were equally unsatisfactory. The *Aurora*, having landed three parties to lay depots of food for Shackleton's advance, had been torn from her anchorage and for nearly a year adrift in the pack with her wireless equipment most of the time out of commission. Late in April 1916, however, a message from the ship was picked up in New Zealand, whence relief was promptly dispatched, and on 27 April Port Chalmers was finally made. See POLAR RESEARCH.

Antarctic Ocean.—The depths of the Antarctic Ocean have been explored in various parts by Ross, Wilkes, Nares (Challenger expedition) and Gerlache. Ross sounded in 4,000 fathoms in the vicinity of South Georgia without reaching bottom. The Challenger found depths of from 1,300 to 1,950 fathoms near the Antarctic Circle, south of Australia, while farther north the soundings ranged from 950 to 2,600 fathoms. Between the Cape of Good Hope and Kerguelen Islands depths of 2,500 to 3,100 fathoms have been reported. There seems to be a gradual shoaling of the waters toward the Pole, for Wilkes sounded in 500 to 800 fathoms off Adélie Land, and in 100 to 500 fathoms off Victoria Land, while Gerlache recorded less than 200 fathoms west of Palmer Land. The bottom in the extreme south is covered with a layer of diatom ooze. Farther northward the bottom is covered with deposits of globigerina ooze made up of the casts of *Foraminifera*, and in still deeper water the characteristic red clay, found at great depths in all the oceans, occurs. The temperature of the surface waters of the ocean range from a few degrees below to a few degrees above the freezing point.

Antarctic Continent.—The question whether there is a large land area of continental character within the Antarctic Circle has not yet been definitely settled, although most geog-

raphers and explorers express an affirmative opinion. Land areas of indefinite extent have been sighted and form an interrupted ring about the Pole. The mountain ranges and peaks discovered by Ross in Victoria Land are apparently of continental character. Granite and gneiss were found by D'Urville near Adélie Land, and Borchgrevinck states that the rock at Cape Adare is micaschist; these are distinctly continental types. Indirect evidence is furnished by the materials transported from the far south by the icebergs, sandstone, basalt, boulders of massive rocks, and fragments of gneiss, granite, diorite and sedimentary rocks. The great icebergs which drift far into the region of the Southern Ocean are difficult to account for on any other theory than that they have been broken off from a vast sheet of land ice like that covering Greenland.

Antarctic Ice.—The conditions of ice formation in the Antarctic differ materially from those of the Arctic region. In the northern hemisphere the polar ocean is enclosed by land, so that sea ice is much more important than land ice, the latter occurring only on the edge of the area, while in the Antarctic the reverse is true. Enormous masses of floating ice, flat-topped with perpendicular walls and oftentimes measuring many miles in width and length, are found throughout the Antarctic Ocean. The newly-formed bergs have evidently been broken off from the edge of a thick ice-cap covering the Antarctic lands and gradually pushed over the surface toward the sea. The thickness of the ice near the Pole is estimated by Croll upon theoretical grounds at from 12 to 14 miles, but off the coast of Victoria Land the ice-wall is only 10 to 20 feet high.

Climate.—The climatic conditions of the Antarctic are imperfectly understood, but temperature is extremely severe. Compared with the Arctic the region is placed at a disadvantage in having its summer during perihelion and winter in aphelion. Observations made by Ross in the vicinity of Victoria Land from 60° to 78° S. showed a mean summer temperature of 28.85° F. for the sea and 28.31° for air; in lat. 66° 29' S. the maximum temperature in the month of December was 45.52° F. Wilkes found the mean temperature for January and February near Wilkes Land to be 30.2° F., with extremes of 34.52° and 23°, while Gerlache reported a winter minimum in 71° 30' S. of -45°. The German station in South Georgia gave a mean temperature of 37.52°. The glaciation of the land areas, the great ice-floes and the saturated condition of the atmosphere, producing heavy fogs, are influential in producing the extreme cold. Barometric observations by Ross indicate a gradual increase in pressure south of 75° S., and it is believed that an area of extreme high pressure exists around the Pole, producing a permanent anticyclone with winds blowing in a south-easterly direction toward the higher latitudes. No estimate of the precipitation has been made, but the atmosphere is probably comparatively dry over the land areas in the extreme south and the precipitation is in the form of fine ice crystals. Farther north there is a heavy precipitation of snow and sleet; rain seldom falls within the ice-bound region.

Fauna and Flora.—The largest of the Ant-

arctic mammals are the whales which frequent the cold waters in great numbers. Many of the species are similar to if not identical with those inhabiting the Arctic seas; rorquals, humpback whales, pilot whales, grampuses and dolphins are known, also a small whalebone whale (*Balæna australis*), but the right whale does not exist in the Antarctic. There are 13 species of seals, including four of fur seals, which are closely related to those found in the north Pacific, the sea-lion and the sea-elephant. Among birds the penguins are most abundant, their rookeries being found on the borders of all lands free from ice. The largest species is the king penguin; a specimen captured by Wilkes measured 4 feet 6 inches in height and weighed 65 pounds. A gull-plover (*Chionis*) is found exclusively in the Antarctic. A small teal frequents Kerguelen, and stormy petrels, albatrosses, gulls, skuas and terns breed on most of the islands. Borchgrevinck found 11 species of fish in Antarctic waters, most of them new to science. Explorers have usually reported that fishes were scarce. A few species of insects have been described by Arctowski and Borchgrevinck. It is believed that no land animals exist in the extreme south. Of plant and invertebrate life inhabiting the Antarctic Ocean there is a great abundance. The pelagic animals include cephalopods, brachiopods and gastropods, which furnish food for the whales, coelenterates and *Protozoa*. The deep-sea fauna is much more strongly developed than the shallow-water fauna living in the vicinity of the Antarctic lands. Thirteen species of phanerogamous and numerous cryptogamous plants have been found near South Georgia. Hooker obtained from Cockburn Island four species of marine algæ, three of fresh-water plants and 12 land plants, the last-named mostly lichens and mosses.

HERBERT L. BRIDGMAN.

ANTARES, än-tá-réz ("corresponding to Ares" or Mars, because assumed to be like Mars in color), or *Alpha Scorpii*, a red double star of the first magnitude, the middle one of three in the body of the constellation Scorpio; much used by sailors in ascertaining longitude.

ANT-BEAR, the great ant-eater, or tamanoir. See ANT-EATER.

ANT-BIRDS, a general term applicable to members of certain groups of birds within the *Formicariidæ* (q.v.), a South American group, all of which subsist largely upon ants. They have no proper oscine or singing organs, yet some of them have clear musical voices, and

their notes of excitement when following the moving columns of destructive tropical ants, feeding not only upon them, but upon the insects they put to flight, are a warning which the natives understand and heed. All these birds are small and long-billed. The sub-family *Thamnophilinæ* is made up of the "ant-shrikes." The "ant-wrens" belong to the sub-family *Formicivorinæ*; and the "ant-thrushes" are a species of the *Formicariinæ*, a typical sub-family. The pitta is also sometimes improperly called an "ant-thrush."

ANT-EATER, a name given to several quite different mammals, but particularly applied to the *Myrmecophagidæ*, a South American family of *Edentata*, with the head extremely long; the snout slender; the mouth, ears and eyes small; the tongue long, cylindrical and covered with a viscid saliva which holds whatever insects are licked up until the tongue can be withdrawn into the mouth. When not in use the tongue lies doubled up in the mouth. The legs are strong and heavy; the toes vary in number in the different species, but in all species are united as far as the base of the large claws, which are adapted to digging, but are turned under the feet when the animal walks. The great ant-eater or ant-bear (*Myrmecophaga jubata*), found in tropical South America, is a sluggish animal, forest-dwelling, but entirely terrestrial; it grows to a height of two feet and a length of four feet, not including its long and very shaggy tail, which is often carried turned over its back like an umbrella. Though timid, it is capable of effective self-defense, using its strong forearms to hug and tear its opponents. Its body color is gray, set off by a black band which crosses the breast and tapers to the top of the shoulders, and by white feet and forelegs. The hair is long, particularly on the back toward the tail, and on the tail itself. It is very unsocial, spending much time asleep, curled up with its tail spread over it as a protection from sun or rain. As more than one is seldom produced at a birth, the great ant-eater is not numerous.

Another, much smaller, species (*Tamandua tetradactyla*), which is also tropical, is arboreal and has a prehensile tail. It is about the size of a cat; its head is broader in proportion than that of the great ant-eater; its hair is bristly and short, black on the body, yellowish white on the head, neck, forelegs and hindquarters. A third species (*Cycloturus didactylus*), the little or two-toed ant-eater, is still smaller than the tamandua and is also arboreal. Its claws are curved and very sharp for climbing, and its structure is peculiarly adapted for life in trees.

Besides the animals of this family, called the true ant-eaters, are their allies, the scaly ant-eaters or Manids (see MANIS), the aardvark, the porcupine ant-eaters (see ECHIDNA) and certain insectivorous marsupials found in Australia and belonging to the genus *Myrmecobius*. Certain birds, such as the *ant-shrike*, are also called ant-eaters (see ANTBIRDS).

ANTECEDENT STREAM. If folding or faulting occurs across the course of a stream slowly enough so that the river is able to cut down through the uplift as fast as it is formed, and the waters are not diverted, the stream is said to be antecedent. A well-known example is the course of the Kanawha where it crosses the Appalachian Plateau in West Virginia.

ANTEDILUVIAN ("before the flood"), theologically referring to the period previous to the Deluge recorded in Genesis. Geologically a term now disused, meaning before the waters of the earth had transformed its surface into the present form by submergence, erosion, etc.

ANTELAMI, ăn'tă-lă'mē. **Benedetto**, Italian sculptor. He flourished from 1177 to 1233. He was the most prominent sculptor of the Romanesque epoch. His first work is a 'Descent from the Cross,' now in the cathedral of Parma. He served both as architect and sculptor of the cathedral of Parma, of which the sculptures on the façade, the holy-water font and the bishop's throne are from his hand. Other works by him are in the cathedral of Borgo San Donino and the portals of Sant' Andrea in Vercelli. Consult Venturi, 'Storia dell' arte italiana' (1907).

ANTELOPE (Greek, *antholops*, a horned animal), an animal of the sub-family *Antilopinae*, placed between the cattle and the goats in the family *Bovidae*. Its members are all short-haired, lightly and gracefully built and carry their heads uplifted; in size they vary from that of a kid to the height of a tall horse, and almost all are timid and fleet-footed. Popularly, the antelopes include such widely varying species as the goat-antelopes (the chamois and the Rocky Mountain goat) at one extreme, and at the other the American prong-horn which has branched deciduous horns; but scientifically both these extreme forms must be excluded, and the term confined to Asian and African species having horns present in both sexes, the cores of which are solid, and which tend to grow upward rather than outward.

Antelopes have been pronounced the most generalized of the living *Bovidae*, and consequently are regarded as representing the form from which the other types within the family have descended. Their earliest fossil remains are found in the Miocene, when they flourished all over Europe and Asia, and their migration into Africa seems to have been comparatively recent. When Africa was first explored by Europeans, however, they were established there and had so enormously multiplied as to be the chief resource for meat of the natives and of carnivorous animals. Colonization so wasted and scattered them, however, during the latter part of the 19th century, that some species are already extinct, and others would be except for preservation on private estates.

Antelopes may be ranged in certain groups, such as the antelope gazelles, including many species which are beautiful in form but do not often exceed 30 inches in height, with goat-like teeth, hairy muzzles and ringed horns, usually either spiral or lyre-shaped. This group inhabits deserts from the Cape of Good Hope in India, and among them are the ariel and other gazelles, the springbok, the black-buck of India, the saiga and various others. Another, the cervicaprine group, contains the little African reedbuck, the small klipspringer and rehbok, the tiny steinbok and the larger waterbucks, etc. A third group comprises several African forest-ranging species, among others the pygmy antelope, only 13 inches tall and the smallest known ruminant. Another group is far larger and has many of the char-

acteristics of cattle, while still another section diverges toward the goats. The largest, most beautiful and valuable group of all is that which contains the Indian nilgai and the African bushbuck and eland.

There is an erroneous notion abroad that antelopes all live in large bands, or even vast herds, that roam over flat plains and perform migrations in large bodies from one place to another as scarcity of food and the weather compel them. Instead of this uniformity, however, there exists great variety in size, shape, color, speed, agility and habits in adaptation to the varied circumstances in which they live. Some dwell altogether in mountains and are as expert in climbing about the rocks as are the goats. Others frequent forests and rarely leave their shade. Still others remain entirely among hills where dense thickets cover the rough surface and dart in and out among the bushes so rapidly and expertly that the sportsman finds the greatest difficulty in getting a shot at them. Aquatic antelopes exist, especially in south Africa, where certain kinds, as for example, the reedbucks, spend nearly all their time in marshes, wading and swimming about and feeding upon aquatic vegetation. It is indeed only the larger, stronger and better armed kinds that can endure existence in plains where they have little means of protection against leopards, lions and other enemies, and must trust entirely to escape by flight or by being overlooked. The result has been the development among them of great speed, but this has not been accompanied by endurance, since few are required or are able to continue to run swiftly any great distance. As an aid to their safety, nature has developed in the desert- and plain-dwelling species an adaptation in color to their surroundings, making them almost invisible when lying down or standing against the rock and thicket. As a rule their coats have the dull colors of a plains landscape, the only somewhat conspicuous markings being those upon the face and tail, which serve the purpose of "recognition marks" but are not sufficiently large to attract attention at any great distance. Sometimes this protective color of antelopes is very striking, as in the case of the red hartbeest of east Africa, which frequents the open country where the soil is rust-red and termite hills are exceedingly numerous. It is said that the most experienced hunters are constantly deceived by the exact resemblance between one of these antelopes when lying down and an ant-hill.

The flesh of most antelopes is regarded as excellent food and some of them yield meat that is most delicate eating. The hides of the larger ones make good leather, and the destruction which has overtaken the race in South Africa has been brought about mainly by hide-hunters. The horns were put to many uses by the native Africans and Asiatics and are still in demand for the making of fancy handles and other articles of ornament.

For additional information see BLACKBUCK; GAZELLE; GNU; HARTBEEST; PRONGBUCK and other names of groups and species in this family. Consult also the general natural histories; Schmidt, 'Mammalia' (New York 1886); Flower and Lydekker, 'Mammals, Living and Extinct' (London 1891); Sclater and Thomas, 'Book of Antelopes' (4 vols., qto.,

col. plates, London 1894-1900); Beddard, 'Mammalia' (New York 1902); Ingersoll, 'Life of Mammals' (New York 1906).

ANTHELIA, luminous rings opposite to the sun, seen when the observer looks toward his own shadow cast upon a cloud or fog bank or on the dewdrops on the grass. The shadow is observed encircled by one or several concentric rings, with the common centre at the anti-solar point. They are attributed to diffraction or interference, are usually colored, red inside and blue without. The radius of the rings increases with the smallness of the globules that make up the fog or cloud. Consult Pernter 'Meteorologische Optik' (Vienna 1901). See **LIGHT**.

ANTHELMINTIC, medicine hostile to intestinal parasites. They are divided into two classes, vermicides, those which destroy; and vermifuges, those which expel. They are administered after a period of fasting, so that the worms will not be protected by masses of food, and are followed within a few hours by a purgative to expel the dead or stupefied parasites. See **HOOKWORM**; **TAPEWORM**.

ANTHER, the part of a stamen which produces pollen. Usually it consists of two diminutive sacs, separated by a certain amount of sterile tissue, which is often merely the top of the axis of the stamen. See **FLOWER**.

ANTHERIDIUM, the male organ of plants, in which the sperms are developed. In some plants it is a single cell; in others, a many-celled organ of varying shape. The antheridium bursts open in the presence of moisture, frees its mass of sperms, which then swim to the female organs. In seed-plants the organ is concealed, while in the lower groups it is conspicuous.

ANTHOLOGY ("nosegay"), a name originally given to a collection of short unconnected Greek poems from many sources, and till lately applied only to that and its various enlargements. In recent times it has been extended to any collection of detached pieces of miscellaneous authorship, prose or verse, to represent a language, a literature, a country, an epoch or any sort of subjective idea as a thread on which to group it. See **GREEK ANTHOLOGY**, **THE**; **LATIN ANTHOLOGY**, **THE**.

ANTHON, Charles, an American educator: b. New York city, 17 Nov. 1797; d. there, 29 July 1867. He was graduated at Columbia College in 1815 and admitted to the bar in 1819, but never practised. He was adjunct professor of Greek and Latin at Columbia 1820-30, and full professor and head master of the grammar school connected with the college 1830-64. In 1835, in connection with the Harper publishing house, he projected a 'Classical Series' to include works used in academies, preparatory schools and colleges. It proved the most successful enterprise of its kind ever undertaken in America. Of the more than 50 volumes edited by Anthon the following are the best known: An edition of Lemprière's 'Classical Dictionary' (1822); 'Horace' (with notes, 1830); 'Dictionary of Greek and Roman Antiquities' (1843); 'Classical Dictionary' (1841).

ANTHONY, Alfred Williams, American clergyman: b. Providence, R. I., 13 Jan. 1860. He was graduated from Brown University and Cobb Divinity School. He also studied two years in Berlin. In 1885 he entered the pastorate of the Free Baptist Church and became pastor of the Essex Street Church of Bangor. From 1890 to 1908 he was professor of New Testament Exegesis in the Cobb Divinity School; 1908 to 1911 professor of Christian literature and ethics in Bates College. Since 1911 he has been the corresponding secretary and treasurer of the General Conference of the Free Baptists. He is author of 'An Introduction to the Life of Jesus' (1896); 'The Method of Jesus' (1899); 'The Sunday School — Its Progress in Method and Scope' (1899); 'Preachers and Preaching' (1900); 'The Higher Criticism in the New Testament' (1901); 'New Wine Skins' (1901).

ANTHONY, an'tō-nī, Clemens Theodor: b. 1755; d. 1836. King of Saxony, who succeeded his brother Frederick August I, 5 May 1827. The French revolutionary movement of 1830, spreading to Saxony, compelled him to grant a constitutional government in 1831.

ANTHONY, Henry Bowen, American legislator: b. Coventry, R. I., 1815; d. 1889. He was graduated from Brown University in 1833 and was editor of the Providence *Journal* for over 20 years. He was governor of Rhode Island in 1849 and 1850, and United States Senator from 1859 till his death.

ANTHONY, John Gould, American naturalist: b. Providence, R. I., 17 May 1804; d. Cambridge, Mass., 16 Oct. 1877. Leaving school at 12 years of age he followed a business career for 35 years. He early developed a taste for natural history, and his publications attracted the attention of Agassiz, through whom in 1863 he became head of the conchological department of the Museum of Comparative Zoology, a post he held until his death. He was a recognized authority on the subject of American *Mollusca*.

ANTHONY OF PADUA, Saint: b. Lisbon, 15 Aug. 1195; d. Padua, 13 June 1231. Shortly after his ordination to the priesthood he was deeply stirred by the recital of the cruel martyrdom of five Franciscan missionaries whose bodies had just been brought from Morocco to Coimbra, where Anthony was then living. Having entered the Franciscan order, he soon started for Africa in the hope of being permitted to die for Christ. He had scarcely landed when illness obliged him to leave. Hearing about the general council of his order which was going on, he started for Assisi, where he met Saint Francis, the founder of the order. His profound knowledge of sacred things, joined to his sanctity, caused him to be made the first teacher in the Franciscan order and later on the provincial of all the convents of the order in upper Italy. His feast is celebrated 13 June. Consult Coleridge, S. J., 'Life and Works'; Meyer, 'Leben des H. Antonius'; Lepitre, 'Saint Anthony of Padua,' translated by E. Guest (1903).

ANTHONY, Saint, the patriarch of monastic institutions: b. near Heraclea, in Upper Egypt, 251 A.D.; d. 356. Giving up all his property, he retired to the desert, where he was

followed by a number of disciples, who thus formed the first community of monks.

ANTHONY, Saint, Cross of, a cross in the shape of the letter T, often styled the Tau Cross. In heraldry the name is given to two stripes, a horizontal and a vertical one crossing in the middle of the escutcheon.

ANTHONY, Saint, Falls of, a noted fall in the Mississippi River, within the limits of Minneapolis, Minn. (q.v.) The entire descent of the stream for three-quarters of a mile is 65 feet. The falls and surrounding scenery are exceedingly picturesque.

ANTHONY, Saint, Fire of, a name now applied to a form of erysipelas. A distemper of this character became epidemic in France in 1089. Many miraculous cures having been effected by the imputed intercession of Saint Anthony, the order of Canons Regular of Saint Anthony was founded the next year for the relief of those afflicted with this disease. The order continued to exist till 1790.

ANTHONY, Sister, American nurse and nun, known before entering religious life as Mary O'Connell: b. Limerick, Ireland, 15 Aug. 1815; d. Cumminsville, Cincinnati, Ohio, 18 Dec. 1897. She came with her parents to this country in childhood and in 1835 entered the order of Sisters of Charity at Emmittsburg, Md., removing to Cincinnati in 1837, there to take charge of work in Saint Peter's Orphan Asylum. On the establishment of Saint Joseph's Orphan Asylum at Cumminsville, in 1854, Sister Anthony was placed in charge and the next year she was transferred to Saint John's Hospital, where she remained 10 years. The terrible slaughter at the battle of Pittsburgh Landing appealed so strongly to her sympathies that with two companions she accompanied the noted surgeon, George C. Blackman, to Nashville to minister to the wounded there winning her title of "The Angel of the Battlefield." She returned to Cincinnati on a hospital steamer with many wounded soldiers whom she cared for at Saint John's Hospital. In 1866 two prominent Protestant business men of Cincinnati purchased the United States Marine Hospital and transferred it to the Sisters of Charity in the hands of Sister Anthony. The name was then changed to "The Good Samaritan," and she remained in charge till 1882. Not only was she in charge of various institutions of her order, but was several times procuratrix of the community. She is buried at the mother house of Mount Saint Joseph and her grave is annually strewn with flowers on Memorial Day by the soldiers of the Grand Army of the Republic.

ANTHONY, Susan Brownell, American reformer: b. South Adams, Mass., 15 Feb. 1820; d. Rochester, N. Y., 13 March 1906. She taught school in New York in 1835-50, in 1852 assisted in organizing the Woman's New York State Temperance Society, and in 1854-55 held conventions in each county in New York, in behalf of female suffrage. In 1857 she became a leader in the anti-slavery movement, and in 1858 advocated the coeducation of the sexes. She was influential in securing the passage by the New York legislature, in 1860, of the act giving married women the possession of their earnings and guardianship of their children. In 1868, with Mrs. E. C.

Stanton and Parker Pillsbury, she began the publication of the *Revolutionist*, a paper devoted to the emancipation of woman. In 1872 she cast ballots at the State and Congressional election in Rochester, N. Y., to test the application of the 14th and 15th Amendments of the United States Constitution. She was indicted for illegal voting and fined, but the fine was never exacted. Her last public appearance of note was as a delegate to the International Council of Women, in London, England, in 1899. In 1900 her birthday was celebrated by an affecting popular demonstration in Washington, D. C., and she retired from the presidency of the National American Woman Suffrage Association, which she had held for many years. Consult 'Life and Work of Susan B. Anthony' (1898).

ANTHONY, William Arnold, an American physicist: b. Coventry, R. I., 17 Nov. 1835; d. 29 May 1908. He was graduated from Yale Scientific School 1860 and taught science in various secondary schools 1860-67. He held chairs of physics and chemistry in Antioch College and Iowa Agricultural College 1869-72, was professor of physics at Cornell 1872-87, and consulting electrician, Manchester, Conn., 1887-93. From 1893 till his death he was professor of physics in Cooper Union School of Science. He contributed many papers to the volumes of the scientific societies of which he was a member.

ANTHONY, Kan., city and county-seat of Harper County, 55 miles southwest of Wichita, on the Atchison, Topeka and Santa Fe, the Chicago, Rock Island and Pacific, the Missouri Pacific and other railroads. It contains a flour mill, an ice plant, a salt plant, and has extensive stock raising and agricultural interests. The principal buildings are the Carnegie library, opera house, two hospitals and seven churches. The city is under the commission form of government, and owns the electric and water systems. Pop. 2,669.

ANTHOSIDERITE, *än-thō-sid'er-it* (from the Greek *anthos*, "a flower," and *siderites*, "iron"), a mineral related to chloropal, occurring in fibrous tufts and sometimes in feathery forms resembling flowers. It is harder and heavier than chloropal, is usually yellowish in color, and has the composition $2\text{Fe}_2\text{O}_3 \cdot 9\text{SiO}_2 \cdot 2\text{H}_2\text{O}$. It is found in Brazil.

ANTHOZOA. See ACTINOZOA.

ANTHRACENE (from *anthrax*, or *anthrac-*, "coal"), a hydrocarbon having the chemical formula $\text{C}_{14}\text{H}_{10}$, and the molecular structure

It is obtained by the distillation of coal-tar, occurring in that portion of the distillate which passes over at temperatures above 500° F. The "anthracene oil," as this part of the crude dis-

tillate is called, is allowed to stand in the cold for a week or so, until the greater part of the anthracene has crystallized out. The solidified portion when freed from the mother-liquor by pressure or by a centrifugal separator is ground up and washed with petroleum spirit to remove as much as practicable of the paraffin and other impurities. Anthracene so obtained is then sublimed and placed on the market as "50 per cent anthracene," although it may contain as much as 65 per cent of the pure substance. Its precise strength is best determined by treating a known weight with boiling glacial acetic acid and chromium trioxide, and observing the quantity of anthra-quinone that is formed. The crude anthracene of commerce may be further purified by distillation with caustic potash to which a little caustic lime has been added. Most of the impurities are removed in this way, and the product is further improved by subsequent washing with petroleum spirit, or with carbon disulphide, and finally by recrystallization from a hot mixture of benzene and aniline. Pure anthracene crystallizes in white, monoclinic tablets melting at 415° F., and boiling at about 680°. It is insoluble in water and dissolves but slightly in other common solvents. It is soluble, however, in boiling glacial acetic acid, and also in hot benzene. It is used in large quantities for the manufacture of alizarin (q.v.) Anthracene is changed, by the action of sunlight, into an isomeric substance known as paranthracene (or paranthracene), which melts at 472° F., and is reconverted into anthracene by fusion. See also COAL-TAR COLORS.

ANTHRACITE, a variety of coal distinguished from other coals by its high proportion of carbon and small quantity of volatile matter. It has a conchoidal fracture, bright lustre, dense black color and superior hardness. The percentage of carbon is variable, ranging from a minimum of about 80 per cent to a maximum of 95 per cent. Anthracite grades by imperceptible stages into bituminous coal, from which it has been produced by the action of heat or intense pressure. Semi-anthracite and semi-bituminous are intermediate grades. The coal-seams of eastern Pennsylvania are included in a series of strata which have been compressed and thrown into folds, while westward in the bituminous fields of Pennsylvania and Ohio the strata lie nearly horizontal. Beds of bituminous coal are frequently observed to grade into anthracite in the vicinity of igneous intrusions, as at Crested Butte, Colo., and near Sante Fé, N. M. Where the heat has been very intense, however, the volatile matter is entirely driven off and graphite is formed.

Anthracite occurs in extensive deposits in many parts of the world. The most productive deposits are those of eastern Pennsylvania which occur in several detached fields, located as follows: The Northern field, extending through the middle of Luzerne and Lackawanna counties; the Eastern Middle, between the Lehigh River and Catawissa Creek; the Western Middle, between the eastern headwaters of the Little Schuylkill River and the Susquehanna; and the Southern, or Pottsville, field, extending from the Lehigh River at Mauch Chunk southwest to near the Susquehanna River. These fields comprise an area of 472 square miles and are classed under three general divisions, namely, Wyoming, Lehigh and Schuylkill re-

gions. The Bernice field in Sullivan County produces a semi-anthracite coal and is sometimes included with the anthracite fields. The strata with the beds of coal have been upturned and the outcropping edges subjected to long-continued erosion. The most important and persistent seam is the Mammoth, which in the Eastern Middle field has a thickness of from 60 to 90 feet and is over 100 feet thick in parts of the Southern and Western Middle fields. Altogether the workable seams number 15 or more, with a total thickness (increasing from west to east) ranging from 70 to 150 feet. The anthracite fields of Colorado and New Mexico are of much less importance. In foreign countries anthracite is mined in South Wales, Ireland, Belgium, France, Westphalia and Russia, and it is known to occur in very large deposits in the province of Shan-Si, China. In the south Wales field only the northern portion yields anthracite, the rest of the output being semi-bituminous and bituminous coals.

Owing to its cleanliness and freedom from smoke anthracite is especially suited for household fuel; for steaming and metallurgical purposes it is inferior to bituminous coal. It ignites with difficulty and burns slowly with little flame, giving out intense heat. The amount of ash is small, ranging from 15 per cent to 6 or 7 per cent. The color of the ash is sometimes used as a basis of classification in trade, as in Pennsylvania anthracites, which are denominated white-ash and red-ash coals. But the color depends entirely upon the amount of iron present and is no criterion of the value. The following analyses show the relative proportions of fixed carbon, volatile matter, ash, etc., in various anthracites:

Fields	Fixed carbon	Volatile matter	Water	Sulphur	Ash
Eastern Middle, Pa.	86.38	3.08	4.12	1.62	5.92
Southern, Pa.	83.81	4.27	3.09	0.64	8.18
Crested Butte, Colo.	82.33	9.96	0.81	0.81	6.90
South Wales.	92.42	5.97	1.60

The preparation of anthracite for the market consists in freeing it from slate and dust and sorting it into suitable sizes. Owing to the practical absence of volatile matter, anthracite will not burn unless the lumps are of fairly uniform size. When hoisted from the mine it is first passed over a screen which allows most of the fine coal to pass through. The lump coal is then sorted for the purpose of removing the shale and slate, and the pure material is crushed between rolls and screened into the market sizes. In the United States the sizes generally recognized are the following: Broken or grate, which passes through a screen of 4-inch mesh but not through 2.5-inch mesh; egg, 2.5-inch-1.75-inch; stove, 1.75-inch-1.25-inch chestnut, 1.25-inch-0.75-inch; pea, 0.75-inch-0.50-inch; and buckwheat, 0.50-inch-0.25-inch. Larger sizes than the above are known as lump and steamboat, and smaller sizes as rice, mustard-seed, etc. The sizes from broken to chestnut, inclusive, are known as the domestic prepared sizes and constitute at present about 60 per cent of the output. The waste or fine coal which commonly amounts to as much as 10 per cent of the material mined is known as culm. Immense heaps of this fine coal have accumulated at the

mines, but with the improved processes of screening and separation much of it is now saved and sold to manufacturing plants.

The growth of the anthracite mining industry in the United States has been very rapid. There are records showing that Pennsylvania anthracite was used for fuel as early as 1768, but mining was not carried on to any extent until about 1820. The growth of the industry from this time to the close of the century is shown in the following table:

	Short tons		Short tons
1820.....	365	1870.....	15,664,275
1830.....	215,272	1880.....	28,649,812
1840.....	967,108	1890.....	46,468,641
1850.....	4,138,164	1900.....	57,367,915
1860.....	8,115,842	1910.....	84,485,236

The production and value of Pennsylvania anthracite during the period 1911-15 were as follows:

	Production short tons	Value
1911.....	90,464,067	*\$175,500,000
1912.....	84,361,598	178,000,000
1913.....	91,524,922	194,948,000
1914.....	90,821,507	188,000,000
1915.....	88,500,000

Almost the entire output of anthracite is consumed as domestic fuel. A small portion is used for manufacturing purposes in large cities, but it is being gradually superseded for this purpose by the cheaper bituminous coal. See COAL.

ANTHRAC'NOSE, a group of fungous diseases caused by various species of *Glaosporium* and *Colletotrichum*, which appear upon the green parts of plants as roundish spots with more or less sunken light centres and darker margins. They often cause serious damage to cultivated crops, especially grape, strawberry, raspberry, spinach, egg-plant, cotton and cucumber, under which titles they will be more fully discussed. For methods of control see FUNGICIDE.

ANTHRACOTHER'IUM, an extinct pig-like animal, inhabiting Europe and North America during the Oligocene and Miocene epochs. The teeth are intermediate between those of pigs and ruminants, but it is not in the direct line of descent of either, forming a side branch which left no descendants. The name, given by Cuvier in 1822, means "beast of the coal" (*ἀνθραξ*, coal, *θηρίον*, beast), and is derived from the fact that its remains were first discovered in the Tertiary lignite beds of France.

ANTHRAQUINONE, *ān'thra-quin-ōn'* (from *anthra-cene* + *quinone*), a substance derived from anthracene by the action of oxidizing agents, and used in the preparation of alizarin. It may be conveniently prepared on a small scale by dissolving anthracene in glacial acetic acid, adding potassium bichromate and heating to 212° F. The acetic acid is then distilled off, and the anthraquinone precipitated by water. On the large scale sulphuric acid is used in the place of acetic acid. Anthraquinone has the formula C₁₄H₈O₂, and is insoluble

(or nearly so) in water and alcohol, and but slightly soluble in benzene. It dissolves in hot sulphuric acid, separating out again, without change, upon cooling.

ANTHRAX, the name of a disease occurring epidemically among herbivora, chiefly oxen and sheep, and occasionally affecting man. It is also called malignant pustule, splenic fever, wool-sorters' disease, charbon, milzbrand. It is caused by a rod-shaped bacterium, the *Bacillus anthracis*, first seen in 1849 and isolated in 1863, and conclusively proved by Koch in 1876 to be the cause of the disease, this being one of the first diseases demonstrated to be caused by bacteria.

In man the bacillus is usually acquired by handling the hide of an animal having died from the disease. A local lesion, the malignant pustule, is formed, and this may lead to widespread infection with œdema and lymphatic invasion, attended by fever, gastro-enteritis, collapse, and death. The infection may remain localized, however, and the patient may recover. Less often the infection takes place in the respiratory tract, the patient having breathed the bacillus in the dust arising from handling hides or sorting wool; in such cases a rapidly fatal form of hæmorrhagic œdema may develop. A still rarer form of the disease in man affects the intestinal tract. The bacillus of anthrax is one of the largest of the pathogenic bacteria. It

is 6-8 microns $\left\{ \begin{matrix} 6-8 \\ 25,000 \end{matrix} \right\}$ inches long and 1.5

microns thick, being a short rod with square edges, and growing in chains. The protoplasm is finely granulated and it forms spores about the centre of the bacillus. It grows very rapidly on all of the commonly used bacteriological culture media, best at a temperature of 35° C., but its multiplication ceases at temperatures below 12° C. or above 45° C. The bacilli are readily killed by temperatures of 60° C., but the spores are very resistant, and dry heat at 140° C. must be applied for several hours to kill them. In a dry condition they remain viable for several years and will resist boiling water for at least five minutes. The gastric juice also does not destroy them readily. The bacteria are found in the blood and throughout the organs of animals dying of anthrax. They are particularly numerous in the spleen and in the lymphatic structures. They poison the body by the development of a toxin or toxins which in turn cause degeneration of the tissues of the body.

Anthrax is one of the diseases in which a serum therapy was instituted early. Thus far it has not proved of signal service, although a protective serum has been made by which animals may be immunized against the disease.

Anthrax in animals is a comparatively common disease, affecting sheep, cattle and, more rarely, horses and members of the deer family. It is rare among the carnivora. The disease is not geographically confined, and animals in various parts of the world are affected by it. It is naturally less common in countries in which there is some legislative control, and rarer at present than in former times. In Britain the mortality is small; in France, at one time, as many as 10 per cent of the sheep died annually of anthrax. Since the modern method of im-

* Based on average of pieces of all grades and sizes at the mines.

munizing cattle has been introduced the mortality has been much lessened. The symptoms vary widely, but at least three marked groups are observable. In some instances the affected animal develops symptoms of extreme collapse; it drops to the ground; the pulse and respiration are quickened, there is difficulty in breathing and the animal dies in convulsions within a comparatively short time. A commoner type of attack is begun by symptoms of general distress, the animal is "off its feed," the pulse and respiration are quickened, chills develop, the temperature rises to 103 or 104° F., bloody diarrhoea occurs, bloody nasal catarrh. There then may develop convulsive movements; there is rapid loss of strength, and the animal may die in from 10 to 48 hours, sometimes at the end of three to four days. A third type is characterized by a slow onset, the lymphatic structures are involved, they swell and form carbuncles, which may ulcerate. General symptoms of infection may develop—the spleen may enlarge, bloody discharges are common and the animal dies of generalized hæmorrhagic œdema. The diagnosis is readily made in all cases by a microscopical examination of the blood. Different animals show marked variations in susceptibility. The sheep, save Algerian, ox, guinea-pig and mouse, are all very susceptible, but the goat, horse, deer and pig are less often attacked. Man may be placed next in the order of liability; the white rat, adult carnivora, birds and amphibia are immune. The disease is conveyed to animals largely by way of the intestinal canal. The bacilli are ubiquitous in the grass and hay about an infected area.

Preventive Inoculation.—Pasteur first evolved a method of inoculation by an attenuated virus, a sort of hardening the animal, as it were, that subsequently made it resistant to the virile bacteria. Although other methods, notably the use of anti-anthrax serum, have been used, the attenuated virus method seems to give the best results. Surgical methods are the only mode of treatment for man. Thorough sterilization of hair, wool and animal skins by dry heat, steam or by chemical agents is now generally adopted to prevent the infection of man from these sources.

Pasteur's method was the injection of a culture attenuated by 24 days' growth at a temperature of 42.5 C., followed in 10 days by an injection of a culture attenuated by a growth of but 12 days at the same temperature. The Dawson method, invented in 1911, is the injection of a single vaccine, differing from that of Pasteur only in degree of attenuation. It is used when animals are dying from the disease and immediate protection is required. A passive immunity lasting from one to two weeks is thus secured within a few hours.

Special References to Its Suppression' (ib. 1909); Dawson, C. F., 'Anthrax with Special Reference to the Production of Immunity.'

ANTHRENU. See CARPET BEETLE.

ANTHROPOID APES, a term applied to those apes (family *Simiidae*) nearest in their organization to man. See APE.

ANTHROPOLATRY, the worship of man, a term always employed in reproach. It was applied by the Apollinarians to the orthodox Christians of the 4th and 5th centuries, who in their devotion to Christ worshipped, as was declared, only a man in whom God dwelt.

ANTHROPOLOGY. Anthropology is the name for a group of problems arising from inquiries as to man's origin. As used in the United States and England this name stands for the science that deals with these problems, but on the continent of Europe the tendency is to restrict the term anthropology to a study of man's body, particularly his bones. This, like most other facts of this kind, has an historical explanation. Thus, the study of anthropology really begins with Blumenbach (1752–1840) of Göttingen, Germany, who conceived of classifying skulls according to form and measurement. While it is true that this idea was in a way entertained by Vesalius, Linnæus and other pioneers, nevertheless it was Blumenbach who first struck the keynote of classification according to form and dimensions of the human skull. Following him were Retzius who devised the cephalic index, Camper who invented the facial angle, and, finally, the great French anthropologists Broca and Topinard who systematized the subject. It will be noted that so far anthropology dealt almost exclusively with man's anatomy, whereas at present it gives even more attention to his modes of life, or his culture.

While the above interest in man's anatomical attributes was taking form other students began to systematize the available knowledge concerning the habits and customs of different peoples. To this study the name ethnology is often applied. The great leaders of this movement were Tylor (England), Ratzel (Germany) and Reclus (France). The published works of these men dealt exclusively with the social life of man and his distribution over the earth and in so far were distinct from the anthropology of the day. From some points of view these two subjects, ethnology and anthropology, as then defined, had little in common and indeed the tendency in Germany and other continental countries is to so regard them still; but the great synthesizing work of Prichard (1786–1848) in England gave a new unity to the whole study of man. According to this author, man should be classified according to all definitive characters: anatomy, psychology, geographical distribution, and habits. Since man's zoological characters were regarded as the pivotal point in his development, the term anthropology was applied to this new synthetic whole. This thenceforth became the ideal for English students of man—to deal synthetically with all the data available bearing upon the problems of man's origin and early career. In the main, American anthropologists have followed the English in this respect.

3 South European (Dark)
4-5 North European (Light)

We can define anthropology, therefore, as the natural history of man, or the science which begins where history leaves off, and which seeks to recover the story of man's origin and varying fortunes in that dim and shadowy era we call the prehistoric. The limitations that must be imposed upon this general statement will be more apparent when we summarize the content of our subject.

The anthropology of any group of people now deals with three great classes of characters: the somatic, linguistic, and cultural.

Somatic Characters.—One of the great problems under this head is to know man's zoological position among mammals. The classification of existing men is the great prerequisite to such investigations. Though as a mere proposition this seems a small task, it proves to be one of very great difficulty, so difficult that even now there is no generally accepted classification. The trouble arises from the almost hopeless blending and intergrading of all the known types, or the existence of many extremely variable characters. There is, for instance, no one somatic character that will consistently segregate mankind; yet there are some such as hair, color of skin, head form, face form, and bodily proportions that almost rise to that level. Of these the most consistent is the character of the hair, of which three gross types are recognized: straight, wavy, and woolly, each with a distinct cross-section and associated peculiarities. On this basis all living peoples fall into three large groups:

1. Straight hair (*leiotrichi*). The Asian-American group.

2. Wavy hair (*cymotrichi*). The Polynesian-European group.

3. Woolly hair (*ulotrichi*). The Australian-African group.

Though the general reader will find many proposed classifications in anthropological literature, all show a tendency to recognize this three-part grouping. Further, the color of skin, the shape of the head and the profile of the face are found to be in frequent association with type of hair. In consequence we have such tentative groupings as that proposed by Giddings:

"I. *The Australian-African Group.*—Characteristics: black skin, dolichocephalic (long-headed), prognathic, woolly or frizzly-haired (cross-section of hair very elliptical). Area of distribution: Australia and Africa, south of the equator.

"II. *The Polynesian-European Group.*—Characteristics: fair skin, mesocephalic, orthognathic, straight or wavy hair (cross-section slightly elliptical). Area of distribution: broad zone from Polynesia northwestward through southwestern Asia and northern Africa and most of the continent of Europe.

"III. *The Asian-American Group.*—Characteristics: yellow or red skin, brachycephalic (broad-headed), narrow-eyed, lank or straight-haired (cylindrical in cross-section). Area of distribution: eastern Asia and western America, chiefly north of the equator along the semicircular shore-line of Asia and America."

This, however, deals only with living men and does not include extinct forms known by their fossilized fragments. Of these the following have been proposed:

1. *Pithecanthropus Erectus.*—A form found in Java, the zoological position of which is still in doubt.

2. *Homo Heidelbergensis.*—Known from a single lower jaw found at Mauer, near Heidelberg, Germany, in 1907.

3. *Homo Neanderthalensis.*—This is generally designated as Neanderthal man and is now known by skeletons from ten or more localities in western Europe.

A fragmentary skull found in Piltdown, England, has been classified as a new species, but since the validity of such a position has been seriously questioned, we omit it here. Finally, mention may be made of extinct varieties of the existing species of man, such as the Crô-Magnon, Brün, Alpine, etc., known by skeletons only.

This enumeration presents the bare content of this division of anthropology, the details of which must be sought elsewhere. As to man's precise zoological position we are still in doubt, since the final solution of that problem will be found in fossils of man and related forms.

Linguistic Characters.—The most striking human character is the art of speech. No people have yet been found who were without a highly complex language by which they were able to express very fine shades of meaning. The comparative study of these languages is one of the highly specialized groups of problems that fall to the lot of the anthropologist, particularly the languages of the wilder peoples. Notwithstanding the complexity of speech in general and the somewhat forbidding nature of the whole subject, it has proved easier to classify men according to language than according to somatic structure. As a result, we now have a scheme of linguistic classification that embraces almost the whole of mankind. The fundamental problem here is the same as in zoology, viz., ultimately to discover the genetic relationship between all languages. As a preliminary to this, the languages of the world are now classified into families or stocks, with their subdivisions of languages, dialects, etc. All that show certain evidences of having a common origin are grouped under one family name. As the subject now stands we have something more than 200 such families, with a large number of distinct subdivisions. Further study promises to greatly reduce the number of these families, or at least discover genetic relations between many of them. It is the hope of anthropology that some day we may be able to project the historical evolution of this great human character. This will be a great triumph, for the birth and development of language must be intimately related to man's origin and subsequent career.

Cultural Characters.—The term culture is used to designate the total complex of man's habits and thoughts, or that which he acquires from the group into which he is born. In the zoological sense it is not inherited and so not inborn. Strictly applied, the term culture should include language also, but for purely practical reasons the two are separated. Culture is conceived of as composed of traits or elements, but recognized in complexes. Thus, the production of pottery in a tribal group would be regarded as a trait complex of that

group. The term complex is preferred because the analysis of the phenomenon into ultimate trait elements is not only extremely difficult, but in the last analysis subjective. The subject matter of anthropology, therefore, is in part data on trait complexes, considered as group characters. Anthropologically speaking, a group of people is not adequately described until we have enumerated its chief cultural trait complexes along with its somatic and linguistic characters.

One peculiarity of trait complexes is their frequent independent distribution over whole geographical areas instead of being peculiar to a single tribe. This condition necessitates a geographical classification for culture trait complexes as the initial task. From this as the point of departure, the anthropologist approaches the great problems of culture, viz., its origin, evolution and principles of distribution. Here are to be found some of the most illuminating and stimulating studies of our subject; for example, the discussions of trait-complex diffusion from a single world centre in opposition to the view that such complexes were independently invented by many tribal groups. This applies particularly to the question as to whether the cultures the Spanish conquerors found in aboriginal Mexico and Peru were independently developed or derived directly from the Old World by mere diffusion. For these and many other enticing discussions, the reader must consult the special literature.

However, the mere question of culture distribution is not the whole story, for many cultures have arisen and died out, leaving behind traces in the soil from which they can be partially reconstructed. The methods of investigating these extinct cultures constitute what is known as archaeology. In fact the fundamental problem in culture as a whole is to work step by step from the existing cultures to the earliest beginnings. The most complete data of this kind are from western Europe, where we find several great culture epochs with many subdivisions, as indicated in the accompanying tabulation:

1. Paleolithic Age (100,000-12,000?).
 - a. Pre-Chellean.
 - b. Chellean.
 - c. Acheulean.
 - d. Mousterian.
 - e. Aurignacian.
 - f. Solutrean.
 - g. Magdalenian.
 - h. Azylian.
2. Neolithic Age (?-2000 B.C.).
 - a. Campignian Culture (?-7,000 B.C.).
 - b. Swiss Lake Dweller Culture (7,000-3,000 B.C.).
 - c. Late Neolithic and Copper Culture (3,000-2,000 B.C.).
3. Bronze Age (2000-1000 B.C.).
4. Early Iron Age, or Hallstatt Culture (1000-500 B.C.).
5. Later Iron Age, or La Tène Culture (500 B.C.).

These early periods of culture in Europe have been exclusively the discoveries of anthropologists but those investigations that deal with the early fringes to the historic nations such as Greece, Rome, Egypt, Babylonia,

etc., fall rather in the domain of the classical archaeologist. The only other part of the world where extensive research of this kind has been attempted is North and South America, but the cultures of the New World peoples were unknown before the voyages of Columbus. Hence we have here a closely unified problem because anthropologists can only begin with the cultures found and trace them backward by archaeological methods. Somewhat less progress has been made here than in Europe, partly because the area to be covered is ever so much greater and partly because the conditions of investigation present more difficulties. Yet the chronology of the Maya of Yucatan has been established for dates 2,000 years ago; that of the Mexicans falls into three quite distinct periods, etc. Yet as compared with the sequences for Europe these are all recent, for there we can trace man back into the glacial period, while in the New World there is yet no good evidence that man arrived until the close of the ice ages.

All these inquiries into the sequence of early cultures deal with geological and palæontological questions, for if remains of man and his culture are found in association with the bones of extinct animals, we must appeal to the above sciences for aid in determining the age of such a deposit. Thus if we look back over this outline of what anthropology is we note that almost everywhere it brings to bear upon its problems data from other sciences. For this reason it may be considered a synthesizing or co-ordinating science. See ARCHÆOLOGY; ANTHROPOMETRY; CIVILIZATION; ETHNOLOGY; MAN-CHRISTIAN ANTHROPOLOGY; MAN, PREHISTORIC; PREHISTORIC RACES.

Bibliography.—The literature of anthropology is highly specialized, but the following will serve to give a general view of the subject: Boas, Franz, 'The Mind of Primitive Man' (New York 1911); Deniker, J., 'The Races of Man: An Outline of Anthropology and Ethnography' (London 1915); Duckworth, W. L. H., 'Morphology and Anthropology. A Handbook for Students' (Cambridge 1904); Graebner, F., 'Methode der Ethnologie. Mit einem Vorwort des Herausgebers' (Heidelberg 1911); Haddon, Alfred C., 'History of Anthropology' (London 1910); Kean, A. H., 'Ethnology' (Cambridge 1896); Margett, R. R., 'Anthropology' (London 1911); Osborn, Henry Fairfield, 'Men of the Old Stone Age: Their Environment, Life and Art' (New York 1916); Ratzel, Friedrich, 'The History of Mankind' (London and New York 1896-98); Tylor, Edward B., 'Primitive Culture. Researches into the Development of Mythology, Philosophy, Religion, Language, Art and Culture' (New York 1889).

Curator of Anthropology, American Museum of Natural History.

ANTHROPOLOGY IN AMERICA.

Since the whole habitable world has long been occupied by man we may expect an anthropology for each grand division of land. Thus, Europe, Asia and Africa being after all one land mass, their peoples have established varying contacts so that the study of any single group can rarely be pursued without some con-

sideration of the whole. On the other hand, Australia and the Americas have no actual land connections with the Old World land mass and consequently the specific anthropological problems of these two areas have little direct bearing upon each other or upon those of Europe, Asia and Africa. Naturally then, when we turn to America, its sharp cultural and racial differentiation from all other parts of the world, together with its great geographical extent and internal anthropological complexity, all combine to make its anthropology a fairly distinct field. Hence, we are justified in treating the anthropology of America as a separate topic.

The history of American anthropology dates back to the first voyage of Columbus, that most famous of all explorers, who found not only a new land, but a new people. The term Indian first given the few known representatives of this people can be consistently applied to all from north to south for an unmistakable somatic unity exists throughout. Since no traces of a totally different people have come to light in either North or South America our subject is strictly the anthropology of the American Indian.

The lead in this study has been taken by the anthropologists of the United States. Among those who have contributed most to the scientific development of American anthropology are Maj. J. W. Powell, D. G. Brinton, Frederic Ward Putnam and Franz Boas. Under the guidance of such men scientific methods were devised and the subject placed on a level with other university studies. However, the greatest impetus came not from the universities of the United States, but from museums and research institutions. Perhaps the most important event in the history of American anthropology was the establishment in 1879 of the Bureau of American Ethnology at Washington, D. C., as a part of the Smithsonian Institution. This institution was from the first effective in research and still serves as an inspiration to all who are engaged in anthropological pursuits. The next great event was the anthropological exhibit at the World's Columbian Exposition at Chicago in 1893, organized by Frederic Ward Putnam. As a result of the great anthropological awakening following this exposition and Putnam's enthusiasm the Field Museum of Natural History was established in Chicago in 1894; the anthropological section of the American Museum of Natural History in New York reorganized; and the University of California museum established in 1901. All of these institutions now maintain a large number of highly trained research men who give their whole attention to anthropological investigations in North and South America.

One of the most signal achievements in American research was the complete linguistic classification of North American tribes under the leadership of Major Powell. This still remains the only true scientific classification of the aboriginal population and it is not far wrong to say that its attainment marks the beginning of American anthropology as a recognized science. Practically all of the native languages spoken in the United States and Canada have been recorded and in many cases texts in the original have been printed. At

present the chief interest of anthropologists is in seeking out relationships between what have so far been considered independent languages. Already some progress has been made in this direction and we may expect in the near future a satisfactory reconstruction of the linguistic history of the tribes inhabiting North America. For South America there has been less progress, but a provisional classification has been made that embraces all the known tribes.

Perhaps the next most distinctive work is that of Lewis H. Morgan and his follower, Adolph Bandelier. Morgan's work stands out as one of the world's great contributions to anthropology and sociology. His theories of marriage and the origin of society broke new ground, but they were all based upon concrete studies among living Indian tribes. Bandelier, inspired by Morgan's genius, made a critical examination of Spanish historical sources of data upon the organization of native society in Mexico City, for the first time making it evident that American native culture from the highest to the lowest had a common basis and in all probability a single origin. However, Bandelier's greatest work was among the ruin-strewn mesas and deserts of southwestern United States, where he skillfully combined documentary data and native tradition with the objective study of the ruins themselves. Though essentially pioneer work, these studies of Bandelier will ever remain the great synthetic classics in American anthropology.

The next great concern of American anthropologists has been the relative antiquity of man's first appearance in America and the establishment of a chronology for his subsequent career. The most important advance in this direction was the deciphering of prehistoric inscriptions found upon the famous ruined cities of the Maya in Yucatan and their co-ordination with our own calendar, according to which we are able to establish dates as early as 200 B.C. Yet in the development of chronologies based upon archaeological stratification, little progress has been made in sharp contrast to what has been achieved in western Europe. However, there is now a newly-awakened interest in chronological research and new developments may be expected at any moment. See **ARCHAEOLOGY; INDIANS; MOUND BUILDERS.**

CLARK WISSLER,
Curator of Anthropology, American Museum
of Natural History.

ANTHROPOMETRY (Greek *ἄνθρωπος*, man, and *μέτρον*, measure), a term denoting both the system of identification based upon measurements of certain portions of the human frame and also—especially at the present time—the science having for its object the systematic examination and study by means of classification, of the height, weight, strength and other physical characteristics of individuals representing the different races of mankind. With the former (the system of identification, and particularly the identification of criminals) the name of the distinguished French investigator, Alphonse Bertillon (see **BERTILLON** and **BERTILLON SYSTEM**) is indissolubly united. The tendency has become strongly marked in recent years to adopt the system of identification by finger prints in lieu of such measurements of the head, of the forearm, etc., as are more difficult to secure with the requisite degree of accuracy, in outlying districts and in fact wherever erroneous measurements might be recorded as a result of insufficient skill in the use of the Bertillon instruments (see **FINGER PRINTS**). Investigations purely scientific in character and covering a wide range of subjects are now classed as anthropometrical. For example, the studies of such modifications as changes of environment produce in the bodily form of human beings, or again the statistics of physical development during courses of training under competent instructors, may be appropriately classified in this manner. As for the comparative studies in this field, and the conclusions reached in the new science that may be called quite properly comparative anthropometry, their interest is merely suggested by the following list, which shows the average height of the adult males of the principal races or nationalities of the world: Polynesians, 69.33 inches; Patagonians, 69 inches; Negroes of the Kongo, 69 inches; Scotch 68.71 inches; Iroquois Indians, 68.28 inches; Irish, 67.90 inches; United States (whites), 67.67 inches; English, 67.68 inches; Norwegians, 67.66 inches; Zulus, 67.19 inches; Welsh, 66.66 inches; Danes, 66.65 inches; Dutch, 66.62 inches; American negroes, 66.62 inches; Hungarians, 66.58 inches; Germans, 66.54 inches; Swiss, 66.43 inches; Belgians, 66.38 inches; French, 66.23 inches; Berbers, 66.10 inches; Arabs, 66.08 inches; Russians, 66.04 inches; Italians, 66 inches; Spaniards, 65.66 inches; Eskimos, 65.10 inches; Papuans, 64.78 inches; Hindus, 64.76 inches; Chinese, 64.17 inches; Poles, 63.87 inches; Finns, 63.60 inches; Japanese, 63.11 inches; Peruvians, 63 inches; Malays, 62.34 inches; Lapps, 59.2 inches; Bosjesmans, 52.78 inches. The average stature of man is thus about 65.25 inches.

B., 'Mental and Physical Measurements of Working Children' (Princeton and Lancaster 1914).

ANTHROPOMORPHISM, a term expressing the representation or conception of Deity under a human form, or with human attributes and affections. Such a conception springs from the natural inaptitude of the human mind for conceiving spiritual things except through sensuous images, and in its consequent tendency to accept such expressions as those of Scripture when it speaks of the eye, the ear, and the hand of God, of His seeing and hearing, of His remembering and forgetting, of His making man in His own image, etc., in a too literal sense. The term is also applied to that doctrine which attributes to animals mental faculties of the same nature as those of man, though much lower in degree: strictly called biological anthropomorphism, to distinguish it from anthropomorphism proper, or theological anthropomorphism.

ANTHROPOPHAGI, the name given to individuals or tribes by whom human flesh is eaten: man-eaters, cannibals. The Caribs are said to have been cannibals at the time of the Spanish conquest of America, and the word "cannibal" is derived from their name.

ANTI, or **CAMPA**, a warlike tribe of southern Peru on the eastern slope of the Andes. Their principal garment is a poncho belted at the waist. The men are workers in metal to a considerable extent, and the women are skillful weavers. They cultivate the ground, wild animals, tamed, serving as beasts of burden.

ANTI-AIRCRAFT GUNS. As a solution of the problem presented by the conditions of firing at great heights and at large angles in order to reach airplanes or balloons, the Krupp firm has brought out three general types of cannon, each of which is adapted for a special use. In the first place, there is the more simple type of cannon with field mounting, while a second type is constructed with a view of being placed upon a motor car. For use on shipboard a third type is designed intended to be rapidly rotated in all directions by the use of a central pivot base such as is usually installed on warships for coast-defense use. On the other hand, the field gun has its wheels arranged so as to turn upon pivots, which allows of placing the wheels in crosswise direction. In order to give effective results it is found that the angle of elevation must be at least 70 degrees, and the field gun is designed to reach this angle. The automobile and ship cannon will, however, make a greater angle, the maximum being for these two types as high as 75 degrees. In all these cases

a rapid rate of firing is given by an automatic opening and closing of the breech. The calibre has been reduced as much as possible, as also the weight of the projectile, while the long bore gives a high initial speed to the shot and diminishes the time required to attain the mark. Owing to the lessening of the calibre, greater lightness is obtained, and this is of service especially in the field and the automobile types of gun.

Sighting is carried out in the most efficient manner by the use of an appropriate form of sighting telescope in combination with a general finder which covers a wider range of field. There is also a range-finder by which the distance is first obtained, and afterward the indications are directly given so as to be able to point the gun for different heights of the air-

Anti-Aircraft Gun

ship without loss of time, and thus the use of firing tables is dispensed with in all these cases.

The question of the kind of shot which is best adapted for firing upon balloons or airships is of prime importance; and this matter has been made the object of a number of experiments. It is recognized that shrapnel will penetrate the balloon envelope, but without doing much damage, at least of an immediate nature, seeing that the holes are closed again for the most part by the internal pressure of the gas, so that the loss of gas is not a rapid one and the airship is able to reach a place of safety in the majority of cases. It is found that the most effective form of projectile is a special kind of grenade, which is designed to explode in the interior of the balloon and to bring about ignition of the gas. The projectile designed by

the Krupp firm is intended to accomplish this, and at the same time the path of the projectile from the time it leaves the gun can be followed by the use of a special smoke produced carried on the shot. By observing the trail of smoke the gunner learns whether the shot comes near the mark. When the projectile leaves the gun, the smoke producer has been set working by an appropriate device. At night the path of the shot is still followed by the light which the smoke producer gives out. When it penetrates the envelope, a very sensitive device causes the detonation of the grenade.

In the case of the field cannon, which has a 6.5 centimetre bore (2.6 inches), the weight of the gun itself is 775 pounds and that of the chassis 1,150 pounds, making a total of 1,925 pounds for the cannon when prepared for actual service. The gun can be turned about through a complete circle, and has a maximum vertical angle of 70 degrees. The weight of the projectile for this type is nine pounds. The initial speed of the shot is 2,050 feet per second. With the field gun it is possible to cover a maximum range of 28,550 feet, and a maximum height of 18,800 feet.

Of a heavier build than the former, and also of greater range, is the second type of gun of 7.5 centimetre (three-inch) calibre, which is designed to be mounted upon a heavy motor car. Like the former, it is provided with hydraulic recoil brake, and in the present case there is used a middle pivot. For elevating and lowering the gun through the required range there is used a double-toothed sector which is driven by pinion and crank. A special arrangement is used for the rotation, by which a slow movement is obtained, but a quick rotation may also be given by the more rapid mechanism when it is needed to turn the gun rapidly into any desired position. It is to be noted that, owing to the high speed at which airships move, such quick movements are one of the features which need to be especially designed in the case of guns for balloon firing. The weight of the gun itself, 990 pounds, combined with the weight of the support, 1,550 pounds, gives a total weight of 2,540 pounds for this type of gun. We have here the maximum angle which is reached in the Krupp cannon, or 75 degrees. The weight of the projectile is 12 pounds, and the initial speed 2,060 feet per second. The maximum range is about 30,000 feet, and the greatest height about 20,000 feet. As regards the automobile car which is designed to take the present cannon, its total weight (exclusive of the gun) is three and a half tons, and it has an average speed of 30 miles an hour.

Owing to the fact that both axles are driving axles, with the use of the 50-horsepower motor the automobile car is able to travel over very difficult ground, and it easily mounts very steep grades. Under the front seat is a roomy chest which holds a good supply of tools and extra fittings, and special attention has been given to this point so that the car will not easily become disabled.

The Ehrhardt gun factory of Düsseldorf has also built various anti-aircraft guns, mounted on motor trucks, whose calibres vary from 50 to 105 millimetres. The most remarkable of these is the 35-calibre 65-millimetre design which fires a 4.1 kg. projectile to a maxi-

mum height of 5,800 metres with an arc of elevation of 75 degrees and a muzzle velocity of 670 metres per second. This gun can fire three varieties of projectiles: (1) Ordinary shrapnel containing 150 steel balls of 9 grams each; (2) a smoke shrapnel of 170 steel balls of the same weight; and (3) a "balloon grenade," which is especially adapted for use against airships. This gun is mounted on an armored motor car and weighs complete 6,650 kg. The Skoda Gun Works of Pilsen, Austria, also supply an anti-aircraft gun which has a bore of one and a half inches and is 70 calibres long. This gun has a muzzle velocity of 1,000 metres per second and fires a projectile weighing 0.8 kg. at an elevation up to 80 degrees. It weighs complete 615 kg. and can be mounted on any suitable high-power motor car.

ANTI-CATHOLIC RIOTS. See **ORANGEMEN.**

ANTIARIN, the poisonous principle found in the milky juice of the upas tree (*Antiaris toxicaria*) in Java. It has the probable formula $C_{16}H_{20}O_8 + 2H_2O$. The gum prepared from the upas juice is used by the natives of Java for poisoning arrows. Antiarin, when taken into the stomach or introduced into the circulation through a wound, causes great prostration and, in sufficient quantity, paralysis of the heart.

ANTIBES, ân-tèb, a fortified town and seaport of France, on the Mediterranean, 11 miles south-southwest of Nice; founded about 340 B.C. by a colony of Greeks, who named it Antipolis. It has a naval school and exports olives, anchovies, perfumery, etc. Pop. town, about 6,000; commune, 11,000.

ANTIBODY. See **IMMUNITY.**

ANTICHLOR, ân'ti-klôr (from *chlorine* and *anti*). In bleaching, any substance used to eliminate, by chemical means, the last traces of chlorine from a material that has been bleached by the action of a chlorine compound. The free chlorine can be largely removed by mere washing, but it cannot be entirely eliminated in this manner, and the residuum, if not removed by chemical means, is injurious to the material and causes it to disintegrate slowly. Sulphur dioxide was long used as an antichlor, its action being indicated by the following formula: $SO_2 + 2H_2O + 2Cl = H_2SO_4 + 2HCl$; that is, it combines with the chlorine to form sulphuric and hydrochloric acids. Sulphite of soda, Na_2SO_3 , is equally effective, its action being as follows: $Na_2SO_3 + H_2O + 2Cl = Na_2SO_4 + 2HCl$. Sodium thiosulphate (better known in the arts as hyposulphite of soda, or "hyppo") is now more commonly used as an antichlor, since it is both cheaper and more efficacious. Its formula is $Na_2S_2O_4$, and its action is as follows: $Na_2S_2O_4 + 5H_2O + 8Cl = Na_2SO_4 + 8HCl + SO_4$. (Sodium thiosulphate, water, and chlorine yield sodium sulphate, hydrochloric acid, and sulphuric acid). In practice carbonate of soda is often added to the antichlor to neutralize the acids formed by the absorption of the chlorine. The resulting salts of soda are easily washed out of the material treated; and no damage results even if they are not entirely removed.

ANTICHRIST, a term of Biblical origin, but occurring only in the Epistles of John,

where it signifies a person or persons who deny the Father and the Son and disown the incarnation and messiahship of Jesus. They are deceivers whose presence in the world betokens the last time. This writer seems to have in mind numerous false human teachers, originally members of, but always alien to the followers of Christ. He seems also to refer to some single arch-deceiver of whom all false teachers are exponents, and in whom is concentrated all antagonism of error and ill will to Christ and His kingdom of truth and grace. There are, however, other Biblical passages in which such antagonisms find acute and culminating expression, and it has been the custom of students to handle all these sections under the study of the Antichrist. Such passages are Matt. xxiv, with its allusions to false prophets and false Christs; 2 Thess. ii, with its "man of sin"; Rev. xi, xii, and xiii, with its dragon and beast; and Daniel vii and viii, with its figures of the terrible beast and the he-goat. In all these passages a central feature is the mighty opponent and assailant of the people and purposes of God. Clustered about this central personified or personal antagonist of all worshipers of the true God numerous significant features continually recur. Such are names, times, places, forms. These features, variant in themselves when differently combined by would-be interpreters, yield perplexingly manifold and divergent schemes, as the history of the theme abundantly displays.

The history of interpretation shows four names to have special eminence alongside the name Antichrist, thus: Dragon, Satan, Demon, Belial. The efforts to identify him cluster around typical views. Some deem him to be a form of Jewish antagonism to the Christian faith. Here he is traced to Capernaum, Chorazin, Bethsaida or to Jerusalem. Frequently he is described as hostile to the Jews, being the counterfeit and foe of the Jewish Messiah. Very many identify him in some way with Rome, naming pre-eminently Nero, or a *Nero redivivus*, or Titus, or Caligula. Quite commonly in the Middle Ages he was seen in Mohammed or in the Turks. Still later some Catholics identified him with Luther, while the Reformers identified him with the Pope. Many emphasized in the Antichrist, whatever his form, the energy or wisdom or very being of Satan or the Dragon. Many writers refer all the Biblical allusions to events current at the time of writing. Many others deem the reference to events still future. Still others hold the Biblical teachings to be pre-eminently predictive, but find their fulfilment partial and manifold throughout all Christian history, until their final consummation will mark the end. As to the place of his appearance or activity mention may be found of the Jewish Temple, Jerusalem, Mount of Olives, heaven itself. Closely connected with these central features are various attendant elements such as Michael, his great antagonist and victor; Gog and Magog and the nations which are his minions; the miracles which he works; the two witnesses, Enoch and Elijah, whom he slays; the sign of the Antichrist and the Son of Man; his world dominion; and his final doom. It is manifest that this theme presents a program of thought and activity of most profound significance, however perplexing its

solution. The persistence of its main elements through such a long train of history attests something vital in human life. But its outline is nowhere complete. In recent years the effort to solve its mystery and find its meaning has taken new form and course. Scholars are trying to trace every element of the Antichrist tradition to its historical source. The leaders here are Dieterich, who, in his 'Abraxas' and 'Nekyia,' traces parallelisms in Greek myths; Gunkel, who, in his 'Schöpfung und Chaos,' attempts the same task in old Babylonian mythology; Bousset, who, in his 'Der Antichrist,' explores post-Christian literature of all types for echoes of the tradition; and Friedländer, who, in his 'Der Antichrist in den Vorchristlichen Jüdischen Quellen,' tries to show that every essential trait of the Antichrist is traceable in Jewish circles before the destruction of the temple. The writer last named conceives the Babylonian dragon myth, the Hebrew sons of Belial, the foes of God and his Messiah in Ps. ii, the Zedim of Ps. cxix, the minim of various Jewish writings, the Belial of the Sybilline oracle, the Gnostics, the great antagonist of Daniel, the man of sin in 2 Thess. ii, the false Christ of Matt. xxiv, the Antichrist of John's Epistles, and the dragon of Rev. xi, to be all and severally various phases in one consistent development of the Antichrist idea. These studies, though but the early stages of a mighty task, disclose a commanding theme. For a history of the exposition of 2 Thess. ii consult Bornemann's 'Commentary' in the Meyer series. For a thorough statement of the Nero speculations consult De Wette's 'Excursus' in his 'Commentary on Revelation xvii'; also Charles, R. H., 'The Ascension of Isaiah' (§ 17).

ANTICLINE. See FOLDS.

ANTICLINORIUM. See FOLDS.

ANTICOSTI, a barren island in the Gulf of Saint Lawrence, 135 miles long and 40 miles at its greatest width. The hills in the interior rise to about 600 feet. The climate is severe; while the surface is an alternation of rocks and swamps. It is visited by fishermen in the summer, but there are few inhabitants save lighthouse keepers and official residents. The island, which is attached to the Canadian province of Quebec, has considerable salmon, trout, cod and herring fisheries and is a resort for seal- and bear-hunting. In 1895 the island was purchased by M. Henri Menier of France, who had much litigation over the rights of some settlers. A decision in his favor was made in 1900. Pop. 250.

ANTICYCLONE, an atmospheric condition characterized by high barometric pressure and outblowing winds—the opposite of cyclone. An anticyclone extends over a wide area and in the temperate zones usually appears in the west and moves eastward with slow velocity. At the centre of the area the winds move downward, thus bringing the cool, dry air of the upper regions into contact with the earth's surface. Anticyclones are generally accompanied by clear, pleasant weather, but when following a storm in winter they may result in cold waves. See METEOROLOGY.

ANTICYRA, ăn-tis'î-ră, the name of three Grecian towns in Thessaly, Phocis and

Locris, famous for the hellebore which grew in their neighborhood. This plant was in high repute as a medicine and was thought to have the effect of clearing the brain and curing stupidity; hence the expression of Horace, '*Naviget Anticyram,*' 'Let him sail to Anticyra.'

ANTIDOTES. See POISONS.

ANTIEMETIC. A remedy employed to relieve nausea and vomiting. The choice of an antiemetic depends very largely on the nature of the cause of the nausea and vomiting. There are local antiemetics, acting solely on the mucous membrane of the pharynx, œsophagus or stomach, and central antiemetics, acting on the nervous system. Among the best local remedies are cracked ice, cold beer, cold carbonated waters, cold champagne, small doses of tincture of iodine, chloroform, belladonna, cocaine, bromides or chloral. The most reliable general antiemetics are ipecac, opium and its alkaloids. See EMETIC.

ANTIÉROSION COATING. This coating for projectiles is used to prevent erosion by eliminating contact between the surface of the projectile and the surface of the bore during travel in the bore. It is not a lubricating but a plastic substance, such as silicate of soda, alone or mixed with powdered clay. Adhesion of the substance is increased by roughening the surface of the projectile, chemically or mechanically. Without such precaution the coating might be stripped off by the rifling.

ANTIETAM, ăn-tē'tăm, **The Battle of,** fought on 17 Sept. 1862, in Maryland; sometimes called the battle of Sharpsburg. It was one of the decisive engagements of the Civil War, as it ended the first Confederate attempt at invasion of the North, though tactically a drawn battle. Lee's army of about 50,000 crossed the Potomac near Leesburg, some 30 miles above Washington, and concentrated around Frederick, about 40 miles from Washington and 20 miles from the Pennsylvania line. When it became known that Lee had crossed into Maryland General McClellan, in command of the Army of the Potomac, pushed forward several corps with the left on the Potomac.

Meanwhile Lee had ordered a movement on Harper's Ferry (q.v.), in his rear at the junction of the Potomac and Shenandoah. It was a valuable defense against invasion through the Valley of Virginia, but once the Confederates were across it became not only worthless but a trap. Nevertheless General Halleck ordered it held; and Lee grasped the chance of capturing its defenders (with the Martinsburg outpost) and opening up his communications at once. This involved dividing his army for days, with a much superior force two or three days' march off, but he gauged his foes justly enough to take the risk. The operation was effected with great skill and success and accurate co-ordination; but it took longer than Lee expected, and a mischance befell which should have undone him. A copy of his order fell into McClellan's hands on the 13th, telling him of the dividing of that army not far off, its object, the position of the separate detachments, and the premium on expedition; but the opportunity was lost to the Federals through Mc-

Clellan's unexplained delay in giving orders for an advance.

Lee, advised by the night of the 13th at Hagerstown that McClellan was advancing on South Mountain, marched back to resist his advance but was defeated and on the night of the 14th fell back to Sharpsburg, a few miles southwest of Boonsboro, as the nearest strong position for his Harper's Ferry detachments to rejoin him, as on the flank and rear of any force menacing Maryland Heights which they occupied, and a very defensible position in itself. Six or seven miles above the Heights the Potomac receives Antietam Creek, flowing through a ravine, with banks rising on the west to a low ridge having wooded patches, ledges, stone and wooden fences, cornfields, etc., as natural bulwarks, and sloping on the western side to the Potomac. Two and a half miles above the confluence a sharp eastern bend of the Potomac brings it within two and one-half miles of the Antietam; and at about the centre of the peninsula thus formed lies Sharpsburg, in a hollow on the western slope. Lee's line, about three miles along the crest, was to rest one flank on an elevation near the Potomac, with the village in the rear centre, and a secure retreat by the Shepherdstown ford of the Potomac in the rear.

The Union troops having forced South Mountain (q.v.) by two sharp battles on the 14th, the main body issued therefrom next morning, marched the eight miles to Antietam Creek and formed in line along the east ridge. By afternoon some 50,000 troops were opposed to about 30,000 under Lee, with Longstreet and D. H. Hill. Late in the afternoon McClellan came up, was received with immense enthusiasm and decided that it was too late to attack that day. On the 16th Jackson and Walker had joined Lee with fully 10,000 more. The chance of splitting the Confederate army being now lost, McClellan waited for his ammunition and supply trains to arrive and ordered no attack save of Hooker's corps on the right late in the afternoon. A list of divisions and commanders now becomes requisite for brevity and intelligibility in describing the battle.

UNION ARMY.

Right Wing.—Joseph Hooker. First Corps: Joseph Hooker; three divisions; commanders, Abner Doubleday, J. B. Ricketts, G. G. Meade.

Centre.—E. V. Sumner. Second Corps: E. V. Sumner; three divisions; commanders, I. B. Richardson, John Sedgwick, W. H. French. Twelfth Corps: J. K. F. Mansfield; two divisions; commanders, A. S. Williams, G. S. Greene.

Left Wing.—A. E. Burnside. Ninth Corps: J. D. Cox; four divisions; commanders, O. B. Willcox, S. D. Sturgis, I. P. Rodman, J. D. Cox (in the battle, E. P. Scammon). But Burnside refused to take personal command of the corps because, while he had previously commanded the right wing with the First and Ninth under him on the day previous, the former (Hooker's) had been taken from him and made an independent command; he feared that acquiescence would lose it to him permanently, and merely transmitted orders through Cox. The corps therefore had a technical commander who would not exercise initiative and a real one who could not.

Reserve.—Fifth Corps: Fitz-John Porter; two divisions; commanders, George Morell, George Sykes. Sixth Corps: William B. Franklin; two divisions; commanders, H. W. Slocum, W. F. Smith. Temporarily attached, D. N. Couch's division from the Fourth Corps. This came from Pleasant Valley during the forenoon and portions were used as reserves. Couch's division did not reach the field until after dark of the 17th.

Cavalry.—Alfred Pleasonton.

CONFEDERATE ARMY.

First Corps.—James Longstreet. Five divisions; commanders, Lafayette McLaws, R. H. Anderson, D. R. Jones, J. G. Walker, J. B. Hood.

Second Corps.—T. J. ("Stonewall") Jackson; four divisions; commanders, I. R. Jones, A. R. Lawton, A. P. Hill, D. H. Hill.

Some crucial points of the battle-ground must be noted. The heart of the fighting was north and east of a Dunkard chapel of red brick, a mile north of Sharpsburg on the west side of the Hagerstown turnpike, with tall woods free from underbrush to the west and north (the "west woods"), and elevated ground with ledges, hollows, etc., to the north (Nicodemus' Hill) and west. Next to and across the road was open ground, with a field of high strong corn opposite the north end of the west woods, and then the "east woods," also interspersed with rocks, with a commanding ridge running south, cut by a sunken road (the "Bloody Lane") running east from the turnpike.

On the morning of the 17th Fitzhugh Lee's cavalry brigade and some artillery formed the extreme Confederate left, holding Nicodemus' Hill; next Jackson, Jones' division, in and in front of the west woods, and the bulk of Ewell's division on Jones' right, in the open ground east of the Hagerstown turnpike; D. H. Hill on the left centre. Longstreet formed the centre and right, and A. P. Hill on the extreme right came up in the afternoon. Hood on the left was relieved by Ewell the night before, and formed a reserve near the Dunkard church. McLaws withdrew from Maryland Heights on the 15th and 16th, crossed and recrossed the Potomac and rejoined Lee early on the morning of the 17th, also taking post on the left.

On the Union side, Hooker having crossed the Antietam, Mansfield also crossed in the night and took position in the rear. Sumner and Burnside remained east of the stream. The Confederates rightly inferred from the Union dispositions that the force of the attack was to be on their left, and strengthened it accordingly; 10 of the best brigades in their army were placed in the west and east woods and south of the cornfield. They had nearly 40,000 men in the battle; the Union troops engaged numbered about 55,000. This superiority was little enough against the immense advantages of the Confederate position; and even so, it was frittered away in a series of disconnected attacks, which left a large part of the Confederate force usable at one time against 15,000 Federal troops at most.

1. Hooker, lying nearly a mile north of the Dunkard church, moved down against Jackson early in the morning; reported strength 14,856; actual, under 10,000. The objective point was

the elevated ground about the church. The march had its right on the turnpike and its left along the west edge of the east woods, from which a withering fire checked it a little; the right was raked by a flanking fire from the west woods. At length the line gained the southern edge of the cornfield and engaged the Confederates in the open ground about 220 yards distant. Under the storm of bullets, shot and shell that rained upon them, they broke and fled through the corn, to reform in a hollow beyond; the Confederates assailed the Union lines in turn, and in turn were riddled by a concentrated fire that drove them back. Again the Union troops advanced, to be forced back in disorder; and again the Confederates followed, to break and fly. This was one of the most frightful carnages of the Civil War: Jackson's famous "Stonewall" division was nearly annihilated, more than half of two brigades killed or wounded and more than a third of another, and all the regimental commanders but two. On the Union side 1,051 in Ricketts' division were cut down, a third of its whole number, and two brigades lost over 40 per cent: Hooker was wounded and was succeeded by Meade. Hood and D. H. Hill now came up to replace Jackson's losses; and Hooker's remnants slowly withdrew northward just as the advance of the Twelfth came up, though Ricketts still held the edge of the east wood.

2. Mansfield was mortally wounded while deploying his troops about 7 A.M., and A. S. Williams took command: reported strength, 10,126; actual, about 7,000. Marching more obliquely to the road, facing southwest, they cleared the cornfield, and about 8.40 A.M. drove the Confederates across the turnpike and into the west woods.

3. The Second corps, under Sumner, had not received orders to march till 7.20, after the First was crippled and the Twelfth in the thick of action; and Richardson's waiting for Morell's division of the Fifth corps to occupy the ground he vacated caused him to be an hour later still. Sedgwick's division, with Sumner at the head, went first, French following; each with perhaps 5,000 men; they crossed the Antietam, moving west by north, till the centre was nearly opposite the Dunkard church; then deploying, faced west, French forming on Greene's left. Sedgwick passed through the east woods and the cornfield; advanced swiftly in three lines, no regiments in column or ready to face to either flank if attacked, swept by Greene's right and pressed through the west woods with left on the church, to the western edge and a wood road along it. Meantime McLaws and Walker with six brigades had come up, one brigade had been drawn from the right to reinforce Early's forces of Ewell's division; and all fell upon Sedgwick's left flank and rear. Nearly 2,000 Union soldiers were struck down at a blow without a chance to retaliate; this division lost 2,255 men in all, more than 40 per cent of its entire number, including Sedgwick severely wounded. Sumner tried to change front, but the lines broke and scattered northward, sweeping away everything in their rush, and only reformed on the north hill where Meade and the First corps had taken refuge. A brigade of the Twelfth came up to help, but lost a third of its number, one regiment losing 60 per cent. The right of the Confederate at-

tacking line crossed the turnpike at the Dunkard church and made two assaults upon Greene's position east of the church, and were repulsed with great slaughter, and Greene, making a counter charge, entered the woods beyond the church. Greene held this position until noon, when the Confederates attacked both his flanks and drove him from the church.

Meantime W. F. Smith of Franklin's corps had come on the field. Hancock (then one of his brigadiers) obtained a regiment from Sumner, took position opposite the woods, drove away the approaching Confederate skirmishers, and silenced their batteries. A second brigade was placed on his left, and with heavy loss advanced to near the church; but on sending for his reserve brigade to support it he found it had been ordered away to support French. The latter moving to the left south of the east woods, over the farm lands, drove back D. H. Hill's skirmishers to his main line in the sunken road, where he engaged him over an hour, when he was joined by Richardson. Here a long and sanguinary conflict ensued: the Confederates turned the "Bloody Lane" into a rough fortress with fence rails, and before carrying it the Union divisions had lost near a third of their total, one regiment losing 60 per cent. They had won the position by perhaps 1 P.M., and shortly afterward French's troops were relieved by a brigade of Smith's division. Richardson withdrew his men to the ridge, and about that time was mortally wounded and succeeded by Hancock. This practically ended the operations on the Federal right, and indeed the battle of Antietam so far as it had any tendency to change the status quo. When Richardson's line had been withdrawn, there was a vigorous contest of artillery. Meagher's brigade took the centre, and somewhat less than two regiments came from French to aid Richardson's division. Despite the application for artillery for the division, none had been obtained. The length of the Union line made it impossible that more than one line of troops be formed; and so far advanced was this line that a part of it was continually swept by the fire of the batteries on the Confederate left, these batteries being protected by the west woods. An attack on the Union left was successfully repulsed by Hexamer's battery (obtained from Franklin) and Battery I, First artillery.

4. Between 4 and 5 P.M. a regiment of Franklin's corps was ordered to drive away some skirmishers of Hill's division south of the Bloody Lane and succeeded at the cost of half its force.

5. The battle which Franklin was not allowed to fight must be mentioned. It has been noted that Smith's action was paralyzed by taking away a third of his force for service elsewhere. About noon Slocum, with the other division, reached the field, and two brigades were at once formed in line to carry the woods around the church; but again the reserve brigade was ordered off. Franklin urged with all his strength to have a grand assault made with his whole corps on Lee's centre, crippled and worn out with half a day's fighting and slaughter. With relatively fresh troops and French and Richardson to aid, it is most probable that few Confederates would have crossed into Shepherdstown. But Sumner refused to permit the movement; still, Franklin was so

urgent that he referred the decision to McClellan, but with so strong a veto that McClellan deferred to him and sanctioned the refusal. Both credited Lee with double or treble his actual numbers, and considered the terrible resistance, not as a proof that it could not be continued, but that any force which assailed him went to destruction. This refusal forms another of the might-have-beens of the battle, with some peculiarly poignant personal tragedy involved.

6. The action of the left under Burnside is an even more acute personal question. His peculiar position has already been noted. About 7 A.M. he received an order to hold himself in readiness to carry by assault a stone ridge across the Antietam about a mile southeast of Sharpsburg. About 10, when the First and Twelfth corps and Sedgwick's division were out of the fight, he received another order to carry the bridge and the heights beyond and advance on the rear of Sharpsburg. He turned it over to Cox, who ordered a brigade to storm the bridge, Rodman to cross by a ford one-third of a mile below, and the two to carry the heights and unite there. At best this could not be done in a moment, and the movement seems a covering rather than an aggressive one. But Crook missed the bridge and could not get back to it under fire: Rodman missed the ford and was two hours or so crossing under fire; a fresh storming party finally carried the bridge, Crook crossed some companies above and others at the bridge, and Rodman and the rest united about 1 P.M., when the battle on the right was virtually over. Meantime Sturgis' division had run out of ammunition and was reported unfit for duty; it was replaced by Willcox's (Burnside assisted in this), and at 3 P.M. the corps was again ready to move, though much damaged by the constant Confederate artillery fire. The right wing broke Jones' division and gained the suburbs of Sharpsburg; but the left was strongly checked, and the two wings grew widely separated. Meantime A. P. Hill came upon the field, having marched 17 miles in seven hours. He took Rodman's division in its undefended flank (the second misadventure of the sort that day), and Rodman was killed, while a concentric fire mowed down his men. The losses of the corps were 2,349; a fearful total, almost exactly those of Sedgwick's division. A panic was averted by Scammon, who changed front and checked Hill for a little; Cox called up Sturgis and made head for a while: but at length the corps was obliged to withdraw to the cover of the hills that border the Antietam.

The Union losses were 12,410: 2,108 killed, 9,549 wounded, and 753 missing. More men were killed on this one day than on any other of the Civil War. The Confederate losses were never known with exactness; but as 2,700 of their dead were counted and buried by the Union forces, and many had previously been buried by their comrades, the total cannot have been less than the Federal. The next day Lee retreated across the Potomac unopposed: the failure to pursue him was one of the grievances against McClellan later, but most of his generals concurred with him. Although Lee had escaped destruction, he had none the less failed in his campaign.

Bibliography.—The Count of Paris' 'History of the Civil War' (Vol. II, 1876), is from the standpoint of a strong admirer of McClellan, whose staff he was on; F. W. Palfrey's 'The Antietam and Fredericksburg' (1882), from a lieutenant-colonel of Sedgwick's division, is sharply critical of nearly all the Union generals; John C. Ropes' 'Story of the Civil War' (Vol. I, 1894), is from a noted military critic; Michie's 'General McClellan' (1901), is from a distinguished engineer officer and professor at West Point; the account in 'Battles and Leaders of the Civil War' (New York 1884-88), is by Gen. J. D. Cox. Consult also 'McClellan's Own Story' (1866), and Hays, H. A., 'Antietam and Its Bridges' (1910).

FORREST MORGAN,

Connecticut Historical Society.

ANTIFEBRIN, a trade name for the substance known to chemists as acetanilide (q.v.).

ANTI-FEDERALISTS, the first political party in the United States after the separation from Great Britain. The loyalists having been expelled, there was no issue to divide upon till the question of replacing the loose Confederation with a stronger bond came up. The representatives of commerce and capital, and the mass of the educated classes, favored ratifying the Constitution; those who feared that a strong government meant a disguised new kingship, the local leaders who wished to retain pre-eminence, and the conservatives who thought no evils comparable to those of change, opposed it. The names were in direct opposition to the facts, the Federalists striving to turn the federation into a unified nation, the Anti-Federalists endeavoring to preserve a loose disintegrated federation. The victory of the superior classes was overwhelming, one great cause being that the men who were later the leaders of the Anti-Federal opposition were Federalists (q.v.) for the time being, as they felt that the existing condition of affairs was intolerable. In the organization of the first Congress and executive under the Constitution, the Federalists proper held every post but three, and even those were not technically "anti" till later. In this Congress, though there was much individual opposition to the Federalist measures, it was unorganized, and the Anti-Federal spirit could hardly be said to animate a body. Hamilton's scheme for clearing up the public debt was the first point of division. The payment of foreign debts was carried unanimously; that for paying the Continental debt at par was opposed by Madison and others except as to original holders; that for assuming the State debts was bitterly fought as defaming the States' solvency and as buying the support of capital for the Federal government, was carried by only five votes, reconsidered and beaten by the seven votes of the new North Carolina just admitted, again reconsidered and carried by Jefferson's log-roll of establishing the new capital on the Potomac. His national-bank scheme (1791, opposed by Madison in the House and Jefferson and Randolph in the Cabinet) and his tariff and excise schemes also excited a growing hostility from this element, which by the time of the 2d Congress (1 Oct. 1791) was becoming a new strict-construction party; no longer opposed to the Constitution as such, but opposed to extending its powers

beyond the most literal interpretation of its terms. Jefferson, Madison, and Randolph were now the chiefs of the new party in public office; but Jefferson disclaimed being an Anti-Federalist, based his policy on love of "republicanism," as sympathizing with the French Revolution, and called the Hamiltonians "monarchists." The Republicans and Anti-Federalists comprised the same elements, however, and were based on the same natural division, and Washington's proclamation of neutrality in the European conflict in 1793 fused them into one as the Republicans, later into the Democratic-Republican party.

ANTIFRICTION METALS, a group of alloys used in the manufacture of machine bearings to minimize friction. The theoretically ideal bearing would be composed of the hardest metal available. Practically, in spite of the highest skill in forming both the journal and its bearing, there are minute inequalities which have the effect of reducing the area of actual contact to a few isolated patches, resulting in the heating and eventual destruction of the shaft. To obviate this difficulty the bearing metals have been developed by so alloying their components that a very large series of plastic metals has been produced with the two essential properties of being soft enough to adapt their form to the journal for which they are intended, and hard enough to hold their form against the pressure upon them.

Two general classes of these antifriction alloys are in common use: the first consisting of a soft matrix in which are embedded small particles of a hard alloy which has crystallized in the cooling of the molten mixture (see ALLOYS); the second, in which the hard constituent of the alloy forms a sort of network, in the meshes of which is contained the soft metal which reduces the friction. Four metals are in use as components of the antifriction or bearing metals, tin, lead, antimony and copper. Some special formulas call for zinc in addition, but it is generally argued that no benefit can be thus secured which cannot be better obtained by increasing the percentage of antimony in the mixture.

By far the larger number of the antifriction metals have a basis of tin as the soft matrix, the hard constituent being particles of tin-antimony and tin-copper alloys distributed throughout the matrix. Tin has the advantage of taking a high polish and this in itself serves to reduce friction. A cheaper class of these metals has a matrix of lead, or tin-lead, with tin-antimony as the hard constituent. Both of these are known as white-metal alloys. The class of bearing metals having a hard matrix with soft metal filling is known as plastic bronzes. They consist of a tin-copper alloy with sometimes a little zinc and occasionally nickel added, and may contain up to 30 per cent of lead. They are not as plastic as the white metals, but are more durable and better adapted for heavy pressures.

The original antifriction metal was invented by Isaac Babbitt in 1839, and was composed of tin 24 parts; antimony 8 parts; and copper 4 parts. A softer variety had 2 parts of antimony and 2 parts of copper to 24 parts of tin. The market was at once flooded with other combinations, good and bad, and all went under the title of Babbitt metal, and the name

still remains in some markets, although the original Babbitt metal was long ago supplanted by more scientifically combined alloys.

For light-work bearings the formulas vary from 73 parts tin, 9 parts copper, and 18 parts antimony; to 85 parts tin, 5 parts copper, and 10 parts antimony.

For heavily loaded bearings: from tin 87 parts, copper 6 parts, and antimony 7 parts; to tin 90 parts, copper 2 parts, and antimony 8 parts.

For bearings of railway car axles: from tin 67 parts, copper 11 parts, and antimony 22 parts; to tin 83 parts, copper 6 parts and antimony 11 parts. The Pennsylvania Railroad uses a special plastic bronze, composed of copper 76.8 parts, tin 8 parts, lead 15 parts, and phosphorus 0.2 part. Another bronze highly recommended for railway bearings is composed of copper 64 parts, nickel 1 part, tin 5 parts, and lead 30 parts.

For locomotive axles a plastic brass is used: copper 5.5 parts, zinc 80 parts, and tin 14.5 parts.

For propeller shafts a plastic brass is composed of copper 57 parts, zinc 29 parts and tin 14 parts.

Ajax bronze, a plastic antifriction metal, has the composition: copper 81.2 parts, in 10.7 parts, lead 7.2 parts, and phosphorus 0.4 part.

The lead-antimony bearing-metals range in composition from: lead 65 parts, antimony 25 parts, and copper 10 parts; to lead 80 parts, antimony 15 parts, and copper 5 parts.

"Universal" bearing metal is composed of tin 6 parts, lead 77.75 parts, antimony 16 parts and bismuth 0.25 part. Consult Buchanan, J. F., 'Practical Alloying' (Cleveland, Ohio 1910); Gulliver, G. H., 'Metallic Alloys: Their Structure and Constitution' (London 1913); Law, E. F., 'Alloys and Their Industrial Application' (London 1909).

ANTIGO, an'ti-gō, Wis., county-seat of Langlade County, a northern county of the State. It is situated in the southwestern portion of the county, 96 miles north-northwest of Oshkosh and 207 miles northwest of Milwaukee; and it is on the Spring Brook River and the Chicago and Northwestern Railway. It is the commercial centre of an agricultural section of considerable importance, and of a timber region which has contributed largely to Wisconsin's position in marketed forest products. Here are located several extensive manufactures of various sorts, including chair, hub, broom-handle, excelsior, veneer and other factories; also foundries, breweries, railway-shops and flour, planing and saw mills. Antigo was settled about 1878, and in 1884 was incorporated; it has the commission form of government. The most noteworthy features of the thriving city include a teachers' training school, a school for the blind, a school chiropractic, a business college and a Carnegie public library. Altitude 600 feet. Pop. 7,196.

ANTIGONE. The subject of the 'Antigone' of Sophocles is that immortal heroine

"who dares
To self-selected good
Prefer obedience to the primal law
Which consecrates the ties of blood."

Though written in 441 B.C., many years before the 'Oedipus at Colonus,' the play treats of a later chapter in the story. It seems to have

been suggested by the last scene in the 'Seven Against Thebes' of Æschylus. At early dawn Antigone comes forth from the palace with her sister, Ismene, to talk with her alone about the edict of the king: will her sister join in her venture? "But Creon forbids." "He has no right to bar me." Thus the situation is unfolded at the very beginning—the conflict of wills between sovereign and subject. Ismene tries to dissuade her sister from the rash undertaking, but in vain. The chorus of elders enter to celebrate the day of deliverance that dawns on Thebes. Creon comes forth and addresses the nobles whom he has convened: "Eteocles shall be buried, but the corpse of Polyneices shall be left on the field, a prey for carrion kites to feed upon and for dogs to tear. Ally yourselves not with the rebellious." The heroic devotion of Antigone, burying her brother, Polyneices, and put to death for her pious disobedience of the tyrant's edict—that is the subject of the drama; and nothing could show more clearly the great originality of the poet's genius than his power to feel and to make others feel the grandeur of that subject. The superior beauty of the play is due primarily to the development of the character of Antigone. In the scene in which she and her sister, Ismene, appear together before Creon we find a happy example of the simultaneous employment of three actors. The rôle of Ismene reveals an innovation in dramatic art; in a manner truly Sophoclean the weaker sister is set over against the firmer Antigone. By reason of the skillful way in which the action is managed Sophocles has succeeded in extracting dramatic reversals of situation from a very simple subject; admiration, fear, sympathy, pity, indignation follow one another from scene to scene, even after the exit of the heroine.

The language of the tragedy is especially beautiful; and the martyrdom of the girl, who does not realize herself how noble her deed is, has commanded universal admiration. Antigone is a noble young woman, who feels that her act is right although she cannot advance arguments to justify that act. That she is truly feminine is seen in many a subtle touch. The character of Creon, the harsh tyrant, is also finely portrayed.

JOSEPH E. HARRY.

ANTIGUA, anté'gwa, one of the British West Indian islands, situated lat. 17° 6' N. and long. 61° 45' W., about 50 miles east of Saint Kitts and the same distance north of Guadeloupe; area 108 square miles; dependencies Barbuda and Redonda, which have an area of 62 square miles; population including those dependencies 34,971 (mainly negroes) in 1901, as compared with 36,819 in 1891; the principal island of the Leeward group; residence of governor and his staff; port and chief town, Saint John; the chief products, sugar and pineapples. See ANTILLES; WEST INDIES.

ANTIGUA, La., city and municipality of Guatemala, and the capital of the department of Sacatepéquez. The municipality consists of the city proper, 8 villages and 13 hamlets. In the time of the Spanish domination it was the colonial capital. Destroyed in 1773, it still has remnants of past grandeur. Number of inhabitants in 1916 about 14,000.

ANTILLES, än-tíl'lez, name given both to the group of large islands forming the northern limit and the chain of small islands forming the eastern border of the Caribbean Sea. Practically all of the West Indian islands (see WEST INDIES), except the Bahamas are thus included. The Greater Antilles (Cuba, Jamaica, Haiti and Porto Rico) have about 6,700,000 inhabitants, or more than three-fourths of the entire population. The Lesser Antilles extend toward the southeast in a curved line from Porto Rico to the coast of Venezuela and follow the line of that coast from the Orinoco delta westward to the Gulf of Maracaibo. Their total area is about 5,500 square miles, and their population is approximately 1,307,000.

The following classification shows the natural grouping of the Lesser Antilles, with the area (in square miles) and the population of the islands in each of the groups: (1) *Virgin Islands*.—Saint Croix (A. 74, pop. 19,683); Saint John (A. 21, pop. 918); Saint Thomas (A. 23, pop. 10,000); Tortola (A. 58, pop. 4,222); Anegada (A. 13, pop. 300); Virgin Gorda (A. 176, pop. 417). (2) *Outer Chain of Caribbee Islands*.—Anguilla (A. 35, pop. 3,890); Saint Martin (A. 38, pop. 6,700); Saint Bartholomew (A. 8, pop. 2,650); Barbuda (A. 62, pop. 639); Antigua (A. 108, pop. 34,971); Désirade (A. 10, pop. 1,400); Marie Galante (A. 65, pop. 13,850). (3) *Inner Chain of Caribbee Islands*.—Saba (A. 5, pop. 1,909); Saint Eustatius or Saint Eustache (A. 7, pop. 1,408); Saint Christopher or Saint Kitts (A. 65, pop. 29,781); Nevis (A. 50, pop. 12,774); Montserrat (A. 32, pop. 12,215); Guadeloupe and dependencies (A. 600, pop. 212,430); Dominica (A. 305, pop. 28,891); Martinique (A. 400, pop. 194,000); Saint Lucia (A. 233, pop. 50,809); Saint Vincent (A. 150.3, pop. 45,605); Grenada (A. 133, pop. 69,307). (4) *Barbados*.—(A. 166, pop. 173,359). (5) *South American Islands*.—Tobago (A. 114, pop. 20,463); Trinidad (A. 1,754, pop. 352,145); Buen Ayre or Bonaire (A. 95, pop. 6,547); Curaçao (A. 210, pop. 32,959); smaller islands (A. 470, pop. 40,000).

English geographers call the northern part of the chain of Lesser Antilles "The Leeward Islands," the capital of the Leeward government being on Antigua, and the southern half "The Windward Islands," Grenada being headquarters of the Windward government. The present holdings of Great Britain, France, and Holland in the Lesser Antilles are reminders of the early struggles of the European nations to win supremacy in the New World; for the West Indies were commonly regarded up to the end of the 18th century as the most valuable part of America, and these islands were the chief battle ground of the rival powers. Admiral Rodney's victory over the French admiral De Grasse, 12 April 1782, gave England her commanding position in this region. Her possessions constituting several distinct colonial governments, include the Virgin group (except the American islands, Saint Thomas, Saint Croix, and Saint John); all below the centre of the chain, namely, Saint Lucia, Saint Vincent, Barbados, Grenada, Tobago and Trinidad; the important island of Dominica, etc. The Virgin Islands are important because they command the deep-water Anegada passage between the Atlantic Ocean

and the Caribbean Sea; and the only deep harbors (except Saint Thomas) in the Lesser Antilles are in Trinidad and Saint Lucia. The French retain among their possessions the somewhat larger islands of Guadeloupe and Martinique in the centre of the chain. The Dutch, in addition to Curaçao and Buen Ayre, have a part of Saint Martin and a few small islands below the Anegada Passage, the whole width of the Caribbean Sea intervening. The economic history of the islands of the Lesser Antilles is simple. Nearly all of them derived their wealth in the past from sugar culture, and with the decline in the price of sugar have sunk into poverty. Meanwhile, the black population has crowded out the Caucasians. The increase in the population of the Greater Antilles since the early years of this century is decidedly noteworthy.

MARRION WILCOX.

ANTIMASONRY. In the United States history, (1) the widespread hostility to the Freemasons, as an order whose oaths were claimed to be superior to public duty and private morality, excited by the fate of William Morgan (q.v.) in 1826. He was a broken Virginian, who had settled in Batavia, N. Y., about 1824, as a mason by trade, and professing to be a Royal Arch Mason; and in the summer of 1826 was reported to be writing a book to expose the secrets of Freemasonry, to be printed at a local newspaper office. Though the Masons were naturally indignant and distressed, the other citizens regarded it as a catchpenny scheme and had Morgan remained in view probably Masonry would have suffered little damage,—certainly none if the Masons had merely denied his statements, for his word would have carried no weight. But, unluckily, just at this time suits against him for debt began suddenly to multiply and bail was either refused or disregarded. Finally on 11 August he was taken to Canandaigua, 50 miles away, on a charge of theft; was released, but at once rearrested for debt; and on the next night, being again released, he was at once seized and never reappeared. The public at once connected this with the Masonic exposure and threats, and vigilance committees were shortly organized which traced him beyond question, in the hands of abducting parties, to Fort Niagara, an unoccupied United States post at the mouth of the Niagara River; the last ever

certainly known of him, though other statements made it seem probable that he had been murdered and thrown into Lake Ontario. The excitement, increased by the belief that prominent Masons obstructed the investigations, was fanned into flame by the appearance, a few weeks later, of the first part of Morgan's book, the other parts ultimately being published also; entitled 'Illustrations of Freemasonry, by One of the Fraternity Who Has Devoted Thirty Years to the Subject'; reprinted under various titles, as 'Light on Masonry,' 'Freemasonry Exposed and Explained,' etc. Along with a mass of dreary "ritual" for "working the degrees," of no moment even if true, and its betrayal a scandalous violation of good faith, it included some passages which if true would have obligated him to make them known at once on joining: such as an oath requiring Masons to place their duty to a brother Mason before their oaths in court; and others pronouncing dire vengeance (graduated according to the degree thus betrayed) on Masons who should reveal the secrets of the order, and obligating every "brother" to make it his business to execute the threat. The denials of the Masons were not thought categorical enough. The alleged agents in the abduction were put on trial between January 1827 and 1830, and several were convicted and sentenced, some pleading guilty to save examination as to conspiracy. They could not be held for murder, but popular judgment charged that crime to the fraternity if not to the individuals. Very soon Antimasonry had become the one issue of the day. Candidates for local office who refused to withdraw from the order were heavily "scratched" at elections, and great numbers of lodges had to give up their charters and dissolve. From New York the feeling spread through the Union, and more than 3,000 lodges surrendered their charters before the storm blew over. The governor of New York and a large number of the leading officials and prominent public men were Masons, as now; but in the campaign of 1828 the National Republicans dared not nominate any who belonged to the order. None the less the Antimasons formed a regular party, holding a convention at Utica and nominating Solomon Southwick for governor. William H. Seward, Millard Fillmore and Thurlow Weed first came forward as Antimasonic candidates. A body was conveniently found in Niagara River and said to be Morgan's, though of course unrecognizable; and Weed is credited with having replied, when questioned as to its authenticity, that it was "a good enough Morgan till after election." The ticket polled 33,345 votes out of 276,583; but it polled some 70,000 in 1829 and 128,000 in 1830; the National Republican party in the State was gradually absorbed and became chief anti-Democratic organization. This is the most singular feature of the whole movement; for the National Republicans, like the Whigs and Republicans later, were distinctly the party of the upper business and professional classes, which were the very ones who formed the strength of the Masons. Yet the same result obtained everywhere: doubtless it was due to the accidental fact that Jackson, the idol of the Democracy and then President, was a Mason. A national convention was held in 1830 to organize a national party; and in

September 1831, in order to force Clay, who was a Mason, out of the field, it held a convention (in Baltimore) before any of the other parties, and nominated William Wirt of Maryland and Amos Ellmaker of Pennsylvania for the Presidency. The National Republicans, however, supported Clay, and in the election of 1832 Wirt received only the electoral vote of Vermont. The party took no further national action, and with the National Republicans was soon absorbed in the new Whig party, though it retained force enough to compel the Whigs to discard Clay for Harrison in 1833 and 1839. In Pennsylvania, however, allied with the Whigs, it survived till about 1840 and elected a governor, Joseph Ritner. (2) Another Antimasonic body was formed in 1868 as the National Christian Association, at Pittsburgh, Pa., though hostility to Masonry was only one of its tenets; it renamed itself in 1875 the American Party (q.v., No. 2), and entered politics. It opposed Freemasonry as "false religion and false politics" and urged the prohibition of oath-bound lodges as acknowledging another government than that of the United States.

Bibliography.—For Morgan, consult Morris, 'History of the Morgan Affair' (1852); Greene, 'The Broken Seal, or the Morgan Abduction and Murder' (1870). For political results, Hammond, 'Political History of New York'; Hopkins, 'Political Parties' (1900).

ANTIMISSION BAPTISTS (their own title is "Old School Baptists"), an American sect founded about 1835, who do not believe in Sunday-schools or theological seminaries, holding that salvation does not depend upon human instrumentalities, but upon divine grace alone.

ANTIMONAN, ăn'te-mō-năn', a seaport town of Luzon, Philippine Islands, province of Tayabas. It is situated on Lamon Bay, about 100 miles southeast of Manila. Pop. about 11,000.

ANTIMONOPOLY PARTY, an American political organization which in 1884 nominated for the Presidency Benjamin F. Butler (q.v.), on a platform advocating election of United States senators by popular vote, an income tax, the repeal of all tariffs, and the prohibition of land grants to corporations. It united with the Greenback Labor party, the combined vote reaching 130,000 votes in the November election of 1884.

ANTIMONY, one of the metallic elements. It is found in nature in the metallic state, but its chief commercial source is the mineral stibnite, which is a sulphide of antimony (Sb_2S_3). Considerable of the metal is produced as a by-product in the smelting of lead-silver ores. The mineral stibnite occurs in veins, commonly associated with other metallic minerals. Stibnite was known in very early times. It has been used by the women of the East for many centuries for painting the eyebrows and eyelashes and giving lustre to the eyes. Before the discovery of the metal itself, stibnite was called "antimony," and it appears that the paint used by Jezebel (2 Kings ix, 30) was finely ground stibnite. The Arabs called this face-paint *al Kohl* (compare ALCOHOL). The first distinct mention of the metal itself is made by Basil Valentine, who gives a process for extracting it from stibnite, though he does not

claim to have discovered it. Several methods for extracting it are now in use, chief of which is the following: Two parts of stibnite are melted with one part of thin scrap iron, in plumbago crucibles. The sulphur, leaving the antimony, combines with the iron, so that sulphide of iron and metallic antimony result, the iron sulphide floating as a slag. The crude antimony so obtained is next melted with a small amount of sulphate of soda and a little of the slag obtained from the operation next to be described. By this means the metal is purified somewhat. It is then cast into molds, and when cold is broken up into small pieces, to prepare it for the third operation, which is called "melting for star metal." This last-named process consists in melting 60 parts of the broken metal with two parts of pearlash and five parts of slag from a previous operation of the same kind. The resulting metal or regulus is poured into square molds, into which some slag has first been allowed to run, and is cooled slowly while still covered with slag. If the metal is of good quality, the resulting blocks will have a stellated or crystalline surface.

Antimony is a brilliant, bluish-white, brittle, crystalline metal, with a specific gravity varying from 6.72 to 6.86. It melts at about 800° F., and if protected from the air boils at a white heat. At ordinary temperatures it is not acted upon by air or water, but it oxidizes quickly when melted, and at a red heat burns at a brilliant white flame, and can decompose water. It expands upon solidifying, and imparts this property to its commoner alloys. Its coefficient of expansion is about .0000064 per degree F. The tensile strength of cast antimony is about 1,000 pounds per square inch of sectional area. It is a comparatively poor conductor of heat and electricity, its thermal conductivity being only about 1/25 of that of silver; its electrical resistance is 0.488 of that of mercury at 32° F., and 0.704 that of mercury at 212° F. Its chemical symbol is Sb (from the Latin word *stibium*), and its atomic weight is sensibly 120. It is diamagnetic; that is, a sphere made from it is repelled by a magnet, though the repulsion is hardly comparable in magnitude with the force of attraction that a magnet exerts upon iron. It also has marked thermo-electric properties, and is used in the laboratory in the construction of thermopiles. Antimony forms valuable alloys with other metals, and this is its most important use in the arts. Type metal is an alloy of lead, antimony, and tin, with sometimes a little copper. The tin adds toughness, while the antimony gives hardness and causes the alloy to expand at the instant of solidifying, giving a sharp cast of the letter. In the manufacture of munitions of war antimony plays an important part. It is employed to give to shrapnel bullets the hardness through which they retain their spherical shape when the shell explodes. Previous to the European War the annual production of metallic antimony in the United States was between 2,000 and 3,000 tons—obtained mainly from antimonial lead. With the growth of the munition making industry the demand for the metal increased rapidly, and in 1915 the total production reached 18,600 tons. About 5,000 tons of this total was produced in domestic mines in Inyo, Kern and

San Benito counties of California; in Humboldt and Elko counties of Nevada; and at points less notable in Arkansas, Idaho, Montana, Oregon, Utah and Washington. A larger degree of interest, however, attached to the output of Alaska, amounting in that year to 1,390 tons of stibnite, carrying nearly 60 per cent of metallic antimony from this entirely new source. A large factor in the total was 8,500 tons from China. South America and Mexico supplied nearly all the rest. The antimony prospects of Alaska are considered most promising, and the showing for 1916 should be much larger, when the smelter returns have been compiled. Besides the localities mentioned, antimony is found in France, Australia, Japan, China, Italy, Spain, Portugal and South Africa. See **ELECTRO-CHEMICAL INDUSTRIES**.

ANTIMONY-POISONING, a variety of poisoning formerly more common than at present. The mortality is about 40 per cent. The symptoms of acute poisoning resemble closely those of arsenic-poisoning. There is sudden acute gastric pain, with nausea and vomiting, pressure in the breast and intense sense of anxiety. This is followed by colicky pains and diarrhoea. The pulse becomes small and frequent, later retarded; the respirations diminish in number, the skin is cyanotic, the temperature sinks and coma and convulsions lead to death. If vomiting develops early, before time has elapsed to permit of the absorption of a large amount of antimony salt, death is less likely to occur. The treatment should include washing out the stomach, inducing of vomiting and the use of tannic acid compounds.

ANTINEBRASKA PARTY. See **KANSAS-NEBRASKA BILL**.

ANTINOMIANISM, the name applied to the doctrine that the dispensation of grace as set forth in the New Testament frees the Christian from the claims and obligations of the moral law as presented in the Old Testament. In the early Church there were antinomian tendencies due to an over-emphasis of faith in opposition to works. This is especially so in some of the Gnostic systems, where faith and love are so emphasized and moral matters appear indifferent, and the contradictions between the law and the gospel are regarded as irreconcilable. Antinomianism marked many of the mediæval sects, but reached its fullest development in the Reformation period. In Luther's emphasis on the doctrine of justification by faith he had used expressions which might be understood to indicate opposition between the law of Moses and the gospel, as though with the establishment of the gospel the law of Moses was no longer of any value. But when Luther carefully expressed himself on this point, as he did in his instruction to the Saxon preachers in 1527, he gave to the teachings of the Old Testament their proper place in the Christian life. This was disputed by Agricola, and a controversy broke out between him and Luther, in which he treated Luther's most extreme statements in regard to faith as though they were to be taken literally. His follower Amsdorf went as far as to say that good works were detrimental to salvation. In England there were Antinomians in the various sects in the time of Cromwell. They were high Calvinists and claimed that, as the elect cannot

fall from grace, any act performed by them, however sinful it may seem to men, is not in reality sinful.

ANTIOCH (Latin, *Antiochia*), the ancient capital of the Greek kings of Syria; on the Orontes, about 21 miles from the sea. It was founded by Seleucus Nicator in 300 B.C., and named after his father Antiochus. The first inhabitants were brought from Antigonía, founded by Antigonus in 307. It was famed for the splendor of its public buildings, the Seleucid monarchs having vied with each other in embellishing their metropolis, and the Roman emperors having also done much to adorn it. It was called the "Queen of the East" and "The Beautiful," and was advantageously situated for trade, being easily approached by the caravans of the East, and through its port Seleucia having maritime communication with the West. The city is frequently mentioned in the New Testament, and it was here that the disciples of our Saviour were first called Christians (Acts xi, 26). In 64 B.C., on the breaking up of the kingdom of Syria, it was captured by Pompey; in 266 was captured by the Persians under Sapor; and in 538 was thrown into a heap of ruins by Persians under Chosroes. It was restored by the Emperor Justinian, but never quite recovered from this last blow. In the first half of the 7th century it was taken by the Saracens and remained in their possession for upward of 300 years, when it was recovered by the Greek Emperor Nicephorus Phocas. In 1098 it was taken by the Crusaders. They established the principality of Antioch, which lasted till 1268, when it was taken by the Mameluke Sultan of Egypt. In 1516 it passed into the hands of the Turks. The modern Antioch or Antakieh is a poor place. It has some manufactures of silk stuffs, leather and carpets, and has some trade in these articles and in goat's wool, beeswax, etc. The population is not far from 20,000.

ANTIOCH, Cal., town of Contra Costa County, on the south bank of the San Joaquin River, on the Southern Pacific and the Atchison, Topeka and Santa Fé railroads, 40 miles northeast of Oakland. Its industries comprise paper mills, potteries, shipyards and planing mills. It has two banks with total resources of \$1,200,000 and a total property valuation of \$900,200. The principal buildings are the town hall, the grammar school and Union High School. For the fiscal year ended 30 June 1917 the town's receipts amounted to \$24,736.23 and expenditures to \$24,191.37. The government is vested in a board of five trustees. Pop. about 2,500.

ANTIOCH COLLEGE, an American co-educational institution in Yellow Springs, Ohio, founded in 1852 with Horace Mann as its first president. It has an endowment of over \$100,000; its grounds and buildings are valued at \$250,000; and its library contains 12,000 volumes. In 1917 it had 20 instructors and 253 students.

ANTIOCHUS, the name of 13 kings of Syria: 1. **ANTIOCHUS I**, or **ANTIOCHUS SOTER**, son of Seleucus: b. about 324 B.C.; d. 261 B.C. He succeeded his father in 280 B.C. and disputed Macedonia with Antigonus Gonatas, but finally relinquished it to him. During the greater part

of his reign he was engaged in a protracted struggle with the Gauls, by whom he was killed in battle. 2. **ANTIOCHUS II**, or **ANTIOCHUS THEOS**, who succeeded his father Antiochus I. Weakened by war with Egypt, he lost Parthia and Bactria by revolt. He was murdered in 246 B.C. by Laodice, his wife, whom he had put away to marry Berenice, daughter of Ptolemy. 3. **ANTIOCHUS III, THE GREAT**, grandson of Antiochus II, who succeeded his father Seleucus Callinicus in 223 B.C. at the age of 15. He made war on Parthia and Bactria, but was compelled, after a long war, to recognize the independence of these kingdoms. He next invaded India, where he remained for seven years (212–205 B.C.). Invading Asia Minor and crossing to Europe he took possession of the Thracian Chersonese. Antiochus gained an important ally in Hannibal, who had fled for refuge to his court; but lost the opportunity of an invasion of Italy while the Romans were engaged in war with the Gauls, of which the Carthaginian urged him to avail himself. In 192, at the request of the Ætolians, he crossed to Greece, but was defeated by the consul Acilius Glabrio and returned to Asia. He was defeated by Scipio near Magnesia, 190 B.C. Peace was granted him in 188 B.C. on the cession of all his dominions west of Mount Taurus, with a heavy indemnity. He also engaged to surrender refugees of his court, but he allowed Hannibal to escape. He was killed while plundering a temple in Elymais. 4. **ANTIOCHUS IV, EPIPHANES**, son of Antiochus the Great; d. 164 B.C. He is chiefly remarkable for his attempt to extirpate the Jewish religion. 5. **ANTIOCHUS V, EUPATOR**, son of Antiochus IV, who reigned from 164 B.C. to 162 B.C. 6. **ANTIOCHUS VI, THEOS**, ruled for three years, 145–142 B.C. 7. **ANTIOCHUS VII, SIDETES**, the son of Demetrius I: b. about 164 B.C.; d. 129 B.C. He defeated the Parthians in several battles. 8. **ANTIOCHUS VIII, GRYPUS**, son of Demetrius II. He ruled 125–113 B.C. and 111–96 B.C. and was slain by Heracleon in the last named year. 9. **ANTIOCHUS IX, CYZICENUS**, son of Antiochus VII. Defeated in battle against Seleucus V, he committed suicide in 95 B.C. 10. **ANTIOCHUS X, EUSEBES**, son of Antiochus IX. He reigned but three years and was obliged to flee to Parthia in 92 B.C. 11. **ANTIOCHUS XI, EPIPHANES**, son of Antiochus Grypus. He reigned 95–93 B.C. and was drowned in the Orontes. 12. **ANTIOCHUS XII, DIONYSIUS**, 85 B.C. He was killed in battle with the Nabatereans. 13. **ANTIOCHUS XIII, ASIATICUS**, the son of Antiochus X, and the twentieth of the Seleucidian dynasty. Beginning his reign in 69 B.C. he was deposed by Pompey in 65 B.C.

ANTIODACTYLA, the suborder of ungulate mammals that includes the "split-hoofed" animals—cattle, deer, antelopes, sheep, etc.—in which only the third and fourth toes bear the weight of the body. See **UNGULATA**.

ANTIOQUIA, ăn'tē-ō'kē-ă, a department of the republic of Colombia, South America, embracing 24,401 square miles and divided into the provinces Centro, Oriente, Aures, Fredonia, Suroeste, Nordeste, Norte, Sopetrán, Occidente and Uraba. The inhabitants are successful both in mining and in agriculture. The departmental capital is Medellín; and as a well-

informed writer tells us, that city is not only the most important trading centre in Colombia, but is also noteworthy for its manufactures. "The population," he adds, "is not quite 70,000, but its wealth is out of all proportion to the number of inhabitants." There are few, if any, cities of its size in the whole of South America that rival it in wealth. Population of the department (1896) 648,190; (1911) 741,816; (1916) 776,000.

ANTIPHLOGISTIC, a term applied to medicines or methods of treatment that are intended to counteract inflammation, such as bloodletting, purgatives, diaphoretics, etc.

ANTIPHONY ("alternate song"), a term denoting in the services of the Christian Church, a psalm, chant or other composition, sung by two parties in alternation, as by two choirs or parts of a choir, or first by a single voice and then repeated by the whole choir. The Roman Church applies the term antiphony in a restricted sense to a series of "words or verses prefixed to and following a psalm or psalms, to express in brief the mystery which the Church is contemplating in that part of her office." The practice of alternate singing formed a part of the old Jewish worship. Its introduction into the Christian Church is ascribed to Ignatius in the 1st century after Christ. The Western Church is said to have received it more particularly from Saint Ambrose.

ANTIPODES, ăn-típ'ō-dēz (from the Greek *anti*, against, and *pous*, a foot), the name given to inhabitants of the earth diametrically opposite to each other, and of course literally applied to those who turn their feet toward each other; or to any part of the earth's surface situated diametrically opposite any given part. The antipodes live in similar and, except at the equator, opposite latitudes, and their longitudes differ by 180°. Hence the difference in their time is about 12 hours, and their seasons are reversed. The spherical form of the earth naturally leads us to the idea of the antipodes, of whose existence some idea was entertained even before the age of Cicero.

ANTIPODES ISLAND, a small uninhabited island in the south Pacific Ocean, about 460 miles southeast-by-east of New Zealand; so called from being nearly antipodal to Greenwich, England. Its area is about 11 square miles.

ANTIPOPE, a pontiff elected in opposition to one canonically chosen. The first antipopes were: Felix, during the pontificate of Liberius (352–66) and recognized during the absence of Liberius; Ursinus, against Damasus (366–84); Eulalius, against Boniface I (418–22); Laurentius, against Symmachus (498–514); Dioscurus, against Boniface II (530–32); Vigilus, against Sylvester, until 540, then canonical; Constantine, against Paul (767); Anastasius, against Benedict III (855); John XVI, Philogathus, against Gregory V (996–99); Gregory, against Benedict VIII (1012–24). During the middle ages several emperors of Germany set up Popes against those whom the Romans had elected without consulting them. Otho the Great displaced successively two bishops of Rome; and when the rival Pope, Sylvester III, had expelled the simonia-

cal and profligate Benedict IX (1033-45), the latter was brought back by the German King, and soon afterward relinquished his dignity in consideration of a large tribute. Gratianus, who had persuaded him to yield, was now named Pope by the Romans as Gregory VI. There were, consequently, three Popes, but their claims were all set aside at a council convened at Sutri by the Emperor, Henry III, and a new Pope elected as Clement II in 1046. Shortly after, Pope Alexander II found a rival in Honorius II, the nominee of the Emperor; but his claim was ratified by a council convened at Mantua. In 1080 the same unseemly spectacle was witnessed, when the Emperor Henry IV elevated to the papal chair Guibert of Ravenna, under the title of Clement III, in opposition to his own implacable adversary, Gregory VII. After the death of Gregory (1085), Clement was antipope successively to Victor III (1087-88) and Urban II (1088-99). Other antipopes at this period were Albert, Theodoric, Maginulf, all in one year (1100-01); Maurice Burdin, against Gelasius II (1118-19) and Calixtus II (1124-30). Innocent II (1130-43) triumphed over the antipope Anacletus II by the help of Saint Bernard; and Alexander III, during his pontificate (1159-81), had to contend with three successive antipopes, the election of only one of whom, however, Victor IV, in 1159, has any appearance of canonical validity. The others were named Pascal III (1168) and Calixtus III, the same year. After a long contest Clement V was elected in 1305, and four years later transferred his seat to Avignon, where his successors reigned for nearly 70 years, losing the while, by their subjection to French influences, the sympathies of Germany and England. Nicholas V (1328-30) was antipope against John XXII. The election of Urban VI in 1378 occasioned "the great schism of the West," which divided the Church for 50 years. He was elected by the Romans, who demanded an Italian Pope after the death of Gregory XI. The French cardinals, then a majority in the curia, on the plea that they had elected the Pope only under intimidation, withdrew to Provence, and elected an antipope under the name of Clement VII, who was recognized by France, Spain, Savoy and Scotland; while Italy, Germany, England and the whole north of Europe supported Urban VI. For 38 years Christian Europe was scandalized by the spectacle of two Popes, one at Geneva, another at Rome, in turn hurling the most awful anathemas of the Church at each other. At the beginning of the 15th century an attempt was made to prevail on both the rivals, Gregory XII at Rome, and Benedict XIII at Avignon, to renounce their claims with a view to promote union, but both evaded this as long as possible. At length, however, the cardinals attached to either court agreed to summon a general council, which met accordingly at Pisa in 1409. The council deposed both Popes and constituted the separate bodies of cardinals into one conclave which elected Alexander V to the papal chair. The schism was finally healed when the council of Constance deposed John XXIII, and Gregory XII and Benedict XIII agreed to abdicate and recognize as Pope Martin V, against whom Peter de Luna and Munoz of Barcelona were antipopes. The council of Basel (1431-47), in its struggle with Pope

Eugenius IV (1431-47) for supremacy, attempted to arrogate to itself the papal functions and proceeded to elect Amadeus of Savoy Pope as Felix V. The attempt, however, failed; the Popes Eugenius IV and Nicholas V (1447-55) secured their authority, the ambitious council finally dissolved itself and Felix V resigned his empty dignity and was raised to the rank of cardinal by the magnanimous Pope himself. This was the last occasion on which the faithful were distracted by the sight of a rival pontiff within Christendom.

ANTIPYRETICS, the name given to remedies employed to reduce temperature in diseased conditions. Direct application of cold in the form of baths, packs, ice-cloths, etc., are the most valuable and efficient antipyretics. In some definite affections, notably in malaria, quinine, by destroying the parasite that causes the disease, reduces the temperature. Of late years a large number of synthetic drugs have been introduced to be used for the purpose of reducing temperature in disease. These are more technically the antipyretics. The field of their usefulness in this particular function, however, is constantly narrowing, since it is being recognized that fever is only a symptom and often not a dangerous one at that. Rational therapeutics would first eliminate the cause of fever, and drugs are then rarely necessary. The more important drug antipyretics are antipyrin, opium, quinine and its allies, salicylic acid and its compounds, alcohol, chloral, squills, phenacetin, acetanilide and others of the modern analgesics (q.v.). The most important of the functions of most of these drugs is their power to relieve pain. Their antipyretic action is often extremely complex—in general they diminish oxidation, increase perspiration or diminish the force and frequency of the heart-muscle contractions. See **ANALGESICS**; **ANIMAL HEAT**; **FEVER**.

ANTIPYRIN, the trade name of an artificial alkaloidal substance known to the chemist as oxydimethyl-quinizin, or, more accurately, as oxy-phenyl-di-methyl-pyrazole. It is a crystalline substance melting at 235° F. and soluble in water, alcohol, ether, and chloroform. Antipyrin is a derivative of coal-tar, an organic nitrogenous basic compound with the composition $C_{11}H_{12}N_2O$. It forms colorless scaly crystals devoid of odor and with a slightly bitter taste. It is soluble in water, alcohol and chloroform. It is one of the first of the modern army of synthetic drugs, and is still one of the most valuable, though not so extensively lauded as formerly, the patent on its exclusive production by one manufacturer having expired in 1899. Its action locally is somewhat antiseptic, and solutions applied to mucous membranes render them slightly anæsthetic and contract the blood vessels. It therefore makes a good local application to catarrhal membranes. Taken internally it is readily absorbed, reduces the force and frequency of the heart action, causes a dilatation of the blood-vessels of the periphery of the body, thus bringing about sweating and increased heat elimination (see **ANIMAL HEAT**). Its chief antipyretic action is due to the co-ordinating mechanism which lowers the heat at the point where the temperature is maintained and accumulated (the skin); the dilatation of the capillaries brings about the dissipa-

tion of this accumulation, which vascular dilatation is caused by the action of the heat-regulating mechanism possibly situated at the base of the cerebrum. Antipyrin is also an efficient and valuable analgesic, particularly serviceable in headache, neuralgias, in dysmenorrhœa, in rheumatism and in affections of the peripheral nerves and joints generally. By its pain-relieving qualities it makes a valuable adjunct in hypnotic mixtures. It is also a good antispasmodic.

Antipyrin is mainly eliminated by the kidneys. It may cause symptoms of poisoning. These are collapse, cold extremities and some degree of cyanosis and heart weakness. It is not one of the aniline (q.v.), analgesic antipyretics and hence has not the characteristic blood-poisoning properties of the anilines (acetanilide exalgen, mathacetin and similar bodies). It may produce a number of untoward symptoms, notably skin eruptions, cramps of the intestine and of the bladder. It also may cause disturbances of sensation in the extremities. Doses of from 10 to 15 grains have caused serious symptoms of poisoning, particularly in children. See ANALGESICS; ANTIPYRETICS.

ANTIQUARIES, persons devoted to the study or collection of antiquities. In most of the countries of Europe and America there are important associations of antiquaries. The object of these societies is the collection and preservation of ancient manuscripts, inscriptions, coins, sculptures, etc.; the examination of ancient edifices and other remains; in short, the investigation of everything likely to throw light on the manners, customs and history of the past. The chief antiquarian society of Great Britain is the Society of Antiquaries of London, founded in 1572, revived in 1707 and incorporated in 1751. The president for the time being is an official trustee of the British Museum. It has published 'Archæologia' (1770, etc.), 'Vetusta Monumenta' (1747), and 'Proceedings' from 1849. The Society of Antiquaries of Scotland was founded in 1780 and incorporated in 1783. The Archæological Institute of Great Britain and Ireland, established in 1843, is a society of similar character. The American Antiquarian Society was organized in 1812.

ANTIQUARY, *The*, a romance by Sir Walter Scott (1816). It is weak in its supernatural machinery, but strong in dialogue and humor. The plot centres about the fortunes and misfortunes of the Wardour and Glenallan families, and the chief character is Mr. Jonathan Oldbuck, the Antiquary, whose odd sayings and garrulous knowledge are inimitably reported.

ANTIQUES, a term specifically applied to remains of ancient art, such as statues, paintings, vases, cameos, and the like, and more especially to works of Grecian and Roman antiquity.

ANTIQUITIES OF THE JEWS, *The*, a famous work by the historian Flavius Josephus, concluded in the 13th year of the reign of Domitian. It was addressed especially to the Greeks and the Gentiles.

ANTIQUITY, a term generally denoting the time prior to the irruption of the barbarians into the Roman empire in the middle of the 5th century, or previous to our era. In a narrower sense it is applied to the period over which the

ancient history of the two principal nations of former times, the Greeks and Romans, extends. The name antiquities is commonly given to the remains of ancient art and industry, such as tools, weapons, sculptures; inscriptions, etc. It is also used in a wider sense to signify anything appertaining to a knowledge of the politics, manners, religion, literature and arts of the nations of antiquity, or of the modern nations, until the existing order of things commenced. See ARCHÆOLOGY.

ANTIRENT AGITATION, in New York State. Although the manorial system of large landed estates with leasehold tenants disappeared early in all other parts of the northern States of the Union, it flourished vigorously along the Hudson and Mohawk until well into the 19th century. This was due probably to the high personal qualities and tenacious landlordship of the Van Rensselaer and Livingston families, and the desire they inspired in others to become semi-feudal country gentlemen of the same stamp. The greatest of these holdings was the Van Rensselaer patroonship, called Rensselaerswick, derived from a Dutch grant confirmed by James II; originally comprising the entire counties of Albany, Rensselaer and Columbia,—20 miles on each side of the Hudson,—and to the last retaining many hundreds of large farms in them. Almost as large was the "Livingston Manor," at one time holding 162,000 acres in Dutchess and Columbia counties. The extensive Hardenburgh Patent, dating from 1749, occupied large sections in Greene and Delaware counties; and there were many other considerable estates. The tendency in the vicinity of these great manors was not to sell farms, but lease them with feudal incidents, in imitation of their great neighbors; so that in 8 or 10 of the east-central counties a large part of the land was in tenant farms, mingled with and surrounded by properties in fee. There were some very annoying provisions in some leases; one for giving the landlord a quarter of the proceeds of the sales of produce in case of alienation of the fee, making the landlord a partner with a one-fourth interest. In practice this provision was either not enforced or was commuted for a fraction of the value, and in the Hardenburgh Patent, where was the fiercest resistance and the most bloodshed, there was no such provision at all; but it served as a common grievance whether present or absent. Also rents were often in kind, fixed or shares, which is always fertile in heartburnings; many, however, had been commuted to money. But the actual grievances were slight, and the tenants were probably better off in income than the owners in fee. In Rensselaerswick the first seven years of a lease were usually rent-free; on the Hardenburgh Patent five years, with the next five at half rent; and arrears and reservations were very laxly enforced, often not at all for years,—which was injudicious charity and produced the crisis, as enforcement of back dues meant being sold out and evicted, and agriculture is the one employment that will not endure that from private owners. The insecurity of the old feudal tenures had been removed by the legislation of 1779 and 1789, which abolished them; and the new leases, though having the same rentals and services, were in fee, so that raising of rent and confiscation of im-

provements were impossible. Further legislative regulation was attempted in 1812 to settle the respective rights of patroons and tenants; but the friction continued, and naturally involved all other land dealings,—contracts, mortgages, etc., having as ill an odor as leases. In 1836 a mob in Chautauqua County destroyed a land office with its records, on a rumor that the mortgages were to be foreclosed; and the same thing was only prevented at Batavia by an armed gathering of the townsmen. The matter was brought to a head by the death of Gen. Stephen Van Rensselaer, the eighth patroon of Rensselaerswick. This fine old gentleman, who commanded at Queenstown Heights and founded Rensselaer Polytechnic Institute, died early in 1839, leaving over \$200,000 of uncollected rents and any number of unenforced quarter-sales, and two heirs to whom he left his estates on the respective sides of the Hudson. These heirs undertook to collect the arrears and enforce the rights left in abeyance; and the tenants formed associations to resist. The first to do so were those in the Helderberg Mountains, west of Albany (whence the disturbance is sometimes called the Helderberg War); but those east of the Hudson in Rensselaer County outdid them by forming a mob in disguise and murdering a man. The counties were in open rebellion, and in December Gov. William H. Seward issued a proclamation against the rioters. The sheriff of Albany County with a posse several hundred strong was stopped by 1,500 armed men; a company of militia was called out, but was forced back by a gathering of nearly 1,000, and at last a body of about 1,000 militia had to be sent to Albany. The executions were finally levied, and on the 12th the soldiers were sent home. On the governor's recommendation the legislature appointed a commission to report on a plan of adjustment; but as the only parties who wished the legal status quo changed were the tenants, the landlords considered the concessions to be all on their side and refused to listen to its recommendations. A stubborn resistance practically nullified the collection of rents year after year. At length in 1844 the rebellion broke out with tenfold violence, in a general organization through Rensselaer, Schenectady, Columbia, Otsego, Delaware, Ulster, Greene, Dutchess and other counties, against the payment of any rent whatever, and to compel the lords of the manor to sell their lands to the persons occupying them as tenants. The justifications legal and equitable may be surmised: that the landlords had no title, that the rent had been waived, that the payment of rent was against republican institutions, etc. A regular agrarian war was instituted: the tenants, plus all the rabble who liked to commit outrage on any side, disguised themselves as Indians and began a reign of terror, flogging, tarring and feathering, boycotting and generally ill-using all who took leases, or in any way dealt with landlords. One laborer who had bought lumber from a leased farm and was taking it to market was shot dead by a mob in a struggle to take it from him. At length, on 7 Aug. 1845, a deputy sheriff of Delaware County was fatally shot by such a mob while serving a process; the extortion which called for this bloodshed was two years' back rent at \$32 a year. These performances went on for months; Gov. Silas Wright, who in

his message of 1845 had favored commutation of rents and ownership in fee though calling for sharp laws to punish outrages, now summoned a military force and sternly put down the rebellion. More than 50 convictions were obtained, two of murder with sentence of death, which the governor commuted to imprisonment for life; but in his next year's message (1846) he recommended the abolition of distress for rent and the limitation of leases to 5 or 10 years. The constitutional convention of 1846 abolished feudal tenures and limited leases to 12 years. This was not at all what the Antirenters wanted, however, but abolition of rent altogether and proclamation of the leaseholders as owners. Their cause had been an issue in State politics for years, fomented by agitators and newspapers; and the Whigs, seeing that they controlled the legislative delegations of 11 counties, nominated for governor in 1846 their chief legislative champion, John Young, against Silas Wright, elected him by their aid, and he promptly pardoned all those who had been sentenced, pronouncing their offenses "political." He also recommended State suits against landlords to try titles. The Antirenters had "adopted" a part of the State ticket and not the rest, to show their strength, and polled about 5,000 votes; the next election (of 1848) they did the same: and the legislature, alive to the value of this body of votes, directed the attorney-general to bring a test suit against Harmon Livingston. The decision in November 1850 was for Livingston; but the nearly 12-years struggle and ruin of property values had wearied the landlords, and the decent tenants were perhaps ashamed of their breach of contract. The former offered to sell the farms, and the latter were willing to buy; and the great patroonship and patents were rapidly broken up. Meantime there was a mass of private litigation, and several cases went up to the Court of Appeals; which in October 1852 declared that without reference to the Constitution of 1846, agreements in restraint of alienation of titles in fee, and therefore reservations of quarter-sales, were void. As this left the landlords no right which could oppress the tenants, and the latter nothing to oppose except a payment of honest debts, the Antirent agitation passed out of sight as a dignified political entity. But the spirit was not quite dead. As late as July 1866 an antirent riot broke out in Knox, Albany County, which had to be suppressed by the militia. The next month a landowner's agent in Berne was fired at and his horses were shot. These, however, were belated strays: for a generation land contracts have been on a footing with all others. Consult Alexander, 'Political History of the State of New York' (Vol. II, New York 1906); Jay Gould, 'History of Delaware County' (1856); Roberts, 'History of New York' (1887); Cheyney, 'Anti-Rent Agitation' (Philadelphia 1887); Wright, 'Life of Governor Silas Wright' (Auburn 1847); Murray, 'Anti-Rent Episode in New York' in 'Report of the American Historical Association' for 1896.

ANTIRRHINUM, the designation of a genus of annual or perennial plants of the natural order *Scrophulariaceae*, commonly known as snapdragon, on account of the peculiarity of the corolla, the lower lip of

which, if parted from the upper, shuts with a snap. The plants are propagated by seeds sown in gentle heat in spring. They all produce showy flowers and are much cultivated in gardens. Many varieties of some of them, such as the great or common snapdragon (*A. majus*), have been produced by gardeners. The plant is not native in America, such specimens as are seen growing wild having escaped from gardens.

ANTI-SALOON LEAGUE. See PROHIBITION.

ANTISANA, *án'te-sá'na*, a volcano in the Andes of Ecuador, 35 miles southeast-by-east of Quito. Whymper, who ascended it in 1880, makes its height 19,260 feet. Tambo de Antisana, one of the highest settlements in the world, is on a slope of this mountain at an elevation of 13,000 feet.

ANTISCIAN (Greek *anti*, over against; *skia*, a shadow), a name applied to those who live under the same meridian, at the same distance north and south of the equator, and whose shadows at noon consequently are thrown in contrary directions.

ANTISCORBUTICS. See SCURVY.

ANTI-SEMITISM. See JEWS — ANTI-SEMITISM.

ANTISEPTIC, any substance which retards or prevents the growth and development of lower forms of organisms injurious to higher forms of life. The discovery that the breaking down or decay of organic bodies was caused by minute plants, fungi, bacteria, etc., led to the idea of preventing the action of these bodies by the employment of some antagonistic substances. In medicine it had been found that many of these bacteria produced a condition known as *sepsis*, or poisoning, and when Sir Joseph Lister first used the carbolic spray to prevent the development of these bacteria the word *antiseptic* came to be applied to any substance that inhibits the growth or destroys bacterial agents of putrefaction. A *germicide* is any agent that kills these low forms of plant life; *fungicides* are used on the large fungi; *bactericides* on the bacteria. The word *disinfectant* properly applies to a substance used for the destruction of a definite infecting agent, such as exists in phthisical sputum, or in typhoid urine or stools, but it too often is employed for some remedy that merely destroys a disagreeable odor—a *deodorant*. Thus most so-called disinfectants, manufactured to place in closets or urinals, are really nothing but strong-smelling deodorants. As disinfectants they are wholly useless. Germicides, bactericides and septicides may be divided into two groups, physical and chemical. In the former group is heat, the most important of all germicides. Burning is the best means for the disinfection of the non-valuable surroundings of patients who have had any severe contagious disease such as diphtheria, typhoid fever, plague, scarlet fever, etc. It is the best agent for the destruction of all tuberculous sputum. Boiling is another efficient means of disinfecting or sterilizing. The boiling of water or milk suspected to contain the bacteria of typhoid or diphtheria is effective. Boiling all bed linen which has been in contact with contagious diseases is advisable.

The boiling of preserves and the airtight sealing of the jars immediately afterward to prevent the entrance of the germs of molds and similar growths is practised by all housewives. When after this the preserved fruit "ferments," it has either not been boiled long enough, the jars were not thoroughly cleansed by boiling water, the rubbers and tops not sterilized or a hole has been left whereby the spores of molds have entered. Cold is a preservative only: it prevents the multiplication of these low forms of plant life, but does not destroy them. The conditions which favor putrefaction are: a moist atmosphere, warmth and the presence of micro-organisms.

Chemical antiseptics have been in use ever since the work of Tyndall, Pasteur, Koch and Lister showed the activity of lower plant forms in putrefaction and sepsis. In the arts many antiseptics are used to preserve foods. The smoking of hams and other meats is the old empirical method, antedating modern means probably by hundreds of years, the smoke containing creosote and bodies related to carbolic acid. Vinegar and spices have been long in use to preserve pickles. Sulphurous acid, alum, salicylic acid, formalin, nitre, common salt, sugar, etc., are all extensively used as food preservatives, but the four first named are considered injurious to health and are forbidden in many States. Other uses of antiseptics in the arts are: the preservation of wood from decay by impregnation with creosote and related fungicides, the preservation of pastes and mucilage with carbolic or salicylic acid, the preservation of sizes used in paper making by sulphurous acid and the use of sodium bisulphate or chloride of lime in sterilizing drinking water. Sodium hypochlorite is used to sterilize swimming pools, and chlorine peroxide for polluted waters. Benzoate of soda is used to preserve prepared foods and permitted by the authorities in limited quantities. Cinnamic acid is used to impregnate the wrappers in which butter is packed. In modern surgery it is not the destruction of bacteria, but rather their prevention, that is desired, and *asepsis*, or the prevention of infection, is the modern method, not *antiseptis*. By thorough sterilization of everything that comes in contact with a patient's body the modern surgeon prevents infection by keeping bacteria out. His instruments are sterilized by boiling in water, by steam or a high degree of dry heat, by washing in chemical antiseptics or by exposing them to formaldehyde vapor. Should the nature of a wound be such that it is already infected, then antiseptics are of service. The most valuable surgical antiseptics are the phenols and their derivatives (carbolic acid, salicylates, etc.), salts of mercury, silver lead, aluminum, copper, and zinc, preparations of chlorine, iodine, bromine, permanganate of potash, benzoic acid, organic aldehydes, formaldehyde, benzaldehyde, alcohol, thymol, menthol, eucalyptol and hydrogen peroxide. Such trade names as Dioxogen, Hydrozone, Glycozone, Pyrozone, and Peroxols, are given to mixtures of hydrogen peroxide with various other disinfectants. See BACTERIA; FUNGI; INFECTION; KOCH; PASTEUR; SPONTANEOUS GENERATION.

ANTI-SLAVERY SOCIETY, The American, was organized in Philadelphia,

December 1833, by delegates from similar local and State societies. The first of these societies was formed in Boston in January 1832 by William Lloyd Garrison and others. The American society took a radical stand for the abolition of slavery. The difference of opinion among the members caused a split in the society in 1840, and eventually both factions joined the Liberal Party. A small coterie of the original society continued to exist however until the adoption of the 15th Amendment in 1870. See LIBERAL PARTY; SLAVERY.

ANTISPASMODIC, a medicine proper for the cure of spasms and convulsions. In general any drug that has a sedative effect upon the nervous system, either by depressing the brain or spinal cord or by stimulating inhibitory centres, and as regulating the production of nerve force. In the former class are the bromides and chloral. The stimulating antispasmodics are asafetida, belladonna, camphor, musk, and valerian. Opium, balsam of Peru and the essential oils of many vegetables are also among the most useful of this class of medicines. Antispasmodics are employed in cases of nervous excitation, particularly of a hysterical nature, in asthma, alcoholism and in convulsions from epilepsy or other causes.

ANTIS'THENES OF ATHENS, a Greek philosopher who founded the sect of Cynic philosophers: b. Athens 444 B.C. He was a disciple of Socrates, and is said to have aided in bringing some of his persecutors to justice. He taught at the Cynosarges, a gymnasium appropriated to Athenians who had foreign mothers. His philosophy was a one-sided development of the Socratic method. According to his teaching virtue should render man independent of the ordinary events of life. He himself lived in a very austere, self-denying fashion.

ANTIS'TROPHE (Gr. *anti*+*strōphē*, from *strephō*, I turn), the name of one of the divisions of a Greek choral ode, corresponding to the *strōphē* and following it. The singing of the strophes on the stage was accompanied with a motion or turn from right to left.

ANTITORPEDO BOATS. The ideal antitorpedo boat is the destroyer. It is big enough to stay at sea in all weathers. In the United States navy it carries an armament of several four-inch guns and with its speed of from 30 to 35 knots an hour it can swiftly dash down upon torpedo-boats—or submarines—and effectively dispose of them. An essential part of antitorpedo boat defense is *decent realization*. The conditions of attack are such that each defense unit must act on its own initiative, and for torpedo craft the best unit is the single gun. For administrative purposes the unit may be a group of two or three guns, and the gun group commander would have the same duties and responsibilities as a battery commander of medium guns; but for tactical purposes the gun is the best unit, and the gun captain or gun group commander, if single gun groups are employed, must act on his own initiative. The passing of orders, once an action has commenced, would be almost impossible except to each gun separately. Constant readiness for action at night and in thick weather is necessary. Consequently the detachments must be divided into watches, enough

men must be kept closely to the guns ready to man them at a moment's notice, and a look-out sentry must be posted at each gun, which must be kept loaded, with an ample supply of ammunition ready to hand on the gun floor. The duties of the sentry are to keep a sharp look-out seaward, and to open fire, without waiting for orders, on any torpedo craft moving at night; only if the gun group commander were actually present on the gun floor would he take his orders before firing. In case of the alarm being given by means of the alarm gong before a target has been sighted, the sentry would pass on the alarm to the detachment. As night attacks are the principal danger, the effectiveness of the antitorpedo boat armament depends on the relative position of the electric lights and guns; and, if fighting lights are used, on their speedy manipulation in accordance with the wishes of those in command of the guns. These conditions absolutely dictate elaborate and expensive preparations in advance; and are quite incompatible with change of position. See SUBMARINES; TORPEDO BOATS; TORPEDORS.

ANTITOXINS, the name given to peculiar bodies developed in the human body or in the body of an animal, supposed to be antagonistic to the poisons, or toxins, of disease. These antitoxins are specific for definite diseases and constitute one of the protective agents in the body's battle with disease. For the full consideration of these and other similar bodies see IMMUNITY; TOXINS and ANTITOXINS.

ANTITRADE, a name given to any of the upper tropical winds which move northward or southward in the same manner as the trade-winds which blow beneath them in the opposite direction. These great aerial currents, descending to the surface after having passed the limits of the trade-winds, form the southwest or west-southwest winds of the north temperate and the northwest or west-northwest winds of the south temperate zones.

ANTITRINITARIAN, a name applied to one who does not receive the doctrine of the divine Trinity as it is represented by the Nicene and Athanasian creeds, and either puts the Son and the Holy Spirit in the Godhead below the Father, or considers Christ as merely a man, and the Holy Spirit an arbitrary personification of the divine mind. Antitrinitarians of the latter class are Unitarians (q.v.), while those of the former class are relatively Trinitarians.

ANTITRUST LAWS, in the United States. The first of these on the statute books was an ordinance of Alabama in 1883 against the pooling of freights by railroads. The first general law against business combinations was enacted by Kansas in 1889. But the general movement against trusts which took shape in legislation was in 1889, when five States and Territories passed laws to render combinations in restraint of trade illegal and punishable, and two more (Washington and North Dakota) incorporated similar provisions into the constitutions with which they were admitted to the Union. In the first half of 1890 three more States joined the movement with legislation; and on 2 July the Federal Congress enacted the "Sherman Law" against trusts. Nearly all the States have since placed like statutes on their books. The provisions are substantially

alike in all, making the persons engaged in such combinations liable to fine and imprisonment, and the corporations or firms punishable by loss of charter or of right to carry on business within the State where the offense is committed. The decisions of the Circuit Courts at first were so narrowed as practically to nullify the provisions of the laws; it being held that the combinations, as at common law, must be proved inequitable and injurious to the public, and calculated not merely to abate competition, but absolutely to monopolize the business for the purpose of extortion. But these decisions were reversed by the United States Supreme Court, which held that the laws made no distinction between partial and complete monopoly, or equitable and inequitable. It had been claimed also that the laws were unconstitutional, as violating the 5th and 14th Amendments, that no person shall be deprived of liberty without due process of law, and that the liberty of making contracts is an essential portion of this; but the Supreme Court interprets them to mean legal contracts, and that under its power to regulate commerce Congress can decide what contracts are legal; while the State courts hold such regulation is competent to the States under their police power.

The Sherman Act is as follows:

1. Every contract, combination in the form of trust or otherwise, or conspiracy, in restraint of trade or commerce among the several States, or with foreign nations is hereby declared to be illegal. Every person who shall make any such contract or engage in any such combination or conspiracy shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine not exceeding \$5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

2. Every person who shall monopolize, or attempt to monopolize, or combine or conspire with any other person or persons to monopolize any part of the trade or commerce among the several States, or with foreign nations, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by fine not exceeding \$5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

3. Every contract, combination in the form of trust or otherwise, or conspiracy in restraint of trade or commerce in any Territory of the United States or of the District of Columbia, or in restraint of trade or commerce between any such Territory and another, or between any such Territory or Territories and any State or States or the District of Columbia, or with foreign nations, or between the District of Columbia and any State or States or foreign nations, is hereby declared illegal. Every person who shall make any such contract or engage in any such combination or conspiracy shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by fine not exceeding \$5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

4. The several circuit courts of the United States are hereby invested with jurisdiction to prevent and restrain violations of this act, and it shall be the duty of the several district attorneys of the United States in their respective

districts, under the direction of the attorney-general, to institute proceedings in equity to prevent and restrain such violations. Such proceedings may be by way of petition setting forth the case and praying that such violation shall be enjoined or otherwise prohibited. When the parties complained of shall have been duly notified of such petition the court shall proceed, as soon as may be, to the hearing and determination of the case; and pending such petition, and before final decree, the court may at any time make such temporary restraining order or prohibition as shall be deemed just in the premises.

5. Whenever it shall appear to the court before which any proceedings under section four of this act may be pending, that the ends of justice require that other parties should be brought before the court, the court may cause them to be summoned, whether they reside in the district in which the court is held or not; and subpoenas to that end may be served in any district by the marshal thereof.

6. Any property owned under any contract or by any combination, or purchased to any conspiracy (and being the subject thereof) mentioned in section one of this act, and being in the course of transportation from one State to another, or to a foreign country, shall be forfeited to the United States, and may be seized and condemned by like proceedings as those provided by law for the forfeiture, seizure, and condemnation of property imported into the United States contrary to law.

7. Any person who shall be injured in his business or property by any person or corporation by reason of anything forbidden or declared to be unlawful by this act, may sue therefor in any circuit court of the United States in the district in which the defendant resides or is found, without respect to the amount in conspiracy, and shall recover threefold the damages by him sustained, and the cost of suit, including a reasonable attorney's fee.

8. That the word "person" or "persons," wherever used in this act, shall be deemed to include corporations and associations existing under or authorized by the laws of either the United States, the laws of any of the Territories, the laws of any State, or the laws of any foreign country.

In February 1913 New Jersey attracted considerable attention by the passage of a bill known as "the Seven Sisters Acts," which were supposed to represent the personal views of President Wilson on the trust problem. These acts defined a trust as an agreement between corporations, firms or persons for the creation of trade restrictions or the acquisition of monopoly, for the limitation of production or for the raising of prices. They fix the personal responsibility of directors, officers or agents and they forbid differences in prices in different sections, allowance being made for quality, cost of freight, etc., when such differences have the obvious purpose of creating a monopoly or killing competition. They also forbid the holding of stock of other corporations, except for payment of debts, for temporary investment of surplus funds in corporations in other lines of business, for the investment of benefit or insurance funds or for depreciation or rebuilding purposes. Rights

previously acquired, however, are exempt. Future mergers must be approved by the board of public utility commissioners and filed with the secretary of the State.

In January 1914 four bills were introduced into Congress by Representative Clayton of the House Judiciary Committee. These defined illegal acts; the granting of relief to persons injured by the operations of trusts; checking the interlocking of boards of directors and the creation of an Interstate Trade Commission. After much discussion and compromising the final result was the passage, 15 Oct. 1914, of the Clayton Anti-Trust Act, designed as a supplement to the Sherman Anti-Trust Act in its more explicit definitions of illegal acts. It also forbids any corporation or firm from selling its commodities at different prices to its different customers if such action tends to create a monopoly or lessen competition. Numerous exceptions are made, however. Another provision forbids a manufacturer to sell his goods to a dealer on the understanding that he will not buy goods of the same nature from a competitor. Decrees in government trust suits shall be sufficient evidence for private suits for damages under the anti-trust laws. Furthermore, in the case of private suits the statute of limitations shall begin to run only from the date that a decree is entered in a government suit. Holding companies are prohibited in that one corporation may not own stock in another where the effect is "to substantially lessen competition" or to tend to create a monopoly. Another section makes it illegal for one person to be an officer in more than one bank, or of two or more corporations engaged in the same line of business. Moreover, common carriers may not deal with corporations having, in common, directors or officers with themselves, except by competitive bidding.

Included in the "Clayton Anti-Trust Act" is the Trade Commission Act, which provides for the formation of the Federal Trade Commission, to consist of five members appointed by the President and the Senate for terms of seven years, not more than three to be of the same political party. This body was to take over the bureau of corporations and continue its investigations. What constitutes "unfair methods" of competition, when not specifically defined by the other provisions of the Act, is to be left to the judgment of the commission, which is a power similar to that given the Interstate Commerce Commission, in the matter of railroad rates. The commission may order hearings and may enforce its commands through the Circuit Court of Appeals. This court is given exclusive jurisdiction and power of review over this law, but not in regard to facts with respect to orders of the commission. The commission has, in fact, almost unlimited powers in pursuing its investigations. On 13 July 1915, the commission had been organized and established, the President's nominees being Joseph E. Davies of Wisconsin; Edward N. Hurley, Illinois; William J. Harris, Georgia; William H. Parry, Washington; George Rublee, New Hampshire. All except the last two were confirmed by the Senate, the objections being raised on account of political activities. Mr. Rublee, however, was given a recess appointment when Congress adjourned. Consult

Walker, F., 'Causes of Trusts and Some Remedies' in *American Economic Association Quarterly* (1910); Giddings, F. H., 'Democracy and Empire' (1900).

ANTITYPE, a word denoting a type or figure corresponding to some other type. It is in the sense of copy or likeness that the word occurs in the New Testament (Heb. ix, 24: 1 Peter iii, 21). By the father of the Greek Church antitype is employed as a designation of the bread and wine in the sacrament of the Lord's supper.

ANTIUM, ăn'shĭ-ŭm, one of the most ancient and powerful cities of Latium, the chief city of the Volsci. It was situated on a promontory, and was a flourishing seaport. It was taken by the Romans in 468 B.C., but soon revolted, and maintained its independence till finally taken by Rome in 338 B.C., and after this it appears as one of the maritime colonies of Rome. Toward the close of the republic and during the empire it was a favorite residence of the wealthy Romans, and both the town and its neighborhood were adorned with temples and splendid villas. Nero and Caligula were born at Antium. It was entirely destroyed by the Saracens; but vestiges of it still remain at Porto d'Anzo, its modern successor, near which many works of art, including the Apollo Belvidere and the Borghese Gladiator, have been found.

ANTIWAR DEMOCRATS, or **PEACE DEMOCRATS**, the Democrats in the North who were in sympathy with the Confederates during the Civil War. They opposed the draft and hindered recruiting, denounced Lincoln and predicted the failure of the war. In the heated controversies of the day they were nicknamed "Butternuts" and "Copperheads." There were among them secret political organizations such as the "Sons of Liberty," "Knights of the Golden Circle," etc. See **DEMOCRATIC PARTY**.

ANTLERS, the weapons borne upon the head of a male deer during the breeding season. They are an outgrowth of true bone supported upon protuberances from the crown of the skull, called pedicels. As the spring approaches, the hairy skin with which these are covered becomes highly vascular and swollen with blood and serum carrying lime salts. This grows outward and gradually assumes the form of the antler, characteristic of the species, which for a time is in a soft and vascular state, and covered with what hunters call "velvet." There is continually deposited within this growth the substance of bone, which fills and solidifies the structure from the centre outward, until in the course of four or five months all has become solid, the outer skin shrinks and dries and presently falls or is rubbed off. These antlers remain firm upon the head and useful as weapons until the middle of the following winter, when they become loosened and fall off. The process is repeated the following spring, and the antlers are thus lost and replaced annually as long as the stag lives. In the deer, with the single exception of the reindeer, antlers are worn only by the males and are a secondary sexual character. That they are associated with the reproductive function, says Beddard, is shown by their being shed after the period of rut; and also by the stunting effect upon the horns which any injury to the

reproductive glands produces. Various degrees of degeneration are to be seen in the antlers of captive deer resulting from varying degrees and periods of gelding.

The sport of stag-hunting has preserved a set of ancient terms, mostly of French origin in the Middle Ages, designating the different parts of the antler and the successive stages of growth, and these have come to stand for a deer of a certain age or condition. They were all derived from and particularly applicable to the European red deer (*Cervus elephas*), which more than any other species is preserved for hunting in Europe. The nomenclature is summarized as follows in 'Cassell's Natural History,' Vol. III: "In the common red deer, in the spring of the year following its birth, the antlers are nothing more than straight, conical and unbranched 'beams,' the animal being then known as a 'brocket.' In the following spring the antler has, besides the 'beam,' a small branch from its base, directed forward, known as the 'brow antler'; it is then termed 'spayad.' In the third year an extra front branch is formed, known as the 'tres,' and the whole antler is larger. The tres is sometimes seen in the smaller antler of the spayad. In the fourth year the brow antler is doubled to form the 'brow' and the 'bez-tine,' at the same time that the top of the main beam divides into the 'sur-royals' of the 'staggard,' or four-year-old male. In the fifth year the sur-royals become more numerous, the whole antler of the 'stag' being heavier than previously, only to be exceeded in weight by those of the fully adult 'great hart' with 10 or more 'points,' each being larger and longer than the year before." A deer of 12 points is known in Scotland as a "royal stag," but although sometimes antlers have more than 12 points, no recent antlers quite equal those which have been preserved from old times before all the best deer were so systematically shot each year. Where the number of points is exceedingly large, as it is in some curious specimens which show 50 or 75, they are no longer a record of the years of the animal's life, but of injuries to the horns, causing unnatural branchings. The horn of antlers is of commercial value, being much used for the handles of knives and similar articles.

ANTLIA, or **ANTLIA PNEUMATICA**, the name of one of the 14 southern constellations placed in the heavens by Lacaille in connection with his work at the Cape of Good Hope in 1751-52. It is situated between Vela, Pylxis, Hydra and Centaurus.

ANTLION, a term applied to the larva of *Myrmeleon*, a neuropterous insect of the family *Myrmeleonidae*. It is a singular-looking creature, the body somewhat broad and flattened behind, the head provided with enormous jaws which have a groove beneath, in which the maxillæ slide back and forth. It can thus pierce the bodies of small soft-bodied insects, flies, etc., and suck their blood without moving the jaws on which the victim is impaled. It makes a pit in fine sand, at the bottom of which it lies with its body buried and its jaws wide open, ready to seize any luckless insect which may fall in. When an insect comes near the edge of the pit, the antlion, by a toss of its head, hurls at it a shower of sand, which knocks it down, so that it slides into the pit and is seized.

Antlions are known in confinement to spend the winter in the larval state if fed with flies, caterpillars and spiders. In the spring the larva spins a rather large, round, silken cocoon covered with grains of sand, within which it changes to a pupa, and the winged insect emerges early in June. The imago has long, gauzy wings, both pairs alike, and is rarely seen in the Northern States. The conical, crater-like pits of the antlion may be seen in sheltered places in loose sand to the number of from 50 to 75.

ANTOFAGASTA, *än'tó-fa-gäs'ta*, Chile, a northern province which extends the whole width of the country and bounded on the north by the province of Tarapacá and on the south by the province of Atacama. Area, 46,609 square miles. It was ceded by Bolivia to Chile after the War on the Pacific. The systematic development, during the last 30 years, of its nitrate industry, and the exploitation of other mineral resources of this region, have greatly increased the revenues of the nation. Population about 120,000. For the War on the Pacific, or "War of the Pacific," climate, irrigated valleys, etc., see CHILE.

ANTOFAGASTA, Chile, capital of the province of the same name; port through which large quantities of nitrate are shipped; terminus of one of the railways connecting cities of the Andean highlands in Bolivia with the Pacific coast. It ranks, among Chilean ports, as second in the value of materials exported and as third in the value of merchandise imported. The number of inhabitants (including, with the city, some of the adjacent regions) is about 65,000. For climate, etc., see CHILE.

ANTOKOLSKII, Mark Matvyeevich, Russian sculptor: b. Vilna 1842. He received his elementary education and his first notions of sculptural art in an engraving factory in Vilna. In 1863 he entered the Academy of Fine Arts and within two years received a prize for his wood carving 'Evening Toil of an Old Jew' and another for the carving in ivory, 'The Parsimonious Jew.' As early as 1865 he attracted general attention and the Emperor sent him abroad at his own expense to continue his studies. In 1871 appeared his remarkable work, 'Ivan the Terrible,' which induced the Academy to elect him a permanent member. By order of Alexander II the statue was founded in bronze and a plaster molding of it was sent to the Kensington Museum in London. At that time Antokolskii made the sketches 'The Controversy about the Talmud' and the 'Attack of the Inquisition on the Jews'; in 1872 the colossal statue of 'Peter I,' also the historic figures of 'Yaroslav the Wise,' 'Dimitrius of the Don' and 'Ivan III.' Three years later his 'Christ before the People' was accepted by Alexander II and a marble copy of it was sent to the Paris Exposition of 1878. His other works executed at that time ('Death of Socrates,' 'The Last Breath,' 'The Head of John the Baptist,' etc.) established his fame and the French Academy bestowed on him the cross of the Légion d'Honneur. In 1880 the Academy of Arts in St. Petersburg organized a general exposition of his works (sculptures and sketches) and bestowed on him title of professor of sculp-

ture. Soon afterward he went to Paris where he produced 'Spinosa,' 'Nestor,' 'Not of the World' and a great number of bust-portraits of notable personalities in France and Russia. Antokolskii's work represents an epoch in the Russian history of sculpture by its originality and individuality; he refrained from imitating the ancients whose aim was beauty of form, but adopted and observed as his key-note beauty of thought and conception. He has lived to the height of his task and has succeeded to a high degree in supplanting the beauty of form by beauty of thought.

ANTOMMARCHI, ăn'tôm-mărk'ĕ, Carlo Francesco, Italian physician: b. Corsica, 1780; d. Saint Antonio, Cuba, 3 April 1838. He was professor of anatomy at Florence when he offered himself as physician of Napoleon at Saint Helena. Napoleon as first received him with reserve, but soon admitted him to his confidence, and testified his satisfaction with him by leaving him a legacy of 100,000 francs. On his return to Europe he published the 'Derniers Moments de Napoléon' (1823). He also wrote the text for a folio series of anatomical plates published in 1823-26, and in 1830 exhibited what he asserted to be a death mask of Napoleon. In 1836 he went to New Orleans, where he practised homœopathy.

ANTONELLI, ăn'tô-nĕll'e, Giacomo, Cardinal, Italian ecclesiastic: b. 1806; d. 1876. He was educated at the Grand Seminary of Rome, where he attracted the attention of Pope Gregory XVI, who appointed him to several important offices, and on the accession of Pius IX, in 1846, Antonelli was raised to the dignity of cardinal-deacon. Two years later he became President and Minister of Foreign Affairs, and in 1850 was appointed Secretary of State. During the sitting of the Œcumenical Council (1869-70) he was a prominent champion of the papal interest. He strongly opposed the assumption of the united Italian crown by Victor Emmanuel.

ANTONELLO DA MESSINA, Sicilian painter: b. Messina about 1430; d. 15 Feb. 1479. But few artists of Antonello's importance have left such slight clues for the biographer, and it is only in recent years that the diligent investigations of archaeologists have brought to light a certain amount of sure material as to the painter and dispelled the errors previously believed. We now know from contemporary documents that he was the son of Giovanni, a sculptor, whose family name was D'Antonio. The painter's history is covered by the few dates we have concerning him. In 1457 he received a commission for a banner for a church at Reggio, Sicily. In 1460 he was in Calabria and in the next years at Messina again. In 1475 he was at Venice, where in March 1476 "he received an invitation to enter the service of Galeazzo Maria Sforza, Duke of Milan. Antonello accepted the invitation; but by the following month of September he was back at Messina." He continued to live there until his death. Vasari's well-known story that Antonello journeyed to Flanders and learned the secret of oil painting from Jan van Eyck by introducing himself in disguise into the studio of that painter has been doubted in recent years because Vasari's account of the great Sicilian is inaccurate in many respects. Yet certain

facts remain which keep open the possibility that our best guide in the history of old Italians may prove to be right again. One of these facts is that Antonello had mastered the technique of oils at a time when no countryman of his knew how to employ them, whereas the Flemings were already proficient in their use. Besides, there are evidences in Antonello's work that he knew Flemish architecture, and if it be allowed that he could have learned oil-painting from seeing Flemish pictures of which there were numbers in southern Italy, it seems extremely improbable that he could have introduced into his work the representation of places that he had not seen. Two examples in point are the 'Head of a Man' at Bergamo and Mr. H. C. Frick's 'Deposition from the Cross' in New York. Again the old claim that he taught oil-painting to the Venetians may easily be substantiated yet, if it is discovered that he was in Venice prior to the journey of 1475 which is the only one of which we have a sure record. We know of no Venetian painting in oil previous to 1473, and we are certain that Antonello's stay in Venetia had a marked influence on the northern painters. The discovery of oils certainly changed Venetian painting most radically. Leaving aside historical considerations which are too apt to absorb attention when writing of Antonello, we see him as one of the very great artists of the Renaissance. The Flemish precision which was the staff on which he leaned in early years was quickly transmuted by him into a greater thing—his Italian feeling for the rhythm of line giving a new meaning to the draughtsmanship he inherited. We have but to consult the 'Saint Jerome' of the National Gallery, London, or the 'Saint Sebastian' in Dresden to confirm this idea. To find his peers in the handling a contour one must go to the supreme men, like Leonardo. His startling insight into the psychology of his portrait-sitters is to be observed in such works as the 'Condottiere' of the Louvre or the 'Portrait of a Man' at the Borghese Gallery in Rome. One feels the tremendous originality of the artist before a composition like the 'Crucifixion' of the Antwerp Gallery, supported by his impeccable mastery of form and his beautiful color. Other important works by him are the 'Salvator Mundi,' probably an early picture, in the National Gallery, London, which also possesses a 'Portrait of a Man'; the 'Dead Christ' at the Vienna Museum, and the very fine 'Man's Portrait' in the Berlin Museum. The last named is considered by many the best example of his work. Antonello was the only great painter of the Renaissance in south Italy. His reputation was as great among his contemporaries as in modern times. Consult the monographs by Di Marzo (Palermo 1903), and D'Amico (Messina 1904), and L. Venturi, 'Le origine della pittura veneziana' (Venice 1907).

ANTONINE COLUMN, the name given to the sculptured pillar erected by Marcus Aurelius to the memory of his father-in-law, Antoninus Pius. The splendid staircase, with 190 steps hewn in the 19 blocks of marble of which the column is composed—the statue of Saint Paul crowning its top—and the bas-reliefs around the column illustrating the victories of Marcus Aurelius over the Marcomans, present an appearance of singular magnificence.

The Doric and Corinthian styles are blended in the architecture of the column in a remarkable manner. The pedestal and top are Doric, while the proportions of the column are Corinthian. The bas-reliefs, in imitation of those of the column of Trajan, are in beauty and purity of execution rather inferior to the original. The column was restored to its present condition in the latter part of the 16th century by Domenico Fontana, the architect of Sixtus V, and still stands in the Piazza Colonna as one of the chief ornaments of Rome.

ANTONINUS, Marcus Aurelius. See AURELIUS ANTONINUS, MARCUS.

ANTONIUS, Gaius, Roman consul, the colleague of Cicero, who defended him when accused of participation in the Catiline conspiracy. He was the son of Marcus Antonius the orator, and an uncle of Mark Antony.

ANTONIUS, Marcus, famous Roman lawyer surnamed the Orator: b. 143 B.C.; d. 87 B.C. He was prætor in 104, when he fought against the pirates of Cilicia; consul in 99, when he distinguished himself by his resistance to the party of Saturninus; and censor in 97. He was famed for his eloquence in the forum, rendering, according to Cicero, Italy the rival of Greece, and for his integrity in public life. As an aristocrat he adopted the party of Sylla, and was put to death by Marius and Cinna, when they triumphed. He was one of the interlocutors in Cicero's 'De Oratore.'

ANTONIUS, Marcus, commonly known as Mark Antony, a Roman triumvir: b. 86 B.C.; d. 30 B.C. He was the grandson of Marcus Antonius, the greatest orator and one of the greatest men of his day. His father, also Marcus Antonius, was surnamed Creticus in derision, from a disgraceful defeat which he suffered in an unprovoked invasion of the isle of Crete. He went abroad early, served with Gabinius in Syria, and distinguished himself greatly, both there and in Egypt, where he already gave tokens of consummate soldiership. He next joined Cæsar in Gaul, where he passed several campaigns with increasing honor as one of his legates, and deserved much of the credit, usually given to his leader, for the total defeat of Vercingetorix at the terrible siege of Alesia. Being elected one of the tribunes of the people, when the Senate ordered Cæsar to disband his forces, he, with Quintus Cassius, vetoed the bill; and, on the Senate proceeding to arm the consuls with dictatorial power by the vote *ne quid respublica detrimenti capiat*, they fled together, disguised as slaves, to Cæsar's camp, feigning to believe that their lives were in danger, thus giving that ambitious general the desired occasion for crossing the Rubicon and marching upon Rome. In reward for this service, when Cæsar went to follow up his fortunes by crushing out the Pompeian party in Spain, he left Antony governor of Italy and lieutenant-general of his forces. He astounded all Italy by the ostentation and cynicism of his vices, but when the last struggle took place between Pompey and his own commander, he at once laid aside the debauchee and resumed the soldier. His skill preserved the fleet and intrenchments at Dyrrachium; it was he who commanded the victorious left wing in the crowning conflict at Pharsalia, and turned the wavering tide of

success to the standards of Cæsar. When the Ides of March had come, and great Cæsar fell at the base of Pompey's statue, it was the masculine and sonorous eloquence of Antony — for he was an orator second to Cicero and Cæsar only — that did actually raise the stones of Rome to mutiny and forced the discomfited murderers to fly from their half-finished task. It was Antony's soldiership and Antony's sword that defeated Cassius and drove Brutus to suicide, while the cold, cowardly, crafty Octavius was sleeping in his secure tent. In the proscriptions which followed it is characteristic of Antony that he was by so much the more insolent, as he was the less cruel, of the triumvirs. But the third triumvir, the imbecile Lepidus, was soon disposed of, and Octavius and Antony divided the Roman world, as masters. Antony took the East; Octavius, the cold formalist, betook himself to the West. Thenceforth the life of Antony was one wild dream. Once he broke from his luxurious lethargy, invaded central Armenia and penetrated Parthia; and then, forced to retreat at length by the circumstances of the country, the climate, the innumerable hordes of Oriental horse, brought off his army by a most extraordinary retreat. In 21 days he fought 18 pitched battles, marched 300 miles, through one continuous skirmish, and when he reached the boundary stream his Parthian pursuers unstrung their bows and bade him go away unharmed. He returned to his life of luxury and to Cleopatra, but his career was run. Rome took arms against him; his troops, his mistress, his fortune deserted him; and Actium saw him, for the first time, with his back to his foes. Deceived to the last by the Egyptian Queen, who imposed upon him by a false rumor of her death, he died by his own hand. Most like he was to Mirabeau in that he was everything at times, and in everything almost the greatest, but nothing long — orator, soldier, statesman; trifler, buffoon; tribune, triumvir, conqueror; faithful lover, false husband, frantic debauchee; and, when the wine of life was quaffed to the lees, a fearless suicide at last.

ANTONY AND CLEOPATRA. On 20 May 1608. Blount entered in the Stationers' Register "A Book called Antony and Cleopatra." This was undoubtedly Shakespeare's 'Antony and Cleopatra.' Internal evidence also places the date of composition at 1607-08, when the dramatist was in the full maturity of his powers. So far as we know, the play was not printed until it appeared in the First Folio of 1623. Shakespeare's single source, 'The Life of Marcus Antonius' in North's 'Plutarch,' is followed closely, except for certain omissions which serve to accelerate the dramatic action and to free Antony from unjust charges of voluptuousness and cruelty brought against him by history. While 'Antony and Cleopatra' ranks high among the great tragedies of Shakespeare's third period of dramatic activity, it is the most faultily constructed of all of them. Certain critics profess to have detected a change of emphasis at the end of the third act, where the purely historical interest of the first part gives way to the psychological and personal interest connected with the two principal characters in the second part of the play. But the apparent change of emphasis is unreal; the latter interest is dominant throughout the

play, the historical material of the first part merely furnishing a spectacular background of empire and war for the drawing of protagonists of almost superhuman proportions. A more serious blemish is the confusion resulting from the introduction, particularly in the fourth act, of short, scrappy scenes of battle with constantly changing groups of actors. As in the fourth act of 'King Lear,' the necessity of taking in imagination frequent and fatiguing journeys over thousands of miles is bewildering to the reader's mind and detracts from the impression of unity necessary in a perfectly constructed drama. In spite of differences of opinion, however, 'Antony and Cleopatra' is a pure tragedy, in which the moral purpose of the dramatist predominates over either historical or political considerations. The whole play is a powerful elaboration, in language of unparalleled beauty and imaginative power, of the theme of inevitable destruction visited upon a man of extraordinary possibilities because of voluptuous self-indulgence. Antony, a man of prodigal powers and of heroic but unsymmetrical proportions, is placed in an enervating atmosphere of sensuous splendors; the strong sensual set of his nature responds to the physical fascination of Cleopatra so that he becomes her slave; his imagination is ensnared by her endless variety; and, in spite of vigorous resistance, he finally plunges to destruction. His nobleness of nature takes corruption from his one "vicious mole of nature." He loses his prodigious energy, forgets the meaning of honor, his judgment becomes impaired and the joy of life is swallowed up in the despair of spent forces, out of which he snatches just strength enough to die bravely. Though Shakespeare denies none of the glory of earthly pomp and the splendor of sensuous passion, still as an artist he is true to the moral law which pronounces the worship of pleasure a deceit and a snare. In Cleopatra, Shakespeare has given us the most complex and wonderful of all his miraculous creations of women. She is the personification of voluptuous attractiveness, whose fascination lies in her power of appeal not merely to the senses but to the sensuous imagination. In spite of her superior mental qualities, her unparalleled grace and beauty, and her vivacity of imagination, we still find in her all that is gross and wanton in womanhood. As Mrs. Jameson says, "Cleopatra is a brilliant antithesis, a compound of contradictions, of all that we most hate, with all that we most admire." Yet such is the art of Shakespeare that the reader is nowhere brought into sympathetic relationship with her personality. We see the disastrous effects of her witchery and charm upon those about her; we have reported to us the fact of her fascination; but when she appears she is for the most part unattractive, irrational, capricious, cunning and at times even repulsive. While we may admire her spirit on occasion, her moral obliquity never has our sanction; we have neither love for her in life nor pity in death. Though her love is not purified by suffering, as some have maintained, still we cannot help feeling that in the creation of this infinite character Shakespeare has given to life a new and fuller meaning.

ANT PLANTS. See MYRMECOPHILY.

ANTRAIQUES, än'trâg, Emanuel De-launay, COMTE D', French politician: b. Villeneuve de Berg, 1755; d. 22 July 1812. His talents first appeared in his 'Mémoires sur les Etats-généraux' (1788), full of daring assertions of liberty, and one of the first sparks of the fire which afterward rose to such height in the French Revolution. When chosen, in 1789, as a deputy, he defended the privileges of the hereditary aristocracy, ranked himself with those who opposed the union of the three estates, and maintained that the royal veto was an indispensable part of good government. After leaving the Assembly in 1790, he was employed in diplomacy at Saint Petersburg and Vienna, where he defended the cause of the Bourbons. In 1803 he was employed under Alexander of Russia in an embassy to Dresden, where he wrote against Bonaparte a brochure entitled 'Fragment du XVIII Livre de Polybe, trouvé sur le Mont Athos.' He afterward came to England and acquired great influence with Canning. He was murdered, with his wife, at his residence near London, by an Italian servant.

ANTRIM, Ireland, county in Ulster Province, bounded on the north by the Atlantic Ocean; east by the North Channel; south by the river Lagan and Lough Neagh and west by the river Bann. Its area is 1,237 square miles (Pop. 193,864), nearly all of which is under cultivation. There are rich beds of iron ore at Glenravel, and extensive mines of fine salt are being worked at Dunerul and Carrickfergus. The chief occupations of the people are the raising of flax, fishing, and the manufacture of linen, cotton and heavy woolen goods. The capital is Belfast, and other places of note are Larne and Carrickfergus. The town of Antrim, situated at the north end of Lough Neagh, on the Six-Mile Water, is not a place of much consequence, though bleaching and malting and the linen and paper manufacturing are carried on here. There is a very perfect round tower near it.

ANTROBUS, än'trö-büs, Sir Edmund: b. 1848; d. 11 Feb. 1915; the last hereditary owner of Stonehenge, which was included in the Amesbury Abbey estate. This remarkable pile of monoliths is considered the oldest structure in the British Isles erected by the hand of man. In 1902 Antrobus was the target of severe criticism owing to his decision to erect a fence around the pile and to exclude visitors, a step rendered necessary to protect the historic monument from the vandalistic propensities of excursionists. Stonehenge was sold by auction in September 1915 to Mr. C. H. E. Chubb, of Salisbury, for \$33,000.

ANTROPOV, Alexeyi Petrovich, än-trö'-pof, a Russian painter, a pupil of A. Matvyeyev,

of the icon painter Vishnyakov and of L. Caravac: b. 14 March 1716; d. 12 June 1795. A prominent "Elizabethan," a master of design and of perspective and in several respects a person of no ordinary calibre, his special and particular merit was that independence of character which prompted the establishment of his own school of painting—a school that counterbalanced the official academy and produced one of the greatest of Russian painters, Levitzky. "The descendants of the latter," writes A. Benois in 'The Russian School of Painting' (New York 1916), "have to this very day preserved memories of Antropov, as of an independent man who held in disdain the official artistic world and warned his young pupils against the pernicious influence of the Academy." He began his quest of an artistic education when only 16 years old, in studios of different Russian and foreign painters, and again, when Rotari came to Russia about the middle of the 18th century, gladly availed himself of the opportunity to assimilate and make his own the firm and lucid manner of that Italian master; for the independence he had asserted and sustained against academic prejudice was not based on obstinacy or complacent self-esteem. It is in the manner perfected under Rotari's influence that Antropov's two best portraits are executed—the portrait in the Tretyakov or Tréliakof Gallery (identity of sitter unknown) and the portrait of the Countess Rumyantzev in the Museum of Alexander III. The latter work, dated 1764, is most characteristic. Incomparably weaker are his portraits of the czars, for the simple reason that Antropov, when painting these, was obliged to have recourse to data supplied by other people. These are not "from life"; and so rather helplessly the artist, unpracticed in this particular form of invention, "heaped up in these portraits all sorts of details" borrowed from Tocqué, Grot and Develis. By Antropov are also various paintings of sacred subjects for the Empress and for many churches (the icons preserved in the Church of Saint Andrew at Kiev being of special interest); a full-length portrait of Czar Peter III, and a portrait of Catharine II in coronation robes.

ANTS MONITE. See STIBNITE.

ANTWERP, Belgium (Dutch, *Antwerpen*; French, *Anvers*; Spanish, *Amberes*; Old German, *Antorff*; from "aent werf," "on the wharf"), the northernmost province, consisting largely of an extensive plain of 1,096 square miles, scarcely diversified by a single elevation. It is sandy but fertile, producing grain, flax, hemp, fruit and tobacco, as well as cattle, sheep and horses; on the north and northeast, however, there are considerable tracts of morass and heath. The principal rivers, the Scheldt and its tributaries, the Rupel, Nèthe and Dyle, are navigable; while railways intersect the country in various directions, and there are also several canals. The chief towns are Antwerp, Mechlin (Malines), Turnhout, Lierre and Boom. Pop. 1,005,000.

ANTWERP, Belgium, capital of the province of the same name, situated about 50 miles from the open sea and 25 miles north of Brussels, in a level tract on the right bank of the Scheldt, which is there about 2,200 feet broad and has a depth at ebb-tide of from 30 to 40 feet, with a rise at spring-tides of 12 or 14.

Since 1905 new docks and granite quays with every modern improvement have greatly added to Antwerp's reputation as one of the finest harbors and one of the busiest commercial ports in the world. The volume of its exports averages annually from 6,500,000 to 8,000,000 tons in recent years, valued at from \$360,000,000 to \$450,000,000, while the imports average slightly above the same amounts—the largest of the imports being grain. The chief manufacturing industries of Antwerp comprise textiles, brewing, distilling, diamond-cutting, sugar refining, cigars and tobacco. Modern Antwerp is one of the most attractive of improved European cities. It still retains a few of its historical buildings.

The Cathedral of Notre Dame, dating from the 14th century, is its most noteworthy edifice, the largest and most beautiful Gothic structure in the Low Countries, with a tower over 400 feet high. Its area is 70,060 square feet and it contains Rubens' paintings, 'The Descent from the Cross,' 'Elevation of the Cross' and 'The Assumption.' Other important buildings are the church of Saint Jacques, begun in 1491, the Hotel de Ville, the Bourse, the Museum, the old Meat Market, the Archers' Guildhall and the restored Steen, part of the old 10th century castle, now occupied as a museum of antiquities. Fine boulevards mark the sites of ancient city walls and ramparts which were gradually extended and improved until they attained a circuit of over eight miles with a system of eight outlying forts for defenses. After the Franco-German War of 1871-72 this system was strengthened by a second extended line of 15 forts which by 1913 were considered to have made Antwerp one of the strongest fortified cities in the world.

Antwerp is the birthplace of a number of distinguished men in various departments, as the painters Vandyck (b. 1599), Teniers the elder (1582), Teniers the younger (1610), Jordaens (1594), Frans Floris (1520), Gonzales Cocques (1618); the philologist Gruter (1560), the geographer Ortelius (1527), the engraver Edelinck (1649), and, among more modern celebrities, Van Materen the historian, Ogier the dramatist, and Henri Conscience the novelist. Rubens was born at Cologne, but his family belonged to Antwerp, and he was educated, resided and died in the latter city.

Antwerp was probably founded some time before the 8th century, when the Antwerpians or Ganerbian, as they began to be called, were converted to Christianity. In 837 the town fell into the hands of the Northmen, who kept possession of it for about 60 years. It was erected into a marquise of the Holy Roman Empire by Henry II in 1008, and as such was bestowed by Henry IV, in 1076, on Godfrey of Bouillon. About the beginning of the 12th century it had considerable commercial prosperity; and in the 13th its municipal institutions took definite shape. It is worthy of notice that the law of 1290 contained provisions identical with those of the Habeas Corpus Act of England, maintaining the inviolability of the citizen's dwelling and acknowledging the right of every man to be judged by his peers and to have a voice in the imposition of taxes. As the result of such security and freedom the commerce of the city rapidly increased. English wools for the great manufactories at Louvain,

Brussels, Tirlemont, Diest and Leau were imported through Antwerp; and English merchants, who formed a "factory" there in 1296, received special protection by charters (1305, 1341, 1346, 1349) from the Dukes of Brabant. Between 1488 and 1570 was the time of the greatest prosperity which Antwerp was destined to attain for several centuries. The discovery of America in 1492, and of the passage to India in 1497, produced a great change in all European navigation, permanently altering the old courses of commerce. While in consequence of this the cities of the Hanseatic League had withered, and Venice, Nuremberg and Bruges were sinking into decay, Antwerp was rapidly growing wealthy, but in 1576 it was taken by the Spaniards and given up to a three-days' pillage. It was vainly besieged by the Duke of Alençon in 1583; and after a very obstinate defense it fell before the assaults of the Duke of Parma, whose triumphal entry took place 17 Aug. 1585. Its glory departed; its commerce was ruined; its inhabitants were scattered. The Dutch in their jealousy endeavored to complete its ruin by building forts on the river to intercept the passage of ships; and finally, by the peace of Westphalia in 1648, the Scheldt was definitely closed. In 1794 the city fell into the hands of the French, who opened the river and made Antwerp the capital of the department of Deux Nèthes. It continued in French possession till 1814. Matters of dispute between Belgium and Holland being settled by the treaty of 1839, Antwerp continued peacefully to advance in prosperity until the outbreak of the great European War in 1914, when during the German invasion, the city was subjected to Zeppelin raids and the forts underwent a bombardment of 10 days and were reduced to ruins. The Belgian army with their British allies withdrew and, without any form of surrender, the Germans entered and occupied the city 9 Oct. 1914, subsequently levying oppressive tribute on the inhabitants. Population (exclusive of suburbs) 312,000; with suburbs, 399,000.

ANUCHIN, Dimitri Nikolaievich, ä-noo'-chën, Russian anthropologist and geographer; b. St. Petersburg, 27 Jan. 1843. Elementary education he received in a gymnasium. Later he studied history and philology at the University of St. Petersburg; specialized in anthropology and zoology at the University of Moscow. In 1880 the University of Moscow awarded him the degree of M.A. for the dissertation 'Concerning Certain Anomalies of the Human Skull.' After a preliminary preparation abroad at the expense of the university, he was appointed assistant professor in anthropology, in 1884 sub-professor in the newly established faculty of geography and anthropology, and in 1887 regular professor. In 1889 the University of Moscow awarded him the honorary degree of doctor of geography. He was the first to introduce the teaching of anthropology, ethnology and agriculture in Russian universities. He originated at the University of Moscow an anthropological museum (1879) and a Museum of Geography (1892). He has been connected with the Society of Amateur-Students of Anthropology, of which he was in succession secretary, associate chairman of the department of anthropology, vice-president and, since 1892, president. At his initiative a department of

geography was established at the University of Moscow (1892), which in 1894 started the publication *Zemleviedeniye* (Geography) with Anuchin as editor. After 1875 he took part in the activities of the Imperial Archæological Society of Moscow, of which he was associate chairman for 20 years. He is an honorary member of the Academy of Science of the University of Kazan, of the London Anthropological Institute and of many other scholarly societies. His most valuable works are his popular scientific articles published in *Priroda* (Nature, 1874-75); 'Obschestvo Liubitelei Yes-testvovedeni,' (Bulletin of the Society of Amateur-Students of Natural History 1887); 'Western Geographical Society' (1889); 'Drevnosti' (Antiques, ed. by Archæological Society of Moscow 1890); 'Zemleviedeniye' (Geography, 1895); 'Trudui VI Odesskavo Archæologicheskavo Syezda' (Vol. VI of the Archæological Society of Odessa, 1886); 'Trudui V Tiflicheskavo Archæologicheskavo Syezda' (Vol. VI of the Archæological Society of Tiflis, 1887); and other scientific publications. A series of his scientific articles is also published in the 'Encyclopædic Dictionary' of Brockhaus and Efsen. He also contributed to *Russkaya Viedemosti* whose publisher he has been since 1883 and one of its editors since the nineties.

ANUS, the external termination of the rectum. The external and internal sphincter muscles keep it firmly closed and the levator ani muscle supports the rectum and pelvic structures and lifts up the lower end of the gut during the act of defecation. Infants are sometimes born with a congenital closure of the rectum, consisting usually of a thin skin. The obstruction is removed by a simple surgical operation. Occasionally there are more complicated cases, such as when the gut terminates in a blind sack at a distance from the rectum, or when the rectum terminates in the bladder or vagina. These cases require opening of the abdominal cavity and creating an artificial anus in the lower part of the abdominal wall. The anus is subject to various diseases. Ulceration around or within the anus is a frequent occurrence in persons of uncleanly habits. Attention to cleanliness and treating the ulcers with caustics generally effect a cure. Fissure or cracks in the folds of the skin at the verge of the anus cause great pain during evacuation and are usually treated by a diet tending to procure regular and softer evacuations, and immediately sponging with warm water. Various ointments are also applied to promote healing. Pruritus ani or itching often causes suffering and discomfort and may result from any general disorder of the system. It generally disappears when the cause is removed. Other diseases of the anus are fistula, piles and prolapsus.

ANVIL, an iron or steel block with a smooth top on which malleable metals are hammered and shaped. They vary in size from the small articles used by gold- and silversmiths or jewelers to the huge blocks of power hammers. Blacksmiths' anvils have a cone at one end of the flat face for rounding metals such as horse-shoes. Anvils generally are made of cast iron faced with steel.

ANWYL, än'wl, Sir Edward, Welsh: philologist and author; b. 1866; d. Pontypridd, South Wales, 8 Aug. 1914. He was formerly

professor of Welsh and comparative philology at the University College, Wales, was member of many educational bodies and published several books on the Celtic language, literature and religion. He was knighted in 1911 and shortly before his death was appointed principal of the Monmouthshire Training College.

ANZAC, an'zác, Turkey, a name given by the British to a cove at Gaba Tepe, on the Gallipoli peninsula. The word is made up of the initials of the Australian and New Zealand Army Corps, previously assembled at the concentration camps in Egypt, which landed at this spot during the Entente Allies' ill-fated Dardanelles campaign 3 March 1915. It was proposed to alter the name to "Anziac," the addition of the letter "i" being meant to include the Indian Corps which arrived in April, and with a powerful force of troops from southern France, reinforced the Allies in their naval attack on the Dardanelles, the British colonials being assigned to the European side and the French to the Asiatic. The operations were successful at first, and the Allies established themselves firmly around their positions, although the Turks under the guidance of their German officers inflicted severe losses. Almost daily fighting continued until a landing was effected by new troops 6 August at Suvla Bay, 20 miles from the Anzac position, and fresh attacks were made in conjunction. The attack by the Anzac troops, after a series of desperate actions, was carried to the summit of the dominating Sari Bahr and the Chanak Bahr ridges, and although repulsed, positions were consolidated effectively close by. More fighting occurred until the abandonment of the Dardanelles campaign led to the successful withdrawal on 19 December of the colonial troops from the lines which they had so gallantly won and held for over five months at Anzac and Suvla Bay in the rear of the Dardanelles forts. See AUSTRALIA AND THE WAR.

ANZENGRUBER, an'tsén-groo-bër, Ludwig, German dramatist: b. Vienna, 29 Nov. 1839; d. Vienna, 10 Dec. 1889. In early life he sometimes wrote under the pseudonym L. Gruber. His father's ancestors were Austrian peasants and his mother was of Viennese descent. The elder Anzengruber, who was an admirer of Schiller, tried his hand at writing dramas and stories but without success. He was instrumental, however, in early turning the attention of his boy to the drama and the theatre. The family lived in straitened circumstances and when the father died young Ludwig had to take a position in a bookstore. The duties of the position did not greatly appeal to him, but he had an opportunity to satisfy his taste for wide reading. His early interest in the theatre developed and in 1859 he became a traveling actor, going about the country accompanied by his mother. On these journeys he had opportunity to become acquainted with various types of characters which he later embodied in his dramas and novels. In fact, these travels brought nearly all the knowledge of peasant life that he possessed, as the rest of his days were spent in Vienna.

In 1869, after having been without a theatrical engagement for some time, he took a position as clerk in the Vienna police department. This experience he always valued, as it

made him more intimately acquainted with human nature and gave him a knowledge of the seamy side of life. He wrote popular plays all along but had achieved success with none of them, when suddenly in 1870 he became famous with his 'Pfarrer von Kirchfeld.' The public was visibly affected when it was presented on the stage and its reputation was helped by the favorable criticism of Heinrich Laube. Anzengruber now resigned his position with the police department and devoted all his attention to literary work. Among his dramas of this period 'Der Meineidbauer' (1871), 'Die Kreuzelschreiber' (1872), 'Der G'wissenswurm' (1874), 'Der Doppelselbstmord' (1875), 'Der ledige Hof' (1877), 'Das vierte Gebot' (1877) are the most important. In 1878 he was awarded the Schiller prize.

Then followed a period of unproductivity in the drama due largely to the failure of two of his plays in 1879. The years 1880-84 were mostly devoted to the writing of novels and short stories and the editing of a journal, *Die Heimat*. In 1885 he secured a fixed income as editor of the humorous paper *Figaro*. Beginning with 1886 the interest in his dramas was again revived in Vienna. In the meantime he had made his reputation in north Germany. 'Das vierte Gebot' had been especially well received in Berlin. In 1886 he was awarded the Grillparzer prize for his drama 'Heimg'funden' (1885). Of his later dramas 'Stahl und Stein' (1886) and 'Fleck auf der Ehr' (1889) should be mentioned. At this time the Vienna theatres were again producing his plays with continued success. When Anzengruber died in 1889 he was the leading dramatist of the German-speaking people of that day.

He also wrote novels of interest and power, the chief ones being 'Der Schandfleck' (1876, rewritten 1883) and 'Der Sternsteinhof' (1885), and a number of excellent short stories. But his great importance as a writer is in his dramas. He was a reformer of the German stage. He put his plays upon a popular basis. His characters are largely original and selected from among the people, many of them using the dialect of the Austrian peasantry. He depicted life in a realistic manner as he himself saw it and had experienced it. The popular farce, as it existed on the Vienna stage at that time, he developed into a dignified drama of psychological depth. The scenic effect of his plays was heightened by making use of music. He was imbued with optimism and a genuine humor emanates from his characters. Withal he was serious of purpose and didactic, at times extremely so, some of his characters having a tendency to preach and to exhort. (See PRIEST OF KIRCHFELD, THE.) Consult *Gesammelte Werke* (10 vols., 1890; 3d ed., 1897); Bettelheim, A., 'Ludwig Anzengruber, der Mann, sein Werk, und seine Weltanschauung' (in 'Geisteshelden,' Vol. IV, 2d ed., Berlin 1898); Friedmann, S., 'Ludwig Anzengruber' (Leipzig 1902).

WILLIAM F. HAUFHART,
Assistant Professor of German, University of Michigan.

AORIST (Greek, *aoristos*, "indefinite"), the name given to one of the tenses of the Greek verb, expressive of indefinite past time. The Greek verb is very rich in past tenses,

possessing besides the aorist the imperfect, perfect and pluperfect. While these express repetition, continuance or the relation between one time and another, no such shade of meaning attaches to the aorist. The difference between the first and the second aorist is in form only and not in meaning.

AORTA, the name given to the great arterial trunk of the body. It springs from the left ventricle of the heart, arches backward to the vertebral column, and, descending in the back portion of the thorax, passes through the diaphragm into the posterior part of the abdomen, at the lower portion of which, opposite the fourth lumbar segment of the spinal column, it divides into the two common iliac arteries. Throughout its course it becomes smaller and smaller, and gives off a large number of branches that send blood to all parts of the body. It is not divided into any distinct divisions, but for conventional purposes of description anatomists describe three parts, the arch, the thoracic aorta and the abdominal aorta. The arch reaches to the lower border of the fifth thoracic vertebra; from this point to the opening in the diaphragm it is known as the thoracic aorta; from the diaphragm to its bifurcation into the iliacs, the abdominal aorta. At its very beginning at the top of the heart it gives off the coronary arteries that supply the walls of the heart with blood. The arch is then conventionally divided into three parts, the ascending, transverse and descending portions. From the transverse portion of the arch the great vessels of the neck, head and arms are given off,—the innominate or brachiocephalic artery, that goes to the head and upper extremity of the right side, the left common carotid, to the head on the left side and the subclavian that supplies the upper extremity of the left side. There are really two large arteries supplying each side, but on the right they arise from the one branch from the aorta, while on the left side the arteries going to the head and to the upper extremities are separate. The thoracic aorta lies close to the spinal column in the chest. It supplies arteries extending to the walls of the chest and to all the viscera in the thorax, lungs, etc., save the heart. The abdominal aorta supplies the diaphragm, the muscles of the walls of the abdomen, the liver, kidneys, spleen, stomach, pancreas suprarenals, the small and large intestines, the spermatic vesicles and a part of the pelvis. The two great branches into which it finally divides supply the pelvic walls, the organs in the pelvis, the external genitals and finally the lower limbs. There are a number of variations in the details of the distribution of the different large vessels of the aorta, but these concern the anatomist. The walls of the aorta resemble in their microscopical structure those of the arteries of the body save in possessing more elastic fibrous tissues. This is necessitated because of the greater pressure on this part of the circulatory apparatus. See ARTERY; CIRCULATION; HEART.

AOSTA, ä-ös'tä, Italy, town in Piedmont, 50 miles northwest of Turin. It is the seat of a bishop, and possesses a collegiate and three parish churches, two colleges and two hospitals. Among its antiquities are a triumphal arch, erected to the memory of Augustus who rebuilt

the town and gave it the name of Augusta Prætoria; a gate with three arches, and the remains of an amphitheatre, and the old Roman walls which still surround the town. It has some trade in wine, cheese, hemp and leather.

AOUDAD, ä'oo-däd, or **ARUI**, a somewhat goat-like wild sheep (*Ovis tragelaphus*), inhabiting the Atlas Mountains of northern Africa. It is about three feet in height, and its horns, which resemble those of the bharal are about two feet long. It is especially characterized by the long whitish hair depending from the throat, chest and forelegs, but elsewhere its coat is short and light brown, enabling it to hide easily among the rocks of its mountain home. Many other names are given to it, as "ruffed moufflon," "bearded argali," "kebsh" (Egypt), "tidal" or "teybal," and "beden" (Nubia). It is a common resident in menageries, where it breeds readily.

AOUL, the finest of the Somaliland gazelles (*Gazella sammerringi*), with massive lyrate horns. Its height is about 30 inches, and the borders of the ears and face are strikingly marked with black.

APACHE, ä-pä'chê (Pima, "enemy"), the name of a large Indian tribe of the Athabaskan stock, kindred of the Navajos, and originally occupying the region from central Texas to the Colorado River in Arizona. The Spaniards applied the name, borrowed from the Pimas, to all the races just north of Mexico, whom they classed as Apachés de Xila, Apachés de Navajo, and Apachés Vaqueros, the first-named being our Apaches. When the United States by the Gadsden Purchase (q.v.) first came in contact with them they numbered about 10,000 and had long been at mortal feud with the Mexicans. For a few years they gave the Americans relatively little trouble of an acute kind, but after a serious raid in 1857 it was urged by those with knowledge that they should be settled north of the Gila, taught industries, and watched. This was not done, however, and in 1860 the whole tribe went on the warpath. The next year the Civil War caused the troops to be withdrawn, and in a short time the Apaches had murdered or driven out every white inhabitant of the Arizona Territory except a few hundred who took refuge in Tucson. For nearly 10 years the Territory was the scene of one of the most awful Indian wars in history, which practically stopped all progress there. On the Indian side it was entirely an affair of ambushes or of sudden raids from mountain strongholds, with burning and slaughtering, and carrying off of captives to be mutilated or outraged and then tortured to death. About a thousand men, women and children perished. Military operations were repeatedly stopped for a considerable period by the government commissioners, who wished to institute a policy of kindness, but finally Gen. George H. Crook was allowed to proceed without interruption in 1872-74, and put an end to the operations of the bands as a whole in 1874. But the government policy of concentrating them all on one reservation of San Carlos, Arizona, had unfortunate results. They objected to live with other bands with whom they were as much at feud as with the whites, and also to leave their chosen districts once given them by the government; but both General Crook and his successor,

who opposed the transfers, were removed to other departments. Again and again the bands escaped while being removed, and renewed their outrages; and for six years more there was a succession of bloody raids which swelled the total of horrors in the unfortunate Territory and New Mexico. In 1882 Crook was restored, and by tact and their confidence in him induced about 1,500, or over a fourth of them, to live on the reservation without rations. But the rest liked their life much too well to give it up; repeatedly they surrendered and returned with Crook only to break their promise and return to the warpath. The last time was in March 1886, when they escaped before entering Arizona and continued their outrages along the border for five months. The uproar against Crook for being duped (he had upheld the essential justice of their cause, and his belief in their willingness to behave, against the people) caused his replacement by Gen. Nelson A. Miles, who finally cornered the band and forced it to surrender. But the attempt to settle the Chirichuas and Hot Springs bands—the fiercest Indians on the continent, according to General Crook—on a reservation in Arizona roused such a storm of protest from Arizonians that they were removed to Florida instead, then to Alabama, and finally to Fort Sill, Okla., where they still remain, to the number of some 300. In all there are now about 5,200 Apaches. The name is sometimes applied to the Jicarillas, Mescaleros and Lipans by reason of linguistic affinities; but incorrectly. Consult Bancroft, 'Native Races of the Pacific States' (Vol. XVII, 1880).

APALACHEE, ăp-ă-lă'chē, or **APALACHI**, a tribe of Indians of the Muskogean stock, first mentioned in 1526 as occupying the territory about Apalachee Bay and Saint Mark's River in northwestern Florida and northward to the mountains to which they have given their name. Near the end of the 16th century Spanish Franciscan friars founded missions among them, till the war of the Spanish Succession, a century later, when the Spanish attempted to use the Indians as allies against the English Carolinas. Twice before the Spaniards had invaded Carolina from Saint Augustine; and now, in 1702, they headed a party of 900 Apalachees and marched into Georgia. The Creeks, who were friendly to the English, not only warned them, but a party of 500 ambushed the Apalachees and routed them with great slaughter. The Carolinians determined to take the offensive and after a fruitless expedition to Saint Augustine in December 1703 one was undertaken into the Apalachian territory, which supplied that city with provisions and contained many Spanish forts. With 50 white men and 1,000 Creeks its leader stormed one fortified town and won a sharp battle, capturing several hundred Indians with women and children. Five other towns surrendered unconditionally, while a powerful cacique capitulated for his own safety. The expedition returned in March 1704 with 100 Indian slaves and 1,300 free Indians, who were settled among the Creeks. Twice more within the next four years Carolina invaded this territory with such results that in 1708 it held 850 Indian slaves in addition to what had been given to the Creeks. The Apalachees were thus practically obliterated; and though for a time they

maintained their individual existence they finally became merged with the Creeks. Consult McCready, 'History of South Carolina under the Proprietary Government' (1897).

APALACHEE, ăp-ă-lă'chē, **BAY**, a large arm on the south coast of Florida, in the Gulf of Mexico, having a breadth of about 90 miles and an extent inland of 50 miles. At the mouth of the Saint Mark's River, which flows into the bay, is the town of Saint Mark's.

APALACHICOLA, ăp-ă-lăch-î-kô-la, Fla., city, port of entry and county-seat of Franklin County, on Saint George Sound (Gulf of Mexico), at the mouth of the Apalachicola River; 85 miles southwest of Tallahassee; on the Carrabelle, Tallahassee & Georgia Railroad and the following lines of steamships: Plant; People's; Merchants and Planters'; Gulf Navigation Company; Central Gulf Coast Company; and the Apalachicola and Chipola River line. The city has an important trade in timber and naval stores. The value of its foreign commerce in 1901 amounted to \$370,000, the most of which was in export trade. The city has one national and several private banks. Pop. (1910) 3,065.

APALACHICOLA, a river flowing from southeastern Georgia across Florida and entering the Gulf of Mexico through Apalachicola Bay. It is navigable throughout its length of 90 miles and is formed by the union of the Flint and Chattahoochee rivers.

APANAGE, or **APPANAGE**, an allowance formerly received by the younger princes of a reigning house in which the right of primogeniture prevailed, from the revenues of the country. It consisted mostly in money, with the use of a residence and hunting grounds, attended frequently with the right of jurisdiction over these domains.

APAR, ă'păr, the three-banded armadillo (*Tolypeutes tricinctus*), which has three movable bands and is one of the small species able to roll itself into a ball. See **ARMADILLO**.

APAREJO, ă'păr-ă'hô. This pack-saddle, most generally used in military service, consists of a strong leather sack, about two feet wide and from 55 to 60 inches long, according to the girth of the animal. A seam running from the front to the rear of the aparejo divides it into two equal parts, each of which is composed of a double layer of hide, with sufficient space between to introduce a suitable stuffing of hay, grass, moss, fibre, etc. These side-flaps, when fastened together at the top, form a ridge within which the backbone of the animal rests free from friction or pressure. On the inside of each flap is left a circular hole through which the stuffing material can at any time be reached. The careful packer should keep the stuffing evenly distributed, or so as to vary with the conformation of the back of the particular animal, as portions of it are constantly shifting and working up into lumps, in consequence of the travel. The drawings show the interior and exterior of the aparejo. To set up the aparejo, or to give it evenness and stiffness, small ash, rose or willow sprouts from one-half to three-fourths of an inch in diameter and as long as possible without springing (any tough and elastic wood will answer), are placed inside of it and at equal distances apart—about two

inches. On the inside of these and toward the animal coarse grass or hay (such as is light and tough and will not break up) is placed layer after layer until the sides are as full as possible. The corners should be stuffed as hard as possible by means of a sharp stick. Serious trouble is often experienced on long and toilsome marches from loss of flesh, causing the aparejo to fit badly and cause a sore back. Great care must be taken to make good all deficiencies in the stuffing, and when the aparejo is too large to be adapted to a thin animal by stuffing a portion should be cut out of the centre. Straw pads are useful for protecting the hips and withers when placed under the cinches of those animals carrying rough loads.

When the aparejo is stuffed it should be put on the animal for which it is intended and the crupper adjusted. The shape of the aparejo enables all loads to be nicely balanced. One hundred pounds on one side may be made to ride with 50 pounds on the other without straining the animal. It presents much more surface for pressure to the animal than any other form of pack-saddle. The lower corners secure the lash-rope and prevent it slipping when on the road. By removing the hay or stuffing from the side a sore back may be easily remedied and by properly adjusting the filling the aparejo may be made to perfectly fit a badly-shaped back. These may be cited as some of its advantages.

APARRI, ʌ-pār'ʀe, Philippines, town of the Cagayan province, on the river Cagayan, near its mouth. Pop. 11,265.

APARTMENT HOUSE, the term used in the United States to designate a structure intended to accommodate several families, each in its own set of rooms, which form a separate dwelling. Such structures are of comparatively recent introduction, but houses of this kind have long been built in Europe. In New York and other American cities there are now great blocks of such houses, which provide excellent and commodious dwellings at a lower rent than if each were a separate building. See ARCHITECTURE, AMERICAN.

APATITE (from the Greek *apatelos*, "deceitful"), a mineral related to raimondite, occurring in small yellow, friable nodules in

the immediate vicinity of Paris, France. It has the probable composition $4Fe_2O_3 \cdot 6SO_3 \cdot 3H_2O$.

APATITE (from the Greek word *apate*, "deceit," in allusion to the fact that apatite is often confused with other minerals), a native phosphate of calcium, combined with fluorine or chlorine and crystallizing in the hexagonal system, though also occurring massive. The crystals have a specific gravity of about 3.2 and a hardness of 5. Apatite is usually green, but it may occur white or strongly red, yellow, brown, or blue. The common variety has the formula $(CaF) Ca_3(PO_4)_2$ and is known as "fluor-apatite"; but the fluorine is sometimes replaced to a considerable extent, or even wholly, by chlorine. In such cases the mineral is known as "chlor-apatite." A variety called "mangan-apatite" is also known, in which the calcium of the typical mineral is partially replaced by manganese. Apatite is widely distributed, particularly as segregations in pegmatite dikes. The Canadian apatite occurs massive or in large crystals. It was formerly extensively mined as a fertilizer, but its use has now been almost entirely supplanted by the "rock phosphate" of Florida, South Carolina and Tennessee.

Apatite Group.—In mineralogy, a group of minerals crystallizing in the hexagonal system and consisting of arsenates, phosphates and vanadates of calcium and lead, associated with chlorine or fluorine. It contains apatite, pyromorphite, mimetite, vanadinite, hedyphane, pleonectite and svabite.

APE (A. S. *apa*, Ger. *Affe*), in modern usage, a term describing an Old-World tailless monkey, such as the gorilla, orang-utan, chimpanzee or gibbon, but originally an exact synonym for monkey and applied to any quadrumanous animal except the lemurs. For examples of this older usage see BABOON; MACAQUE; MONKEYS. In its modern sense it applies particularly to the family *Simiidae*, or anthropoid apes, found in the forests of the equatorial regions of the Old World and called "anthropoid" on account of their great resemblance to man. This likeness is especially marked in young individuals before the face has attained its full brutality of expression, the canine teeth their great size, and the skull its final thickening and growth into crests and ridges. Except for the shape of the jaw (which, instead of being curved, comes to a noticeable angle on each side with a canine tooth at the apex of each angle) and for the development of the skull already mentioned, as well as for the relative length of the arms and shortness of the legs and the fact that the great toe is short and more or less opposable to the other fingers, an ape's skeleton is practically the same as man's though larger and heavier in proportion to the body and lacking certain curvatures of the spine which adapt the human frame to ease in an erect position. The braincase and the brain itself are much smaller than in man, yet similar in development and the brain is much convoluted. The teeth are of the same number as man's and of like character. In certain divergences of structure exhibited between the inferior families of monkeys and man, the ape resembles man and differs from the monkeys.

The gibbons (noticeable for standing erect with less difficulty than any other apes), the chimpanzee (which has the largest brain), the gorilla, and the orang-utang, together with several extinct and fossil species, make up the anthropoid apes. All are clothed with hair on all parts of the body except the face and palms; they have no cheek-pouches, no tail and either no trace or but very slight traces of the naked spots or callosities seen upon the buttocks of the lower apes. All are as large or larger than man and all can walk upright, though they are more at ease in climbing than in walking. When on the ground they make their way slowly, sometimes closing the hands in order to walk on the knuckles instead of the palm and either similarly closing the foot or walking on its side. Their food is mainly vegetable, yet their great strength, their intelligence and their savage nature place them among the most dangerous of wild animals. See CHIMPANZEE; GIBBON; GORILLA; ORANG-UTAN; PITHECANTHROPUS.

APEGA, the wife of Nabis, a tyrant of Sparta, who invented an infernal machine which he called after his wife, "Apega." It was a box exactly resembling his wife in her royal apparel, but the interior was full of spikes which wounded the victim enclosed in almost every part of the body. The "Iron Virgin" was a similar instrument employed by the Inquisition. It represented a woman of Bavaria and the spikes were so arranged as to pierce the least vital parts in order to prolong the sufferings of the victim enclosed.

APEL, ä'pël, **Johann August**, German author: b. Leipzig 1771; d. 1816. His 'Gespensterbuch' and 'Wunderbuch' were both popular, the former containing the bases for the text of Weber's opera of 'Der Freischütz.' His 'Metrik,' which includes a survey of ancient prosody is his best-known work.

APELDORN, ä'pël-dörn, or **APEL-DOORN**, a notably attractive town of Holland, province of Guelderland, 17 miles north of Arnhem; with manufactures of paper, morocco leather and copper-plates. The Loo, a favorite palace of the late King of Holland, is at Apeldorn. Pop. about 28,000.

APELLES, the most famous painter of ancient Greece and of antiquity: b. in the 4th century B.C., probably at Colophon. He first studied at Ephesus, under Ephoros, and attracted by the renown of the Sicyonian school, he studied later at Sicyon. In the time of Philip he went to Macedonia and there a close friendship between him and Alexander the Great was established. The most admired of his pictures was that of Venus rising from the sea and wringing the water from her dripping locks. His portrait of Alexander with a thunderbolt in his hand was no less celebrated. His 'Anadyomene'; 'Artemis Surrounded by Maidens'; and 'Slander' were also famous and the detailed description of them by Lucian inspired later artists, among others Botticelli and Dürer. He appears to have returned to Asia after Alexander's conquests. He visited Protogenes at Rhodes and admired his work. He was noted for his just appreciation of his rivals. His industry was unremitting, especially in drawing, so great as to give rise to the proverb "No day without

a line." He is also the subject of many anecdotes, among which may be cited his reproving the cobbler. It was Apelles' habit to listen to the criticisms of the common people of his pictures by concealing himself nearby. A cobbler, having pointed out a fault in the shoe of a figure, Apelles rushed out and rectified it, but when the cobbler later criticized the legs of the figure Apelles told him to stick to the shoes, or, as the proverb has it, "Let the cobbler stick to his last." His renown was at its height about B.C. 330, and he died near the end of the century. Consult Houssaye, 'Histoire d'Apelles' (Paris 1867); Wustman, 'Apelles' Leben und Werke' (Leipzig 1870); Woltmann and Woermann, 'History of Painting' (Vol. I, Eng. trans., New York 1886).

APENNINES, the chief mountain range of Italy, about 800 miles long and 25 to 85 miles wide, extending from Savona to Reggio in the form of a bow. Geologically the Apennines resemble the Alps and connect them with the north Sicilian and north African mountain ranges. Granite and crystalline schist (gneiss and mica-schist) are found in the Ligurian Apennines, especially in Calabria, south of the Gulf of Policastro. In the Apennines proper these older crystalline formations are entirely lacking. They consist principally of limestone, dolomite, sandstone, and marl, of the Chalk and Tertiary formations, in which occur strata of serpentine in the north, and sometimes trachyte and basalt, especially on Mount Vulture. In the northern Apennines and also in the Tuscan highlands, there are large quantities of marl, shale and blue-gray sandstone, which belong in part to the Chalk formation and in part to the early Tertiary. Limestone is found in large quantities in the composition of the whole mountain range. Carboniferous, Permian, Triassic and Liassic deposits occur in the Apuan Alps, the famous marble of Carrara belonging to the Liassic or Triassic period. The Apennines are divided into six parts, according to the regions through which they pass and these fall into three groups, the northern Apennines (including the Ligurian and Etruscan); the middle Apennines (the Roman Apennines and the Abruzzi); the southern Apennines (the Neapolitan and Calabrian). The Ligurian Apennines reach from the Col de Tenda, the geological boundary of the Alps, to the Pass of Cisa (about 700 miles). The southern slope falls abruptly to the sea, the northern slope gradually, with many valleys, toward the river Po. Numerous passes lead from the coast towns over the range, among them the Bochetta Pass and the Giovi Pass from Genoa; and the Genoa-Alessandria Railroad has cut a tunnel through near the last named pass. From there to the east the range almost doubles its width and increases in height. The eastern half, consisting of several parallel chains, is difficult to cross and a serious hindrance to transportation. In this portion there are practically no thoroughfares except the railroad from Parma to Spezia.

The Etruscan Apennines, extending to the valley of the Metauro, have a southeasterly direction throughout and consist of several ranges, one in front of the other, like the links of a chain. The most noted peaks are in the northern part, the Alpe de Succiso (about

6,600 feet), Mount Cusna (over 6,900 feet) and Mount Cimone (7,103 feet), the latter being the highest peak in the northern Apennines. The northern portion includes the Apuan Alps, bounded by the valley of the Serchio, the Magra and the Antella, which reach the height of about 6,400 feet in Mount Pisano and are of pure marble (Carrara) on the slope toward the sea. The most important thoroughfare of the Etruscan Alps is the railroad from Bologna to Florence, which passes through a tunnel near Prachia; the La Fluta Pass, over which the road from Florence to Bologna passes, should also be mentioned. The Roman Apennines, beginning between the valleys of the Tiber and the Metauro, extend to the valley of the Tronto and Belino and consist of numerous parallel chains. In the north the main peak is Mount Catria (about 5,420 feet); in the south, the chain of the Sibilline Mountains rise to the height of 5,100 feet (Mount Vitore). The formation of the range here renders the crossing easy and the railroad from Ancona to Florence and Rome crosses here. The Abruzzi extend southward from the valley of the Tronto and in their eastern chain in Gran Sasso d'Italia reach the greatest height in the whole Apennines (Mount Corno, 9,585 feet). The western chain, which, with the eastern, encloses the Plain of Aquila, has a height of almost 8,150 feet (Mount Velino) and south of the Pescara tunnel is the Majella range with a height of 9,200 feet. The Neapolitan Apennines extend from the valley of the Sangro and Volturno to that of the Crati, but their altitude is much less than that of the middle Apennines, the Matesian Mountains reaching the height of over 6,700 feet in Mount Miletto. Rounded, wave-like shapes prevail in this range. On the eastern range is the extinct volcano of Mount Vulture. The roads and railroads from the west to the east coast encounter no particular difficulty in crossing this range. In the south the Apennines reach again a noticeable height in Mount Pellino (7,450 feet) and slope abruptly to the valley of the Crati. The Calabrian Apennines consist of a small chain sloping abruptly to the Tyrrhenian Sea and of the granite plateau of the Silagian Mountains with a mean height of 3,000 feet. This north Calabrian mountain land is separated from the south Calabrian by a neck of land between the Gulf of Santa Eusemia and the Gulf of Squillace. The outer northerly and northeastern slope of the Apennines is gradual, the eastern slope almost everywhere so abrupt that on the Adriatic coast there is only room for a road. Since the Apennines to the west of the Gulf of Salerno lie near the coast, but in the north extend farther and farther away from it, there exists a three-cornered space in which lie the so-called Lower Apennines. The volcanic formation is especially characteristic of these mountains and these regions are the classic ground of present and former volcanic action. Therefore there are here active and extinct volcanoes and hot springs, among them the springs of Voltena. The Lower Apennine region is divided into several parts by the broad valleys of the rivers flowing from the Apennines. Of these divisions the Tuscan highland is the most noted, ending on the south at the lower Tiber. In the interior are fertile plains sloping gently

toward the valley of the Arno; in the west the highlands end with an abrupt slope, between which and the coast lie the plains of Maremma, from which rise a few single peaks. The part of the Lower Apennines between the valleys of the Tiber and the Garigliano includes two small mountain-groups: the Alban Mountains, famed for their beautiful scenery, and the Volsker Mountains extending as far as the coast near Terracina. West of these Volscian Mountains lies a plain whose northern portion includes the Campagna of Rome, while the southern part contains the Pontine marshes. The southernmost part of the Lower Apennines extends from the Garigliano to the mountain range of Castellamare, north of Salerno, and includes the plain of Campagna, noted for its fertility as well as its beauty. From this plain rise several single volcanoes, including the extinct Mount Della Croce in the north and Vesuvius (4,200 feet) in the south. The climate is on the whole more severe than would be expected from the latitude and the position of Italy, while the heat in summer reaches a degree almost unendurable in the low and sheltered valleys, and palms and other tropical vegetation can thrive on almost all the west coast; neither fruit nor grain grow on the exposed, windy heights, with their elevation of over 3,000 feet, and the trees are few and stunted. The region of vegetation may be divided into four sections: (1) The olive region to the 1,500-foot elevation, with Mediterranean flora, garden plants and winter pasturage; (2) the region of the chestnut and oak, to the elevation of 3,000 feet with agricultural products and chestnut woods; (3) the region of the beech and coniferous trees at the height of 3,000 to 6,000 feet; (4) the region of the shrubs and Alpine plants with summer pasturage extending to the highest peaks. In climate, therefore, the northern Apennines form a line of separation between north and south; only on their northern slopes does Italy really begin. The northern part only presents great difficulties in traveling. The mountains are now traversed by several railroads, mostly by means of tunnels.

APENRADE, ä'pën-rä'dé (Danish, *Aabenraa*), seaport of Prussia, in the district of Schleswig-Holstein, on the Little Belt and in the Bay (fjord) of Apenrade. It is beautifully situated in a deep valley surrounded by woody heights and a fertile country. Apenrade has a school of navigation and carries on a considerable seafaring trade. It is a popular bathing resort and is a place of considerable antiquity. Pop. about 7,000.

APERTURE, in *anatomy*, *zoology*, *botany*, etc. The aperture of a univalve shell is the opening or mouth. In mollusks which feed on vegetable matter it is entire; while in those which are animal feeders it has a notch or canal. In some families it has an operculum or cover. The margin of the aperture is called the peristome. In *optics*, see **MICROSCOPE**; **TELESCOPE**.

APE'S HILL (Arabic, *Jebel Zatul*), the ancient Abyla, the extremity of a mountain range in northern Morocco, opposite Gibraltar, and one of the "Pillars of Hercules."

APEX, in mining, the highest point of outcrop of a mineral vein or lode. This is the

common definition of the term as used by miners, although its legal significance must be interpreted in connection with the local conditions and cannot be defined in general terms. According to the Revised Statutes of the United States for 1872 the owner of a mineral claim which includes the apex is allowed to follow the vein along the dip for an indefinite distance without regard to the ownership of the overlying surface, so that the proper location of the apex is of the utmost importance in establishing the lines for a claim. It has been decided by the courts that the apex need not appear necessarily at the surface, and hence the term does not exactly coincide with the term outcrop. In the case of an inclined vein whose apex is concealed, but which outcrops at some point lower down, the right of mining is conveyed to the owner of the apex-claim in preference to the owner of the outcrop-claim. This law has been the cause of much confusion and of expensive litigation in settling the ownership of valuable mining properties in the Western States. A wiser provision is that obtaining in most European countries, which grants the owner the right of mining only within the vertical limits of his claim.

APEX OF THE SUN'S WAY, a term signifying the point in the constellation Hercules to which the sun's motion in space is directed. This point is about in right ascension 18 hours 30 minutes, and declination 35° north. The point is therefore somewhat south of the zenith for the most of the United States in the early part of the evenings of August. Of course this statement is meant to indicate the locality only in the most general way. That the solar system is moving toward this part of the heavens is indicated by the apparent spreading apart of the stars in this region, together with an apparent crowding together of the stars in the opposite direction, as the trees open in front of one walking through a grove and shut together behind him. The velocity of this motion is shown by spectroscopic observation to be about 11 miles per second. The movement, so far as observed, seems to be in a straight line, but may turn out to be in a vast curved orbit.

APHANESITE, a-fan'e-sit (from the Greek *aphanes*, "obscure," in allusion to the difficulty of recognizing it by its crystals), a mineral now better known as clinoclasite.

APHANIP'TERA, an order of wingless insects having a sucker of three pieces and a true metamorphosis. The thorax is distinctly separate from the abdomen, and two horny plates mark the spots where wings would be in the higher insects. It contains the *Pulicida*, or fleas.

APHANITE, äf'ä-nit (derivation same as for aphanesite), a variety of the rock known as diorite, in which the constituent minerals occur in such small grains that the aggregate rock appears almost (or quite) homogeneous, except when examined through a lens.

APHASIA, a-fä'zhī-ä, the designation of a disorder of speech due to disturbance of the brain mechanism independently of any muscular defect. This mechanism is complex and is usually divisible into two parts, the receptive

or sensory and emissive or motor. To the former belong those parts of the brain that store concepts of spoken words or written words; to the latter those parts concerned in co-ordinate speech or in writing. Thus aphasia may be of at least four different and independent types. Frequently it is a combination of one or more of these. The zones in the brain that store intellectual auditory impressions are located in the first temporal convolution. Any injury to this part of the speech mechanism may produce auditory aphasia or word deafness. A patient thus affected is able to hear words and to speak, but he does not comprehend what is being said to him. He has lost his hearing word memories, and his own language is as a foreign language that he hears but cannot comprehend. In an analogous manner, if there is disorder of the occipital lobes, about the calcarine fissure, or of its related fibre tracts, a patient may have visual aphasia or word blindness. His own written language might as well be in Arabic, for he has lost all his memory of written words. These types of aphasia are much less common than the true type of motor aphasia or aphemia. In this the trouble is in the third left frontal convolution in the brain, Brocas convolution, or its related fibre tracts, and a patient thus affected has lost the power to say the words he desires to say. He is perfectly able to talk, may repeat words, but knowing in his mind precisely what he wishes to say is unable to express it, not because of any failure of the muscular power of the tongue to articulate, but because of the defect in the storage centre or its fibre paths for motor speech. A fourth type is *agraphia*, in which the affected patient is unable to write with understanding the words with which he is familiar. The site of the lesion here is undetermined. It usually accompanies motor aphasia. There are also forms of combined aphasia in which the fibre tracts from one centre to another are cut off. These make paraphasias, and their symptoms are extremely complex. Aphasia in its various forms may differ very widely in its extent. It may be very slight or very profound. It may be temporary or permanent, depending on the nature and extent of the brain injury. Aphasia is most frequently a symptom of hæmorrhage from some artery or arteries in the brain; it may be caused by the growth of a tumor or result from an injury. The treatment is that of the causing disease. In the sensory aphasias education of the non-affected areas is of great importance. If there is word blindness, the memory for spoken symbols should be cultivated, and vice-versa.

APHE'LION, that part in the orbit of the earth (or any other planet) which is farthest from the sun.

APHELIOTROPISM, the form of sensitiveness in planets by which their organs direct

their axes away from the source of light. See **HELIO-TROPISM**.

APHEMIA, a term employed to designate a motor aphasia. See **APHASIA**.

APHID, a plant-louse of the family *Aphididae*, order *Hemiptera*. Aphides are among the most abundant of insects and do much injury to vegetation by their habit of sucking the sap of leaves and stems of plants. They are usually very small, never over a quarter of an inch in length. Their mouth-parts form a slender beak adapted for puncturing leaves and sucking the sap. Their antennæ are from three to seven-jointed, and generally longer than the body. The ocelli are usually present, and the beak is three-jointed and developed in both sexes. The legs are long and slender, with two-jointed tarsi. The males and females are winged, and also the last brood of asexual individuals, but the early summer broods are wingless. Their bodies are flask-shaped, being cylindrical, the abdomen thick and rounded, and in aphid and lachnus provided with two tubes on the sixth segment for the passage of a sweet fluid (honey-dew) secreted from the stomach, which attracts crowds of ants (see **ANT**). The wings are not net-veined, having few veins, which pass outward from the costa. They are usually green in color with a soft powdery bloom exuding from their bodies. Bonnet first discovered that the summer brood of wingless individuals were born of virgin parents, hatched from eggs laid in the autumn, and that the true winged sexes composed the last generation, which united sexually, and that the female laid eggs in the autumn which produced the spring brood of asexual wingless individuals.

In the early autumn the colonies of plant-lice are composed of both male and female individuals. These pair, the males then die, and the females begin to deposit their eggs, after which they die also. Early in the spring, as soon as the sap begins to flow, these eggs are hatched, and the young lice immediately begin to pump up sap from the tender leaves and shoots, increase rapidly in size, and in a short time come to maturity. In this state it is found that the whole brood, without a single exception, consists solely of females, or rather, and more properly, of individuals which are capable of reproducing their kind. This reproduction takes place by a viviparous generation, there being found in the individuals in question young lice which, when capable of entering upon individual life, escape from their progenitors and form a new and greatly increased colony. This second generation pursues the same course as the first, the individuals of which it is composed being, like those of the first, sexless, or at least without any trace of the male sex throughout. These same conditions are then repeated, and so on almost indefinitely, experiments having shown that the power of reproduction under such circumstances may be exercised, according to Bonnet, at least through nine generations, while Duval thus obtained 11 generations in seven months, his generations being curtailed at this stage not by a failure of the reproductive power, but by the approach of winter, which killed his specimens. Huber observed that a colony of *Aphis dianthi*, which had been brought into a constantly heated room continued to propagate for four years in this

manner without the intervention of males, and even in this instance it remains to be proved how much longer these phenomena might have been continued.

Certain species feed on the roots of plants, as asters, lettuce, grasses, etc., and these also attract numerous ants. The corn plant-louse has been found by Forbes to hibernate in the wingless, asexual form in the earth of previously infested corn-fields. In the spring an ant (*Lasius alienus*), which runs its tunnels along the principal roots of the corn, collects the aphides and conveys them into its galleries, where they are watched and protected. The white-pine aphid (*Lachnus strobi*) is destructive to young white-pine trees. Another aphid is the grape *Phylloxera* (q.v.). The woolly aphids (*Schizoneura tessellata*) flock on the stems of the alder, their bodies concealed by a flocculent mass of wax. Another destructive species is the apple woolly louse (*S. lanigera*). Aphides can be exterminated by frequent spraying.

Bibliography.—Buckton, 'Monograph on British Aphides' (Ray Society, London 1879-83); Miall, L. C., 'Injurious and Useful Insects' (London 1908); Osborn, Herbert, 'Agricultural Entomology' (Philadelphia 1916); Thomas, 'Eighth Report of State Entomologist of Illinois' (Springfield 1879).

APHONIA, medical term used to designate a loss of voice more or less complete. It may result from paralysis of the respiratory muscles, pneumonia, or pulmonary emphysema, or from diseases of the larynx, œdema of the glottis, polypus, etc., or by pressure on the larynx caused by abscesses or any morbid growth. In general it is caused by anything which interferes with expiration or with the functions of the vocal cords. It differs from mutism, in which is lost the ability of forming articulate sounds. Aphonia may exist in varying degree according as the voice is totally or partially lost, and is very often associated with hysteria.

APHRODISIACS, ā'ró diz'i-ākz, drugs that excite erotic desire. True aphrodisiacs are rare and their use is attended with considerable danger. The principal are hashish, cantharides, *blatta orientalis*, and damiana. Drugs with an opposite effect are known as anaphrodisiacs.

APHTHÆ, āf-tha, small round ulcers surrounded by a red border which appear on the mucous membrane of the mouth in the disease known as aphthous stomatitis. The ulcers usually appear on the under surface or sides of the tongue or in the fold between lips and gums. Aphthæ attack children during the dentition period, when lowered vitality is often a predisposing cause. Unclean nursing bottles and faulty oral hygiene are also factors in inducing an attack. It is not known to be contagious and as far as known there is no specific germ connected with the disease. Cleansing the mouth with antiseptic washes, treating the ulcers with caustics, such as nitrate of silver, and strict attention to oral hygiene are the usual methods of treatment.

APHYDROTROPISM, a form of sensitiveness by which a plant organ turns its axis away from the source of moisture. It is observed in the fruiting bodies of several fungi.

The vegetative filaments remain in the moisture but the reproductive filaments grow out into the drier air.

APIDÆ, the family of *Hymenoptera* including the bees. It is characterized by its members being clothed with feathered hairs, and by having the basal segment of the hind foot flat and broad. The family is very numerous and is world-wide in range. See **BEE**.

APIS (Egyptian *Hapi*), a bull at Memphis to which divine honors were paid by the ancient Egyptians, and which was regarded as the representative of Osiris. It was necessary that he should be black, with a triangle of white on the forehead, a white spot in the form of a crescent on the right side and a sort of knot like a beetle under his tongue. Other marks are also mentioned. When a bull of this description was found he was fed four months in a building facing the east. At the new moon he was led to a splendid ship with great solemnity, and conveyed to Heliopolis, where he was fed 40 days more by priests and women, who performed before him various indecent ceremonies. From Heliopolis the priests carried him to Memphis, where he had a temple, two chambers to dwell in, and a large court for exercise. His actions were thought to have prophetic significance, and he was believed to impart prophetic power to the children about him. His birthday was celebrated every year, when the Nile began to rise. The festival continued for seven days, and it was said that the crocodile was always tame as long as the feast continued. Notwithstanding all this veneration, the bull was not suffered to live beyond 25 years, the reason of which is probably to be found in the astronomical theology of the Egyptians. The death of Apis, however, excited universal mourning, which continued till the priests had found a successor to him. As it was extremely difficult to find one with all the above distinctions, fraud was often practised by the priests.

APJOHNITE, a native manganese alum, or hydrated sulphate of aluminum and manganese, found in fibrous form and as incrustations at Lagoa Bay, South Africa, and in Sevier County, Tenn. It is variable in composition, but some analyses indicate $MnSO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$. It is usually white or nearly so and tastes much like common alum.

APLANATIC LENSES, a term applied to lenses nearly or quite free from spherical aberration. If the curved surfaces of a single convex lens are portions of spheres, the rays of light from one point of an object are not accurately brought together at one corresponding point of the image, the rays passing through the outer portions of the lens being too much refracted. The result is a distorted image. Theoretically it is easy to correct this error by substituting ellipsoidal surfaces for the spherical, but such surfaces cannot be accurately constructed. Spherical aberration is corrected, in practice, by combinations of two or more lenses in one, the surfaces being of differing curvatures. The results are quite satisfactory, and the method is applied in the manufacture of objectives and eye-pieces for telescopes and microscopes, as well as in the making of lenses to be used in photography.

APOCALYPSE (Greek, *apokalypsis*, from *apokalypthō*, I reveal), the name frequently given to the last book of the New Testament. It is generally believed that the Apocalypse was written by John in his old age, at the end of the 1st century (95–97 A.D.), in the Isle of Patmos, whither he had been banished by the Roman Emperor Domitian. Though commonly regarded as genuine in the first centuries of Christianity, critics have not been wanting who have doubted the evidence of its being the work of Saint John. Its genuineness was maintained by Justin Martyr (c. 150), Irenæus (195), Clement of Alexandria (200), Tertullian (207), and many others; and doubted by Dionysius of Alexandria (240), Cyril of Jerusalem, Chrysostom, and nearer our own times, by Luther and a majority of eminent German commentators. In recent times a composite authorship has been suggested and some have regarded it as a Jewish work adapted by a Christian writer. The Apocalypse, on account of its metaphorical language, has been explained differently by almost every interpreter, and for the same reason it has furnished all sorts of sects and fanatics with quotations to support their creeds or pretensions. There can be no doubt that the hopes of the early Christians and the severe persecution they endured led them to regard the Roman empire as the object of prophetic denunciation, and the coming of Christ and the millennium as near at hand. When, under Constantine, however, the Christians became dominant and prosperous, the empire was considered as the scene of a millennial development, and in course of time the barbarous hordes who were closing round Rome were regarded as fulfilling the woes predicted in the Apocalypse. At the Reformation the Protestants identified Babylon with papal Rome, and the second beast of Antichrist with a universal pontiff. The modern interpreters may be divided into three schools: namely, the historical school, who hold that the prophecy embraces the whole history of the Church and its foes from the time of its writing to the end of the world; the Præterists, who hold that the whole, or nearly the whole, of the prophecy has been already fulfilled, and that it refers chiefly to the triumph of Christianity over Paganism and Judaism; and the Futurists, who throw the whole prophecy, except the first three chapters, forward upon a time not yet reached by the Church—a period of no very long duration, which is immediately to precede Christ's second coming. The Apocalypse contains 22 chapters, which may be divided into two principal parts. The first comprises "the things which are"—that is, the then present state of the Christian Church, including the epistolary instructions and admonitions to the angels or bishops of the seven churches of Ephesus, Smyrna, Pergamos, Thyatira, Sardis, Philadelphia and Laodicea, situated in Asia Minor. The second part comprehends a prediction of "the things which shall be hereafter," referring either to the future state of the Church through succeeding ages, from the time of the apostle to the grand consummation of all things, or to the state of the souls of men after the general resurrection. SEE APOCALYPTIC LITERATURE.

APOCALYPTIC LITERATURE. A distinct type of religious literature emanating from Jewish and Christian sources. The formative period of its growth and development reached from 200 B.C. to 100 A.D. The name "Apocalypse" comes from the Greek, meaning "disclosure" or "revelation," and refers to a special kind of literature. The occasion for the appearance of this particular kind of literature among the Jews was the Maccabean revolt and the attendant causes leading up to the revolt. The rebellion itself was no more or less than a severe reaction against Hellenism and the threatened domination of Jewish thought and life. It was the clash of two nationalities and two religions that were almost mutually exclusive. It was in the heat of this period of strife that this literature found its voice and its mission, and by means of its encouragements became veritable "tracts for bad times."

Origin.—The origin of the apocalyptic literature has been the source of much discussion during the past few years. Almost every branch of Jewish society has been accredited with its production. Some authorities contend that it must have come from the Essenes, others from Persian sources, and still others from Hellenistic sources. The best conclusion seems to be that the literature is first of all distinctly Jewish and Palestinian in origin, and that it emanated from the lay classes instead of the recognized official classes. This condition easily accounts for its Pharisaical teachings, its demonology so often accredited wholly to Persian sources and its traces of Hellenism. The place of writing is still a matter of conjecture, but there is much to favor the idea that it was written (that is, the most of it) in Galilee.

Characteristics and Problems.—The outstanding characteristics of the apocalyptic literature are three in number. The most significant one is the characteristic of pseudonymity. Some have concluded that this is the only mark of an apocalypse, and as a consequence much confusion has arisen in the use of the modern term "pseudepigrapha." The typical apocalypse is written under the assumed name of some ancient worthy and purports to come from his time. The use of the name in this way is regularly followed out in all apocalypses down to the 14th century A.D., with a few exceptions in the New Testament. The real reason for this assumption of another name, as

the medium of revelation, is to be found in the crystallization of the idea of a sacred canon of Scripture. To writers of the apocalypses the canon was practically closed, the time of revelation had passed, and so in order to reach the people with a new message the Patriarchs, Enoch, Moses and Daniel are made expositors of elaborate revelations. Another marked characteristic of the apocalyptic literature is the use of symbolical language, visions and imagery. The visions are elaborate and rendered somewhat mysterious in their use of symbolical language. The "horn" of an animal generally represents a king. The "little horn" of Daniel represents Antiochus Epiphanes. The patriarchs are represented as "white bulls." The righteous Israelites are "sheep" or "lambs." Foreign nations are pictured as ravenous beasts. Further the legalistic emphasis of the apocalyptic is very noteworthy. In every case, with the exception of 4 Ezra, allegiance to the Law or the Torah is affirmed or assumed. In some cases the validity of the Law is recognized, even as last authority. Hand in hand with this recognition of the Law is the general expressed loyalty to the Temple and its worship.

One of the greatest problems of apocalyptic literature is its relation to Old Testament prophecy. The similarities between the two forms of literature are marked. In the face of much discredit that has been thrown upon the apocalyptic writers, it must be said that they were the best successors of the great prophets, both in spirit and deed. They have the same basis of revelation and inspiration. Both possess an eschatology and are highly ethical. On the other hand the differences are very striking. Old Testament prophecy is always conditional in regard to future events; but in the case of the apocalyptic, the conditions are of minor importance, as the prediction will come to pass in a mechanical way irrespective of human conduct. The most striking difference is found in the scope of the two eschatologies. In Old Testament prophecy eschatology is almost entirely concerned with the nation, but in the apocalyptic the eschatology of the individual is highly developed. A firm belief in the future life is one of the cardinal doctrines of the apocalyptic. Again the belief in a new heaven and a new earth is one of the finest products of this literature.

The most representative apocalypses come from the period 200 B.C. to 100 A.D. It must not be concluded that the apocalyptic sprang into being at one time. The transition toward the apocalyptic was made in the Old Testament itself, as shown by the appearances of the apocalyptic tendencies in Ezekiel and Isaiah 24-27, and one of the best apocalypses, the book of Daniel. The principal Jewish apocalypses of the period 200 B.C. to 100 A.D. are, arranged in chronological order, Enoch, Testaments of the Twelve Patriarchs, Assumption of Moses, Secrets of Enoch, 2 Baruch, 3 Baruch and 4 Ezra (2 Esdras). A general survey of the character and contents of these books is as follows:

Enoch.—It is a composite collection of writings coming from different centuries. There are indications of at least five books, so that a more appropriate title would be the "Books of Enoch." The oldest sections of this Enoch literature are in chapters 83-90 and 1-36. These

chapters date from the first half of the 2d century B.C. Chapters 83-90 are the oldest sections of the book, and by far the most complete and typical of the apocalyptic. They consist of dream visions from the beginning to the end of time. History is allegorized by use of symbolical language. Chapters 1-36 narrate the visions of Enoch and his journeys through earth, Sheol and heavenly places. This has been truly named the work of a "Jewish Dante." The 1st century B.C. sections are chapters 37-71 and 91-108. Chapters 37-71 have been named the "Parables of Enoch," and they picture the judgment of the wicked, the lot of the apostates, the blessedness of the saints and the idea of a new heaven and a new earth. Chapters 91-108 are a series of exhortations. Chapters 72-82 are a little uncertain in regard to the date, but they probably come from the 2d century B.C.

The Testaments of the Twelve Patriarchs.—It is a series of apocalyptic writings in the name of the 12 sons of Jacob. The entire set of writings, with the exception of a few later Jewish and Christian interpolations, comes from the latter part of the 2d century B.C. The Testament of each Patriarch in turn follows the same literary form of division into a triple arrangement. The first division of each one is a historical sketch based upon Genesis. Some particular vice or virtue is emphasized. In the second division an exhortation is given relative to these vices or virtues. The third division deals with the future of the family and in predictive ways outlines future events. The book as a whole marks the high-water mark of Jewish ethics in this early period.

Assumption of Moses.—It was written in Palestine during the first part of the 1st century A.D. The interest in this apocalypse dates from the discovery of a Latin manuscript in Milan in 1861. By means of this Latin fragment, the Greek fragments and the New Testament allusions in Jude and 2 Peter, the restoration of some of the details of the original is about complete. The author evidently was a man with Pharisaic beliefs. The chief value of the book is its close relation to the New Testament writings.

Secrets of Enoch.—The apocalypse is sometimes called 2 Enoch. The text has been largely recovered from the Slavonic versions of the 16th and 17th centuries. It was written by a Hellenistic Jew, probably in Egypt, during the middle of the 1st century A.D. One of the prominent marks of its Hellenistic tendencies is its doctrine of the pre-existence of man.

2 Baruch.—This apocalypse is often called the Syriac Apocalypse of Baruch, because of the discovery of a very fine copy of it in the Syriac language. This manuscript was a translation from an original manuscript in the Greek and was discovered in 1866. The book is composite in origin, parts of it being written as early as 50 B.C. and other parts of it coming from after the fall of Jerusalem in 70 A.D. The outlook, as far as the future is concerned, in the earlier sections is very hopeful, while in the later sections all hope for a messianic kingdom is practically abandoned. The greatest value of the book is its inter-relation to the Epistles of Paul.

3 Baruch.—It is called the Greek Apocalypse of Baruch. It was not definitely recog-

nized as a separate book from the other books of Baruch until the discovery of a manuscript in 1896. It was written in the days of the early Christian Church in the 1st century A.D. It refers to only five heavens, while Enoch refers to seven and Secrets of Enoch to ten.

4 Ezra.—Chapters 3-14 of 2 Esdras of the Old Testament Apocrypha are the apocalypse of 4 Ezra. This order of the different books of Ezra is derived from the Vulgate. It is not a unit; some parts were written before the fall of Jerusalem in 70 A.D., and some were written as late as 120 A.D. The main section of the book is found in chapters 3-10, generally designated as the Salathiel Apocalypse. The remaining sections consist of several significant visions. The main value of the book lies in its relation to the problems of pre-Talmudic days and the New Testament.

In addition to these more important Jewish apocalypses there are numerous Christian apocalypses. Some are found in the New Testament, as, for example, the book of Revelation. The most important ones outside of the New Testament are the Apocalypse of Peter, the Testament of Hezekiah, Shepherd of Hermas and numerous Christian Sibylline Oracles. Some of the Sibylline Oracles have a few ancient Jewish elements in them coming from the 2d century B.C. The New Testament apocalypses are not written under assumed names, which can largely be accounted for by the new emphasis upon personality in Christianity. However, closely following the period of the New Testament the literary form of pseudonymity is again assumed. See APOCRYPHA.

Bibliography.—Charles, R. H., English editions of nearly all the Jewish Apocalypses, 'The Apocrypha, and Pseudepigrapha of the Old Testament' (Oxford 1913), 'Eschatology' (2d ed., London 1913), 'The Religious Development between the Old and the New Testaments' (New York 1914); Deane, 'Pseudepigrapha' (New York 1891); Encyclopædia Biblica, article 'Apocalyptic Literature' (New York 1899); Fairweather, W., 'The Background of the Gospels' (Edinburgh 1911); Schürer, 'History of the Jewish People in the Times of Jesus Christ' (Eng. trans., New York 1891).

LESLIE E. FULLER,
Assistant Professor of Old Testament Interpretation, Garrett Biblical Institute.

APOCALYPTIC NUMBER, the mystic number 666, which, according to some authorities, should be 616, mentioned in Revelation xiii, 18. As early as the 2d century ecclesiastical writers found that the name Antichrist was indicated by the Greek characters expressive of this number, numbers being expressed in Greek by the letters of the alphabet. By Irenæus the word *Lateinos* was found in the letters of the number, and the Roman empire was therefore considered to be Antichrist. Another solution is *Neron Kesar* (Hebrew form of Nero Cæsar). Omitting the *e's* and the *a*, not written in ancient Hebrew, we get 666 as the value of the letters.

APOCRYPHA. The term "Apocrypha" is generally applied to distinct groups of religious literature closely associated with the canons of the Old and New Testaments. This literature was not regarded as canonical, although much

read and quoted in church and synagogue. The Old Testament group, a collection of 14 books of Jewish origin, is found in the Greek and Latin versions, but not in the Hebrew versions. The New Testament group is rather an indefinite body of early Christian literature consisting of parallels and additions to the writings of the New Testament.

The use of the term "Apocrypha" and "Apocryphal" varies to great extent, especially among Protestants and Roman Catholics. The authorities of a Protestant persuasion apply the term Apocrypha to the two groups known as the Old and the New Testament Apocrypha proper. However, the term Apocryphal is made not only to include these two groups, but also many of the Jewish pseudoepigraphic writings. The Catholics designate the books of the Old Testament Apocrypha proper as Deutero-Canonical books (except 1 and 2 Esdras and the Prayer of Manasses), and group all the remaining Jewish and Christian literature of a kindred origin under the term Apocryphal.

The meaning of the term Apocrypha (coming from the Greek word meaning "hidden") has undergone several very significant changes in the course of its use and application. Historically considered three principal changes in the meaning of the word should be noted. In its earliest use it was restricted to the writings of more or less sacred character, but containing certain mysterious and esoteric teachings intended only for the wise and the initiated (2 Esdras xiv, 45f). In this case there was no discredit thrown upon the writings, because of authorship or contents. Still another meaning was given to the term by some of the Church Fathers, especially Origen, wherein it was applied to all writings of a secondary or questionable character. Many of the works thus branded were discredited as to their teachings and withdrawn from public use. Finally the term was used to designate false and heretical literature.

In addition to this general uncertainty much confusion has prevailed in regard to the value of the literature. Some of these differences can be traced back to the different ideas of canonicity as held in Jewish and Hellenistic circles. Some of the Church leaders, especially in the Western Church, ascribed full scriptural authority and inspiration to the apocryphal writings. This view finally bore fruit in the Council of Trent in 1546 when 11 of the books of the Old Testament Apocrypha were declared canonical. On the other hand a great number of the leaders, because of their close association with Hebrew traditions, denied scriptural authority and value to any of the books. This view was championed by Jerome and finally found expression in the Protestant-Christian view of Reformation times. There were some who did not accept either one of these two extreme views. They clearly recognized the value of the literature, but at the same time they were not willing to place the books on the same level with the Biblical books. This latter view finally found expression in the teachings of the Church of England.

Old Testament Apocrypha.—The Old Testament Apocrypha proper contains 14 books, and represents, except for a few minor variations, the excess of the Greek canon over the

Hebrew canon. The books may be classified in the following way:

1. *Parallels or Additions to the Old Testament.*—The Prayer of Manasses, The Song of the Three Holy Children, The History of Susanna, Bel and the Dragon, The Rest of Esther, 1 Esdras and Baruch (including the Epistle of Jeremiah).

2. *Historical.*—1 Maccabees and 2 Maccabees.

3. *Legendary.*—Tobit and Judith.

4. *Wisdom Literature.*—Ecclesiasticus and Wisdom of Solomon.

5. *Apocalyptic.*—2 Esdras (4 Ezra).

A brief survey of these books is as follows:

The Prayer of Manasses.—It is a product of the 1st century B.C., and was intended to be used in connection with the story of Manasseh's Babylonian captivity (2 Chron. xxxiii). Parts of the Prayer have found their way into Protestant liturgy.

The Song of the Three Holy Children.—One of the principal additions to Daniel. It was written about 100 B.C. and was found inserted in the book of Daniel, the third chapter, right after the 23d verse.

The History of Susanna.—Another 1st century B.C. addition to the book of Daniel. It is generally found prefixed to the book. The purpose of the story is to magnify the powers and the judgment of the hero of the book.

Bel and the Dragon.—It was written about 100 B.C. It is the story of Daniel's sagacity in exposing some of the flagrant abuses of idolatry.

The Rest of Esther.—This writing consists of a number of additions to the Biblical book of Esther. The additions were made to add detail and make up for some of the deficiencies of the canonical book. It was written about 100 B.C.

1 *Esdras.*—It is the Greek version of and in some parts a reconstruction of the canonical Ezra. It was written about 100 B.C. Some of additional subject matter is from the book of Nehemiah.

Baruch.—The greater part of this book was written in the 1st century A.D. The book is written under the assumed name of Baruch, the private secretary of Jeremiah. The 6th chapter is known as the Epistle of Jeremiah. Both books contain a series of exhortations and encouragements and severe denunciations of idolatry.

1 *Maccabees.*—It is one of the best sources on the period from 175 to 135 B.C. It treats of the causes of the Maccabean rebellion and the rebellion itself down to the death of Simon in 135 B.C. It was written by a Jew in Palestine during the latter part of the 2d century B.C.

2 *Maccabees.*—It is a mixture of history and fiction. It is an abridgment of a much larger work in existence at the time of its writing in latter part of the 2d century B.C. It treats of the period leading up to the rebellion of the Maccabees under Mattathias in Modcin, and the rulership of Judas down to 161 B.C.

Tobit.—It is a popular story of romance and legend from the Jewish Dispersion in Egypt. The story was written in the 3d century B.C., and was based upon the well-known Egyptian stories of 'The Fable of the Ungrateful Dead' and 'The Tractate of Khons.' The purpose of the story was to teach some useful lessons,

and at the same time to correct some of the current superstitions.

Judith.—It is a legendary story of a Jewish widow who succeeded in outwitting and finally slaying a great Assyrian general, thus bringing deliverance to her oppressed people. It was written in Palestine during the latter half of the 2d century B.C., probably by a Pharisee.

Ecclesiasticus.—It is a book of proverbs and practical observations on life closely resembling the Wisdom Literature of the Old Testament. It was written about 180 B.C., and forms one of the most valuable records of early Rabbinical thought. It was translated into Greek in 132 B.C. by a grandson of the author (Jesus ben Sira).

Wisdom of Solomon.—In some respects it is one of the most valuable of the books of the Apocrypha. It was written by a Jew of the Dispersion about 65 B.C. It is similar to the Wisdom Books of the Old Testament. It was written with the distinct purpose to combat the materialistic tendencies of the canonical book of Ecclesiastes.

2 Esdras.—It is an apocalypse, especially chapters 3-14. It is composite in origin, dating from 65 B.C. to 120 A.D. The book is especially valuable, as it bears on the period of Jewish thought in relation to the fall of Jerusalem in 70 A.D. Its views on eschatology are closely allied to the teachings of the New Testament.

There are several books worthy of note belonging to the general class of Jewish apocryphal literature but still outside of the Apocrypha proper of the Old Testament. The most noteworthy books of this class are the books of Jubilees, 3 Maccabees, 4 Maccabees, Psalms of Solomon and the Martyrdom of Isaiah. See APOCALYPTIC LITERATURE.

Jubilees.—It has been called the "Little Genesis," as it represents the book of Genesis rewritten from the standpoint of the Law or legalistic Pharisaism. It was written during the latter half of the 2d century B.C. by a Pharisee. Religious institutions and concepts of the 2d century are read back into the days of the patriarchs.

3 Maccabees.—It is a religious novel coming from Hellenistic Judaism in the 1st century B.C. Its central theme is the marvelous deliverance of the Jews from Egyptian persecution by divine intervention.

4 Maccabees.—It belongs to the great body of Jewish Wisdom literature, coming from Hellenistic centres. It attempts to discuss in treatise form the power of inspired reason over the passions. It was written during the 1st century A.D.

Psalms of Solomon.—A collection of Psalms resembling the Hebrew Psalter. They were written about 50 B.C. by Pharisees.

Martyrdom of Isaiah.—It is a product of the 1st century A.D. It records the tradition of the death of Isaiah at the hands of Manasseh, King of Judah.

New Testament Apocrypha.—The general character of the books of the New Testament Apocrypha is quite different from that of the Old Testament Apocrypha. In the first place the books of the New Testament group form somewhat of an indefinite body of literature, as new ones are being discovered from time to time. The majority of the writings come from the 2d century A.D. and represent all shades of re-

ligious belief. Further the literature differs from the Old Testament group, in that there is a deliberate attempt to fill in the gaps in the New Testament narratives, and in some cases even to supersede the earlier ones. For the most part they are writings filled with tradition, fiction and the description of the marvelous. Many of the ecclesiastical dogmas of the Middle Ages can be traced to this fruitful source.

The books of the New Testament Apocrypha can be arranged under three heads, namely: Gospels, Acts, and Epistles. A few of the more important under each group will be mentioned:

GOSPELS. *The Gospel according to the Egyptians*.—It reflects a severe belief in asceticism and agnosticism. *Gospel according to the Hebrews*.—It was written by some of the followers of the Nazarenes and the Ebionites. *Gospel according to Peter*.—It was discovered in 1885 and published in 1892. It was popular among the Syrian Christians. *Gospel according to Thomas*.—It is an attempt to fill in the story of Jesus' infancy. Jesus is described as a miracle worker from the beginning.

ACTS. The most important one in this class is the *Acts of Paul and Theba*. It is a romantic story of a woman converted under Paul's ministry. In addition to this writing there are the *Acts of Andrew, John and Peter*.

EPISTLES. *The Epistle of Abgar*.—It contains the message of Abgar, the King of Edessa, to Jesus and his answer. *Epistle of Barnabas*.—An important Epistle of 21 chapters teaching the dangers of relapsing into Judaism. *Epistle of Clement*.—It seeks to bring and to restore harmony into the Church at Corinth.

LESLIE E. FULLER,
Assistant Professor of Biblical Interpretation,
Garrett Biblical Institute.

APOCYNACEÆ, the designation of an extensive natural order of monopetalous exogamous plants, characterized by perfectly symmetrical flowers, the segments of the corolla all twisted one way like a catherine-wheel, five distinct stamens, a superior ovarium, which when ripening opens into two parts that diverge from each other at right angles; fruit follicular or capsular, or drupaceous or baccate, double or single. The order consists of trees or shrubs, many of whose stems yield, when wounded, a copious milk, usually poisonous. Generally found in tropical regions, they appear to be most abundant in the hot parts of Asia, are less common in the tropics of America, and still more rare in Africa. About 100 genera, including 566 species, have been enumerated. The plants of this order are in many cases poisonous, and very generally to be suspected, although in some cases they are used medicinally, and in others have an edible fruit. One of the most deadly plants of the order is the *Fanghina venenata*. The kernel of the fruit, although not larger than an almond, is sufficient to kill 20 men; it was formerly used in Madagascar as an ordeal. The common oleander (*Nerium oleander*) is a formidable poison and death has resulted from eating its flowers.

APODICTIC JUDGMENTS, a logical term adopted by Kant from Aristotle to distinguish judgments or conclusions which are beyond contradiction from those which are merely empirical; or to put it differently, a judgment or conclusion which is founded on the impossibility of the opposite, not upon grounds of experience, is an apodictic judgment.

APOGAMY. In all plants which have reached the level of sexuality, a new individual is initiated by the union of two cells, called *gametes*. In exceptional cases the ability to reproduce sexually is lost, either temporarily or permanently. Plants which have lost this power, after having attained it, are said to be apogamous and the condition is apogamy, the word meaning that the union of gametes has been left out. The new individual may be developed from any part of the gametophyte, or

is the most thoroughly investigated illustration. The prothallium, or gametophyte (see **ALTERNATION OF GENERATIONS**) becomes thickened along its median portion, making it look like a very small prostrate leaf with a midrib. This thickened region grows out beyond the border of the prothallium, curves upward, then becomes entirely erect and develops leaves, stem and roots. This plant, in every way, looks just like one arising from a fertilized egg. The essential feature of the phenomenon is the transition from the gametophyte to the sporophyte generation without any fusion of gametes. The thickened rib-like region of the prothallium, viewed from the under side, is shown in Fig. 1, *s*. A later stage, after the young apogamous sporophyte has developed leaves, is shown in Fig. 2, in which *g* is the gametophyte and *s* the sporophyte. Vegetative apogamy has not been found in Thallophytes, liverworts, mosses, lycopods or equisetums; but a score of cases have been reported in the true ferns and water ferns. No case has been established in Gymnosperms. In the Angiosperms several cases are well known. In the common onion (*Allium Cepa*), embryos have been found developing from the antipodal cells and from synergids. (See **ALTERNATION OF GENERATIONS**). In the fern (*Nephrodium molle*) the number of chromosomes in the nuclei of the new sporophyte is the same as the number of nuclei of the gametophyte. In the flowering plants the gametophyte which gives rise to the apogamous embryo has the sporophyte, or $2x$, number of chromosomes. Some persist in using the phenomenon of apogamy as an argument for or against certain theories of alternation of generations; but in our opinion, apogamy is a secondary, highly specialized condition which has no bearing upon the subject.

H., 'On Apogamy and the Development of Sporangia upon Fern Prothallia' (Philosophical Translations, Royal Society of London, Vol. 190, p. 189, 1898); Yamanouchi, S., 'Apogamy in Nephrodium' (*Botanical Gazette*, Vol. XLV, p. 289, 1908); consult also any modern textbook of botany.

CHARLES J. CHAMBERLAIN,

Professor of Botany, University of Chicago.

APOGEOTROPISM, the form of sensitiveness to gravity in plants evidenced by the universal tendency to grow vertically upward, in a direction opposite to that of the earth's attraction. When centrifugal force is brought to bear upon the plant in place of gravity the stems grow toward the centre of revolution while the roots grow in the opposite direction.

APOLLINARIANS, a sect of Christians who maintained the doctrine that the Logos (the Word) holds in Christ the place of the rational soul, and consequently that God was united in him with the human body and the sensitive soul. Apollinaris, the author of this opinion, was, from 362 A.D. till about 382 A.D., bishop of Laodicea, in Syria, and a zealous opposer of the Aryans. As a man and a scholar he was highly esteemed, and was among the most popular authors of his time. He formed a congregation of his adherents at Antioch, and made Vitalis their bishop. His teaching was condemned at Alexandria in 362; by Pope

gamete-bearing plant. When the new individual arises from an egg, without fertilization, this kind of apogamy is called *Parthenogenesis* (q.v.). When the new individual arises from any other part of the gametophyte except the egg, some prefer to call the phenomenon vegetative apogamy. A familiar case of vegetative apogamy is found in some common ferns, especially in highly cultivated greenhouse varieties. The beautiful fern, *Nephrodium molle*, which can be found in almost any greenhouse,

Damasus in 375; and in the Council of Constantinople in 381. The Apollinarians, or Vitalians, as their followers were called, soon spread their sentiments in Syria and the neighboring countries, established several societies, with their own bishops, and one even in Constantinople. The sect was denounced in 428 by imperial edict, and its members gradually returned to the Church or became Monophysites (q.v.). Consult Harnack, 'History of Dogma.'

APOLLO, son of Zeus (Jupiter) and Leto (Latona), who being persecuted by the jealousy of Hera (Juno), after tedious wanderings and nine days' labor, was delivered of him and his twin sister, Artemis (Diana), on the island of Delos. He was the most important of the Olympian deities after Zeus and appears in mythology as the god of poetry, music and prophecy, the patron of physicians and shepherds and the founder of cities. He aided Zeus in the war with the Titans and the giants, and destroyed the Cyclopes because they forged the thunder-bolts with which Zeus killed his son and favorite Asklepios (Æsculapius). All of the male sex dying suddenly without previous sickness were supposed to be smitten by the arrows of Apollo. In the oldest poems Apollo is exhibited as the god of song, being known in this function as Apollo Citharædus. Two statues of Apollo Citharædus are extant, one of them at the Glyptothek in Munich, the other at the Vatican, but their date is unknown. In the festivals of the gods and those of men in which they took part he plays and sings while the Muses dance around him. According to some traditions he invented the lyre, though this is generally ascribed to Hermes (Mercury). Marsyas, who ventured to contend with him on the flute, was conquered and flayed alive by the god. Apollo had another contest with Pan, in which the former played on the lyre, the latter on the pipe. Tmolus had already decided in favor of Apollo, when Midas, opposing the sentence, was decorated with a pair of ass's ears for his stupidity. That Apollo had the gift of prophecy appears from the Iliad, where he is said to have bestowed it upon Calchas and Cassandra; and in the Odyssey mention is made of an oracular response delivered by him in Delphi. The oracle at this place became very famous. He also revealed future events at Abæ in Phocis, Didyma near Miletus, Claros near Colophon in Ionia, Tenedos and Patara in Lycia. Apollo, in later times, came to be regarded as the god of physic, and was represented to be the father of Asklepios, the god of healing. He is reported to have taken charge for a long time of the herds of Admetus, according to some authorities voluntarily, according to others compelled by Zeus, on account of the murder of the Cyclopes, or the serpent Python. As a builder of cities, the founding of Cyzicum, Cyrene and Naxos in Sicily is ascribed to him, while Homer relates that he built the walls of Troy together with Poseidon (Neptune), and afflicted the city afterward with a pestilence, because Laomedon defrauded him of his pay. According to the poets and sculptors, Apollo, with Ares (Mars), Hermes (Mercury) and Dionysos (Bacchus), belongs to the beardless gods, in whom the dawns of early manhood

appear. He is figured with a bow, a quiver and plectrum, a serpent, a shepherd's crook, a griffin and a swan, a tripod, a laurel, an olive-tree, etc. He was originally the sun-god and though in Homer he appears distinct from Helios (the sun) yet his real nature is hinted at even here by the epithet Phœbus, the radiant or beaming. In later times the view was almost universal that Apollo and Helios were identical and by this theory of his origin we can easily understand how he should be regarded as the god of pastures (Nomios) and of flocks (Karneios), the god that protects and causes the fruits of the field to grow, the god that gives fair winds to mariners (Embasiōs), etc. As he slew the Python, that is, the hostile powers of darkness, with his arrows (the sunbeams), so in later times he was looked on as the averter of evil, the bringer of help and the punisher of overweening pride (as in the story of Niobe). From being the god of light and purity in a physical sense he gradually, as he became endowed more and more in the Greek mind with an ethical character, became the god of moral and spiritual light and purity, the source of all intellectual, social and political progress. Thus he came to be considered as the god of song and prophecy, the god that purifies after the commission of crimes, that averts and heals bodily suffering and disease, the institutor and guardian of civil and political order and the founder of cities. Though not one of the original gods of the Romans, his worship was introduced at Rome at an early period, probably in the time of the Tarquins. Among the ancient statues of Apollo that are extant the most remarkable, and in the judgment of the learned and acute Winckelmann the best and most perfect that art has produced, is the one called the Apollo Belvedere, from the Belvedere Gallery in the Vatican at Rome; also called the Pythian Apollo, because it is supposed that the artist has represented the god in the moment of his victory over the serpent Python. This statue was found in the ruins of Antium in 1503. It is conjectured to be a careful copy of a Greek original, perhaps of the 4th century B.C., or possibly a century or more later.

APOLLO, Pa., borough of Armstrong County, 25 miles northeast of Pittsburgh, on the Kiskiminetas River and the Pennsylvania Railroad. It has manufactories of lime, steel and woolens, and a large trade in coal, which is mined extensively in the district. Apollo was first settled about 1790, was laid out in 1816 and became a borough in 1848. Pop. 3,006.

APOLLO BELVEDERE, bĕl'vā-dā'rā. See **APOLLO**.

APOLLODORUS. (1) An Athenian painter of the 5th century B.C. He is credited with the introduction of rendering light and shade instead of flat coloring. (2) A Greek grammarian of the 2d century B.C. He studied philosophy at Athens and afterward became a follower of Aristarchus at Alexandria. He wrote several grammatical works and a history in iambic verse. His 'On the Gods' was a history of the Greek religion. It is lost and its nature can only be judged from passing references. (3) A famous Roman architect of the 2d century A.D. The Emperor Trajan employed him in the construction of his great

bridge over the Danube, in the building of the Forum, since known as the Forum Trajani, and other works. He censured the architectural plans of Hadrian and was banished from Rome.

APOLLONIUS, Pergæus, from Perga in Pamphylia; lived about 250–200 B.C. He was educated in Alexandria under the successors of Euclid, and became one of the greatest mathematicians of antiquity, being commonly called the "Great Geometer." His most important work was a treatise on conic sections, in eight volumes, of which the first four, with the commentary of Eutocius, are extant in Greek, and all but the eighth volume in Arabic. We have also introductory 'lemmata' to all the eight by Pappus, edited by Halley, 'Apollonius Pergæus Conic,' lib. VIII, c., Oxon. 1710 fol.

APOLLONIUS OF TYANA, Pythagorean philosopher: b. Tyana, in Cappadocia, about whom many wonderful stories are told. He was born in the beginning of the Christian era, early adopted the Pythagorean doctrines, abstaining from animal food and living in the simplest manner, and according to the Pythagorean precept maintained a rigid silence for five years. He traveled in Asia, disseminating his doctrines and doing many wonderful things, and proceeding as far as India, where he became initiated into the doctrines of the Brahmans. When Domitian ascended the throne Apollonius was accused of having excited an insurrection in Egypt in favor of Nerva, but readily submitting to a trial he was acquitted. After this he went once more to Greece and passed over to Ephesus, where he opened a Pythagorean school, and died in 96, or, according to others, 110 A.D.

APOLLOS, an early Christian missionary and companion of Saint Paul. He was born at Alexandria, where he was converted to the new faith by disciples of John the Baptist. He at once became an earnest and zealous propagator of Christianity. He came to Ephesus, where he received further instruction from Aquila and Priscilla, and next proceeded to Corinth, where he labored with great success. He returned to Ephesus, but his followers recalled him to Corinth. He is last mentioned in the New Testament as about to start for Crete. Tradition has it that he became first bishop of Crete. Consult Acts xviii, 24–28; 1 Cor. i, 10–12; iii, 4–6; xvi, 12; and Titus iii, 13.

APOLLYON, ă-pŏl'li'ŏn, or ă-pŏl'yŭn, a rendering of the Hebrew Abaddon, meaning destruction. Apollyon is personified as the keeper of the bottomless pit.

APOLOGETICS, the department of theological science which deals with the defense of the Christian faith. It differs from dogmatics which strives to reduce the doctrines of religion to a systematic form; and from polemics, which is the science of controversy, and while its subject matter comprises the differences found in different schools of believers, apologetics deals with attacks upon the faith which are made by unbelievers. Apologetics may be again distinguished from apologies. The former has to do with the fundamental principles of the religion and with the methods of defense which apply to all attacks, but an apology has to do with some special form of unbelief.

The former is the science of which the latter is an application. Yet, apologetics as a science may be best understood through its historical applications and the distinction named is made more readily in theory than exhibited in detail.

Owing to the nature of Christian theology as historically formulated, apologies have fallen under two main divisions, popularly known as natural theology and the evidences of Christianity. The former is usually put before the latter. It discusses the nature of God and the proofs of His existence as revealed to us in nature. It may also investigate the nature of man, his moral sense, the freedom of his will and his capacity for knowing God. Its chief reliance has been upon four arguments: the ontological, which starts from our idea of a perfect being and shows that it implies actual existence; the cosmological, which from the long line of causes and effects, each contingent, argues backward to a first great cause, which is itself uncaused; the teleological, which shows the marks of design in nature, and from them argues to a great designer; the moral, which starts with the moral sense in man and argues to a holy and righteous maker. Some writers add an æsthetic argument, from our sense of beauty and its gratification in the universe. Then these various arguments are combined and the perfect being is shown to be the first great cause, righteous, wise and a person whom therefore we call God.

The evidences of Christianity assume the existence of such a God, and from this basis prove Christianity to be His peculiar revelation, constituting the absolute religion. This proof ordinarily is divided into two great divisions, external and internal. The external proofs are miracles and completed prophecy, which evince a power and wisdom which are Divine and guarantee the Divine authorship of the writings which they authenticate. The external proofs include also the historical evidence to the genuineness of the scripture writings. The internal evidences show the adaptation of the contents of the Bible to the needs of men, their agreement with the highest teachings of reason, and their elevating and purifying effect upon the mind and life. A further argument is based upon the experience of the Christian as testifying to the truth of the doctrines involved.

This argument in both divisions, natural theology and the evidences of Christianity, occupies the chief place in the textbooks, but, evidently, it is a form of specific apology and at best only in part illustrates essential apologetics. This it appears from a wider survey for the argument as stated above, while it meets a special situation, neither represents the actual argumentation in the first ages of the Church nor in our own day. Even in the New Testament some of the writings have an apologetic purpose. Christianity in its early form met two opponents, Judaism and heathenism. To the first, the apostolic writers attempted to prove its truth by showing it as foretold in the Old Testament, and as completing the earlier Scriptures. When Christianity encountered Greek thought the situation was wholly different, and the apologists formulated the contents of the gospel in a manner which appealed to the common sense of all the serious thinkers and intelligent men of the age. That is, Chris-

tianity was presented as completing, or at least harmonizing with, the later Greek philosophy. In this it succeeded and then ensued a long period when apologetics was in abeyance. The intellectual life of the Church was engaged in formulating dogmas and in conflicts with heresy. Only long after the Reformation was the strife renewed with men who seriously denied the truth of Christianity.

In the end of the 17th century and the beginning of the 18th century the minds of English Churchmen were engaged by the Deistic controversy. This had to do with the evidences of Christianity. The Copernican astronomy, changing men's conceptions of the physical universe, the discovery of China, or better its rediscovery and its effect upon the imagination of thoughtful men, and the attacks of the British clergy upon the miracles of the Roman Catholic Church, brought on a crisis. The new astronomy suggested the thought that the God of so great a universe could not be identical with Jehovah, the God of a Semitic people; nor could men conceive of the earth, no longer central but a mere planet, as the scene of the drama of the incarnation and the redemption; the consideration of China with the thought of its relatively high civilization suggested that if China had got on so well without the special teaching of the gospel with the light of reason only, the special revelation must also be valueless to Englishmen; and the attacks of the clergy upon the Roman Catholic miracles as the frauds of priests led to the position that all miracles, including those of the Bible, may be put into the same category. It was further urged that the description of Jehovah in the Bible and in the doctrines of the Church does not accord with the righteousness and wisdom and power of the God disclosed by nature. The conception of nature as a vast machine was taking possession of men's minds, and God was thought to be the maker and starter of the machine, and as having no further occasion to interfere with its running. He was not denied, therefore, but He was made infinitely remote, and there seemed no opportunity for miracle, redemption or prayer. The attack called forth a multitude of replies, the 'Analogy' of Bishop Butler being the most effective and distinguished. He argued that revealed and natural religion are not opposed, but that the second supplements the first, and that its peculiarities are what we should expect from a study of nature itself; and that further, the difficulties urged by the Deists against the God of the Bible lie with equal force against their own teaching of the God of nature. It was further argued in particular, that the account of the gospel miracles is to be accepted, because the witnesses were competent, and moreover had everything to lose and nothing to gain by their invention, proving their sincerity by dying as martyrs. The Wesleyan revivals were perhaps more influential than the arguments of the apologists by supplying the powerful evidence of the effectual working of Christianity in the hearts and lives of men. From England the controversy was carried to France, and to Germany, with phases too varied for even the briefest review here.

In the 19th century, from the middle decades on, the apologetic warfare was renewed, with issues far more fundamental. Already

Hume had stated positions which threatened the beliefs of Churchmen and of Deists alike, and under the influence of an extreme empiricism, reinforced by influences from German philosophy, men denied that God could be known at all. Hence apologetics again busied itself with the first division of topics, and discussed man's capacity for knowing the Infinite, and reviewed all the evidences for God's existence in the light of the modern science of knowledge. The progressive establishment of the scientific conception of the universe also revived the discussion as to miracles and forced a renewed examination of the whole subject. In addition the historic credibility of the gospel narrative and the authenticity of the Biblical writings have been re-examined from many points of view, while the discovery of the ancient religions of the past and of the living religions of Asia have caused prolonged debate as to the uniqueness and the absoluteness of the Christian teachings. Hence, the apologist is engaged in a discussion which involves philosophy, science, history, comparative theology and criticism.

In general, we may put apologists at present into three classes: those who hold substantially the old positions and seek in part by compromise and in part by adaptation to show that their essential truth may be maintained notwithstanding the progress in philosophy and science; those who abandon the old arguments, and overcome the conflict between science and philosophy on the one hand and theology on the other, by adopting wholly the modern views and reconstructing theology by their aid; and those who attempt to discriminate between religion and science and philosophy, and by penetrating more completely into its essence to find an independent basis for the religious life which shall abide however men's views may change in these other departments. Particular arguments in reply to special attacks are of less moment than a discussion of the meaning and essence of Christianity itself, and of the principles which underlie all defenses of its truth. That is, this age needs not so much an apology or defense of Christian truths as a thorough-going study of the science of apologetics itself.

GEORGE WM. KNOX,

Late Professor of Philosophy and History of Religion, Union Theological Seminary.

APOLOGIA PRO VITA SUA (first published in parts, April to June 1864; revised and republished as a whole, 1865), by Cardinal Newman, is the autobiography of a great soul. In 1845 Newman left the English for the Roman Church. Almost 20 years later Charles Kingsley included him in an incidental aspersions (*Macmillan's Magazine*, January

1864) of the Roman clergy's attitude toward "truth for its own sake." The following interchange of letters, pamphlets and articles convinced Newman of the necessity of reviewing, for an end larger than the defense of his own integrity, the whole course of his spiritual progress. This larger aim, suggested in a title that Newman can hardly have chosen without thinking of the great 'Apologia' of Socrates, gives his work a deep general interest. The debate between the two English men of letters went so unquestionably to Newman that it could hardly arouse posterity; the actual immediate issues between the two churches were too clouded by prejudice and politics to hold attention long in that form; but beneath the controversy lay an issue that remains vital; and beneath the history set forth in the book moves an eternal human quest.

The issue was the catholicity of the Church of England. To restore to the Church in which they were priests a general consciousness of Catholic heritage, a wider view of Catholic doctrine and history, and a wider use of the sacraments was the mission of the young Newman and his friends, Keble, Pusey, and others less well known, in what came to be known as the Oxford Movement (q.v.). Working as scholars and as preachers toward this common end in various ways, they made their most direct and effective appeal in a series of 'Tracts for the Times'; and their ultimate success amounted to a reformation. That the Church of England rose from insular prejudices and political bondage to become a great national Church was due largely and directly to the Oxford Movement. The Catholic heritage had, indeed, been cherished and followed even in the 18th century in spite of the general depression of the Church by rationalism and politics. It had animated, for instance, those missions to the New England colonies which moved and brought about the Episcopal Church of the United States. The consecration of the first bishop of that Church was attested in a proclamation "*Omnibus ubique Catholicis.*" But that consecration was by "non-juring" bishops in Scotland. The actual ecclesiastical administration in England then and in Newman's time insisted, if not on a narrower view, at least on a narrower practice. The bishops generally, the dominant ecclesiastical party, and the religious habits of the mass of Church people were far narrower than the doctrine of the Book of Common Prayer or the interpretation of the Caroline divines. The mission of Newman and his friends was restoration. It succeeded ultimately; but meantime it met such ecclesiastical opposition as to drive some of them to the Roman Church. Newman found himself unable to read in the repudiation of some 'Tracts for the Times' and in other ecclesiastical pronouncements and measures of British bishops anything short of a repudiation of catholicity. Becoming convinced that the Church of England was not in fact Catholic, he changed his allegiance.

This is the issue underlying 'Apologia pro Vita Sua'; but vital as it remains, and deeply as it is explored, it has less appeal than the autobiography for itself. The lucidity, sweetness and force spring from aspiration. The steady quest of the soul, set forth with a sincerity that makes one first pity and then for-

get Charles Kingsley, is told with that high preoccupation which gives to a few autobiographies permanent hold. An accomplished reasoner, Newman understood better than most men the limitations of reasoning in effectiveness on conduct. "It has not pleased God to save His people through logic," he quotes from Saint Ambrose on the title page of the most philosophical of his longer works, 'A Grammar of Assent.' This book inculcates systematically the right ways of the mind seeking truth; but the 'Apologia' by narrating the stages of his own search brings it home. We need not be convinced by his arguments nor subscribe to his conclusions to be uplifted by a noble and single mind following the "kindly light" which he invokes in his famous hymn.

CHARLES SEARS BALDWIN,
Professor of Rhetoric and English Composition, Columbia University.

APOLOGUE, a story or relation of fictitious events intended to convey some useful truth. It differs from a parable in that the latter is drawn from events that pass among mankind whereas the apologue may be founded on supposed actions of brutes or inanimate things. Æsop's fables furnish excellent examples of apologues.

APOLOGY, a term at one time applied to a defense of one who is accused, or of certain doctrines called in question, but at present commonly applied to an acknowledgment of error. The apologies of Socrates attributed to Plato and Xenophon are works of the first-named character. Later rhetoricians wrote upon the use of apologies and caused them to be composed by their scholars. Of this sort are the Apologies of Libanius. Thus the name passed over to Christian authors, who gave the name of apologies to the writings which were designed to defend Christianity against the attacks and accusations of its enemies, particularly the pagan philosophers, and to justify its professors before the emperors. Of this sort were those by Justin Martyr, Athenagoras, Tertullian, Tatian and others. There are also apologies for the doctrines of particular sects; for example, Robert Barclay's 'Apology for the People in Scorn called Quakers.'

APOLOGY FOR THE LIFE OF COLLEY CIBBER, An, an autobiography published in 1740, when the author, poet-laureate, actor and man-about-town was in his 70th year. In the annals of the stage this curious volume holds an important place as throwing light upon dramatic conditions in London after the Restoration, when the theatre began to assume its modern aspect.

APOMECOMETER. An instrument used for measuring heights, constructed in accordance with the principles which govern the sextant, viz.: As the angles of incidence and reflection are always equal, the rays of an object being thrown on the plane of one mirror are from that reflected to the plane of another mirror, thereby making both extremes of the vertical height coincide exactly at the same point on the horizon-glass, so that by measuring the base-line we obtain a result equal to the altitude. The eye of the observer when in position will be at the lower end of the hypotenuse, and the summit of the object at the other. Keeping the line of vision, which

forms the base, exactly horizontal, the observer approaches the object till the images coincide, when the base will agree in length with the perpendicular and the measured length of the former will give the height of the latter.

APOMORPHINE. See MORPHINE.

AP'ONEURO'SIS. See TENDON.

APOPHYLLITE, ä-pöf'i-lit (from the Greek words *apo*, "off," and *phyllon*, "leaf," in allusion to the tendency of the mineral to separate into thin leaves before the blowpipe), a native hydrated silicate of calcium and potassium, having the general formula $K_2O.8CaO.16SiO_2.16H_2O$, but with some portion of the oxygen replaced by fluorine. It crystallizes in the tetragonal system, and also occurs massive. Its crystals are usually white or gray, with a pronounced pearly lustre on the basal plane, and a vitreous lustre elsewhere. Apophyllite cleaves easily into thin folia parallel to the basal plane. Its hardness is from 4.5 to 5, and its specific gravity about 2.3. It occurs in many parts of the world. Beautiful crystals, three or four inches across, are found in India, and others nearly as large have been found at Bergen Hill and Paterson, N. J.

APOPLEXY. See BRAIN, DISEASES OF.

APOSIOPESIS, äp'ö-si-ö-pe'sis, a rhetorical term denoting a sudden break or stop in speaking or writing, usually for mere effect or a pretense of unwillingness to say anything on a subject; as, "his character is such — but it is better I should not speak of that."

APOSPORY. Apospory is the natural complement of apogamy (q.v.). It may be defined as the production of a gametophyte from a sporohyte (see ALTERNATION OF GENERATIONS) without the intervention of a spore. The word means that the spore has been left out. Apospory was first discovered in the common bracken fern (*Pteris aquilina*), where it occasionally appears as an interesting freak. Tissue near the border of the leaflet, which normally develops sporangia containing spores, grows out into thin ribbon-like structures bearing some resemblance to ordinary gametophytes (prothallia). These structures bear the antheridia or archegonia or both, which give rise to the sperms and eggs, and, therefore, constitute a sexual generation. A transverse section of a normal leaflet of the bracken fern bearing normal sporangia (*s*) is shown in Fig. 1; while Fig. 2 shows a leaflet in which prothallia (*p*) with antheridia (*a*) have developed instead of sporangia. A comparison of the two figures shows that apospory is a "short cut" in the life history, since, normally, a spore in the sporangium would have given rise to the prothallium. In some ferns, under moist conditions, the tips of the leaflets may develop into prothallia bearing archegonia and antheridia. In a few ferns, the first leaf of the young sporophyte, if bent over and brought into contact with moist soil, may produce prothallia along its border. Other instances of apospory in ferns might be cited, but no case has yet been reported for lycopods or equisetums. Apospory occurs in liverworts and mosses, but is not common, and no case has been proved in Gymnosperms. In Angiosperms there are several cases, including the common dandelion, in which the egg-bearing generation (embryo

sac) does not develop from a normal spore and we must admit that apospory is present. All these plants, however, develop their embryos from eggs without fertilization and, conse-

FIG. 1

FIG. 2

quently, are apogamous, as well as aposporous. This type is so closely associated with *Parthenogenesis* (q.v.) that it well may be considered under that heading.

H., 'On Apogamy and the Development of Sporangia upon Fern Prothallia' (Philosophical Transactions, Royal Society of London, Vol. CXC, 1898, p. 189); Yamanouchi, S., 'Apogamy in Nephrodium' (*Botanical Gazette*, Vol. XLV, 1908, p. 289).

CHARLES J. CHAMBERLAIN.

APOSTASY (Greek, *apostasis*, a standing away from), a term signifying a renunciation of opinions or practices and the adoption of contrary ones, and usually applied to renunciation of religious opinions. It is always an expression of reproach. What one party calls apostasy is termed by the other conversion. History mentions three eminent apostates — Julian the Apostate, who had never been a Christian except nominally and by compulsion; Henry IV, King of France, who thought that "Paris vaut bien une messe," and that of course all France was worth the whole Catholic faith; and William of Nassau, the stadtholder, who separated himself from the Roman Catholic Church and became a Protestant. The statute 9 and 10 of William III, cap. xxxii, provides that if any person educated in or having made profession of the Christian religion shall deny it to be true, he shall be rendered incapable of holding any office for the first offense, and for the second shall be made incapable of bringing any action, of being guardian, executor, legatee or purchaser of lands, and

shall suffer three years' imprisonment without bail. This act is commonly called the "blasphemy act."

A POSTERIORI. See **A PRIORI.**

APOSTLE (literally one sent out, from the Greek *apostellein*, to send out) and in the Christian Church the title given to the 12 men whom Jesus selected to attend Him during His ministry, witness His miracles, learn His doctrines and thus be able to promulgate His religion. Their names were Simon Peter and Andrew his brother; James the greater, and John his brother, who were sons of Zebedee; Philip of Bethsaida; Bartholomew; Thomas; Matthew; James, the son of Alphaeus, commonly called James the less; Lebbeus, his brother, who was surnamed Thaddeus, and was called Judas or Jude; Simon the Canaanite; and Judas Iscariot. Of this number Simon Peter, John, James the greater and Andrew were fishermen; and Matthew a publican or tax-gatherer. When the apostles were reduced to 11 by the suicide of Judas, who had betrayed Christ, Matthias was chosen by lot on the proposition of Saint Peter. Soon after, their number became 13 by the miraculous vocation of Saul, who, under the name of Paul, became one of the most zealous propagators of the Christian faith. The Bible gives the name of apostle to Barnabas also, who accompanied Paul on his missions (Acts xiv, 14), and Paul seems to give it to Andronicus and Junia, his relations and companions in prison. Generally, however, the name is used in the narrower sense to designate those whom Christ selected himself while on earth, and Paul, whom he afterward called. In a wider sense those preachers who first taught Christianity in heathen countries are frequently termed Apostles; for example, Saint Denis, the apostle of the Gauls; Saint Boniface, the apostle of Germany; Saint Augustine, the apostle of England; the Jesuit Francis Xavier, the apostle of the Indies; Adalbert of Prague, apostle of Prussia proper. Tradition reports that several of the early apostles were married. The wife of Saint Peter is said to have accompanied him on his journeys, and died a martyr. The tradition further states that Saint Peter had a daughter Petronilla, who was also a martyr; this at least say Saint Augustine, Saint Epiphanius and Saint Clement of Alexandria. Saint Philip also is said to have been married and to have had several daughters, among whom was Saint Hermione. Hegesippus speaks of two martyrs, grandsons of Saint Jude. His wife was called Mary. Saint Bartholomew is also said to have been married. Their history is largely a matter of tradition, save as it is recorded in the Acts of the Apostles.

APOSTLE OF THE ARDENNES, title bestowed on Saint Hubert, son of the Duke of Aquitaine. He was made bishop of Liège in 708 and died in 728 A.D. About 800 his body was transferred to the Benedictine monastery of Andoin, in the Ardennes, which soon came to be called Saint Hubert. See **HUBERT, SAINT.**

APOSTLE OF THE ENGLISH, title bestowed on Saint Augustine, who, with several companions, was sent as missionary to England by Pope Gregory I, whose interest in that people had been aroused by seeing some captives of that race exposed for sale in the public mart at Rome. Saint Augustine is rather

the Apostle of Kent than of all England, since his labors were confined entirely to the south-eastern part of the country. See **AUGUSTINE, SAINT.**

APOSTLE OF FREE TRADE, title bestowed on Richard Cobden (q.v.), because of his constant advocacy of the repeal of the high-tariff schedules prevalent in England in 1830-46. He foresaw the rise of American competition with England's manufactured products, and pointed out the disadvantages which would arise from a policy of high protective duties and showed that the best policy was that of free trade.

APOSTLE OF THE FRENCH, title of Saint Denis, patron of France, who suffered martyrdom at Paris in 272 A.D.

APOSTLE OF THE GENTILES, appellation of Saint Paul, who undertook "to preach the Gospel to all mankind."

APOSTLE OF GERMANY, title bestowed on the English missionary, Saint Boniface, d. 755, for his untiring labors in Christianizing the German tribes. See **BONIFACE, SAINT.**

APOSTLE OF THE HIGHLANDERS. Saint Columba, founder of the monastery of Iona in the 6th century and missionary to the Scots of Alba, is known by this title. See **COLUMBA, SAINT.**

APOSTLE TO THE INDIANS, title given to John Eliot (q.v.) for his efforts in Christianizing the Indian tribes of New England in the 17th century.

APOSTLE OF THE INDIES. Name given to Bartholomew de Las Casas (q.v.), a Dominican monk, whose untiring efforts for the spiritual and temporal betterment of the American aborigines show him to have been far in advance of his time.

APOSTLE OF INFIDELITY, term applied to Voltaire (q.v.), for his persistent attacks on organized Christianity, and for the protection afforded by him to those whom he believed persecuted or hounded by the clerics of his day.

APOSTLE OF IRELAND, title applied to Saint Patrick, who, about 432 A.D., began his mission of converting Ireland to the Christian faith, a work which he brought to a successful conclusion before his death in 493 A.D. See **PATRICK, SAINT.**

APOSTLE TO THE SCOTS, appellation given the Scottish reformer John Knox for his efforts in spreading the doctrines of Calvin in Scotland. He is also styled the Apostle of the Scottish Reformation. See **KNOX, JOHN.**

APOSTLE SPOONS, a name applied to sets of spoons with handles formed of images of the Twelve Apostles and the Virgin. Such sets were common as christening gifts as late as the 17th century. Sets of this kind are now rare and when complete fetch fancy prices, a set being sold some years ago in London for \$24,000.

APOSTLE OF TEMPERANCE, title given to the Rev. Theobald Mathew, a native of Cork, Ireland, who performed heroic work in the cause of temperance in the first half of the 19th century. He brought hundreds of thousands under the banner of temperance in

Ireland, Scotland and the United States. See MATHEW, THEOBALD.

APOSTLES' CREED. See CREEDS AND CONFESSIONS.

APOSTLES' ISLANDS, or **THE TWELVE APOSTLES,** the name given to a group of 27 islands in Lake Superior, belonging to Wisconsin. The principal islands of the group are Ile au Chêne, Stockton, Bear, Madeline, and Outer. They have an area of 200 square miles. Brown sandstone is exported and the islands are covered with a rich growth of timber. The cliffs have been worn into strange forms by the action of the waves. La Pointe, on Madeline Island, formerly the county-seat of Ashland County, Wis., was settled by the French, who established Jesuit missions on the islands as early as 1680.

APOSTLESHIP OF PRAYER, a pious association founded in France in 1844 by Rev. Francis Gautrelet for the purpose of advancing its members in the spiritual life and particularly of honoring the Sacred Heart of Jesus. There are three degrees of membership, composed of those who promise to make the morning offering of their thoughts, words, actions and sufferings to God in union with the intention of Christ; those who recite once each day the Lord's Prayer and the Hail Mary 10 times; and those who receive Holy Communion monthly as an act of reparation to the Sacred Heart of Jesus. The membership throughout the world is supposed to be about 30,000,000, and there are about 5,000,000 in the United States. The central office is at Saint Francis Xavier Church, New York.

APOSTOLIC BRETHERN, APOSTOLICI, or **APOSTOLICS,** the name given to certain sects who professed to imitate the manners and practice of the apostles. The last and most important of these was founded about 1260 by Gerhard Segarelli of Parma. They went barefooted, clothed in white, with long beard, disheveled hair and bare heads, accompanied by women called spiritual sisters, begging, preaching and singing, throughout Italy, Switzerland and France; announced the coming of the kingdom of heaven and of purer times; denounced the papacy and its corrupt and worldly Church; and inculcated the complete renunciation of all worldly ties, of property, settled abode, marriage, etc. This society was formally abolished (1286) by Honorius IV. Segarelli was burned as a heretic in 1300. Another leader now appeared, Dolcino, a learned man of Milan. In self-defense they stationed themselves in fortified places whence they might resist attacks. After having devastated a large tract of country belonging to Milan they were subdued (1307) by the troops of Bishop Raynerius in their fortress Zebello, in Vercelli, and almost all destroyed. Dolcino was burned at Vercelli, 1 June 1307. The survivors afterward appeared in Lombardy and in the south of France as late as 1368.

APOSTOLIC CHURCH, the Church in the time of the apostles, constituted according to their design. The name is also given to the four churches of Rome, Alexandria, Antioch and Jerusalem, and is claimed by the Roman Catholic Church and occasionally by the Episcopals.

APOSTOLIC CONSTITUTIONS AND CANONS, a collection of regulations attributed to the apostles, but generally supposed to be spurious. They appeared in the 4th century, are divided into eight books and consist of rules and precepts relating to the duty of Christians, and particularly to the ceremonies and discipline of the Church.

APOSTOLIC DELEGATE, a permanent representative of the Pope in a foreign country. The term is sometimes confounded with the word ablegate, the latter meaning a temporary representative of the Pope for some special function.

APOSTOLIC FATHERS, the disciples and followers of the apostles, more especially those that have left written records behind. Many of these writings are in the nature of continuations of the apostolic epistles and throw much light on the early history of the Church. These writings comprise the Epistle of Clement of Rome and the so-called Second Epistle (which is not his); the seven Epistles of Ignatius of Antioch; the Epistle of Polycarp of Smyrna; the Martyrdom of Polycarp; the Teachings of the Apostles; the Epistle of Barnabas; the Shepherd of Hermas; the Epistle of Diognetus; the fragments of Papias and the Reliques of the Elders. Editions of these writings have been published by J. B. Cotelerius (Paris 1672); W. Jacobson (Oxford 1838); C. J. Hefele (Tübingen 1839); A. R. M. Dressel (Leipzig 1857); Gebhardt, Zahn and Harnack (Leipzig 1876-78; text ed. 1877; 3d ed. 1900); J. B. Lightfoot (texts and English trans. London 1891, 2d ed. 1893).

APOSTOLIC MAJESTY, a title granted by the Pope to the kings of Hungary, first conferred on Saint Stephen, the founder of the royal line of Hungary, on account of what he accomplished in the spread of Christianity.

APOSTOLIC PARTY, a name given to a body of Spanish fanatics who early in the 19th century clamored for the restoration of the Inquisition. About 1830 they became merged in the Carlist party.

APOSTOLIC SEE, official title of the seat of the Pope of Rome, who, according to the doctrine of the Catholic Church, is the apostolic successor of Saint Peter.

APOSTOLIC SUCCESSION. The doctrine of the direct and hierarchical succession from Christ's apostles. Its defenders maintain that the Christian ministry is a succession, that valid ordination is transmitted to the clergy only by accredited bishops who have received the power of ordination in direct line of succession from the apostles. The points of controversy are (1) as to when and how the exclusive authority of ordination was given by Christ and the apostles; (2) by what act, if any, the transmission of this authority is to be made valid; (3) along what lines has this supernatural commission come; and (4) whether or not this supernatural grace and spiritual authority are restricted to definite official lines of transmission. In later years differences have arisen among the Anglican scholars regarding these various points. Independents and Dissenters in England, of course, argue in favor of the theory that the Church itself as a body may constitute a legitimate ministry, with full

powers of ordination, etc. This in general is the attitude of non-prelatical bodies. In defense of the doctrine consult Gore, 'The Church and the Ministry' (1892); in opposition consult Brown, John, 'Apostolic Succession' (1898). Consult also Brightman, 'What Objections have been made to English Orders' (1896); Denny, 'Anglican Orders and Jurisdiction' (1893); Haddan, 'Apostolic Succession in the Church of England' (London 1869); Moberly, 'Ministerial Priesthood' (1898).

APOSTROPHE, a term in rhetoric indicating a figure of speech by which, according to Quintilian, a speaker turns from the rest of his audience to one person, and addresses him singly. Now, however, the signification is wider, including cases in which an impassioned orator addresses the absent, the dead, or even things inanimate.

The name is also employed in grammar to denote the substitution of a mark like this (') for one or more letters omitted from a word, as *tho'* for *though*, *'twas* for *it was*, *king's* for *kinges*. It is also applied to the mark indicating such substitution, especially in the case of the possessive. The old possessive singular was *es*, and the apostrophe stands for the omitted *e*.

APOTHEOSIS, a Greek term indicating the ceremony by which a man was raised to the rank of the gods. The custom of placing mortals who had rendered their countrymen important services among the gods was very ancient among the Greeks, who generally followed in so doing the advice of an oracle. On their coins most of the founders of cities and colonies are immortalized as gods; and in subsequent times living princes assumed this title. The Romans for several centuries deified none but Romulus, and first initiated the Greeks in the fashion of frequent apotheosis after the time of Cæsar.

APPALACHIAN AMERICA, a term used to designate the southeastern mountain region of the United States. This territory has a certain sociological unity, based on physical conditions, which was long obscured by the fact that it was parceled out among several different States.

Physiographically it is a mountainous territory without arms of the sea, inland lakes or other national waterways; and furthermore it is a territory which forbids canals. Its universal characteristics are difficulty of communication, isolation and remoteness. These conditions were less severe, and were largely overcome by greater commercial and intellectual activity in the portions of the Appalachian system which lay in the northern free States. Accordingly, as a sociological grand division, Appalachian America begins with the southern boundary of Pennsylvania and the Ohio River, and embraces the mountainous portions of the Virginias and Carolinas, Kentucky and Tennessee, Georgia and Alabama. In this vast area, which is all a land of saddles and bad roads, there are, of course, great varieties of elevation and climate from the "dissected plateaus" of Kentucky to "the land of the sky" in North Carolina. Descriptions of the geological formations, minerals, forests and other resources, and physiographic conditions appear

under the several States. But the one great fact about the whole territory is that it condemns its inhabitants to the ills of isolation.

Historically Appalachian America received its first sparse settlements about the time of the Revolutionary War. A great tide of migration passed through it and around it to the west, and the valley land was occupied by hardy settlers. It was these who fought the battle of King's Mountain, and in the War of 1812 riflemen from the mountains gave material assistance in defeating the British at New Orleans. When the slave power developed in the South subsequent to the Revolution, Appalachian America, retaining its revolutionary spirit of liberty, came to be looked upon with hostility by its Southern neighbors. Slavery was never common in the mountains, and the scorn of the slaveholders for those who did not hold slaves was heartily returned by the mountaineers. Thus social barriers were added to the barriers of nature and the mountain people still further isolated from the world. In the Civil War, however, they emerged from their obscurity and surprised both the North and the South by their vigorous and effective stand for "union and liberty." They held Kentucky in the Union, made West Virginia "secede from secession," well-nigh divided Tennessee, and furnished recruits to the loyal armies even from Alabama and South Carolina. Many of these recruits were not enrolled as coming from these States, but the regular regiments enlisted from slave States, nearly all from the mountains, aggregated about 200,000 men. The sufferings of the loyal people throughout the mountains, and especially in East Tennessee, and the eloquence of "Parson Brownlow," for the time fixed the attention of the nation. Naturally the mountaineers have since the war followed the fortunes of the Republican party.

Sociologically Appalachian America reveals most interesting survivals of the spirit, arts and conditions of colonial times. Within its area are many valleys and villages which differ from other parts of the United States only in superficial matters like the greater number of saddle horses and the more free hospitality. But there is an immense population (commonly estimated at 2,000,000) which has been little affected by modern ideas. The stock is mainly British, representing rural England and the Scotch-Irish, though with traces of the Huguenot and the German. A large number of Washington's soldiers settled in the valley land of Appalachian America, and there is no evidence that the pioneers of the mountain region were in any way inferior to the first settlers in the more favored "blue grass sections." The early settlers had the education of their time, which lessened in succeeding generations. The conditions of life grew harder when the valley land and game were exhausted, and the public school did not come in until the "reconstruction period." As a result, a great part of all the native-born illiterates in the United States—many of them people of good character and good abilities—are in this region. In some counties the illiterate white voters exceed a third of the whole number. It is among these people that we find a survival of pioneer conditions—the woodcraft, the log cabin, the open fireplace—with a noble stone chimney in Kentucky, degenerating into a stick

and mud chimney farther south. The arts of spinning, dyeing and weaving are still found, together with a wealth of Saxon speech, and even old British ballads which have come down by oral tradition. Survivals in language consist of ancient pronunciations and constructions, and the persistence of words and meanings elsewhere obsolete; as "pack" for carry, "gorm" meaning to muss, etc. A kind of minstrelsy still exists among the ruder classes, so that we may find drinking songs and folk-lore still in the making. Preachers are few and poorly paid, and religion is of a mediæval and fatalistic type. The feuds and homicides which attract so much attention belong with these other survivals. Weapons are carried to some extent in all parts of the South, because men retain the Elizabethan idea that while the government protects the land from foreign foes, each man is to protect his private honor and interests with his own right arm. In the mountains this view is more plausible because the law is not always carried out with the certainty and majesty which could inspire either confidence or dread. Considering these adverse conditions of life, the general good order and morality of the mountains is very creditable. A woman or a stranger who behaves properly is always safe. The chief disorders arise from corrupt political leaders and the whisky bottle, and the mountain people have taken the first great step of progress in very generally enacting local option laws which prohibit the sale of intoxicants. Yet the "moonshine still"—the secret manufacture of spirits on which no tax is paid—survives in many places, and makes Christmas or election time a terror to the mothers of mountain boys.

A most striking characteristic is the absence of any foreign element in the population. The 35 mountain counties of Kentucky, for example, contain about 480,000 people, with only 2,000 or 3,000 who are of foreign birth, and these massed in a few counties where mines or lumber interests have been recently established. There are 15 counties each containing less than 10 persons of foreign birth. The massing of so great a population of purely American birth and breeding is very significant. And these people who owned land but did not own slaves (never to be confused with the "poor whites") constitute the true yeomanry of the South, its best nucleus for a true middle class. Large families are the rule, and the standard of physical development is high. With this large birth-rate the mountain region is approaching the limit of population and must either improve the means of subsistence or emigrate. Both movements have begun. In time the mineral wealth will bring railroads to a larger extent, and if proper educational guidance is furnished Appalachian America will become what Scotland is in Great Britain, a storehouse of national vigor and patriotism.

Printed information regarding Appalachian America is fragmentary and partial. Chas. Dudley Warner reported a charming tour 'On Horseback Through Virginia' and important notices occur in Fisk's 'Old Virginia and Her Neighbors,' Roosevelt's 'Winning of the West,' and Draper's 'King's Mountain and Its Heroes.' The spirit of war times is reproduced in Barton's 'Hero in Homespun,' and the general

characteristics of mountain life appear in the tales of John Fox, Jr., and Mary N. Murfree ('Charles Egbert Craddock').

APPALACHIAN MOUNTAIN CLUB, the name of an organization interested in the exploration and study of the mountain ranges of eastern North America and the preservation of their woodlands, waters and historic sites for the use of the public. The club has published a journal, called *Appalachia*, devoted to the objects of the organization, since 1894. Headquarters, Boston.

APPALACHIAN MOUNTAINS, the great mountain system of the eastern United States extending from northern Alabama into the State of New York and according to the best recent opinion embracing also the New England system. Thus defined it includes a number of ranges and mountain groups of which the most important are the Alleghanies, the Blue Ridge, the Cumberland, the Black Mountains, the Catskills (formerly regarded as the northern termination), the White Mountains and the Green Mountain range extending northward to the Laurentian formations. But in comparison with this great length north and south, its measurements east and west are very moderate, the width at no point much exceeding 100 miles. The most remarkable feature of the general formation of the Appalachians is the regular arrangement of its ridges and valleys, these being, in general, parallel to the Atlantic coast line. This arrangement is particularly noticeable in the central part of the system, through Pennsylvania and Virginia. In general the ridges lie along two parallel lines from 50 to 100 miles apart, thus enclosing a longitudinal valley whose sides rise rather abruptly to culminating points of the mountains. This great central valley extends from New York to the southern end of the system, including the Cumberland Valley in Pennsylvania and the great valley of Virginia and of Tennessee. This region is very fertile throughout its whole length, and is especially well cultivated in Lancaster, Berks and Lehigh counties, Pa. The Appalachians show no remarkable elevations and the height of the summits appears less than it really is, because the mountains rise from a plateau varying from 500 feet in Pennsylvania to 1,500 and 2,000 feet in Virginia and Tennessee. The lowest peaks are found in Pennsylvania, none rising much above 2,000 feet. The culminating point of the whole system is Mount Mitchell, in the Black Mountains (6,711 feet); others of the high peaks, also found in the Black Mountain range, are Balsam Cone 6,671 feet, Black Brother 6,619 and Mount Hallback; the Smoky Mountains, too, include some high peaks, for example, Clingmann Dome 6,619, Guyot 6,636, Mount Alexander 6,447, Mount Seconto 6,612 and Mount Curtis 6,568. The culminating point of the northern part of the system is Mount Washington, New Hampshire (6,233 feet). The peaks are generally of rounded outline and lack the bold picturesqueness that characterizes the Rocky Mountains and other geologically "young" ranges in the western United States. Their low altitude and smooth contour are the result of the long-continued erosion which has removed great thicknesses of strata since the first uplift.

Geology.—The Appalachians show all geological formations from the metamorphic group of the Pre-Cambrian to the so-called coal-measures of the Carboniferous, the latter including sandstones, shales, limestones and coal. The strata of the western slope with their regular horizontal arrangement show a great contrast to the disturbed stratification of the eastern slope. There the rock formations are confused and pressed into folds and wrinkles with an inclination generally southeast. The strata of the system are all of marine or terrestrial origin, the latest being those of the coal formation. After the formation of these strata, probably during Permian time, the mountains were elevated to their present position by a force that proceeded from the southeast, working probably by many successive impulses. Subsequent erosion by rivers carved the gaps through the ridges so characteristic of the Appalachian topography and gave the mountains their present conformation. The chief minerals of the Appalachians are iron and coal. Iron ores, magnetite, hematite, and limonite, are very abundant; the magnetic iron is found especially in what is called the Champlain Iron District. The hematite and limonite ores are found all along the great Appalachian Valley and are of great commercial importance; while the earthy carbonite of iron found in many parts has been largely manufactured. Coal is perhaps the most important product; the coal deposits of the Appalachians include the whole anthracite field of Pennsylvania and New York with an area of 400 to 500 square miles, and the bituminous fields of Pennsylvania and other States, with an area of 56,000 square miles. Gold, silver, copper and lead are found in comparatively small quantities and are of little importance commercially, but the deposits of marble, limestone, fire-clay, gypsum and salt are abundant and valuable.

Drainage.—The Appalachians form the watershed between the Atlantic Ocean and the Mississippi River systems; this does not lie in one continuous line, but shifts its position from one line of ridges to another, so that many of the rivers cut their way through the mountains from west to east, or east to west; the Delaware and Susquehanna, for example, with their branches. These two rivers, with the Potomac and James, drain much of the eastern slope; the Ohio, with its tributaries, is the chief means of drainage on the western slope.

Flora and Fauna.—The mountain slopes are heavily wooded throughout the whole system. The white pine is found in all portions; the sugar maple, the white birch, ash and beech grow on the northern mountains; the oak, cherry, white poplar, white and yellow pine farther south. On the poorer lands the evergreens flourish, such as spruce, hemlock and balsam-fir, which, on account of their dark foliage covering the summits of the Black Mountains, have given this range its name. There are large quantities of flowering shrubs, particularly the rhododendrons, azaleas and laurel often growing in almost impenetrable thickets, and many varieties of smaller plants and flowers. Panthers and wolves have practically disappeared from the mountains, but bears, deer and wild-cats are quite common. Small game birds are plentiful and wild turkeys also on the southern ranges. Rattlesnakes

and copperheads are found in all parts of the Appalachians, but not in great numbers.

MARRION WILCOX.

APPALACHICOLA RIVER. See BOUNDARIES OF THE UNITED STATES.

APPAM CASE, The. In February 1916 the British steamship Appam was captured at sea by the German raider Moewe; a prize crew was put on board and the vessel was taken into Hampton Roads. Her British owners filed suit to recover possession of her from her captors. Federal Judge Edmund Waddill of Virginia, in a 15,000-word opinion, directed, 29 July 1916, that the vessel, with the cargo remaining aboard her and the proceeds of the perishable cargo already sold, should be restored at once to the British owners. The German government appealed to the Supreme Court of the United States, which on 6 March 1917 handed down a decision that a belligerent nation may not bring prizes of war into a neutral port. The Supreme Court held that it would be unneutral for the United States to permit either belligerent to bring prizes into American ports, and that Germany could not claim such right under any of the existing treaties between that country and the United States. In bringing the Appam into an American port, it was held, the German officials were committing a clear breach of American neutrality. Ship and cargo, valued at between three and four million dollars, were delivered to the British owners 28 March 1917. The decision, written by Justice Day, affirmed decrees by Federal Judge Waddill, and upheld the original ruling by Secretary of State Lansing that prizes coming into American ports unaccompanied by captor warships have the right to remain only long enough to make themselves seaworthy. The court stated that neither the Treaty of 1799 with Prussia, the Hague conventions nor the Declaration of London, entitled any belligerents to make American ports a place of deposit of prizes as spoils of war under such circumstances.

"The principles of international law," the opinion adds, "leaving the treaty aside, will not permit the ports of the United States to be thus used by the belligerents. If such use were permitted, it would constitute the ports of a neutral nation harbors of safety into which prizes might be safely brought and indefinitely kept.

"From the beginning of its history this country has been careful to maintain a neutral position between warring governments, and not to allow use of its ports in violation of the obligations of neutrality, nor to permit such use beyond the necessities arising from perils of the seas or the necessities of such vessels as to seaworthiness, provisions and supplies."

APPARENT, a term employed by mathematicians and astronomers to denote things as they appear to the eye in distinction from what they really are. Thus they speak of apparent motion, magnitude, distance, height, time, etc. So important is this difference between reality and appearance, particularly in regard to the heavenly bodies, that we find all early astronomers, who were ignorant of this fact, running continually into error; and a great advancement in science was required before mankind was able to establish systems opposed to appearances. Every one knows that a body may appear to move while it is, in fact, at rest, and the motion is in the spectator, or the place on which he stands, as is the case with the sun in relation to the inhabitants of this earth. The apparent altitude of a heavenly body is what appears to be its angle of elevation above a horizon which may itself be apparent—that is, the seeming junction of sea and sky; or "sensible"—that is, a plane passing through the point of observation at right angles to the plumb-line; or true—that is, a plane parallel to the "sensible" horizon and passing through the centre of the earth. When the altitude of a heavenly body is measured corrections are made for refraction, parallax, and, if the measurement is from a visible sea horizon, for the height of the observer above the water.

The phrase heir apparent signifies one whose right of inheritance is indefeasible provided he survive his ancestor; as the eldest son or his issue, who must, by the course of the common law, be heirs to the father. Heirs presumptive are those who, if the ancestor should die immediately, would in the existing state of things be his heirs.

APPARITION, the name given to an illusion involuntarily generated, by means of which forms not present to the actual sense are depicted with intensity sufficient to create a temporary belief in their reality. It is now generally held to be the result of the reaction of an excited imagination, renovating past feeling or impressions, with an energy proportioned to the degree of excitement. But although the illusion thus generated is necessarily co-existent with the state of excitement in which it has its origin, or, in other words, ceases to be active when the phenomena vanish, it does not therefore follow that the mind, when it regains its ordinary condition, becomes immediately sensible of the hallucination under which it has for a time been laboring, or capable of distinguishing between perceptions of sense and phantasms of imagination. On the contrary, observation proves what theory equally sanctions, that the conviction of reality generally outlasts the impressions which originally produced it; and that, so far from any suspicion of illusion being entertained, or any power of discriminating the actual from the imaginary being evinced, this conviction takes entire possession of the mind, in many instances

maintaining its hold with a firmness which all the force of argument and reason is insufficient to overcome. Hence the tenacity, and, we may add, the universality of the belief in apparitions; and hence also the prodigious diversity of forms under which these spectral illusions are presented in the popular legends and superstitions—a diversity, in fact, which seems commensurate with the incredible variety of influences, whether morbid or other, by which the imagination may be excited, and past feelings or impressions vividly renovated in consequence of its reaction on the organs of sense. Sir D. Brewster has remarked as a physical fact that "when the eye is not exposed to the impressions of external objects, or when it is insensible to these objects, in consequence of being engrossed with its own operations, any object of mental contemplation, which has either been called up by the memory or created by the imagination, will be seen as distinctly as if it had been formed from the vision of a real object. In examining these mental impressions," he adds, "I have found that they follow the motions of the eyeball exactly like the spectral impressions of luminous objects, and that they resemble them also in their apparent immobility when the eyeball is displaced by an external force. If this result shall be found generally true by others it will follow that the objects of mental contemplation may be seen as distinctly as external objects, and will occupy the same local position in the axis of vision as if they had been formed by the agency of light." This goes to the very root of the theory of apparitions, all the phenomena of which seem to depend upon the relative intensities of the two classes of impressions, and upon the manner of their accidental combination. In perfect health the mind not only possesses a control over its powers, but the impressions of external objects alone occupy its attention, and the play of imagination is consequently checked, except in sleep, when its operations are relatively more feeble. But in the unhealthy state of the mind, when its attention is partly withdrawn from the contemplation of external objects, the impressions of its own creation, or rather reproduction, will either overpower or combine themselves with the impressions of external objects, and thus generate illusions which in the one case appear alone, while in the other they are seen projected among those external objects to which the eyeball is directed, in the manner explained by Sir D. Brewster. It may be added that the reasoning applied to the impressions derived from the sense of sight is equally applicable to those received through the medium of any other sense,—as the ear, for instance, an organ which ministers abundantly to the production of spectral illusions. This theory explains only those apparitions known to be subjective illusions, but it does not account for those objective apparitions, of which there are many and well-authenticated accounts. Modern science has explained some of the objective apparitions.

APPEAL, a legal term signifying the removal of a cause from an inferior tribunal to a superior, in order that the latter may revise, and, if needful, reverse or amend, the decision of the former.

In the United States the distinction between an appeal, which originated in the civil

law, and a writ of error, which is of common-law origin, is that the former carries the whole case for review by the higher court, including both the facts and the law; while the latter removes only questions of law. An act of Congress of 1875 provides that the judgments and decrees of the Circuit Courts of the United States shall not be re-examined in the Supreme Court unless the matter in dispute shall exceed the sum or value of \$5,000, exclusive of costs. No judgment, decree, or order of a Circuit or District Court, in any civil action at law or in equity, shall be reviewed in the Supreme Court on writ of error or appeal unless the writ of error is brought or the appeal is taken within two years after the entry of such judgment, decree, or order; save in the case of infants, insane persons and imprisoned persons, when the period is two years exclusive of this term of disability. An appeal from a District Court to a Circuit Court of the United States must be taken within one year. An appeal from the District Court in admiralty to the Circuit Court must be made immediately after the decree, in open court, before the adjournment *sine die*; and should be taken to the next succeeding Circuit Court. An appeal may be taken from the State courts to the Supreme Court of the United States, in cases involving the validity of a treaty or statute of, or authorized under, the United States, on the ground of repugnance to the Constitution, etc.

The effect of an appeal is generally to annul the judgment of the lower court so far that no action can be taken upon it until after the final decision of the cause. In many States, before the judgment of an inferior court will be reversed on the ground of error, the appellant, as the party taking the appeal is called, must show to the court that substantial injustice has been done him. In other States courts have held that when an error is shown to have been committed it will be presumed to have been prejudiced to the complaining party, and the judgment will be reversed unless the respondent shows that the error was harmless. Appellate courts, however, will not reverse the judgments of trial courts for technical or other errors where it appears from the record itself that the errors complained of were not prejudicial to the appellant.

In legislation an appeal is the act by which a member of a legislative body who questions the correctness of a decision of the presiding officer, or "chair," procures a vote of the body upon the decision. In the House of Representatives of the United States the question on an appeal is put to the House in this form: "Shall the decision of the chair stand as the judgment of the whole House?" If the appeal relate to an alleged breach of decorum, or violation of the rules of order, the question is taken without debate. If it relate to the admissibility or relevancy of a proposition, debate is permitted, except when a motion for the previous question is pending. Consult "Appeal and Error" (in 'Corpus Juris,' Vol. III, pp. 256-1449, New York 1914).

APPEARANCE, a legal term implying the coming into court as a party to a suit or action, whether as plaintiff or defendant. On the part of the plaintiff no formality is required. The appearance of the defendant may be effected by making certain formal entries in

the proper office of the court, expressing his appearance, or in case of arrest it is effected by giving bail, or by putting in an answer or a demurrer.

APPENDICITIS, the name applied to an infectious disease of the vermiform appendix, a small organ occupying the lower right side of the abdominal cavity. The first authentic record of the distinct localization of a lesion in the appendix was made by Saracenus in a letter 28 Aug. 1642. A number of observers described the disease in later years, but it is to the honor and credit of American medicine that Reginald Fitz of Boston wrote his epoch-making memoir in 1886, 'On Perforative Inflammation of the Vermiform Appendix.' Two years later Fitz advanced the sound theory that the diseases variously described as typhlitis, peri-typhlitis, para-typhlitis, appendicular peritonitis, and perityphlitic abscess were all varieties of one and the same affection, namely, appendicitis. Rapid strides have been made during the last decade in the study of the disease, and mainly through the exertions of American surgeons the treatment of appendicitis has been placed upon a sound and rational basis. In the embryologic development of the human intestinal tract there is at first a straight tube, divided into the foregut, midgut and hindgut, each of which gives rise to different structures. From the midgut a diverticulum or pouch appears which marks the dividing line between the large and small intestine. This pouch becomes larger and is called the cecum, but its terminal portion does not keep pace with the growth of the base and remains as a small projection depending from the cecum. This is the appendix vermiformis; it has no function and from its liability to disease is merely a constant source of menace.

During early intra-uterine life the appendix lies near the umbilicus (navel), but at about the sixth month descends into the right iliac fossa. If two lines are drawn at right angles to each other, intersecting at the umbilicus, the abdomen will be divided into four quadrants. The lower right quadrant will include the right iliac fossa and in the majority of cases the appendix. The base of this organ will usually be found at a point two inches from the umbilicus on a line drawn from the latter to the anterior superior spine of the iliac bone and known as McBurney's point.

The appendix is held in place by a fold of peritoneum called the meso-appendix through which a single artery runs to supply the needed nutrition. The meso-appendix is derived from the lower layer of the mesentery, the fold of peritoneum which suspends the small intestine. In women there is usually also another blood-vessel which comes up to the appendix from the ovary. The end of the appendix is free and may point in any direction. This fact explains the great diversity of the symptoms often noted in appendicitis.

Bearing in mind, then, that the appendix is without a function, hangs in a dependent position from a portion of bowel always containing irritating material, and has a very poor blood supply, it can readily be understood why this organ is so often attacked by disease. It hangs in a cavity lined by peritoneum, a delicate membrane covering the inner surface of the abdomen and the exterior of the intestines, which easily

absorbs poisons and transmits them to the whole body. Inflammation of this membrane is known as peritonitis, a very fatal disease and often caused by appendicitis. Many deaths supposed to be due to peritonitis pure and simple are really caused by appendicitis. The intestines at all times are loaded with germs which under favorable conditions may be converted into deadly little organisms. These microbes attack the inner coat of the appendix, destroy it with the formation of pus, and may ulcerate through all the walls of the appendix causing an abscess, with peritonitis. But the recurrence of such a sequence of events requires certain other contributing factors. The old idea that foreign bodies, such as grape-seeds, are the cause of the disease, has been disproved. While foreign bodies are frequently found in the appendix, in rare instances only are they seeds, etc., but are almost always found to consist of masses of fecal material which having entered the appendix while soft, become dry and hard, and form a fecal concretion (*fecal calculus*). By exerting pressure on the wall of the appendix these hard bodies may aid in the production of the disease. In rare instances pins have found their way into the lumen of the appendix and induced appendicitis. It is interesting in this connection to note that worms are frequently discovered in the appendix. The *Oxyuris vermicularis*, or seatworm, has been found in large numbers completely filling the appendix, and the *Ascaris lumbricoides*, or roundworm, has sometimes occupied this organ. In studying the etiology of appendicitis we find that young persons are more frequently attacked than the older ones, the disease occurring less commonly after the 50th year of life. It is fortunate that such is the case, because older people, as a rule, do not stand operations so well as those in early adult life. Their resistance to shock is less, and their greater liability to kidney breakdown and to pneumonia would close their prognosis in many instances. The greater susceptibility of young adults to appendicitis is due to the more frequent disturbances of their gastro-intestinal tracts from dietary indiscretions, and, secondly, to the tendency to inflammation of the adenoid (glandular) tissues throughout the body during adolescence. Analogy is found in the predominance of lesions of the tonsils and of the glands in the neck and mesentery during the period of development. In children appendicitis is characterized by the intensity of the lesion as well as by the remarkable recuperative power which children have.

About two-thirds of all cases of appendicitis occur in males. The reason for such a disparity is due to several factors. Females are less exposed to inclemencies of the weather and other deleterious influence; they undergo less muscular exertion and the female appendix in the majority of instances, has a better blood supply. Of diseases that predispose to appendicitis may be mentioned: constipation, gastro-enteritis, dysentery, typhoid fever, influenza, etc. Constipation exerts an influence by causing sluggishness of the bowels, resulting in poor drainage of the appendix. Noxious materials may be retained and thus favor an increase in the virulence of bacteria, especially the *Bacillus coli communis*. Gastro-enteritis, or inflammation of

the stomach and intestines, is a very important etiological factor in appendicitis. In this disease the cecum may become inflamed and by extension involve the appendix. In many instances the alterations in the walls of the appendix are slight and fail to produce any clinical manifestations. At times, however, the lining membrane of the appendix is directly attacked, with acute appendicitis as the result. Under other circumstances, catarrhal changes of mild degree persist and lead to chronic appendicitis. Dysentery and typhoid fever are among the more remote causes of appendicitis. They cause catarrhal alterations, swelling, congestion and edema of the adenoid (glandular) follicles of the organ. Not uncommonly ulcerations occur, and the resulting scar is one of the most important factors in the subsequent development of appendicitis by causing a stricture in the lumen of the appendix, obstructing the drainage of the organ, and thereby favoring the retention of irritating material. Influenza owing to the intestinal lesions to which it gives rise may also favor the development of appendicitis.

In general it may be stated that the underlying cause of all cases of appendicitis is infection. Emphasis has more recently been laid on the rôle of the streptococcus group of microorganisms which frequently make their way into the circulation through the tonsils, adenoids and foci of suppuration about the teeth, as well as other portals of entry in the respiratory and gastro-intestinal tracts. It is probable, however, that this so-called hematogenous infection of the appendix is less common than direct infection from its own interior; the latter being favored by local abnormal conditions, such as kinks, adhesions, torsions, strictures, and contained concretions.

The most important predisposing cause of appendicitis is the fact that the appendix has already been the seat of one or more attacks of the same affection. The apparently greater number of cases of appendicitis observed in recent years is not due to an actual increased incidence of this disease, but rather to a greater refinement in diagnosis which has enabled physicians more readily to recognize the true nature of the malady, which in former years was variously styled inflammation of the bowels, peritonitis, gastritis, obstruction of the bowels, etc. The appendix is less resistant than other portions of the intestinal tract to the onslaught of bacteria and other deleterious influences. This is due to several factors: The blood supply may become defective because of the liability to partial or complete obstruction of the blood channels, as a result of kinking, twisting (*volvulus*), or the formation of external bands of adhesions, etc., secondary to primary inflammation of the appendix. Disturbances of circulation, and hence of nutrition, may also be produced by active and sometimes ineffectual muscular efforts of the appendix to rid itself of fecal concretions or even inspissated fecal matter. Defective drainage, which has been referred to, is of great importance in the pathogenesis of appendicitis because of the anatomical and physiological peculiarities of this organ. The average length of the appendix is about 8 to 9 cm. ($3\frac{1}{2}$ inches), while its diameter is only 3 mm. to 5 mm. ($\frac{1}{8}$ to $\frac{1}{4}$ inch), thus forming a long narrow tube not favorable for

free drainage. The peritoneal covering forms what is known as the meso-appendix in such a manner as to draw the appendix into a curve and thus aid in any angulation resulting from disease. Additional factors of importance are the relatively large extent of mucous membrane presented by the appendix and the large amount of lymphoid (glandular) tissue, not only in the neighborhood of the valve-like opening into the cecum, known as Gerlach's valve, but also scattered throughout the wall of the appendix. The latter is of especial significance in view of the tendency of adenoid tissue throughout the body to inflammation when subjected to even slight irritation by bacteria and their poisons. An analogous condition may be observed in the tonsils, which are so frequently invaded by bacteria with a resulting tonsillitis (quinsy). Owing to this similarity the appendix has frequently been called the "abdominal tonsil."

In considering the symptomatology of the two forms of appendicitis—the acute and the chronic—it must be borne in mind that the extent of disease which has actually taken place in the appendix cannot always be determined by the clinical manifestations. While it is true that, in general, the clinical symptoms become more marked with the increased severity of the appendicular and peritoneal lesions,—that is, when perforation, abscess or gangrene supervene—it is also a fact that remission of all symptoms may occur, and yet the disease may be progressing to a fatal termination. It is likewise a fact that the symptoms suggestive of perforation of the appendix with abscess formation in one patient may, in another case, be due to the development of an abscess without perforation of the organ. It is better, therefore, to consider acute appendicitis as a clinical entity. Similar reasoning obtains with regard to chronic appendicitis, although in the latter the questions requiring solution are less complicated.

Acute Appendicitis.—There are three symptoms of acute appendicitis so constant and, when associated, so characteristic of the disease that they are designated the "three cardinal symptoms." These are pain, tenderness, and rigidity of the right lower quadrant of the abdominal wall. Pain is the initial symptom, and usually develops suddenly in an individual previously well. At the onset of the affection the pain is paroxysmal or colicky in character, coming in storms with intervals of rest, in which respect it simulates an attack of acute indigestion. The location is at first centred about the umbilicus, or the pit of the stomach, later it becomes diffused all over the abdomen, and finally localizes in the right iliac fossa. In recurring cases the initial pain of the later attacks is often referred immediately to the right iliac fossa. The pain of appendicitis may, however, be referred to any region of the abdomen. It is ignorance of this fact that leads to many errors of diagnosis in acute abdominal affections. The location of the pain depends to a great extent upon the position and direction of the appendix. For instance, with an appendix lying behind the cecum and pointing upward until its tip nearly reaches the gall-bladder, symptoms are produced resembling very closely those induced by affections of the latter organ. In other cases pain is felt in

the left side of the abdomen and denotes that the appendix occupies a left-sided position or that it hangs into the pelvis. Tenderness upon pressure is one of the most valuable and constant signs of appendicitis. It is always present, but, unlike the subjective symptom, pain, it is limited at first to the site and the position of the appendix. To elicit this symptom abdominal pressure should be made in as light and delicate a manner as possible. The open hand should be laid over the tender area and the fingers gently depressed, ceasing as soon as the patient complains of pain. It should be remembered that the appendix may be distended with pus and on the verge of rupture, and any undue roughness in palpation may endanger the life of the patient. A celebrated German surgeon has truly said that "many a doctor who has sufficient practice and experience nevertheless never learns to palpate, since he is wanting in lightness of hand." It is a good plan to begin to palpate over on the left side away from the seat of pain, and gradually approach that region. As complications arise the point of tenderness may vary; for instance, in those cases previously referred to where the appendix occupies a pelvic position, the point of greatest tenderness will usually be found to the left of the median line. With the appendix thus located, where the disease has advanced to a stage where an abscess has formed in the pelvis, vaginal or rectal examination will reveal a point of resistance on the right side with more or less marked tenderness. The third cardinal symptom is rigidity of the right side of the abdomen and particularly of the rectus and other abdominal muscles. It is the most constant symptom of the three and appears shortly after the onset of the attack. It varies in degree in different cases, but is generally well marked, and is most intense over the site of the inflamed appendix. The variations observed range from rigidity so slight as to be barely appreciable up to a condition absolutely precluding any palpation, and to which the term "board-like" rigidity is applied. The degree of rigidity is usually, but not invariably, in direct proportion to the severity of the lesion. When the peritoneal cavity becomes involved and peritonitis develops the entire abdomen becomes rigid and board-like, followed by distension or tympany from paralysis of the intestines. While the three cardinal symptoms are the most important indications of acute appendicitis, there are other clinical manifestations that are more or less constantly present and are of value in arriving at a diagnosis. Among these are disturbances of the gastro-intestinal tract (nausea and vomiting, etc.), elevation of the temperature, increased pulse and respiration, changes in the urine, etc. Nausea is practically a constant symptom in appendicitis and usually coincides with the initial pain; it may be followed by vomiting, which at first consists of the gastric contents, then of bile or bile-stained fluid, and finally, if septic peritonitis develops, of the contents of the intestines. This condition, unless seen early, has frequently been mistaken by the family physician for intestinal obstruction.

In cases of appendicitis which progress rather rapidly to peritonitis, with the marked nausea and vomiting characteristic of the condition, the pain suffered is apt to be very severe.

The attending physician, often following the promptings of the patient, administers the too-convenient hypodermic of morphine, which while relieving the patient, at the same time masks the symptoms and renders the task of the surgeon, called in for consultation, an exceedingly difficult one. The giving of morphine for the relief of pain in appendicitis is a pernicious habit. Nausea and vomiting rarely persist after the pain has become localized to the right iliac fossa, though in some unfavorable cases vomiting may be continuous and uncontrollable. The condition of the bowels previous to the attack of appendicitis is very variable. In the majority of cases constipation is observed, and such sluggishness may represent an etiologic factor of some importance. But there are many cases where diarrhoea ushers in the attack, and other instances when it may alternate with constipation. Fever must not be relied upon as a diagnostic sign, as it bears no direct relation to the gravity of the anatomical lesions. While with the onset of the disease the temperature usually rises to 101° and 102° F., it may return to normal again despite the advance of severe complications such as perforation or gangrene of the appendix. Coincident with the development of an abscess around the appendix there is usually a rise of temperature, but again such a rise is not constant. There are, finally, some cases in which the temperature continues high from the commencement to the termination of the attack, and yet the patient makes an easy recovery. The amount of fever should therefore be considered as the expression of the reaction and resistance of the individual to infection. The condition of the pulse is a more constant diagnostic aid than the temperature and its quality is of more importance than its rate of speed. If the pulse is strong, of good volume, regular, and the rate proportionate to the temperature, the outlook is favorable, and vice-versa. Variations in the respiration are not of much importance. The breathing is embarrassed in toxic states, from the distension of peritonitis, and sometimes, owing to the pain, the patient will use the chest muscles entirely. A quite characteristic position often assumed by the patient, and from which he resents being disturbed, is with the right leg and thigh flexed, while the left leg remains prone. In addition there may be perspiration, a furred tongue and a slight expression of anxiety upon the features. When the appendix occupies the pelvic position the patient will frequently complain of rectal and vesical (bladder) irritability. An increased frequency in urination is the usual symptom, yet there may be inability to void urine. The symptoms which have been described are typical of the usual attack of acute appendicitis, though marked variations may occur, depending upon the position of the appendix or the presence of adhesions from former attacks. With a history of previous more or less severe attacks of abdominal colic, not necessarily referred to the appendix, a person previously well is suddenly seized with severe pain, usually throughout the abdomen followed by nausea and sometimes vomiting, pain soon becoming more intense over the site of the appendix, and in a few hours this locality alone is involved; if such a patient should be so fortunate as to see

his physician at this time, namely, within 24 hours of the attack, and if operation is advised and performed, recovery is practically assured; but unfortunately this is not always the course pursued. The disease at this time is in its earliest stage, with the inflammatory lesion confined to the appendix, and the particular sequence of events which may follow in a given case cannot be foretold. In some cases the appendix under the influence of rest is able to eliminate the noxious materials causing the inflammatory lesions, recover its vitality, and apparently return to as good condition as before the attack: but lymphoid (glandular) tissue which has once been the seat of infection is exceedingly prone to future attacks. In still other cases the disease extends through the wall of the appendix and induces a mild peritonitis localized in the coils of intestines and tissues immediately contiguous to the appendix. With the appearance of infecting bacteria or of their poisons in the peritoneal cavity, this membrane throws out a thin fluid or serum and an exudate (lymph) which organizes into firm tissue, known as adhesions. These adhesions glue the coils of intestine surrounding the appendix together, causing them to adhere to the roof of the cavity, which is the abdominal wall, and with the aid of the omentum, a fatty apron-shaped body covering the intestines, form a firm wall about a cavity containing the appendix and thus prevent the escape of toxic materials into the general peritoneal cavity. Should the disease, under medical treatment, subside, the lymphatics and the white blood corpuscles speedily destroy the infectious material, but the adhesions too often remain and cause constant irritation. In time a period of chronicity is reached when any unusual exertion provokes a dull ache in the lower right quadrant of the abdomen. The digestion is impaired, and the bowels become sluggish in their movements from the dragging of the adhesions upon the valve between the large and small intestines. In women subject to chronic appendicitis with involvement of the ovary and fallopian tube on the right side, slight attacks of appendiceal colic will recur during each menstrual period, and all treatment directed against dysmenorrhoea will prove unavailing. The appendix in such cases may become obliterated into a mere fibrous cord, or, more commonly, occlusion takes place at the opening into the cecum or at the site of a stricture, and the appendix becomes distended with clear mucus. While operations upon chronic forms of appendicitis in the presence of adhesions are attended with but little risk, the operation itself is more tedious and the incision longer than when the disease is operated on in its early stages. Having dealt with the favorable terminations of acute appendicitis, it remains to consider that far too numerous class of cases in which the appendix perforates, with abscess formation and sometimes general peritonitis. If the infection of the appendix is severe enough, its walls may become gangrenous and break down and perforate into the peritoneal cavity. In this case the peritoneum usually becomes infected in advance of the perforation and enough time is gained for the formation of adhesions such as have been described. In what is known as fulminating appendicitis the prog-

ress of the disease is so rapid that no adhesions are formed, and in 24 hours, or less, after the onset of the initial symptoms the patient may be suffering from a violent general peritonitis. But, as a rule, the escape of purulent material through a perforation in the appendix occurs into a preformed cavity, the walls of which consist of the abdominal wall, the iliac fossa, the cecum and matted coils of small bowel and the infiltrated omentum. This cavity becomes filled with pus and a true appendiceal or peri-typhlitic abscess is formed. The amount of pus varies from a teaspoonful to a pint, or in extreme cases even more. With the formation of the abscess the symptoms change somewhat. The severe pain of the early inflammatory stage becomes more dull; sometimes is referred to the back or to the left side, tenderness is increased, while the rigidity is more marked. The tongue becomes coated and the breath foul, chills are rarely observed even in the presence of pus, and when present—especially a single, severe chill ushering in an attack—usually mean a gangrenous condition of the appendix. There is fever, increased pulse-rate, and the patient shows the effect of absorption of poisonous products into his general circulation. An examination of the blood shows an increased number of the white blood corpuscles (leucocytosis). Palpation of the abdomen will reveal a mass in the right iliac fossa, rounded, hard and often tender. The patient may not complain of any pain beyond the dull ache referred to, though the act of coughing or taking a deep breath usually results in an exacerbation of pain. In some cases with an appendix deep in the abdomen and behind the cecum, an abscess may exist which cannot be palpated. When such a condition is suspected it is not wise to prod the abdomen too hard for fear of rupturing the abscess. If the pus extends into the pelvis the additional symptoms of vesical and rectal irritability will be present and vaginal or rectal examination will detect a bulging area extremely tender to the examining finger. In women and girls the effect of such a pelvic abscess is frequently disastrous. The open ends of the fallopian tubes become bathed with the pus, and either a salpingitis or occlusion of the tubes takes place. The tubes are thereby prevented from fulfilling their function of transmitting the ova to the uterus, and sterility may result. The extension of the pus upward toward the liver causes symptoms very much resembling infectious gall-bladder disease; this will be discussed under differential diagnosis. In neglected cases this upward extension of pus has resulted in the formation of an abscess beneath the liver, with rupture through or behind the diaphragm, and entrance of the pus into the lung and pleural cavity from which it has been actually evacuated by coughing and expectoration. If an appendiceal abscess is small, recovery may occur without operation, although such a happy result is doubtful. The disease is progressive, and the pus tends to increase, and if not evacuated will frequently rupture the walls of the containing cavity into the cecum, occasionally, but more often, unfortunately, into the peritoneal cavity, with a resulting general purulent peritonitis and almost invariably a fatal outcome. In such a case the pulse increases in frequency and becomes full

and strong, the face becomes pinched and anxious, the eyes brighten, the mind becomes active, though delirium appears later, the abdomen slowly distends, accompanied by marked pain and restlessness of the patient. These three pathognomonic conditions, a bright eye, an active mind and a swollen belly, indicate approaching dissolution. The distension is due to a paralysis of the bowels, gas and feces being retained in spite of all treatment. Nausea and vomiting soon begin, the latter at first green, but later black, from evacuation of the contents of the intestines into the stomach. Death rapidly follows.

The diagnosis of appendicitis from other lesions of the abdominal cavity, if seen early, is comparatively easy in the great majority of cases. Particular attention should be paid to the history of the patient, and especially to the character of the onset of the illness and the earlier symptoms. While inflammation of the stomach and intestines (gastro-enteritis) has caused some confusion at times, yet, unfortunately, the mistake is made more often in the wrong direction. That is, a true attack of appendicitis is thought to be gastro-enteritis and treated accordingly until the appearance of an abscess with its unmistakable symptoms warns the attending physician of the true nature of the malady with which he is dealing. While the pain in both diseases may begin over the stomach (in the epigastric region) and continue over the whole abdomen, in appendicitis the region of the appendix will be tender to palpation from the onset, and this tenderness will persist and even become more acute after the general abdominal pain has ceased. Unilateral rigidity is quite constant in the beginning of the appendiceal attack, while in the gastrointestinal disease the entire abdomen may be rigid. In certain cases of gastric ulcer, with perforation and escape of the stomach contents into the peritoneal cavity, the shock is more marked from the onset, and the more severe symptoms will occur in the upper abdomen. Ulcer of the stomach is much more common in women than in men, and often gives symptoms which can be recognized long before the ulcer has advanced to the stage of perforation. In enteritis, or inflammation of the bowels, and particularly when poisonous food products have been eaten, the symptoms produce early and often marked shock. In the summer months iced drinks are a frequent cause of this complaint. About 18 hours after the dietary indiscretion there will be marked general abdominal pain, diarrhoea, chilliness, perspiration and a feeling of great weakness. In severe cases the depression may be so pronounced as to cause death (acute ptomaine poisoning). The greatest area of tenderness will be found about the centre of the abdomen, and careful palpation of the appendix region may find this organ neither enlarged nor tender.

Mention was made earlier in this article of the symptoms produced by inflammation of an appendix behind the cecum and pointing upward toward the gall-bladder. In such instances the symptoms resemble very closely those due to inflammation of the gall-bladder and sometimes the two diseases cannot be differentiated with certainty. But as both affections require surgical intervention to effect

a permanent cure, and as the incision in both instances is made in nearly the same place, the failure to make a correct diagnosis is not detrimental to the patient. The pain in the gall-bladder affection, if referred, will cause a dull pain in the region of the liver radiating upward to the right shoulder blade. Tenderness is limited to the gall-bladder region and is a very important symptom, provided the rigidity of the right rectus muscle does not prevent palpation. The appearance of jaundice, or the characteristic gallstone colics should decide the diagnosis. Later in the progress of the disease, the infection of the gall-bladder may produce pus, or empyema, as it is called, and the gall-bladder can then be palpated as a round, tender and firm mass beneath the edge of the ribs and moving with respirations. An appendiceal abscess would rarely reach as high as the costal margin without implication of the right iliac fossa, but in a high position it might be mistaken for a ruptured gall-bladder following empyema. In such a case the diagnosis would be almost impossible and practically immaterial, since the condition makes an operation imperative. Neither an infected gall-bladder nor an appendix should ever be allowed to advance to the purulent stage without an operation being advised. Inflammation of the fallopian tubes has been mistaken for appendicitis and vice-versa, particularly when the tube leaking into the pelvic peritoneum causes a localized inflammation of that membrane. With the knowledge that the appendix frequently occupies the pelvis and may lie adjacent to the tube, the exact diagnosis of acute appendicitis from acute salpingitis may be difficult, and in chronic cases even more so. From the close proximity in which the two organs may be found the tube may be infected from the appendix or the latter may become involved secondarily from a pyosalpinx (pus in the tube). This still further complicates the differential diagnosis. If a history of specific infection can be obtained, with symptoms indicating the commencement of the disease in the lower part of the abdomen, and a vaginal examination shows induration of the vault with tenderness to pressure on either side of the uterus, a diagnosis of salpingitis would be reasonable. A number of other diseases may be suspected in deciding upon a diagnosis. Among these may be mentioned extra-uterine pregnancy, ovarian cysts, some kidney affections, intestinal obstruction, typhoid fever, pancreatitis, etc. The nature of this article does not warrant the full discussion of these affections.

The treatment of appendicitis has been a mooted question for some time, and it has only been within the last few years that the medical profession has accepted the dictum of those whose experience with the disease has been the greatest, that appendicitis is a surgical disease. The soundness of this teaching rests upon the fact that it is impossible to foretell in any individual case what the outcome will be, and which case will terminate favorably, or which will progress to perforation or gangrene, and the attendant peritoneal and other complications and sequelæ. It is essential that physicians appreciate the importance of early surgery, while a few patients for various reasons may refuse operation, the majority will

depend upon the attending physician for advice and accept the treatment which he advocates.

The mortality of the early operation, before the peri-appendicular structures have become involved, is *nil*, barring accidents, and the incision in the rectus muscle can be so closely approximated that the abdominal wall is not weakened in the slightest by the operation. The peritoneum, the sheath of the rectus muscle and the skin, are usually sewed up in tier suture,—that is, in layers,—and the resulting scar, about two inches long, can barely be perceived after the lapse of several years. As the disease progresses the mortality increases in direct proportion to the extent to which the peri-appendicular structures have become involved. When an abscess develops, the search for the diseased appendix is difficult and often dangerous, and many surgeons simply evacuate the pus cavity and establish drainage. But the presence of a necrotic appendix is a constant menace, frequently causing secondary pus collections which may lead to a fatal termination. In all cases where pus is found the employment of drainage is imperative. This means that sterile gauze must be so disposed that the purulent material is caught up and carried off by capillary drainage, thus forcing the abscess cavity to heal from the bottom upward, and avoiding "pocketing." The course of these cases is tedious and the convalescence prolonged. The complications incident to acute appendicitis with abscess are attended with great risk to life. The most dreaded is peritonitis with invasion of the entire peritoneal cavity by the purulent and infectious products due to inward rupture of the abscess. Nearly every patient developing general peritonitis from an appendiceal abscess will die in spite of the most careful treatment and skillful operation. In advanced stages of the disease, when the appendix becomes necrotic and gangrenous, the cecum will frequently be implicated and be so diseased that the removal of the appendix cannot be followed by closure of the wound in the cecum. In cases of this character gauze must be so placed as to isolate the fistulous opening from the general peritoneal cavity, with the hope that granulation will lead to spontaneous healing of the bowel opening; but this does not always follow, and in such instances the hole in the cecum becomes a fecal fistula, discharging the contents of the bowel through the wound in the side. *Fistulæ* require very frequent dressing, heal slowly and are extremely annoying and disgusting to the patient. A third complication which may result in abscess cases is intestinal obstruction. The manner in which adhesions form has already been described. They are nature's barriers against infection, but sometimes they prove a veritable boomerang. The author has more regard for the results of the aseptic scalpel of the surgeon administered at the opportune time than he has for nature's attempts at cure. It is well known that after burns of the hands the resulting scar tissue will cause contraction and deformity of the fingers. In the same way the adhesions by uniting the coils of intestines together to prevent the spread of infection may encircle the bowel, and by contraction occlude its lumen, obstruct the flow of bowel contents and thus necessitate a second operation the mortality of

which is quite high. Finally, if convalescence is uninterrupted and the wound heals slowly by granulation, the resulting scar is quite weak and nearly always produces a hernia (rupture).

In consideration of the facts that the course of appendicitis can never be accurately foretold, and that the dangers resulting from delay in operation are many and severe, the following outline of treatment is justified from our present knowledge of this disease: Upon the appearance of severe pain in the abdomen, with the maximum intensity over the region of the appendix, nausea, or vomiting, and a point of tenderness in the right iliac fossa, the patient should be placed at rest, all food withheld and the family physician sent for. When the attending physician has made the diagnosis of appendicitis there is no treatment to be discussed save operative interference. Whether the operation should be performed immediately will depend upon the extent of peritoneal involvement, but this question should be decided by the surgeon called into consultation and in whose hands the management of the case belongs. In fatal cases which have been followed by a reopening of the wound, a study of the conditions is of great interest. When death has taken place from a rapid septic poisoning or toxemia the abdomen may show nothing except some thin cloudy fluid in the pelvis and congestion of the peritoneum covering the intestines, giving them a "scalded" appearance. In the abscess cases the right iliac fossa is found filled with a green purulent exudate adhering closely to the groin and the intestines. There may be small quantities of pus which have formed since the operation. If death does not occur for several days after operation, and nature fails to check the spread of the disease, this purulent exudate may reach from the liver to the pelvis with infection of the portal vein, the liver and the lymphatics behind the peritoneum. With extensive leakage, the entire peritoneal cavity may be filled with greenish pus.

There are many more cases of minor manifestations of appendiceal inflammation than of the acute disease. Both clinical and microscopical evidence proves that it is a great exception for an adult to have escaped some slight disease of the appendix. That it is possible to have a chronically diseased appendix, or occasionally even a high grade of acute inflammation of that organ, without symptoms is now definitely known; on the other hand, such conditions often produce symptoms which are so slight or non-characteristic that their origin or significance is entirely overlooked. The more typical cases of chronic appendicitis give rise to symptoms referable to the location of the appendix itself, that is, discomfort, distress of some sort or actual pain in the right lower quadrant of the abdomen. Occasionally, by reason of an abnormal situation of the appendix, the symptoms and signs may be either higher or lower than usual, or even, as occasionally happens, on the left side. Most curious and difficult of interpretation are the so-called referred symptoms. Through the medium of the nervous system and the interdependence of different portions of the gastrointestinal tract, chronic irritation of the appendix may manifest itself by symptoms pointing to disease of an entirely different portion

of the tract, most often the stomach and the duodenum. The function of the large intestine also may be disturbed, suggesting disease of that organ, whereas the primary source is to be found in the appendix. This so-called appendiceal dyspepsia is by no means uncommon and usually goes unrecognized until an attack definitely incriminating the appendix occurs. It is not far from the truth to say that appendicitis is the most common cause of dyspepsia. The only treatment of avail in such cases is removal of the offending organ, a procedure which often remedies diverse dyspeptic conditions in a most remarkable manner. Consult Brewer, G. E., 'A Textbook of Surgery' (New York 1915); Deaver, J. B., 'Appendicitis: Its Diagnosis and Treatment' (1913); Kelly, H. A., 'Vermiform Appendix and Its Diseases' (1910).

JOHN B. DEEVER, M.D.,
Specialist, Philadelphia, Pa.

APPENZELL, ä'pën-tsël, Switzerland, a canton wholly enclosed within the territory of the canton of Saint Gall, and, though covering an area of only 162 square miles, divided into two independent portions, Ausser-Rhoden (101 square miles) or Outer-Rhodes, which is Protestant, and Inner-Rhoden (61 square miles), or Inner-Rhodes, which is Catholic. It is an elevated district, traversed by branches of the Alps; has large tracts of rich pastureland and extensive forests of pine, and is watered by the Sitter and by several smaller affluents of the Rhine. Its climate is cold, but healthful. Glaciers occupy higher valleys. Flax, hemp, grain, fruit, etc., are produced, but the wealth of Inner-Rhodes, the more elevated division of the canton, lies in its numerous herds and flocks; that of Outer-Rhodes in its manufactures of silk, muslins, gauzes, cambrics and other cotton stuffs. The construction of railways has now made the canton more accessible, and great numbers of strangers flock hither annually to take advantage of the whey-cure establishments of Gais, Weissbad, Gonten, Heiden and Heinrichsbad. The inhabitants speak a peculiar dialect, which even those who are well acquainted with Swiss-German have great difficulty in understanding. The town of Appenzell (German, *Abtenzelle*, abbot's cell), is the capital of Outer-Rhodes, beautifully situated on the Sitter, with 5,126 inhabitants. Trogen, with 2,347 inhabitants, is the capital of Inner-Rhodes. Schools are numerous and education widely diffused. The division between the Protestant and Catholic portions of the canton has existed since 1597. They have each an independent local government with representation in the Federal Assembly. Pop. Outer-Rhodes (1910) 58,670; Inner-Rhodes (1910) 14,860. The former is one of the most densely-peopled parts of Europe, its population being equal to more than 500 per square mile. Consult Richman, 'Appenzell' (1895).

APPENZELLER, ä'pën-tsël'-ër, Henry Gerhart, American missionary to Korea: b. 6 Feb. 1858; was drowned 11 June 1902 while on his way to attend a meeting of the Bible Translation Committee. He was a graduate of Franklin and Marshall College and Drew Theological Seminary. Soon after graduating from the latter he went to Korea as one of the first missionaries of the Methodist Episcopal

Church. He served the mission efficiently in many positions. He was superintendent, treasurer, manager of the book concern, editor of the official organ of the mission and one of the editors of the *Korean Repository*. His life has been written by William Eliot Griffis.

APPERCEPTION, a psychological term referring to higher consciousness. Until recently there has been considerable confusion among English and American writers on psychology as to the meaning of the terms perception and apperception. To point out the source of this confusion requires a brief history of the term apperception. The word was first used by Leibnitz in connection with his philosophy of "windowless" monads. With him every human soul is a monad which develops by an inner unfolding. When this development reaches the point of clear self-conscious being it attains what he calls apperceptive consciousness. If, on the other hand, the development is only partial, if its states are vague and only partially self-conscious, the monad has attained the level of perceptive consciousness. Thus for Leibnitz the terms perception and apperception designated simply different degrees of clearness and distinctness of consciousness, with no reference whatever to the apprehension of external things. In fact the theory of Leibnitz rendered any such use of the terms impossible. In more recent German psychology the term perception has been dropped and that of apperception retained as an expression of all the higher forms of clear consciousness. There is, however, one important exception to this. Wundt has retained both terms and attempted to restore to them their Leibnitzian meaning without, of course, committing himself to Leibnitzian monadology. Mental processes which are clear and distinct and are also under the control of volition are called by Wundt processes of apperception. But when the mental act is merely association in character and not directly controlled by volition, or when it is obscure, Wundt calls it an act of perception.

The philosophy of Herbart doubtless, more than that of any other German writer, has brought the term apperception into prominence in American psychology. If we consider his system we shall find that here again the terms perception and apperception mark different degrees of clearness and completeness of the forms of mental activity. With Herbart all mental processes are but the interactions of ideas. When a new idea enters the mind it causes a connection among the ideas already present. It disturbs the equilibrium. It is welcomed by the ideas akin to it, and opposed by those which are not. When it finally becomes adjusted and settled into its proper position among pre-existing ideas the new relation thus brought about is the result of apperception. Coming over to English and American psychology we meet with that difficulty and confusion referred to above. This confusion had its origin in the fact that in translating the Leibnitzian terms perception and apperception into English these same identical terms were used, regardless of the fact that in our psychology we had already a term, perception, which had acquired a fixed and definite meaning. The English word already in use stood for the recognition of objects through the senses, and this is

still its meaning. Hence it stands for the clear and self-conscious recognition of things as well as the vague and imperfect apprehension of them. The term perception brought over from German psychology, and the same word already in use, thus stood for widely different meanings, and hence the confusion. The Germans have a wholly different word (*Wahrnehmung*) for what we mean by perception, and consequently they cannot understand our difficulty. The result is that we have all along used the terms perception and apperception as though they distinguished wholly different mental activities instead of marking only different degrees of the same processes, as they actually do. Apperception is only clear and self-conscious perception. It involves in a highly complex way the various mental processes of memory, imagination, judging, inferring, etc., when these processes are clear and self-conscious. A full treatment of apperception therefore requires that these processes be taken into account. It is only necessary here to indicate briefly something of the pedagogical bearing and value of the term. Mainly through the influence of the so-called Herbartian movement in America, this term apperception has centred attention upon, and emphasized the importance of, the processes involved and the conditions requisite for the successful acquisition and assimilation of new knowledge with that which has already been learned. As the bodily organism separates and assimilates only such elements of the food taken into it as are needed for its growth and repair, so in a somewhat similar manner does the mind select and appropriate only such of its presentations as manifest a certain kinship to what is already consciously and vitally present, and rejects the rest. Elements wholly foreign to the mind's present stock of ideas escape it altogether. We must therefore learn the new by means of the old. Hence before presenting the new it is necessary to call up and make alive, by arousing interest and curiosity, those ideas and materials of knowledge that by similarity or other bond or relation will best serve for the ready reception and complete assimilation of the truth or fact to be taught. The goal of intellectual development is mainly the acquisition of clear, distinct and adequate general conceptions, and the ability to make correct application of these to new particulars as they arise, or to see in each new fact the old in disguise.

In the development of such general conceptions, two stages are recognized which may be appropriately designated by the terms perception and apperception of German psychology, if these terms be employed without reference to whether the mental facts considered are externally or internally derived. The process in the first stage is for the most part involuntarily and unconsciously directed, in the second it is voluntary and self-conscious. The process is not, however, first, sense impression, then percept, concept, judgment and reasoning in turn, each leaving off where the next higher begins. It dates its origin far back in the mental history of each individual, and all along in actual experience, sensing, perceiving, conceiving, judging, etc., are inextricably joined in one indivisible movement of thought-development. To use James' expressive phrase, the infant's consciousness is a "big, blooming,

buzzing confusion." This is the child's world. It is not, however, a world with which he can be satisfied. It must be broken in pieces and continually made over again. Chaos must be made cosmos, the irrational must become progressively rational. In fact, to rationalize the "big confusion" becomes the great and never-to-be-finished work of education and of life. Therefore the manner of this rationalization is of especial interest to the teacher. The "confusion" is not monotonous. It is not always the same. There is change. Certain elements come and go and some of them return again. By repeated recurrence these elements come to stand out in the foreground of the dark "confusion." Some of them are uniformly repeated together simultaneously or in close succession. These consequently become associated and form the basis of perception. Perception occurs when the presentation of one element immediately calls up the others belonging with it in the unity of consciousness which these elements represent. The presented element or sensation becomes the sign to which the mind at once adds the proper interpretation and accompaniment. The richness of the interpretation depends upon the mind's present attitude and condition, and its past experiences with the object presented. In other words, in all perception there is more or less of apperception. See **PSYCHOLOGY**; **ASSOCIATION OF IDEAS**.

NORBERT WIENER,
Editorial Staff of *The Americana*.

APPERT, a'pär, Benjamin Nicolas Marie, French philanthropist prominent in educational matters: b. in Paris 1797; d. 1847. He made a careful study of prison conditions, spending much time in this pursuit, his researches being published in his 'Journal des Prisons' (1825-30). He was much opposed to solitary confinement and is said to have taught 100,000 soldiers to read and write. Besides the 'Journal' he published 'Dix Ans à la Cour du Roi Louis Philippe' (1846), and 'Conférences contre le Système Cellulaire.'

APPERT, a'pär, François French scientist, brother of Benjamin Appert (q.v.): d. 1840. His method of preserving food without chemicals is given in his 'Art of Preserving Animal and Vegetable Substances' (1811). It is the familiar method of placing the article to be preserved in a can after heating, and then hermetically sealing it, and for his invention he was awarded a prize of 12,000 francs from the French government.

APPETITE, a term in its widest sense denoting the natural desire for gratification, either of the body or the mind; but generally

applied to the recurrent and intermittent desire for food. A healthy appetite is favored by work, exercise, plain living and cheerfulness; absence of this feeling, or defective appetite (*anorexia*); indicates diseased action of the stomach, or of the nervous system or circulation, or it may result from vicious habits. Depraved appetite (*pica*), or a desire for unnatural food, as chalk, ashes, dirt, soap, etc., depends often in the case of children on vicious tastes or habits; in grown-up persons it may be symptomatic of dyspepsia, pregnancy or chlorosis. Insatiable or canine appetite or voracity (*bulimia*), when it occurs in childhood, is generally symptomatic of worms; in adults common causes are pregnancy, vicious habits and indigestion caused by stomach complaints or gluttony, when the gnawing pains of disease are mistaken for hunger. See **DIETETICS**; **DYSPEPSIA**.

APPIAN OF ALEXANDRIA, the governor and manager of the imperial revenues under Hadrian, Trajan, and Antoninus Pius, in Rome. He wrote a Roman history, from the earliest times to those of Augustus, in 24 books, of which only 11 have come down to us. It is written in Greek, in clear and simple style; but it is little else than a compilation, characterized by many inaccuracies and absurd blunders. The best modern edition is that of Schweighäuser.

APPIAN WAY, a famous Roman highway leading from Rome to Capua by way of Bovillæ, Aricia, Terracina, Formiæ, Minturnæ, Sinuessa, etc.; called by Statius *Regina Viarum*, the Queen of Roads. It was made by Appius Claudius Crassus Cæcus when he was censor, 313 B.C., and afterward extended to Brundisium by way of Beneventum. It was paved with hexagonal blocks of lava, exactly fitted to one another, resting on an admirable substructure of considerable depth, and there may still be seen, particularly at Terracina, important remains which prove its excellent workmanship.

APPIANI, ä'pe-ä'ne, Andrea, an Italian painter: b. Milan, 23 May 1754, of noble but poor family; d. in 1817. He visited Rome three times in order to penetrate the secret of Raphael's style of fresco-painting, and soon excelled in this art every living painter in Italy. He displayed his skill particularly in the cupola of Santa Maria di S. Celso at Milan, and in the paintings representing the legend of Cupid and Psyche, which he prepared for the walls and ceiling of the villa of the Archduke Ferdinand at Monza (1795). Napoleon appointed him royal court-painter, gave him the order of the Legion of Honor and that of the Iron Crown, and made him member of the Italian Institute of Sciences and Arts. Appiani painted afterward almost the whole of the imperial family. His best works are the fresco-paintings on the ceiling of the royal palace at Milan, allegories relating to Napoleon's life, and his 'Apollo with the Muses,' in the Villa Bonaparte. Almost all the palaces of Milan have fresco-paintings by him.

APPIUS CLAUDIUS CRASSUS, a Roman patrician, of the family of the Claudii. In 451 B.C., when the decemvirs were appointed to compose a complete legal code for Rome (afterward known as the Laws of the Twelve Tables), and to wield the supreme power in the

state for a year Appius Claudius was chosen one of the 10, and when the office was continued for another year he was re-elected. As he and some of his colleagues had ruled in a very tyrannical manner, the people had become incensed against them, and the following circumstances led to their overthrow. Appius Claudius had conceived an evil passion for a damsel named Virginia, the daughter of Lucius Virginius, a respected plebeian, and at his instigation Marcus Claudius, one of his clients, claimed Virginia as the daughter of one of his own female slaves and offered to prove this even to the satisfaction of her reputed father, while Appius Claudius decided that in the meantime she should remain in the custody of the claimant. This decision being directly contrary to law, and Icilius and her uncle Numitorius having exposed the decemvir's criminal designs, the aspect of the people became so threatening that he was forced to leave the maiden in the hands of her family, declaring, however, that he would finally settle the case next day. Virginius, hastily summoned from the army, appeared with his daughter next day in the forum in mourning robes and appealed to the people; but Appius Claudius, attended by a strong guard, again adjudged her to M. Claudius. Unable to rescue his daughter, the unhappy father snatched a knife from a butcher's stall and plunged it into her bosom, saying, "There is no way but this to keep thee free." Virginius escaped to the camp and with the army returned to Rome, demanding revenge. The decemvirs were deposed by the indignant people, and the government by tribunes and consuls restored 448 B.C. Appius Claudius died in prison or was strangled, while Marcus Claudius was banished.

APPLE. Horticulturists regard this tree and its fruit as the progeny of two original stems, the *Pyrus malus* and *Pyrus baccata*, all the common species of apples being modifications of the *P. malus* of Linnæus.

Origin and Antiquity.—The common apple appears in the mythology, traditions, history and archæology of the most ancient nations, the Bible, Code of Menu, Book of the Dead, Hesiod's 'Theogony' (v. 215). Its charred remains have been found in mud of the prehistoric Lake Dwellings of Europe, while it is represented with sufficient fidelity in some of the most ancient stone carvings. It is mentioned in the earliest annals of China, Babylon, Phrygia and Egypt. Relying upon its hybrid origin, it has been assigned by some horticulturists to Higher Asia, where the *P. malus* and *P. baccata* are most likely to have become associated; a theory, however, which is contested by others, who advance many reasons for its conventional origin in Asia Minor. No contest appears to have arisen with regard to the habitat of *P. baccata*, in Higher Asia. There were and are still *baccata* which, unless they came from Higher Asia, are indigenous to America. Such are the *P. ioensis*, or Prairie States' crab, and *P. coronaria*, or Eastern States' crab. The latter is a sweet scented fruit about three-fourths of an inch in diameter, which grew wild in all the Northern and Middle States. The tree was about 15 to 20 feet high, with light-green leaves and rose-colored blossoms, which appeared in May. This plant is now cultivated in

all the States mentioned. There is also the *P. rivularis*, with yellow-red fruit, about the size of a cherry, native to the north Pacific, and eaten by the Chinooks; also the *P. angustifolia* of the Allegheny range; both of them native to this continent.

Appearance.—The apple tree (*P. malus*, order, *Rosaceæ*), as a rule, is not over 30 feet high, the trunk and branches crooked and gnarled, leaves short-stemmed, blossoms having permanent calyces and emerging in clusters. When in leaf, the tree presents that symmetrical outline which suggests long domestication. The fruit usually round, sometimes oblate or ovoid, depressed at both ends, varies in size from two to six inches diameter, with a white, crisp, watery, sweet (or acidulous) pulp, centred by a core containing several small brown seeds and covered by a thin glossy (sometimes russet) skin, which, when cut open, yields an agreeable odor. In some varieties this becomes quite pungent.

Uses.—When eaten raw the apple is used as common food or as dessert to meals. It can be baked, roasted, stewed or boiled, made into marmalades, jellies, tarts, pies, puddings, cakes, preserves, sauces, apple-butter, Chinese chop suey or French raisiné; in short, into very varied dishes. The expressed juice of selected apples forms a sparkling sweet cider, much esteemed and commonly drunk wherever the apple grows. Very strong cider is made by separating the water from the fermented juice. This is sometimes done by freezing, and skimming off the ice. Pomona wine is made by adding a gallon of brandy to six gallons of new cider, allowing the mixture to stand still several months, racking off and bottling for future use. Verjuice is a product of the crab apple, *P. baccata*. Apples, when pared, cut and dried in the sun, afford an excellent substance for pies and sauces. Pomatum, as the name indicates, used to be made by mixing apple pulp with lard. Apple-wood is of fine grain and hard enough, when stained black, to pass for ebony. It is also employed in the manufacture of furniture, shoe-lasts, small cog-wheels, buttons, oriental imitations of olive wood and other objects. Dwarf apple trees are sometimes cultivated simply for ornament, as when planted for hedges, forming very beautiful ones, when judiciously selected with regard to color of blossoms and fruit. They are also planted in limited grounds, when a variety of fruit is required to be produced in a narrow space. Many varieties grafted on the wild crab seedling grow successfully and become dwarfed. The French paradise apple, a small variety, dwarfs other varieties grafted upon it. It is less dwarf than the crab, and more dwarf than the Daucain or English paradise stock, another stock in common use for this purpose. The dwarfing of trees is carried to an astonishing degree in China and Japan, where trees not more than a single foot high are produced and kept in flower-pots holding scarcely more than a quart. In England, France and the Low Countries apples are trained not only as dwarfs, but more commonly as espaliers and balloon-shaped.

Apple crops exhibit great variance from year to year, sometimes halving and at other times doubling normal produce. The following

table shows a normal crop at the present time of about 240,000,000 bushels. Upon a rough computation, for which no accuracy is claimed, if 10,000,000 additional bushels of apples are annually reduced to cider and vinegar, the world's product of apples would amount to 250,000,000 bushels. Counting 200 apples to a bushel, the product would be 50,000,000,000 apples. As the Chinese, Japanese and other far eastern people export no apples and import but few, the product is substantially consumed in Europe, America and the colonies, which together contained, at the average date embraced by the table, about 625,000,000 people. This would make an average of 80 apples a year to each person, or 400 to the average family of five persons.

APPLE CROPS OF THE WORLD.
(Latest official returns and estimates).

Equivalents employed: 1 bbl. = 2 1-2 bushels, each of 50 lbs.; 18 bbls. = 1 long ton; 16 bbls. = 1 short ton.

Grand total.....	240,000,000

Value.—The average value of the apple crop of the United States of America, as shown in the last census, was about 66½ cents per bushel.

Packing.—Experience has demonstrated the necessity of extreme care and method in packing of apples for shipment, especially when intended for exportation; the California packers having exhibited such superior devices that they have been invited to instal them in Australia and other apple-growing countries. As yet, however, no uniform system prevails throughout the United States. Apples for shipment are packed in baskets, crates, boxes and barrels; the last two containers for export. The Northwestern standard box is 10½x11½x18 inches, equal to 2,173½ cubic inches; each apple being wrapped in unprinted paper and the box stuffed with paper, or fine shavings, to allow for shrinkage and the effects of jolting in transit. The barrel is 17½ inches in diameter at the head, 26 inches between heads, 64 inches in circumference at the bulge, with staves 28½ inches long, being somewhat smaller than its Canadian compeer. The latter, the legal apple barrel of Canada, is of a size to contain 96 imperial quarts; the Canadian apple-box measuring 10x11x20 inches of space, inside, equal to 2,200 cubic inches.

Exportation.—During the calendar year ended 31 Dec. 1915 the exportation of domestic apples from the United States was as follows: Apples, green or ripe, 2,176,948 barrels, valued at \$7,086,094, such exports being chiefly to the United Kingdom. Of apples dried, the exports were 33,905,608 pounds, valued at \$2,671,601. The average value of the green apples was about \$3.50 per barrel, and of the dried apples about eight cents per pound. A large proportion of the fruit exported to the United Kingdom was probably re-exported to other countries.

Varieties.—In addition to productiveness, an essential to the value of any food plant, the 12 points mentioned and explained below should be looked for in an apple variety. Of course all 12 of these qualities cannot be found greatly developed in a single variety because some are in a measure antagonistic, but by keeping these points in mind the prospective orchardist may avoid planting a variety that would not meet his own expectations or the market demands. (1) Richness, dependent upon the relative proportion of sugar to malic acid. When these are deficient in amount the fruit is insipid, but each may be present in large amount without making the fruit pronouncedly sweet or tart to the taste. Many tart apples contain more sugar than some of the so-called sweet apples. In ripe specimens of improved varieties the range of acid is from 0.19 to 1.11 per cent, and of sugar from 10 per cent or even less in poor sorts to 14 per cent or somewhat more, the usual range being from 11 to 13 per cent. (2) Flavor, a quality distinct from the taste of acid and sugar, and, like perfume, dependent upon minute quantities (seldom more than 0.5 per cent) of a volatile oil. A highly perfumed apple is, however, not necessarily highly flavored. (3) Firmness not sponginess, crispness not hardness, tenderness not softness, meltingness not juiciness are dependent upon cell structure. (4) Color is often of more importance in the uneducated market than form, size, richness and flavor combined. It is an unsafe index of the last two qualities, except that, as a rule, well-colored specimens are superior to poorly colored ones of the same variety. Color varies in all varieties with season, soil, management, etc. The favorite color in the general market is red. (5) Form: a nearly globular shape is most desirable because fruits of that form pack better without bruising than other forms. (6) Size and uniformity. In general, a diameter of about three inches and a weight of six or eight ounces is preferred, and a variety producing such as the bulk of its crop will usually, on account of the lessened necessity for grading, be more valuable than another variety of equal productiveness but with widely varying size of fruit. (7) Smooth, tough but thin skin resists insect and fungous attacks, injuries in handling and shipping, and is more economical with respect to waste. (8) Small core and few seeds save waste. (9) Maturity: The commercial variety should be ready to harvest all at once. (10) Firm adherence to the tree; self-evident. Defectiveness in this respect may be due to attacks of enemies. (11) Culinary qualities: of prime importance in commercial varieties because such are used mainly for cooking. Sweet varieties usually make in-

* Trees, U. S. A., 1910 of bearing age, 151,523,000; non-bearing age, 67,792,000; total trees, 219,315,000.
† Trees, Canada, 1911, of bearing age, 10,617,372; non-bearing, 5,599,894; total trees, 16,217,266.

acid pies but good baked apples; tart varieties make best pies and sauce. (12) Good-keeping is not dependent solely upon firmness but is usually associated with locality, climate, soil, etc., as well as with the variety and the stock upon which it is grown. Grafting and long domestication have resulted in several hundred varieties, some say 1,000. Even in Pliny's time, nearly 2,000 years ago, there were 22 varieties known to the Romans, many of them taking the name of the cultivator, a custom which prevails to the present day. Those varieties which are held in the highest esteem in the United States are the Baldwins, Newtown Pippins, Spitzenburgh Russets, Ben Davis, Gano, Black Gilliflower, Blue Permain, Grimes, Hubbardston, Yellow Newtown, Northern Spy, Rhode Island Greening, York Imperial, Rome Beauty, Wealthy, Stayman, Golden Russet, Oldenburg, Fameuse, Ralls, Gravenstein, Jonathan, Tompkins King, Missouri Pippin, Pennock, Peck, Twenty Ounce, Willow, Wine Sap, Wolf River and McIntosh Red.

A matter of importance in the selection of varieties of apples, and even more markedly of pears, is the determination of the fertility of the blossoms. Sterility, indicated by annual dropping of the fruit, may result from one or a combination of the following causes: Impotence of the pollen or the pistils, or the premature ripening of one or the other; injuries to the blossoms by fungous attacks, rain, frost, or continued cool weather or other cause more or less beyond the grower's control. On the other hand, it often results from impotence of the pollen to fertilize the pistil of the same variety and is noticed when trees stand singly or in blocks of one variety remote from other varieties. This may be obviated by the grower, who should plant varieties that blossom at the same time in proximity, usually in alternate rows through the orchard, or by grafting such in orchards already set. A practice resulting from this and the varying maturity of varieties with respect to fruit-bearing is the planting of "filler" trees in permanent orchards. The fillers are quick-maturing varieties of usually upright growth and small size, which are set alternately with the slower-growing, more-spreading permanent trees, and cut out when crowding seems to threaten. For such practice four varieties are usually selected, two fillers and two permanents, each pair blossoming at the same time. Each pair is placed alternately with the other and each member of the pair alternately with its partner. Trees in such orchards are often planted 28 feet apart on the diagonal, so that when the fillers are removed the permanents will be left in rectangles of about 40 feet, the usual distance recommended for large-growing varieties. Some growers plant as close as 30 feet, but this is too close except for trees of small growth. No other tree fruit than the apple should be planted in an apple orchard, because no two fruits demand the same treatment, and where two are planted, one or the other, perhaps both, must suffer more or less. See ORCHARD CULTURE.

Propagation.—New varieties of apples are propagated from seeds, but since seeds rarely improve upon the parent, seedlings are chiefly used to produce stocks for grafting or budding. Standard (that is, natural-sized) trees are so

propagated. Dwarf trees result from grafting or budding the same varieties upon the small-growing, almost bush-like varieties, paradise and doucin, the stocks of which are produced by mound layering. Voluminous discussion has arisen concerning the relative advantages of grafting over budding, and also concerning certain methods of grafting. Opinions in the first case are very conflicting; in the latter they seem to favor the use of a small piece of apple-root as stock and a rather long scion to be set deeply in nursery and orchard in order to ensure the rooting of the scion and thus obtain a tree drawing its nourishment from its own roots instead of from the nondescript roots of the seedling stock. In northern rigorous climates very hardy varieties are selected upon which to top-work less robust sorts, thus to increase their hardiness. When the trees are set the tops must be cut back severely to balance the loss of root due to digging from the nursery and to start the head at the proper height from the ground. Formerly six feet was the usual length of trunk desired, but half that length is now preferred and in the central Western States even less. Trees with short bodies and low heads are less likely to be injured by wind and sun-scald than those with high heads and long bodies. Established unprofitable trees and undesirable varieties are often top-worked to valuable ones; not more than a third of such trees being grafted each year because of the danger of producing water-sprouts. See GRAFTAGE; PRUNING; TRANSPLANTING.

Soils, Fertilizers, etc.—Apples thrive upon nearly all kinds of soils, certain varieties being better adapted to light soils and others to heavy rather than the reverse in each case; but the great majority of the almost innumerable varieties succeed best upon medium to clayey loams, especially if they are somewhat elevated, inclined or rolling, and in a clear, dry climate. Since air and water drainage are usually good in such places the fruit produced is generally of fine color, flavor and size. Upon low lands and in damp climates the fruits are usually of inferior quality and the trees more susceptible to fungous attacks (see ORCHARD). The fertilizers demanded by apples are mainly potash and phosphoric acid (see MANURES). Some growers use a mixture of 100 pounds of muriate of potash to 200 pounds of 16 per cent superphosphate at the rate of 100 pounds an acre while the trees are small, increasing to 500 pounds and even as much as 1,500 pounds an acre for trees in full bearing, the amount depending upon the character and condition of the soil, and the grower's management. If cover crops (see GREEN MANURING) such as clover, vetches or cow-peas are grown, they will supply all the nitrogen needed; indeed, if long continued or if several very heavy crops be turned under, too much nitrogen may accumulate, and recourse to a cereal crop be necessary to remove the excess. Too much nitrogen induces a sappy, easily winter-killed growth, generally at the expense of fruit-production. Lack of nitrogen is indicated by pale green or yellowish foliage. The preparation of the land does not differ materially from that for other crops such as corn or potatoes, each of which is often grown the season previous to planting in order to fit the land for the orchard. The trees may

be set in spring or autumn and the cost of cultivation may be met by cropping the land for the first few years with potatoes, melons or some other low-growing, inter-tilled crop. Annual cultivation consists in an early spring plowing followed by narrowings at intervals of two weeks and after rains that form a crust until mid-summer, when a cover crop is sown to be turned under in the following spring. Deep plowing during the first five years or so will induce deep rooting which in after years will assist in withstanding drought and obviate the necessity of annual deep plowing. See TILLAGE.

Growers' opinions differ as to the length of trunk an apple tree should have, and also as to whether there should be a main trunk above the principal lower limbs, but all agree that a few (some growers say five, four or even three) well-placed main limbs are better than a large number. These mains should start far enough from one another to avoid the danger of splitting when under load of fruit, and should be made to rebranch near the main trunk. Some of these branches should be trained upward, the others more horizontally, so as to develop a well-rounded, symmetrical top. Four or five years' careful training should so fix the character of the tree as to obviate in great measure the necessity of subsequent pruning. See PRUNING.

Insects.—Several hundred insects feed upon the apple, but the most of them are so well controlled by their enemies or by natural checks that their injuries are seldom noticed. There are, however, many that are frequently troublesome, among which the following are perhaps the most commonly destructive. In connection with the specific means of control here mentioned, the reader should refer to the general article FUNGICIDE. (1) Codlin moth (*Carpocapsa pomonella*) is perhaps the best-known and most widely distributed apple pest. The eggs are laid upon the fruit, the larvæ almost invariably entering the calyx, burrowing through the flesh and causing premature ripening. Since two or even three broods are produced in a season, the destruction of the first by spraying is of prime importance. This spraying must be done before the calyx closes, because the caterpillar's first meal must be poisoned, to accomplish which the sepals must not have closed. A second spraying is recommended a month later. The destruction of culls, cores and parings and the use of moth-traps in the windows of storage-rooms also assist in controlling the pest. (2) Apple maggot (*Rhagoletis pomonella*), the footless grub (one-fifth inch long) of a two-winged fly, tunnels in the fruit and is especially troublesome in New York and New England, attacking thin-skinned summer and autumn varieties. Windfalls may be eaten by stock running in the orchard, and stored apples may be fumigated with carbon disulphide. (3) San José scale (*Aspidiotus perniciosus*), a minute scale insect of enormous prolificacy found upon many species of woody plants which in a few years die. When full grown it so closely resembles some of its relatives that a microscopic examination is necessary to determine its identity. When abundant, infested twigs have a somewhat scurvy appearance resembling a coating of ashes. From be-

neath the female scale the young appear, crawl to new feeding ground, fix themselves and reproduce with great rapidity. It has been estimated from careful records of close observations that more than 3,000,000,000 scales may be produced in a single season from one female. Spraying with kerosene emulsion, lime, sulphur and salt solution, or fumigating with hydrocyanic acid gas, are the popular ways of combating this pest. (4) Canker-worm, the larvæ of certain moths (species of *Anisopteryx* and *Paleacrita*), most common in the northeastern United States and adjoining Canada. They attack the leaves of apple, pear and some other trees, entirely defoliating them when especially abundant. The wingless females crawl up the trunks and lay their eggs upon twigs or bark. The larvæ, measuring-worms, appear shortly after the foliage from which, when disturbed, they drop at the ends of silk threads. If they reach the ground they climb the trunk to resume feeding. Pupation occurs in the ground. This climbing habit of both females and larvæ, especially of the former, suggested impassable bands upon the trunk as a means of control. To be most effective these must be applied just before the female begins to climb, and since those of one species are active in the late fall and upon warm days during the winter, and those of the other in the spring, the bands must be kept in good condition during most of the year. (Consult New Hampshire Experiment Station Bulletin, No. 85, 1901). (5) Tent caterpillars, the larvæ of a moth (*Chsiocampa americana*), attack various trees in a large part of the United States and Canada. The eggs are deposited in gluey-looking masses upon the twigs in summer and hatch in very early spring. The larvæ are gregarious, and spin a protective web from which they emerge to feed. When numerous they frequently strip large limbs or even trees of foliage. Gathering the eggs during the winter and cutting off the nests as soon as seen are the two most effective methods of control. Since several parasites attack the eggs of this moth, the egg masses should be kept out of doors in a place from which the parasites, but not the newly hatched worms, can escape. (6) Web worm (*Hyphantria cunea*) is a caterpillar similar in habits to the preceding, but enclosing the foliage upon which it feeds inside a web until nearly full grown, when like the former species the larvæ disperse. The eggs are laid by a moth in late spring upon the undersides of leaves near the tips of branches of many trees, bushes and even clover. Cutting and burning is the most effective remedy. (7) The round-headed and the flat-headed borers are serious pests. They bore in the young wood, the latter mainly near the ground in the trunk, the former more frequently in the larger limbs. They are the larvæ of two beetles (respectively, *Saperda candida* and *Chrysobothris femorata*). Their presence is indicated by the presence of chip-like castings at the mouths of their burrows. The only effective means of control are cutting out the larvæ or prodding them to death in their burrows with a flexible wire. The application of repellants to prevent the laying of eggs upon the trunks is sometimes recommended. (8) Woolly aphid (*Schisonaura lanigera*) often called American blight in England and Australia, is a serious pest, especially

upon young trees. Two forms of this insect appear; one above ground, the other upon the roots. The former, readily recognized by its woolly appearance, is easily controlled by kerosene emulsion; the latter is hard to fight without injuring the trees. Tobacco dust worked into the ground seems to be the most effective and least harmful remedy. Nursery stock should always be carefully examined for this pest and treated, if necessary, before being planted. (9) Bud moth (*Tmetocera ocellana*), a tiny insect, the larvæ of which appear in midsummer, pass the winter in the larval state and attack the opening buds and young leaves, over which they weave a little web in early spring, when they are most destructive. Paris green is effective. (10) *Aphis fomi*, the green-apple leaf aphid, which injures the leaves of young trees and stunts the growth of the fruit. It can be controlled by spraying with lime-sulphur solution in February or March, and by various insecticides, especially nicotine solutions, later on. (11) Various caterpillars, especially the tent caterpillar, that of the gipsy-moth and that of the brown-tail moth (q.v.). The methods of controlling these insects are treated under their respective names. The caterpillars of *Tmetocera ocellana* and *Eccopsis malana* attack the flower-buds. (12) The pear thrips also attacks the blossoms. (13) The plum curculix *Conotrachelus nenuphar*, attacks the fruit, and is controllable by the same methods as the codlin moth. (14) The green-fruit worm, *Xyliner*, eats a cavity out of the side of the apple. See INSECTICIDE.

Protection from Mice and Rabbits.—Wherever mice and rabbits exist they are liable to do much damage to young trees during the winter months, especially when the ground is covered with snow. Anything that affords protection to mice, such as grass, weeds or leaves, should be removed from around the trunks of trees. It is only when the natural food of the rabbit is cut off by being covered with snow that this destructive little animal is forced to resort to gnawing the bark from fruit trees. To prevent this pest from doing this damage, the most effective plan is to tie some material around the body of the tree to the height of two feet or more. Cornstalks cut to the desired length serve the purpose well; building paper, plain or tarred, and even old newspapers are effective.

Diseases.—Apple scab (*Fusicladium dendriticum*) is probably the most serious apple disease, since it causes the loss of much fruit and injures the appearance of much more. It appears as black spots with grayish borders on apples and pears, commonly seen on greening, snow, and yellow harvest varieties that have not been sprayed. Often the abundance of the confluent spots prevents the normal development of the fruit, which becomes lop-sided. The leaves are also attacked, but the markings are not so pronounced. Spraying with Bordeaux mixture is very effective. Rust (*Ræstelia pirata*) appears upon the foliage in early summer as orange spots more or less confluent. The fruit is also destroyed. The spores of this fungus will not germinate upon the apple but find a congenial host in the juniper or cedar, upon which they are called cedar apples (botanically, *Gymnosporangium macropus*). These, when matured in the following spring, look

something like orange yellow sponge. Their spores will not germinate upon the cedar, but will upon the apple. Sometimes the fungus perpetuates itself by its mycelium, which may live from year to year upon the young twigs and buds of the apple. Destruction of the cedars and spraying are effective. Apple canker (*Nectria ditissima*) destroys the bark and younger wood, and eventually the tree, but small areas may be cut out and the wounds painted with Bordeaux mixture. In fact, since this disease gains entrance through wounds, all such should be similarly treated. Burning badly infested trees is the only means of checking the spread of this disease. Powdery mildew (*Podosphæra oxycantka*), a grayish growth upon the foliage, is often troublesome in the South upon young trees and seedlings in the nursery. It may readily be controlled by a standard fungicide. Bitter rot (*Glomorella rufomasulans*) appears upon the fruit as brown spots extending until they often involve the whole apple. It may attack at any time and is especially destructive to the early varieties, more in the South than in the North. Black rot (*Sphærospis malorum*) resembles bitter rot and is similarly controlled. Two important bacterial pests are pear blight (*Bacillus amylovorus*), which causes cankers on the limbs and trunks, and crown-gall (*Bacterium tumifaciens*), causing swellings on the trunk and roots just below the surface of the ground. Oregon canker is *Neofabra malicorticis*. See FUNGICIDE.

Harvesting, etc.—As the fruit ripens, the starch which it contains becomes changed into sugar, the leaf green is replaced by tints characteristic of the variety, the flow of sap into the fruit diminishes until the apple has attained full size and weight, when the flow practically ceases. Since the changes that now take place are mainly chemical and continue independent of the tree, the fruit may be picked. Fruit-growers agree upon this time, which they determine with each variety from experience. The fruits are still hard, but have brown seeds, and, having reached the development mentioned, may be picked by slightly twisting the stem without danger of breaking the twig upon which it is borne, thus preventing a loss of bearing-wood. Fruits gathered at this time and ripened properly are superior to those allowed to hang longer upon the tree. For best results in keeping, apples should be stored as soon as possible after picking; the temperature kept uniform and near 33° F., so as to check the ripening process; draughts avoided, since they hasten decay and increase shriveling, hence closed packages are better than shelves; odors should be excluded.

By-Products.—Apple culls may be used in more ways than the culls of any other fruit crop, and each product finds a ready market, mainly at home. The better specimens are usually evaporated, the cores and peelings of such being utilized either for cider-making or more frequently they are dried and shipped to Europe for the manufacture of certain kinds of champagne and other wines. The others are usually made into cider, which in turn may be remanufactured into jelly, apple-jack (apple brandy, a distilled liquor) or vinegar. When cider and apples are mixed and boiled with or without sugar the product is called marma-

lade, and, if spices be added, apple butter. The pomace (as crushed fruit is called, especially after the expression of the juice) is washed to obtain the seeds, which are dried and used for planting.

W., 'Practical Orchardng on Rough Lands' (Akron, Ohio, 1911); 'The Apple' (Nebraska State Horticultural Society, Vol. XXV, Lincoln 1894); Todd, 'Apple Cultivist' (1871); Warder, 'American Pomology' Part I, *Apples* (1867); Waugh, F. A., 'The American Apple Orchard' (New York 1908); Wilkinson, A. E., 'The Apple' (Boston 1915); Woolverton, L., 'The Canadian Apple Growers' Guide' (Toronto 1910), and various reports of horticultural societies, especially of the American Pomological, Michigan Pomological and Western New York Horticultural societies; also various works on fruit culture.

APPLE BRANDY, or APPLE JACK, a liquor made from the fermented juice of apples by ordinary processes of distillation.

APPLE OF DISCORD, according to Greek mythology, the golden fruit thrown among the Olympian divinities by the goddess of discord (Eris), bearing the inscription "for the fairest." Aphroditē (Venus), Hera (Juno), and Pallas (Minerva) became competitors for it, and its award to the first by Paris so inflamed the jealousy and hatred of Hera to all of the Trojan race (to which Paris belonged) that she did not cease her machinations till Troy was destroyed. This story is introduced in Tennyson's 'Enone.'

APPLE OF SODOM, the title of a fruit described by old writers as externally of fair appearance, but turning to ashes when plucked. It is probably the fruit of *Solanum sodomium*, a nightshade (q.v.) of northern Africa, which when eaten may produce delirium and even death. An American nightshade is also so called.

APPLE-SHELL, the designation of one of the large, handsomely ornamented, globose, bush-climbing pond-snails of tropical Africa and America, belonging to the genus *Ampullaria*. Some species are to be found along the southern border of the United States. These mollusks are truly amphibious, having both lungs and gills, and are thus able to breathe in water or in air, whenever disposed to exchange an aquatic for a terrestrial existence. Consult Semper, 'Animal Life' (1881).

APPLETON, Charles Edward Cutts Birch, English editor and author: b. Reading, England, 16 March 1841; d. Luxor, Egypt, 1 Feb. 1879. He was graduated from Saint John's College, Oxford, in 1863, studied for two years in German universities, and was appointed lecturer in philosophy at Saint John's College. His best service to literature and his time was his founding the *Academy, a Monthly Record of Literature, Learning, Science, and Art*, whose first number appeared 9 Oct. 1869. Its characteristic feature was the signing of all the critiques and leading articles with the writers' names in full, and these included men of the highest eminence in literature and science. Appleton remained editor until his death.

To a volume of essays on the 'Endowment of Research' he contributed two articles: 'Economic Character of Subsidies to Education,' and 'Endowment of Research as a Form of Productive Expenditure' (1876). Consult Appleton and Sayce, 'Life and Literary Relics' (1881).

APPLETON, Daniel, American publisher: b. Haverhill, Mass., 10 Dec. 1785; d. New York city, 27 March 1849. After engaging in the dry-goods business in Haverhill, Boston and New York, he began importing English books with his merchandise. He presently devoted himself exclusively to the business of printing and publishing, and between 1830 and 1849, together with his sons, laid the foundation for the successful career of the American firm D. Appleton & Company. Its publications extend over the entire field of literature, and it has rendered great service in issuing the works of modern scientists at moderate prices; for example, Herbert Spencer, Tyndall, Huxley, Darwin, etc. Medical books form a special department, and Spanish books for the South American market a specialty which the firm has made its own. In *belles-lettres* and American history it has a strong list of names among its authors.

APPLETON, Jesse, American theologian: b. New Ipswich, N. H., 17 Nov. 1772; d. Brunswick, Me., 12 Nov. 1819. After his graduation from Dartmouth College in 1792 he was ordained pastor of the Congregational Church at Hampton, N. H., in 1797. He was president of Bowdoin College, 1807-19. A man of fine culture and attractive personality, he was constantly in demand as a preacher on important occasions. His daughter married President Franklin Pierce. His lectures, sermons and other writings, with a memoir, were published by Prof. A. S. Packard, 'The Works of Jesse Appleton, D.D.' (1837).

APPLETON, John Howard, American scientist: b. Portland, Me., 3 Feb. 1844. He was graduated from Brown University in 1863 and was instructor in chemistry there 1863-89, and full professor 1868-1914 and professor emeritus since 1914. He was a member of the United States Mint Commission 1891. His chemical textbooks have been widely used, and include 'Qualitative Chemical Analysis' (1878); 'Quantitative Chemical Analysis' (1881); 'Chemistry of the Non-Metals' (1884); 'Metals of the Chemist' (1891); 'The Carbon Compounds' (1892).

APPLETON, Nathan, American merchant: b. New Ipswich, N. H., 1779; d. 1861. He started the first cotton power-loom in the United States and was one of the founders of the city of Lowell. He sat several times in the Massachusetts legislature, and in 1830 and again in 1842 was a member of Congress.

APPLETON, Samuel, American merchant, well known as a philanthropist, brother of Nathan Appleton (q.v.): b. New Ipswich, N. H., 1766; d. 1853. He retired from business in 1823 and at his death bequeathed \$200,000 for benevolent and scientific purposes.

APPLETON, Thomas Gold, American author and artist: b. Boston, Mass., 31 March 1812; d. New York, 17 April 1884. He was graduated from Harvard University in 1831 and spent much of his life abroad. A generous

patron of the fine arts, he was himself an amateur painter of considerable ability. In society he was a well-known figure, being a brilliant talker with a gift of epigram. His witticism "Good Americans, When They Die, Go to Paris" has been erroneously ascribed to O. W. Holmes and others. His books are 'A Sheaf of Papers' (1874); 'Nile Journal' (1876); 'Chequer Work: Tales and Essays' (1879); 'Syrian Sunshine' (1877); 'Windfalls' (1878). His poem 'Faded Leaves' was once popular. Consult Hale, Susan, 'Life and Letters' (1885).

APPLETON, William Henry, American publisher, the eldest son of Daniel Appleton (q.v.): b. Haverhill, Mass., 27 Jan. 1814; d. 1884. In 1835 he was sent to represent his father's firm in London, and in 1836 a permanent agency was established there. In 1838 he was taken into partnership, and upon the retirement of his father in 1848 he formed a copartnership with his brothers to continue the house of Daniel Appleton & Company.

APPLETON, Wis., city and county-seat of Outagamie County, on the Fox River and the Chicago & N. W. and the Chicago, M. & St. P. railways, 25 miles southwest of Green Bay. It is at the head of navigation on Lake Winnebago and on the Green Bay waterway, on a plateau 70 feet above the river, and near the Grand Chute rapids, which by a series of dams are made navigable for steamboats and with a 50-foot fall supply extensive water power for manufactures. The principal industries are the manufacture of farm implements, furniture, paper, flour, pulp, machinery and woolen and knit goods. The United States census of 1914 reported 108 manufacturing establishments of factory grade, employing 2,576 persons, of whom 2,207 were wage earners, receiving a total of \$1,259,000 annually in wages. The capital engaged was \$10,261,000 and the year's output was valued at \$7,777,000; of this, \$2,835,000 was added by manufacture. These figures show an increase over those of 1909 amounting to 15.5 per cent. It is the seat of Appleton Collegiate Institute and Lawrence University (Methodist Episcopal), and has university and public school libraries, three national banks, daily and weekly newspapers and a property valuation of over \$3,500,000. The city was settled in 1848, incorporated as a village in 1853 and as a city in 1857. It has adopted the commission form of government. Pop. (1910) 16,773.

APPLIED MECHANICS. Applied mechanics, based on the same laws and principles as theoretical or rational mechanics, nevertheless differs from it in methods of solving problems as well as in the problems themselves. It is the aim in applied mechanics to obtain a faithful representation of the circumstances which condition the state of rest and motion of real, actual systems. It deals therefore with the rational and economic design and construction of structures (bridges, buildings, waterways, etc.) and machines (engines, motors and machinery in general). We no longer meet with the "perfect" fluids, the "perfectly" elastic, rigid, or smooth bodies of theoretical mechanics. Friction, viscosity, plasticity, deviations from the laws of Hooke, Boyle, and Charles are brought into every problem so far as mathematical difficulties and experimental deficiencies

will permit. No problem is considered solved until a result is obtained which is verified by experiment and which can be used in making numerical computations. Consider for instance the behavior of a steam engine. The actual steam pressure on the piston varies every instant according to a law compared with which Newton's law of attraction is a model of simplicity; added to that the yielding of the parts, the rubbing of interacting surfaces, the exact rôle of lubricants, the vibrations of the supports, the escape of heat through the cylinder walls, the friction of the steam in passing through the slide valve, and the almost erratic variation of the resistance offered by the machine actuated by the steam engine make what the mathematician terms a "complete solution" hopeless of attainment. Applied mechanics does not attempt the impossible, yet some solution of such problems as this must most urgently be found. But the solution need not be more reliable than the measured experimental data. The precision of engineering data is hardly ever better than 1 per cent and sometimes does not exceed even 10 per cent. Therefore bold approximations and graphical processes will usually give results as precise and correct as, and decidedly more rapid than, those found by analytical methods. Sometimes the conditions which make an analytical solution too difficult to be attempted are neglected; the formulas or results obtained by this simplification—they might be called qualitative as opposed to quantitative solutions—are then compared with experiment and properly modified by means of empirical constants. Thus, the volume of water discharged from an orifice in a tank is calculated on the assumption of steam line flow (see HYDRODYNAMICS); when multiplied by an empirical coefficient it gives the precise discharge and applies also to flow under many different circumstances. Here is the keynote of the science of applied mechanics: Correct and precise results deduced as far as possible from first principles and co-ordinated with experiment. Correctness and precision differ from exactness; a yardstick may be correctly and precisely measured as being one yard long but its exact length may never be known. In physics and engineering "correct" means according to fundamental laws, "precise" means according to measurement. "Exact" implies a finality and absoluteness which science regards as unattainable.

Theoretical mechanics was fully developed early in the 19th century before applied mechanics existed at all. Pioneers like Euler, the Bernoullis, Cauchy, Lagrange, Laplace, Gauss, Poisson, Fourier and Hamilton were primarily mathematicians. They were indeed men capable of building a utilitarian science, but it seems the element of interest was lacking. It is difficult to explain by other reasons why the perturbations in the solar system were worked out before the simple problem of finding the forces in a truss had been solved graphically, or why the analytical theory of heat conduction should have been finished almost a quarter century before thermodynamics was really begun. But it was nevertheless a mathematician who wrote the first systematic treatise on applied mechanics. Isolated problems had of course been studied long before. Galileo had experimented, although unsuccessfully, with

cantilever beams, and Euler, Bernoulli, Coriolis Napier, Smeaton and others had made important contributions to hydraulics and the strength of materials. Poncelet, professor of geometry in Metz, was commissioned by the French Ministry of War in 1824 to found a course in the "science of machines" at the Ecole d'Application. His 'Cours de mécanique appliquée aux machines' appeared in 1826. The mathematician Dupin saw at once that applied mechanics was in itself a science and not merely a collection of isolated applications of theoretical mechanics. He reported to the Academy in 1827:

"It is a production remarkable for the rigor of the mind that developed it [*qui en a tracé la marche*] and for the simplifications made to render less difficult of application to practice those calculations reserved for the most part to transcendental speculations."

Poncelet's work was soon followed by that of others. In 1858 Rankine published the 'Manual of Applied Mechanics' containing his celebrated preface on the 'Harmony of Theory and Practice in Mechanics.' The inclusion of this essay in a textbook is significant in showing that the ancient scholastic contempt for experiment had been completely transformed in the minds of engineers into contempt for what they called "pure theory." To-day, fortunately, the fictitious clash between theory and practice has vanished and to its disappearance must be attributed some of the most valuable contributions, from a utilitarian standpoint, that have been made to engineering science by such mathematician-engineers as St. Venant, Bousinesq and Grashof. Rankine's 'Prime Movers' shortly followed the treatise on mechanics and contained for the first time in an English book the new science of thermodynamics which he and Clausius had developed independently. Willis and Reuleux had meanwhile laid the foundations of the kinematics of mechanism. Applied mechanics thus reached maturity soon after the middle of the 19th century. Still one field, however, remained to be developed: the dynamics of machinery. The necessity of this arose in connection with the balancing and stabilizing of high-speed engines which were now beginning to be introduced. Although investigations along these lines were made from about 1850, by Lechatelier, Villarceau, Résal and Redtenbacher, to the important contribution by Radinger in 1870 ('Dampfmaschinen mit hoher Kolbengeschwindigkeit'), it was left to Yarrow (1892) and Schlick (1893) to make complete application of the new methods. Since then the whole subject of balancing, governing and gyroscopic effect has been exhaustively examined with the aid of the most powerful mathematical analysis. But in spite of its value it has not yet succeeded in displacing in most textbooks a host of academic problems on falling bodies, friction, centroids and moments of inertia.

Applied mechanics is subdivided on pedagogical grounds into KINEMATICS OF MECHANISM; GRAPHICAL STATICS; DYNAMICS OF MACHINERY; STRENGTH OF MATERIALS; HYDRAULICS; THERMODYNAMICS; AERODYNAMICS. These are treated in this Encyclopedia under their respective titles.

R. F. DEIMEL,

Assistant Professor of Mechanics, Stevens Institute of Technology.

APPOGGIATURA, a-pód'jg-too'ra, a musical term applied to a small additional note of embellishment preceding the note to which it is attached, and taking away from the principal note a portion of its time. It is expressed thus:

and performed

Long ap-

poggiatura invariably occurs on the beat, and short appoggiatura, now commonly styled a grace-note, is written as an eighth note with a stroke through the stem.

APPOINTING POWER, Military. It has been contended by advocates of executive discretion that army appointments are embraced in the power granted to the President in the section of the Constitution, to nominate and, by and with the advice and consent of the Senate, appoint "all other officers of the United States whose appointments are not herein otherwise provided for and which may be established by law. But the Congress may, by law, vest the appointment of such inferior officers as they think proper in the President alone, in the courts of law, or in the heads of departments." If due regard, however, be paid to the words, "whose appointments are not herein otherwise provided for," the pretension set up in favor of executive power will receive no support from the terms of the Constitution. The powers granted to Congress to raise and support armies, and to make all rules for the government and regulation of the land and naval forces, are necessarily so comprehensive in character as to embrace all means which Congress according to circumstances may deem proper and necessary in order to raise armies, and to govern them when raised. Rules of appointment to office, rules of promotion—another form of appointment—and all rules whatever in relation to the land and naval forces, save the appointment of the commander-in-chief of those united forces, who is designated by the Constitution, are hence within the competency of Congress. It is true that this great power vested in Congress has been exercised, in most cases, by giving to the President a large discretion in appointments and other matters connected with the army. But the principle itself—that supreme command is vested in Congress—has been often asserted in military legislation. Contemporaneously with the foundation of the government, laws have been passed giving to general and other officers the right of appointment to certain offices; in other cases the President has been confined in his selection to classes designated by law; again, rules have been made by Congress for the promotion of officers, and in 1846, an army of volunteers was raised by Congress, the officers of which Congress directed should be appointed according to the laws of the States in which the troops were raised, excepting the general officers, who were to be appointed by the President and the Senate—a clear recognition that the troops thus raised were United States troops and not militia.

APPOINTMENT, the designation of an individual, by the person or persons having authority so to do, to perform the duties of some office or trust. The making out of a commission is conclusive evidence of an appointment to an office for holding which a commis-

sion is required. 1 Cranch (U. S.) 137; 10 Pet. (U. S.) 343. An appointment is usually made by one person or a limited number acting with special authority, while an election is made by all of a class. In chancery practice an appointment is the exercise of a right to designate the person or persons who are to take the use of real estate. 2 Washb. R. P. 302.

APPOINTMENTS, Federal, State and Local. The act of appointing a person to an office or governmental position is complete when the officer or body vested with the legal power has made the selection, or, if the approval of some other authority be necessary, when such authority has sanctioned the selection. To be legal it is not necessary that a certificate of appointment or commission be issued, but this is usually done as a formal evidence of the appointment. There is no exact line of demarcation between an officer and an employee of the government, but a legal distinction is made according to the duties and responsibilities of the position, and to a certain degree this distinction affects the appointment and tenure of office.

FEDERAL APPOINTMENTS.

The Appointing Power.—When framing the Constitution, the Federal Convention of 1787, while vesting "executive power" in the President, did not intend that he should be subjected to the annoyance of making selections of persons for minor positions. Hence Art. II, Sec. II, ¶ 2, provides that the President

"shall have power, by and with the advice and consent of the Senate, to nominate and appoint ambassadors, other public ministers and consuls, judges of the Supreme Court, and all other officers of the United States, whose appointments are not herein otherwise provided for, and shall be established by law; but the Congress may by law vest the appointment of such inferior officers, as they think proper, in the President alone, in the courts of law, or in the heads of the departments."

All three branches of the government—legislative, executive and judicial—exercise the power of appointment to public office, but from the time the first departments were established the heads thereof have made the majority of appointments, since most of the officers are connected with the executive branch of the government. For this reason the executive authority alone is restricted in its power to make appointments. With few exceptions, legislative bodies choose their own officers and employees practically without interference or regulation by either of the other two branches of the government; nor do the other branches, save in a few cases, hinder the independent appointments to subordinate positions connected with the courts that are made by the judicial branch. An executive appointment is usually subject to the approval of some other body.

Appointment of Members of Congress to Office.—Article I, Sec. VI, ¶ 2 of the Constitution provides that "no Senator or Representative shall, during the time for which he was elected, be appointed to any civic office under the authority of the United States, which shall have been created, or the emoluments whereof shall have been increased, during such time; and no person, holding any office under the United States, shall be a member of either House during his continuance in office." With regard to the first clause of this paragraph there has been some dispute, though its sig-

nificance is apparent. Some have questioned the right of a Senator, who was appointed to a Cabinet position, to receive the increased emolument of the new office if the salary of the Cabinet officers had been increased during the time for which the Senator was elected, but such a Senator is not held to be ineligible to the Cabinet position if he surrender voluntarily the increase of salary. The last clause evidently was intended to make a sharp distinction between the legislative and executive branches, but it has been necessary to define the word office. Accordingly the House judiciary committee has decided that members of commissions appointed for purposes of investigation but which possess or exercise no legislative, executive or judicial powers are not officers of the government within the meaning of this clause; nor can a contractor under the government be disqualified from serving as a member. A distinction has been made also "between the performance of paid services for the executive, like temporary service as assistant United States attorney, and the acceptance of an incompatible office." There is also a distinction between a member and a member-elect, the latter possessing the right until Congress meets to choose between the seat and an incompatible office. On the other hand, persons holding commissions in the army and an officer in the militia of the District of Columbia are considered ineligible.

History of the Appointing Power.—Up to the administration of President Jackson (q.v.) in 1829, there was comparatively little abuse of the power to make appointments to Federal offices either for personal or partisan purposes. The President assumed responsibility for his appointees, endeavored to make appointments from all parts of the country so that no section would feel slighted, and after 1793 usually made his selections from among the adherents of the dominant party, keeping the fitness of the appointee constantly in mind. But there were some attempts to gain a partisan advantage by use of the appointing power, such as Adams' appointment of the "Midnight Judges" and Jefferson's removals and appointments with the object of securing a more even balance between the parties in the civil service. The States had become more or less permeated with the spirit of the spoils system, particularly New York, Pennsylvania, Rhode Island and Massachusetts; in New York the Council of Appointment and the Albany Regency (q.v.) held sway for a number of years and finally the Federal service in New York and Pennsylvania became tainted. There was a wholesome distrust of the life-tenure in executive and legislative office with the result that the States began to enact laws substituting a fixed term for tenure during "pleasure" or "good behavior." The influence of these laws was felt in the Federal service, when, in 1820, Congress passed a law known as the "Four Years Law," limiting the tenure of office of the majority of United States officials, such as district attorneys, naval officers, surveyors, collectors of customs and others having the custody of public money. This served as an entering wedge for the introduction of the spoils system, which was used for purely partisan purpose by President Jackson and his successors without serious hindrance until 1871 and has continued in a modi-

fed form since that time. For details of the spoils system, see UNITED STATES — THE NEW DEMOCRACY AND THE SPOILS SYSTEM.

Attempts at reforming the system of appointments were made prior to the Civil War. In 1853 Congress passed an act which graded the clerical positions according to salary and required examinations of applicants before appointment, but as these were merely non-competitive or "pass" examinations and were conducted by boards selected by department heads, the spoils system received no serious check. In 1871 the first reform law was passed as a rider to an appropriation bill, which empowered the President "to prescribe such regulations for the admission of persons into the civil service of the United States as may best promote the efficiency thereof." President Grant appointed a commission, with George William Curtis (q.v.) as its first chairman, which formulated a set of rules for competitive examinations, but these were rendered inoperative by the refusal of Congress to appropriate sufficient money, though in 1877 they were revived for the New York custom house and post-office. On 16 Jan. 1883 the first comprehensive and detailed civil service act became law, and under it the President has power to extend its jurisdiction, so that the competitive system now covers two-thirds of the entire executive civil service of the Federal government. See CIVIL SERVICE REFORM.

STATE AND LOCAL APPOINTMENTS.

State Appointments.—In making appointments most States follow the practices of the Federal government, the major portion of the appointing power being exercised by the governor and the heads of the State departments, though there are a number of officials, elected by the people, who exercise the appointing power absolutely independent of the governor. In most States, the senate must confirm the governor's appointees, and his removals from office are subject to the same restriction. Most States limit the term of office of all the important officials, whether appointive or elective. In Maine, Massachusetts and New Hampshire there is an elective council who confirm appointments. In the Northern States the spoils system developed early, and by 1805 had become the recognized system of appointments to office; in both North and West it still prevails, but the system never gained a strong foothold in the South. The few weak attempts to break its influence in the North have proved unavailing and only six States now have civil service laws that apply to the State service.

Local Appointments.—City and local governments have no uniform system of appointments to office. As first constituted the elective city council had the power of appointment, with the exception of the most important city officials, who were appointed by the governor of the State. Later the mayor was given power to appoint, but his appointments were subject to the approval of the city council or, if the bicameral system (q.v.) were in vogue, to the approval of the upper chamber of the council. The mayor's privilege of appointing his official family is limited also by the large number of elective officials in city governments and by the retention by the city council of the power of appointing department heads and subordinates.

In all cities the most important officials are limited in their term of office. Some cities employ the "Brooklyn plan" of holding the mayor responsible by vesting in him unrestricted power of appointment and removal of department heads, and this provision was incorporated in the New York city charter. In cities under commission government, the city council usually possesses the power of appointment. In county, town and village governments all the important officials are elective. More than 200 cities are enforcing civil service laws, and they have been applied to a very few of the largest villages in New York State, but they have not been applied in smaller units save in the police and fire departments of a few Massachusetts towns. See AMBASSADOR; CIVIL SERVICE REFORM; CONGRESS; CONSULAR SERVICE; JUDICIARY; PATRONAGE; SENATE; TENURE OF OFFICE; and the following titles under the general heading UNITED STATES: THE BEGINNINGS OF PARTY ORGANIZATION, THE CABINET OF THE JUDICIARY OF THE, THE NEW DEMOCRACY AND THE SPOILS SYSTEM, THE PRESIDENT'S OFFICE, THE VICE-PRESIDENCY, THE SPEAKER OF THE HOUSE OF REPRESENTATIVES.

IRVING E. RINES.,

Author 'History of the United States.'

APPOLD, ăp'öld, John George, English mechanic and inventor of automatic machinery: b. 1800; d. 5 Aug. 1865. He invented a centrifugal pump, a brake which was used in laying the Atlantic cable, and a process for dressing furs.

APPOMATTOX COURT HOUSE, Va., village 20 miles east of Lynchburg on the Norfolk & Western Railroad. It is the seat of an agricultural school and a government experiment station. It was the scene, 9 April 1865, of General Lee's surrender to General Grant, an event which virtually concluded the American Civil War. Pop. about 500.

APPONYI, Albert, Count, Hungarian statesman: b. 1846. He is the son of the Count George Apponyi (q.v.) leader of the Conservative party that opposed the revolutionary movement of 1848, and one time Chief Justice of Hungary. Count Albert was educated at the universities of Vienna and Budapest, entered Parliament in 1872 and became the leader of the Conservative National party. He

joined the Liberals in 1899, was elected President of the Reichstag in 1901, Speaker of the Chamber 1902-04. Seceding from the Liberal party, he reorganized the National party in 1904, and was Minister of Public Education from 1906 to 1910. Beyond these few years of office, he spent nearly the whole of his parliamentary career in opposition. Together with Andrássy he led the coalition which drove Count Stephen Tisza, the pro-German "Iron Man" from office in 1905. As a delegate to the World Peace Conference at Saint Louis he visited the United States in 1904. He made another trip to this country in 1911, when he delivered some lectures on International Peace. Count Apponyi is undoubtedly the greatest figure in Hungarian politics, an orator, statesman and born leader of men. His remarkable eloquence is of the soothing yet compelling type; in some of the stormy scenes enacted in the Hungarian Parliament, when strong words, ink-bottles and fisticuffs rent the air, the masterful presence and dignified language of Count Apponyi rarely failed to restore peace and order. Intensely patriotic and absolutely honest, he can hardly be said to have found adequate opportunities to test his administrative abilities. His real strength lies in opposition, to rouse men to lofty ideals and to create enthusiasm. He is a voluminous writer and a clever linguist, able to "switch off" into half-a-dozen languages with astonishing ease. Though his political career has been many-sided, abounding in fluctuations and party vacillations, the purity of his life and motives has never been challenged. Like his colleague Count Andrássy, he has contributed numerous articles, mainly on questions of Hungarian public law, in native and foreign magazines. He published 'Æsthetics and Politics: the Artist and the Statesman' (1905), and 'A brief sketch of the Hungarian Constitution and of the relation between Austria and Hungary' (1908).

APPONYI, őrpö-nyí, György (George), COUNT, Hungarian statesman: b. 1808; d. 1899. He was Hungarian Court Chancellor in 1847. He was leader of the Conservative party, and opposed the revolutionary movement of 1848-49. After some years of retirement he entered the Reichsrath of Vienna in 1859 and was active in furthering schemes for the welfare of Hungary, materially assisting in bringing about the union of Austria-Hungary on the present basis. As Royal Commissioner he opened the Diet at Budapest in 1861 and presided over the Upper House. He was especially successful in restoring the Constitution of Hungary.

APPORTIONMENT, a term signifying the division or distribution of a subject matter in proportionate parts. In relation to contracts an apportionment is the allowance, in case of the partial performance of a contract, of a proportionate part of what the party would have received as a recompense for the entire performance of the contract. But where the contract is to complete a thing for a certain sum of money or other consideration, there can be no apportionment.

Apportionment-incumbrances.—The determining of the amounts which each of several persons interested in an estate shall pay

toward the removal or in support of the burden of an incumbrance.

Apportionment-rent.—A term denoting the allotment of shares in a rent to each of several persons owning it. It is also applied to the determination of the amount of rent to be paid when the tenancy is terminated at some period other than one of the regular intervals for the payment of rent.

APPORTIONMENT. National Legislators.—Article I, Sec. III, ¶ I, of the Constitution provides that the United States Senate "shall be composed of two senators from each State," and as provided by Article XVII (adopted in 1913) these senators shall be elected for six years by the direct vote of the people of each State. Article I, Sec. II, ¶ 1-3, provides that the members of the House of Representatives shall be chosen every second year, and the number shall not exceed one for every 30,000, though every State must have at least one representative. Hence the number of members of the lower House varies with the population. When the Constitutional Convention of 1787 debated the question of representation the delegates of the small States insisted on an equal representation of the States as such in Congress, while the delegates from the large States advocated making population the basis of representation. A compromise was effected whereby all the States were to have equal representation in the Senate, the members being chosen by the State legislatures, and the members of the lower House were to be chosen by the people and apportioned according to population. For many years the question of electing Senators by the direct vote of the people agitated the country and finally in 1913 the 17th Amendment was passed. See CONSTITUTION OF THE UNITED STATES.

Having decided that the basis of membership should be one for every 30,000, the Convention guessed at the relative population of the States and divided the 65 members among them. A question then arose as to whether the number of members should be ascertained by dividing the whole population of the country by 30,000 or by dividing the population of each State separately by 30,000 and adding the quotients. The latter method was adopted and pursued for 50 years, no attention being paid to fractions of population. In 1840, the population having grown enormously, the ratio was placed at 70,680 and each State was allotted as many representatives as its population would contain the ratio, with an additional representative if there remained a fraction of more than one-half the divisor. In 1853 another change was made. The whole number of representatives was first determined and the ratio ascertained by dividing the whole population by that number; the population of each State was then divided by the ratio and the quotient represented the number of members for the State. If this did not make the total number of representatives agreed upon, the number lacking was divided among the States having the largest fractional remainders. Hence it sometimes happened that a representative was allowed to a State that did not have a remainder of one-half, while at other times States that had remainders of more than one-half failed

to receive an extra member; occasionally the number of representatives of one State would be decreased by an increase of one in the size of the House. In 1910 a method introduced assumed that the divisor was a continuous quantity between certain limits, that is, subject to slight indefinite changes or increments. It would be easy to determine the critical points at which the decimal part of the quotient for each State passes one-half and divisors were selected midway between each two critical points. Thus a series of tables was obtained under which each one apportioned one more representative than its predecessor and one representative for every major fraction, the minor fractions being disregarded. As decided at various times the ratio of population to each representative has been as follows:

Census	Date of Apportionment Act	States	Members	Ratio
	Constitution 1789	13	65	30,000
1790	14 Apr. 1792	15	105	33,000
1800	14 Jan. 1802	16	141	33,000
1810	21 Dec. 1811	17	181	35,000
1820	7 Mar. 1822	24	213	40,000
1830	22 May 1832	24	240	47,700
1840	25 June 1842	26	223	70,680
1850	23 May 1850	32	234	93,423
1860	23 May 1860	34	243	127,381
1870	2 Feb. 1872	37	293	131,425
1880	25 Feb. 1882	38	325	151,911
1890	7 Feb. 1891	44	356	173,901
1900	16 Jan. 1901	45	386	194,182
1910	8 Aug. 1911	46	433	211,877

Ofentimes after an apportionment has been made a new State or States have been admitted and they are allowed one representative until the next apportionment. Hence, while the Apportionment Act of 8 Aug. 1911 provided for 433 members, the admission of Arizona and New Mexico raised the membership to 435.

Under the Constitution the States were to be represented according to their respective members, but only three-fifths of the slaves were to be counted. Accordingly the whites of the South had a greater proportional representation than the Northern whites, but the total population of the South had less representation than the total population of the North. When slavery was abolished the question of representation again arose and the 14th Amendment was passed providing that if the right to vote in any State were abridged "the basis of representation therein shall be reduced in the proportion which the number of such male citizens shall bear to the whole number of male citizens 21 years of age in the State." Thus if a State should allow full negro suffrage it should have full representation, but under the terms of the 15th Amendment, which soon followed, the States could not limit the suffrage because of race, color or previous condition of servitude. All States have full representation, albeit some do restrict the suffrage for reasons other than those specified in the amendment (such as educational limitations). See ELECTORAL QUALIFICATIONS.

When the apportionment has been made by Congress it is the business of the State legislature to lay out the State in districts for the election of Congressmen. These districts must

be contiguous and compact and as nearly equal in population as possible. In arranging these districts the dominant party by combinations of various kinds and unworthy scheming and trickery so maps the State that their opponents are in a hopeless minority at the polls. Such methods are known as the "gerrymander" (q.v.), the "shoe string" or the "saddle bag." If a State has not been divided into districts all the Congressmen are elected by general ticket, which is also the case if Congress has reduced the representation. If there be an increase of representatives and the State be not redistricted before election, the additional members are chosen by general ticket. See CONGRESS; HOUSE OF REPRESENTATIVES; SENATE OF THE UNITED STATES.

State Legislators.—In most States the county is the unit of representation, though in a few of the older States the township is the unit. Some States require that county lines be considered in arranging the legislative districts and while this holds true in New York, a county may be divided into two or more districts. The endeavor is usually made to equalize the population of districts, but some of the States still retain the original privileges of their local areas, thus causing great inequalities in population. In some States each county is limited to one senator regardless of population, while in Rhode Island each town has a senator and one only, so that Providence has no more voice in the upper branch of the State legislature than a small village. In Massachusetts the numerical system has been fully adopted. In some of the States with cities of enormous population, the constitutions have placed restrictions on the power these cities may exert in the legislature; for instance, New York city may never elect more than one-third of the members of the legislature. Such a restriction obtains in Pennsylvania. The legislature usually divides the State, but in some States (as New York and Michigan) the legislature only indicates the senatorial districts, leaving the establishment of assembly districts to the local authorities. There are great differences in the States regarding the methods and details of legislative apportionment. In Illinois minority representation is in use. There senatorial and assembly districts are identical, one senator and three assemblymen representing each district. Each voter has three votes for members of the assembly.

Municipal Legislators.—The State controls city government in varying degrees and in diverse particulars. Most cities, under charters granted by the States, have a mayor and council, elected by popular vote, the first representing the administrative branch of the government and the latter the legislative. The majority of the councils consist of a single body elected by wards or districts usually for one or two years. In some cities there is a bicameral council, the members of one branch being elected by districts, one member to each, while the members of the smaller branch are elected by the whole city or by larger districts. The districts or wards are usually determined by city officials and there too gerrymandering plays its part as well as in State or national politics. Under the commission form of government there is no question of appointment

since the commissioners are elected at large and are presided over by the mayor, who is one of their number. These men constitute the executive and legislative branches of government combined, pass all ordinances, handle the city funds, and hence centralize in themselves all legislative and administrative powers,

IRVING E. RINES,
Author 'History of the United States.'

APPOSITION, a grammatical term implying the relationship in which one or more nouns or substantive phrases or clauses stand to a noun or pronoun, which they explain without being predicated of it, and with which they agree in case: as Cicero, *the orator*, lived in the 1st century before Christ; the opinion *that a*

severe winter is generally followed by a good summer is a vulgar error.

APPRAISEMENT, a formal valuation of property, according to legal requirements, or by agreement between the parties interested. Official appraisements in legal proceedings are usually performed according to statute; the principal cases where such appraisals are ordered are in the case of goods subject to duty, the personal estate of a decedent, of property taken over by government or other authorities by right of eminent domain, etc. Unofficial appraisements take place by agreement of the parties interested, such as in the case of insured property which has been partially or totally destroyed. See CUSTOMS; TARIFF LAWS.

APPREHENSION (Latin *apprehensio*, from *ad* + *prehendere*, to seize), a term employed to denote the subjective character of perception. In the philosophy of Aristotle the act of attaining direct acquaintance with any truth or object of knowledge was called *θρηνησις*, which figuratively means a touching or immediate contact with truth. The scholastics translated this term by the word apprehension, which has descended with modified and extended meaning to modern philosophy. This word has accordingly been employed to designate the act or faculty (1) of perceiving anything through the senses, (2) of forming an image in imagination, (3) of conceiving without judging, the so-called simple apprehension of nominalistic logic; or (4) a relatively simple and immediate act of intellection with or without reference to an external object. In this use of the word it distinguishes this form of intellection from the more complex and elaborated forms of knowledge denoted by the words comprehension, judgment, etc. Thus, for example, when an object or event is viewed apart from other things or events, it is said to be apprehended. When brought into systematic relations with kindred objects of knowledge we say it is comprehended. Stone makes a rather important distinction between implicit and explicit apprehension. Through frequent recognition of an object of knowledge the mind acquires the ability to distinguish and identify it as a whole without apprehending any of its constituent elements. The act which thus grasps its object without conscious combination or synthesis of parts is an implicit apprehension. If attention lingers upon the object, a tendency toward multiplicity arises, the component parts become discernible, and implicit apprehension becomes explicit. In the one there is a distinctionless unity; in the other a conscious synthesis. Implicit apprehension is a form of what Professor Ladd calls the condensation of a series and is an important aim and result of correct mental training.

Wundt distinguishes apprehension from apperception, or what we should call clear and self-conscious perception, in a very suggestive though highly figurative way. He, of course, recognizes that in a series of temporarily successive ideas or mental states the one immediately present in perception has the most favorable position as regards clearness and distinctness. Likewise, in a spatial series, or in a complex of simultaneously interconnected factors present in consciousness, some factors are

more favorably located than others. There is, accordingly, a state of clearest grasp in consciousness, which, when accompanied by a special feeling, is called attention. This state of clearest grasp is figuratively styled the fixation point of consciousness, or, more briefly, the inner fixation point. In contrast the whole complex psychical content is called the field of consciousness. A conscious process which passes into an unconscious state is said to pass below the threshold of consciousness. A psychical compound which enters the field of consciousness passes on to the inner fixation point, then out again into the field, and finally descends below the threshold, is an apperceived compound. But just as such compounds may enter the field of consciousness before reaching the point of fixation, so may other compounds enter the field and pass out again without entering the fixation point at all. Such compounds are only apprehended. Thus it appears that Wundt's distinction between apprehension and apperception is simply one of relative clearness and distinctness of perception. Perceptions that are vague and unclear are called apprehensions, while those which are clear, self-conscious and voluntary are apperceptions. Consult Wundt, 'Outlines of Psychology' (Leipzig 1907); Stout, 'Analytical Psychology' (London 1909); Titchener, E. B., 'Textbook of Psychology' (New York 1910).

APPRENTICESHIP, in law, a contract by which a person called a master, who understands some art, trade or business, undertakes to teach the same to another person, commonly a minor, and called the apprentice, who, on his part, is bound to serve the master, during a definite period of time, in such art, trade or business. At common law an infant may bind himself apprentice by indenture, because it is for his benefit. But this contract, on account of its liability to abuse, has been regulated by statute in the United States, and is not binding upon the infant unless entered into by him with the consent of the parent or guardian, or by the parent or guardian for him, with his consent. The contract need not specify the particular trade to be taught, but is sufficient if it be a contract to teach such manual occupation or branch of business as shall be found best suited to the genius or capacity of the apprentice. This contract must generally be entered into by indenture or deed. The contract is to continue, if the apprentice be a male, only during minority, and if a female only until she arrives at the age of 18. The duties of the master are to instruct the apprentice by teaching him the knowledge of the art which he had undertaken to teach him, though he will be excused for not making a good workman if the apprentice is incapable of learning the trade, the burden of proving which is on the master. Ordinarily the indenture should contain, among other things, a stipulation that the apprentice shall be taught the general rules of arithmetic. The master must not abuse his authority, either by bad treatment or by subjecting his apprentice to menial employments unconnected with the business he has to learn; but he may correct him with moderation for negligence and misbehavior. He cannot dismiss his apprentice except by consent of all the parties to the

indenture. He cannot remove the apprentice out of the State under the laws of which he was apprenticed unless such removal is provided for in the contract or may be implied in its nature; and if he do so remove him the contract ceases to be obligatory. An infant apprentice is not capable in law of consenting to his own discharge. After the apprenticeship is at an end the master cannot retain the apprentice on the ground that he has not fulfilled his contract, unless specially authorized by statute. An apprentice is bound to obey his master in all his lawful commands, take care of his property, promote his interests, endeavor to learn his trade or business and perform all the covenants in his indenture not contrary to law. He must not leave his master's service during the term of the apprenticeship. If, without the knowledge or consent of the master, an apprentice is employed by a third person, the master is entitled to all his earnings, whether the person who employed him did or did not know that he was an apprentice. In an action for harboring or enticing away an apprentice it must be shown that the defendant had a knowledge of the apprenticeship. The enlistment of an apprentice in the military service dissolves the relation of master and servant, and the master has no claim to the bounty money or pay of the apprentice so enlisted. A master cannot delegate to another the power to chastise his apprentice, as his authority is a personal one. At common law an apprenticeship is a relation which cannot be assigned, but if under such an assignment the apprentice continue with his new master with the consent of all the parties and his own, it will be construed as a continuation of the old apprenticeship. Consult "Apprentices" (in 'Corpus Juris,' Vol. IV, pp. 1412-54, New York 1914).

APPROACHES, Military. The successors of Vauban followed up, as far as practicable, the methodical stages in conducting the attack founded upon his long experience, and which consisted in a single or a double connected attack: approaching the points assailed by as many lines of communication, directed upon them, as circumstances seemed to demand, and protecting these approaches by three continuous main lines of trenches, termed the parallels, and several portions of parallels, termed demi-parallels, placed between the second and third parallels, all of them very carefully placed so as to be in good tactical relations to one another.

The approaches were usually run in zigzag directions toward the salients of the defenses, crossing the lines of the capitals of these salients, the front of each approach gradually contracting as it was advanced toward the salient, and each boyau of the approach receiving such a direction as not to expose it to an enfilading fire from any point of the defenses within cannon-range. In addition to the communications between the parallels, two or more lines of approaches were run, from the positions selected for the depots of the trenches, to points of the first parallel convenient for the supplies for this and the other lines of works. These were also usually run in the direction of the capitals of some two or more of the salients.

Besides giving the boyaux directions unfavorable to an enfilading fire from the defenses, each one is extended some 12 or 13 yards back, to the rear of the one behind it, so that should the besieged endeavor to take up a temporary position, exterior to his main defenses, each boyau would still be covered by the portion of the one in advance of it run to the rear, not only from an enfilading but from any slant reverse views, except from points so far beyond the defenses as to make their temporary occupation very perilous to the besieged, from their exposure to open assaults.

The positions given to the approaches along the capitals are not obligatory; but will generally be found to offer more advantages than any other that could be given them on ground entirely unobstructed. In the first place, the capitals are the shortest lines from the parallels to the salients of the defenses. In the second, running the boyaux across the capitals, and gradually diminishing the extent of their front, the entire approach will be better flanked by the fire of the parallel in its rear; will be in a position to receive but little if any of the fire which is delivered from the two faces of the salient upon which it is run; will be out of the line of fire of the batteries enfilading these two faces; and will usually be in the most favorable position to defile each boyau from the fire of the besieged.

The front occupied by each approach will depend upon the length given to each boyau. As a general rule, the boyau should not receive a greater length than 100 yards, in order not to expose too long a line to tempt the besieged to enfilade it, and the approach may be started at the first parallel with a front of 60 yards, which should be gradually narrowed, so as to have a front of about 30 yards at the position of the third parallel.

Prior to the great European War, one of the most tremendous combinations of approaches in the history of war was at the siege of Sebastopol. It comprised the digging of no less than 70 miles of sunken trench, and the employment of 60,000 fascines, 80,000 gabions and 1,000,000 sand-bags to protect the men working in the trenches and at batteries. See SIEGE.

APPROPRIATION, a term denoting a specific sum set apart by the legislative power for a designated purpose. In the United States no money can be drawn from the Treasury excepting by appropriations made by law (Constitution, Art. 1). See APPROPRIATIONS, AMERICAN SYSTEM OF.

Appropriation of payments refers to the application of a payment made to a creditor by his debtor, to one or more of several debts. The debtor has the first right of appropriation. No precise words are required of him, his intention when made known being sufficient, but such facts must be proved as will lead a jury to infer that he did intend to make the specific appropriation claimed. An entry made by the debtor in his own book at the time of payment is an appropriation if made known to the creditor, but otherwise if not made known to him. The same rule applies to a creditor's entry communicated to his debtor. If the debtor does not apply the payment, the creditor may do so. There are, however, some restrictions upon this right. The debtor must have known

and waived his right to appropriate. Hence an agent cannot always apply his principal's payment. He cannot, upon receipt of money due his principal, apply the funds to debts due himself as agent, selecting those barred by the statute of limitations. A creditor having several demands may apply the payments to a debt not secured by sureties, where other rules do not prohibit it. The court will direct the application of a payment upon the failure of both debtor and creditor to do so. Payments made on account are first to be applied to the interest due thereon at the time of payment, and if the payment exceed the amount of interest, the balance goes to extinguish the principal. 3 Sandf. Ch. (N. Y.) 608; 11 Paige Ch. (N. Y.) 619. Funds must be applied by the creditor to a judgment bearing interest, in preference to an unliquidated account. When no other rules of appropriation intervene, the law applies part-payments to debts in the order of time, discharging the oldest first. The general rule is that neither debtor nor creditor can so apply a payment as to affect the liability of sureties without their consent. Where a principal makes general payments the law presumes them, *prima facie*, to be made upon debts guaranteed by a surety rather than upon others, although circumstances and intent will control this rule, as they do other rules of appropriation. 5 Leigh (Va.) 329. Payments upon continuous accounts are applied to the earliest items of account unless a different intent can be inferred. 5 Metc. (Mass.) 268; 23 Me. 24; 3 Sumn. C. C. 98. Where a creditor of an old firm continues his account with the new firm, payments by the latter will be applied to the old debt, *prima facie*, the preceding rule of continuous accounts guiding the appropriations. A different intent, however, clearly proved, will prevail. The appropriation cannot be changed, when once made, but by common consent, and rendering an account and bringing suit declaring in a particular way is evidence of an appropriation. 9 Paige Ch. (N. Y.) 165.

APPROPRIATIONS, American System of. The Constitution of the United States provides that no money shall be drawn from the treasury except under appropriations made by law (Art. I, Sec. IX, ¶ 7) and that no appropriation for the army shall be made for more than two years (Art. I, Sec. VIII, ¶ 12). In 1789, when the Treasury Department was established, Congress directed the Secretary to prepare estimates of public expenditures, but as explained elsewhere (see BUDGETS, AMERICAN) this is purely a formal duty and the executive estimates (known as the Book of Estimates) merely form a basis from which Congress can formulate the plans for revenues and expenditures. Thus the only manner in which the Executive Department participates in the framing of appropriation bills is through the presidential power of veto, and accordingly the Legislature may be said to have complete control over the expenditure of public funds. The Constitution provides that all bills for raising revenue shall originate in the House of Representatives (Art. I, Sec. VII, ¶ 1), wherefore it was easily assumed that, having the initiative in raising revenues, the House should also have similar control over expenditures. This right has been jealously

guarded, but the placing of control of the expenditure of public funds in the hands of Congress has resulted in scattering the responsibility, though this latter evil was not so noticeable when the committee on ways and means had charge of both revenue and appropriation bills. In 1865, however, the task of preparing appropriation bills was taken away from this committee and delegated to a special committee on appropriations. In 1880 and 1885 still more sweeping changes were made, the committee on appropriations being deprived of some of its powers which were given to new committees created to prepare bills for separate departments of administration. These bills were 14 in number, of which the committee on appropriations was to have charge of six, namely: (1) Legislative, executive and judicial; (2) District of Columbia; (3) fortifications; (4) pensions; (5) sundry civil; (6) deficiency. The other appropriation bills with the committees handling them were as follows: (1) Agriculture, committee on agriculture; (2-3) army and military academy, committee on military affairs; (4) diplomatic and consular, committee on foreign affairs; (5) Indian, committee on Indian affairs; (6) naval, committee on naval affairs; (7) post-office, committee on post-office, and (8) rivers and harbors, committee on rivers and harbors. With this divided initiative there is a tendency for each committee to magnify the importance of the work intrusted to it and to attempt log-rolling in an effort to secure as large an appropriation as possible, regardless of the needs or merits of claims of other departments.

Annual Appropriations.—Appropriations are divided into three classes: Annual, permanent specific and permanent annual. The first class is enumerated above. Under an act of 20 June 1874, unexpended balances of appropriations (with few exceptions) remaining in the treasury books for two fiscal years are to be carried to the surplus fund and turned back into the treasury. The exceptions consisted of: (1) Permanent specific appropriations; (2) continuing appropriations such as those for rivers and harbors and public works; (3) pay of the army and navy marine corps, since they often participate in long cruises; (4) claims arising under a treaty with Great Britain and pre-existing contracts. Under the head of permanent specific appropriations come those specifically made for certain definite ends but which remain available until entirely expended, such as appropriations for improving rivers and harbors and the construction of public works. Among the permanent annual appropriations (which do not require annual vote but which rest upon prior enactment of laws) are payments of interest on public debt, the requirements for the sinking fund, refunds and taxes collected through error, salaries of judges and expenses of collecting customs duties. The salary items contained in the regular appropriation bills might properly be classed under the head of permanent annual appropriations, since they are authorized in other statutes. An appropriation bill not only may grant money for a specific and definite object and for a given year, but may authorize the making of contracts that will necessitate expenditures for many years to come. Though the objects of

these future expenditures may be specified and the amounts apparently restricted, the contemplated new works, once begun, may constitute a basis for new demands, the ultimate cost of which cannot be foreseen.

Unless unanimous consent be obtained, new legislation cannot be introduced in an appropriation bill, nor can a general appropriation bill or any amendment thereto carry an expenditure not previously authorized by law. But this rule is elastic since oftentimes an appropriation bill may be passed providing salaries for new clerks or officials in a department whose positions have not previously been sanctioned by Congress; and sometimes the clerical force of a department is reduced or part of a service already established is eliminated. Strictly speaking, the reduction as well as the increase would constitute new legislation. In practice it would be impossible to consider every item which involved an increase or decrease of administrative force or equipment and few objections are made to such items. But occasionally party strife becomes bitter and numerous items are objected to and thrown out. Accordingly in 1906 the House adopted a rule virtually depriving members of the right to object and placing the committee in complete power, subject, of course, to majority vote under the ordinary procedure.

Department Heads and the Deficiency Bills.—While Congress is supposed to control expenditures and appropriations, instances have occurred whereby, through loose practices, a department head has placed Congress in such an embarrassing position that it was really coerced into making appropriations. As Mr. Tawney, chairman of the committee on appropriations, once said: "Many of the Executive Departments proceeded on the theory that they, and not Congress, should fix the standard of public expenditure, and if the amount appropriated for the service under their jurisdiction was not in their judgment adequate, they proceeded to extend the appropriation upon the basis of their estimates, and then, at the next session, would submit deficiency estimates, which, if not allowed, would necessitate the suspension of the service." Accordingly in 1905, in a general appropriation bill, Congress decreed that grants to departments should be apportioned by monthly allotments so as to avoid deficiencies, though this apportionment might be waived by the department head if he stated the reason in writing. But department heads used this privilege so freely that Congress later enacted that the apportionment might be waived only in case of emergency. Sometimes, if appropriations for a department have been reduced and a certain bureau of that department be affected considerably by the reduction, the bureau chief endeavors to secure the funds he had requested by drawing upon the general or permanent fund, which often causes a deficiency. Large amounts are still carried in deficiency bills, in spite of all efforts to harmonize estimates of revenues and expenditures, but this is largely due to legislation that was not contemplated when the regular appropriations were under consideration. There is also lack of harmony between the executive and legislative departments. Sometimes a department head recom-

mends economical changes for the good of the service or the abolition or consolidation of certain customs districts which have no fiscal justification, whereupon fearing a loss of patronage, the Congressman of the district affected attempts to defeat the proposed change. Often Congress is prodigal in its appropriations in spite of executive appeals for economy, in one case the appropriations exceeding by \$115,000,000 the estimates submitted by the Secretary of the Treasury. In another instance the departments asked for an increase of 171 employees, but instead of granting the request the appropriations committee reduced the existing number by 61. Hence Congressmen do not know whose recommendations to follow.

Appropriation bills in the Senate receive somewhat different consideration since they do not originate there. Originally the finance committee considered all appropriation bills, but in 1867 all bills except the rivers and harbors bill were taken away and assigned to the new committee on appropriations. But in order to insure harmony, one member of each of the most important committees dealing with general legislation is a member of the committee on appropriations. Through its power of amending House bills the Senate exercises an important influence in determining grants and usually increases appropriations.

The President and Controller.—The President may veto an appropriation bill, but is powerless to reduce it; he must consider the bill as a whole and cannot veto separate items. He is loath to hinder the operations of government because of opposition to appropriations of a certain character and, knowing this, various riders are attached by Congress in the hope of passing the Executive, who perhaps will prefer not to quarrel if the bill as a whole be good. The Controller of the Treasury determines whether Congress has expressly authorized an appropriation, and the appropriation is not finally secure until he has passed upon the warrant for its payment from the treasury. This official may raise technical objections which would prevent the payment of appropriations presumably sanctioned by the necessary authority.

State and Local Appropriations.—General appropriation bills are passed by the legislatures of all but 11 of the States, but these may not include all the money appropriated. New York has a general appropriation bill covering only absolutely necessary expenses; a supply bill which provides for unforeseen expenditures and deficiencies; and a supplementary supply bill at the end of the session to care for all items omitted by the others. There are a large number of separate appropriation bills in Massachusetts. As a rule, State appropriations run for a year and any balances revert to the treasury, but in some States they run for a year after the year for which they were made. In some States the governor has the power to veto items in the appropriation bills; in some States officials have authority to borrow to meet deficiencies in their departments, though the amount and rate of interest are generally limited. No Massachusetts official may incur liabilities greater than the amount appropriated and the commonwealth cannot be held responsible for an excess. In

some States an officer so exceeding his appropriation is held personally liable. In 32 States there is a constitutional limitation on the amount of indebtedness for deficiencies of revenues. In cities appropriation bills may be prepared either by a city council or board of aldermen, or by a board of estimate consisting of executive officials. As a rule mayors may veto separate items. See BUDGETS, AMERICAN—*State and Local*.

IRVING E. RINES,

Author 'History of the United States.'

APPROXIMATION, a term in mathematics signifying a continual approach to a quantity required, when no process is known for arriving at it exactly. Although, by such an approximation the exact value of a quantity cannot be discovered, yet in practise it may be found sufficiently correct; thus the diagonal of a square whose sides are represented by unity is $\sqrt{2}$, the exact value of which quantity cannot be obtained; but its approximate value may be substituted in the nicest calculations. This process is the basis of many calculations in pure and applied mathematics and is of frequent use and great importance in all practical operations.

APPURTENANCE, in legal phraseology anything belonging to another thing as principal, and which passes as incident to the principal thing, 10 Pet. (U.S.) 25; 1 Serg. & R. (Pa.) 169. For instance, if a house and land be conveyed, everything passes which is necessary to the full enjoyment thereof and which is in use as incident or appurtenant thereto. If a house is blown down, a new one erected there shall have the old appurtenances. 4 Coke 86. The appurtenances of a ship include whatever is on board of it for the objects of the voyage and adventure in which she is engaged and which belong to her owner.

APRAXIA, a term denoting a loss of power to appreciate the use and nature of common objects. Thus a patient with this affection might try to comb his hair with a toothbrush or blacken his boots with a dinner-plate. It is chiefly due to a cutting off of one brain

hemisphere from the other and is thus present in hemorrhage or tumor of the brain, chiefly involving corpus callosum fibres.

APRAXIN, а-пракс'ин, Feodor Matejevitch, a Russian admiral: b. in 1671; d. in Moscow in 1724. He may be considered as the creator of the Russian navy and was the most powerful and influential person at the court of Peter the Great, who made him chief admiral. In 1708 he defeated the Swedish general Lübecker in Ingermannland and saved the newly-built city of Saint Petersburg from destruction. In 1713 he took Helsingfors and Borgo and defeated the Swedish fleet. He was twice fined for embezzlement, but, being too useful to be dispensed with, Peter in both instances neutralized the effects of the condemnation by conferring upon him additional riches and dignities.

APRAXIN, Stepan Feodorovitch, Russian general, grandson of F. M. Apraxin (q.v.): b. in 1702; d. in 1760. He defeated the army of Frederick the Great at Gross-Jägerndorf in 1757 but, omitting to follow up his victory by proceeding to Berlin, was tried by court-martial but died before sentence was pronounced.

APRICOT, a small tree (*Amygdalus armeniaca*), of the family *Amygdalaceae*, long grown for its fruit and supposed to be a native of China, whence it reached Europe by way of western Asia in the time of Alexander the Great. The fruit resembles the peach in form, color and its downy skin and has a large smooth or slightly furrowed plum-like pit. It usually ripens earlier than either the peach or the plum. The choice varieties, of which, considering the length of time that it has been in cultivation there are comparatively few, are firmer, less juicy, but probably higher flavored than the peach. The tree is plum-like in leaf and habit and peach-like in bark. The apricot demands practically the same general management and is as hardy as the peach and succeeds in similar climates and situations.

The Russian apricot is a rather hardy race of the common species, with small fruits of generally inferior flavor. The Japanese apricot (*Amygdalus mume*), rather recently introduced into the United States as the Bunge plum, bears small greenish or yellowish rather hard and dry clingstone fruits. Its flowers are fragrant. The little cultivated black or purple apricot (*Amygdalus dasycarpa*), bears globular plum-like acid clingstone fruits. See GRAFTAGE; ORCHARD.

Eastern Apricot Growing.—Though grown to some extent in the eastern United States the apricot has not become widely popular for four principal reasons: Its susceptibility to injury from late spring frosts which destroy the very early-appearing blossoms; the attacks of its special enemy, the curculio (see PLUM); incomplete knowledge of suitable stocks upon which to work it so as to ensure its most perfect growth in various soils, etc.; and ignorance of its dessert qualities, probably owing to the lack of systematic exploitation by nurserymen. Best results seem to be obtained upon the deep, dry, gravelly loams suited to the apple, where such lands are situated

on the leeward side of large bodies of water or elevated and facing the north. The trees are usually set 20 feet apart and cultivated like the peach but since the fruit-bearing habit is similar to that of both the plum (on spurs) and the peach (on wood of the previous season's growth), pruning resembles most nearly that of the plum. When properly managed and grown under favorable conditions the apricot probably equals the peach in productiveness, but like other tree fruits the fruit must be systematically thinned to obtain specimens of good size and to prevent bearing in alternate years. Since the apricot is even more a dessert fruit than the peach and must be carefully grown, picked, packed and marketed, only the most careful Eastern fruit-growers attempt its extensive cultivation. The chief disease, leaf-spots, is treated under PEACH.

California Apricot Growing.—Though the apricot has been known in California for more than a century in the vicinity of the missions, where it was grown mainly from seeds, it has become commercially important only since American occupancy, in the early years of which improved varieties were introduced from Europe. In the Old World these varieties were trained to walls and otherwise coddled; in California they require no such treatment. As a consequence the apricot has become a leading fruit of the State where now about 40,000 acres are devoted to this crop. The world-wide demand for the fruit, fresh, dried, canned and candied, is fostering still wider planting, and California, already the greatest apricot-growing region of the world, seems destined to be still greater. The tree is found to succeed well on the higher ground of interior valleys upon a variety of soils, but, as in the East, is susceptible in the low ground to injury by late spring frosts. For detailed account of California apricot-growing consult Bailey 'Cyclopedia of American Horticulture' (1914).

APRIL (Latin, *Aprilis*), the fourth month of the year, consisting of 30 days, so-called probably from the word *aperire*, to open, as the buds begin to open at this time of the year. It was called Ooster, or Easter month, by the Anglo-Saxons and Charlemagne, in his new calendar, called it the grass month. In the Roman calendar April was the second month of the year and it was Julius Cæsar who added the 30th day to it; during Nero's reign it was called Neroneus; and in the Athenian calendar it corresponds to the latter portion of Elaphebolion and to the greater part of Munychion. In the French revolutionary calendar, as adopted by a decree of the National Convention on 24 Nov. 1793, it was merged into the last part of Germinal (bud month) and the first part of Floréal (flower month). Thus Germinal corresponds to the period 21 March to 19 April, and Floréal to the period 20 April to 19 May. See CALENDAR; EPOCH.

A PRIORI, a term in logic denoting the negation of a posteriori. To prove anything a priori means to do it on grounds preceding actual experience or independent of it. Mathematical proofs, for example, are a priori. On the contrary, judgments or proofs a posteriori are founded on knowledge before acquired,

like the conclusions of natural history and all experimental science. In ordinary speech a thing is said to be proved a priori when deductively derived from a more general principle, even though that principle may itself be derived from experience. This, however, is not the sense which the phrase bears in philosophy. By a priori knowledge Kant, who originated the transcendental method of philosophy, means that which is independent of all experience, such as, in his opinion, the knowledge of the fact that space has three, and no more than three, dimensions. The marks of a prior knowledge, according to that philosopher, are, first, that it is necessarily true, and second, that it is absolutely universal, in the logical sense—that is, true of the whole subject: in the example just given it was Kant's opinion that space not only has, but must have, three dimensions and can have no more; and that this is true of all space and not merely of some spaces. See LOGIC; KANT; DEDUCTION; INDUCTION; EMPIRICISM; TRANSCENDENTALISM; etc.

APSE, an architectural term applied to a semi-circular or polygonal portion of a building, roofed in by itself and most commonly appearing as the eastern termination of a church. The apse is a feature of Roman origin, corresponding to the curved recess in which sat the presiding magistrate and his assessors in the basilica or hall of justice. In front of the apse stood an altar for public sacrifices. When the Christians received the protection of the state in the time of Constantine, basilicas were frequently used for their assemblies, the bishops occupying the seats originally appropriated to the presiding magistrates and the inferior clergy filling the seats of the assessors, the altar still keeping its place. In the cathedrals of France, Germany and Italy the apsidal termination is frequently met with; in England it is less common, but examples are found in Westminster Abbey and the cathedrals of Canterbury, Rochester, Norwich and Peterborough and several parish churches; examples may also be seen in Scotland in the churches of Kirkliston and Dalmeny in Linlithgowshire and of Leuchars in Fifeshire. Transepts with apsidal ends occur on the Continent, while apsidal chapels opening eastwardly from the transepts are found in England in churches of Norman date.

APSIDES, äp'si-dēz (the plural of *Apse* or *Apsis*), an astronomical term designating the two points in the elliptic orbit of a planet where it is at the greatest and the least distance respectively from the body around which it revolves. The moon moving in an elliptic orbit around the earth, which is situated in one of the foci, is at what was anciently called its higher apse when in apogee and at its lower one when in perigee. Similarly the primary planets, including the earth and some of the comets, moving in elliptic orbits around the sun, which is situated in one of the foci, pass through their higher apse when in aphelion and their lower one when in perihelion. It is the same with the satellites of Jupiter when they are farthest from Jupiter and nearest to it.

The line of the apsides is the line connecting the two apsides of a primary or secondary planet.

The progression of the moon's apsides is a slow movement in the position of the apsides of the moon produced by the perturbing attraction of other heavenly bodies. It is about three degrees of angular motion, in one revolution of the moon and in the same direction as her progression in her orbit. The apsides of the primary planets are also perturbed.

APSLEY STRAIT, a narrow channel between Melville and Bathurst Islands, off the north coast of Australia. It is about 40 miles in length, with a breadth varying from two to five miles. The land is low on either side and the shores bordered by a broad belt of impenetrable mangroves and indented by numerous salt-water creeks, which present the appearance of rivers. Alligators of enormous size abound in the Straits, many of them measuring from 14 to 17 feet in length. A settlement was formed in 1824, on the Melville Island side of the channel, about 8 or 10 miles from its northern entrance, but subsequently abandoned.

APTERYX, a strange flightless bird of New Zealand, representing the *Apteryges*, a group of ratite birds nearly related to the extinct *dinornis*. Four or five species are known in the various islands of the New Zealand group, besides two fossil species. These curious birds, called "kiwis" by the natives, are about the size of domestic fowl and have very stout legs, wings reduced to a mere useless stump, long snipe-like beaks and no visible tail. The plumage is colored in streaked browns and grays, and the feathers are incomplete, the disunited filaments giving them the appearance and feeling of coarse hairs. Kiwis inhabit the forested hills, going about in small flocks which during the day hide in the thickets or in cavities of the ground or rocks. They sleep during the bright part of the day rolled up into a ball, but sometimes rest for a long period in a standing position, with the point of the bill touching the ground, as though they were leaning upon it. Their feeding-time is in the dusk of early morning and at evening and their diet consists chiefly of worms, which they search for apparently mainly by the sense of smell and obtain by probing the ground with their long bills. The nostrils are at the tip of the beak, which is also flexible and extremely sensitive to the touch, so that a worm may be detected when it is touched, although the bill may need to be thrust its length into the ground. The nest is usually at the end of a round tunnel dug in soft earth by the female and consists of a little dry fern or a few leaves. The eggs, generally two in number and incubated mainly by the male, are remarkable for their size, since they are equal to a quarter of the mother's weight. They are greenish white in color with a smooth surface. As might be expected from the size of the egg, the development of the young reaches a high degree of maturity before hatching. The Maoris are very fond of the flesh of the kiwi, either roasted or boiled, and their persistent hunting had greatly decreased the number of the birds before white men reached the islands. Since

that time dogs and other accompaniments of civilization have nearly exterminated these birds, which are the sole survivors of the moas. The most complete description of their habits will be found in Buller's 'Birds of New Zealand' (2d ed., 1888). For anatomical details and relationships consult Parker's memoirs in the 'Philosophical Transactions' for 1891 and 1892. A good summary of this information will be found in Newton's 'Dictionary of Birds' (1896). See *DINORNIS*; *MOA*.

APTHORP, William Foster, American dramatic and musical critic: b. Boston, Mass., 24 Oct. 1848; d. 1913. He was graduated from Harvard University in 1869 and pursued his musical studies under J. K. Paine and B. J. Lang. He taught in the New England Conservatory and College of Music to 1884, was musical critic for the *Atlantic Monthly* 1872-76; the *Boston Sunday Courier* 1876-78; and the *Evening Traveler* 1878-80. He was musical and dramatic critic for the *Boston Evening Transcript* for 20 years and was the critical editor of Scribner's 'Cyclopædia of Music and Musicians.' He wrote 'Hector Berlioz' (1879); 'By the Way'; 'Musicians and Music Lovers'; 'The Opera, Past and Present.'

APUKHTIN, ä-pooh'tën, Aleksei Nikolayevitch, Russian man of letters. b. Bolkhov, 15 Nov. 1840; d. 17 Jan. 1893. He descended from an old noble family. A man of extraordinary ability, he, while yet a child, betrayed an astounding memory and a fondness for reading, especially of poetry. While yet under 10 he knew by heart the works of Pushkin and Lermontov. Besides these his favorite poets and authors of later years were Griboyedov, Baratinski, Tyuchev, Fet, A. Tolstoi, L. Tolstoi, Turgenev, Dostoyevski and Ostrovski. In 1852 he entered a law-school from which he was graduated with distinction in 1859. He then entered the civil service as a member of the Ministry of Justice and after two years retirement in the country (1862-64), became associated with the Ministry of the Interior. Because of a chronic disease (obesity), which began developing in his youth, he kept away from society. He spent most of his life in Saint Petersburg. His literary career began while he was yet a student. To his juvenile productions belong 35 poems which due to his self-criticism appeared only in a posthumous edition. His other attempts of childhood ('Epaminondas,' 'Imitation of the Arabic,' 'Ode on the occasion of the birth of the great duchess Vera Konstantinovna') were published in the *Invalid*, 1854-55. His poems of 1859-62 appeared in the periodicals *Sovremennik*, *Vremya* and *Russkaya Riech*. They met with great success and earned the approval of Turgenev, Nekrassov and Fet. Despite this approval he wrote nothing during 1862-68. His best works belong to the period which followed this pause. At first he did not publish anything. His works of 1868 'Requiem,' 'A Night in the Monastery,' 'Old Love,' and a few others were circulated in manuscript. In 1872 his poem 'The Unfinished Monument' appeared anonymously in *Grashdanik* (Citizen). Only in 1884 did he begin to contribute to *Viestnik Yevropus*, *Russkaya Muisl* and *Sievernui Viestnik*. The

first edition of his works appeared in 3,000 copies in 1866. In 1890 he began writing novels. At his request his three novels 'From the Archives of a Countess' (1890), 'Diary of Pavlik Dolski' (1891) and 'Between Life and Death' (1892) were published posthumously. He was, however, at his best in his poems. His poetry is characterized by sincerity, simplicity, purity and deep feeling. Their form is elaborated with great care. Some of his poems ('Mad Nights') have been set to music. Translations of some of his works ('The Russian Parnassus,' 'Flies,' 'I am not sorry,' 'Old Love') are contained in the collection of Fidler. Criticisms can be found in *Russkaya Muza* (No. 5, 1886); *Viestnik Yevropui* (Vol. 2); Arsenyev, K. K., 'Critical Studies'; Gogorov K., 'Contemporary Poets'; Vengerov, 'Critical and Biographical Dictionary of Russian Writers and Scholars'; Skabichevski, 'History of Modern Literature.'

APULEIUS, or **APPULEIUS**, **Lucius**, a satirist and philosopher of the 2d century: b. at Madaura, in Numidia; the time of his death is unknown. He was author of the celebrated satirical romance called the 'Golden Ass.' He first studied at Carthage, then renowned as a school of literature, and afterward went to Athens, where he became an ardent follower of the Platonic philosophy. Falling ill while on a journey he was hospitably received in the house of Sicineus Pontianus, a former fellow-student, whose widowed mother Apuleius married. Soon after Pontianus died, and the relatives of the rich widow publicly accused Apuleius of having used magical arts to gain her love. The speech by which he successfully defended himself 'Apologia sive Oratio de Magia,' is still extant. The remainder of his life, which he devoted to oratory and literature, seems to have been passed at Carthage, where, as in some other cities, a statue was erected in his honor. His 'Metamorphoses,' 'Golden Ass,' a romance in 11 books, contains wit, humor, powerful satire and much poetical merit. It is supposed to have been intended as a satire on the hypocrisy and debauchery of certain orders of priests, on the tricks of pretenders to supernatural powers and on the prevalent vices generally. The finest part of this work is the episode of Psyche, called by Herder the most tender and many-sided of all romances. It is sufficient to render him immortal, even if he be, as some have supposed, only the narrator and not the inventor of the story. Apuleius was also the author of many works on philosophy and rhetoric, some of which are still extant. Cervantes, Le Sage, Boccaccio and others are indebted to Apuleius for various episodes. Consult edition of his complete works, Hildebrand (1842); Van Vliet (1897-1900). An English translation by Head was published in Bohn's Classical Library in 1851. See GOLDEN ASS, THE.

APULIA, province of southern Italy, composed of the provinces of Foggia, Bari and Lecce; area, 8,539 square miles; pop. about 2,000,000. The northern part forms the Apulian Plain, a rather barren tract on the whole, although affording extensive sheep pastures and isolated spots capable of cultivation, on which are wine, olives, southern fruits and maize. The isolated mountain Gargano here attains

the height of nearly 5,000 feet. The most important river is the Ofanto (Aufidus). There are four coast-lakes of considerable size. Lake Salsi dries up in a great part in summer, and on its banks are the great salt-boiling works of Barletta. There is a considerable trade in grain, oil, salt; southern fruits, cattle, wool, etc. Apulia was in ancient times inhabited by several peoples, such as the Apuli, Messapii and Daunii. It was subdued by the Romans in 317 B.C.

APURE, ä'poo-rä', river in Venezuela, formed by the junction of several streams issuing from the Sierra de Merida. After an eastern course of about 300 miles it falls into the Orinoco at Capuchino. It is navigable throughout almost its entire course.

APURIMAC, ä-poo're-mäk', a highland department of Peru, embracing a territory of 8,187 square miles and lying between the departments of Cuzco and Ayacucho. Its capital is Abancay. It has extensive upland pastures, and the soil, fertile in the main, is watered by the Apurimac River and its tributaries. Agricultural products are cereals, sugar, rice, coffee, maize, potatoes and cocoa. The products of the mines are gold, silver, saltpetre and copper. The provinces are Abancay, Aimaraes, Andahuailas, Antabamba and Cotabambas. Number of inhabitants (1916) 133,000.

APURIMAC, Peruvian river in South America, the outlet of a lake in the Andes of Peru, in the province of Arequipa, not far from Caylloma. It is probably the tributary of the Amazon rising nearest the Pacific Ocean. It flows through a mountainous country in a northerly direction, and, joining the Yucaj or Vilcamayu at lat. 9° 15' S.; long. 72° 30' W., forms the Ucayale, one of the principal tributaries of the Amazon. Its entire extent is between 500 and 600 miles.

APUS, a name designating a fresh-water phyllopod crustacean, remarkable for having 47 body-segments, 20 being the normal number in *Crustacea*. It also has 60 pairs of limbs. The body is protected by a large carapace resembling that of the king-crab (q.v.) in that it is adapted for burrowing in soft mud at the bottom of lakes or pools. Apus is locally distributed over western North America, Asia and Australia. One form (*Lepidurus gacialis*) lives in pools in the Arctic regions. It undergoes a complete metamorphosis, its larva being a "Nauplius" (q.v.). Consult Packard, 'Monograph of North American Phyllopod Crustacea' (1883); Bernard, 'The Apodidæ' (1892). See PHYLLOPODA. The family (*Apodidæ*) appears to be of great antiquity.

AQUA (Latin, water), a word used by the alchemists and early chemists for solutions or other fluid preparations in which the menstruum is water. *Aqua ammoniac* ("ammonia water") is an aqueous solution of ammonia gas (NH₃). *Aqua fortis* ("strong water") is nitric acid. *Aqua regia* ("royal water") is a mixture of nitric and hydrochloric acids, the name (bestowed by Basil Valentine) referring to its power of dissolving gold and other so-called noble metals. *Aqua vitæ* ("water of life"), so-called by Avicenna, is common grain alcohol. The word "aqua" is still in general use in pharmacy for designating aqueous solutions or infusions.

AQUADAG. The name of a lubricant whose basal constituent is graphite. It is made by treating graphite with tannin and various plant extracts which reduce it to so fine a state of subdivision that it passes readily through a standard filter paper and remains permanently diffused in water. The treatment by which the graphite is thus reduced to infinitesimal particles is called "deflocculation." The name of the product is formed from the word "aqua," meaning water, and the initial letters of the phrase "deflocculated Acheson-Graphite." This lubricant has the valuable power of preventing the rusting of metal which is immersed in the water carrying the graphite. The benefits of such a product are numerous and practical in the manufacturing world. Patents on the various processes of the manufacture of Aquadag have been taken out in 23 countries, which practically include the whole of the industrial world, and the word itself has also been trade marked in many countries.

AQUÆ SOLIS, the ancient Roman name of the modern English city of Bath. It was famed for the splendor of its buildings and its many springs, and the remains of several Roman baths have been discovered here.

AQUAMARINE, ă-kwă-mă-rĕn' (from the Latin *aqua marina*, "sea water," a bluish-green variety of beryl (q.v.) esteemed as a gem. Siberia and Brazil have long been celebrated localities, while magnificent gem material has lately been mined in North Carolina.

AQUARIANS, a name applied to Christian ascetics in the primitive Church, who consecrated water instead of wine for the celebration of the Lord's Supper—either for the sake of abstinence, or because they thought it unlawful to drink wine.

AQUARIUM (Latin, a watering-place for cattle, from *aqua*, water), a term applied to a tank or smaller receptacle filled with water and stocked with aquatic animals and plants for study, or, in the smaller examples, for mere beauty and interest. To maintain natural conditions, both plants and animals must be present—the plants to give off oxygen for the animals, as well as to furnish food for many of them and the animals to supply carbonic acid to the plants. With aeration and the removal of any dead animal or rotting plant, the water may be kept in good condition for a long time if supplied with a number of mollusks for the consumption of the too abundant growth of the algæ and of their spores, which otherwise soon fill and discolor the water. When aquaria are placed in insufficient light noxious fungi sometimes develop in them, doing injury to the other inmates. The secret of success in conducting an aquarium in a necessarily confined space is the scientific balancing of plant and animal life, and their proper relation to the volume of water. This once accomplished, the water need never be changed. There may be a small accumulation of sediment to be removed at long intervals, and sufficient water may be added to replace that lost by evaporation. The commonest mistake (to be avoided) is overcrowding. The space in which a few animals will thrive in delightful fashion may prove a "chamber of horrors" if too many animals are placed in it.

There is not the same danger in an oversupply of plants, and it is better to err in this direction than to scant the provision. However, if there are too many plants, the weaker growers will begin to die off. Then either the vegetation may be reduced or another animal may be added to secure the perfect balance.

It should be remembered that in nature the only light reaching a pool comes from overhead. The artificial pool should counterfeit the natural conditions as nearly as may be. While it adds much to the pleasure to be derived from an aquarium to have it at a window so that the light may come through the sides, the ends should be dark, and in no case should the direct rays of the sun be allowed to penetrate into it. A curtain or shield which may shut out all light as high as the top of the tank is an advantage. It can be lowered when a clear view is desired.

Plants give off oxygen only under the influence of light and none at all at night. For this reason aquarium plants able to give just the needed oxygen by day are not sufficient to leave enough oxygen dissolved in the water to last the animals all night, and it is not uncommon to see the fish at the top of the water in the morning "sucking air," even in carefully handled aquariums. This condition suggests its own remedy in the addition of one or more plants. In winter, for the same reason, the aquarium requires at least one-third more plants, the daylight being so short and the period of inaction of the oxygen producers so long.

A cubic foot of water gives room enough for not more than three fish three or four inches long. Besides these there may be two newts, which obtain a large amount of the oxygen they need by rising to the surface and filling their air sacs. Two or three tadpoles and as many water snails will be needed to act as scavengers. They clean up decayed vegetation, surplus food and the excreta of the higher animals. A crawfish and a small turtle may be added. In choosing the fish it is well to know that gold fish and all kinds of carp are not carnivorous, and so more easily fed, and there is less danger from uneaten food. The catfish and sunfish, however, are easy to keep, and specially prepared food may be bought for them. A variety of plants is desirable, but every aquarium should have several specimens of *Vallisneria spiralis*, noted as an abundant producer of oxygen. The marine aquarium is even more interesting than the fresh water type and falls under the same rules. Salt water fish are in general carnivorous, and while they are easily fed with bits of fish or oysters, any uneaten food rapidly decomposes and fouls the water.

All aquarium fish, but particularly those in fresh water, are subject to fungous parasites which attack their eyes, gills or any chance wound. They may frequently be cured by removal to a separate vessel in which is a large oversupply of plants, and where the light is strong on one side. Any ailing fish should receive this "oxygen cure." The large public aquaria which exist in many cities are a great aid to students and a constant source of entertainment to the people. In America the aquarium of the United States Fish Commission at Washington and New York city

aquarium are most important. The latter is under the control of the New York Zoological Society and was established in 1897 in old Fort Clinton (known for many years as Castle Garden) on the Battery. It is entirely free and has a daily average of 4,000 visitors; both marine and fresh-water animals are exhibited. In the floor are seven large pools, and the wall tanks number nearly 100. All the arrangements are the best which experience has yet suggested, and opportunities for special study of ichthyology and the natural history of marine animals are afforded. In Europe the aquarium at Brighton, England, and particularly that connected with the Marine Laboratory at Naples, are of the greatest interest and importance. Consult Smith, G. E., 'The Aquarium' (New York 1900); Smith, E., 'The Aquarium and How to Care for It' (New York 1902); Eggeling, O., and Ehrenberg, F., 'The Fresh Water Aquarium and Its Inhabitants' (New York 1908); Verrill, 'Invertebrates of Vineyard Sound,' in the annual reports of the United States Fish Commission for 1871-72; Wolf, H. T., 'Goldfish Breeds and other Aquarium Fishes' (Philadelphia 1908).

ERNEST INGERSOLL.

AQUARIUS (the water-bearer), in astronomy (1) the 11th of the 12 ancient zodiacal constellations, now generally called signs of the Zodiac. (2) A division of the ecliptic—that between 300° and 330° of longitude which, on account of the precession of the equinoxes, has gradually advanced from the constellation Aquarius, once within those limits. The sun enters this part of his course about the 21st of January, at which time there are generally copious rains in Italy, whence the name Aquarius—the water-bearer or water-man (Herschel's 'Astronomy,' §§ 380, 381). It is marked thus ♒.

AQUATIC ANIMALS, a term denoting animals living constantly in water, and also those which swim on its surface or plunge beneath it for food. While the great majority of crustaceans are aquatic, a few, such as the wood-louse and the land crab, are modified for life ashore. Among mollusks there is occurrence of both aquatic and terrestrial habit, while numerous forms illustrate the transition from the former to the latter. The ascidians are exclusively marine. Some fishes have a limited power of life out of the water, the double-breathing *Dipnoi* being in this connection especially instructive. Among many amphibians the transition from water to terra firma is seen in the individual life-history, when the fish-like gilled tadpole becomes the lunged gill-less frog; while in a few exceptional cases such as the black salamander of the Alps, the life is terrestrial from first to last, and even the young dispense with their preliminary swim as tadpoles, although a brief recapitulation of their aquatic life is still represented by a gilled stage within the body of the parent. The instance of the gilled axolotl becoming, in the absence of sufficient water, the gill-less amblystoma, forcibly illustrates the importance of the medium as a factor in evolution. Among reptiles there are numerous aquatic forms—chelonians, lizards, snakes and crocodiles—though the absence of any gill respiration

marks the progressive general adaptation to terrestrial life. While an emphatically terrestrial amphibian like the tree-frog seeks a watery hole for the rearing of the young gill-breathing tadpoles, the habit is reversed in such reptiles as the sea turtle, which, having returned to the more primitive aquatic home, yet revisits the land for egg-laying purposes. The cradle of the young in both cases indicates the ancestral habit of the parent. Among the emphatically aerial birds there are cases, like that of the penguin, where the structure has become adapted to an almost exclusively aquatic life. Among mammals the sea-cow, the seal and the whale are familiar illustrations of very different types which have returned to the primeval watery home and aquatic habit, with consequent change of structure.

It is important to note the general fact that, in the water, animals are subjected to influences somewhat different in detail from those which mold their congeners ashore. Even contact with a different medium, varying in composition, in currents, in pressure, in contained food and oxygen, and the like, obviously involves a great diversity in structure. Modes of motion, from the swimming-bell of a medusoid contracting and expanding in the tide, to that of the lowest vertebrates as illustrated in the pelagic tunicates, or from the paddling of worm and crustacean to that of fish and frog, duck and seal, are at once familiar adaptations to, and necessary results of, aquatic life. Similarly the smooth and frequently fish-like form, especially of actively locomotive water-animals, is a very noticeable adaptive result of the conditions of life. In the more thoroughly aquatic animals, which have remained in the primitive environment, and not merely returned to it, the blood is usually purified by being spread out on feathery gills which catch the oxygen dissolved in the water; while in terrestrial forms which have betaken themselves to an aquatic life, the ordinary direct "air-breathing" is still accomplished at the surface of the water, or in some isolated cases of insects and spiders, by means of the air entangled in their hairs, or even conveyed into their submerged homes. The aquatic respiration of some larval insects, the power that some crustaceans and fishes have of keeping up a respiration on land with a minimum of water about their gills and, above all, the cases of the double-breathing fishes or *Dipnoi*, and of amphibians already referred to, are especially instructive in regard to the problem of transition from one medium to the other. The genuinely aquatic animals are known to have a body temperature not much higher than that of the surrounding medium, and often survive even the freezing of the water; while in the higher warm-blooded vertebrates which have returned to an aquatic habit, various modifications, such as thick fur and plumage, water-proof varnish, formation of blubber, serve as protections against the cold.

AQUATIC PLANTS, a term applied to plants growing in or belonging to water. All vegetation was probably aquatic at first, certain plants becoming terrestrial by degrees. Numerous plants are, moreover, in the strict sense of the word aquatic, having never acquired or having lost all direct connection with

the soil. The algae are mainly aquatic, though many occur in damp situations on land, or on other organisms, while others remain for long periods quiescent in comparative dryness. Many algae are absolutely isolated in the water, while others are more or less intimately fixed to some solid substratum. Fungi are very seldom found in water, and lichens are also emphatically terrestrial. Some liverworts, again, occur floating in lakes, but the majority grow in very damp places and mark the transition to the generally terrestrial life of mosses and ferns. Some rhizocarps, such as *Salvinia*, are aquatic, with leaves rising to the surface, while others are land or marsh plants, like the higher horse-tails and club-mosses.

Among the flowering plants, or phanerogams, a return to aquatic life is exhibited by numerous though exceptional cases, while a very large number grow in moist situations and have a semi-aquatic habit. The simple monocotyledons, known as *Helobia*, or marsh lilies, are more or less strictly water-plants. The arrow-head (*Sagittaria*), and other *Alisma*-ceæ; the *Butomis* of the marshes; *Hydrocharis*, with floating kidney-shaped leaves; the water-soldier (*Stratiotes*), with narrow submerged leaves; and the Canadian pond-weed (*Anacharis*), which, though entirely flowerless in Europe, threatens to choke some canals and lakes, are familiar representatives. The little duckweed (*Lemna*), floating on the surface of stagnant pools, is one of the commonest aquatic monocotyledons; and the pond-weeds (*Potamo*) found in both fresh and salt water; the lattice plant (*Ouvirandra*), with its skeleton leaves; various estuarine and fresh-water naiadaceous plants—for example, *Zostera* and *Najas*, are also common instances, while those growing in marshy ground are far too numerous to mention. Among dicotyledons the white water-buttercup (*Ranunculus aquatilis*), with its slightly divided floating and much dissected submerged leaves; the yellow and white water-lilies (*Nymphaea*); the sacred lotus flower of the Ganges and Nile (*Nelumbium*); the gigantic *Victoria regia* of tropical South America; and the insectivorous bladderwort or *Utricularia*, are among the more familiar aquatic forms.

AQUATINTA, the name given to a method of engraving or etching upon copper or steel, invented by Leprince in 1760. The outline of the subject having been etched and bit, the plate is thoroughly cleansed and a thin layer of etching ground is again spread over it. When dry the parts of the subject to be aquatinted are carefully painted over with a mixture of olive oil, turpentine and lamp-black; this fluid, laid on with a hair pencil, quickly dissolves the parts of the ground it covers, which are then wiped off. The plate is next dusted all over with a finely-powdered white resin or mastic, and when equally distributed the superfluous resin is shaken off and the plate gently heated over a charcoal fire till the resin dissolves and adheres to the bare metal. In dissolving, the grains of the resin run into small granules, leaving minute and peculiarly shaped portions of the metal open to the action of the aquafortis, a weak solution of which is then poured over the plate. When corroded to the proper strength the subject has acquired what may be termed the first wash of

color. The plate is then cleaned, re-covered with ground, and treated as before, for the second tint. The process is repeated until all the deeper tones of shading are completed. These operations are sometimes reversed, the darkest shades being first bit in and the lighter ones added by degrees.

AQUEDUCTS. Aqueducts are artificial channels and structures connected therewith, for conveying water from one point to another. In a broad sense the word is generic, applying to all such channels or structures, but it is now generally restricted to elevated structures or tunnels designed to convey water by gravity for municipal water supply, though it is not infrequently used in connection with irrigation, water power and other hydraulic developments.

Water being a prime necessity for the support of both animal and vegetable life, it is not surprising that devices and means for supplying it in large quantities for domestic use in cities and for irrigation purposes attracted the early attention of mankind. Their construction and use dates far back of the historical period, and they were doubtless among the earliest and most important engineering undertakings of ancient times. The ruins of these early canals and water-supply works are found in Phœnicia, Babylonia, Assyria, Egypt, Persia and Palestine. Some of them were of such magnitude and designed and constructed with such boldness and skill as to excite the wonder and admiration of the modern world.

Ancient Aqueducts.—The Phœnicians were especially notable for the character, extent and boldness of their hydraulic works and, considering the means at their command, it is surprising what they accomplished.

At a later period Greece and Rome became famous for their water-supply projects and the building of great aqueducts. In Greece, early examples of tunnel constructions for water supply were quite common, some of them being of comparatively great length and, at places, more than 100 feet below the surface. One such tunnel at Samos was four-fifths of a mile long, the interior dimensions being 8x8 feet—the water conduit proper being an independent stone trough. Athens was supplied by several aqueducts, built from time to time as the city grew and a larger water supply became needed. One of these, begun some 600 years B.C., under the Emperor Hadrian, is still in use.

Rome was supplied with water by about a dozen aqueducts built at different periods, nine of which are commonly referred to by writers as the more important. The first, the Aqua Appia, was built about 300 years B.C. It was about 11 Roman miles long and almost wholly underground. Among the latest of the nine to be built were the Aqua Claudia and the Anio Novus, completed in the first half century of the Christian era.

Some of these aqueducts would be considered as stupendous undertakings in modern times. Thus the second one built, the Anio Vetus, was more than 40 miles long, mostly in tunnel. The Aqua Marcia, built about 140 B.C., was 60 miles long, about six miles of which were above ground, carried on masonry arches.

The Aqua Tepula, some 11 miles long, was carried for more than half the distance on a second series of arches, superimposed upon

those of the Aqua Marcia. The Aqua Augusta was 22 miles long, of which something over 1,000 feet were carried on masonry arches. The Anio Novus, 62 miles long, was carried across the Campagna for more than nine miles by a series of masonry arches, part of which still remains a conspicuous feature of Roman scenery. The water channel carried above the arches was from three to four feet wide and nine feet high, the inside being lined with Roman cement.

Not only at Rome, but in many places throughout the empire did the Romans build great aqueducts. Among the most noted of these may be mentioned those at Servigonia, Italy; Segovia and Tarragona, Spain; Metz in Alsace-Lorraine; Carthage, Constantinople, and Nimes in France. The latter, now known as the Pont du Gard, is a magnificent structure across the river Gardon, built in the 4th century A.D. It has three tiers (or stories) of masonry arches, one above the other. The lower tier has one arch (over the river), of 75 feet span and five others of 60 feet span. The third or uppermost tier is made up of a series of smaller arches, in all 873 feet long, the greatest height over the river being 188 feet. The masonry water conduit, covered by flat stones and lined with cement, is about four feet wide and four and one-half feet high. This grand structure, still standing in a good state of preservation, compares favorably in its engineering and architectural features with any similar work of modern times.

The aqueduct at Segovia has an arched masonry structure nearly half a mile long, having 109 arches which reach a height of slightly over 100 feet. The aqueduct at Tarragona, Spain, is 876 feet long and 83 feet high; that at Metz, built in the 4th century A.D., now partly in ruins, was carried across the river Moselle by a masonry structure 60 feet high; that at Antioch, Syria, of rather unusual design, is 700 feet long and 200 feet high; that at Moris is about 500 feet long and 80 feet high, built in three tiers of arches, the uppermost of which is of brick. The Roman aqueduct at Carthage was about 60 miles long, a part of it carried by an arched masonry structure about 50 feet high. Many other notable aqueducts were built in early Roman times in Europe, Asia Minor and Africa.

With the decline of the Roman empire the building of great aqueducts almost ceased during the Middle Ages, though there are a few notable examples. That at Spoleto, Italy (800-900 A.D.), seems to have been the first instance where the Gothic arch was introduced into aqueduct work. With a height of 300 feet and its 10 arches of 66 feet span, it was of especially light and graceful design. Among several mediæval aqueducts at Constantinople, that of Justinian ("Muallak Kemer") is remarkable for the beauty and excellence of its design and construction. It is 720 feet long and 108 feet high, having two tiers of pointed arches, the lower having spans of 55 feet and the upper ones of 40 feet.

The Greeks and Romans had little choice in the materials or methods of aqueduct building. Large pipes, of any material, were not available, though where pressure was to be resisted the earlier builders sometimes used as a

substitute large blocks of stone pierced with a hole of the required size for the conduit, the faces of the blocks being dressed to fit together and to make joints as nearly watertight as possible. The Romans built their water conduits, both in tunnels and over viaducts, of masonry lined internally with Roman cement. The driving of long tunnels, often at considerable depths below the surface, must have been a slow and costly process with the tools and methods then known. The difficulties of following correct alignments and gradients underground, with the knowledge and instruments then available, were very great, as evidenced by the tortuous course of many of these tunnels. For the elevated structures stone masonry was the only adequate construction then available. The extensive use of hydraulic concrete had not been developed, though occasionally employed, but Roman cement was generally used for water-proofing. Their masonry was generally built up of large blocks of granite or other hard and durable rock, with fairly well-dressed joints, laid dry; that is, without mortar. Their foundation work seems to have been of a high order, for foundation failures in these great structures were very rare. Brick was used to some extent, especially in their later constructions, and there are examples of brick-faced masonry backed by concrete.

Modern Aqueducts.—The resumption of aqueduct building on a large scale dates back less than 200 years, and most of the aqueducts of any considerable magnitude are of quite recent construction. A few of the more notable on the eastern continents may be mentioned.

Marseilles has a (now navigable) canal, constructed 1837-48, 97 miles long, connecting the river Durance with the Mediterranean, and the city's water supply is carried from this canal over the river Arc by the magnificent masonry aqueduct of Roquefavour.

The Thirlmere Aqueduct supplies Manchester with about 50,000,000 gallons of water per day, bringing it from lakes 96 miles from the city. Of this length, 14 miles are in tunnel, 37 miles are "cut and cover" work, with a water channel 7x7 feet, and 45 miles are of cast-iron pipes, the design being for five pipes of 40 inches internal diameter adjacent to each other, only three of which have yet been laid. (The term "cut and cover" work may be briefly defined as a conduit of masonry or other material, constructed in an excavated trench wide enough to receive it and of such depth that when completed and the excavated material filled back, the conduit will be entirely covered and thus become, in effect, a tunnel). The cost of this aqueduct in its present condition has been in the neighborhood of \$20,000,000.

Liverpool is supplied with water from the river Vyrnwy in northern Wales, delivered through an aqueduct 68 miles long, consisting, for the most part, of two lines of cast-iron pipe from 39 to 42 inches in diameter, provision being made for a third pipe when it becomes necessary. The fall from the Vyrnwy to Liverpool is so great (550 feet) that it was necessary to relieve the pressure in the pipes by interposing equalizing reservoirs at a number

AQUEDUCTS

1 Catskill Aqueduct — Typical cut-and-cover aqueduct construction, showing excavated trench, steel forms, partial and complete concrete aqueduct and ungraded earth cover. The waterway is 17 feet high and 17½ feet wide, and has an area of 241 square feet

2 Typical pressure tunnel construction, showing completed excavation and partial and completed concrete lining. The predominating diameter is 14 feet, 6 inches and the pressure tunnels always have a cover of at least 150 feet of sound rock

of different points. Birmingham is supplied with 75,000,000 gallons daily by an aqueduct 74 miles long.

One of the greatest and most important modern masonry aqueducts is that known as the Nadria Bridge which carries the great irrigation canals conveying the water of the lower Ganges canal over the Kala Naddi. Its length is very nearly one-quarter of a mile and the width between vertical ends of the arches is 150 feet. It is constructed with 15 arches of 60 feet span. The foundations were the most troublesome feature of its construction, as they consisted of 268 circular, concrete-filled, brick cylinders carried to a depth of about 50 feet below the bed of the river. The aqueduct was opened in 1889 and is said to have a capacity of 4,100 cubic feet per second.

The evidence of early aqueducts on the western continent is meager, and the remains of them so far discovered are few. It seems to be well established that the Indians of the western part of the United States constructed canals of considerable magnitude to supply water for irrigation. Recent exploration in Peru, in the heart of the Andes, has disclosed canals and aqueducts of great extent, built by the Incas or their predecessors, some of which are wonderful constructions considering their antiquity and the difficulties to be overcome. Consult Cook, O. F., in *National Geographic Magazine* (May 1916).

The Spanish during their occupation of Mexico built aqueducts of considerable magnitude to supply the City of Mexico with water. The remains of at least one of these still exist in and near the city, consisting of an arched masonry structure quite like its Roman predecessors. It terminated in the city with a masonry fountain structure of no little artistic merit.

There are three aqueducts now supplying water to New York city. The first, or old Croton Aqueduct, was begun in 1837 and completed in 1843. It is mainly a masonry conduit, following the surface topography wherever practicable, but there are two stretches of cast-iron pipe. It takes water from the Croton Reservoir, 41 miles north of the city. The Harlem River is crossed at a point about 11 miles north of the Battery by a masonry viaduct, known as High Bridge, 1,450 feet long, the greatest height above the foundations being about 150 feet. There are eight semi-circular arches of 80 feet span and seven of 50 feet span. Both in design and construction it is a beautiful and substantial structure, a fitting monument to its builders. The aqueduct has a capacity of 80,000,000 gallons per day and cost between 11 and 12 millions of dollars.

The new Croton Aqueduct was begun in 1887 and water was turned into it 15 July 1890. The water is taken from the same source—the Croton Reservoir (or lake)—as the Old Croton Aqueduct, the two inlets being near each other. The new aqueduct follows the same general course, but is much more direct than the old and crosses the Harlem River near the masonry structure of the earlier Croton aqueduct. While the aqueduct proper ends at 135th street, the water is carried from there to the Central Park Reservoir through eight lines of 48-inch cast-iron pipe. The length is 30.87

miles, of which all but slightly over one mile is in tunnel. The capacity of the aqueduct is about 300,000,000 gallons per 24 hours.

The tunnels are lined with masonry and concrete, the section for 23.7 miles being of horseshoe form, 13 feet 7 inches wide, and about the same in height. The remainder is of circular section, varying in diameter from 14 feet 3 inches to 10 feet 6 inches under the Harlem River. The difference in elevation between the crest of the new Croton dam and the surface of the water in the Central Park Reservoir is 33.65 feet, and as the total distance is 33¼ miles, the average hydraulic gradient is about 3.3 inches per thousand feet.

The most interesting construction feature of this aqueduct is the crossing of the Harlem River. At the eastern approach to this crossing, where the tunnel is about 150 feet below the surface, it drops on a 15 per cent descending grade for about 850 feet, followed by a 2 per cent descending grade for 200 feet, where it enters a vertical shaft 12¼ feet in diameter and 168 feet deep. From the bottom of this shaft the tunnel crosses under the river upon a 1 per cent descending grade with a diameter of 10½ feet for 1,270 feet, and rises in a vertical shaft 321 feet deep, from the top of which it descends on a slight falling grade to 135th street. The bottom of the tunnel at the river crossing is 300 feet below mean tide. This aqueduct was, at the time, by far the greatest engineering feat of its kind in America, if not in the world. Its cost was very close to \$30,000,000.

The great Catskill Aqueduct, the completion of which was celebrated with appropriate ceremonies on 12-15 Oct. 1917, augments the water supply of Greater New York by from 500 to 600 million gallons per day. Its purpose is to carry to the city the water from a new source of supply in the Catskill Mountains. The water entering it from the colossal Ashokan Reservoir, about 12 miles west of Kingston, N. Y., flows by gravity through the new Hill View Reservoir just north of the city line, into the distribution system of the city. Its length to the northern boundary of the city is 92 miles, of which 55 miles is cut and cover work, 31 miles is in tunnel and 6 miles is steel pressure pipe. Seventeen miles of the tunneling is below the hydraulic grade and, therefore, subjected to greater than normal pressure and is called "Pressure Tunnel." These pressure tunnels, of circular section, generally 14½ feet inside diameter, are used to carry the aqueduct under streams or depressed areas along the route. As the route crosses the drainage system of the region, several of these pressure tunnels are required, though steel pipes are used for the purpose where the conditions made them necessary or more economical. The pressure tunnels are placed at a sufficient depth below the surface of the rock formation, usually about 150 feet, to insure sound rock and to resist the internal water pressure. The great pressure tunnel under the Hudson River at Storm King, about four miles above West Point, is by far the boldest and most remarkable undertaking of the kind in the world. In order to secure sound rock and to withstand pressure and leakage, it was found necessary to drop the aqueduct tunnel to a position 1,100

feet below the surface of the river and about 1,500 feet below the hydraulic grade. Vertical shafts from the approach tunnels were sunk on each side of the river, 3,022 feet apart, to the necessary depth, and the horizontal river tunnel driven between them.

All the tunnels are lined with concrete; those upon the hydraulic grade, of horseshoe section, have a completed width of 14 feet 3 inches and a total height, from invert to the soffit of the arch, of 17 feet. The pressure tunnels are of circular section, varying in diameter from 16

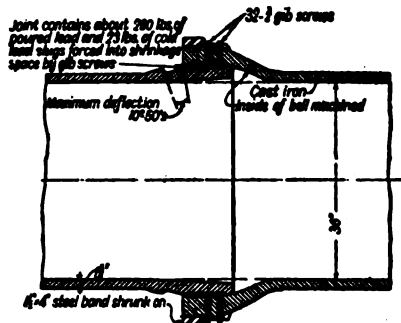

The aqueduct proper strictly may be considered as extending from the Ashokan Reservoir to the Hill View Reservoir, though in fact it extends into and under the city. The distribution of such an enormous volume of water to the different boroughs of the greater city presented a troublesome problem. It was solved by continuing the great tunnel southward through the borough of Manhattan and under the East River into Brooklyn. From the termini of this tunnel the water is carried eastward into the borough of Queens and south-

feet 7 inches to 14 feet—the latter being at the Hudson River crossing. Where steel pressure pipes are used they are lined inside and sheathed outside with concrete. The cut and cover work consists of a strongly designed concrete conduit with arched invert, sides and crown, constructed in place and surrounded and covered to a depth of not less than 14 feet with earth.

The difference in elevation between the flow-line of the water as it emerges from the Ashokan Reservoir and the water surface of the Hill View Reservoir is 216 feet, giving an average hydraulic gradient of about 2 1/2 feet per mile.

ward to the borough of Richmond (Staten Island) through pipes, the last named branch involving the crossing of New York Bay at "The Narrows" by a pipe laid in a trench dredged into the bottom of the bay. The length of the city tunnel is 18 miles. Its diameter, 15 feet at the northern end, decreases to 11 feet at its ends in Brooklyn as the quantity of water to be delivered diminishes. Its depth below the surface varies from 200 to 750 feet. Frequent shafts facilitated construction and provide for connection with the distributing pipe system under the streets. The cost of the aqueduct proper from the Ashokan Reservoir to the city

line has been \$61,000,000, and the tunnel from the city line to Brooklyn has cost \$22,500,000. The total cost of the project was \$140,000,000.

Another of the greatest aqueduct projects in the world is that recently completed to supply the city of Los Angeles, Cal., with water. The source of the supply is the Owens River in the heart of the Sierra Madre Mountains. The total length of this aqueduct, including the diverting canal and reservoirs, is about 233 miles. It is designed to deliver 260,000,000 gallons per day. As this quantity is greater than will probably be needed for the domestic use of the city for many years, it is intended to utilize the surplus for irrigation purposes, and the great fall in the course of the aqueduct is intended to be utilized for water power purposes. The water is taken from the Owens River at an elevation of 3,815 feet above the sea, and carried thence by an open canal a distance of about 60 miles to the Haiwee Reservoir, where the aqueduct proper begins, the water surface in this reservoir being 3,760 feet above sea-level. The length of the aqueduct from this reservoir to its end in the San Fernando Valley is about 171 miles. The leading types of construction and the aggregate length of each type in miles is: Unlined canal, 24; lined canal, 37; covered conduit, 98; tunnel, 43, and steel syphon, 12.

The covered concrete canals are approximately of rectangular section, covered by flat slabs of reinforced concrete, with an interior cross-sectional area of 94 square feet. The tunnels, lined with concrete, have curved inverts, straight (inclined) sides and arched roof. Steel pipes are chiefly used to carry the aqueduct under streams and gorges and down the steep declivities below the hydraulic gradient. Such declivities or steep descents occur at three principal localities, creating great pressure, which is to be utilized for generating water powers. This will result in no loss of water, since it will be returned to the aqueduct at a lower level. The cost of the aqueduct and its accessories has been \$24,600,000.

The city of Winnipeg, Canada, has built a gravity aqueduct for a new water supply. It receives water from Indian Bay on Shoal Lake and is approximately 100 miles long. It involved comparatively simple construction, 85 miles being of covered concrete conduit, 10 miles of five feet steel pipe, less than one-fifth of a mile of tunnel, and slightly over two miles of 48-inch cast-iron pipe. It is designed to deliver over 100,000,000 gallons per day.

The city of Denver, Colo., has been supplied with water by an aqueduct about 20 miles long, consisting of two lines of wood-stave pipe, one of 30 inches and one of 24 inches diameter—the two delivering about 30,000,000 gallons per day.

Many other American cities have aqueducts of greater or less extent and importance connected with their water supply, and a large number of water power developments and irrigation projects utilize like structures.

Modern Construction.—High, massive stone masonry aqueducts are now seldom constructed, and where such elevated structures are unavoidable, they are usually built of hydraulic concrete. The modern engineer finds it generally better and more economical to

carry his conduits under, rather than over, streams and depressions.

The introduction of cast-iron and steel pipes of large size, and their comparative cheapness, as well as the wonderful development in the science and art of tunneling, have practically revolutionized aqueduct building since the days of the Romans.

Cast-iron pipes of sufficient strength to withstand the pressures ordinarily required are now available up to a diameter of at least 48 inches and riveted steel pipes of double that diameter and capable of carrying even greater pressures are not uncommon, particularly when encased in concrete.

The general substitution of tunnels for aerial structures is largely due to the very

Kensico Dam during construction, showing the division of the dam by the expansion-joints. The two cableways spanning the valley aided in handling materials and equipment. The system of derricks on travelers and the single derricks, for placing stones and concrete, are also shown, as well as the railroad tracks for delivering materials to the derricks.

great advancement in the speed and economy of driving tunnels. The perfecting of power rock drills, the introduction of modern high explosives, and improved appliances and methods for handling the excavated material, have greatly simplified and expedited rock tunneling. The invention of the "shield" method, the application of compressed air to resist the ingress of water and mud, supplemented by powerful pumps, together with the use of cast-iron or concrete tunnel linings, has made tunneling in soft or sub-aqueous material comparatively safe and rapid.

The ability, skill and practical ingenuity of the modern civil engineer and the perfection of instruments of precision for determining and maintaining underground alignments and gra-

dients have also been an important factor in overcoming the difficulties and reducing the cost of modern tunneling.

The construction of pipes and flumes of wood has marked another important advance in aqueduct building in this country. Comparatively large pipes built of wooden staves, accurately jointed with each other and bound by steel hoops at suitable distances apart, are in common use in the western States; and wooden flumes or canals supported upon wooden trestles, often of considerable height, may take the place of stone, concrete or steel viaducts. The durability of such wooden aqueducts has not yet been satisfactorily determined, but as they are constantly filled with water and often buried in the earth, their useful life extends over considerable periods, as experience has already demonstrated, while their low first cost compared with more permanent constructions makes them very attractive where available capital is an important and often controlling consideration. Many miles of such wood-stave pipes are now in successful use.

S. WHINERY,

Consulting Civil Engineer; Author 'Municipal Public Works,' etc.

AQUEOUS HUMOR, the designation of the transparent lymphatic fluid in the anterior chamber of the eye, or that portion of the interior of the eye in front of the crystalline lens. In its chemical composition aqueous humor closely resembles the cerebro-spinal fluid. It is a clear alkaline liquid, specific gravity, 1003-1009, and contains about 1 per cent of solids, one-tenth of which are proteids. These are fibrinogen, serum albumin and serum globulin. Traces of urea and sarcolactic acid are present. The secretion of aqueous humor is rapid. It is supposed that this fluid is derived from the posterior surface of the iris and the ciliary body. See EYE.

AQUEOUS ROCKS, the title of a rock class including all rocks that have been deposited under water. It is the most important class of the sedimentary series, and comprises such common and widely distributed strata as

sandstones, conglomerates, shales and limestones, and many valuable products, as gypsum, salt and coal. According to their manner of origin the aqueous rocks may be subdivided into (1) mechanical deposits, (2) chemical precipitates, (3) organic accumulations. The mechanical deposits have been derived from the disintegration of pre-existing strata and the transportation of the materials by rivers, tides and currents. They are being formed at the present time beneath the ocean and in rivers and lakes. Sandstone, conglomerate, clay and shale are the most important members of this subdivision. The chemical precipitates owe their origin to the deposition of materials from solution either as a result of evaporation or by the action of precipitating agencies. Oölitic limestone, gypsum, rock salt, siliceous sinter and many iron ores are included in this subdivision. The organic accumulations have been formed from materials once belonging to living organisms. Limestones and chalk represent the comminuted and compacted remains of shells, corals, crinoids, foraminifera, etc., while certain organisms secrete silica and their casts have accumulated in the form of diatomaceous earth and chert. Peat and the different varieties of coal are deposits of vegetable matter, more or less completely transformed into carbon under the influence of pressure and sometimes also of heat.

AQUIFER, any rock mass that is sufficiently porous to be a good water carrier. It is a term much used in discussions of water supply. Due to the large size of the individual pores and the high percentage of porosity, sandstones constitute the best aquifers. Quartzites, shales and most igneous rocks have either very small pores or a very low percentage of pore space or both, and rarely constitute good aquifers. See WELLS; WATER SUPPLY; ARTESIAN WELLS.

AQUIFOLIACEÆ, ă'quí-fō-li-ă'cē-ē, the designation of a family of plants, composed of shrubs or trees with alternate or opposite persistent leaves, of thick texture and smooth surface, with a toothed margin, the teeth being sometimes spinous. The flowers are solitary, or variously grouped in the axils of the leaves. The fruit is always fleshy, containing from two to six indehiscent woody or fibrous nucules or minute nuts enclosing single seeds. The American holly, *Ilex opaca*, has foliage less glossy, and berries less red than its European relative, *Ilex aquifolium*. Both are important commercially, being mostly used for decorative purposes. The leaves of a species of *Ilex* afford the famous Paraguay tea. But one member of this family is found in Europe, the common holly (*I. aquifolium*). The other members are found sparingly scattered over different parts of the world, especially the West Indies, South America and the Cape of Good Hope. The Latin *Ilex* is the holm-oak (*Quercus ilex*).

AQUILA, ă'kwē-lă, one of the early Christians associated with Saint Paul, was of Jewish origin and a native of Pontus. In the year 52 he, with other Jews, was expelled from Rome by an edict of Claudius. He and his wife, Priscilla, went to Corinth, where they first became acquainted with Saint Paul. The apos-

the shared their lodgings, at the same time assisting them at their trade of weaving tent cloth. He was indebted to them for many acts of kindness and none of the Christians who aided him ever received such warm praise from his pen. Consult Epistle to the Romans xvi, 3. There are many references to Aquila in the New Testament: Acts xviii, 1-3, and 26-28; 1 Corinthians xvi, 19; 2 Timothy iv, 19. Nothing definite is known about the death of Aquila. Though he led a poverty-stricken life in Corinth and Ephesus, better days came to him; for in the year 58 we again find him in Rome, where he and Priscilla kept a house on the Aventine, large enough to be used as a sanctuary by the Christians of Rome, to whom it was always open. Consult Fouard's 'Saint Paul and His Missions' (Chap. xii) and 'Saint Peter and the First Years of Christianity' (Chap. xviii).

AQUILA, Johann Kaspar, a celebrated German Protestant theologian: b. in Augsburg in 1488: d. 12 Nov. 1560. After studying several years in Italy he was appointed pastor of Jenga, a village near Augsburg. Here he embraced the doctrines of Luther; but his boldness and zeal in the cause of reformed faith led the bishop of Augsburg to order his arrest. Aquila passed the winter of 1519-20 in the prison of Dillingen, and from Dillingen he went to Wittenberg, where he became personally acquainted with Luther. He was subsequently appointed professor of Hebrew at Wittenberg, where he rendered valuable assistance to his colleague, Luther, in his translation of the Old Testament. In 1527 he became pastor and the following year Protestant bishop at Saalfeld; but his vehement opposition to the *Interim* of Charles V in 1548 obliged him to flee. He was appointed to the deanery of Schmalkalden in 1550, and restored two years after to his office at Saalfeld, where, without further molestation, he continued to discharge his duties till his death.

AQUILA, Ponticus, a native of Pontus, who flourished about 130 A.D., and is remembered for his exceedingly close and accurate translation of the Hebrew Scriptures into Greek. Consult Burkitt, 'Fragments of the Book of Kings, According to the Translation of Aquila' (1897).

AQUILEJA, a'kwē-lā'ja, AQUILEIA, or **AGLÄR**, Austria, town 22 miles northwest of Trieste. Before the fall of the Roman empire it was the great emporium of trade between the north and south of Europe, and was often called the "Second Rome." Cæsar Augustus frequently resided here, and several councils of the Church, the first in 381, were held at Aquileja. In the 6th century, the title of patriarch was taken by the bishops of Aquileja, who assumed second rank to the Pope. The town was destroyed by Attila in 452, when the inhabitants numbered 100,000. It is now a small fishing village containing a number of interesting remains of its ancient splendor, and often rewarding the researchers of the antiquary with relics of value. Pop. about 2,000.

AQUILIDÆ, the family of raptorial birds that includes the typical eagles (q.v.). By some it is now classed as a subfamily (*Aquilina*) of the *Falconidæ*.

AQUINAS, Thomas, a celebrated scholastic theologian, related by birth to several of the royal families of Europe: b. near Aquino in 1227; d. Fossanora, 7 March 1274. He studied at the Benedictine monastery of Monte Casino and the University of Naples. About the age of 17 he entered a convent of Dominicans, much against the wishes of his family. Partly to evade the endeavors of his family to recover him, and partly on account of the extraordinary aptitude he displayed for theological studies, his superiors sent him to Cologne to hear the lectures of the famous Albertus Magnus. He was so remarkable for taciturnity, and the assiduity and apparent stolidity with which he pursued his studies, that he was known among his fellow-students as "the great dumb ox of Sicily." His teacher, however, discerned his abilities and is said to have foretold that "this ox would one day fill the world with his bellowings." In 1245 he visited Paris in company with Albertus. Becoming involved in the dispute between the University and the Begging Friars as to the liberty of teaching, he advocated the rights claimed by the latter with great energy, and, being called upon to defend his side in this controversy before the Pope, did so with complete success. In 1248 he returned with Albertus to Cologne, but revisited Paris in 1257, when he received the degree of doctor from the Sorbonne and began to lecture on theology, rapidly acquiring the highest reputation. The remainder of the life of Aquinas was one of the most varied activity. He was almost constantly engaged in lecturing and preaching, and was often sent on distant journeys in the service of his order. In 1263 he is found at the Chapter of the Dominicans in London. In 1268 he was in Italy, lecturing in Rome, Bologna and elsewhere. In 1271 he was again in Paris lecturing to the students; in 1272 professor at Naples. In 1263 he had been offered the archbishopric of Naples by Clement IV, but refused the offer. A general council being summoned at Lyons in 1274 for the purpose of uniting the Greek and Latin Churches, Aquinas was called thither to present the council with a book which he had written on the subject, but died on the way. The honors paid to his memory were prodigious; beside the title of Angelic Doctor, bestowed on him after the fashion of the times, he was called the Angel of the Schools, the Eagle of Divines and the Fifth Doctor of the Church; in 1286 he was made by the Dominicans the doctor of their order (*doctor ordinis*); at the request of the Dominicans he was, in 1323, canonized by John XXII, his tomb supplying the necessary testimony of miracles; and 1567 was declared by Pius V the "Fifth Doctor of the Church." The numerous works of Aquinas are all written in Latin. The most important of them is the 'Summa Theologiae,' which, although only professing to treat of theology, is in reality designed to form a complete and systematic summary of the knowledge of the time. All the minor works of Aquinas may be looked upon as preparatory to this great one. These are 'A Commentary on the Four Books of Sentences of Peter Lombard'; 'Quodlibeta Disputata et Quæstiones Disputatæ'; the 'Catena Aurea,' or Golden Chain, in form of a commentary on the four Gospels, but in substance an exhaustive exposition of the cardinal doctrines in theology of

the greatest fathers of the Church; and commentaries upon Isaiah and Jeremiah, the Epistles of Saint John the Divine and the Psalms, as well as upon Aristotle. His works were published in Rome in 1570-71 in 17 volumes, but his 'Summa Theologiæ' has passed separately through various editions. The resemblance in thinking and writing between Augustine and Aquinas is so marked, that it has been fancifully said that the soul of the one had passed into the body of the other. The disciples of Aquinas are called after him Thomists. Consult Werner, 'Der Heilige Thomas' (1858); Gibelli, 'Vita de S. Tomaso' (1862); Vaughan, 'St. Thomas of Aquin, his Life and Labours' (1872); Cavanagh (1890).

AQUINAS, Saint Thomas, Philosophy of.

The philosophy of Saint Thomas Aquinas is the culmination of the philosophic efforts of the Christian schools of the Middle Ages. These schools, dating from their foundation in the reign of Charlemagne, set up a tradition of Aristotelian commentary and of independent speculative activity which, until the middle of the 12th century, were almost entirely circumscribed by the limits of dialectic, or logic. After the middle of the 12th century the physical and metaphysical works of Aristotle (q.v.) became known in the Christian schools of Europe, and with them were introduced Arabian commentaries which interpreted the text of Aristotle in a sense contrary to Christian theism. At the beginning of the 13th century a number of Christian teachers, especially Alexander of Hales and later, Albert the Great, undertook the task of expounding the theistic and spiritualistic philosophy of the Christian schools on the basis of Aristotle's physical and metaphysical doctrines, rejecting from the current Aristotelian teaching whatever they considered to be due to the influence of the Arabian commentators. These teachers prepared the way for Saint Thomas Aquinas (1225-74), whose chief merit is, not that he created a new method or contributed a new system of thought, but that he gave to the work of his predecessors and contemporaries a more compact synthesis and expounded this synthetic system with a simplicity and lucidity rarely to be met with in systems which like his carry complexity to a high degree of organic unity. Saint Thomas' most important works are the 'Summa contra Gentiles' and the 'Summa Theologiæ.' The former, begun at Paris about the year 1257 and completed some time between the years 1261 and 1264, was undertaken at the request of Saint Raymond of Pennafort for the purpose of defending the truths of Christianity against the Arabian pantheists and their followers. It is, therefore, apologetic rather than constructive in method and contents. The 'Summa Theologiæ' was commenced at Bologna in 1271, and was never completed. Unlike the 'Summa contra Gentiles,' it is constructive in aim and method. It is Saint Thomas' greatest work, his last and most important contribution to Christian theology and philosophy; for, although the work is entitled 'Summa Theologiæ' and is, in fact, a compendious treatise on all the questions of Catholic theology, it is also a summary of philosophy. It begins with the question of the existence of God, treats of the attributes of God, traces the origin of things from God

and the return of man to God through Christ. It deals, therefore, with the creation and government of the universe, with the origin and nature of man, with human destiny, with virtues, vices and laws—with all the great problems of speculative and practical philosophy. It contains the maturer views of its author, so that whenever discrepancies occur between the doctrines of the *Summa* and the views expressed in his earlier works, the *Summa* is to be taken as the key to the mind of the master.

The method used by Saint Thomas in all his constructive works is a developed and perfected form of the dialectic method which we find anticipated in a short treatise by Gerbert (Pope Sylvester II, died 1003) and of which the first definite example is the *Sic et Non* of Abélard (d. 1142). In this treatise Abélard presents in contrast the affirmative (*Sic*) and the negative (*Non*) opinions of patristic writers in reference to each successive problem of Catholic theology, without, however, furnishing principles by which the discrepancies, real or apparent, are explained. This was, as far as we know, first done by Alexander of Hales (d. 1245), whose method was to set forth the arguments against his thesis, then the arguments for the thesis and finally to answer the objections. Saint Thomas practically adopted the method as he found it in use in the schools of his day, giving to each article discussed the recognized tripartite division *videtur quod non* (introducing objections), *sed contra* (introducing the argument for his thesis), and *respondetur ad primum*, etc. (answers to objections). Underlying this somewhat formal method was the principle which the schoolmen derived from Aristotle, that it is only by the dialectic discussion of the affirmative and negative sides of a question the truth is to be discovered and defined. In other words the faculty of the mind on which philosophy chiefly relies is not intuition but ratiocination.

In describing the content of Saint Thomas' philosophy one must advert, in the first place, to the Aristotelian mold in which all his philosophical doctrines are cast. For him Aristotle is the philosopher. On the questions of method and doctrine which divide the Platonists from the Aristotelians Saint Thomas unhesitatingly and invariably takes the side of Aristotle. In fact, he is the Christian Aristotelian in the sense in which Saint Augustine is the Christian Platonist. It would, however, be fatal to a proper estimation of his philosophy to overlook the elements in it which cannot be traced to Aristotle. He was no slavish imitator; he maintained as a principle of method that the argument from authority is (in philosophy) the weakest of all arguments. It was only in the age of decay of the philosophy of the schools, when the letter rather than the spirit ruled the tradition of Thomistic teaching, his name and the name of Aristotle were invoked as authority to put an end to all discussion.

To say that Saint Thomas was an Aristotelian means little when we remember that in his day there were mere followers of Averroes, materialists and pantheists, who might with equal justice claim to be representatives of the Stagyrte. Saint Thomas was an Aristotelian who brought to the elucidation of his Master all the tradition of Christian speculation from Justin, the first of the Apologists, down to his

own immediate predecessors and contemporaries. The thought which inspired the Christian philosophers was that above the order of natural truth, that is, of truth which can be attained and comprehended by the human mind unaided, there is another order of truth, the supernatural, which human reason cannot of itself attain, but which is known to us on the authority of divine revelation. Natural truth belongs to reason, and supernatural truth to faith. Christian philosophy from the beginning took its stand on the principle that these two orders of truth must, in some way, be capable of harmonious adjustment. Rationalism exaggerated the power of reason, mysticism tended to slight reason and to emphasize and unduly extend the scope of faith. Throughout the early Middle Ages these two tendencies were at war with each other in the Christian schools. It is one of Saint Thomas' chief titles to distinction that he united in his system what is true in rationalism with what is true in mysticism. The rationalism of Abélard obliterated all distinction between supernatural and natural truths when it treated mysteries of faith as if they were conclusions of theology and used the Scriptures as if they were sources of argument in philosophy. In an opposite sense, the mysticism of Erigena removed all distinction between the two orders of truth, when it maintained that even truths of the natural order are known to us by a special *theophania*, or divine manifestation. Saint Thomas taught that the two orders of truth are distinct; that our knowledge of supernatural truth rests on the authority of revelation, while our knowledge of natural truth rests on the evidence of reason. He maintained, at the same time, that they are consonant with each other, that since God is the author of all truth there can be no contradiction between what revelation proposes for our belief and what reason proclaims to be evident. This thought, namely, that revelation is reasonable and reason divine, crystallized the fundamental concepts of all the preceding systems of Christian speculation, reconciled mysticism with rationalism and gave permanent form to the *credo ut intelligam* and the *intelligo ut credam* of scholasticism. The reconciliation of reason with revelation is of interest not merely to the Christian Apologist but to the philosopher as well. For it is inspired by the desire to establish between the supernatural and the natural that relation of continuity which Greek philosophy at the highest point of its development established between the spiritual and the material.

To the controversy concerning the mode or manner of the existence of universals, which, during the 11th and 12th centuries, had been so prominently before the minds of philosophic thinkers, Saint Thomas contributed his doctrine of moderate Realism. The Nominalists contended that universals are mere names; the exaggerated Realists, influenced for the most part by Plato, maintained that universals are things really existing outside the mind as completely developed universal forms. The doctrine of moderate Realism (q.v.) is that, while universals are not mere names but real things, they exist outside the mind not as full-blown universals but only as potentially universal essences which receive their formal aspect of universality from the mind in the act by which

it compares and discusses individual objects and abstracts therefrom the formally universal concept. Saint Thomas found this doctrine established in the schools of his time. He adopted it and gave to it, as to so many other tenets of the schools, its final and most clear-cut form.

One of Saint Thomas' most noteworthy contributions to philosophy was his elucidation in the Christian and theistic sense of some of the more obscure points of Aristotelian teaching. Having before him a translation made directly from the Greek text—a translation which is, indeed, far from correct, yet which in spite of many ludicrous verbal blunders is immeasurably superior to the translations made through the medium of Syriac and Arabic—he sought to free from the accretion of Neo-Platonic and Arabian commentary the original doctrine of Aristotle on the question of the nature of the Active Intellect. Rejecting what may be called the transcendentalist view, which held the Active Intellect to be something more than human, something akin to God and in some way common to all men, he defended the anthropological view, which held that the Active Intellect is a part of the individual soul, and, therefore, not common to all, but proper to each. In this way, he strengthened the defense of the immortality of the individual soul.

Saint Thomas founded a school within the schools. To the Franciscan teachers, such as Alexander of Hales, Saint Bonaventure and Roger Bacon, certain doctrines of Saint Augustine recommended themselves, to the detriment of the strict Aristotelianism which they professed. These Franciscan teachers were opposed by the Dominicans, who, like Albert the Great and Saint Thomas, recognized in the Augustinian doctrines in question an element of Platonism which was inconsistent with thorough Aristotelianism. The struggle between Augustinianism (q.v.) and Aristotelianism (q.v.) was waged in the schools, especially at Paris, during the first decades of the 13th century. The doctrines under discussion were mostly psychological: for instance, the Aristotelians maintained that there is but one substantial form in man, the soul, while the Augustinians maintained that there are several substantial forms; the latter contended that there is no real distinction between the soul and its faculties, while the former defended the real distinction; the Aristotelians maintained that there are subsistent forms, that is to say, purely spiritual created substances, without any matter, while the Augustinians taught that all creatures, even the angels, are composed of matter and form. On all these questions Saint Thomas took the part of the Aristotelians and thus became the leader in the Dominican, or, as it is sometimes called, the Thomistic school in the stricter sense of the word.

The controversies between the Dominican and the Franciscan schools brought out an important general trait of Saint Thomas' philosophy. Duns Scotus (1274–1308), the ablest of the Franciscan opponents of Saint Thomas, adopting the principle of voluntarism, brought to the surface the intellectualism which pervades Saint Thomas' speculative system. Saint Thomas pushed to its utmost consequences the *intelligo ut credam* of the earlier scholastics: he made intellect superior to will and sought in every thing to find an intellectual basis for be-

lief. Scotus maintained that on many questions of the highest importance reason fails to give a satisfactory explanation or proof and that we must fall back on will.

To say, however, that Saint Thomas was an Aristotelian in the Christian, as opposed to the Averroistic, sense; that he gave final form to the idea which inspired scholastic, and indeed all Christian, speculation; that he was a moderate Realist; that he held to the strict systematic Aristotelianism and excluded certain Augustinian and Platonic elements; that he was an intellectualist, is to give but a faint idea of his claims to pre-eminence as a representative of scholastic philosophy. Of him, as of all the great speculative thinkers, it may be said that the spirit of his work is more potent than the letter. To the modern mind, especially, he appeals in virtue of the spirit in which he undertook the work of adjusting his beliefs as a Christian to the scientific and philosophic thought of his age. To this task he addressed himself with an instinctive sense of completeness which impelled him to leave nothing incomplete or imperfect except so far as everything human is incomplete and imperfect. He brought to his task a mind appreciative of the value of truth wheresoever truth is found, whether in pagan, Jew or Gentile, and a belief—stronger in him than in any other Christian writer since Saint Augustine—that all truths and all contributions to knowledge, from whatsoever source they are derived, must be capable of harmonious adjustment.

Mittelalters' (Berlin 1896), p. 1601.

WILLIAM TURNER,

Professor of Philosophy, Catholic University.

ARABESQUE, ă'r-ă-bĕsk', a term applied to a particular species of decoration employed in Arabian and Moorish architecture. The followers of Mohammed, being prohibited by the Koran from representing the figures of men and beasts, endeavored to evade this law by inventing a series of monsters, griffins, dragons, strange birds and chimeras; affixing the head, wings and talons of birds to the bodies of lions, horses and other quadrupeds; and making the upper parts of children, men and beasts spring from among clusters of foliage and the like. In the Vatican there are paintings, executed by Giovanni da Udine from the drawings of Raphael, in this style, which are deservedly much admired.

ARABGIR, ă'răb-gĕr', or **ARABKIR**, town in Asiatic Turkey, 147 miles southwest of Erzerum. It owes its enlargement and prosperity to the Armenians, who form about one-fourth of the population, and it is especially

noted for its manufacture of silk and cotton goods. Pop. about 28,000.

ARABI, a-ră'be, **Ahmed El** (usually known as Arabi Pasha), an Egyptian national leader: b. in Lower Egypt about 1837; d. Cairo, 21 Sept. 1911. He was the son of a common peasant, and, entering the army, rose to the rank of colonel and became the head of a party desiring to replace Turkish officers by Egyptians. On 9 Sept. 1881 he led the troops to the Khedive's palace and demanded the dismissal of the ministry, the convocation of a parliament and the increase of the army. The first two demands were granted, the third was referred to Constantinople; but the military party, which was mistakenly regarded by foreign observers as a Nationalist and Home Rule party, gradually became dominant, and Arabi was made War Minister. Flushed with success, he acted as if head of the state and rashly undertook to overthrow the Anglo-French control of the finances. In view of the situation a conference was held at Constantinople, and British and French fleets were sent to Alexandria; a massacre of Christians took place in that city (11 June 1882) and the British fleet, in the belief that the forts were preparing to fire, bombarded them, the French fleet withdrawing. Alexandria was burnt by the Egyptian troops, and the British expedition to Egypt followed. Arabi gave himself up and was tried for treason; acting on advice he pleaded guilty, an understanding having previously been arrived at with the Marquis of Dufferin, then Special British Commissioner, that the sentence would be commuted to banishment for life. Khedive Tewfik's desire was to put Arabi out of the way for good, and was only induced with great difficulty to consent to the arrangement. Arabi was sent to Ceylon, where he lived as a political prisoner on a small pension, but in May 1901 the Khedive Abbas Hilmi pardoned him and he returned to Egypt. A new generation of nationalists had grown up, which neglected him; observing the remarkable progress of his country during the 19 years of his exile, Arabi became converted to approve of British rule.

ARABIA, the peninsula in the southwestern part of Asia, called by the natives Jeziret el Arab, that is, the Peninsula of the Arabs; and by the Turks and Persians, Arabistan. It is encompassed on three sides by the sea, namely, on the northeast by the Persian Gulf and Gulf of Oman, on the southeast by the Indian Ocean and on the southwest by the Red Sea. Its extreme southern point, Ras-Arah (the Cape Saint Anthony of some maps), lies in lat. 12° 35' N.; long. 44° 4' E. Thirty miles west of it are the Straits of Bab-el-Mandeb. The extreme eastern point of Arabia, Ras-el-Had, stands in lat. 22° 23' N., long. 60° 5' E. A line drawn from the head of the Gulf of Suez to that of the Persian Gulf, and marking the limits of the Arabian peninsula on the north, will be found to run nearly in the 30th parallel of north latitude, but a portion of what is considered Arabia extends north of this. Arabia includes also the peninsula of Sinai, between the Gulf of Suez and that of Akabah. The whole area of the vast country thus described does not probably fall much short of 1,250,000 square miles.

Divisions.—According to Ptolemy, ancient Arabia consisted of Arabia Petraea, Arabia Deserta and Arabia Felix, a division likewise followed in modern times, but which is not only founded on erroneous principles, but unwarranted by the example of the inhabitants of the country. The name of Arabia Felix, or Arabia the Happy, is derived from an incorrect translation of the word *Yemen*, which does not signify happy, but the country lying to the right of Mecca, in the same manner as the Arabic term for Syria, Al-Sham, denotes the country lying to the left of that city. Arabia Petraea likewise has been erroneously translated Stony Arabia, the epithet Petraea having been bestowed on it by Ptolemy, from the once flourishing city of Petra.

The first of the divisions met with in proceeding down the Red Sea is Hejaz, which, as it includes the sacred cities Mecca and Medina, is always set forth conspicuously by Arab geographers. It extends a short way within the mountain barrier and terminates in the south in about lat. 20° N. Next comes Yemen which, according to some writers, embraces the whole of south Arabia; but the name is now generally used in a confined sense, Yemen proper occupying the southwest part of the peninsula, and comprising a Tehama or maritime lowland on the shores of the Red Sea, with an elevated inland district of considerable breadth. It contains the towns of Sana and Mocha. Appertaining to Yemen is Aden, now a free port in the hands of the British. Next Yemen, on the east, is Hadramaut, the western portion of which is a desert five days' journey in length. The limits of this province are, however, variously assigned by authors, some extending the name to almost the whole of the southeast coast, while others confine it to a district only 100 miles in length. Beyond Hadramaut, in the latter narrower sense, lies Mahrah, beyond which again extends the principality of Shejer or Shehr, at the eastern termination of which, near the coast, is the populous district of Dho-far, which has occasionally figured as an independent state. At the east angle of the peninsula is situated Oman. On the south shores of the Persian Gulf is Bahrein, from which, toward the head of the Gulf, extends the maritime district of Hasa, while at a short distance southwest in the interior lies the fertile district of El-Ahsa, the name of which is sometimes also given to the coast. The interior of Arabia from Hejaz and Yemen across to the vicinity of the Persian Gulf is comprised by Arab geographers under the single name of Nejed. The Sinaitic peninsula is called Al-Tih. The remaining divisions are Dahna, the great territory between Hadramaut, Oman and Nejed. Toward the north are the deserts of Sinai and those of Sham, Jezireh and Irak (Syria, Mesopotamia and Babylon). The two most populous districts are Yemen and Oman.

The climate of Arabia resembles that of Africa. The mountains obstruct the mitigating influence of the sea breeze; scorching aridity and barrenness characterize both high and low grounds, and the date palm is often the only representative of vegetable existence. There are even districts which in the course of the year are refreshed by only one shower of rain, while a sky almost perpetually unclouded over-spreads the sterile plains. The short rainy

season, which, in consequence of the shifting winds prevailing in the Red Sea, visits the west coasts in our summer months, fills with water, but only periodically, the depressions in the surface, or *wadis*, and a winter marked by slight frosts occurs in the table-lands of the interior and northeast. The simoom occasionally blows during the hot season, though only in the northern districts.

Productions.—Arabia is destitute of large forests, and plains of green turf have their place supplied by steppe-like tracts, which, however, covered with aromatic herbs, afford excellent pasture to noble breeds of horses. The terrace portions of the country, which enjoy a more temperate climate, exhibit a greater luxuriance of vegetation. Here the date and coconut palms and various excellent sorts of fruit flourish along with durra (a species of millet which is here generally cultivated instead of European corn), the finest coffee in the world (the staple commercial product of the country), and many aromatic plants and substances, such as gum-arabic, benzoin, mastic, balsam, aloes, myrrh, frankincense, etc. There are also cultivated in different parts of the peninsula, according to the nature of the soil and climate, beans, rice, lentils, tobacco, melons, saffron, colocynths, poppies, olives, the kath bush (*Catha* or *Celastrus edulis*), the leaves of which are in general use, like those of the coca in Peru, as an excitant, sesame, the castor-oil plant, etc. In its fauna also, as corresponding with the desert nature of the country, Arabia presents much of an African type. Sheep, goats and oxen supply man's immediate domestic and personal wants; the horse and camel are his faithful attendants on his travels; asses and mules, of a stronger make and better appearance than those of Europe, are common in the mountainous districts; the desert is inhabited by gazelles and ostriches hurrying rapidly from oasis to oasis; and the lion, panther, hyena and jackal crouch in ambush for the passing prey. Monkeys, pheasants and doves are the peaceful occupants of the fertile districts, in which, however, locusts frequently commit tremendous havoc. There are several species of serpents and lizards, and scorpions and poisonous spiders are numerous. Fish and turtles abound on the coasts, and pearl oysters in the Persian Gulf. Among mineral products may be mentioned saltpetre, mineral pitch and petroleum, which are found in the interior highlands, salt, sulphur (in Hadramaut), and several precious stones, as the carnelian, agate and onyx. Iron, copper and lead are far from abundant, and the country is also poor in the precious metals.

Population.—The population of Arabia has been estimated by some authorities at 12,000,000, by others at no more than 4,000,000. The former number is certainly too high. Palgrave estimated that Hejaz contained about 1,000,000 inhabitants, Yemen 1,000,000, Hadramaut and Mahra 1,000,000, Oman and Hasa 2,500,000 and Nejed 2,000,000. This would make a total for Arabia of about 7,500,000, which figure is probably too high, but in the absence of any regular census and with our total ignorance of a large part of the interior it is impossible to verify any statement on this point. The Arabs present, as a nation and as individuals, much that is peculiar both in their mental and physical

development. They are of middle stature, of a powerful make and have skin of a brownish color. Their features express dignity and pride; they are naturally active, intelligent and courteous; and their character is marked by temperance, bravery and hospitality, along with a strong propensity for poetry. On the other hand, they are revengeful in their disposition and predatory in their habits. The women have the entire education of the children in their early years. The most fortunate events in the estimation of an Arab are the birth of a camel, a mare of noble breed bringing forth a foal or a triumph achieved by a poet. The first religion of the Arabs, the worship of the stars, was supplanted by the doctrines of Mohammedanism, which succeeded rapidly in establishing itself throughout Arabia. Besides the two principal sects of Islam, the Sunnites (the most numerous) and the Shiites (on the east coast), there also exists, in very considerable numbers, a third sect, the Wahabees, which arose in the latter half of the 18th century, and to which the Bedouins of Nejed belong. There are also numerous Jews, who dwell among the Arabians and are chiefly employed in trade.

The whole of the west coast, comprising the districts of Hejaz and Yemen, and in quite recent times part of the east coast, namely Koweit, at the head of the Persian Gulf, and the district of El Ahsa, are more or less under the suzerainty of the Turks. The area of the western strip is about 200,000 square miles in extent, and has a population of about 1,130,000; while the eastern has an area of about 31,000 square miles and a population of nearly 200,000. Even in these districts, however, the chief offices of government are performed by the chieftains of the small territories into which the districts are subdivided. The most extensive districts politically united in the rest of Arabia are the kingdoms of Oman and Nejed, the former with an area of 81,000 square miles and a population of 1,598,000; the latter (the kingdom of the Wahabees) with an area of perhaps 200,000 square miles and a population of about 1,219,000.

The mode of life of the Arabs is either nomadic or settled, or in other words, they either live in tents and derive their subsistence from the rearing of cattle, wherever sufficient pasture is obtainable, and from the transport of caravans through the desert; or from the pursuits of agriculture and commerce. The nomadic tribes in Arabia are termed Bedouins, Beduins or Bedawins; those following settled occupations, Hadji and Fellahs. A considerable trade, partly overland, partly maritime, is carried on, chiefly in coffee, dates, figs, spices and aromatic substances of various kinds, though its present amount is scarcely a shadow of what it was in times previous to the discovery of the passage by the Cape of Good Hope. Commerce is partly in the hands of foreigners, among whom the Jews and Banians are the most numerous. The latter are a tribe of Indian merchants, who, however, only remain long enough in the country to enable them to return with wealth to their own land. At present the trade of Arabia is almost exclusively confined to exports of raw material or imports of foreign manufactures, domestic industry being scarcely able to supply the most necessary articles of consumption, and the in-

habitants are thus rendered dependent on foreign nations for the greater portion of their manufactured commodities. The period of intellectual development among the Arabs is now indeed long past its zenith, but it does not appear yet to have sunk so low as is often assumed. Even in the desert children are taught to read, write and cipher, and in the towns there are higher schools for satisfying the taste for scientific pursuits. The political constitution of the Arabs is patriarchal, and based on a love of freedom. The titles of the chiefs of the tribes are emir, sheikh or imam, personages whose functions appear in general to be limited to the command of the army in war, the collection of tribute and the administration of law by the cadis or judges.

History.—The history of the Arabs previous to Mohammed is obscure, and, owing to their slight connection with the rest of the world, of little interest. The evidence of language, tradition and other things, establishes the fact that Arabia must have been settled at a very early date by two branches of one race. One of these branches inhabits the south and east of the peninsula (Yemen, Hadramaut and Oman), and considers itself as forming the "pure" Arabs, while to the other branch it gives the name of Mostareb, or "Arabified." The oldest traditions regarding the origin of the former branch point to an immigration from Africa which took place about the southwest corner of the peninsula, and the physical appearance and structure of the southern Arabs, the remnants of their dialect (which is now superseded by that of the northern branch), and various institutions and customs prevailing in the parts of Arabia inhabited by them, all confirm the notion that they were originally identical with the nearest inhabitants of Africa. The northern branch, on the other hand, though bearing an unmistakable affinity with the southern, shows (in its language and other respects) more traces of Asiatic than African influence. The Arabs of the southern branch were the first to attain any considerable political power. A kingdom belonging to this branch is said to have existed in the south for upward of 2,000 years, embracing, when in a flourishing condition, the whole of the south half of the peninsula, and sometimes extending its boundaries by conquest very much farther. There is no doubt that there was actually such a kingdom, called the kingdom of Yemen, and having its capital first at Mareb and afterward at Sana, both in the district of that name; but how long that kingdom subsisted cannot be determined. Its kings belonged to the Himyarite dynasty, but this designation Himyarite is sometimes applied by Arab writers to the ruling classes of the southern branch, and sometimes to the whole branch. The Yemenite kingdom was rendered subject by the Abyssinians for upward of 70 years in the 6th century of the Christian era, during which period Christianity was proclaimed in the land. Ultimately the heir to the throne of the Himyarite dynasty was restored through the assistance of Chosroes, King of Persia (605 A.D.), but about 30 years later the kingdom was finally overthrown by the followers of Mohammed. Another Himyarite kingdom was that of Hira on the west shore of the lower Euphrates. It seems also to have extended at times to the region between the

Euphrates and the Tigris, so as to give the name of Irak Arabi to that district. The dates given for the foundation of this kingdom are widely different. Its overthrow is placed in the 5th century of our era. In the 1st century of the Christian era the Himyarite kingdom of Ghassan was founded in lower Syria and Hejaz. It lasted till the time of Mohammed. The last Himyarite kingdom that need be mentioned is that of Kindeh, which detached itself from that of Hira early in the 3d century, and lasted about 160 years. Its sway extended over northern Nejed. The divided forces of the Arabs could not always successfully resist the Roman arms, and though their country was never completely reduced to the condition of a province, yet the princes in the north at least lived in a state of dependence on the Roman emperors, and were regarded as their viceroys. In the south the Romans had no influence. An expedition was fitted out against Yemen in the reign of Augustus (24 B.C.), but it completely miscarried. With the decline of the Roman empire Arabia made vigorous struggles for independence, which could easily have been brought about by a union of the various tribes. But the Arabian peoples continued dispersed and broken, and passed many centuries in internal conflicts, during which the central highlands (Nejed) became the theatre of those chivalrous contests so celebrated by the native poets. Christianity early gained many adherents in Arabia, though it did not succeed in entirely banishing the ancient worship of the stars. Several Christian bishoprics were established, subject to the metropolitan at Bozra, in Palestine. The town of Elhira, near the Euphrates, contained many Arabian Christians and convents, and the reigning King, Ennomän-ben-el-mondsir, became a convert to Christianity not long before the time of Mohammed. The conflict of the Arabs with Roman despotism was more especially the cause of attracting to their country numbers of Christian sects, among others the Monophysites and Nestorians, seeking a refuge from the persecutions to which they were subjected by the maintainers of orthodoxy throughout the East. Jews also were very numerous in Arabia after the destruction of Jerusalem, and even made some proselytes, chiefly in Yemen. The wide differences between the various sects produced in the minds of many an indifference to all the existing religions, and was probably one of the principal causes that the doctrines of Mohammed found so speedy an acceptance in Arabia. With Mohammed a new phase commences in the history of the Arabian peoples, who are wont to designate respectively the periods before and after the appearance of the Prophet as those of ignorance and knowledge. Mohammed belonged to the Mostareb, and among them to the tribe of Koreysh, which had occupied a position of great influence in Arabia since the beginning of the 5th century, when it managed by craft to obtain possession of the city of Mecca, which was not only a city of great commercial importance, but was regarded as sacred by the Arabs on account of its containing the Kaaba. During the whole of the 6th century the Mostareb generally were increasing in power, and by the beginning of the 7th, when Mohammed had grown to manhood, they had absorbed the kingdom of Kindeh, and had

extended their sway at the expense of those of Yemen, Hira and Ghassan. By the time of Mohammed's death, in 632, his religion had acquired a firm hold in Arabia, and after that event his successors, acting on the commands of the Koran, began to spread it by force of arms beyond the bounds of the peninsula. The nation, now for the first time acting as a body, played for several centuries an important part in the world's history, advancing in a career of victory beyond its natural frontiers, to found empires in three-quarters of the globe. The brilliant period of Arabian history, indeed, as regards foreign countries, came to a termination in Asia in 1258, on the fall of the caliphate of Bagdad, as also about the same time in Africa and Europe, in the latter of which the Moorish dominion was finally overthrown (in the kingdom of Granada in Spain) in the last decade of the 15th century; yet the epoch of the Arab sway must ever occupy a distinguished place in the intellectual history of mankind. The internal history of the country, during its foreign conflicts presents little more than unimportant accounts of some Bedouin tribes, and the fortunes of the caravans which made the annual pilgrimage to Mecca. In 1517 Turkey subjected Hejaz and Yemen, and received the nominal submission of the tribes inhabiting the rest of Arabia. The subjection of Hejaz has continued down to the present day, with a brief interval in the latter half of the 16th century, and another longer interval in the 19th century, when the Pasha of Egypt was dominant in Arabia; but Yemen achieved its independence in 1630 and maintained it till 1871, when the territory again fell into the hands of the Turks. In 1839 Aden, in Yemen, was occupied by the British.

In the east Oman became virtually independent of the caliphs in the middle of the 8th century, and grew into a well-organized kingdom. In 1507, however, its capital, Maskat, or Muscat, was occupied by the Portuguese, who were not driven out till 1651. Oman was temporarily subjugated by the Persians under Nadir Shah in the first half of the 18th century. They were expelled by Saood, who was made imam of Oman, and under whom it extended its sway over part of the opposite coast of Persia as well as the islands lying between and over the coast of Zanzibar. Since 1867 the kingdom of Oman has been again confined to the mainland of Arabia. The appearance of the Wahabees about the middle of the 18th century is the first event since the time of Mohammed that affected Arabia generally. The moral effects of this event exercise still a powerful influence; the political were soon effaced by the ruler of the neighboring country of Egypt. Mehemet Ali, Pasha of Egypt, subdued the coast of Hejaz, as also several places on that of Yemen, and in 1818, by means of a great victory gained by Ibrahim Pasha, and the destruction of their capital city Derreyeh, put a stop to the further extension of the Wahabite power. He also expended large sums in the maintenance of his sway in Arabia, which secured to him the trade of the Red Sea. The events of 1840, however, in Syria, compelled him to concentrate his forces, and he soon found himself obliged, as thwarting the European line of policy, to renounce all claims to the territories lying beyond a line drawn from

the Dead Sea to the Gulf of Akabah. The Hejaz thus again became immediately subject to Turkish sway. Turkey afterward extended its rule not only over Yemen as already mentioned, but also over the district of El Ahsa on the Persian Gulf. During the great European War, strategic points of Arabia became scenes of active operations on the part of Turkish troops led by German officers against British domination in Egypt, the Sinaitic Peninsula being a dependency of Egypt, now a British possession. Hejaz and Yemen, on the west coast, and Hasa, on the east coast, were Turkish vilayets. There was an independent imam in Oman, and Aden and the surrounding district was a protectorate of Great Britain. The remainder consisted of several independent and semi-independent states under chiefs, elected or hereditary, bearing the title of emir, sheikh or imam. During the progress of the war, Arabia was the scene of revolts, uprisings and conflicts against Turkish authority and on 25 Oct. 1916 the Kingdom of Arabia was established with Grand Sherif Hussein Ben Ali as King, and Mecca as capital. On 3 Jan. 1917, the Grand Sherif of Mecca adopted the title of the King of the Hejaz, and the new kingdom was recognized by England, France and Russia. See WAR, EUROPEAN.

Modern Explorations.—Until about 1760 our knowledge of Arabia was based mainly on Greek and Latin writers such as Herodotus, Strabo, Pliny, Ptolemy and others. This information was meagre and not altogether reliable. The best sources were the Arabic writers and geographers, such as Hamadani's 'Arabian Peninsula,' Bekri and Yaqut's geographical and historical dictionaries. These works and others of their kind contain various fabulous and legendary traditions, based partly on native legends and partly on Jewish fancies. The Assyrian cuneiform inscriptions have yielded us much valuable material on the early history of Arabia. But above all we are indebted to scholars like Halévy, Müller, Glaser, Hommel, Winckler and others. The first European to engage in a scientific exploration of Arabia was C. Niebuhr, who, in 1761-64, at the order of the Danish government, undertook an expedition to the peninsula. In 1799, Reinand, an agent of the East India Company, followed Niebuhr and in 1808-11 the Russian scientist, U. J. Seetzen, undertook a similar journey of exploration and for the first time copied several south-Arabian inscriptions in the district of Himyar. A few years later, in 1814-16, one of the most distinguished of Arabian explorers, the Swiss, J. L. Burckhardt, journeyed to Hijaz and also to Mecca and Medina. His information is accurate, copious and interesting. Captain W. R. Wellsted, in 1834-35, made a tour of Oman and Hadramaut, and in 1838, C. J. Crittenden journeyed from Mokha to Sana and copied several south-Arabian inscriptions, which Rödiger and Geseinius undertook to decipher. In 1843, Adolf von Wrede, a German, visited Wadi Doan and other parts of Hadramaut and discovered and copied an important five-line inscription. In the same year T. J. Arnaud journeyed from Sana to Marib, the capital of the ancient kingdom of the Sabeans, and gathered about 56 inscriptions. In 1845-48 Wallin journeyed through Hayil, Medina and Taima. In 1853

Richard Burton, translator of the 'Arabian Nights' made a pilgrimage to Mecca and Medina and in 1877 and 1878 visited twice the land of Midian, in north Arabia. In 1861, Jacob Saphir, a Jew of Jerusalem, visited Yemen, where he formed several Jewish settlements, and other parts of Arabia. In 1862-63 W. Gifford Palgrave, an Englishman, journeyed from the Dead Sea to Oatif and Oman, visiting the northwestern territory between the Sinaitic peninsula, the Euphrates, Hayil, Medina, Nejed, and nearly all central Arabia, till then unknown. Central Arabia was visited by Pelly in 1865 and in 1869 Halévy, the great Orientalist and pioneer in Sabeian philology, disguised himself as a poor Jew from Jerusalem, and penetrated Yemen and south Arabia. On this trip he copied about 700 inscriptions. He succeeded in reaching the south-Arabian Jof, the territory of the ancient Mineans. In 1870-71, H. von Maltzan made several trips from Aden along the coast, and, in 1876-78, Charles Doughty made a famous tour to Mada in Salih, Hayil, Taima, Khaibar, Boraïda, Onaiza and Tayif. He unearthed several Sabatean, Lihyanian, or Tamudic, Minean and so-called proto-Arabic inscriptions. In 1877-80, the Italian, Renzo Manzoni, made three journeys to Sana, the Turkish capital of Yemen. Glaser, in 1882-84, made his first journey to south Arabia, where he discovered and copied numerous inscriptions and in 1883-84, with Euting, visited north Arabia, where they discovered the famous Aramaic inscriptions of Taima (6th century B.C.). In 1884-85, Glaser again visited southern Arabia and collected several Minean inscriptions. His third journey was made in 1887-88 and was remarkably fruitful, especially as far as epigraphical results are concerned. The inscriptions copied numbered over 400, the most valuable among them being the so-called "Dam-inscription," of 100 lines (5th and 6th centuries A.D.), and the "Sirwah inscription," of about 1,000 words (about 550 B.C.). Glaser's fourth journey was made in 1892-94 and was also rich in results. In 1893, Leo Hirsch visited Hadramaut, and so did Theodore Bent and his wife in 1893-94. In 1896-97, Count Carlo Landberg, a distinguished Arabic scholar, visited the coast of south Arabia, where he made special studies of the modern Arabic dialects there, in addition to other geographical and epigraphical researches. In 1898-99 the Vienna Academy sent an expedition to Shabwa under the direction of Count Landberg and D. H. Müller. Other expeditions have since been engaged in the work of exploration. The results of all these have been threefold: geographical, epigraphical and historical. These results have opened the way not only to fresh views and studies concerning the various ancient south-Arabian dialects, such as Minean, Sabeian, or Himyarite, Hadramautic and Katabanian, but have also thrown unexpected light on the history of the old south-Arabian kingdoms and dynasties. These same discoveries have also added to our knowledge of Old Testament history and of Hebrew and comparative Semitic philology. See ARABIAN PHILOSOPHY; ARABIC LANGUAGE and ARABIC LITERATURE.

ARABIA, Kingdom of. See HEJAS.

ARABIAN NIGHTS, The. 'The Arabian Nights,' or more properly 'The Thousand Nights and a Night' (*Alf leilah wa-leilah*), is a collection of stories in Arabic connected by a frame-story, probably Persian in origin and much older than most, possibly than any, of them. This frame-story, the distinctive feature of the 'Nights,' is essentially as follows: Shahrîar, King of India and China, finding his wife false and that his brother and a genii are in like misfortune, kills the unfaithful wife and afterward each successive bride on the morning following the marriage. Public distress induces the vizier's daughter, Sharazad, to offer herself "to be a ransom for the daughters of the Mohammedans or the cause of their deliverance." She "beguiles the waking hour" of the king by beginning a story which she interrupts at a point of suspense. Her life is spared that she may continue it. She repeats the device, linking tale to tale or involving one in another, till at the end of the 1,001 nights she asks her life, receives favor and is made full queen.

A Persian collection of tales with the same frame-story is mentioned by the Arabian historian Masudi in 943; another historian, Abu Yakub al Nadim, writing in 987, says this collection was written by Princess Homai, daughter of Bahman, that it counted 200 tales distributed through 1,000 nights, and was a "meagre and uninteresting publication." It has perished, but it seems probable that some fifth part of the 'Nights' we know was derived from it, though with far-reaching modifications throughout. The frame-story is much older, possibly, if the ingenious identification of Sharazad-Homai with the Biblical Esther, attempted by the late Professor de Goeje of Leyden, be accepted, as early as 300 B.C.

Such a frame-story offers indefinite possibilities of extension and adaptation. Few manuscripts of the 'Nights' agree in their version of any single tale, in the order of the stories, or even in the make-up of the collection. We may suppose that some favorite and favored *rawi*, professional story-teller, found a recorder, or was asked by some wealthy admirer to furnish a record of his narrations, in which professional successors would make developments, suppressions, substitutions, as conditions changed or their genius suggested. The division into 'Nights' was obviously convenient for the professional narrator, living by his art. It is found in manuscripts of tales that do not form part of any regular manuscript of the 'Nights' known to scholars. The very popular story of Aladdin and the Wonderful Lamp is rarely found in such manuscripts; Ali Baba and the Forty Thieves, no less popular among the Bedawi, occurs in none of them. Sir Richard Burton, after translating one manuscript of the 'Nights' in 10 volumes, could fill six more with "supplementary" tales, often with equal literary claim to inclusion. We have not and are not likely to have any "canon" for 'The Arabian Nights.'

The stories of 'The Arabian Nights' are of many countries and times, but whatever their age or source all have been so transformed

that they are Moslem to the core, thoroughly Arabian in temper and in spirit. The scene is sometimes in China, India, even the land of the Franks; the time is often of the 8th or 9th century, or even earlier; but the *rawi* is as indifferent as his auditors to anachronisms, and will speak in these very stories of cannon or coffee, neither of which were known in Egypt till late in the 14th century. In one instance he names tobacco, which was not known till the 16th. The manners and customs assumed throughout are those of Egypt from about 1400 to 1550, and it was during this period, probably at Cairo, that the 'Nights' took their present form.

A *rawi* must be ready with a tale to suit any audience. He may have to gain his bread to-day in camp, to-morrow in the bazaar or the inn, among simple folk, or, if fortune smile, at the festivities of the rich. So a collection made from his lips or for his benefit will show wide variation in tone and theme. There are the old "Household tales," an Arabic Cinderella among them, animal fables, like those of Bidpai and Æsop, Bedawi adventures, lovers' romances, merchant voyages to strange and distant lands, adventurous wanderings in the spirit, and now and then, almost in the letter of the Odyssey, quests in the land of the Amazons and the isles of Wak-Wak in search of the lost beloved, tales of chivalry, taken from the historians, showing curiously the other side of the crusades and Moslem reaction to the Christian Church-Militant, some of them deadly serious, others frankly burlesque, picaresque tales of successful knavery, and finally a curious group in which the *beau rôle* is so persistently given to women, either some Princess Badoura or some slave Zumroud, that they seem designed less for any male audience than for idle hours of the *haremlük*. In nearly all the stories the actors live and move in momentary expectation of supernatural intervention. Any jar or well may hold an efrî or a genii, any lamp respond to a rub, any talisman to a turn, or rock to an "open-sesame." Any day may see the pauper a prince, the prince a pauper, the "sleeper awakened." Fancy sits here on her magic carpet and travels in a twinkling wherever she will to "expatiate free" without trammel from laws of probability, gravity or economics. There, in its power to give passing release from the cares and burdens of work-a-day life, lies the primary appeal of 'The Arabian Nights' to the Arab or Egyptian who reads or more probably listens to them.

The style of the 'Nights' is hardly ever studied, often it is slovenly to a degree suggested by none of the translations, meant, like its abounding poetical tags, to be spoken or chanted, rather than read. Character studies, such as the admirably comic barber, El Samet, are very rare. But there is a verve and fire of imagination in the stories that has defied even inept translators to quench, though the interest that these tales awaken in a western man or boy, Oriental scholar, or plain reader, must at best be different from that which they arouse in those to the manner born when heard on Arabian nights.

First to introduce the 'Nights' to western readers was the French traveler, Abbé Galland. His adaptation and transmutation of

the manners and speech of Cairo to those of Versailles, appearing in successive volumes from 1704 to 1717, won immediate popularity. Its first English echo was Addison's retelling of the story of Alnashar in the *Spectator* of 13 Nov. 1712. The popular English versions of the 'Nights' are humbler adaptations of Galland's paraphrase, whatever their pretention of "revision" and new translation from the Arabic. This was first seriously attempted by the Irish novelist Henry Torrens, who issued in 1838 a translation of the first 50 'Nights,' made at Simla and, though abounding in errors, conveying more of the spirit of the East to English readers than does any of those that have followed. In 1839 the distinguished Egyptologist Lane at Cairo issued the first volume of a translation finished in 1842, and Torrens abandoned his work; unfortunately, for, though Lane knew far more Arabic, he had less imagination and was more attracted by the sociological interest of the 'Nights' than by their power to work illusion. His version is very scholarly, very labored. It omits or softens with over-anxious care all that seemed likely to offend European morals or even Victorian conventions. John Payne's privately printed version (1882-84) is complete and written with purely literary aim, solely for the story's sake, but with more of the temper of mediæval Europe than of Egypt or Arabia. It is least happy in its rendering of the simplest folk-tales. Sir Richard Burton knew more of the 'Nights' and of the life they depict than any of his predecessors. His translation (1886-88) is also complete for the manuscript selected. Six supplementary volumes contain stories found in others only. Burton's notes bring together a vast deal of curious information, hardly to be found elsewhere, but the English reflects the extreme eccentricity of the translator, even to the point of perversity; and though his work was pruned for a household edition, of matter that could not be published, it has not become popular. The judgment of the multitude is not altogether unenlightened in continuing to abide faithful to the Gallic English of the adapters of Galland's adaptation, so long as their desire is less to know of Arabian manners or Egyptian ways than to be made fancy free. For such no literal translation can serve, least of all in case of the frequent lapses into verse. Some adaptation there must be. English readers have still to await a satisfactory re-creator of 'The Arabian Nights.'

The stories in any of their versions are of very varying interest. Beside Ali Baba and Aladdin, which may lack a bibliographer's title to inclusion but have every other, it is enough to recall the names of Sindbad the Sailor, of Abou-Hassan, the Sleeper Awakened, of the scapegrace Ali of Cairo, of Nouredin and Bedreddin, of Hassan of Balsora, Joudar, Alishir, Zumroud, Camaralzaman, Badoura, Gulnare, Marouf, prince of ready-tongued impostors, the Hunchback and El Samet, the barber of unquenchable garrulity; of the gracious Peri Banou, of the Porter and the Three Ladies of Bagdad; of the Magic Horse, the Magic Carpet and the City of Brass, to realize how large is the debt of English literature and English readers to 'The Arabian Nights.' They have made it hard to think in terms of

historical reality of the Caliph Haroun al Raschid.

BENJAMIN W. WELLS,

Author 'Modern German Literature,' 'Modern French Literature.'

ARABIAN PHILOSOPHY. Speculative activities were stimulated into action among the Arabians with the appearance of sects in the world of Islam. As soon as Mohammedanism came in contact with older civilizations, notably with that of Persia, the ideas and mental habits of the new converts created a spirit of investigation into the doctrines of the Koran, which until then had been accepted in blind faith on the authority of divine revelation. The first manifestation of this spirit was the coming into existence of the sect known as "Kadariyah" (from the Arabic *Kadara*, to have power), whose partisans proclaimed the freedom of the will, in contrast with the "Jabariyah" (*jabara*, to force, to compel), who defended the generally accepted belief of the orthodox that man is completely dependent upon the divine will, and that not only his destiny but also his conduct is determined, and his own will does not count.

From the "Kadariyah" developed the school of the theologians known as the Motazilites (from *itazala*, to separate oneself). In addition to the doctrine of free will the Motazilites taught that God is an absolute unity, and no attributes can be ascribed to him. They further asserted that revelation is a natural product of the human faculties; that all knowledge necessary for the salvation of man emanates from his reason. To defend their doctrines against the attacks of the orthodox, the Motazilites elaborated a system of a rational theology, which they designated "Ilm al-Kalam" (science of the word). Its professors the *Motekallamin* (known in Hebrew as *Medabberim* and as *loquentes* in the Latin versions) may be compared with the scholastics of the Catholic Church. After the introduction of the Greek philosophy among the Arabians, the *Motekallamin* directed all their efforts against the philosophers. Their principal aim was to defend against the Peripatetics the creation of matter, and the existence of a god who exercised a direct action upon the making and the keeping of the world. To that end they adopted the theory of atoms as enunciated by Democritus. They taught that space is pervaded by atoms possessing no quality or extension, and time was similarly divided into innumerable instants. The atoms were originally created by God, and are created now as occasion seems to require. Bodies come into existence or die through the aggregation or disintegration of these atoms. There is no causality in the laws of nature, God alone is the cause. The supposed uniformity and necessity of causation is only an effect of custom; the universe could be entirely different from what it is.

In reaction against both the *Motekallamin* and the philosophers there arose, in the land of the Magis, the mystic sect of the "Sufis" who subsequently exercised a great influence on the Islamic world. The Sufis protested against all philosophical inquiry, and declared theological knowledge to be far inferior to inward perception, or mystic intuition acquired through religious ecstasies. From the

conflict of these divergent forces there arose, in the 9th century, the tendency of thought represented by the philosophers of Islam. The initiators of this tendency were Syrian Christians, who, encouraged by the enlightened caliphs of the Abbasside dynasty, and especially by Almamun (813-33), transplanted Greek science and philosophy to the Arabian soil. In addition to works of science, they translated the 'Timæus,' the 'Laws' and the 'Republic' of Plato, and when, attracted by the medical treatises of Galen, they were led to the study of Aristotle, the Arabians translated not only the genuine writings of the Stagirite, but also the so-called 'Theologia Aristotelis' which was merely a compilation from the 'Enneads' of Plotinus, and the 'Liber de Causis' which was a compilation from the 'Elements of Theology' of Proclus. The erroneous attribution of these two works to Aristotle, together with the translations of the neo-Platonic commentators, such as Porphyry and Ammonius, imparted from the beginning to Aristotelian teaching a neo-Platonic meaning; and even those of the Arabian philosophers who came to be recognized as the most faithful exponents of Peripateticism were not entirely free from the influence of neo-Platonism.

Among the Arabian philosophers of the East the most prominent were Abu Jusuf Ja'Kub ben Ishak al-Kendi (d. about 870), Abu Nasr Mohammed al-Farabi (d. 950), Abu Ali ibn Abdallah Ibn Sina (Avicenna, 980-1037) and Abu Hamed Mohammed Al-Ghazali. Of the 200 treatises which Al-Kendi is said to have composed on all themes of science and philosophy, there remained only a few works on medicine and one on the astrological-astronomy of his age, in which he expresses the opinion that all things are bound together by harmonious causal relations, that each, when completely conceived, must represent as in a mirror the whole universe. Al-Farabi gave the tone and direction to nearly all subsequent speculations among the Arabians, and his works on logic became authoritative among the Latin schoolmen. Among the contents of his metaphysics mention is to be made of his proof of the existence of God, which was employed by Albertus Magnus and later philosophers. Taking for base the Aristotelian principle that all change and all development must have a cause, Al-Farabi distinguishes between that which has a possible and that which has a necessary existence. If the possible is to exist in reality, a cause is necessary thereto. As the world is a composite it must have had a beginning or was caused; but as the series of causes and effects can neither recede in *infinitum*, nor return like a circle into itself, it must depend on some necessary link, and this link is the first being (*ens primum*). This first being exists necessarily; it is the cause of all that exists. It is simple and unchangeable. In his teaching respecting that which is caused from God, Al-Farabi follows the neo-Platonists. His fundamental conception is expressed by the word *emanation*. Prophecy is in Al-Farabi's opinion merely a natural manifestation of the intellect. It emanates from a soul of purified reasoning powers; the soul associates itself with the active reason and receives from it

aid and instruction. Man's supreme aim is to elevate his capabilities to the highest degree of perfection attainable. Contemporary with Al-Farabi was the semi-religious and semi-philosophical society of the "Brethren of Purity." The treatises of this society afford a kind of encyclopedic survey of the sciences of all nations and religions known to their time. Their philosophy of nature, however, ends almost entirely in psychology. The soul is the real being of man which has developed on a mystic path of ascent from the lower natural orders through the animal stage to an increasingly higher grade of perfection.

Avicenna exercised a great influence in Europe both by his medical canon and by his works on logic and metaphysics. In the domain of the latter he set out from the doctrines of Al-Farabi, but modified them by omitting many neo-Platonic theorems and approximating more nearly to the real doctrine of Aristotle. He taught that while all things are primarily traceable to the agency of an immediate influence of such a deity, inasmuch as the immutable cannot itself create substances subject to the element of change, the first and only immediate product of God is the *intelligentia prima*, from which the chain of emanations extended through the various celestial spheres down to our earth. But the issuing of the lower from the higher is to be conceived not as a single, temporal act, but as an eternal act. The cause which gave to things their existence must continually maintain them in existence. However, notwithstanding its dependence on God, the world has existed from eternity. Time and motion always were. Avicenna distinguishes a twofold development of our potential understanding into actuality, the one depending on instruction, the other rare and dependent on immediate divine illumination.

Ghazali, the last philosopher of the East, marked a reaction of the exclusive religious principles of Mohammedanism against philosophical speculation. After having expounded in his 'Makasid al-Filasafah' (Tendencies of the Philosophers) the teachings of the Peripatetics, he shows in 'Tahafut al-Filasafah' (Destruction of the Philosophers) their weakness. He makes a critical analysis of 20 points—16 of which belong to the domain of metaphysics, and four to that of physics—and demonstrates their contradictions. Like the *Motekallamin* he rejects the theory of causality, and asserts that there is not necessarily any connection between phenomena that usually occur in a certain order. This indictment against liberal thought was afterward refuted by Averroes, who reproaches Ghazali with duplicity; but it sounded the death knell of the study of philosophy in the East.

The Arabian philosophers of the West showed greater independence than their predecessors of the East and freed themselves more from the theological bias. The first among them was Avicenna who, considered by the Christian scholastics as an Arabian, was identified by modern scholars with the Jewish famous poet Ibn Gabirol. His main thesis in his work, which was rendered into Latin in 1150 under the title 'Fons Vitæ,' is that the *materia universalis* is the substratum of all that exists; one and the same matter

runs through the whole universe from the highest limits of the spiritual down to the lowest limits of the physical, excepting that matter the further it is removed from its first source becomes less and less spiritual. Though essentially a neo-Platonist, Avicenna departed from the pantheistic emanation doctrine, originating that of the divine will.

An exponent of a purer Aristotelianism was Abu Bekr Mohammed ben Jahya Ibn Badja (d. 1138), known to the Latin world as Avempace. Besides commenting on various physical treatises of Aristotle, he composed the 'Conduct of the Solitary,' in which he treats of the degrees by which the soul rises from that instructive life which it shares with the lower animals through gradual emancipation from materiality and potentiality to the acquired intellect, which is an emanation from the active intellect or Deity. This idea is more fully developed by Abu Bekr Mohammed ben Abd al-Malik Ibn Tofail (1100-85) known as Abubacer, in his philosophical novel 'Hay ben Jokdan' (the Living, the Son of the Waking One). Borrowing from Avicenna the allegorical character of the ideal man Hay ben Jokdan, Ibn Tofail describes the development of a thinker growing up far from all human intercourse on a lonely island. He creates for himself the conditions of material existence, and in his mature age is led by the contemplation of nature to the vision of God. He then meets a philosopher who has risen beyond the limitations of human society, and the two resolve to communicate this pure knowledge to the people; soon, however, they realize the vanity of the undertaking, as the people are ripe only for Mohammed's allegories.

The last and greatest philosopher of the West was Abu al-Walid Mohammed Ibn Roshd (1126-98), known as Averroes. While his predecessors sought more or less to attenuate the theories of Aristotle when they were in direct opposition to religion, Averroes endorsed them to their utmost, and seemed to take pleasure in emphasizing them. In his opinion science is the sole arbiter in matters of this world; and religion is not a branch of knowledge to be reduced to propositions and systems of dogma, but an inward power, an individual truth which stands distinct from, and not contradictory to, the universalities of scientific law. The perplexing problems of creation, providence and immortality were solved by Averroes in a true Aristotelian spirit. With regard to creation he goes still further than Aristotle himself, declaring that not only is matter eternal, but that form even is potentially existent, otherwise there would be creation *ex nihilo*, which is inadmissible.

With Averroes the Arabian philosophy came to a close in the Islamic world, but it exerted for centuries great influence on Christian schoolmen. Though the Arabian philosophers can lay no claim to originality, civilization owes them a debt of gratitude for having preserved the writings of Aristotle the study of which led to the birth of the modern philosophy.

ISAAC BROYDE,

Jewish Department New York Public Library.

ARABIC LANGUAGE. Among the languages termed Semitic, subdivided into Northern, embracing Aramean, Canaanitic, and Hebrew, the Babylonian and Assyrian, and Southern, including Arabic, Himyaritic, Geez or Ethiopic, the Arabic in its historical growth and development and its present-day wide diffusion and prominence, is the richest and most important of the entire group. Compared with its sister idioms, it has the merit of modernity and completeness. Regarded as an ancient tongue, it has the vigor and freshness of youth. In the earlier times, as the Bible and the inscriptions show, the constant migrations from central Arabia into Babylonia, Egypt, and south into Yemen and Abyssinia brought about reciprocal changes in dialects and customs. It was Schrader's view, contested by other authorities, that Arabia was the starting-point of Semitic culture. Historical and geographical conditions, however, tended to preserve its earliest roots and forms until the 6th or 7th century of our era, being more fortunate than Aramean and Canaanite and the Phœnician in their closer contact with foreign nations that was disturbing and led to destruction. Another happy circumstance was the fixation by the Koran of the Koreish dialect, the tribe settled in and around Mecca, and from which branch Mohammed sprang, as the future literary language of the whole nation. Even if with Nöldeke we deny the theory that classical Arabic is nothing but the dialect of Mecca which the Koran brought into fashion, we must admit how vital the Koran has proved, despite some variations from classical rules, as the storehouse of the national tongue. Mohammed's grammatical and orthographic errors were later sanctified and introduced into the language as standard authority. Hence the essential unity of Arabic wherever spoken or written. From the mouth of the Tigris, through all Mesopotamia, Syria and Palestine, in Arabia proper, Egypt and north Africa as far as Morocco, the language is the same, although some decay in inflection is to be observed. Wright claims its purest form is found among the Bedouin and its most corrupt on the Island of Malta. In its long stretch of history it has not been untouched by foreign influences; it has absorbed in particular Greek elements of culture, but not to the same extent of assimilation as an Indo-Germanic dialect would have done. Its antiquity and influence are shown in the earliest records of the Old Testament in grammatical forms and words, while in later centuries Arab wisdom was personified in the Queen of Sheba, in the friends of Job and in Solomon's own sagacity being compared to that of the Arab.

It was the Koran and the religion of Mohammed which made Arabic one of the chief languages in the world and subjected half the earth to the sway of Islam. The linguistic changes that naturally followed the military domination of the 1st century disappeared a century later when Arabic grammar was constructed so firmly as to undergo subsequently no essential variation. The zeal of Arabic philologists has opened to the world the vocabulary of the language, its wealth of words and ease of modification, which is the more wonderful when we consider the simple conditions of Arab life and how monotonous the land. The grammatical forms, too, are exceedingly rich, with the lavish development of broken plurals and verbal nouns, while it possesses the poetical freedom that seems the characteristic of the Hebrew. It is adapted as well for business as for society, and for abstract subjects in particular. Minor Arabic dialects developed with time and diverged one from the other. The present speech of Egypt and the African coastal lands—the Maghrib—from Tripoli to Morocco have been made intelligible by special grammars. Maltese for nine centuries has been isolated from the influence of literary Arabic and exposed to that of Italian, and forms an interesting language for the philologist. Nöldeke asserts, however, that with all their variations these dialects do not differ as much from classical Arabic as French and Rumanian do from Latin. Despite the puzzling appearance to the novice of Arabic script, it is comparatively easy to learn. The real mystery of the Semitic languages, seen in the Arabic in its most bewildering form, is the triliteral root which consists of three consonantal letters. While the vowels are only subordinate, expressing the word's modifications, the consonants give its meaning.

In the group of Arabic is to be included the South Arabian or Himyaritic, called also Sabæan, which extends along the south coast of Arabia from the strait of Bab-el-Mandeb on the west to the mouth of the Persian Gulf on the east. Inscriptions found in great numbers particularly in the province of Yemen are in the ancient Himyaritic, dating to the 3d and 4th centuries of our era. None of the monuments in that dialect are older than the 7th century. The paucity of vowels in the inscriptions renders its knowledge more difficult, but the resemblances to Arabic are marked. Geez or Ethiopic is the language of the Abyssinians—its modern dialects are found in the Tigré and Amharic in the mountainous regions southwest of Arabia. The oldest Ethiopic monuments—apart from the Ethiopic version of the Bible—are a few inscriptions which date from the first five or six centuries of our era. When the ancient language had died out among the people it was still cultivated by the priesthood. Its literature is largely modern, consisting of translations from the Coptic and more often from the Arabic from the 13th to the 16th centuries.

ABRAM S. ISAACS,

Professor of Semitic Languages, New York University.

ARABIC LITERATURE. While it is only the last century before Mohammed which has left a few traces of early Arabic literature, from the era of the prophet of Islam it grew with marvelous rapidity to become one of the most widely cultivated in successive ages. An outgrowth of the wandering Bedouin of the desert, it was to include nearly all the branches of human knowledge and research. Theology, medicine, philosophy, philology, history, mathematics, geography, astronomy and poetry, in particular, were extensively represented, even if the modern world has had, as yet, only an introduction to these treasures, which were less cultivated after the 14th century. The beginnings sprang from the desert, when the Bedouin with his camel, long his only steed, his nearby herbage and frequent encampments, became rhymer and balladist in a fashion. His subjects were limited—the face of some dear one, the abandoned camp and its lost treasures, the strife over camel or caravan—nothing very monumental or superhuman as might be traced in the early literary effort of the Indo-European. The primitive Arabic poems in quaint measures are satires and sharp epigrams, passing from tribe to tribe of a common origin, and composed by the *Sha-ir*, sage and diviner as well. Of such productions nothing remains. Popular songs orally transmitted in memory of victory over the Romans were soon forgotten, for nothing was written in those times.

It is not surprising that the most ancient of the Arabic poems date only from the 6th century of our era when Nabatean travelers brought the Estrangelo alphabet from Syria and applied it to the Arabic. The poets of the desert traced their rhymes and metre to the soothsayer's formula and chant; the measure was to be changed as new conditions of life arose with music and the dance, and the bustling town supplanted the wilderness.

Out of the pre-Islamic period the earliest poems comprise the seven *mu-allaqat* or literally the "suspended"—a term of later origin to indicate the high honor in which they were held, like some glittering pendant; they were also called a "necklace of pearls." The word is also held to signify "excellent." The seven poets whose names were thus strung together are Imru'u'l-Qais, Tarafa, Zuhair, Labid, Amr, Antara and Al-Harith. In the opinion of some the two last are Nabigha and A'sha. They created the *qasida*, with its definite rules and forms. It treated of the abandoned camp, and

those who had forsaken it. Some love theme is interwoven and then the hard desert journey is mentioned, with the faithful steed's desperate plight. The last lines dwell on the glory of the ruler before whom the poem is recited and from whom a gift is expected. Of these the name of Antara survives in the Romance of Antar—a true desert poet, as contrasted with the courtier poet Nabigha or with Imru-ul-Qais of royal lineage and regarded by Mohammed as best of all.

Other pre-Islamic poems preserved are the *Diwans* (anthologies arranged according to the alphabetical order of the rhyme) of the six poets brought together by the grammarian Al-Asma'i, preserved in revised form by a learned Spanish Arab of the 11th century, and published by Ahlwardt. In the same class is Al-Mufaddal's collection of poems, *Mufaddaliyyat* in one volume in the 11th century, of whose publication Thorbecke has made a beginning; and also the *Jamharat Ash'ari al Arab*, quoted in the 11th century by Ibn Rashiq and printed at Bulaq. Better known is the *Hamasa* or anthology of war-like exploits, by Abu Tammam, translated into German by Rückert. Leyden has a manuscript copy of a work of the same name and kind and dating from the same century, the ninth, compiled by Al Buhturi. Wright has issued a fragment of Sukkari's stories of brigands. But the most valuable source to early poems and poets is the *Kitab al Aghani* (Book of Songs) by Abul'-Faraj, published at Bulaq in 20 volumes, with an additional volume by M. Brunnnow from manuscripts discovered in European libraries. Sukkari has also collected poems of the Hudhailites, who dwell southeast of Mecca, which have been studied and translated in part by Kosegarten, Abicht and Welhausen. In addition to their anthologies many warriors sang their own deeds in love and war, like Ta'abbata-Sharran and his companion Shanfara, Urwa ibn al-Ward, Dhul-Asba, Al-Hadira, Abid, Hatim, Umayya, whose subjects were religious, and who died in 630. Of a religious turn and famous in his day was Al-Asha. Al-Khansa was renowned for her elegies, a necessary part of funerals, and whose composition was confided to women. There were a number of Jewish poets in that early period, whose colonies dated from the Roman conquest of Palestine; local legend asserts an earlier origin. Their language had been Arab, but they had retained their religion and were propagandists in a way as Arab tribes associated themselves with them. The greatest was Samuel ibn Adiya, and next to him in fame was possibly Al Rabi, whose sons were bitter enemies of Mohammed. Christianity had made proselytes in Arabia, with churches and monasteries in Syria, with the constant caravans of northern Arabs, while Mesopotamia was wholly Christian. Adi ibn Zaid was the most famous of the Christian poets, coming from Hira, with its mixed elements of Arameans and Arabs. Of the prose of these early centuries, there are no traces extant, as nothing was written or deemed worthy of such honor. The literary art which attained later such magnificent development was limited to stories and recitals of martial deeds, to proverbs and legends. With the Koran began a new period of Arabic

thought. Whatever elements, whether Jewish, Christian or a blend of the two, like the Essenes, were at the basis of Islam, the Koran founded the classic literature of the Arabs. Revealed in bits and fragments, with its style differing according to the periods of the prophet's life at which he was inspired, written throughout in rhymed prose, and finally edited under Caliph Uthman, with its chapters or *suras*, excepting the first, arranged artificially according to their length, the work became corner stone and temple, foundation and edifice, authority and inspiration to worshipper and worker. All copies of the Koran now existing are copies of Uthman's edition—other texts were done away with by that Caliph, except the authoritative text of Abu Bekr, which was soon afterward destroyed by the governor of Medina. Unanimity and unity had been preserved. In the largest measure Arabic literature is the Koran, studied, interpreted in prose or verse, eulogized, made the point of departure for thought in a thousand fields, all closely connected with the history of the Arab people at home and in their conquered realms.

Under the Ommeyyads, when less simplicity prevailed than under the first four caliphs, as town life grew more attractive, the old forms of poetry were maintained with all their artificial character. Three brilliant names appear in this period—Akhtal, Ferazdaq and Jarir, whose merits were a constant source of dispute at the court. Minor poets were numerous. Many, the best known of whom was, Ajjjaj and his son, Ruba (edited in 1903 by Ahlwardt and translated by him a year later), revived the *rajaz*, a very simple prosodic metre, used for improvisation in pre-Islamic times. With the rise of the Abbasside line and the wider diffusion of Persian influence, a new literary period began. Bagdad was founded, and became a famous centre. The Arab gave way to the Persian in poetry, theology and law. If Arabic now became the sole language of the vast empire of the caliphs, it was written and spoken by men who were Arabs only by education. Changes in the character of poetry and its subjects were soon to follow. Less and less attention was paid to the quarrels and exploits of the tribes and more to general culture and interests. Among the large group of poets, the most distinguished was Abu Nuwas, born in the heart of Susiana about 756. He practised every form of Arabic verse with a range and ability that gave him fame. Others of more or less prominence were Muti ibn Ayas; the blind Bashshar, ibn Burd (d. 783), Abu Dulama, Marwan (d. 797), a Jewish writer from Khurasan; Ibn al-Ahnaf, Muslim (d. 803), who at the point of death caused a rough copy of his poems to be cast into the river; Abul 'Atahihah, Di'bil (d. 850), Ibn al Mutazz, a caliph's son who was a dainty poet and wrote the first great Arabic work on rhetoric. The list could be greatly extended. The provinces claimed a full share of writers, some of whom rivaled those of the capital, names like Ismail of Bassora (d. 789). Dik-al-Jinn of Syria (d. 809), Al-Ma'arri born in Syria 973; Abu Firas, of princely family; Al Nami of Aleppo (d. 963); Tughra'i, born at Ispahan (d. 1121), Al-Wawa, of Damascus, Al Haziri of Turkish origin (d. 1235). The most famous representative of the provinces was Mutanabbi, Syrian

(b. 905), who became so popular that 40 commentaries were written to explain his verse. Persia had a group of poets in Arabic, among whom can be mentioned Al-Busti (971-1010), who composed in prose and verse; Al-Abiwardi, poet and scholar; Al-Khayyat (1058-1123, whose 'Diwan' was widely read in the Middle Ages; Al-Ghazzi (1049-1130), a Palestinian; and the most illustrious of all Sadi (d. 1291), who wrote Arabic odes as well as his immortal 'Gulistan' and 'Bustan.' Besides flourishing in Syria, Persia and Egypt, Arabic poets were found in Spain and Sicily. In rhymed prose Al-Hamadhani (968-1008) wrote his 'Maquamas,' or lectures with rare skill. Al-Hariri (1054-1122) was the most brilliant in this field. As late as the last century he was imitated by the Sheik Nasif (d. 1871). Tales in a similar vein, written in the 9th and 10th centuries, are found in the anthologies. Stories, too were borrowed from the Pehlevi version of Bidpai's fables in Arabic translation by Ibn Muqaffa in the 8th century, under title 'Kalila wa Dimna,' and from the Indian through the Persian, made as early as the 9th century, of 'The Book of the 1001 Nights,' which took its present form with local variations about the 13th century.

During the dynasty of the Abbassides the science of languages was studied as zealously as poetry. The schools of Kufa and Bassora furnished a long array of authors in Arabic, with their grammars, word-studies, philological treatises on the Koran. The Nizamiyya University of Bagdad proved a centre of research for studies in poetry, rhetoric and lexicography chiefly by scholars of Persian origin. History, which began with works devoted to the sway of Mohammed, was soon concerned with the biography of the prophet as the tradition was more closely investigated. Early historians were Ibn Ishaq (d. 768), the great part of whose biography of Mohammed, preserved in Ibn Hisham's compilation, was translated into German by Weil, and Al-Waqidi (747-823), whose work was issued at Calcutta by von Kremer. There were many others who followed in the field of history, some very celebrated. Tabari (838-923), is probably the most important; his 'History of the Prophets and Kings' is the most ancient record in its line extant. Mada'ini's 'History of the Caliphs,' issued before Tabari, is known only in the selections given by later writers. Historical anecdotes and legends were embodied in a number of works. Out of this period, too, comes the 'Fihrist,' a bibliographical treatise of writings which have disappeared, owing largely to the destruction of the Bagdad libraries by the Mongols in the 13th century and by Tamerlane in the 15th. Provincial histories, biographies of Saladin and others, autobiographies which began with Ibn Munqidh (1095-1188) were written, while jurisprudence attracted numerous authors, commentators on the canonical books, criticism of the authorities of the tradition, and an endless array of treatises on Moslem law in its varied ramifications, and on dogmatic theology and mysticism. Translations from the Greek formed an integral portion of Arabic literature. Greek works on philosophy and science had been translated by the Syrian monks and were thus reproduced by the Arabs. Caliph Al-Ma'mun by founding a

university at Bagdad was the first to give distinct impetus to Arabic science which through Moslem Spain was to arouse all Europe. Then followed a rapidly increasing mass of books on philosophy, mathematics, astronomy and astrology, geography, medicine, alchemy, encyclopædias, whose influence was widely extended through the then known world. One famous name may be mentioned, Ibn Khallikan (1211-1282), whose anecdotal biographical work, 'Obituaries of Great Men,' was translated into English by de Slane (London 1842-71).

It is difficult to do justice to the strength and character of Arabic literature in the centuries of its fullest blossoming. Rulers as a class vied with each other in establishing schools and colleges. Besides Bagdad, Basora and Kufa, Aleppo, Ispahan and Samarcand became homes of science, while Cairo, Fez and Morocco contained academies of learning, with rich libraries, the precious storehouses of knowledge for later times. Cordova was to Europe what Bagdad was to Asia for several centuries. Students from other parts of Europe journeyed to the Arab schools in Spain to learn particularly medicine and mathematics. In arithmetic, geometry and astronomy the Arabs were the pathfinders of their day. Arab Spain furnished a remarkable contrast to the spectacle of comparative ignorance in the rest of Europe. In mathematics their influence was of signal character. They added the decimal system and the Arabic numerals, whose origin, however, can be traced to India; they simplified the trigonometry of the Greeks and widened the application of algebra. In the line of inventions and discoveries they merit much distinction; they brought paper from Asia and were the first to employ cotton instead of silk in its manufacture. Gunpowder was known to them a century earlier than before any trace of it appeared in European history. Already in the 11th century they had the compass.

With the rise of the Turkish body-guard under Ma'mun's successor in the 9th century began the gradual decline of the Abbassides, which became more rapid as the Caliphates ended when the Mongols in 1258 captured Bagdad. The changed conditions now under Turkish and now under Persian sway had their natural effect on Arabic literature. Yet it can point none the less to a continuous array of works on poetry, history—in the latter branch Ibn Khaldun (1332-1406) is one of the greatest in Arab annals—philology, anthologies and romances,—which Lane describes in his 'Modern Egyptians'; with fables such as those of Luqman, through the medium of a Syriac version (1299), by Barsuma, a Christian (d. 1316). Luqman is considered by some to be identical with Æsop.

The 19th century witnessed much literary activity in Arabic-speaking lands, not only in Egypt, Syria, Tunis, Algeria and Morocco, but also in cities like Constantinople and Paris, where Oriental writers are accustomed to meet and the learned recognize the wealth and power of the Arabic. Among the more notable writers were Sabbagh (d. 1816), who left a number of works in manuscript in the fields of history and grammar; his friend Boqtor (1784-1821), who left an Arabic-French dictionary; Shaikh Rifa'a, who spent the closing years of his life as head of the Translating

Office at Cairo; Faris Al Shidyaq (d. about 1890), who translated the Bible into Arabic and wrote on Arabic synonyms, on animal nature, on his travels, and made various literary and scientific contributions to an Arabic newspaper; Butrus Bistani (1819-83), a Maronite who became a Protestant, wrote on Arabic literature, arithmetic, grammar, etc. Rushaid Dahdah published a number of Arabic texts, chiefly in France. Beyrout was the centre of a literary movement in the 19th century; poems, grammars, dictionaries, biographies were written and the knowledge of the Arabic classic spread, Father Cherkho of the Beyrout University of Saint Joseph being the chief pioneer. History was much cultivated in the Lebanon. Damascus in the seventies and eighties produced many books on law, philosophy, logic, hygiene and theology. Egypt has vied with Syria in its literary activity, the printing presses at Bulaq and private enterprise at Cairo familiarizing the public with Moslem classics, while new writers have done their share in poetry, geography, history. Two historical novels were composed by Zaidan (1834-90), a Syrian Christian. Ali-pacha (1823-93), Minister of Public Instruction, wrote on the metric system (1892) and founded the Cairo Viceregal Library (1870). Habib A. Salmoné of Beyrout and London compiled a great Arabic dictionary and translated Swedenborg's 'Heaven and Hell' into Arabic (1896). In physics, chemistry and natural science there have been numerous authors. The woman question has its expositors and topics of the day are discussed by some writers. To this summary must be added the issue of many newspapers and copious translations from European languages.

ABRAM S. ISAACS,

Professor of Semitic Languages, New York University.

ARABIC, The. A steamship of the White Star line, torpedoed without warning by a German submarine about 60 miles off Fastnet (not far from the scene of the *Lusitania* wreck), on the morning of 19 Aug. 1915, one day out from Liverpool. Bound for New York, the *Arabic* was unarmed and carried 180 passengers (29 Americans) and 243 in crew. She sank in 11 minutes; 44 lives were lost—19 passengers and 25 of the crew. Two American citizens were drowned, Dr. Edmund F. Woods of Janesville, Wis., and Mrs. Josephine L. Bruguière of New York. The effect of the sinking of the vessel was to aggravate the strained diplomatic relations between the United States government and Germany created by the sinking of the *Lusitania* (q.v.) three months earlier. On 21 July the American government had informed Germany that a repeti-

tion of such "illegal and inhuman acts" as the sinking of the *Lusitania* would be regarded by the United States as "deliberately unfriendly" when American citizens were affected. Nevertheless, the *Arabic* was sunk; none saw the submarine and no attempt had been made to search the vessel or to warn the captain. Five days later (24 August) the German Ambassador in Washington informed the Department of State that the German government trusted that the American government would "not take a definite stand at hearing only the reports of one side, which, in the opinion of the Imperial government, cannot correspond with the facts, but that a chance will be given to Germany to be heard equally." Although the German government "does not doubt the good faith" of the eye-witnesses of the disaster, "it should be borne in mind that these statements are naturally made under excitement which might easily produce wrong impressions." This somewhat naive communication overlooked the central and indisputable fact that the vessel had actually been torpedoed and sunk; it wound up with the declaration that "if Americans should actually have lost their lives, this would naturally be contrary to our intentions"; that the German government "would deeply regret the fact," and tendered "sincerest sympathies to the American government." On 25 August the German Chancellor did "not even know whether the sinking of the ship was caused by a mine or by a torpedo fired from a German submarine," nor did he know whether "the *Arabic* herself may not by her actions, perhaps, have justified the proceedings of the commander of the submarine." On 1 September the German Ambassador wrote Mr. Lansing to the effect that his government had already accepted the American declaration on the submarine warfare before the sinking of the *Arabic*, and he produced the following extract from a proposed reply to the hitherto unanswered American note of 21 July: "Liners will not be sunk by our submarines without warning and without safety of the lives of non-combatants, provided that the liners do not try to escape or offer resistance." Seven days after the wreck of the *Arabic* a dispatch from Berlin announced "on the best authority that the *Arabic* incident may be considered as eliminated as a source of discord between Germany and America; or at least is regarded by the German government in that light." Furthermore, "in its desire to continue its friendly relations with the United States," Germany "had adopted before the sinking of the *Arabic* a policy designed to settle completely the whole submarine problem as affecting America, on the basis of goodwill and mutual understanding." The German report on the *Arabic* case, dated 7 Sept. 1915, was cabled to Washington by Mr. Gerard, American Ambassador in Berlin, on 9 September. It stated that on 19 August a German submarine stopped the English steamer *Dunsley* south of Kinsale and was on the point of sinking her by gunfire after the crew had abandoned the ship. "At this moment the commander (of the submarine) saw a large steamer making directly toward him. This steamer, as developed later, was the *Arabic*. She was recognized as an enemy vessel, as she did not fly any flag and bore no neutral mark-

ings. When she approached she altered her original course but then again pointed directly toward the submarine. From this the commander became convinced that the steamer had the intention of attacking and ramming her. In order to anticipate this attack he gave orders for the submarine to dive and fired a torpedo at the steamer. After firing, he convinced himself that the people on board were being rescued in 15 boats." The commander's conclusion, the report continued, was "all the more obvious as he had been fired upon at a great distance in the Irish Sea on 14 August—that is, a few days before—by a large passenger steamer apparently belonging to the British Royal Mail Steam Packet Company, which he had neither attacked nor stopped." While regretting that lives had been lost, the German government was "unable, however, to acknowledge any obligation to grant indemnity in the matter, even if the commander should have been mistaken as to the aggressive intentions of the *Arabic*." Against this presentation of the case must be placed the statement of Captain Finch of the *Arabic*: "I did not see a single sign of a submarine, and, as far as I am aware, nobody else saw a submarine, either before or after the occurrence." In case a harmonious opinion on the point could not be reached, the German government "would be prepared to submit the difference of opinion, as being a question of international law, to The Hague Tribunal for arbitration. . . ." Having collected all the available evidence of the ship's officers and passengers, the United States government demanded a disavowal of the act and reparation for the American lives lost. While the arbitration proposal was rejected—the principle involving the safety of American lives—the German assurance of 1 September was accepted. On the question as to the amount of indemnity, arbitration would be agreed to. The unalterable determination of the American government led to the desired result, for on 5 Oct. 1915 the German Ambassador in Washington presented to Mr. Lansing the German government's disavowal of the submarine commander's act and expressions of regret for the incident. The Ambassador was also authorized to accept liability for all damages caused to American citizens through the sinking of the *Arabic*, and to negotiate the amounts of the claims. See ANCONA; FALABA; LUSITANIA; ORDUNA; SUSSEX; WILLIAM P. FRYE.

ARABIN, the chief constituent of gum-arabic, obtained by precipitating an acidulated aqueous solution of gum-arabic with alcohol.

ARACAJÚ, a-rāka-zhoo', a city of Brazil, capital of the state of Sergipe. It is situated on the Cotindiba River about seven miles from the Atlantic Ocean, lat. 10° 58' S., and is the port through which passes Sergipe's limited coast-wise and foreign commerce. Products of agricultural industry, especially sugar, rice, cotton and hides, are shipped in vessels of moderate draught, and there is transportation by rail between Aracajú and the interior towns Signão Diaz and Capella. Pop. about 6,000 actual residents of the city, or 30,000 if we include the district, as is customary.

ARACEÆ, the designation of an order of endogenous plants having for their inflores-

cence a spadix placed within a spathe. They have neither calyx nor corolla. The leaves are frequently cordate; the fruit succulent, with many seeds. They are acrid in character and often poisonous. The *Caladium sequinum*, or dumb cane of the West Indies and South America, when chewed, causes the tongue to swell so as to cause temporary dumbness. A common English species is the wake-robin. The nearest relatives of the family in America are the Indian turnip, water-arum and skunk's cabbage.

ARACHNIDA, the name applied to the class of arthropods represented by the scorpion, spider and mite. The body is divided into two regions, the cephalothorax and abdomen, the head having been in embryonic life folded back over and fused with the thorax. There are no antennæ, the first pair of appendages resembling mandibles, and called chelicera; the second pair end in a large forceps, or chelæ, or in a palpus-shaped appendage called "pedipalpi." The head appendages are not differentiated into antennæ, mandibles, maxillæ and maxillipeds, as in *Crustacea*. There are four pairs of legs ending in a pair of minute claws. On the abdomen there are no appendages. The respiratory organs are spiracles opening into tracheas or air-tubes, or pouches containing numerous leaves or their sacs, resembling the leaves of a book, and hence called "book-lungs." The eyes are simple, never compound, two being situated in the middle of the head, others on each side of it. There may be as many as five pairs of nephridia. The genital outlet is single instead of being double, as in *Limulus*. They have a pair of malpighian tubes or urinary vessels, but, like *Limulus*, possess two large digestive glands, the "liver."

The young are hatched in the form of the adult, there being no metamorphosis except a slight one in the mites. Their embryos have, on at least six abdominal segments, rudiments of limbs, which indicate their descent from animals like *Limulus*. All of the *Arachnida* are terrestrial, none of them living in or near fresh-water, except a few mites. Their embryology is like that of *Limulus*, which suggests that the *Arachnida* have descended from the *Merostomata* (q.v.) Whether we take into account the mode of development or the very primitive nature of the appendages, it appears that the *Arachnida* are much less closely allied to insects than was formerly supposed. On the other hand, they differ from the merostomes, and especially their living representative, the king crab (q.v.), in having no gills. Their embryology and morphology tend to show that the class has probably descended from limuloid ancestors, of which there are examples in the Silurian rocks, intermediate between limuloid (*Xiphosura*) and eurypteroid (*Eurypterida*) forms. The characters in which *Arachnida* resemble insects, as respiration by tracheæ and the presence of urinary tubes (which do not occur in *Crustacea* or in any other marine or branchiate arthropods), are probably adaptive and were acquired during a change from a marine to a terrestrial life, and not primitive heirlooms. *Arachnida* also show their later origin than merostomes by the fact that their sexual ducts (oviduct, etc.) are in most cases single, unpaired and in all cases open externally by a common single genital aperture in

the median line of the body, at the base of the abdomen. In this respect *Limulus*, with its pair of genital (male and female) openings, situated each at the end of a papilla, which are placed widely apart at the base of the first abdominal legs, is decidedly more archaic. The *Arachnida* are divided into six groups or orders: (1) *Scorpionida* (scorpions); (2) *Pseudoscorpionida* (false- or book-scorpions); (3) *Pedipalpida* (*Phrynus* or scorpion-spiders); (4) *Solpugida* (galeodes); (5) *Phalangida* (harvest men); (6) *Araneida* (spiders); (7) *Acarida* (mites and ticks), the latter comprising the aberrant and degenerate forms, many of them parasitic; while of somewhat doubtful relationship to the *Acarina* are three aberrant groups: the *Linguatulida*, *Pycnogonida*, and *Tardigrada*. See MITE; SCORPION; SPIDERS.

Several of the *Arachnida* are of interest in medicine. A few of the scorpions are poisonous, their sting even causing death, although it is quite certain that there are no poisonous spiders north of Mexico. A number of the mites are found in man. One, the *Demodex canis*, is frequently found in the sebaceous follicles of the skin, notably in comedos, or black-heads. The itch mite (*Sarcoptes scabiei*) bores little canals under the skin, in which it deposits its eggs. The itch is a common disease of Europe, and is becoming more frequent in this country. Sulphur ointment is one of the best parasiticides for this small nuisance.

In the warm countries ticks (*Ixodes*) are troublesome pests. See PARASITES.

ARAGO, à-ra-gò, Dominique François, a celebrated French astronomer: b. in Estagel 1786; d. in Paris, 2 Oct. 1853. After studying at the Polytechnic School at Paris he was appointed secretary of the Bureau des Longitudes, and in 1806 was associated with the Biot and in completing the measurements of Delambre and Mechain to obtain an arc of the meridian which was to serve as the basis of a new metrical system. In 1809 he was elected to fill the seat left vacant by the death of Lalande in the Academy of Sciences, and at the same time he was appointed a professor of the Polytechnic School. In 1811 he communicated to the Institute a paper on a particular modification which the luminous rays experience in their passage through certain transparent bodies, thus paving the way for some of the most brilliant discoveries made in optical science since the days of Newton. In 1812 he began a series of lectures on astronomy, which created an immense sensation. With Gay-Lussac he established in 1816 the 'Annales de Chimie et de Physique.' His discovery of the magnetic properties of substances devoid of iron procured him the Copley medal of the Royal Society of London in 1825, and a further consideration of the same subject led to the equally remarkable discovery of the production of magnetism by electricity. In 1830, on the death of Fourier, Arago succeeded him as perpetual secretary to the Academy of Sciences, becoming in the same year director of the Observatory. After the expulsion of the Bourbons Arago was elected to the Chamber of Deputies as representative of the Pyrénées-Orientales, taking his place on the extreme left, and proving a ready and effective speaker. The revolution of 1848 brought him still more prominently upon the scene, first as Minister of War and Marine in the provisional

government, and then as a member of the executive committee of the National Assembly. His 'Works,' edited by Barral, appeared in 1854-62.

ARAGON, an ancient kingdom in the northern part of the Iberian Peninsula, comprised in the modern Spanish provinces of Huesca, Teruel and Zaragoza. Its area is 18,294 square miles. It is drained by the Ebro and its tributary streams, which traverse a central plain. The northern and southern portions are mountainous and the climate varies according to the elevation above sea-level. It is often very sultry in the plains and valleys while generally cool at higher elevations on the mountain slopes. Wheat, corn and other crops of the cooler climes are grown in the more elevated portions while the olive and vine thrive in the warmer valleys. Copper, lead, salt and sulphur are mined in small quantities in Teruel. Manufactures are in a backward state, coarse linens and woollens being almost the only products. Agriculture is carried on in a primitive fashion; indeed, the burdens imposed on the farmer and agriculturist leave him little incentive to improve his methods or extend production. Trade is hampered with like restrictions. The total population of the region to-day is 971,515. Zaragoza is the chief city, with a population of 112,000. Aragon formed a part of the Roman province of Hispania Tarraconensis, fell to the Visigoths in the 5th century and to the Moors in 711 A.D. A few of the Christian inhabitants fled to the fastnesses of the north where they managed to maintain a degree of independence. This small state was long ruled by Gothic counts, who joined it with Navarre. Ramiro I secured its complete independence in 1035 and it began its 450 years of existence as a kingdom. It was in constant conflict with the Moors and gradually wrested from them important towns and fortresses. By 1118 the kingdom had attained its full territorial growth in the Peninsula, and in 1137 it was joined to Catalonia through the marriage of the respective sovereigns. The new state extended its power to the Balearic Islands, Sardinia, Sicily and Naples, all of which came under its sway before 1340. Barcelona became the commercial rival of Genoa and constant war was waged between them. Aragon was united with Castile in 1479, Ferdinand of Aragon having married Isabella of Castile in 1469. Aragon became definitely merged in the new Spain in 1516 when Charles I ascended the throne. See SPAIN; SICILY.

ARAGONITE, a mineral having the formula CaCO_3 , and therefore identical with calcite in composition. It is classed as a separate species, however, because it crystallizes in the orthorhombic system. Its specific gravity is also somewhat higher than that of calcite. Occasionally it contains a little strontium, lead, or zinc, and it often occurs in connection with pyrites, galena, or malachite. It is translucent and usually white with a vitreous lustre. In hardness it varies from 3.5 to 4, and it has a specific gravity of about 2.94. Aragonite occurs in fine crystals at Aragon, Spain (whence its name), near Bilin, Bohemia, in Hungary and Sicily, and near Frizington, England. There are no important American localities, though it occurs on stalactitic calcite in caves in New

Mexico, Arizona and elsewhere. The coral-loidal form, called "flos-ferri," is most beautifully developed in Styria. It is said to be forming rapidly at the present time in the Eureka mine in Nevada.

The minerals aragonite, bromlite, witherite, strontianite and cerussite, all of which are carbonates crystallizing in the orthorhombic system, are classed together as the "aragonite group."

ARAGUA, a-rä'gwä, one of the states of the republic of Venezuela, including the nine districts of Bruzual, Gisardot, Mariño, Ricaurte, Roscio, San Casimiro, San Sebastián, Urdaneta and Zamora. It is bounded on the north by the Caribbean Sea and Federal District, on the east by the state of Miranda, on the south by Guárico and on the west by Carabobo and Zamora. Its capital is La Victoria, a city of 8,000 inhabitants founded by Francisco Loreto in 1593 in the fertile valley of Aragua. Principal towns are Barbacoas, Ciudad de Cura, Maracay, Ortiz and San Mateo. Chief rivers are the Guarico, Aragua, Tiznados and Chirqua, the first three being affluents of the Orinoco. The last flows into the great Lake of Valencia. The mean annual temperature of the state varies between 74° F. in La Victoria and Maracay and 80° F. in Ciudad de Cura and Ortiz. The industries are chiefly agricultural and pastoral, the products of the former being coffee, sugar, cocoa and cereals. Pop. (1916) 154,000.

ARAI HAKUSEKI, ä'rî, hä'koo-sä-kë, Japanese scholar: b. 1657; d. 1725. He is one of the most noted of the brilliant group of scholars in Yeddo who followed the philosophical doctrines of Chu-Hi. He was a liberal thinker and opposed to the Kogaku school of philosophy. Banned and oppressed his followers instructed young gentlemen throughout the country and so molded public opinion that supreme power was restored to the Mikado in 1868. Hakuseki wrote an autobiography in 1716, one of the first of such works in Japan. He wrote the 'Hankampu' in 1701. It is a history of the Daimios of Japan from 1600 to 1680 in 30 volumes. The 'Tokushi Yoron' is a general history of Japan covering a period of 2,000 years. His 'Seiyo Kibun' gives an account of Europe; it was translated by S. R. Brown and appeared in the 'Transactions' of the North China Branch of the Asiatic Society (London 1827-31). Consult Aston, 'History of Japanese Literature' (New York 1899), and Florenz, 'Geschichte der japanischen Litteratur' (Leipzig 1906).

ARALIA, the designation of a widely distributed genus of about 20 species of dicotyledonous shrubs, trees and perennial herbs typical of the family *Araliaceæ*. The species have large alternate compound deciduous leaves, small umbels of whitish flowers usually arranged in panicles, and two- to five-seeded, variously colored, globular, berry-like drupes. All parts of the plants have a warm, aromatic taste. *A. spinosa*, devil's walking-stick, angelica tree, Hercules' club, toothache tree, a very ornamental shrub or small tree about 12 feet tall (sometimes 40 feet), is common in moist woods and along river banks from Pennsylvania to Indiana and southward to the Gulf of Mexico. Its very stout, prickly stems, large

pinnate leaves and clusters of flowers which appear in midsummer, give a decided subtropical effect upon lawns in the South. It is not hardy in the North. *A. racemosa*, spikenard, a widely branched herbaceous species, with large, spicy, aromatic roots and greenish-white flowers which appear in midsummer, is common in rich woods from New Brunswick to Minnesota and southward to the mountains of Georgia. *A. nudicaulis*, wild sarsaparilla, small spikenard, a nearly stemless herbaceous species with a single pinnate leaf a foot high, is common in rocky and sandy places from Newfoundland to Missouri and southward to the mountains of North Carolina. It bears from two to seven umbels of greenish flowers in late spring. The long, horizontal, aromatic roots are believed to be equal to those of sarsaparilla as an alterative and tonic. *A. hispida*, wild elder, bristly sarsaparilla, a bristly stemmed perennial, is found in the same localities and soils as the preceding. It bears several terminal umbels of white flowers in early summer. Among foreign Aralias the Asiatic species are perhaps of most importance. Some, notably *A. cordata*, known as Udo, are of value as human food; others as stock food when grasses are scarce. *A. chinensis*, Chinese angelica tree, is much like its American relative, *A. spinosa*, but is hardier and blossoms somewhat later.

ARAMÆANS, a branch of the Semites, who dwelt in the districts comprised in the Syria of the ancient Greeks, and in Mesopotamia. Their language spread to the neighboring peoples and this fact often renders it difficult to determine the precise limits inhabited by the true Aramaic stock. Their original home is unknown. It is now generally held that the Aramæans moved from northeast Arabia into Syria, Mesopotamia, Assyria, Babylonia and beyond the Tigris about 1500 B.C. They spread the knowledge of the alphabet and exercised a great influence on the advance of civilization. Consult 'Aram' in 'Encyclopædia Biblica' (1899); Meyer, Eduard, 'Die Israelitien' (1906); Schiffer, Sina, 'Die Aramäer' (1911). See SEMITES.

ARAMAIC LANGUAGE. Among the Semitic languages, which are variously grouped as Northern or Assyrian, Central or Aramaic, Western or Canaanite, Southern or Arabic and Ethiopic, according to Wright, or as East Semitic, that is Babylonian and Assyrian, and West Semitic, Aramaic, Canaanite, Arabic, Ethiopic, which is Zimmern's broader and more historical division, the Aramaic has many elements of distinction and covers a long range of centuries. It includes monuments of literature as well as the literature of monuments. While of its original home nothing definite is known, at an early date Aramaic appears in the Old Testament to designate certain districts in Syria ("Aram of Damascus") and in Mesopotamia ("Aram of the Two Rivers"). A number of Aramaisms in the vocabulary of the older Biblical books shows the close relationship between Hebrew and Aramaic, although the latter was considered by the Hebrews a foreign tongue and 100 years before the Babylonian Exile was understood in Jerusalem only by people of culture, a fact proved by the episode in 2 Kings xviii, 26; Isaiah xxxvi,

11. Centuries earlier kinship was illustrated by genealogical tablets and primitive narratives, as for instance, when Kemuel, a son of Nahor, the brother of Abraham, is called "father of Aram" (Gen. xxii, 21). Jacob is termed "A wandering Aramæan" (Deut. xxvi, 5). During the entire period of the Kings, Israel and the Aramæans of the west, whose land was later called Syria and lies north and northeast of Palestine, were in steady intercourse. By a curious fate, Aramaic was to supplant Hebrew, after national decline, as the vernacular and acquire a prominent rank, with the adoption of Aramaized Hebrew forms, as the literary language of the Jews for many centuries in the lands of their dispersion. Before Palestine was Aramaized the language spread gradually and occupied all Syria. It was spoken in the Euphrates toward the east and throughout the districts of the Tigris north and west of the Armenian and Kurdish mountains. "The country of the Aramæans" was the name applied to the province in which the capitals of the Arsacids and the Sassanids were situated. We know, too, that although Assyrian was the language of the government, at a very early date a large body of the people in Babylonia and Assyria were probably Aramæans.

Dialects.—Owing to the rapid spread of the Aramæans, their language received varied development both in grammatical form and idiom as well as in its literary development. Among its chief dialects may be mentioned the Syriac of northern Mesopotamia, in particular the district around Edessa, and it flourished as a literary language from the 2d to the 13th century. Then the Aramaic, as commonly known, includes besides two words in Genesis (xxxii, 47) and a verse in Jeremiah (x, 2), as its oldest remains in the branch passages in Ezra (iv, 8; vii, 8; vii, 12, 26) dating from the end of the 6th or beginning of the 5th century B.C. Next come the portions of the book of Daniel, whose exact date is still a matter of doubt. A much more extensive monument is the Targum literature, which in Onkelos and Jonathan differ little from Biblical Aramaic. To this must be added Talmud and Midrash, which contain much Hebrew as well as Aramaic. The Aramaic portions of both Talmuds (Babylonian, completed at end of 5th century, and Palestinian, completed in beginning of 5th) are of great value. The Aramaic literature of the Jews includes as well certain portions of the Apocrypha, legal decisions of the Geonim, rabbinical authorities in the early centuries of the Diaspora, when Aramaic at first was the vernacular; liturgical selections, the book Zohar, famous in the Cabala, together with a large part of rabbinical literature. Further must be added the dialect of the Samaritans, exemplified in their Targum of the Pentateuch, their liturgy and hymns; Egyptian Aramaic; the Nabatean and Palmyrene of the inscriptions. There is also to be mentioned the dialect retained for some time by the Christians of Palestine as a literary and ecclesiastical language and in which appear Gospel translations and fragments of other works dating from about the 5th century. The language of the Mandæan writings closely resembles that of the Babylonian Talmud. The spread of the Aramaic was effectually checked

in the 7th century by the Arab conquests and it gradually lost its predominance for more than 10 centuries, yielding to a more forceful rival.

Inscriptions.—Some Assyrian weights, which go back to the 7th and 8th century before our era, with some gems and seals of nearly the same age, furnish the oldest data as to the Aramaic alphabet. In the field of inscriptions the material is richer; the most ancient include the colossal statue of the god Hadad, found in 1890 near Zenjirli, in northwest Syria, from the first half of the 8th century B.C. with other writings in that vicinity of a slightly later date, and two inscriptions found in 1891 at Nerab, near Aleppo, alleged by Cl. Ganneau to belong to the 6th century B.C. Some Aramaic inscriptions have been found in Egypt, of the Persian period, one bearing the date of the year of Xerxes, 482 B.C. A few ancient Aramaic inscriptions have been found in Arabia, at Tema, probably from the 5th century B.C. Within recent decades valuable data have come to light from the 4th century, bearing upon Jewish military colonists and others who came to Egypt—the Judæo-Aramaic papyri are likely to be supplemented in time. Of special interest by reason of their number and contents are the Palmyrene inscriptions, votive, honorary, sepulchral, etc., which began shortly before the Christian era, and extend to about the middle of the 3d century, as well as the Nabatean, whose kingdom was centred at Petra, in northern Arabia, and who were Arabs, but used Aramaic for writing and commerce. It was finally absorbed by Rome in 106 A.D. To this class belong the Sinaitic inscriptions, written in Nabatean dialect and script and dating from the first four centuries A.D. They were found along trade routes in out-of-the-way valleys. Their number can be gathered from the fact that Euting has recorded 677 in his standard collection (1891). This fact would indicate the extent of Aramaic influence.

Characteristica.—Nöldeke denies any poverty in Aramaic, as has been asserted, and claims that, despite its larger borrowings from foreign languages, the proportion of really foreign words in older Aramaic writings is smaller than the proportion of Romance words in German or Dutch. With its special treatment of dentals, it is poorer in vowels than Hebrew. It is rich, however, in conjunctions and adverbs, thus enabling it to express slight changes in meaning, and permits much freedom in the order of words, becoming rather diffuse as well in its use of additional pronouns. One peculiarity may be mentioned; in the western dialect the prefix of the third person of the imperfect is *y odh*; in Syriac, with changes in other of the eastern dialects, it is *nu*.

ABRAM S. ISAACS,

Professor of Semitic Languages, New York University.

ARAN ISLANDS, or **SOUTH ARAN**, Ireland, three islands situated on the west coast

at the entrance of Galway Bay, to which they form a natural breakwater. They lie in a southeasterly direction. Beginning with the northernmost they are called respectively Inishmore or Great Island; Inishmaan or Middle Island; and Inishiar or Eastern Island. The highest elevation is 354 feet. The islands are formed of carboniferous limestone, and the soil is very sandy, affording scant pasturage and yields little to cultivation. The total area of the islands is about 11,500 acres. The inhabitants are perhaps the most primitive people of Europe in their mode of life and thought. Gaelic is the common tongue, although English is understood fairly well on Inishmore. Here may still be seen a curious intermingling of Christian and Druidic worship. The main industries are fishing and kelp-burning. There is steamer communication with Galway, 30 miles distant. The population in 1911 was 2,679. These islands are remarkable for a number of architectural remains of early date. On Inishmore, on a cliff 220 feet high, stand the remains of a circular cyclopean fortress called Dun Aengus; its *chevaux de frise* is still to be seen. It is ascribed to the 1st century of our era. Inishmore is often called *Ara na Naomh*, Aran-of-the-Saints, from the numbers of religious recluses who dwelt here soon after the introduction of Christianity in the 5th century. Here too are the remains of the abbey of Saint Enda, the patron of the islands. The chief town is Kilronan, on Inishmore, with a population of 460. In recent years the islands have been the hunting ground for philologists, linguists, artists, etc., who find here open chapters in the history of the race which have been long since closed elsewhere. The islands were a favorite resort of the late John Millington Synge, the Irish playwright, who made them the scene of his drama 'Riders to the Sea,' and has recorded his impressions of the islands and their inhabitants in 'The Aran Islands' (Dublin 1903).

ARANSAS, *ā-rān'zās*, **BAY**, an inlet on the coast of Texas, connected with the Gulf of Mexico by a channel known as Aransas Pass. A bar at its mouth renders its harbor of very little commercial importance, in spite of the money lavished in various attempts to establish there a harbor and port of entry. During the Civil War it was the scene of a conflict between the Confederate and Federal troops.

ARANSAS PASS. See **ARANSAS BAY**.

ARANY, *ó-róny*, **János**, Hungarian poet: b. Nagy-Szalonta, 1 March 1817; d. Pesth, 22 Oct. 1882. He was of humble parentage; his parents were very poor, but they made every effort to give him an education. At 15 he entered the college of Debreczin, where he distinguished himself. He was attracted to the stage, joined a company of strolling players, but soon returned discouraged to his father's house. He became a notary and lived in retirement for several years. In 1845 he published the satirical epic 'Az elveszett alkotmány,' which won a prize for the most humorous poem offered by the Kisfaludy Society of Pesth. Two years later he was awarded a second prize for the first part of 'Toldi,' his great trilogy founded upon Magyar traditions. This work brought him a widespread popularity both among the learned and among the

lowest ranks of the people, who recognized his gift of weaving their traditional legends and his appeal to the spirit of national pride so characteristic of the Magyar peoples. In 1860 he became director and afterward secretary of the Kisfaludy Society, and in 1870 he was appointed general secretary of the Hungarian Academy of Science. His more noteworthy works are 'Murány ostroma'; 'King Buda's Death,' an epic in 12 cantos; 'Toldi's Love' and 'Toldi's Evening,' the second and third parts of the Toldi trilogy. Arany is regarded as, next to Petöfi, the greatest of modern Hungarian poets; the one who raised Hungarian poetry to its greatest height. His work is noted for its artistic finish and its happy combination of the spirit of old Magyar folklore with the classic polish of a master. His works have been translated several times into German, among others, by Kertbeny (Leipzig 1851); Kórodi, L., (Kronstadt 1863); Dux (Pesth 1861); and Spöner (Leipzig 1880).

ARARAT, or PILOT MOUNTAIN, an American mountain about 3,000 feet in height, in Surrey County, N. C. It is situated between the Ararat and Dan rivers and is visible for a long distance.

ARAS, a-räs, a river of Armenia, rising in the Turkish pashalic of Erzerum. After flowing for some miles through Turkish territory to the new Russian frontier, it turns eastward to the Ervian plain north of Ararat, whence it sweeps in a semi-circle mostly between the Russian and Persian territories to its confluence with the Kur, 60 miles from its mouth in the Caspian Sea. Its entire course is about 500 miles. Modern research has discovered that it originally flowed directly into the Caspian Sea, as ancient writers had claimed. It is identical with the ancient Araxes.

ARAUCANA, ä'rou-kä'ne-a, LA, the famous "epopeya," as it is called by Chilean scholars, written by D. Alonso de Ercilla y Zúñiga. It describes, in 37 cantos, the conquest of Chile, and takes rank as the finest heroic poem in the Spanish language. Further, as Señor Medina writes in his preface to the recent edition (Santiago de Chile 1910), of which he is both editor and publisher, Chile's good fortune, unique in modern times, is most remarkable in this respect, that its *origines* (he might have added *aborigines*) have been immortalized by the most notable epopeya of Castilian literature. Ercilla, who was born in Madrid, 7 Aug. 1533, came to the New World in his 21st year, and, as a soldier, shared the adventurous life of the Spanish conquerors or their successors in South America's far south for eight years, more or less. After returning to Spain (in 1562) he completed the 'Araucana,' the composition of which he had begun in Chile. We shall not at present discuss the editions; it is enough in this brief note to say that the edition of Madrid (1589-90) was in its day truly definitive, inasmuch as it was undoubtedly printed under the immediate inspection of the poet—the last edition, indeed, to receive his personal attention. It is known that Ercilla died at Madrid; the date is given conjecturally as 29 Nov. 1595. See CHILE.

ARAUCANIANS, ä'row-kä'ne-ans, a South American native race in the southern

part of Chile, formerly occupying Chile, Argentina, Chiloe and the Chonos Archipelago, etc. When first encountered by the Spaniards in 1535 they were a confederacy of the loosest kind, with many tribes and sub-tribes in entire independence, and in about the same political stage as the North American Indians, electing a *toqui* or war-chief and deposing him at will, with no authoritative head in peace, practising polygamy, and for worship conciliating an evil spirit, Quecubu,—probably the same as the Fuegian spirit immortalized by Shakespeare as "Setebos," the shape given it by Magellan's sailors. They were divided into Picun-che or North-men, living north of the river Maule; Pehuen-che or Pine-men, occupying through central Chile and the pine forests on the western slopes of the Andes (the chief division of the tribe, and from whom most of the modern Araucanians are descended); Huilli-che or South-men, occupying the rest of the Chilean mainland; Puel-che or East-men; South-men or Patagonians; Chono; Lubu-che or Watermen; Cuncho; Payo, etc. But their instant and indomitable cohesion in face of the Spanish attack shows that they were of much higher political stamp than the North Americans. No other native race in the western hemisphere retained its independence anything like as long. For over two centuries they waged warfare with the Spaniards, broken only by truces sought by the latter, though their numbers were small compared with Aztecs or Quichuas, who went down at a blow. Ercilla's famous epic 'Araucana' (q.v.) commemorates their early heroism and that of their powerful chief, Cautopolican. In 1641 Spain conceded their independence, confirming it in 1655, imposing only the condition that no enemies of Spain should be allowed to enter their country; an easy condition, as it amounted only to keeping out all foreigners, which they were glad to do. The territory left them was about 30,000 square miles, from the Andes to the sea, and from Arauco Bay to the river Calle-Calle. The war was renewed nevertheless, and went on a century and a third longer; till in 1773 the natives, weakened by war and social practices, were compelled to submit. They had not lost the memory of their past, however, and in 1861 a French adventurer named Antoine Tounens, originally a provincial lawyer, had himself elected king of Araucania as Orélie Antoine I; but the Chilean government conquered and deposed him and sent him back to France. In 1870 the Araucanians recognized the sovereignty of Chile. Araucania occupies a great part of the province of Arauco in south Chile, and is divided into four parallel north-and-south districts, each formerly governed by a *toqui* whose rule had become hereditary before its extinction. The inhabitants are now a mixed race with much Spanish blood. They number perhaps about 50,000, but are said to be decreasing, owing to smallpox, dysentery, liquors and polygamy. They are of a pale yellow color, and in character and life resemble the higher North American plains Indians, such as the Navajos. They are uncivilizable and unchristianized; nomad herdsmen of horses, cattle and sheep; despising agriculture, eating little but meat, and living in skin tents; but skillful wool-weavers, skin-dressers and weapon-makers. Their language is so harmonious and flexible

that an enthusiastic missionary student once attempted to introduce it into Europe to supersede Latin. Their stock in Chiloe are called Chilotes.

ARAUCARIALES, a greater group of coniferous trees, once of cosmopolitan distribution, but now restricted to two genera, *Araucaria* and *Dammara*, both of the southern hemisphere. The name is derived from Araucania or Arauco, the district of southern Chile where the superb form *Araucaria imbricata* of the Nahuel Butte mountains and upper Biobio valley was early observed (1786). The seeds of large size formed an important food of the indigenous Araucanian Indians.

Araucaria imbricata, the Chile pine, Pehuén or "monkey puzzle" is the hardest forest-maker of its order. The Andine forest occupies the higher volcanic ridges and crests along both flanks from lat. 37° 30' to 40° S. with a width of little more than 100 kilometres, between the altitudes of 600 and 2,000 metres. On the Chilean side there is a heavy snowfall. According to altitude, and to exposure which is greater in the Argentine extension, the trees vary much in size; but they may grow straight as a granite column to an extreme height of 45 metres and diameter of two or more metres. Both stem and branches of the young trees are closely beset by the imbricating spirals of broadly spinose leaves, as persistent as those of cycads. The stem tends to retain a nearly constant diameter throughout its length as the irregular whorls of lesser lateral branches are constantly shed and overgrown. Only a thick-set crown finally surmounts the heavy columnar trunk. After excision of the leaves the outer bark slowly divides into irregularly polygonal deeply-pitted plates. The appearance of the trees is singular, that of the pure stand forests remarkable. Like most other members of the Araucariales these trees are characteristically dioecious. The staminate cones are larger than in any of the Coniferales, having the size seen in some of the cycads. They are oval, 10 or more centimetres long, by 5 centimetres thick, and borne terminally in groups of four or five in the lateral branches. Ovulate cones are terminal on the lateral branches and may reach a length of 16 centimetres with a diameter of 20. There is a more gradual transition from foliage to fertile leaves than in any other existing gymnosperm. The megasporophyll bears a single large dicotyle-donous seed four or more centimetres long. The wood is rather hard, smooth and durable; but the forests, owing to their isolated position, retain nearly their primæval facies. In Chile lofty hardwood forests with a dense undergrowth of bamboo give way to the Araucarias. These then extend to the tree line as a more and more open forest. As seen about Llaima and other volcanoes of the Biobio, the sharp transition to grassy slopes, often ending in more or less permanent snow fields, produces a rarely picturesque effect. Rather the purest stands occur on the Argentine side of the Andes in the lake region between lat. 38° and 40° S. Lago Alumíné and other lakes where the trees are abundant have their North American counterparts in the Cascade Mountains south of the heavier coniferous forests and next the dry interior Washington basin. Lake Chelan is

one of these physiographic equivalents with like climate and soil. Trees a half metre in diameter with an age of possibly 100 years prove the successful introduction into California.

Araucaria brasiliana, the Brazil pine, a closely related more sub-tropical species, is a culminating forest constituent of the uplands of southern Brazil, mainly between 25° and 30°. Especially in the state of Santa Catarina, to the south of the Iguassu River, this tree dominates a remarkable stratified columnar facies. There the open forest is about equally made up of tree ferns three to five metres in height, slender-stemmed palms 10 metres high and the over-topping pines 20 to 30 metres in height. Some outliers of this imposing forest occur further north in the state of Minas Geraes. At Cobijan in the mountains of south-eastern Bolivia (lat. 21° S.) there is also a small area of *A. brasiliana* or a closely related form (*A. saviana*).

Other species with large leaves are *Araucaria Bidwillii*, the Bunya Bunya of Queensland, and *A. Hunsteinii* of Kaiser Wilhelm's Land. The remainder of the Australo-Malayan species are small and narrow-leaved, but lofty forms. They centre in New Caledonia with *A. Cookii*, *A. Balansa*, *A. montana*, *A. Muellieri* and *A. Rulei*. The two latter have staminate cones of unusual length (24 to 25 centimetres). The majestic *Araucaria excelsa*, or Norfolk Island pine, was discovered by Captain Cook, who says that on nearing Norfolk Island the stems were taken for basaltic columns! This species attains a height of over 200 feet. The cone scales are winged with a hooked apex. The half-hardy young plants are widely grown in conservatories. *Araucaria Cunninghamii*, the Moreton Bay pine, is the most widely spread of the Australian species, extending to Cape York and New Guinea.

The genus *Dammara* (dām'-à-rà) is continental only in Queensland (*D. robusta*, *D. Palmerstoni*) and the Malay Peninsula (*D. loranthifolia*). It is essentially a Malaysian island type. *D. obtusa* occurs in New Hebrides, *D. Moorei* is New Caledonian and *D. Vitiensis* Fijian. *D. macrophylla*, with the largest leaves of all (17 centimetres long by five broad), is a native of the Queen Charlotte Islands. One of the best-known species is the Amboyna pitch pine, *D. orientalis*, found also in Java, Sumatra, Borneo and other eastern islands. The highly aromatic gum of this tree, called by Amboyna islanders "Dammarr puti," gives its name to the genus. The Kauri pine (or *Kowrie*), *Dammara australis* of New Zealand, abundant in the North Island between the North Cape and lat. 38° S., is perhaps the most striking species. The finest forest tree of New Zealand, it often reaches a height of 30 metres and thickness of three metres. But columnar forms with bushy heads may reach 50 metres high by five to seven metres in diameter. Darwin says ("Voyage of the Beagle"), "The crown of branches at the summit is out of all proportion small to the trunk; and the leaves are likewise small compared with the branches." The bark is thick and resiniferous. As in the other Dammarran forms the leaves are narrow-based with a broad lamina and much like those of cycads; they are

four to five centimetres long by one centimetre broad, thick, leathery and persistent. The seed cones are spherical and five to eight centimetres in diameter, or much smaller than in *Araucaria*. The rich brown amber yellow Kauri gum or resin is abundant in the sites

strength, durability and easy working; lumbering and destructive fires are fast limiting the forests.

Fossil Record.—The geological history of the Araucariales is long. Owing to the resemblance of the wood to that of Cordaitaleans

FIG. 3.—*Araucaria Braziliiana*. Left above, staminate, right above, young ovulate cones. Right below, mature ovulate cone. *a a'* and *b b'*, side and front views respectively of micro- and megasporophyll; *c c'*, cone scale; *d*, cone scale showing seed. All figures about half size, except *a a'*, which is enlarged.

of previous forests in lumps reaching the size of the largest Araucarian cones. The properties are similar to that of the "cat's eye" or Dammar of *D. orientalis*. This gum oozes from the tree in large quantities in a soft, viscous state. The timber is notable for

it is difficult to prove which of the so-called *Araucarioxylon* types, so abundant in the Palæozoic, are directly related to the modern forms; but from the Rhætic on, the presence of Araucariales closely related to those of today is well attested. Hollick and Jeffrey de-

ARAUCARIALES

Fig. 1 — *Araucaria imbricata*, pure stand forest of the Chali, Argentina. (Observe the young plants, some springing from roots)

Fig. 2 — *Araucaria imbricata*, pure stand forest of the Chali, Argentina, at upper limit of two thousand meters or over

scribe various forms from the Cretaceous of Staten and Long Island. A fine cone called *Araucaria hespera* occurs with the horned dinosaurs of the Laramie, also a branch (*A. Hatcheri*) closely related to the Brazil pine. Araucarian types had a wide distribution in the climax forests of both the northern and southern hemispheres during all of the Jurassic, and appear to culminate in the Cretaceous. Toward the close of the Cretaceous they ceased to play a greater rôle as forest dominants and began a retreat or restriction which lasted throughout Tertiary time, and ended in the scant distribution outlined above. Geologically speaking the Araucariales are very slowly moving toward extinction.

Relationships.—The origin of the Araucariales, and their relationships to other gymnospermous groups, are uncertain. Neither systematists nor morphologists are here in accord. Every possible hypothesis of descent has been suggested. It is urged (1) that the Araucariales sprang from Cycadoflicaleans direct, (2) that they are of Cordaitan origin, (3) that they are Lycopodiaceous derivatives, (4) that the Abietinæ are the oldest conifers and Araucarians a modern offshoot from them. (I) The possibility of Cycadoflicalean origin is much strengthened by recent investigations of the Cycadeoids. It is now seen that *Araucaria* has much in common with both Cycads and Cycadeoids: the robust armored stem is analogous to that of the Cycadeoids, this being true of structure, cortical development and both the major and minor branching; the roots freely send up young plants, and seedlings are stout and tenacious of life; the renewed growth of the reproductive shoot from a lateral bud is cycadaceous and cycadeoid; the large pith and thin, woody cylinder of the shoots, vegetative and reproductive, and the complete transition from foliage to fertile scales of the large cones are also cycad-like; while the megasporophyll with its small ligule finds a counterpart in the decurved microsporophyll of the Cycadeoids. Finally the presence of a leaf gap opposite the outgoing foliar trace, not only in the cone, but in stem and seedling, is also a Pteropsid feature and not lycopodiaceous. (II) Relationship to the Cordaitales is found in the retention of pitting of the tracheids in different regions of the plant recognized as primitive. Especially in the cone the pitting may be as much as five-seriate, with the pits alternate, hexagonal and extending from end to end of the tracheid. As in Cordaitans, too, the medullary ray cells are thin-walled and less specialized than in the pines. The resin tissue of the secondary wood consists simply in resinous tracheids associated with the medullary rays, and of parenchyma derived from tracheary tissue. Stem and leaf morphology, as well as habitus, suggest Cordaitan affinity. (III) In defense of a lycopodiaceous derivation it is pointed out that *Cheirostrobos* serves to bridge the gap between the male sporophylls of *Araucaria* and the Lycopods; that *Lepidocarpon*, which is outwardly a seed, is the link between the Araucarian seed and the Lycopod sporangium; that lycopodiaceous wood with its scalariform pitting does not fundamentally differ from Araucarian wood; that transitions between the pitted and scalariform sculpturing of

the radial tracheidal wall occur in various plants recent and extinct. (IV) The theory of an Abietinean ancestry depends on certain traumatic "revivals," and on the Cretaceous occurrence of Abietineans (*Prepinus*) with leaf bundles possessing centripetal wood like those of *Cordaites*. Even more than the preceding views of relationship and descent, this latter theory requires rigid examination in the light of the fossil record and all the evidence it may be made to yield. It has been suggested that all the forms discussed have been discrete since Palæozoic time.

Bibliography.—Complete references to the literature bearing on the Araucariales will be found appended to the following five major contributions: 'Plant Succession,' an analysis of the development of vegetation, by Frederic E. Clements (Carnegie Institution of Washington Pub. No. 242, 1916); 'Cretaceous Coniferous Remains from Kreischerville, N. Y.,' by Arthur Hollick and E. C. Jeffrey, Mem. New York Bot. Garden (Vol. III, 1909); 'The Araucariæ, Recent and Extinct,' by A. C. Seward and Sibille O. Ford (Phil. Trans. Roy. Soc. London, Series B, Vol. 198, 1906); 'On the Comparative Anatomy and Affinities of the Araucarinæ,' by Robert Boyd Thomson (Phil. Trans. Roy. Soc. London, Series B, Vol. 204, 1912); 'American Fossil Cycads,' by G. R. Wieland (Carnegie Institution of Washington Pub. No. 34, Vol. I, 1906; Vol. II, 1916).

GEORGE R. WIELAND,

Lecturer in Paleontology, Yale University.

ARAUCO, a-ro'kō, a province of Chile with an area of 2,457 square miles. It is bounded by the provinces of Concepción, Biobío, Malleco and Cautín, forming but a strip along the Pacific coast. The inhabitants number about 62,500 or 63,000 (1916). The capital is Lebu, with population of 3,500.

ARAÚJO DE AZEVEDO, a-row'zhō dā ä-zā-vā'do, Portuguese statesman: b. Sa, 1754; d. Rio de Janeiro, 1817. In 1789 he became Ambassador at The Hague and in 1797 negotiated a treaty in Paris which the Directory refused to ratify. Soon afterward he was appointed Ambassador in Berlin and later to a similar post at Saint Petersburg. He became Minister of Foreign Affairs in 1803, but on the capture of Lisbon by Napoleon in 1807 accompanied the King to Brazil. At Rio de Janeiro he founded schools of fine arts and medicine, introduced the tea culture into Brazil and was an active patron of agriculture and other industries. In 1815 he was created Count of Barca. His literary pretensions were not inconsiderable. He wrote two tragedies, and translations from Horace, Gray and Dryden.

ARAÚJO PORTO-ALEGRE, a-row'zhō pōr'tō-a-lā'grā, Manoel de, Brazilian poet and architect: b. Rio Pardo, 1806; d. 1879. He studied art at Rio de Janeiro and studied architecture and art in Paris and Italy and became professor at the Academy of Art in Rio de Janeiro. In 1859 he was appointed Consul-General at Stettin. He not only designed several important buildings in Rio de Janeiro, but was the author of several comedies, of 'Colombo,' an epic, and 'Brasilianas,' a collection of poems (1863).

ARAUNA, ä'ra-oo'nā, the name of a South American tribe of Tacanan stock, whose

home is on the borders of Peru and Bolivia, regarding whose appearance and customs travelers differ widely. According to some accounts they are naked and ill-formed cannibals, while according to others they are light-colored, mild-mannered agriculturists. Another account states that they have temples with idols of wood and stone and exclude women from all religious rites. See TACANA.

ARAURE, ă-row'rá, Venezuela, a town in the state of Lara, 20 miles south of Barquisimeto, the centre of a fertile region producing coffee, cotton and cattle. The battle of Araure took place near here, 4 Dec. 1813. Pop. 4,000.

ARAVULLI, ăr'ă-vul'le or **ARAVALLI**, a mountain range in Hindustan about 300 miles in length and a width varying from 10 to 60 miles from lat. 22° 40' N. to lat. 26° 50' N. Its river system is extensive, but the valleys enclosed within the range are mainly sterile. The vegetation is poor.

ARAWAKAN, ă-ra-wă'kan, **STOCK** (from the Arawaks, q.v.), the most widely diffused linguistic stock of South America, and originally forming a curious and significant link between the South and North American regional if not philological stocks. Their habitat reached from Bolivia and southern Brazil not only to the northern coast of Venezuela, but — while barred to the westward by the Colombian Chibchas or Mucayas of the Magdalena basin — occupied the entire West Indies and had an outlier of several villages in Florida. Just before Columbus' discovery, however, they had been expelled from the southern Antilles and part of the adjoining South American coast by the fierce Caribs (q.v.) from the lower Orinoco, who had seized their women for wives, most of the latter still speaking Arawak when the Spaniards found them. The larger Antilles were still Arawak, and the names given in the early West India voyages are intelligible in this set of languages yet. The Arawakans have neither the energy and cohesiveness of the Araucans, the splendid physique and fiery vigor of the Caribs, nor the political development of the Quichuas in the past; they are below the medium stature, and of no great stamina. Yet they had, perhaps owing to this very lack of savage vigor, an intellectual and artistic development and a stage of culture above the surrounding tribes: they made fictile vases decorated with grotesques of men and animals, were skilled artisans in stone, gold and wood and excellent weavers; and the island Arawakans cultivated not only corn and manioc for food, but cotton and tobacco, whose use the Europeans took from them. There are probably a hundred or more different tribes of this stock scattered through Brazil, Bolivia, the Guianas, Venezuela and Colombia. Among the chief, besides those mentioned below under Arawaks, are the Manaos near that city, at the junction of the Amazon and Negro; the Waupes, Maipures and Miranhas, in the extreme west of Brazil next to Colombia, on the llamos between the Negro and Amazon; the Goajiros on that peninsula west of the Gulf of Venezuela; the Piaroas on the Orinoco near its junction with the Meta; the Maneteneris in the north-west angle of Bolivia; the Baures and the Moxos or Mojos in northeast Bolivia, next Matto Grosso; and the Antas in extreme south

Brazil, near Uruguay. Beuchat and Rivet within recent years have in their studies sought to extend the original territory occupied by the Arawakan stock. Consult recent works of Beuchat and Rivet, Chamberlain, Koch-Grünberg, Schmidt, especially Koch-Grünberg's 'Die Aruak-Sprachen Nordwestbrasilens' (Vienna 1911).

ARAWAKS, ă'ra-wăks (name most improbably defined 'meal-eaters' — that is, of cassava bread — from a Tupi word: not more descriptive of them now than the Tupis or any other South American race except the Araucanians, and they hunt and fish as well as raise corn and manioc. Their own name is Lokono or Lukkunu, "men": cf. the names Illinois, Inuit, Alemanni, etc.), a tribe of South American Indians living on the coast of British and Dutch Guiana, across the Corentyne and Berbice rivers, and taken as the type of the great Arawakan stock (above). They are not pure-blooded, however, being mixed with Caribs, etc., in a conglomerate of plantation laborers. The term is also used in a broader sense to include all the tribes of this stock in British Guiana and the neighboring corner of Brazil, with the extension noted into Dutch Guiana: Tarumas and Atoradis of the upper Essequibo basin, Wapisianas of the upper Rio Branco in Brazil, etc., as well as Arawaks proper. All these are in a very primitive stage of culture, making marriages by abduction after orgies on corn spirits, counting descent through females, having the clan system, and practising the couvade (q.v.). The Atoradis are almost white, or not duskier than South Europeans, with fine figures, especially the women having much beauty and dignity of appearance. The Wapisianas are browner and less graceful, but their language is so soft, sonorous and vocalic that it is the general medium of communication for trade and other intercourses among all the tribes in this region, even the Caribs; and the Atoradis have nearly abandoned their own for it.

ARAXES. See ARAS.

ARAYAT, ă-rî'at, Philippines, town on the island of Luzon, province of Pampanga, 12 miles north of Bacolor, occupied by the American army under General Young 12 Oct. 1899. Nearby is an extinct volcanic cone, 3,564 feet high. Pop. 12,904.

ARBACES, a Median general under Sardanapalus and the founder of the Median empire in 876 B.C. The dynasty founded by Arbaces lasted till its overthrow by Cyrus, 559 B.C.

ARBALEST. See CROSS-BOW.

ARBELA, now **ARBEEL**, a small town in Asiatic Turkey which gave its name to a decisive battle fought by Alexander the Great against Darius at Gaugamela, about 20 miles distant from it, 1 Oct. 331 B.C. There are several large mosques in the modern town. Pop. about 6,000.

ARBER, Edward, English scholar: b. 1836; d. London, 23 Nov. 1912. He was professor of English literature at the University of Birmingham, 1881-94. Mainly self-educated, he became a clerk in the Admiralty, studied English literature in his spare time and undertook the editing and republication of many English books and tracts of the 16th and 17th

centuries, beginning in 1868 with Milton's 'Areopagitica.' He was knocked down and killed in the street by a taxicab. His best-known editions are 'English Reprints' (1868-80); 'Tyndale's New Testament of 1525' (1871); 'A Transcript of the Registers of the Company of the Stationers at London' (1875-94); 'An English Garner' (1877-96); 'An English Scholar's Library' (1878-84); 'The First Three English Books on America' (1885); 'The Story of the Pilgrim Fathers, 1606-23' (1897) 'British Anthologies' (1899-1901); 'The Term Catalogues' (1904-06).

ARBITRATION, History of in the United States. See UNITED STATES — ARBITRATION.

ARBITRATION, Industrial. This is the process by which an authoritative decision is obtained in the case of a controversy arising between one or more employers and a group of employees, or between two or more groups of employees, when such controversy cannot be settled by direct negotiations between the parties concerned. In such cases it is customary to refer the questions at issue to one or more persons, called "arbitrators," who are appointed to investigate the facts and to render a "decision" or "award." Conciliation and mediation are less formal methods of settling industrial disputes, and consist merely of endeavors on the part of some person or group of persons, not a party to the dispute, to promote amicable negotiations between the disputants, which may lead, either to an immediate settlement, or to an agreement to submit the matter in question to arbitration.

Statutory provision for the formation of permanent official or semi-official boards of arbitration is made in many countries and smaller political subdivisions. In some instances the submission of matters in controversy is compulsory, but more often it is provided that upon application of one or both of the parties the board shall provide for the holding of hearings, at which testimony is taken, and following which the board shall render an award. Where arbitration is voluntary, it is customary for both parties to enter into a formal agreement to abide by the decision of the arbitrators.

In the settlement of controversies with reference to wages, hours of labor and general conditions of employment, voluntary arbitration has proved very effective, and in many instances disastrous strikes and lockouts have been averted or brought to an end by this means; but where questions of principle or general policy, such as recognition of the union, exclusive employment of union labor, use of union label, etc., are involved, the parties frequently decline to voluntarily submit the question at issue to arbitration, when, therefore, it becomes necessary for public authorities in the interest of public welfare to insist that the matter be so submitted. Such compulsory arbitration may be limited merely to the reference of the dispute to arbitrators for investigation, during which period hostilities shall be suspended, as in Canada; or, in addition to such reference, the arbitrators may be empowered to compel the attendance of witnesses and the production of papers, as in Germany; or it may be even further provided, as

in New Zealand and other Australian states, that the disputants shall be compelled by law to abide by the decision of the arbitrators, under specific penalty for non-observance of the terms of the award.

In the following paragraphs several important systems of industrial arbitration provided for by law are briefly described. Purely unofficial boards of arbitrators, most of which are formed merely in connection with a single controversy, are not, because of the great variety of such boards, included within the scope of this article.

France.—The first definite provision for the settlement of industrial disputes appears to have been the tribunal established before the French Revolution at Lyons, France, for the settlement of disputes in the silk industry. Although this tribunal was abolished with the trade guilds in 1791, it had proved so effective that, in 1806, Napoleon created the councils of experts (*Conseils des Prud'hommes*) having quite similar functions. The councils, at first established in only a few cities, are now found in all of the important industrial centres in France, and similar councils have been established in other countries. For many years these councils considered only controversies between employers and individual employees, and it was not until the passage of the Conciliation and Arbitration Act in 1892 that provision was made for the settlement of collective disputes, that is, disputes between one or more employers and a group of employees. To the extent that application has been made for the settlement of industrial disputes under the provisions of this act, its operation has been fairly successful; but unfortunately only minor matters are thus referred for settlement, and it does not appear that the act has, to any great extent, served to prevent strikes and lockouts, which during very recent years have been both numerous and important.

Germany.—Industrial courts having jurisdiction in the manufacturing industries (*Gewerbegerichte*) had been established in various localities in Germany since the first quarter of the 19th century, and previous to 1869 three states—Prussia, Saxony and Saxe-Weimar—had passed laws providing for the establishment of such courts. By a provision of the industrial code of 1869 local authorities were authorized to establish such courts, provided employers and employees were equally represented thereon. In 1890 an imperial act was passed establishing uniform regulations governing the form and procedure of the local courts and extending their functions so as to provide for the arbitration of collective disputes. An act passed in 1901 amended in certain important particulars the act of 1890, especially with reference to the settlement of collective disputes, which prior to that date had not been arbitrated with any large measure of success. The act of 1901 authorized the courts to act on their own initiative without waiting for either party to the dispute to make application for its services, and provided that the arbitrators should be appointed by the parties concerned in the controversy. The appearance of the parties to the dispute was made compulsory and a penalty was provided for non-attendance. When both parties ask for

arbitration the court then ceases to be a board of conciliation and becomes a board of arbitration; and if only one party makes application it is the president's duty to urge arbitration upon the other party. Decisions in cases of arbitrations are rendered by a majority of the arbitrators, but the president may abstain from voting in case of tie. The acceptance of the decision is not compulsory except when both parties have previously agreed to abide by the award. The act of 1901 further provided for the compulsory establishment of industrial courts in all cities having a population of over 20,000, and they may be formed elsewhere at the option of the state or upon joint application of employers and wage earners. In 1904 mercantile courts (*Kaufmannsgerichte*) for the settlement of disputes between merchants and their employees were established. Although the records for recent years show that there has been a growing disposition to refer industrial disputes to the courts, nevertheless the number of disputes thus referred has constituted only a very small percentage of the total number arising.

Great Britain.—Several important acts with reference to the settlement of industrial disputes by conciliation or arbitration were passed in Great Britain during the 19th century, among which may be mentioned the Consolidation Act of 1824, the Conciliation Act of 1867, the Arbitration (Masters and Workmen) Act of 1872 and the Conciliation Act of 1896. Of these four acts, the last named may well be described briefly in this connection. This act provides for the registration of private conciliation or arbitration boards by the British Board of Trade. Registration is optional, but any board so registered is required to "furnish such returns of the proceedings and other documents as the Board of Trade may reasonably require." Should it appear to the Board of Trade that no adequate conciliation board has been established to which may be submitted disputes which might arise in any locality or industry, the board is authorized to inquire into the causes and circumstances and to take such steps as are deemed expedient for the purpose of bringing the parties together with a view to conciliation and, on application of either party, to appoint one or more persons as conciliators, and on application of both parties to appoint an arbitrator. In 1911, following the great railway strike, an Industrial Council was established for the purpose of considering matters referred to it, especially with reference to disputes which would affect the principal trades of the country. The Industrial Council has no compulsory powers. Its primary function appears to be the encouragement of voluntary arbitration and the establishment of rules and regulations governing the procedure of unofficial boards. In 1915 and 1916 acts known as "The Munitions of War Acts," providing for conciliation and arbitration of disputes arising in munition manufacturing industries, were passed, and in making awards under these acts it is held that the rights of employers and employees engaged in these industries may not be exercised as freely as in times of peace, and although parties to the controversies are not compelled to abide by any award, they are called upon and expected, during the continuance

of the war, to forego certain principles, in order that harmonious relationships may be maintained and production continued without interruption. In the settlement of minor disputes the English system appears to have been quite successful, and undoubtedly the number of serious industrial disputes has been somewhat diminished, but a large number of very serious disturbances have arisen notwithstanding the provision which has been made for voluntary arbitration.

New Zealand.—A statute enacted in New Zealand in 1894 provided for the compulsory arbitration of industrial disputes, and several other Australian states have since passed similar measures. An act of this character, passed by the commonwealth in 1914, was made applicable to disputes "extending beyond the boundaries of any one state." Under the provisions of the New Zealand act district boards of conciliation are created, on which board associations of employers and of workmen are equally represented, and an "imperial chairman" is elected by each board. In 1909 the act was amended so as to provide for the appointment of three commissioners of conciliation. When a controversy arises one of these commissioners endeavors to bring about a settlement and, if successful, he organizes a council of conciliation, consisting of two or more representatives of each party, to whom the matter is referred. Should such council fail to effect a settlement of the dispute, it is then referred to the Industrial Court, which consists of three members appointed by the governor for a term of three years, one of whom (the presiding officer) is a judge of the Supreme Court, another a representative of the employers, and another a representative of the employees. Cases also may be referred directly to the court without first having been referred to the council of conciliation. Pending consideration of a dispute by the court, strikes and lockouts are forbidden. The awards of the court are binding upon both parties and penalties are imposed for failure of either party to observe the conditions of the award. The factory inspectors are charged with the enforcement of the awards. For some years, under this system of compulsory arbitration, New Zealand was properly described as "a country without strikes," but during recent years strikes have been wholly prevented in that state, even though rather heavy penalties have been imposed for failure to observe the awards of the court. Some of these controversies, however, which have resulted in open conflict, have not come within the scope of the law.

Canada.—The Conciliation Act, passed by the Canadian Parliament in 1900, followed closely the phraseology of the British Act of 1896, which sought to encourage voluntary arbitration of labor disputes. The Railway Labor Disputes Act, passed in 1903, introduced the principle of compulsory investigation of railway disputes and recognized "the influence of an informed public opinion upon matters of vital concern to the public itself." In 1907, following a serious and protracted strike of coal miners in one of the Western provinces, the Industrial Disputes Investigation Act was passed, which provided for the compulsory investigation of all disputes involving 10 or

more persons employed in mining, or in connection with public service utilities. This act has since been amended so as to include all controversies arising in connection with the manufacture of military supplies. Employers and workmen are required to give at least 30 days' notice of an intended change affecting the conditions of employment with respect to wages and hours, and a strike or lockout is prohibited while the matters in dispute are being considered by an official board to which they shall have been referred for investigation. Heavy penalties may be imposed for failure to observe the provisions of the law. It is the duty of such boards to endeavor to effect a settlement by means of conciliation and mediation, and, if unable to do so, they are required to investigate the questions at issue, to prepare a report and to render an award which shall be made public, but they are not empowered to enforce the provisions of their awards. Although strikes in the industries covered by the act have not been altogether prevented, nevertheless the operation of the act has been remarkably successful, and it has been found that the weight of public opinion, based on authoritative facts determined after thorough investigation by such official boards, has been sufficient in most instances to induce the parties to the disputes to accept the awards of such boards without resorting to strike or lockout.

Norway.—During the year 1915 industrial unrest in Norway assumed alarming proportions and early in 1916 a lockout affecting approximately 20,000 employees in the metallurgical industries was declared by the mine operators and a general sympathetic strike in all branches of industry was imminent. This situation made it necessary for the government to take extraordinary action and Storting therefore passed, on 9 June that year, an act providing for compulsory arbitration of industrial disputes by an impartial commission, consisting of an equal number of representatives of employers and workmen. Provision is made for compulsory investigation and for a cessation of hostilities pending investigation and the rendering of an award. In this respect the act is similar to the Canadian Industrial Disputes Investigation Act of 1907, discussed above.

Sweden.—In accordance with the provisions of a law passed in 1907, Sweden is divided into seven districts, in each of which a "Conciliator," appointed by the Crown, shall endeavor to promote the settlement of industrial disputes and to advise and assist in the framing of agreements designed to preserve amicable relations between employers and workmen.

United States.—At least 29 of the 48 States have statutory provision for conciliation, mediation or arbitration in the case of industrial disputes. New York State and Massachusetts each created such a board as early as 1886. In 15 States a special board has been created for this purpose; in 11 States these functions are performed by boards, commissions or departments having other duties, and in three States provision is made for the appointment of special boards when deemed advisable. In no case are the awards of such boards binding, but in several States the boards may initiate action and have powers similar to those of the

lower courts as respects the summoning of witnesses, compelling testimony, production of records, etc.

A Federal statute passed in 1888, applicable only to disputes between railroads and other transportation companies engaged in interstate commerce, created machinery for voluntary arbitration of railway disputes at the request of either party and for public investigation of such disputes upon the initiative of the government. This act remained practically a dead letter, and it was superseded in 1898 by the "Erdman Act," which provided for mediation and voluntary arbitration in the case of controversies arising between railroad companies and those employees directly engaged in the movement of trains, namely, engineers, firemen, conductors, trainmen, switchmen and telegraphers. By this act the chairman of the Interstate Commerce Commission and the Commissioner of Labor were designated "Federal Mediators," who, upon the request of either party, should first seek to bring about an amicable adjustment of controversies through mediation and, if unsuccessful, they should endeavor to have such controversies submitted to boards of arbitration to be established as provided for in the act. The "Newlands Act," passed in 1913 and now in effect, established the United States Board of Mediation and Conciliation consisting of a commissioner, an assistant commissioner and two other officials of the government, all of whom are appointed by the President. In general the provisions of the Erdman Law were re-enacted and provision was made for the appointment of six-member boards of arbitration composed of two representatives of each party to a controversy and two members representing the public, instead of the former three-member boards on which the neutral member alone held the deciding vote. Since the organization of the board in July 1913 and up to 18 Oct. 1916, the services of the board were requested in 61 controversies between railroad companies and their employees. Of this number 46 were settled by mediation, 11 by arbitration and four by mediation and arbitration. Two of these controversies were of unusual importance—one in 1913 involving over 92,000 conductors and trainmen in the eastern section of the country, and another in 1914-15 affecting about 55,000 locomotive engineers and firemen employed on railroads west of the Mississippi River. In each of several other controversies over 25,000 railway employees were involved. It has been authoritatively stated that in railway controversies "the results which have been accomplished under the Newlands Law have been without a parallel abroad." In only one case has the board failed to effect a peaceful settlement of a controversy referred to it. The recent refusal of the four large railway brotherhoods (Locomotive Engineers, Locomotive Firemen and Engineers, Railroad Conductors and Railroad Trainmen, together representing nearly 400,000 employees) to refer to arbitration the so-called "eight-hour" controversy, resulted in a deadlock, and in August 1916, a general railroad strike appeared to be imminent. In order to prevent such a public calamity President Wilson urged the immediate passage of legislation by Congress, then in session and early in September the Adamson bill was passed

by a large majority in both Houses. The act provided that, beginning 1 Jan. 1917, eight hours should, in contracts for labor and service, be deemed a day's work and the measure or standard of a day's work for the purpose of reckoning the compensation for services of all employees engaged in the operation of trains (with certain specified exceptions), and further provided for the appointment of a commission which should observe the operation and effects of the institution of such eight-hour standard work day for a period of not less than six months, nor more than nine months, and within 30 days thereafter should report its findings to the President and Congress. It was also provided that, pending the report of the commission and for a period of 30 days thereafter, the compensation of railway employees covered by this act should not be reduced below the present standard day's wage, and, for all necessary time in excess of eight hours, such employees should be paid at a rate not less than the pro rata for such standard eight hours of work. Penalties for violation of the provisions of the act were also provided. This law not only regulated the hours of labor of railway employees but also determined wage standards. As a measure fixing wages, its constitutionality has been questioned, and pending a determination of its constitutionality several railway companies declined to observe the provisions of the act. Accordingly the chiefs of the four railroad brotherhoods called a strike to begin on 17 March 1917 on certain eastern railroads and to extend successively to other railroads until a general strike on all important railroads should result. Conferences between the railroad managers and the brotherhood chiefs were held, but without resulting in concessions by either party. Thereupon the President, through a special committee of mediation, urged that in view of the gravity of the international situation at the time, the two parties to the dispute, as a patriotic duty, should reach an immediate settlement of the controversy. Through the efforts of the mediators a postponement of the strike for 48 hours was secured, and on 19 March the railroad managers agreed to establish the basic eight-hour day and the threatened strike was averted. On the same day a decision of the Supreme Court upholding the constitutionality of the eight-hour law was announced. This decision established the principle that Congress has authority not only to regulate the hours of labor of employees engaged in interstate commerce, but also to determine wage standards. It was further established by the decision that: "The public right to have interstate commerce uninterrupted is a basic principle paramount to the interests of the railroads or of their employers, both in public service, and subject to the supreme, unrestricted power of Congress to take any action necessary to maintain freedom and uninterrupted interstate commerce." A precedent having thus been established, it remains to be determined whether or not the settlement, by special legislation, of controversies which seriously endanger the public welfare shall prove as satisfactory or effective as adjustments through mediation and voluntary arbitration. See EIGHT-HOUR LAW; LABOR LEGISLATION; LABOR MOVEMENT IN AMERICA; LABOR UNIONS.

CHARLES F. GETTEMY,

Director Massachusetts Bureau of Statistics.

ARBITRATION, International. A quasi-judicial mode of settling controversies between states which it has not been possible to settle through diplomatic negotiation. This method of adjudicating international disputes is an old one, many such instances having occurred in ancient times, notably among the Greeks and Romans. It has been frequently resorted to in modern times and the increasing disposition in late years to employ it justifies the hope that it may ultimately take the place of armed force as the accepted method of determining international controversies. According to Dr. W. Evans Darby in his 'Modern Pacific Settlements,' six international controversies were settled by arbitration in the 18th century; 471 in the 19th and 63 during the first three years of the present century. Since the beginning of our national existence some 83 disputes between the United States and some 24 different countries have been amicably settled through the decisions of mixed commissions or arbitral tribunals. Of the pecuniary awards made in these cases, 74.8 per cent, or a total of \$69,501,682, were

made in favor of the United States, and 25.2 per cent, or a total of \$23,353,762, were made against the United States. Numerous boundary disputes have been settled in this way; the Alabama claims controversy with Great Britain, growing out of the Civil War; the fur-seal controversy; and several fisheries disputes with Great Britain are examples of other important differences which have been arbitrated.

The history of international arbitration has gone through an interesting evolution. In the beginning bilateral arbitration treaties and general international conventions for the pacific settlement of disputes were unknown. Whenever two states wished to arbitrate differences existing between them they entered into a special agreement called a *compromis*, which defined the nature of the controversy, named the arbiters or designated a mode of selecting them, set forth their powers and laid down the rules of procedure by which they were to be guided in reaching a decision on the points at issue. Early in the 19th century the practice of inserting an arbitral clause in general treaties became common. This clause usually stipulated that in case a difference of opinion should arise regarding the interpretation of the treaty or some one of its provisions, the contracting parties would submit the question to arbitration. Thus the duty to arbitrate in certain cases was made obligatory. It has been stated that 142 such treaties have been entered into by the countries of America since 1832. The next step was reached when states began to conclude permanent arbitration treaties with one another which provided for the settlement by this mode of all disputes of a certain character which might arise in the future between the contracting parties. Finally, The Hague Peace conferences of 1899 and 1907 adopted general conventions for the pacific settlement of international disputes and provided for the creation at The Hague of a so-called permanent court of arbitration to which the contracting parties might submit their differences.

The first arbitration treaty concluded between the United States and a foreign power was that of 1897 with Great Britain. This treaty provided that certain classes of disputes which might arise between the two governments should be submitted to the arbitration of judges to be appointed according to a mode prescribed by the treaty and in accordance with certain rules of procedure which it laid down. The Senate, however, declined to give its advice and consent to the ratification of this treaty and it never went into effect. In 1905 President Roosevelt negotiated a number of arbitration treaties with foreign powers, but they were ratified only after the Senate had amended them in important particulars. The amendments being unacceptable to the President, he refused to lay them before the other parties for their approval. In 1908 arbitration treaties were concluded between the United States and France, Switzerland, Mexico, Denmark, Italy, Great Britain, Norway, Portugal, Spain, Sweden, the Netherlands and Japan and these were duly ratified by the Senate. Similar treaties have since been concluded with various other foreign powers, so that at the present time arbitration

agreements exist between the United States and 28 different countries, or more than half the sovereign states of the world. In 1915 Brazil was a party to 33 such treaties, Italy to 25, Portugal to 18, Salvador to 20, Spain to 31, etc. Between 1902 and 1915, 164 arbitration treaties were concluded between the various powers of the world, and at the outbreak of the European War the German Empire was the only great power which was not a party to one or more arbitration agreements.

The majority of these treaties provide that differences of a legal nature which it may not have been possible to settle by diplomacy shall be referred to the permanent Court of Arbitration at The Hague (see HAGUE COURT, THE). Disputes, however, which affect vital interests, the honor or the independence of the contracting parties, or which involve the interests of third parties, are generally excluded from the provisions of the treaties, and there is therefore no obligation to submit them to arbitration. These exceptions are obviously quite elastic and it would be possible for one of the contracting parties, by a liberal interpretation of the terms "honor" and "vital interests," to avoid the obligation to arbitrate any dispute which it might choose to regard as one which involved its "honor" or "vital interests." In 1911 President Taft concluded treaties with several powers, the purpose of which was to remove the possibilities of evasion which these expressions create. In general, these treaties provided for the arbitration of all differences which were "justifiable in their nature by reason of being susceptible of decision by the application of the principles of law and equity," but they were radically amended by the Senate, in consequence of which they were dropped by the President.

Lange, in his work entitled 'Union Interparlementaire; l'Arbitrage obligatoire en 1913,' thus summarizes the scope of the existing arbitration treaties:

1. Arbitration of all disputes without reserve—36 bipartite treaties.
2. Arbitration of all disputes subject to reserve of constitutional provisions—13 treaties.
3. Arbitration of all disputes except those affecting vital interests, honor, or independence, or the interests of third parties—46 treaties.
4. Arbitration of all disputes of a legal nature or those relative to the interpretation of treaties—65 treaties.
5. Arbitration of differences relating to the interpretation or application of international law or conventions—44 treaties.

As stated above, the first Hague conference of 1899 adopted a convention for the pacific settlement of international disputes, and the conference of 1907 revised and extended in certain particulars the earlier convention. These conventions were ratified or adhered to by practically all the states of the world, and being of unlimited duration, they are permanent. The conventions provide for the creation of a permanent Court of Arbitration to meet at The Hague for the decision of cases that may be referred to it, and through the generosity of Mr. Andrew Carnegie a palace has been erected there for the holding of the sessions of the court and for

the housing of its permanent offices. The conventions stipulate that each contracting power shall select not more than four persons, of known competence in questions of international law and of the highest moral character, to constitute a panel from which arbitrators may be selected whenever any of the contracting parties shall agree to submit a dispute to the court for adjudication. The conference of 1899 formulated a code of procedure to be followed by the court in the hearing of cases submitted to it, and this code was revised and elaborated by the conference of 1907. Since 1899, 15 cases have been submitted to the court for decision, the first one being a dispute between the United States and Mexico concerning the so-called Pious Fund (q.v.) of the Californias. The decision was rendered 14 Oct. 1902 in favor of the United States and was duly carried into effect. The second case involved the question of whether Great Britain, Germany and Italy, three Powers which had blockaded the ports of Venezuela and seized certain of the Venezuelan customs houses on account of the refusal of the government of Venezuela to settle various claims preferred against it by those Powers, were entitled to priority of payment over other governments, including that of the United States, which also had claims against Venezuela, but which had not participated in the blockade of her ports. The decision was rendered 22 Feb. 1904 in favor of the blockading Powers. Among the other more important cases decided by The Hague Court were: The controversy between Germany, France and Great Britain on the one hand and Japan on the other, regarding certain perpetual leases in Japan (decided 22 May 1905); a dispute between Germany and France concerning aid alleged to have been given by the German consul to certain deserters from the French legation in Morocco (decided 22 May 1909); an important and long-standing dispute between Great Britain and the United States regarding the north Atlantic fisheries (decided 7 Sept. 1910); the dispute between France and Great Britain regarding the arrest by the French authorities at Marseilles of a fugitive named Savakar, who had escaped from a British vessel upon which he was being transported to India for trial (decided 24 Feb. 1911); and a controversy between France and Italy concerning the seizure by the Italian authorities of two French vessels during the Turco-Italian War (decided 6 May 1913).

In every case the decision of The Hague Court was accepted by the parties and was duly carried into effect. It soon became evident, however, that the organization of the court was defective. In the first place, it was not a court in the true sense of the word, but simply a panel of names from which the judges were to be selected by the parties whenever disputants had occasion to resort to the court. This involved long and expensive delays; besides, under such an arrangement, the court lacked permanency and continuity. These defects were the subject of serious consideration at the second conference in 1907, and with a view to remedying them, the conference adopted a convention providing for the creation of a permanent court of arbitral

justice to be composed of judges appointed for terms of 12 years and to be paid regular salaries. The proposed tribunal was intended to be not merely a list of names kept at The Hague, but a fully organized body which was to meet once a year and to proceed with any cases which might be on its docket. It would not be necessary, therefore, to constitute a court every time a case was to be decided. Unfortunately, however, it proved impossible for the powers to agree upon the size of the court and the mode of selecting the judges. The smaller states at the conference insisted on equality of representation in the court, the effect of which, had their contention been admitted, would have been to create a tribunal of such size as to be unworkable. Various modes were proposed for selecting the judges and insuring some representation to all the powers, but no agreement was ever reached, and as a consequence the proposed court remains unorganized. The so-called permanent court provided for by the conventions of 1899 and 1907, however, may still be called into existence whenever recourse to it is desired.

The desirability of establishing a general system of compulsory arbitration has been much discussed in recent years and various projects with this end in view have been put forward. In 1890 the first Pan-American conference at Washington adopted a project for a general treaty of obligatory arbitration but it was never ratified by the states represented at the conference. At both The Hague conferences of 1899 and 1907 several projects for limited obligatory arbitration were proposed, but largely on account of the opposition of Germany they were defeated. The Russian proposal of 1899 provided for *inclusive* obligatory arbitration for differences involving pecuniary claims and those relating to the interpretation of treaties. In 1907 a similar, but more elaborate, project proposed by Portugal was discussed, but like the project of 1899, it was defeated. At the latter conference a project of *exclusive* obligatory arbitration was proposed—one which provided that "differences of a legal nature and primarily those relating to the interpretation of treaties" should be submitted to arbitration, provided they did not involve the vital interests, honor or independence of the disputing parties, or did not affect the interests of other states not parties to the dispute. This project had the support of a large majority of the states represented at the conference, but it was dropped mainly because of the opposition of Austria-Hungary and Germany. Nevertheless the conference of 1907 unanimously adopted a *væu* admitting the principle of compulsory arbitration and declaring that certain differences, particularly those relating to the interpretation of treaties, might be submitted to arbitration without restriction. Finally, the conference, in adopting the Porter convention respecting the limitation of the employment of force for the recovery of contract debts, in effect sanctioned obligatory arbitration for one class of disputes.

It is apparent from the above summary that the movement looking toward the substitution of judicial methods in the place of armed force for the settlement of international disputes has made remarkable progress in re-

cent years. The obstacle which has stood in the way of further progress has of course been the feeling among states that they cannot consent to submit their international controversies to the decision of judges representing other nations without compromising their sovereignty and running the risk of surrendering their rights. If every nation which becomes involved in a controversy with another were absolutely certain of finding an impartial and unprejudiced tribunal to which it could resort with the certainty of obtaining justice, there would be little reluctance to adopt this method of settling disputes. As yet, however, no means has been discovered by which the selection of competent arbiters without national prejudices and sympathies can always be assured. The method provided by The Hague conventions for the constitution of an arbitral tribunal has not escaped criticism. Its members are to a certain extent under the control of the governments which select them and therefore tend to represent the views of their governments; in some instances, indeed, they have been regular legal or diplomatic officials. Greater independence and impartiality might be obtained by forbidding the appointment as members of the court of persons holding official positions under the government which they represent. Furthermore, it might be desirable to forbid any judge of the court from practising before it; it might, indeed, be desirable to go still further and prohibit any citizen of a disputing state from sitting in a case in which his government is a party; finally, a more advanced step, which is quite in line with sound judicial theories, would be to exclude the parties from choosing their own judges, this, because so long as they are allowed to do so they will appoint representatives who are prepossessed in favor of the claims of their own government. In short, arbiters so chosen are more likely to assume the rôle of advocates rather than that of judges. It would seem that if The Hague Court were constituted according to these principles, and if, in addition, the judges were appointed for life and were paid salaries commensurate with the dignity and importance of their positions, we should have a tribunal composed of men as nearly independent and free from prejudices as it would be possible to obtain. See HAGUE COURT, THE; INTERNATIONAL LAW; MEDIATION; PAN-AMERICAN CONFERENCE; TRIPLE ALLIANCE; TRIPLE ENTENTE.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

ARBOGA, är-bō'ga, a Swedish city, once important commercially but now only of historical interest from having been at one time a residence of the royal family of Vasa, the scene of church assemblies and national diets and for the antiquities in its neighborhood. Pop. about 5,250.

ARBOLEDA, är'bō-lā'da, Julio, South American poet and statesman: b. Barbacoas, Colombia, 9 June 1817; d. 1862. He was educated in Europe and on his return to Colombia engaged in journalism. In the various Colombian revolutions he was a liberal Conservative and more than once declined the vice-presidency of the republic. His poems are much esteemed in Spanish-American literature.

ARBOR DAY, an annual tree-planting day appointed by nearly every State and Territory of the Union, sometimes as a legal holiday and sometimes merely advisory, to assist in foresting or reforesting scantily-wooded tracts or shading or beautifying towns. It is generally in special connection with the public schools, to impress children with the importance of forestry and natural beauty in our civilization. The date depends on the climate of different sections and is absolutely fixed in but few; most northern States hold it in April or early in May; Arizona, Texas and Alabama in February, the two latter on Washington's birthday; Florida in January, Georgia in December and New Mexico in March; many make it optional either with the State or with localities, and West Virginia holds it twice a year, in spring and fall. It arose from the alarm felt by the most far-sighted public men over the rapid and reckless deforestation of many parts of the Union, and the prospects of its extending to all the States, and a realization of what that deforestation meant to the future welfare and development of the United States (see FORESTRY). Most civilized governments at different times have looked after their forests to assure a supply of timber for naval construction; New Hampshire and New York, even in the colonial period, felt it needful to check the inroads on them; the United States government at the beginning of the 19th century bought timber lands and a quarter of a century later authorized the President to take measures for their preservation; and about the same time the Massachusetts Society for Promoting Agriculture offered prizes for forest planting. But the first widespread realization of its importance was caused in 1864 by the notable book of George P. Marsh (q.v.), the eminent American scholar and diplomat, entitled 'Man and Nature'; the chapter on 'The Woods' aroused especial attention and in 1865 Birdsey G. Northrop, then secretary of the Connecticut Board of

Education, suggested that States might profitably plant trees every year at the proper time, or supervise their planting. The subject brought out several books and many articles; the late Dr. Franklin B. Hough, the first Forest Commissioner, publishing a work upon it as early as 1873. But the first to propose a regular Arbor Day for the purpose was J. Sterling Morton, late Commissioner of Agriculture, then of Nebraska, who in 1872 succeeded in inducing his almost treeless State to set apart a day for the purpose. Great enthusiasm was aroused and over a million trees were planted that year. In 1885 it was made a legal State holiday on 22 April, Mr. Morton's birthday. The movement did not at first spread very rapidly, though some localities took it up; the first States to copy the legal enactment were Kansas and Tennessee in 1875, and the next year Minnesota. It was six years before another joined, Ohio in 1882, followed by West Virginia in 1883; then the tide began to rush in and within five years 26 more States and Territories had adopted the observance. See FORESTRY; FOREST SERVICE and consult Schauffler, R. H., (ed.) 'Arbor Day' (1909).

ARBOR VITÆ (Latin, "tree of life"), the designation of several trees belonging to the family PINACEÆ and allied to the cypress. The genus consists of evergreen trees and shrubs, with flattened branchlets and small, imbricated or scale-like leaves. The common arbor vitæ (*Thuja occidentalis*) is a native of eastern North America and reaches a height of 50 feet in favorable locations. The cones are small; the young twigs have an agreeable balsamic smell; the wood is soft and light, but tough and durable. The other North American species is *T. plicata*, found on the Pacific coast from the region of San Francisco Bay north to Alaska. The Chinese arbor vitæ (*T. orientalis*) is often cultivated. Its upright branches and larger cones easily distinguish it from the former. It yields a resin which was formerly thought to have medicinal virtues, like the wood and young twigs of *T. occidentalis*; hence the name—arbor vitæ.

ARBORETUM (Latin *arbor*, a tree), a place set apart for the cultivation of different trees and shrubs for scientific or educational purposes. See BOTANIC GARDENS; FORESTRY.

ARBORICULTURE, the scientific cultivation of trees. It embraces that part of horticulture which treats of the planting and cultivation of ornamental and fruit trees and that part of forestry known as silviculture. For the horticultural growing of various trees see under the corresponding special headings. See also FORESTRY.

ARBUTHNOT, John, Scotch physician and author: b. Arbuthnot, Kincardineshire, Scotland, 29 April 1667; d. London, 27 Feb. 1735. Arbuthnot was the eldest child of Alexander Arbuthnot, rector of Arbuthnot, and Margaret [Lammy] Arbuthnot. Little is known of John Arbuthnot's early life; he was probably educated at Marischal College, Aberdeen, but almost nothing else can be stated of his minority. It is known, however, that as a result of the Revolution of 1688, his father who was a stout supporter of the Stuarts, lost his preferment and, on his death in 1691, his sons were obliged to seek their

fortunes abroad. John went to London, where he supported himself by teaching mathematics. The following year he probably published a little book entitled 'The Laws of Chance,' but it may not be definitely assigned to him. In October 1694 he entered University College, Oxford, and in September, two years later, took his doctor's degree in medicine at Saint Andrews. Shortly afterward, in all probability, he settled in London for the remainder of his life.

Arbuthnot's first important work was 'An Examination of Dr. Woodward's Account of the Deluge' (1697), a work in which Arbuthnot showed his interest in questions of science and the candor and fairness of his mind. His next piece, 'An Essay on the Usefulness of Mathematical Learning,' appeared in 1701. His progress in distinction was so rapid that in 1704 he was elected a Fellow of the Royal Society and the following year was made Physician Extraordinary to the Queen. In 1709 he was appointed Physician in Ordinary to the Queen, and the following year was admitted as Fellow to the College of Physicians. His publications of the period are of a somewhat miscellaneous character: 'Tables of the Grecian, Roman and Jewish Measures, Weights and Coins, Reduced to the English Standard' (1705), 'A Sermon Preached to the People at the Mercat-Cross of Edinburgh; on the subject of the Union' (1706) and 'An Argument for Divine Providence, taken from the Constant Regularity Observed in the Births of Both Sexes' (1710). Because of his well-known good humor, fairness of mind and ability he was frequently named to settle vexed questions and rival claims.

Arbuthnot is remembered in English literature chiefly for the friendships which he made and the work that he did during the next four years. He became acquainted with Swift in 1711 and with Pope two years later, and both friendships were close and life-long. It was possibly under the influence of the former that he contributed several interesting satires to the support of the Tory administration. In February 1712 appeared 'The Story of the Saint Albans Ghost, or the Apparition of Mother Haggy,' a satire upon the Duke and Duchess of Marlborough. In the spring and summer of the same year there appeared in five instalments, the much more important 'Law is a Bottomless Pit,' called later and better known as 'The History of John Bull.' Both were attributed to Swift and have been included frequently in his published works, in spite of his denial of them. 'John Bull' is undoubtedly one of the masterpieces of English political satire of the milder sort. It pursues throughout the method of the narrative parts of Swift's 'Tale of a Tub' and it gives an account of the history of English foreign politics of the time, but its quality is more genially humorous than violently satirical. It is particularly notable for the name and character of John Bull, which Arbuthnot created. In October of the same year Arbuthnot published 'The Art of Political Lying,' a satire of an extraordinary rather than a dramatic cast.

The friendship of Arbuthnot with Swift, Pope and the Tory leaders resulted in a society for the diversion of its members in times of political turmoil. Out of that sprang the

Scriblerus Club. The object of the club was, in the words of Pope, "to have ridiculed all the false tastes in learning, under the character of a man of capacity enough, that had dipped into every art and science, but injudiciously in each." The members were Arbuthnot, Swift, Pope, Gay, and Parnell, but almost exclusively to Arbuthnot alone belong the 'Memoirs of the Extraordinary Life, Works, and Discoveries of Martinus Scriblerus,' probably written in 1713-14, but published in 1741 by Pope. The 'Memoirs' are usually included in Pope's works, who wrote only the excellent 'Art of Sinking in Poetry.' The reason that so many of Arbuthnot's works have been attributed to other writers is that literature was to him a diversion and he made little attempt to keep his writings.

On the death of Queen Anne in 1714, Arbuthnot, along with the Tory ministers and their supporters, lost their places at court, but Arbuthnot retained his favor with influential people. In his profession he was honored by being made, in 1723, Second Censor by the College of Physicians and, possibly in 1730, Physician to the Queen. His writing up to his death consisted of an amplification of his 'Tables of Ancient Coins' (1727), some satirical notes, with Swift, to the 'Dunaid' (1729), a popular 'Essay Concerning the Nature of Ailments and the Choice of Them' (1731), to which the following year he added 'Practical Rules of Diet,' an 'Essay Concerning the Effects of Air on Human Bodies' (1733), and a poem, 'Know Thyself' (1734). Alone and in collaboration with his friends he probably wrote a number of satirical pieces, which are often included in his works but which cannot be definitely assigned to him. The last 10 years of his life were marked by several illnesses, but he never lost his cheerfulness and good-nature. A few weeks before his death appeared Pope's masterly 'Epistle to Dr. Arbuthnot,' which is interesting in part as a proof of the esteem in which he was held by his friends and by which he is best known to the average reader.

Bibliography.—The chief source of information about Arbuthnot is George A. Aitken's 'The Life and Works of John Arbuthnot' (Oxford 1892), wherein all that is definitely known to be Arbuthnot's is included except the technical treatises. The other chief source of information is Leslie Stephen's article in the 'Dictionary of National Biography.' References to the history of the Scriblerus Club and Arbuthnot's relations to the great men of letters of the time are to be found in the separate lives of these men and in the literary histories.

WILLIAM T. BREWSTER,

Professor of English, Columbia University.

ARBUTHNOT, Marriot, English admiral: b. 1711; d. 1794. With Sir Henry Clinton he captured Charleston, S. C., 20 May 1780, after the city had withstood a long siege, and commanded in a sea fight with a French fleet off Cape Henry in March 1781.

ARBUTUS, ăr'bū-tūs, the designation of a genus of about 20 species of shrubs and small trees, mostly evergreen, of the family *Ericaceæ*, natives mainly of Europe and North America. The species, many of which have smooth, red branches, are often used for ornamental purposes. *A. unedo*, the strawberry tree, a species

from southern Europe, is often planted in California, its profusion of white or rosy flowers and strawberry-colored fruits which ripen during the blossoming period of the following year being greatly admired. In Spain this fruit is used to make sugar and a kind of liquor. *A. menziesii*, the madrona, a native of the Pacific Coast States, attains a height of about 100 feet and is the hardiest and perhaps the handsomest species of the genus. *A. arizonicus*, another American species, which sometimes reaches a height of 50 feet, has white bark on the trunk, red branches, pale-green leaves, loose panicles of white flowers and dark orange-red fruits.

ARBUTUS, Trailing, an evergreen creeping plant (*Epigæa repens*) of the family *Ericaceæ*, growing in shaded sandy and rocky soils especially in pine woods, from Newfoundland to Florida and westward to Minnesota. It is known in New England as the Mayflower and in the southern United States as ground laurel, and is everywhere prized for its fragrant rose-colored or white flowers.

ARC, a geometrical term denoting a portion of the circumference of a circle, often cut off by two lines which intersect it. The name is also applied to a portion of any other curve. The magnitude of an arc of a circle is stated in degrees, minutes and seconds, which are equal to those of the angle at the centre which it subtends. Hence, counted by degrees, minutes and seconds, the arc of elevation and the angle of elevation of a heavenly body are the same, and the two terms may be used in most cases indifferently. The straight line uniting the two extremities of an arc is called its chord. Equal arcs must come from circles of equal magnitude, and each must contain the same number of degrees, minutes and seconds as the others. Similar arcs must also each have the same number of degrees, minutes and seconds, but they belong to circles of unequal magnitude. Concentric arcs are arcs having the same centre. In mathematical geography an arc of the earth's meridian, or a meridional arc, is an arc partly measured on the surface of the earth from north to south, partly calculated by trigonometry. By these measurements the earth was discovered to be an oblate spheroid.

ARC, Electric. See ELECTRIC LIGHT.

ARC, Joan of. See JOAN OF ARC.

ARCA, a term applied to a genus of conchiferous mollusks, the typical one of the family *Arcadæ*. The shell is strongly ribbed or cancellated, hinge straight, with very numerous transverse teeth. They are universally distributed, but are commonest in warm seas. They inhabit the zone from low water to 230 fathoms. The fossil species are found in the United States, Europe and southern India.

ARCADELT, Jacob, Flemish composer: d. Paris 1570 or 1575. The date of his birth is uncertain, but it was probably during the first quarter of the 16th century. His works are among the finest examples of contrapuntal music of the time. He assisted in founding the classical Italian school of music. From 1539 to 1555 he was engaged as singer and teacher in the Papal Chapel at Rome. He composed madrigals, masses and motets. He entered the service of Cardinal Charles, Duke of Guise, in

1557, and accompanied the latter to Paris, where he died. Consult Ambros, 'Geschichte der Musik' (Vol. II, Leipzig 1909); Burney, 'General History of Music' (Vol. III, London 1789).

ARCADIA. The 'Arcadia' of Jacopo Sannazaro (1456-1530) is the most celebrated of the Italian pastoral romances of the Renaissance. Composed between 1481 and 1486, it first appeared in a pirated edition at Venice in 1502, in an authorized print at Naples in 1504 (edited by Summonte), finally in the Aldine edition of Venice 1514. It is this text of Aldo Manuzio that has formed the basis of the numberless more recent editions of the work. A large variety of considerations have tended to give the 'Arcadia' a greater eminence in literary history than for intrinsic value it would seem to deserve. It is the most considerable production of the Neapolitan school of literature in the 15th century, a group comprising Pietro Jacopo de Jennaro, Caritheo, Pietro Antonio Caracciolo and Giannantonio Petrucci. This school, aside from affirming the Petrarchistic trends in Italian poetry, is important as showing in diction the curious linguistic hybridism that preceded the constitution of the national Italian language on a classic basis (imitation of Dante, Petrarch and Boccaccio). The 'Arcadia,' in fact, has in its earlier forms a distinct Neapolitan coloring. But in successive redactions, Sannazaro made it conform more and more to the language and style of the Tuscan Boccaccio; and the triumphant classic purism of the 16th century came to recognize the 'Arcadia' as one of the supreme models of linguistic correctness and good taste. The Renaissance doctrine of "imitation" likewise enthroned this romance of Sannazaro as the perfect model of the pastoral "genre," especially as regards the eclogue. The imitation of the 'Arcadia,' beginning with Serafino dall' Aquila, extends in Italy through Castiglione, Tasso, Guarini and lesser men down to the end of the 18th century. Castiglione himself seems to have introduced the 'Arcadia' to the Spanish court. Its popularity in Spain is attested by imitations by Garcilaso de la Vega, by Montemayor (*Diana*), by Cervantes (*Galatea*) and hosts of others. In France the 'Arcadia' inspired the 'Bergerie' of Remy Belleau and to some extent also the work of Ronsard. For England we have the 'Shepherd's Kalendar' of Spenser and the 'Arcadia,' no less, of Philip Sydney. To be sure, in all these epigones of Sannazaro's work, it is not always easy to separate the influence of the 'Arcadia' from that of its own sources. Sannazaro composed it directly on the model of Boccaccio (e.g., 'Ameto'), utilizing also Virgil, Ovid, Theocritus, Bion and Moschus. The later pastorals, moreover, borrowed largely from the Spanish romance.

The 'Arcadia' tells the story of an idyllic, unhappy love, to which legend assigns a biographical value for the poet. Sincerus (Sannazaro) driven wandering by love, goes breathing the sighs of his melancholy spirit through the groves of Arcadia, inhabited by the most erudite, æsthetic and delicately sensualistic shepherds imaginable. Sincerus is warned by an evil dream that his "nymph" is in danger; he returns to his home, to find her dead.

Around this tenuous plot is arranged a whole gallery of word-paintings, brilliantly colored and elaborated in detail. The work is suffused with tints of quintessential delicacy; we meet there only the softest murmurs, the tenderest emotions, the most fainting languors. There is a constant tickling of the senses with stimuli attenuated to the point of vanishing, but calculated to arouse in souls properly "sublimated" greatest intensity of emotional strain. Thus the 'Arcadia' expresses the ideal of æsthetic refinement held up before the court society of Italy, and by the Italians passed on as the foundation of good manners to France and the rest of the world. However, such sublimity always totters on the brink of the ridiculous. There is a vein of possible humor underneath which alone can save such artificiality. The self-consciousness of this humor is the saving quality of Tasso's pastoral art; the lack of it constitutes the prevailing defect of the 'Arcadia' of Sannazaro.

ARTHUR LIVINGSTON,
Professor of Romance Languages, Western
University, London, Ont.

ARCADIA. 'The Countesse of Pembroke's Arcadia,' a long and elaborate romance by Sir Philip Sidney, was written during or before 1580, and sent in scraps of manuscript by the author to the Countess, his sister. Its five books, in prose, with "eclogues" in verse after each in the manner of Sannazaro's 'Arcadia,' told the story of a king who, to avoid the fulfilment of a threatening oracle, retired with his wife and two daughters to a lodge in the forest, but whose plan was frustrated by the arrival of two princely heroes, so that after many chivalrous and pastoral episodes all the virtuous were made happy. The contents—the travels, shipwrecks and hairbreadth escapes, the courtships, captivities, trials at law and harangues, the disguises and mistaken identities, deaths real and deaths feigned, rebellions and tyrannicides, children lost and restored, in a word, the strange turns of love and fortune—were partly Sidney's invention, but were chiefly derived from romances of chivalry (in particular the 'Amadis of Gaul') and from the Greek romances (in particular the 'Æthiopica' of Heliodorus and the 'Clitophon and Leucippe' of Achilles Tatius). The narrative was straightforward and easy to follow.

This original or "Old" 'Arcadia' had circulated in manuscript for several years when Sidney began a revision, which he left unfinished at his death. He had, however, recast about half his old material, and cast a considerable quantity of new material with it into the elaborate and complex structure of Heliodorus's 'Æthiopica,' which conceals the key of the narrative, overlays, interlaces and interrupts the main story with many episodes, and inverts the chronological order to conform to the antique epic convention in *medias res*. The first edition, 1590, quarto, consists of this new version only. The second edition, published by the Countess and her friends in 1592, consists, first, of the new version as far as it goes, that is, to the middle of the third book; next, of a few words of transition; and, finally, of the remainder of the old third book and the whole of the old fourth and fifth books.

This patchwork is the current or standard version. The original 'Arcadia' has never been printed, though several manuscript copies of it were found by Bertram Dobell, the London bookseller and scholar, in and after 1907.

As a romance of love and adventure the 'Arcadia' is still good reading, despite the riddle of its plot, which one soon "gives up." Its sweet, rhythmical style, full of Renaissance imitations of late Greek and Roman rhetoric, full of antitheses and conceits and lofty sentiment and show-pieces of description and oratory, is one phase of the Italianate style of Elizabethan courtly literature.

The intrinsic merit of the 'Arcadia' gave it deep literary influence. Elizabethan books allude often to both the old and the new versions; Greene and Lodge imitated its plot and structure in several prose romances; Shakespeare borrowed from it the story of Kent in 'King Lear'; Beaumont and Fletcher derived from it the plot of 'Cupid's Revenge'; King Charles I adopted from it his prayer on the eve of execution. It was often reprinted in the 17th century, when also it reached France in translation, and helped in the elaborate construction of the French "heroic romances." It is the only work of Elizabethan fiction that continued to be popular throughout that century and into the 18th, where its influence—certain as regards Richardson—has yet to be fully worked out. Scott's 'Ivanhoe' exhibits many borrowings. On the whole, the 'Arcadia' probably brought into English fiction that sustained elaboration of structure which distinguishes the novel from the short story and the picaresque tale. It is thus a literary prototype. Editions: 1590 (quarto); facsimile reprint, ed., H. Oskar Sommer (London 1891); ed. Albert Feuillerat (Cambridge 1912); 1592 version often reprinted, recently ed., Ernest A. Baker (London and New York 1907). Consult Dobell, Bertram, 'New Light on Sidney's Arcadia' (*Quarterly Review*, Vol. 211, pp. 74-100, July 1909); Wolff, Samuel L., 'The Greek Romances in Elizabethan Prose Fiction' (New York 1912, pp. 262-366, 461-64).

SAMUEL L. WOLFF,

Instructor in English, Extension Teaching, Columbia University.

ARCADIA, Fla., city and county-seat of De Soto County, 75 miles southeast of Tampa, on the Charlotte Harbor and Northern, the Seaboard Air Line and the Atlantic Coast Line railroads. The principal industries are cattle, orange and citrus fruit and vegetable farming, phosphate production, etc. It contains a city hall, county courthouse and two school buildings, and has 15 miles of asphalt streets. The city's two banks and a trust company have resources aggregating \$225,000. In 1917-18, during America's preparation for entering the European War, two aviation camps were located at Arcadia. Pop. 6,000.

ARCADIUS, the first Emperor of the East: b. 377; d. 408. He was son of the Emperor Theodosius, on whose death in 395 the empire was divided, he obtaining the East and his brother Honorius the West. He proved unable to govern for himself and was a mere tool, first in the hands of Rufinus, then of the eunuch Eutropius, and then of his Queen, Eudoxia.

ARCESILAUS, ä'r'kè-si'lòs, Greek philosopher: b. Pitane, Aeolis, 316 B.C.; d. 241 B.C. He studied philosophy at Athens and was largely influenced by Crates and Crantor. At the latter's death he became the head of the Academic School. Arcesilaus denied the certainty of intellectual and sensuous knowledge and recommended abstinence from all dogmatic judgments. In practice he held we must act on grounds of probability. He wrote nothing and confined his activities to expounding the Socratic method, yet he wielded a vast influence on philosophic thought. He was noted for his clearness of thought, his wit, facility of speech and amiable disposition and bearing both to his opponents and pupils. Consult Zeller, 'Geschichte der griechischen Philosophie' (Leipzig 1893).

ARCH, an architectural term denoting a structural form made up of a series of wedge-shaped stones or bricks so arranged over a door or window in an edifice for habitation, or between the piers of a bridge, as to support each other and to carry in addition the weight of the superstructure. These stones and bricks, of a truncated wedge shape, used in building arches, are called voussoirs. The side of an arch between the crown and the springer, or skewback, is called its haunch or flank, and by old English writers of the 16th century, its hanse. The highest part of the arch is called its crown, or by the old English authors, the scheme or skeen, from the Italian *schiena*, the back. The lowest voussoirs of an arch are called springers, or skewbacks, and the central one, the keystone. The under or concave side of the voussoirs is called the intrados, and the outer or convex one the extrados of the arch. A chord of the arch at its lower part is called its span, and a line drawn at right angles to this chord and extending upward to the under side of the keystone is called its rise. The impost of an arch is the portion of the pier or abutment whence the arch springs; the thrust of the arch is its outward pressure against the abutments. The voussoirs are also called ring-stones. The spandrel is the part above the haunches, or, in a bridge, the part between the arch-ring and the roadway. If the height of the crown of an arch above the level of its impost be greater than half the span of the arch, the arch is said to be surmounted. If, on the contrary, it be less, the arch is said to be surbated. The curved arch was known to the Assyrians and the old Egyptians. Sir J. G. Wilkinson considers that it existed in brick in the reign of Amenophis I, about 1540 B.C., and in stone in the time of Psammethichus II, 600 B.C. The evidence is derived from the ruins of actual buildings, but paintings appear to carry the arch back to about 2020 B.C. There is no mention of the genuine arch in Scripture, the term "arches," in Ezek. xl, 16, being a mistranslation. The round arch was brought into extensive use by the Romans and prevailed everywhere until

the 12th century A.D., when the arch pointed at the apex, and called in consequence the pointed arch—the one so frequently seen in Gothic architecture—appeared in Europe as its rival. The forms of both curved and pointed arches may be varied indefinitely. Of the former may be mentioned the horseshoe arch, a name which explains itself, and the foil arch, from Latin *folium*, a leaf, of which there are the trefoil, the cinquefoil and the multifoil varieties, so named from the plant-forms after which they are modeled. Other arches are the equilateral, in which the centres of the circles whose intersection constitutes the pointed arch coincide with the angular points at the two sides of the base; the lancet, in which the centres of the circles fall beyond these points; the drop arch, where they fall within the base; and the segmental arch, the sides of which constitute segments of circles containing less than 180 degrees. Besides these there are several other varieties of arch distinguished by their respective forms. The names applied to arches may be divided into several classes, as referring to geometric or familiar forms, style or position in the building. The following are different geometrical forms: The flat arch, with voussoirs radiating from one centre. Arches with one centre are: semi-circular, segmental, horseshoe. Arches with two centres are: the equilateral pointed arch, where the centres of the circles coincide with the angular points at the two sides of the base; the drop arch, where they fall within the base; the lancet, where they fall outside of it, and the pointed horseshoe. The common three-centred arch is called basket-handled arch, this being the form generally used instead of an ellipse. Four-centred, six-centred and other similar forms are occasionally used. The names horseshoe, lancet, basket-handled, etc., are given because of their resemblance to familiar forms. Gothic, Roman and Moorish arches are names given because these forms were used in those architectural styles. Certain names are given with reference to the position of the arch in the building, such as discharging or relieving arch, where the arch is placed over a lintel to carry pressure to the sides.

Examples of arches are the Cloaca Maxima, built about 641 B.C., with three concentric rings of voussoirs, inside diameter, 14 feet; the Pont du Gard, built by Agrippa, 19 B.C., which has semi-circular arches, built of Pozzuolani concrete with stone or brick facing. The longest masonry span in Europe is the railway bridge over the Pruth, Jaremcze, Austria, 213 feet wide with a rise of 59 feet, and built in 1892. This shows hollow spandrels, which are constructionally and artistically correct. The Cabin John Bridge, near Washington, D. C., which carries an aqueduct and highway, 220 feet. The Wheeling, W. Va., Main St. Bridge, built in 1892, 159 feet long, 28 feet rise, is deceptive, as spandrels are hollow, but appear to be solid. The great arch now built for the cathedral of Saint John the Divine, New York, is of masonry resting on the top of piers 86 feet high. The span is 114 feet from outside to outside of voussoirs. In 1896 was built the first large concrete arch in the United States, 40 feet span, seven feet rise, all of concrete. This was for a highway bridge. There is also a 60-foot arch of steel-concrete in

Franklin Bridge, Forest Park, Saint Louis, Mo. "Concrete reinforced" is the name given to the combination of concrete with steel or iron in building. Steel-concrete, armored concrete, *béton armé*, *ciment armé*, are various terms for such construction, now coming into frequent use.

The Melan arch system was developed by Prof. Joseph Melan, using stiff steel ribs or beams embedded in concrete to form the arch ring, following Austrian experiments. Examples of Melan arch are found in Eden Park, Cincinnati, Ohio, 70 feet span; railway bridge over Southern Boulevard, Detroit, Mich.; road bridges over the Passaic, Paterson, N. J.; Kansas Avenue, Topeka, Kan., this being the longest, having five arches, one of 125 feet, two of 110 feet each, two of 97 feet each; Hyde-Park-on-Hudson for F. W. Vanderbilt, 75 feet span; a foot bridge in park, Stockbridge, Mass., 100 feet span, rise 10 feet, only nine inches thick at crown; three-hinged arch, Steyr, Hungary, span 137 feet, rise only nine feet, or one-fifteenth of span. The Monier method is concrete with wire netting embedded near the soffit. Arches of long span and slight rise in building construction are being made with the Guastavino system of cohesive construction, which is practically a revival of ancient and mediæval building methods. See ARCH, MEMORIAL AND TRIUMPHAL; BRIDGE; BUTTRESS; VAULT.

FRANK D. BOURNE,
Architect, Boston, Mass.

ARCH, Memorial and Triumphal, a monumental structure erected in honor of a prominent person or memorable event. In the custom of temporarily decorating the gates of cities with garlands and trophies, on the return of a victorious general, we can find the origin of the triumphal arch. These are similar in form whether commemorating a peaceful event or a military triumph. In the time of the Roman republic temporary arches were erected in honor of triumphant generals. At that period also memorial arches or *formices*, were erected in memory of some individual or to ornament a city, but it was not until the time of the empire that the triumphal arch, the *arcus*, came into use, to perpetuate the glory of a person who had obtained the honors of a triumph. Arches were often placed at the entrances of cities, becoming in such a position merely monumental forms of city gate. The usual form of triumphal or memorial arch employed a high and imposing semi-circular arch as its central motive, resting on heavy piers, which were decorated generally with Corinthian columns and other architectural details, statuary, and bas-reliefs. Above this was a heavy mass of stone-work or attic, on which was placed a suitable inscription. The arch of Titus, at Rome, is the most remarkable for its purity, the beauty of its sculpture and the harmony of its proportions. It was probably erected by Domitian in honor of Titus to recall his conquest of Jerusalem. In panels on the inner sides of the piers are sculptured, on one side the triumphant Titus on his *quadriga* surrounded by soldiers; on the other side the triumphal procession, with the spoils of the Temple, the sacred vessels and the seven-branched candlestick. At the foot of the Capi-

tol, at the side of the Forum, is the arch of Septimius Severus, erected in honor of this emperor and his two sons to commemorate their victories over the Parthians and the Arabians. It has small side arches reached by a few steps, and a large central arch. The most important arch in Rome is that to Constantine, which is similar to that of Septimius Severus. It was erected by the Senate and the Roman people in honor of Constantine. The arch of Trajan at Ancona was erected on a pier which serves as a base, and was a memorial of the completion of that port. It is said that another arch of Trajan at Benevento was erected to commemorate an extension of the Appian Way. In modern times the name "triumphal arch" is given to a structure of wood or staff decorated with flags, banners and floral designs, as a part of some public celebration, or in honor of some person; for example, the Dewey arch in New York. This is an outgrowth of the old Roman idea. Modern history has illustrations of many examples of this form of arch. Albert Dürer has made many engravings of the triumphal entry of the Emperor Maximilian, and of the arches erected in his honor. There are also illustrations of arches for Charles V at Boulogne; to Henry III at Lido, on his trip to Venice. Rubens made the designs for the triumphal arch for Ferdinand of Austria at Antwerp, and a large arch was erected to Louis XIV at the Barrière du Trône. There are also triumphal arches in Paris: the Arc du Carrousel near the Louvre, built by Napoleon I, now destroyed; Porte Saint Denis, built by Louis XIV; the large Arc de l'Étoile, dedicated by Napoleon to his soldiers and sailors; and Porte Saint Martin (1674); in Berlin the Brandenburgerthor at the entrance of the Thiergarten. In the United States there are arches of this character in Brooklyn, N. Y., and Hartford, Conn., and the Washington arch in New York.

Among celebrated arches of this character, mediæval and modern, may be named the following gateways: At Naples, the Arch of Alfonso of Aragon (1470), and the Porta Capuana; at Burgos, the Santa Maria; at Montpellier, a 17th century memorial of the revocation of the Edict of Nantes; at Milan, Della Pace; at Munich, Siegesthor (Victory Gate) (1850); and at London, the Marble Arch. See ARCH; GATEWAY.

Fontaine' (1830); Piccioni, M., 'Sculpture of the Arch of Constantine and Trajan's Column' Romæ, n.d.; Reina, J., 'Description of the Arch of Peace in Milan' (Milan 1839); Reinach, S., 'L'Arc de Titus' (1800); Reland, 'De Spoliis Temple Hierosolymitani in Arcu Titans'; Rossini, L., 'Gli Archi Trionfali, Onorarii e Funebri degli Antichi Romani Parsi per Tutta Italia' (1836).

ARCH BRIDGES. See BRIDGE CONSTRUCTION, MODERN METHODS OF.

ARCH OF CONSTANTINE, a triumphal arch at the junction of the Via Sacra with the Via Triumphalis, Rome. It was erected in 315 A.D. in commemoration of Constantine's victory over Maxentius and is the best preserved monument of ancient Rome, probably because it was built by a Christian emperor. The inscription on its face is interesting to Christians as revealing the Emperor's conversion from paganism. (See ARCH, MEMORIAL). Consult Platner, 'The Topography and Monuments of Ancient Rome' (New York 1911).

ARCH OF SEPTIMIUS SEVERUS, a well-preserved triumphal arch, erected 203 A.D., in the Forum, Rome, to commemorate the victories of Severus over the Parthians. The arch is 75 feet high and 82 feet broad. Above the outer arches are panels representing the campaigns of Severus; the pedestals of the columns show groups of prisoners taken during the war. The arch was used as a stronghold in the Middle Ages and for a time in the 17th century the side passages were turned into shops. See ARCH, MEMORIAL.

ARCH OF TITUS, a memorial arch at Rome on the Via Sacra, erected in 80 A.D. in honor of the conquest of Judæa. It is richly sculptured and shows reliefs of Titus in triumph, with the plunder of the temple at Jerusalem, including the seven-branched candlestick and the table of showbread. In the Middle Ages the fortifications of the Frangipani were built up about the arch, and when these were taken down in 1822, the arch was also taken down and rebuilt as fears were entertained for its safety. See ARCH, MEMORIAL.

ARCH OF TRAJAN. 1. A well-preserved memorial arch at Ancona, Italy. It was erected by the Roman Senate in 112 A.D. to commemorate the new harbor works erected by Trajan. It has a single archway 29 by 46 feet. 2. A white marble arch erected at Benevento, Italy, in 114 A.D. to commemorate the completion of a new road to Brundisium by Trajan. It is 50 feet in height and its reliefs portray Trajan's victories over the Dacians. It is one of the best-preserved specimens of the Roman arch.

ARCHÆAN. See ARCHEAN.

ARCHÆAN, ä-r-kē'än, **PERIOD**, a term applied to the most ancient division of the geological time-scale. The rocks referred to this period underlie the oldest sedimentary and fossiliferous strata and hence are often called the fundamental complex. They are entirely of crystalline character, consisting of granite and basic eruptives, gneisses and schists, all of which bear evidence of having undergone great disturbance and metamorphism, so that it is impossible to work out any order of stratigraphic succession that will apply to different regions. Their great uniformity of composition over wide areas, their marked characteristics which differentiate them from all other groups of rocks, and their basal position in the geological scale have led many geologists to believe that the Archæan rocks represent a portion of the original crust of the earth as it solidified from molten magma. While this view has not found universal acceptance, it is quite certain that if the first solidification of

the earth is still preserved anywhere, it is present in this formation. The Archæan rocks are known to occur in all of the continents, although in some regions they have been brought to the surface only after long periods of erosion during which immense thicknesses of overlying strata were removed. In North America they cover much of the region between the Arctic Ocean and the Great Lakes, and are also found in the Adirondacks, along the Appalachians and in the Rocky Mountains. They occur in many parts of Europe, especially in Scandinavia, France, Germany and Austria, in eastern Asia and in central Africa. See GEOLOGY.

ARCHÆOLOGICAL, ä-r-ke-ö-löj'i-käl, **INSTITUTE OF AMERICA**, a society formed in 1879 for the purpose of promoting and directing archæological investigation and research. Under its direction several important excavations were conducted on the site of the ancient city of Assos. It publishes a bi-monthly *Journal*, which is its official organ. It has a membership of 1,050.

ARCHÆOLOGY, ä-r-ke-öl'ö-j'i ("antiquity-study"), the history of antique human progress as inferred from relics of man's industry or presence, apart from written records. It is thus identical with history where there are no such records, and supplementary material for it when they exist. It is distinguished from anthropology as concerned chiefly with industrial and artistic rather than social and political progress. But its limit neither of date nor of subject can be sharply fixed. The antiquities of a country are relative to its present and its records; 400 years in Mexico brings us to pure archæology, 2,000 in Greece and Rome is almost this side of it, all west-Asian history belongs to it. Even written records, if inscriptions on stone or brick, or papyri, are archæological when pertaining to an extinct civilization; if classical, they are history, epigraphy, or palæography. Nor can we wholly dissociate the biological study of the bones found in a prehistoric camp, river drift or cave (palæontology), from that of the flints, worked bones, drawings, etc., found with them, as evidences of mechanical and intellectual progress (archæology), and the social organism implied by the camps, food, ruddle, etc. (anthropology). The genesis of the science restricted the name at first to remains of classical art and architecture, still often regarded as its most important section, through its illumination of classic literature; but general archæology does not merely supplement a developed history; it reveals the very existence of empires, nations, races, cultures, stages of human progress, otherwise unsuspected, and carries our knowledge far into the geological past.

The classical branch, whose material was relatively accessible and its bearing obvious, naturally originated first in the 18th century; general archæology is the creation wholly of the 19th century and has two independent origins. On one side it springs from the decipherment of the Egyptian hieroglyphs, unveiling a remote history implying a still more remote one and making scholars realize for the first time how futile were the distorted scraps of classical tradition. This was fol-

lowed by excavations in Mesopotamia which uncovered the remains of the Assyrian culture, and by the decipherment of the cuneiform characters. Here it was first realized that archæology is the one branch of history, (for numismatics is a department of archæology) that absolutely settles historical questions. A written statement may be a falsehood or mistake, but an inscription is conclusive as to its date and writer. On the other side, archæology springs from the examination of relics of antique man in burial mounds, kitchen middens, lake dwellings, caverns and river drifts, showing his coexistence with animals long extinct and in geologic ages long gone by. These two streams have gradually resulted in a vast storehouse of verified knowledge, not only unsuspected, but revolutionary of assertions previously supposed axiomatic. Briefly, archæology has shown that civilization is not a sudden mushroom growth of a few dozen centuries, from a single centre and a highly developed group, but a gradual evolution through enormous ages in all parts of the world, from that intermediate condition between apehood and manhood which we know must have existed, but of which no positively demonstrable evidence has been discovered. Savagery, as we know it, is a long step in advance.

In place of the convenient division into "civilized, half-civilized, and barbarous," we have many stages of culture, based on the knowledge of natural forces, the utilizing of natural products by art and the co-ordination of social groups, in combinations almost as endless as the notes of an organ, the same tribe being almost civilized on one side and wholly savage on another. The classification of these grades is somewhat different in archæology and anthropology. The latter, in Lewis H. Morgan's system (which needs much qualification) marks seven stages: The first prior to the use of fire; the second marked by the discovery of fire (fire can hardly be said to have been discovered by man, as it long preceded the dawn of humanity, and its availability for warmth, and subsequently for cooking, would come about naturally, i. e., without any effort of intellectuality on man's part), and of catching fish; the third by the bow and arrow (the significance of the bow and arrow in archæology is not the same wherever this form of weapon was in use. It had an independent origin in each continental area, and whatever the starting point or prompting of the inventive faculty, the ultimate outcome would necessarily be the same. If, as persistently claimed, North America received its quota of humanity from Asia, it is certain it was at a date so early that the bow had not anywhere been invented); the fourth by pottery; the fifth by the domestication of animals, or the use of irrigation, polished stone or bronze tools, and the occurrence of adobe or stone architecture; the sixth by the use of iron; the seventh, or true civilization, by phonetic alphabets and written records. Archæology, however, finds it convenient to classify man wholly according to the material and construction of his implements, these having in fact accompanied and determined with great accuracy a corresponding set of changes in industrial arts and even social development. Accordingly it divides human progress into the Eolithic ("Stone-Dawn")

the Palæolithic or Old Stone, the Neolithic or New Stone, the Bronze and the Iron Ages; a portion of these being still further subdivided.

For vast epochs after the appearance of man upon the earth no record of his presence exists or can exist except a paleontological one—his bones. He doubtless wrenched off tree branches and threw or hammered with stones, like the higher simians, but we cannot prove a broken branch or scratches on a stone to be artificial, or due to man rather than to orang. When, however, a stone is rubbed, or evidently bruised from repeated use, still more when a number of these are found near together, we know that something more than casual use by an animal has produced the result; but it may mark only the utterly unrisen savage, who lives on nuts and fruits and sleeps under any casual tree or bank and has not thought of improving on nature.

The distinction must be kept in mind, however, between an implement and an artifact and the former is even more durable than any skeleton or part thereof; but no amount of use of a pebble as a hammer can distinguish its abraded surface from that of one in use by the latest aborigines. This is peculiarly true of quartzite pebbles, that seem to take on no appreciable patinations, that sure guide to the antiquity or lack of it, of an artifact. The first identifiable stage of real culture is:

The Eolithic Age.—This probably began (probably elsewhere also) in Kent, England, where loose flints lay about or might be easily dug from the chalk. These were very roughly hammered into an edge that would bruise off a stick or into a grip for the hand; so roughly, indeed, that their having received deliberate art at all was long bitterly contested. They are found in river deposits on the top of hills 600 feet above the present stream-beds, which must therefore have been excavated since. Even in this remote antiquity man was no new organism on the earth, and this stage of culture, from the excessive slowness of progress in the early stages, must have lasted for a long period.

The eolithic implement will always be a subject for dispute, because so like in every characteristic the unfinished implement of a more specialized type. Wherever the unmistakable polarlithic artifact is found, there will also be a still cruder object, yet distinctly artificial, which comes within the classification of "eolith." It may or may not be, under such circumstances, but such objects tell quite another story when they are found in deposits of gravel older than the latest glacial drift, and unassociated with any other trace of man's handiwork. This occurs in North America and serves the double purpose of establishing the geological antiquity of man on this continent and demonstrating the fact of an eolithic culture in Europe and presumably in Asia and Africa.

The Palæolithic Age succeeded; the former till recently was reckoned a part of it. It is now further divided into two chief periods, from the anthropological differences implied, those of the river gravels and of the cave-dwellers; and the latter again into three others, with well-marked stages of culture. More specifically:

1. River gravels up to 200 feet above present beds ("Achuleen"). The remains are mas-

sive flints scarcely less rude than the former, but unmistakably worked. They still antedate any permanent dwelling or shelter.

2. Cave-dwellers. Man now has a permanent though not artificial dwelling, and the germ of family life is born. (a) "Moustérien": Flint flakes split off (the first true artificial tool), and massive flints hammered into definite shapes, with others rude like the former. (b) "Solutrien": Flints carefully worked and finely shaped. (c) "Magdalénien": Well-shaped flint tools, plentiful bone-working with them, and drawings on implements and the walls of caves.

All these remains have been found, along with fossils of the mammoth, cave-bear, cave-lion, sabre-toothed tiger and other extinct forms, in ancient river deposits, deep under stalagmitic accumulations in caves, beneath American lava-beds, etc. The age assigned to these deposits by geologists is from 100,000 to 300,000 years. Another clue of the same significance is the circumstance that in Egypt flints are found together, of which the latest, neolithic, were dug and worked fully 7,000 years ago, and are tinged only a faint brown, while others, palæolithic, have turned nearly black. The most conservative estimate is 100,000 B.C. for the beginning of the eolithic period; the palæolithic had not ended yet, but in the advanced regions it began to be displaced by the neolithic perhaps 10,000 B.C. Roughly speaking, the Old Stone periods cover a space 10 times as long as all those since put together, the latter succeeding each other with relative swiftness, as progress accelerates by its own development. In some respects the 19th century has shown more advance than all the previous half-million years of man's existence. The rate of progress has depended greatly also on the natural advantages offered: the flint mines of the English chalk hills with the early savage perhaps corresponded to the coal and iron mines of the present, producing rapid advance in skill and also competition of tribes, the stronger expelling the weaker from the coveted districts. On the other hand, the lack of domesticable animals in America had much to do with its slight progress under barbarism.

The occurrence of a *Palæolithic Age* in North America gave rise, when first suggested, to intemperate opposition and as this was based on ignorance, the illogical position was more amusing than convincing; but the evidence of a geological antiquity steadily accumulated until now the existence of man in North America in what is accepted as the palæolithic culture is a commonplace in the world's range of knowledge.

What is included in the term *Palæolithic* is still a subject of debate. The name, as originally applied by Lubbock (Lord Avebury) to the large almond-shaped artifacts of ancient gravel deposits, has been extended until it includes more specialized forms of artifacts and, as a whole, indicates that man at that time and under those conditions was not as bestial as some groups of man, not yet, or but recently, extinct.

Our knowledge of man's career on earth, *ab initio*, is too fragmentary to speak in positive terms as to the progress any group made before its disappearance, for there is no instance of a people continuing from late tertiary

time to the present in any one locality. Occupation, abandonment and reoccupation was the rule, and hence it follows that no worked instance has been brought to light of a strictly palaeolithic people gradually becoming neolithic in culture. The more specialized status replaced the less advanced, and two peoples, not one, appear in the change. That the North American Indian emerged from a palaeolithic to a neolithic stage is a natural inference, as we have no geological conditions as in Europe to guide us in determining relative antiquity of this or that area and its artifacts, but so distinct are the conditions that separate one deposit of sand, gravel and clay from another, and so characteristic are the artifacts of those different deposits, it is logical to assume that one period of occupation ceased before a succeeding one began. Were we dealing with stratified rock, there would be no confusion; no question could arise, and the determination of actual conditions could, in the case of sands, be accomplished by excavations on so great a scale that demonstration could be had by virtue of numbers of artifacts found and circumstance of occurrence recorded. This has now been done and not only has the antiquity of man in North America been fully established, but the incoming and vanishing of one or more peoples occurred prior to the final possessing of the land by the historic Indian.

The Neolithic Age is the evident beginning of modern life, made possible by improved working tools. The remains of this period are not buried under geologic deposits, but lie on or near the surface. Recent finds in Florida of apparently neolithic culture have occurred at such depth and under such geological conditions as to indicate a greater antiquity of Neolithic Man in North America than had been held. They are no longer merely hammered or chipped, but rubbed or ground to shape, giving a sharper edge and a smoother surface. There is a gradual advance in the best specimens to weapons and tools almost equal to metal, such as lance heads, arrow heads, knives, daggers, awls, chisels and axes of razor-like sharpness and needle points, serviceable for and accompanied by highly developed arts and manufactures, agriculture and navigation, of remarkable magnitude and variety. As timber could now be easily cut, men built large wooden dwellings and rowing galleys. Early in the period we find immense earthworks both for defense and for burial; later, in the cities, brick architecture and fine engineering. The lake dwellings of central Europe and England belong to this period, and, being built on piles over the water, combined security against wild beast and animals with easy fishing, a fashion that spread widely and no doubt rapidly; indeed, some of them with their neolithic inhabitants lasted into historic times. From these discoveries it is evident that man not only hunted and fished, but raised grain, vines, fruit and flax, breeding domestic animals to draw the plow, another immense gain to agriculture; spun and wove; made pottery, and not only ornamented that but his tools as well, shaping them for beauty as well as use, thus showing development of æsthetic taste. Still more important was the social development. The large camps indicate a settled tribal society, the careful selection of material

from considerable depths indicates combined labor in mining.

Between this and the Bronze Age there existed in some countries what is called by some archaeologists a Copper Age, where native copper was hardened with oxide of arsenic; but as it did not drive out flint tools, but only supplemented them, it is hardly entitled to be called an epoch, and is not accompanied by any identifiable advance in general progress consequent upon it, like the others.

This is peculiarly true of North America, where copper was used extensively and fashioned not only into useful but ornamental shapes, but it always supplemented and never replaced the use of elaborately chipped and polished stone artifacts. It is known almost to a certainty that the Indians were well supplied with copper at the time of initial European contact, and some of it appears to have been mistaken for gold by the avaricious colonists. As metal, it was of use to the Europeans and collected wherever possible for conversion into vessels for culinary use. In this way was lost a vast amount of valuable ethnological material, which, had it been preserved, would have thrown much light on the status of the aborigine at that time.

The Bronze Age, however, was an enormous step forward. It was earlier in Assyria than Egypt, probably from the Armenian copper: the former introduced it by 5000 B.C.; the latter not fully till about 3000, and did not use it freely till 1600, only 500 years or so before iron displaced it. And in all countries stone implements were still used in sacrifices to the gods, who did not like new inventions. The hardness of the alloy of copper and tin seems to have been realized before its toughness and the many advantages given by ability to cast it; hence at first the stone tools and implements were simply copied in massive bronze, and were needlessly heavy and limited in pattern. But as its properties became evident the tools were much lightened, and made thin yet stiff with embossed patterns, and various kinds invented which could not have been made in stone, as the sickle gouge, etc. The axe, or celt, was first made as a plain bronze wedge fastened by a thong, as with stone; then cast with a socket for the helve, an extraordinary gain in efficiency. There were light cups and kettles, knives and chisels, spear- and arrow-heads, swords and daggers and bronze-bound shields and a mass of personal fastenings and adornments. Some of these were impossible in stone, as buttons, buckles and pins, necklets, bracelets, rings and earrings. A priceless collection of these objects was found at Bologna, Italy, in the shape of the abandoned stock of an ancient bronze founder. The industrial advantage of this newly found hardness, toughness and variety developed industries and trade immensely; it also made possible for the first time true stone architecture and engineering of hewn and dressed stone. No small branch of business in stoneless Egypt was the quarrying and transportation of stone for the public works from the southern rockier regions.

Megalithic remains, wherever they occur, have always given rise to much speculation as to age and origin. If our present actual knowledge of such antiquities in Europe and Asia lays bare the secret of their origin and approx-

imate date of construction, the same cannot be said of somewhat similar structures in North, Central and South America. Led by resemblances, real or fancied, these examples in American forests of masonry on a gigantic scale have been held to demonstrate the "influence" of that people of another continent, whose work "appears" to have been the model for the American structure.

This is scarcely logical. Close resemblance may be accidental and the same thought may arise in minds that have no knowledge of the existence of another people than themselves. A rock-shelter or a limestone cavern may readily suggest an artificial shelter of stone and once this thought arises, the steps toward elaborate, artistic and we may add scientifically constructed buildings would inevitably follow. The engineering difficulties would be solved, if not everywhere in the same, always in a similar way, and no borrowing of ideas is called for.

As it cannot be shown that the climatic or physical conditions in the Americas was ever such that local advance was impossible among its native races, the "influence" or actual presence of a foreign people is not called for to make plain the peopling of these continents, and the checkered careers of its various nations, races, tribes or whatsoever designation may be preferred in distinguishing them.

The Iron Age is the present (though the 19th century developed what is really a distinct era, the Steel Age, making possible many advances beyond those of iron), and the most of its course belongs to history. It originated from about 1200 to 1000 B.C.—that strange period, in seeming the blackest in the calendar of the ancient world, when the old civilization of Mesopotamia had collapsed under the Semitic invaders, Egypt had sunk into decay, and barbarism seemed to have reasserted its reign over both the Eastern and Western world, yet in which lies the birth of perhaps the three greatest factors of human progress in historic times—the use of iron, the alphabet, and the Hebrew nation. The first is thought to have sprung from Armenia; regarding the second, the Phœnician origin is still valid; the third is a mysterious gift of Arabia.

Babylonia and Assyria.—The civilization of the Mesopotamian plain is not only the oldest in the world so far as known, but the first (unless with the possible exception of Egypt) where men settled in great city communities under an orderly government with a developed religion, practising agriculture by irrigation, erecting adobe buildings and using a syllabified writing. All modern Western civilization is its direct descendant through Greek and Roman periods, so that in studying it we are studying our own ultimate intellectual and even religious pedigree. Its astronomers gave us the division of the year into months, weeks and days, the signs of the zodiac, the constellations, the division of the circle into degrees; its art was the foundation on which Greek and Etruscan art was built; its religious names, forms and traditions are a deep element in the Hebrew, as in its cosmogony and mythology and such forms as the Psalms, and hence enter into Christian thought. Nor are we the only beneficiaries. For some 6,000 years the cuneiform was the business and literary script of the whole civilized world, the one method of writ-

ing from the western Mediterranean to India, and probably the origin even of the Chinese, as Mesopotamian civilization was the parent of Chinese civilization.

The physical difficulties and dangers of exploration in this district (once a garden and turned into a desert by Turkish misgovernment, a region without supplies or administrative order, and infested by hordes of dangerous Bedouins), as well as the difficulty of obtaining justice or possession of one's goods from the Turkish authorities after finding them, have kept it far behind that of Egypt in thoroughness; but the results have been not less splendid in additions to our knowledge of the past. The earliest studies—those of J. B. Rich, Indian Consul-General at Bagdad, in 1818–20, who collected sculptures and outlined Assyrian art; the excavations by the French consul, Botta, at Khorsabad in 1843, of Nimrud and Nineveh by Layard in 1845–51, and Hormuzd Rassam in 1854—were of relatively modern Assyrian sites. The first entrance on the ancient Babylonian civilization was made at Erech (1849–52) by Loftus; a further one by Sarzac in the important Tello excavations of 1876–81; but by far the most important was by the Americans, Peters and Haynes, with Hilprecht, at Nippur from 1889 down. This was probably the first city foundation in the world, dating from about 7000 B.C., then a seaport and now 120 miles inland; and the great temple library has poured floods of light on the political and social condition of this mother-land of modern culture. Next to this, our greatest source of information—for Babylonian history almost the whole—has been the library of Nabonidus, the last king, at Babylon. The whole fabric of Assyrian chronology rests on his statement that Naram-Sin, the son of Sargon, lived 3,200 years before his time—a suspicious number, the dubiousness of which leaves half that chronology a thousand years or so doubtful. But the subject was practically sealed till the decipherment of the inscriptions gave the key; and this was immensely complicated by the fact that the cuneiform character, like the modern alphabet, did not imply any given language, but was used for all the tongues of the then civilization. The first step was taken in 1800 by Grotefend, who identified Persian names and then applied the characters to other names, till he made out several Persian inscriptions, while Bournouf (1836) and Lassen (1836–44) worked out the rest of the Persian alphabet. But this was only a small part of the enormous Assyrian syllabary of 600 signs. The task was finally accomplished by Sir Henry Rawlinson by means of the great trilingual Behistun (q.v.) inscription, in Assyrian, Median, or Vannic, and Persian; his knowledge of old Persian gained from Zend and Sanskrit enabled him to identify the Persian words in Assyrian character, and thus resolve the vast Assyrian syllabary. This has given the clue in turn to the other languages written in the cuneiform: the old Sumerian, Median, etc.

The general results are as follows: The earliest inscriptions show us a mixed people speaking two languages: one certainly Semitic, the other an archaic Semitic or Aryan (the Ural-Altaic affinity is now discredited). The non-Semitic element known as Sumerian

("river-men"?) is believed to be Aryan, related to the Caucasian tribes, and to be the original settlers of the valley. Into this valley came, somewhere between 10,000 and 8000 B.C., a Semitic invasion (Accadians—"highlanders"?) from the upper Euphrates-Tigris valleys, and by 5000 B.C. had developed, through the mixture of two powerful stocks, the wonderful civilization we know. The beginnings were in the Neolithic Age, but by 7000 B.C. the people were already organized into nations, and built fortified towns, the centre and heart of each being the temple of the local god, raised on immense piles of brickwork. They had finely colored and ornamented pottery, made with the potter's wheel. The principle of the arch was known as early as 5000 B.C.; the architecture was careful and related to the nature of material; drainage systems were constructed to prevent soaking into the adobe. Several important centres existed by about 7000 B.C., including Nippur, Ur, Eridu and probably Erech. When we first find inscriptions, perhaps about 4000 B.C., there had already been evolved from the old picture-writing a system of conventionalized line-symbols, some pure pictographs, some ideographs, some syllables; and while at first the writing was entirely votive or commemorative, and stone used as the material with straight lines, it was soon applied to business and record, the ever-present clay utilized and the lines assumed the familiar wedge or cuneiform shape. Sculpture and the engraving of gems and gold were already at a high level shortly after 4000.

The history will be found under Assyria and Babylonia. The great landmarks are the reign of Sargon, the Charlemagne of the ancient world, who founded a huge west-Asiatic "empire" from north Arabia to Armenia and west to the Mediterranean; the second great Semitic invasion from Arabia about 2500 B.C., overrunning south Babylonia, and the Elamite invasion from the Karun valley in Persia about 2300 B.C., subjugating the remainder; the expulsion of the Elamites about 2250 by Hammurabi ("Amraphel"), and the founding of Babylon, which became for 17 centuries the Rome of the Asiatic world, the political and religious centre at once; the first emergence of Assyria, on the Accadian highlands, about 1800; the Kassite invasion from the Persian highlands 1782 B.C., founding a dynasty which ruled Babylonia till 1207; their expulsion; the great double invasion of Semites from the south and Aryans from the north, which broke up the Hittite empire and overwhelmed Babylonia and Assyria in a common wreck; the collapse of the Old World civilization; the re-emergence of Assyria and its domination over Babylonia, from about 900; its eclipse by the growth of Armenia in the 8th century; its new and enormous power under Tiglath-Pileser II, who annexed Babylonia; the destruction of Babylonia by Sennacherib, 689 B.C.; and its rebuilding by his son Esarhaddon; the rebirth of Babylonia under Nabopolassar, the Chaldean, who extinguished Assyria, 610 or 609 B.C., and, after a short, brilliant career, the end of the Babylonian-Assyrian power forever through its conquest by Cyrus. The relation of the Assyrian power to the Babylonian was much like that of Rome to Greece; though on a lower scale, for the Assyrians, though great warriors,

had none of the organizing and assimilating power of Rome. Assyria copied laboriously, and on the whole clumsily, the literature and art of its intellectual masters, and produced no literature proper of its own. But its libraries, copied from the Babylonian tablets with minute textual and critical accuracy, give it an imperishable claim to our gratitude.

Egypt.—The archaeological history of prehistoric civilizations was studied in Egypt earlier, and has been studied there more fully, than elsewhere, from the accessibility of relics and safety of work, the involution of Egyptian politics and history with records in a classic language through the existence of an Egyptian state under classic rulers, and the survival of a descendant of the Egyptian language to our own day. It was the latter which furnished the key to the decipherment of the hieroglyphic records. The Rosetta Stone (q.v.), discovered by the French in 1799, bearing a proclamation in hieroglyphic, demotic and Greek, invited a textual comparison. An Englishman, Young, devised a correct principle, but had neither knowledge nor interest to apply it in full; Sir William Gell utilized his knowledge of Coptic, and identified three-fourths of the signs; Champollion, the Frenchman, was a thorough Coptic student, and in 1821-32 worked out the entire system for use. This first made it possible to rescue Egyptian history in pre-classic times from the fog of distorted Greek legends, scraps of priestly record and misapplied Biblical comparisons, while the excavations at Thebes in 1820-30 opened up the Ramesside and neighboring periods 1500-1000 B.C. Later, Lepsius and Mariette were foremost in revealing the period of the Pyramid-Builders, carrying us back to far past 3000 B.C.; and still later Dr. Flinders Petrie has not only turned the First Dynasty and others still farther back, from myth into solid history, but has recreated the prehistoric world prior to the organization of the monarchy, about 4800 B.C., with a surety as great as that of written record. In the historic periods, the total lack of any chronological sense in the Egyptians, who in this respect were very different from the Assyrians, and the catastrophe of the Hyksos invasion, make its history in large portions less clear than the Babylonian; but we know its general outline at worst, and the synchronism and variations of arts and industries often supply the lack of dated chronology.

The oldest inhabitants of upper Egypt known were of the same race as the Algerian Kabyles of to-day—a white-skinned, blond, blue-eyed, narrow-headed race, with a negro strain, allied to the south European races. They had acquired by 5000 B.C. the highest grade of Neolithic civilization ever reached in the world, so far as evidenced by tools and implements—the finish of the flint-knives and lances being incomparable—and were using copper ones also. They built brick towns and carried on an active Mediterranean commerce in large rowed galleys; they made leather and woven linen clothes, beautiful and varied pottery without the wheel, perfect vases of the hardest stone without the lathe, applied colored glazes even to great rock carvings, manufactured ornaments of precious stones, metals and ivory, ivory spoons and combs, games, etc. Their art, however, was very crude, and they had no

system of writing whatever, though using marks. About 5000 B.C. a much more developed race invaded Egypt—probably from Arabia, whence the Hyksos and the Hebrews and the other Semites came: a race which used metals more freely, had a system of writing, a better government organization and higher artistic taste. Here, as in Assyria, the blending of two able but diverse strains made the great Egyptian type and civilization of the Old Kingdom which we know from their monuments and achievements. They were a grand people in every way: active warriors and administrators, firm in policy, fine mechanicians, adepts in organizing combined labor; strong artists, with lofty conceptions; withal a sensitive, kindly, sympathetic folk, with the least strain of ferocious savagery of any great people in history. This long era has left us the pyramids and magnificent monumental tombs, masses of grand and accurate architecture and noble sculpture. This great age could not last forever, and for some centuries after about 2500 B.C. it was in decline, to revive only less brilliantly in the 12th dynasty about 2000 B.C., considered by Egyptian writers their Golden Age of art and literature. The tremendous catastrophe of the Hyksos invasion, already mentioned, took place probably about 1780 B.C., and the "Shepherd Kings" remained till about 1600. Their final expulsion opened a new and brilliant era, of expansion into and domination over west Asia, of the closest relations with the Mediterranean countries, of a general spread of luxury through the people. Egypt for the first time threw off its exclusion and became part of the current of the world's progress. In this period (about 1600-1200) we find, near the beginning, the great Thothmes III, whose exploits were exaggerated into the Sesostris of Greek tradition; near the end the rather braggart King Rameses II, commonly identified with Joseph's Pharaoh, and his son Menepthah, often accredited as the Pharaoh of the Exodus. But the empire had the doom of all states which live on the tribute of foreign districts: the outside revenue stopped, the habits of luxury remained and the nation declined. In the thousand years to follow before it was absorbed in Rome, it had much prosperity and some periods of brief glory, but the vital spirit had gone.

Syria.—While the work of the Palestine Exploration Fund, from 1866 onward, has thoroughly mapped out the surface of the country, relatively little has been done in excavation here or in Turkey; for political reasons, (as before noted) mainly, as the interest in Biblical sites and classical remains is the keenest of all. The chief part thus far has been at Jerusalem and the Philistine cities, and in the north at Zinjirli; but few inscriptions have been found even where the excavation has been done, and no very ancient ones. The most important historically is that of Mesha, King of Moab (? 896 B.C.). It would seem that by the time the Jewish nation was advanced enough to make inscriptions, its intellectual activity was drawn off in other directions, and the hope of finding masses of archaeological confirmation of or supplement to Biblical records has been disappointed. The chief historical result of Syrian research has been to restore the Hittites (q.v.) to history: formerly

regarded as a Canaanitish tribe, they are now known to have been a powerful people from Cappadocia, which formed for a couple of centuries a strong state ruling north Syria and much of Asia Minor, with its centre at Carchemish, till broken up by the great southward Aryan movement of which the Dorian invasion was a part. Its writing is almost undeciphered. Curiously enough, the most important documents for ancient Syrian history have been found not in Syria, but in Egypt—the Tel-el-Amarna tablets, containing a 15th century correspondence with Egypt in cuneiform.

Classical Archaeology.—Till the very recent excavations at Troy, Mycenæ, etc., resulting from enthusiasm for the Homeric poems, archaeological research in the classic lands was mostly confined to illustrating historical periods, and to a study of Greek and Roman art and architecture; even now the light on prehistoric times is not from written records and inscriptions as in the East, but inferential from material objects. It has, however, in confirmation of Egyptian and other records, and by comparison of objects with those of known date in that country and Babylonia, given unmistakable proof of a hitherto unsuspected stratum of old Greek history. From foreign pottery found in Egypt, 5000-3000 B.C., Greece and Italy probably had a Neolithic pottery-making population at those times. But the first positive beginning of civilized settlement is in the lowest Troy, dating certainly before 2000 B.C., and perhaps 3000; almost no metal is found there. Still before 2000 is another Troy with fine vases and golden ornaments. This was contemporary with the supremacy of Crete, then the mistress of the seas, as the Etruscans and Phœnicians were later; and there was a direct connection between Crete and Troy. The legends of the great law-making Cretan kings and their suzerainty over Greece and exactions of tribute from it are doubtless based on fact; even the Labyrinth has been uncovered, and a nucleus of fact in much of the old Greek legendary lore made probable. Three times after this was Troy abandoned and rebuilt before the contemporary of the Mycenaean kingdom of about 1500 B.C. is reached. At this time the coasts of Greece and the Ægean islands were the seat of a high culture radiating in all directions, and even influencing the East, so that this has been styled the "Ægean Period" of civilization. There was a powerful and wealthy kingdom with its centre at Mycenæ, where we find magnificent domed tombs, fine jewelry and metal work, exquisite pottery and ornaments, etc., as also at other great towns marked by hill fortresses, Athens, Tiryns and other places. This rich and prosperous land traded with all the Mediterranean countries, but chiefly with Egypt, in whose ruins are found hosts of Greek objects of this period. By 1100 B.C. this civilization had begun to droop, and about 1000 the invasion of the barbarous Dorians from the north temporarily overwhelmed it on the mainland. But it was only for a time: even where the Dorians had conquered, the union of old and new flowered into richer bloom, and Athens, the chief city which they had not conquered, became the head and heart of a far more splendid revival of every art and literature, the foremost in the world to the present time. By the 7th century the immortals had begun to spring

up: Archilochus and Sappho were islanders, and the great time of Athens had not yet come, but the thronging masters show that society had become fairly settled once more.

The development of civilization was very much later in Italy than in Greece, and more slowly affected by outside civilizations except on the southern coast. The Neolithic Age, with black pottery and lake dwellings, lasted down to nearly or quite 1000 B.C., the full development of the Bronze Age not taking place till about 800. The Etruscan invasion, which tradition brings from Asia Minor, cannot be dated, but was probably later than 1000 B.C. The art and religion of the Etruscans were entirely foreign, indicating rather a Northern than an Eastern origin; but they were not an original people, and borrowed elements of civilization and art from every nation they came in contact with,—Italians, Greeks, Egyptians and Assyrians. In this assimilativeness they remind one of the Northmen, and the tradition of their origin may be wholly wrong. The one great specialty of the Etruscans was engineering. Their history and affiliations remain a mystery chiefly because their language is such. Known since historic times, and in the last century thousands of inscriptions in it copied, and even many words translated for us, the language remains an absolute secret to the laborious and penetrating scholarship directed on it.

Revised by CHARLES CONRAD ABBOTT.

ARCHÆOLOGY, American. America's place in the world's history has been an abundant source of discussion among geologists and archæologists and there existed until recently a wide range of opinion, particularly concerning the antiquity of man on this continent. There is uniformity of opinion as to the occurrence in definite superficial strata of traces of man's handiwork, but the geological history of these strata has been variously considered. It is now generally concluded, however, that they are the products of the concluding activities of various Glacial Epochs, material laid down by floods caused by the melting of the glaciers that filled the valleys and not improbably accompanied by rainfall far in excess of any in post-glacial times.

As yet the evidences of man's antiquity may be summed up in the discoveries made in the valley of the Delaware River (1872-1902) on the Atlantic slope and the shell-heap discoveries (Dall) on the Pacific slope. In the interior of the continent there have been many reported discoveries of evidences of equal antiquity, but so generally were they held to be open to possible errors of observation, due to lack of the skill required in such investigations, that their acceptance has not been general, but their claim is now more and more seen to be valid, in view of similar discoveries elsewhere, where no possible error of observation could occur. This is true even of the much-discussed Calaveras skull and Nampa image. This, however, is not true of the human cranium known as the "Lansing skull," from Kansas and the age of the deposit in which it was found only is in dispute. Much more satisfactory is the result before mentioned obtained by Dall in his investigation of the Pacific coast shell-heaps. Here we have evidence of a gradual change of habit, of a succession of occupations of the region that enables us to deal with "time relative" if not "time absolute," and to feel assured that man's first appearance on the western coast of North America was in the extremely long distant past as measured by years. As shown that traces of man occur in deposits on the Atlantic coast, notably in the valley of the Delaware River, the dual question arises just when and whence came man to the American continent? It is inherently improbable that he did so while glacial conditions obtained in the northern half of the country, for in that case he would have confined himself to those unglaciated regions in the south, where the struggle for existence was reduced to its minimum. It is far more probable that his arrival on the continent was preglacial and that when driven southward by the steady encroachment of the ice-sheet he lingered at its southward limit of extension and lived in a manner not essentially dissimilar to that of the present boreal races, but more favorable in that the fauna was richer than that of the circumpolar regions of to-day. This is not to say that the glacial man of the Delaware Valley and the Es-

kimo of to-day were racially the same, but merely that similar physical conditions would produce essentially the same modes of living.

It can scarcely be questioned that man originally was a tropical animal, and the existence of boreal races indicates that primitive man was slowly differentiated and spreading over the earth, so far changed in habit as the environment required. Preglacial man—at least in North America—is yet to be demonstrated by unquestionable discoveries of his remains, but theoretically nothing can be more reasonable than the claim of his one-time existence. A modification of this view is that in some one of the inter-glacial periods, man may have first appeared. These inter-glacial periods were of sufficiently long duration to permit of vast changes and give ample time for a nomadic man to reach this continent or part of it from some distant point. What that point may be is still a matter of conjecture. We have many theories, but painfully few facts.

From what other continent man came to America is still an unsettled question. The necessity for an ultra-American origin is insisted upon, perhaps illogically, but, accepting the necessity, a migration route is fancied from the direction of Japan or directly across Bering Strait from Siberia and that North America was peopled by an incursion of wandering humanity into the northwest portion of the continent and thence followed down the Pacific coast and finally spread eastwardly until the Atlantic checked the movement. That the Japanese archipelago was the "home" of the first American is possible, so far as our present knowledge warrants our forming any opinion on this point; but, accepting this or another Asiatic origin of this country's "first" people, it is clearly evident, from the traces of them that have been discovered, that the trans-Pacific migration occurred in what we known as preglacial time, and so, so far in the past that race-differentiation had not progressed to an extent at all comparable to what has since occurred. The pioneer invaders of the American continent were doubtless much the same as folk wherever found at that time; in other words, still very near to that primitive condition in which man remained so long after losing all visible traces of its pithecoïd ancestry. If such was his condition, man might well have wandered over a wide territory, tracing each river's valley, up or down, as the case might be, and, depending upon his physical strength and the simplest of weapons, it is little wonder that no recognizable traces of him should be found. His inventive ingenuity was subsequently developed and it is in tracing this from its humblest manifestations to the degree of skill in tool-making ultimately acquired that the archæologist is able to demonstrate that man in the lowest state of savagery originally peopled this continent and that there has been here a growth or development of human faculties which may be considered strictly indigenous. This advance toward what we call "civilization" reached its highest point in Mexico, in Central America and in Peru. That it was influenced in Mexico and Central America, if not elsewhere, by an occasional influx of Asiatic people who had outreached their distant cousins, is persistently

claimed; and certainly, if at a far more remote period an Asiatic savage had reached this country, it is not improbable that such an occurrence should happen in later time, when savagery had given way to a higher cult and travel by land and water was a less formidable undertaking. Such influence may have been impressed at times upon the growing American civilization, but never to such a degree as radically to change its character. The American race was too firmly fixed to be wholly altered, and whatsoever reached it from the East in recent times—geologically speaking—made but an inconsiderable impression.

The very exhaustive study of this whole subject by the late Dr. A. H. Keane is quite sufficient to show that the Americans have always been equal to the task of producing all that exploration has shown these people did produce, and without aid or hint from peoples of other continental areas. Fortuitous resemblance has been allowed to play too great a part in ethnological speculation and the writings therefore of any author who has a preconceived idea, as notably the late O. T. Mason and other students of the historic Indian—a subject unrelated to archæology—lose much of their value. The chapter entitled *Homo Americanus* ('Ethnology' by A. H. Keane, chap. xiii) may be taken as the most logical and authoritative yet written. Therein, the specious pleadings of a non-American origin of all superior output of human skill is shown in its proper light of defective scholarship and lack of experience in the field, where impressions are obtained by the unbiased mind that cannot be had from specimens of stone implements displayed in museum cases.

Dating, then, the appearance of man on this continent prior to the first (Kansan) Glacial period (q.v.) and inferring that his career of differentiation from the universal or palæolithic status commenced in the first inter-glacial period, we find him a "stone-using animal" rather than a man as now recognized, and living such a life as that pictured by European archæologists as obtaining on that continent. Inevitably change took place as soon as the rigors of an Arctic condition (if they obtained) gave way to the temperate conditions of the inter-glacial interims; for it is now established that not one but three or four periods have occurred and so ample time is allowed for the many changes that have taken place since man's advent. The principal indications of the earliest, i.e., palæolithic man, are almond-shaped, circular and oval implements, the first mentioned distinctly pointed and all edged so sharply as to be available for cutting. While quartzite pebbles were largely used, the majority were fashioned from basalt and greatly decomposed on surface, and of argillite—slate that has been fused by volcanic heat—and these likewise are decomposed to a greater or less extent. It has been suggested that this alteration of surface was due rather to submergence in salt water, than to ordinary weathering. (Winchell.)

The intermediate periods were of indefinitely long duration and the changes incident to the first were repeated subsequently, and inferentially man witnessed them all, as he was unquestionably present at the beginning of

the Pleistocene period. During these, the surface was at first but sparsely clad with vegetation and tree growth may have been limited to coniferous forests, and even later to a deciduous forest, which was swept away by the recurrence of glacial conditions. At some undetermined point in time, the bow came into use and there was a faint foreshadowing of the manifold activities of later date, and possible pottery of the very rudest form, but this is doubtful. It was not until these several periods of occupation had passed and traces of them largely obliterated that the "Indian" occupation really commenced. The Indian is a man of history and of that misty borderland of history and geology known as prehistoric time. That there were interims when the "argillite" man was absent and the flint-chipping, pottery-making Indian finally appeared, has been demonstrated. It has been suggested by Hrdlicka that if the argillite man was in possession of the land when the later Indian arrived, there would be found a modification in skull type resulting from the absorption of one race by another. As yet such crania have not been discovered. This is negative evidence and it is offset by the fact that skulls have been discovered in undisturbed glacial strata that are of wholly different type from that of the Indian. How far we can be guided by craniology alone has yet to be determined, but taking in this case all conditions under consideration, in the Delaware valley, where exhaustive researches have been made (Volk), there is evidence that can scarcely be disputed that man was here to witness the closing acts of the ice-dramas—if not their entire progress—and continued to live in this river valley during the subsequent centuries that bring us to the confines of historic time. What relation he bore to the Indian who succeeded him has yet to be determined. The appearances to-day of the soil and underlying sands, each with its imperishable traces of man, suggest continuous occupation of the region, but do not prove it. In 1914, the anthropological department of the American Museum of Natural History, New York, under general direction of Dr. Clark Wissler, made a most thorough examination of the region, near Trenton, N. J., and the scene of Abbott's and Volk's labors for many years previously. The result was to confirm in every particular the conclusions reached by Abbott and Volk. (Consult 46th and 47th 'Annual Reports' of American Museum of Natural History, New York). The author of this article was present at these explorations and was firmly convinced that there was no evidence of actual contact of an earlier and later people, but the probability is strong that such contact did occur. If it did not, Hrdlicka's criticism fails in pertinence and, as yet craniology has not shown that a pre-Indian might not have had the same skeletal structure as his successor. Such osteological differences might have obtained in the formative period of the human species, but not later, when race differentiation was well established. The basalt-chipper need not have been essentially different from the more skillful fabricator of chert implements. However all this may be, it does not affect the se-

quence here given of man's career on the Atlantic slope of North America.

A. PLEISTOCENE MAN
(pre-glacial and palæolithic in culture)

B. INTER-GLACIAL MAN
(neolithic in culture but absence of polished stone?)

C. HISTORIC INDIAN

The so-called Indian of this continent has been so closely studied and his handiwork, whether of stone, bone, metal or clay, scrutinized so exhaustively by ethnologists that everything relating to him is familiar to all. But our knowledge is not as definite and free from contradiction as might be wished. Theories beyond count have been elaborately set forth, each claiming to fix finally the career of these people. The literature of the subject is enormous and stands quite as much a monument to our ignorance as to our erudition. That the Indian is a descendant of the man who reached the continent in pre-glacial time or during an immediately succeeding period is in all probability true. That the variations in his degree of culture and all that he has succeeded in accomplishing are due to his environment on this continent—are an unfolding of his faculties uninfluenced except by Nature—may be accepted as in all probability true of him; even such advanced outreaching toward our own conception of civilization as was found in Mexico, Central America and in Peru does not call for the incoming of a superior people. The Indian of North America, in possession when the country was invaded by the European, has been denied any significant antiquity and not a trace of his labors, whether earthwork, shell-heap or deeply-buried implement has been admitted to possess an age at all suggestive. All the "mounds" have been declared to be of Cherokee origin and not one dating so far back that the years may not be easily counted. Here the pendulum swung too far toward the craze for modernity. As well confuse the Aztec and the Eskimo. There are mounds and mounds—mounds proper, the history of which had faded from the traditions of the Indians; and earthworks that were not beyond the capabilities of the various tribal groups or tribes known to the Jesuit fathers who saw the people to such excellent advantage.

It is to the careful examination of our sea-coast shell-heaps that we must look for those evidences of prolonged occupation of the country which admit practically of no dispute. These accumulations of clam and oyster shells in many localities show that they were begun when the shore level was not what it now is: the base of the heaps being now several feet below the water's surface at low tide. These shell-heaps are to be judged by the traces of handiwork found in them and likewise by a careful study of the shells themselves. The implements and pottery have been found in some instances to be of the rudest description, while in others the traces are of workmanship that was reached only in the palmiest days of Indian time. This might prove a snare to the archaeologist if all considerations were not kept in view, for not a one-time village site in the land but shows a curious commingling of crude and elaborate implements, weapons and ornaments; but it has been found—on the North

Atlantic coast, at least—that shell-heaps that are apparently older are really such from the fact that argillite and basalt implements, and no pottery, are found. This significance of argillite and basalt unassociated with objects of other material has already been pointed out. But more full of meaning than all else is the fact that the same species of mollusk has gradually undergone a change during the time that elapsed between the laying down of the base of the shell-heap and the day of its final abandonment. Evolution is as slow as it is sure, and the change mentioned is alone sufficient to indicate beyond cavil the antiquity of the sea-coast dweller, who must be considered strictly post-glacial, but impressively prehistoric. An overlooked feature of the subject is that of the marked difference in the traces of man found in different village sites scattered over a limited area, as of 10 or 20 square miles. It has not infrequently happened that traces of human occupation have been brought to light wherein nothing but the rudest forms of implements and coarsest grade of pottery occur. Such have been found, too, remote from present watercourses, deeply buried, and the spot still retaining evidences of being heavily forested after the site was abandoned by man. No one can unearth such evidences of one-time human presence without being impressed with their antiquity as counted by years; but of far greater significance is the occurrence of such a village site finally abandoned, overgrown and buried by drifting sands, and then, when not a vestige of it remained visible, the spot being reoccupied by an Indian of greater skill in handicraft. Exposing the relics of the two occupations and placing them side by side, the difference is eloquent of the lapse of time beyond the skill of pen to picture.

That a family likeness should be traceable among the native races of the Americas is not remarkable and as yet there has been no sufficiency of evidence to lead us to the conclusion that the so-called "Indians" are referable to diverse origins. The cranial differences are of degree only, and when a number of skulls are brought together, the extremes are united by a series of gradations that stamp them all as one in anatomical essentials. Yet, viewing the vast territory as a whole, we find wide differences among these people, differences which may be explained, however, by the wholly dissimilar environment; this not including the strictly boreal people, though their variations from the typical Indian are not, perhaps, so great as has been asserted. The marked feature of the handiwork of Arctic man is skill in carving ivory and very strikingly etching it in such a manner that frequently the fauna of the region and mode of life of inhabitants are plainly depicted. But considering that bone and ivory take the place of stone so largely and that there is so much enforced idleness during the long Arctic winter, this artistic taste has been most naturally developed. There must of necessity be some occupation, and the artistic instinct is common to all mankind. Whether or not it flourishes—is a vigorous or a stunted growth—is, again, a matter of environment only. The comparatively few stone implements found in the far North are not noticeably well-fashioned, and the majority of their

patterns are to be duplicated in the one-time Indian village sites of the temperate regions.

The purported Indian etchings on slate are not as artistic in any instance as those on ivory made within or near the Arctic circle, and it is possible that all or nearly all of them should be ruled out of court. They usually tell too much, when they pass from a series of "tally marks" or merely ornamental zigzag lines, which may or may not have had a significance beyond the fabricator's idea of decoration. The tablets from Iowan mounds and the remarkable Lenâpe stone (q.v.) from eastern Pennsylvania stand out so prominently among the Indian relics of their respective neighborhoods, and especially the latter, that an unqualified acceptance cannot be accorded them. If they were the culmination of artistic effort on the part of the Indians of the central West and Atlantic seaboard respectively, the question arises where are the pictured tablets of lesser degree of merit. There is too great a difference between the notches, straight or zigzag lines and the thrilling scene of battling with a mastodon that finally is stricken by lightning. If all this ever occurred we have no evidence that any Indian of that day had the skill to tell the story in this manner. The same is true of the Iowan tablets. That the Indian had not knowledge of the mastodon we do not claim, for there is every reason to believe that it became extinct in comparatively recent times; probably not more than 25 centuries ago. The conditions under which its bones have been found and the instances of association of human and elephantine bones show that before this country's "autochthonic hunter, Behemoth melted away."

As ethnologic importance continues to be claimed by its sole protagonist, of this "Lenâpe stone," it may be well to state that it has recently been examined by one well qualified for the task and the decision reached was that, *if genuine*, its fabricator was familiar with all the folk-lore of North America from Hudson Bay to Florida. This at once shows the object's fraudulent origin. Consult Keane, 'Ethnology,' p. 343.

What the Indian was at the time of the Columbian discovery has a distinct bearing on the archaeology of the country he occupied, inasmuch as an agriculturist he was in possession of maize and grew it extensively. This plant had become during that time a product of artificially or cultivated growth, so modified that but for man's care it would have been lost. Whatever the plant from which it came there is no resemblance to it now. To effect such a change calls for an immense lapse of time. Other products of agricultural skill were as carefully grown and the impression that the results of the chase were the main food supply is not a correct one. The researches of Carr on this subject show how methodical these people were as tillers of the soil and that great suffering followed when their crops failed. The Indians did not come to America as agriculturists; of that we can be very sure, and to pass from the hunter-stage of life to that of cultivator of the ground is not conceivable as a sudden transition; but is intelligible as a slow evolutionary process. This development, in no mean stage as finally reached, shows the upward tendency of the Indians in given areas

over what is now the United States, and how much beyond the status gained they would have progressed had not European invasion checked their career is conjectural. Herbert Spencer believes they had reached the full limit of their capabilities, but among such a people as these Indians in the 15th century it is conceivable that superior intellects might appear occasionally and such men would have their following. If such men are philosophers and not fanatics, a distinct gain is the result. When it is considered that people with merely a novel view and usually an absurd one become prominent for a day and have a host of applauders, it is not unreasonable to suppose that among the Algonkins or Iroquois there might have risen those who saw the folly of war and set forth convincingly the manifold blessings of peace; who realized the advantages of agriculture over the difficulties attending hunting and so brought into existence a train of thought that would influence the people who gave them a hearing. Attracted first by the novelty of the suggestion, they would later see the logic of the argument, if such existed, and a distinct gain be made. That their growth toward our civilization would ever have been equal to our own is quite improbable, as these people have been as long upon the earth as any other race and America offers opportunities for intellectual growth equal to Asia or Europe. What does appear is that the upward growth was in existence when the blight of European contact fell upon them. Certainly the savage of 10,000 years ago was far lower in skill, in handicraft and culture generally than the men who witnessed the landing of the Norsemen. Then, or about that time, a fatal scourge seems to have raged along the Atlantic seaboard and the natives suffered a serious check, the result of which appears to have lowered their status, as smallpox and syphilis, introduced by Europeans later, largely decimated their numbers. The Indians for a time were driven to the dire necessity of daily struggle for bare existence, and many of the better things of which they were capable fell into disuse. So, at least, it seems most rational to explain the fact that these people, when European contact became permanent, were not what they had been. They had not been able wholly to recover from one disaster before another overtook them; the last, Spanish, French and English invasion, proving as destructive as fire upon the dry prairie.

The accounts of what the Jesuit fathers saw and the records of Kalm, Loskiel, Hæckewelder and many others make no mention of many forms of implements, ceremonial objects and talismans that are now familiar objects in all considerable collections of Indian antiquities; but the simpler forms, as the grooved axe, the polished celt, the arrow-head, flake-knife and pottery are not only referred to definitely, but the method of manufacture is given in considerable detail. Their hunting and agriculture are made plain, and we know with what tools they sought their game and tilled the soil, and more prominent than all else, the culture of tobacco, and the pipe in which it was burned, figure in the pages of the early travelers. Not less conspicuous as objects were more than one form of wrought stone implements to which no refer-

ence is made. It is inconceivable that they were successfully hidden, and we can only conclude that they had passed wholly out of use. Assuming that all the products of the Indian's skill in shaping stone, of which we now know nothing, were wholly in disuse and either intentionally hidden or effectually lost, it is strange that the pioneer explorers should have had so little of the archæological instinct as not to have detected traces of them.

With so great an extent of country and such diverse physical and climatic conditions, it is obvious that what were originally one people should by force of environment become widely differentiated in habits of life, and that what are now the almost tropical regions of Arizona, New Mexico and southern Colorado have been long peopled with Indians that superficially differ widely from those of the more northern regions. Their cliff dwellings, rock shelters and well-built permanent dwellings other than those on the faces of cliffs; their pottery, which they had learned to color; their weaving, basket-making and skill in stone chipping and polishing, all point to a distinct advance over the more northern nomadic tribes. It is practically demonstrated, in the judgment of those who have most exhaustively explored this southwestern region of the United States, that when the country was first occupied by the ancestors of the present Pueblo Indian, the physical conditions and climate were more favorable for human occupation than at present; a fact that has its significance, for the antiquity of man in America is one that has been long disputed; at least an antiquity at all comparable to that of man in Europe. Wandering along our Atlantic coast and laboriously picking from the accumulated shells that have almost hardened into rock, trifling potsherd, or a rude arrow point, or inland, walking over a newly-ploughed field, we gather a grooved stone axe, a celt, spear-head, arrow-point, skin-scraper or a drill; some one or two or perhaps all of these in the course of a morning, we are enabled at best to picture man in but an humble way and think of him as almost one with the wild beasts of the forest on which he preyed—an erroneous, but common impression—then, transplanted quickly to the vast southwest, note the substantial dwelling and skillful products in many lines, it is, at first, difficult to think that these people are but as branches of the same tree. The contrast is impressive and by just so much is it misleading. Step by step the gradations may be traced and when familiar with the handiwork of early man everywhere in North America, the relationship is quite apparent. The need of foreign influence to produce the differences, impressed here and there and again and again, is not apparent.

Mexico and Central America present problems that are not yet solved. Here we are brought face to face with what may be dignified as a real civilization, and so far as its genesis and continuance have been determined, it is essentially a thing of itself and points to no influences other than those that the country might exert. That a foreign element gained lodgment here and through intellectual superiority gained control over and finally absorbed a pre-occupying people has not been demonstrated. So far as we now know of it, it is not

a civilization beyond the reach of a native American race. All that is in it that resembles the culture in other continents is far more likely to be coincidence than a transplantation. That essentially the same ideas in given lines may independently arise is beyond dispute. So much more impressive is all that remains of ancient Mexican centres of population that attention has been called to the subject for more than a century and the literature of the subject is enormous, and not free of the curse of undue haste in reaching a conclusion. The Aztec has not been shown to be other than an American Indian, but one advanced beyond the "hunter stage" and so with a fixed habitation. He dwelt where his forefathers had lived and so a more rational, that is, truthful form of tradition was preserved. They were mechanics and artists. They "made useful implements and weapons and high-grade ornaments and jewels from stones, obsidian, and metal (copper, tin, lead, silver, gold); made paper and dyes and were far advanced in weaving, embroidery and feather-work." (Hrdlicka). They knew well the properties of clay and so ceramic skill was highly developed. With these accomplishments, it is not to be wondered at that they were also skilled in architecture and erected not dwellings merely, but temples on an elaborate scale and carved their surfaces in most intricate manner. The advanced artisan is always an aspirant and not satisfied, as he might well be, with the acquirements of reasonable creature comfort; in this instance of the Aztec he devised an intricate form of government and formulated a religion, polytheistic and including "the cult of the sun, moon, and stars; but with this there was a well-defined belief in a single Supreme Deity." (Hrdlicka). This Aztec civilization was not alone in America. The Mayans of Yucatan were equally advanced as architects, as artisans and with society established on an elaborate and intricate basis. If their records have been read aright, they reach back for some 75 or more centuries, and granting this as approximating the truth, and claiming the culture existing as an indigenous growth, the date of man's appearance on the continent is carried so far into the past that we must reckon by centuries and not by years. Pure-blooded Aztecs still survive, but the glory of their culture as it blossomed in pre-conquest times is a matter of history. How great, how far comparable this civilization was to our own can be judged by the exhaustive studies of Madam Zelia Nuttall in her work, 'The Fundamental Principles of Old and New World Civilizations' (Peabody Museum Memoirs 1901). There is nothing suggestive of the "Indian" as we know him in all these pages. Astronomy, mathematics and abstruse philosophical disquisition are dealt with and we find, not unnaturally, that in striving to compass the unknowable they were led to the most extreme cruelty through that anthropomorphic idea of Deity which universally has proved a curse to mankind. The conclusion reached by Mrs. Nuttall is directly the opposite of what has been held in this article as almost if not quite demonstrable; the home, origin and growth of what has been revealed by archæological research. She writes: "I can but think that the material I have collected will also lead to a recognition that the rôle of

the Phœnicians, as intermediaries of ancient civilization, was greater than has been supposed, and that it is imperative that future research be devoted to a fresh study and examination of those indications which appear to show that America must have been intermittently colonized by the intermediation of Mediterranean sea-farers."

Southward, when the adjoining continent is reached, we find in the vast plains, forests, and following the wonderful rivers of that region, savages that have not as high a standing as those of the temperate regions of North America. The struggle for existence has been, in the tropics, and is, too keen to give opportunity to a mental growth not directly concerned with the bodily passions and demands. Above all else, the savage must eat, and if the food supply is to be had without effort, the result is bodily inactivity and mental stultification. If the food required must be struggled for, then the body only is excited to vigor; and food obtained, the body is too fatigued to follow physical exertion by mental. This is the result in the extremes of tropical conditions and it is not surprising that man shows to more advantage as the climate becomes more temperate. Mind and body seem then to have more equal chance; and the same unevenness of development is found among South American Indians that originally obtained in North America. The differences are those that the different physical features of the country suggested. As Mexico stands to the country north of it, the favored spot wherein flowered and fruited the native civilization of that continent, so in Peru, we find a people who abandoned the more primitive features of a nomadic life, and establishing cities, organized government, society, gave such attention to art, agriculture and skill in varied handicraft, that they stood apart, finally, from the other peoples of South America. Compared with the advanced civilization of to-day it may seem crude indeed, but if we take their products of handicraft separately into consideration we shall find that they made most excellent thread and dyed it so honestly that to-day many a fabric a thousand or more years old has not lost its brilliancy of color. They were honest workmen as well as artists. It has often been asked would this culture in the interior of Peru have gone on developing had not it been snuffed out by a really as savage but more powerful a people. It cannot be determined, but as civilization is merely evolution, there is no logical reason why the potter in Peru should not finally have vitrified and glazed his wares, and the metal workers have wrought even greater wonders with the product brought to them by miners who knew their work. Peruvian products in pre-Columbian time never found a foreign market, but it is rash to say they never would have found it had they not been molested and their career destroyed for all time by the infamous invader. An antiquity of the South American native has been frequently claimed by those well qualified to express an opinion, equal to that of the North American aborigine. This is inherently probable. The indications of such antiquity are well attested, and the recent efforts of modernists of the radical type to minimize the importance of the conclusions of South American archæologists have proved an

utter failure. The antiquity of man in South America may yet be in the non-proved stage, but to date the claimants of antiquity have far the better of the question.

Whether in North, Central, or South America, there were centres where things higher than mere animal wants found chance to flourish and the upward growth toward rational rather than mere physical man took place, and all about these centres roamed those outlying people, who were not degenerates, but the as yet unadvanced descendants of that original people of the early stone age to whom it fell to populate these two continents. See MOUND BUILDERS.

Bibliography.—The bibliography of American archæology is more extensive than comprehensive and much more theoretical than practical. The 'Smithsonian Contributions to Knowledge' (Washington, D. C., 1847-1900) contain many important monographs; also the 'Annual Reports' of the same institution. The volumes of the 'Antiquarian Society of Worcester,' Mass., of the now non-existent American Ethnological Society, also, are valuable; likewise the 'Annual Reports of the Regents of the State University,' Albany, N. Y. The Bureau of Ethnology, Washington, D. C., has issued an annual volume of inestimable value for many years; and the publications of the Peabody Museum of Archæology, Cambridge, Mass., and certain of the bulletins of the American Museum of Natural History, New York, are authoritative and necessary for a full understanding of the subject. The separate works that have been published are of less importance. Those prior to 1850 are purely of a speculative character. Of later date, the works of Brinton are of most importance; notably his 'American Race'; 'Essays of an Americanist'; and 'Notes on the Floridian Peninsula.' Of equal importance is Bancroft's 'Native Races of the Pacific Coast.' Consult also Dellenbaugh, Moore, Jones, and Volk for résumé of subjects covering North America, Florida, the Southern States and valley of the Delaware River, and in the order named; Abbott, C. C., 'Stone Age in New Jersey' (*American Naturalist*, 1872), 'Stone Age in New Jersey' (Smithsonian Annual Report, 1876), 'Primitive Industry' (Salem, Mass. 1881), 'Archæologia Nova Casarea' (1907-09), 'Ten Years' Diggings in Lénapé Land' (1912), 'Archæological Significance of an Inland Dune' (in *Proceedings American Philosophical Society*, 1917); Balch, 'Early Man in America' (in *Proceedings American Philosophical Society*, 1917); Keane, A. H., 'Ethnology' (1900); id., 'Man: Past and Present' (1900); Keith, A., 'Antiquity of Man' (1914); Sellards, E. H., 'Human Remains and Assorted Fossils from the Pleistocene of Florida' (Annual Report State Geologist, 1916); Spier, L., 'New Data on the Trenton (N. J.) Argillite Culture' (*American Anthropologist*, Vol. XVIII, No. 2, 1916); Volk, E., 'Archæology of the Delaware Valley' (Peabody Museum Papers, Vol. V, 1911); Winchel, N. H., 'Weathering of Stone Artifacts' (Minnesota Historical Society, 1913).

Mexico.—Kingsborough, 'Antiquities'; Mayer, 'Mexico as It Was and Is'; Humholdt, 'Vues des Cordillères'; and the publications of Zelia Nuttall in the series issued by Peabody Museum, Cambridge, Mass., not

ably 'The Fundamental Principles of the Old and New World Civilizations.' Consult also Stephens, 'Yucatan.'

Peru.—Transactions of the Ethnological Society of London; biennial reports of International Congress of Americanists; von Tschudi, 'Peru.'

Brazil.—Bates, 'Naturalist on River Amazons' (1863); Agassiz, 'Journey in Brazil' (1868); Kidder and Fletcher, 'Brazil and Brazilians'; Burton, R. F., 'Explorations in Highlands of Brazil' (1869).

Patagonia.—Dobrizhoffer, 'Abiponec' (1822); Muster, 'At Home With the Patagonians'; and for South America generally, transactions of learned societies in Europe—German, French and English. Also Bingham, Hiram, 'Explorations in Land of Incas'; Cook, O. F., 'Staircase Farms of Ancients' (No. 5, Vol. XXIX of *National Geographic Magazine*). These articles settle the question forever of the geological antiquity of man in South America.

CHARLES CONRAD ABBOTT,

Author 'The Stone Age in New Jersey'; *Archæological Explorations in the Valley of the Delaware*, etc.

ARCHÆOLOGY, Christian. See CHRISTIAN ARCHÆOLOGY.

ARCHÆOPTERYX, ä'r'kə-öp'tě-riks, an extinct bird exhibiting many reptilian characters, especially in having jaws provided with teeth, and a long tail of many vertebræ; and it constitutes a link between birds and reptiles. It lived during the Jurassic period and is by far the most ancient bird known. Its distinctness from all other birds is expressed by placing it by itself in a separate sub-class; the Archæornithes birds are the rarest of fossils, and this one is known only from two skeletons and a single feather, all preserved in the lithographic limestone quarries of Solenhofen, Bavaria. The skeletons, one in the British, the other in the Berlin Museum, are wonderfully well preserved in the fine, smooth-grained stone and have the impressions of the feathers in their natural position. They show that the Archæopteryx had short wings with primary and secondary feathers arranged much as in modern birds; but the bones of the wing are not so specialized for their peculiar use as in modern birds; the metacarpal bones are separate and the digits free and complete, each with a claw on its tip, while in modern birds the first and third digits are rudimentary and the metacarpals fused into a single bone. The long tail of 23 separate vertebræ has the feathers arranged in pairs springing from the sides of each vertebra except toward the tip; in modern birds the tail-feathers spring from a triangular bony plate at the end of the short rudimentary tails. (See BIRDS). The teeth are like those of many lizards, sharp, conical, each set in a separate socket, and there is no horny bill as in modern birds.

The extinct Dinosaurs are the reptiles which come nearest to Archæopteryx, and it is probable that they are descended from a common stock, the ancestors of the birds becoming arboreal and acquiring rudimentary wings to assist them in leaping from tree to tree. A somewhat analogous case is seen in the fold of skin and hair which the modern flying squirrels

have developed for the same purpose; if further developed and specialized this would enable them to accomplish true flight. In *Archæopteryx* the wings are short and the attachments for the breast muscles (those chiefly used in flight) are small in comparison with those of modern birds, so that the creature must have had very limited powers in this direction.

ARCHÆORINTHES, one of the two sub-classes of birds, including only *Archæopteryx* (q.v.). The other sub-class, *Neornithes*, includes all the remainder, either fossil or living.

ARCHÆOZOIC. See **ARCHEAN**.

ARCHAMBEAULT, Sir Horace, Canadian priest: b. L'Assomption, Quebec province, 6 March 1857. He was educated at L'Assomption College and Laval University, Montreal, where he was graduated Master of Laws in 1878 and was afterward (1881) professor of commercial and maritime law. Appointed to the legislative council of Quebec in 1888, he was speaker of that body and Attorney-General (1897-1905). In 1890 he became a member of the Council of Public Instruction. He was appointed a puisne judge of the Court of King's Bench of Quebec in 1908, and Chief Justice in 1911. He was knighted in 1914.

ARCHANGEL, an angel of superior or of the highest rank. They are seven in number, of which Michael, Gabriel and Raphael are mentioned in Scripture.

ARCHANGEL, ärk-än'jël, seaport, capital of the Russian government of same name, on the right bank of the northern Dwina, about 20 miles above its mouth in the White Sea. The port is closed for six months by ice. Archangel, founded in 1584, was long the only port which Russia possessed. Pop. 21,930. The province contains 331,490 square miles; pop. 348,500.

ARCHBALD, Pa., borough in Lackawanna County, 10 miles northeast of Scranton, on the Delaware & Hudson and the New York, Ontario & Western railroads. It was first settled by Welsh miners in 1831 and is to-day essentially a mining town. It has many churches and schools and several imposing public buildings. Silk mills give employment to 350 persons, while over 3,500 men and boys are employed in coal mining. Pop. (1910) 7,194.

ARCHBISHOP. The name of a chief bishop. The attentive reader of the Acts of the Apostles, noting that nearly the whole missionary energy of Saint Paul was expended upon the cities and chief towns rather than on the villages and the country districts, will be prepared to learn that there were flourishing churches in the leading centres of population, while, as yet, nearly all other parts remained pagan. So strong, however, was the evangelistic spirit prevailing that a number of younger and less powerful congregations were called into being. The pastors of these new churches being called bishops, that term no longer appeared a dignified enough appellation for the spiritual chief of the mother church, and about A.D. 340 the Greek title of *archiepiscopus* was introduced.

An archbishop is often called a metropolitan. He exercises a certain supervision over the bishops of his province, who are called his suffragans; convenes and presides over them

in provincial councils, receives appeals against their decisions in matters of discipline and, in the event of the death of one of them, provides for the administration of the diocese. In the United States the Roman Catholic Church is the only one which has dignitaries of this rank, and in 1900 the entire country comprised 14 archdioceses, Baltimore, as the first established see, having the dignity of primacy.

In England the early British churches were, in large measure, swept away by the Anglo-Saxon invaders, who were heathens, and the country consequently required to be reconverted. The great southern centre from which this was done was Canterbury, then the capital of Kent, where King Egbert gave Augustine, the chief missionary, a settlement. In the north, York, the chief town of Northumbria, where King Edwin built a shrine for Paulinus, became the great focus of operation for that part of England; hence the two archbishoprics now existing are those of Canterbury and of York. The prelate who occupies the former see is Primate of all England, while his brother of York is only Primate of England, the superiority of the see of Canterbury, long contested by that of York, having been formally settled in A.D. 1072. The former is the first in dignity after the princes of the blood; the latter is not second, but third, the Lord Chancellor taking precedence of him in official rank. In Ireland the same distinction holds for Armagh and Dublin. When the Catholic hierarchy was established in England in 1850, Westminster was constituted the metropolitan see.

ARCHBOLD, John Dustin, American oil magnate: b. Leesburg, Ohio, 26 June 1848; d. Tarrytown, N. Y., 6 Dec. 1916. After attending the public schools at Leesburg Mr. Archbold became a clerk in a country store at Salem, Ohio. He remained there for two years and in 1864 went to the Pennsylvania oil regions, where for 11 years he was actively identified with various branches of the industry in Oil City, Pa. He became chief owner and president of the Acme Oil Company and in 1875 director of the Standard Oil Company. Of the first nine trustees of the Standard Oil "Trust" formed in 1882, Mr. Archbold alone remained in that capacity until its dissolution in 1911, by the order of the United States Supreme Court, after which he became president and director of the Standard Oil Company of New Jersey. He was an intimate associate of John D. Rockefeller; active in philanthropic associations and president of the board of trustees of Syracuse University, to which institution he gave large endowments. His fortune at the time of his death was estimated at \$100,000,000.

ARCHDALE, ärch-däl, John, American colonial governor: b. Buckinghamshire, England, probably about 1635. Ferdinando Gorges, the last proprietor of Maine, married his sister Mary in 1660, and in 1664 sent him to Maine to set up Gorges government afresh in opposition to Massachusetts, under whose protection the settlements there had placed themselves. (See **GORGES**). They resisted Archdale so fiercely that the next year he sailed for home, entirely baffled. In May 1681 he acquired a dubious title to a share in the proprietorship of the Carolinas, and in 1682 the proprietors

commissioned him to come over and receive their rents from "Albemarle" (North Carolina). He was there by 1683, with the intention of settling permanently (as his daughter did) — perhaps drawn by a liking for the Quakers in the colony, he having been converted by George Fox. A few years later, however, he returned to England, and was one of the chief managers of the proprietary affairs. In 1688 he appears on depositions in the Gorges matter, private claims being still unsettled; but there is no evidence that he visited Maine again. In 1694, the Carolina proprietors needing some manager on the spot he was induced to become governor of South and North Carolina by the title of "landgrave" and the attendant barony of 48,000 acres; but it was not till 17 Aug. 1695 that he assumed the government at Charleston, and he retained it but a year, then turning it over to a deputy and returning to England again. The complimentary address of the assembly on his departure has been taken literally as a proof of influential and pregnant statesmanship; but in fact he dissolved his first assembly in haste from a quarrel over abatement of quit-rents, compromised with the second, left the Huguenots unenfranchised and the unsatisfactory Indian trade as it was and made no strong impress. His spirit was good, however: he treated the Indians with humanity and modified some hard restrictions on them; drew up a militia act (into which the assembly unanimously refused to put a clause exempting the Quakers), and established a bureau of public charities.

He is also credited with having introduced rice culture into the Carolinas, through a bag of rice which a merchant vessel brought from Madagascar and he distributed among his friends.

In 1698, elected a member of Parliament, he refused to take the oath; would only affirm, and was not permitted to take his seat. In 1707 appeared 'A New Description of that Fertile and Pleasant Province of Carolina,' by him, a vindication of his administration, of little value except for some original documents.

ARCHDEACON, an ecclesiastical dignity next in rank below a bishop, who has jurisdiction either over a part of or over the whole diocese. He is usually appointed by the bishop, under whom he performs various duties, and he holds a court which decides cases subject to an appeal to the bishop. The dignity is still maintained in the Anglican but not in the Roman Catholic Church, the canons or rural deans exercising the same functions as archdeacons.

ARCHDUKE, a duke whose authority and power is superior to that of other dukes, a title in the present day assumed only by the princes of the imperial house of Austria. In France, in the reign of Dagobert, there was an Archduke of Austrasia; and at a later period, the governors of provinces of Brabant and Lorraine were termed archdukes. The dukes of Austria assumed the title of archduke in 1156; but the dignity was not confirmed till 1453.

ARCHEAN, a geologic time unit usually given the rank of a period, and the system of rocks laid down during that period. It is the earliest division of the Proterozoic Era. This

time unit is sometimes given the rank of an era under the name of Archeozoic. The rocks of the system are well exposed in the Lake Superior region, though rocks believed to be of equivalent age are exposed in the Piedmont Belt, in the Ozarks, at many points in the Rocky Mountains, over much of Canada and northern Europe and at places in other continents. The rocks are dominantly igneous, consisting of thick lava flows interbedded with minor amounts of sediment (the Keewatin) and cut by great batholiths (q.v.) of granite (the Laurentian). They contain the iron ores of the Vermilion Range (q.v.) in Minnesota. No direct evidences of life have been found in Archean rocks. Of the climate or geography of the period practically nothing is known.

ARCHEGONIUM, the female organ of mosses, liverworts, ferns, conifers, etc. It is usually flask-shaped with a neck of varying length and a venter more or less bulbous. A single egg reposes in the venter, and in the process of fertilization the sperm enters by the neck and reaches the egg. The archegonia are variously placed in the bryophytes, pteridophytes and the gymnosperms. The neck cells secrete a substance which attracts their own particular sperms toward them.

ARCHEGOSAURUS, ăr'kē-gō-sō'rūs, a fossil saurian reptile, found in 1847, in large concretionary measures of clay-ironstone, from the coal field of Saarbrück. Four species have been described. Professor Owen makes it a connecting link between the reptile and the fish, and on these grounds: it is related to the salamandroid-ganoid fishes by the conformity of pattern in the plates of the external cranial skeleton, and by the persistence of the chorda dorsalis, as in the sturgeon, while it is allied to the reptiles by the persistence of the chorda dorsalis, and the branchial arches, and by the absence of the occipital condyle or condyles, as in *Lepidosiren*, and by the presence of labyrinthine teeth, as in *Labyrinthodon*, which, however, also ally it to the ganoid *Lepidosteus*. See **STEGOCELPHALIA**.

ARCHELAUS, ăr'kē-lā-ūs, the name of several personages in ancient history, of whom we need mention only Archelaus, the son of Herod the Great. This prince received from Augustus, with the title of Ethnarch, the sovereignty of Judea, Samaria and Idumea. His reign is described as most tyrannical and bloody. The people at length accused him before Augustus, who, after hearing his defense, banished him in A.D. 10 to Vienne, in Gaul, where he died. To avoid the fury of Archelaus, Joseph and Mary, with the infant Jesus, retired to Nazareth.

ARCHENHOLZ, ăr'nēn-hōlts, **Johann Wilhelm von**, German historian: b. 5 Sept. 1743; d. 28 Feb. 1812. He took part in the closing campaigns of the Seven Years' War and retired as captain, 1763; traveled extensively in Europe, lived in England the greater part of 1769-79, and settled in Hamburg in 1792. His book on 'England and Italy' (1785), extensively translated, obtained a phenomenal success. A sequel to it was 'Annals of British History' (1789-98, 20 vols.). His 'History of the Seven Years' War' (1789; augmented 1893, 13th ed. 1892) is still the most popular account of that war.

ARCHEOZOIC. See **ARCHEAN.**

ARCHER, Branch T., Texan revolutionist: b. Virginia 1790; d. Texas, 22 Sept. 1856. He studied medicine in Philadelphia, practised many years in Virginia and was repeatedly a member of the legislature. In 1831 he removed to Texas, and was one of the leaders in preparing for the revolution determined upon far in advance of the actual crisis. On 3 Nov. 1835 he presided over the celebrated "consultation" of the American settlers concerning independence, and immediately after was one of three commissioners — the others being Stephen Austin and N. H. Wharton — to solicit aid from the United States. The next year he became speaker of the House in the first Texan Congress; and he was Secretary of War for Texas 1839-42, when bodily infirmity compelled him to retire from public life.

ARCHER, Frederic, organist and musical director: b. Oxford, England, 1838; d. Pittsburgh, Pa., 1901. Educated at Oxford, London and Leipzig, and held important positions as organist in Oxford, London and Glasgow, 1852-79. Organist Plymouth Church, Brooklyn, N. Y., 1880-85; conductor Boston Oratorio Society, 1887; founded Pittsburgh Symphony Orchestra, 1896; organist Church of the Ascension, Pittsburgh, 1899-1901. He gave recitals and lectured on musical subjects throughout the United States and Canada. Founded and edited *The Keynote* (1885).

ARCHER, John, American physician: b. Harford County, Md., 6 June 1741; d. there 1810. He was graduated at Princeton, 1760, and in 1768 received from the Philadelphia Medical College the first medical diploma issued in America. He raised and commanded a military company during the Revolution, served several years in State legislature, was a presidential elector in 1801, and member of Congress 1801-07. He made several discoveries in medicine which have been adopted by the profession.

ARCHER, William, English author and critic: b. Perth, Scotland, 23 Sept. 1856. Educated at Edinburgh University; became barrister, Middle Temple, 1883. Went to London 1878, became dramatic critic of the *Figaro*, 1879-81, and *London World*, 1884-1905, afterwards of the *Tribune* and *Nation*, now of the *Star*. He has edited and translated Ibsen's 'Prose Dramas' (5 vols.) and with his brother translated Ibsen's 'Peer Gynt.' He has written 'Life of Macready' (1890); 'English Dramatists of To-day' (1882); 'The Theatrical World' (5 vols., 1893-97); 'Study and Stage' (1899); 'America To-day' (1900); 'Poets of the Younger Generation' (1901); 'Masks or Faces: a Study in the Psychology of Acting'; 'Real Conversations' (1904); 'Through Afro-America' (1910); 'Play-making' (1912); 'Life, Trial and Death of Francisco Ferrer' (1912); 'The Great Analysis' (1913).

ARCHER-FISH, a fish reputed to be able to shoot drops of water from its mouth at insects in the air above, thus bringing the insects down where they can be seized. The name is most frequently applied to a single species, *Toxotes jaculator*, a fish six or seven inches long, a native of Java and the neighboring islands, which represents an aberrant group of chætodonts, or coral fishes (q.v.). This,

however, is an error of identification, the true fish with this habit being a related small coral fish (*Chelmon rostratus*) of India. This genus has its mouth extended into a tube-like snout, forming a sort of nozzle. When it perceives an insect perched on a plant over the water, it swims to within a distance of from four to six feet, and then with surprising dexterity will eject a single drop of water with so true an aim as to knock the insect into the water where it is instantly seized. Captives will do this in a tank or aquarium; whereas experiments show that the *Toxotes* never does such a thing for which its mouth is entirely unfitted.

ARCHERY. Ages after the bow and arrow had disappeared in general use from Europe and many other countries, it was the universal arm both for war and sport in the Americas, from Patagonia to the Arctic Circle, and its use lingered on the borders of advancing civilization till within the memory of thousands living. It may indeed be considered the most characteristic American weapon, yet the practice of archery as a recreation is limited. A few societies of Toxophilites exist and hold monthly meetings and annual contests. The principal clubs are in the neighborhood of Washington, D. C., and of Cincinnati.

A faithful band, too, of whom the late Maurice Thompson, author of 'Alice of Old Vincennes,' was the exponent, have continued into this 20th century to take the bow and arrow into field and forest, and to live while in camp by the product of their skill in its use. Several charming pen pictures may be found in the pages of *Scribner's*, *Harper's*, *Outing* and the *Badminton* magazines, relating their hunts after turkeys, herons, wild duck, wood-duck and squirrels, and even fish, in Florida, Georgia, Illinois, Indiana and other States. For practical purposes, however, the attention may be confined to archery as popularly understood: that is, shooting at the target as a recreation and to acquire skill. This form of its use continued long after gunpowder had become common: in fact the first book of instruction in archery, that of Roger Ascham, the teacher of Lady Jane Grey, and professor of Greek at Cambridge, 'Toxophilus or the Schole of Shooting,' was published in 1571, when the bow had practically become obsolete as a weapon of offense. The bow used for recreation is the long-bow and not the arbalest or cross-bow which was used by William Tell. That style of the bow was never popular in England. As gunpowder came more and more into use in sports, the interest in the bow and arrow faded. About the year 1760 the possibilities of archery as a builder up of the body and the eye-sight were rediscovered, and from thenceforward it had a lusty growth and has always had a considerable following of devotees both in England and America. Bows are made either of one piece of wood, or two or more strips glued together, preferably of yew. A man's bow is about six feet in length, and a woman's some half a foot shorter. A man's bow requires a pull of from 40 to 50 pounds, a woman's about half that amount. The distance shot varies with the kind of contest. A Potomac round consists of 24 arrows at 80 yards, 24 at 70 and 24 at 60; a double Columbia round of 48 arrows at 50 yards, and 48 at 40. A double York round of 144 arrows

at 100 yards, 96 at 80 and 48 at 60. A double National round of 96 arrows at 60 yards and 48 at 50, and a double American round of 60 arrows at 60 yards, 60 at 50 and 60 at 40. The arrow's shape and feathering is a matter of personal inclination. The targets are four feet in diameter, made of banded straw with a canvas front painted in five concentric rings, the centre gold, then red, blue, black and white; the value in counting shots being, respectively, 9, 7, 5, 3 and 1. There are in the National meet also competitions for longest flight and annual team competitions of 96 arrows at 60 yards for men and 96 arrows at 50 yards for women. Consult Ascham, Roger, 'Toxophilus, or the Schole of Shooting' (London 1868); Hansard, G. A., 'The Book of Archery' (ib. 1840); Morse, E. S., 'Archery, Ancient and Modern' (Worcester, Mass., 1792); Thompson, Maurice, 'The Witchery of Archery' (New York 1878); Roberts, T., 'The English Bowman' (London 1801); Waring, T., 'A Treatise on Archery' (ib. 1828).

ARCHES COURT, the chief and most ancient consistory court, belonging to the archbishopric of Canterbury, for the debating of spiritual causes. It is named from the church in London, Saint Mary le Bow, or Bow Church (so-called from a fine arched crypt), where it was formerly held.

ARCHIBALD, SIR Adams George, Canadian statesman: b. Truro, Nova Scotia, 18 May 1814; d. Halifax, 14 Dec. 1892. He was secretary of state for the provinces in the Dominion government, 1867-68; lieutenant-governor of Manitoba and the Northwest Territories, 1870-72; and held the same office in Nova Scotia, 1873-83. He was created K. C. M. G. in 1885.

ARCHIDAMUS, ăr'ki-dă'mūs, the name of several kings of Sparta. I. The son of Anaxidamus, who lived during the Tegeatan War, which broke out soon after the termination of the second Messenian War, in the year 668 B.C. II. The son of Zeuxidamus, who succeeded to the throne in the year 469 B.C. In the fifth year of his reign there was an earthquake in Laconia which almost destroyed Sparta. In that trying period the foresight of Archidamus probably saved the surviving citizens from being massacred by the Helots. In the discussions at Sparta and Corinth, which preceded the rupture with Athens, he acted a prominent part, and always as the advocate of peace and moderation. He survived the outbreak of the Peloponnesian War about five years, during which time he had the conduct of three expeditions against Attica and one against Plataea. Archidamus died in the 42d year of his reign, 427 B.C. III. Son of Agesilaus II. While yet a boy he prevailed on his father to pardon Sphodrias, who had dared to make an irruption into Attica at a time of profound peace. In 371 B.C. he was sent to the relief of his countrymen who had been vanquished at Leuctra. In 367 B.C. he defeated the Arcadians and Argives in what the Spartans termed the "scarless battle," because they had won it without the loss of a single man. Archidamus III appears to have been a warlike prince, but he was neither a great general nor a great statesman, and makes but a poor figure in either capacity after such kings

as his father and grandfather. IV. Son of Eudamidas I and grandson of Archidamus III, was King of Sparta in 296 B.C. V. Son of Eudamidas II. Archidamus V was the last king of the Eurypontid race that reigned in Sparta. When he was killed the rights of his children were disregarded and his crown was given to a stranger.

ARCHIL, ăr'kil, or **ORCHIL**, őr'kil, a coloring matter obtained from various kinds of lichens, the most important of which are the *Rocella tinctoria* and the *R. fuciformis*. The *Lecanora tartarea*, or cudbear, is another of the same nature; orchella-weed and dyer's-moss are common names for them. The *R. tinctoria*, or archil plant proper, is abundant in the Canaries and Cape Verde Islands, and in the Levant; the *R. fuciformis* also grows chiefly in warm climates, as the coasts of Africa (Angola) and Madagascar. The lichens, which are chiefly collected from rocks near the sea, are cleaned and ground into a pulp with water, after which some ammoniacal liquor is added, when the coloring matter, red, violet or purple, is evolved and falls to the bottom. The red coloring matter of *Lecanora tartarea* produces litmus when lime or an alkali is added. Archil has a beautiful violet color. It is used for improving the tints of other dyes, as from its want of permanence it cannot be used alone.

ARCHILOCHUS, ăr-ki'l'ō-kūs, a Greek poet, classed by Cicero with Homer and Sophocles: b. in the Island of Paros, flourished between 720 and 660 B.C. While a resident of Thasos, he incurred disgrace by throwing away his shield in a battle. He was the inventor of iambics. His terrible invective is said to have caused several suicides. A hymn to Hercules was the most esteemed of his poems, and used to be sung three times in honor of the victors at the games.

ARCHIMANDRITE, ăr'ki-măn'drit, in the Greek Church, an abbot or abbot-general, who has the superintendence of many abbots and convents.

ARCHIMEDES, ăr'ki-mē'dēz, one of the most celebrated among the ancient physicists and geometers: b. Syracuse about 287 B.C. Though, according to some accounts, a relation and certainly a friend of King Hiero, he appears to have borne no public office, but to have devoted himself entirely to science. We cannot fully estimate his services to mathematics for want of an acquaintance with the previous state of science; still we know that he enriched it with discoveries of the highest importance, upon which the moderns have founded their admeasurements of curvilinear surfaces and solids. Euclid, in his 'Elements,' considers only the relation of some of these magnitudes to each other, but does not compare them with surfaces and solids bounded by straight lines. Archimedes has developed the propositions necessary for effecting this comparison in his treatises on the sphere and cylinder, the spheroid and conoid, and in his work on the measure of the circle. He rose to still more abstruse considerations in his treatise on the spiral, which, however, even those acquainted with the subjects can with difficulty comprehend. Archimedes is the only one among the ancients who has left us anything satisfactory on the theory of mechanics, and

on hydrostatics. He first taught the principle "that a body immersed in a fluid loses as much in weight as the weight of an equal volume of the fluid," and determined, by means of it, that an artist had fraudulently added too much alloy to a crown which King Hiero had ordered to be made of pure gold. He discovered the solution of this problem while bathing; and it is said to have caused him so much joy, that he hastened home from the bath undressed, and crying out, *Eureka! Eureka!* "I have found it; I have found it!" Practical mechanics, also, received a great deal of attention from Archimedes. He is the inventor of the compound pulley, probably of the endless screw, etc. During the siege of Syracuse he devoted all his talents to the defense of his native country. Polybius, Livy and Plutarch speak in detail with admiration, and probably with exaggeration, of the machines with which he repelled the attacks of the Romans. They make no mention of his having set on fire the enemy's fleet by burning-glasses,—a thing which is in itself very improbable, and related only in the later writings of Galen and Lucian. At the moment when the Romans, under Marcellus, gained possession of the city by assault, tradition relates that Archimedes was sitting in the market-place absorbed in thought, and contemplating some figures which he had drawn in the sand. To a Roman soldier who addressed him, he is related to have cried out, "Disturb not my circle!" but the rough warrior little heeded his request, and struck him down. The conquest of Syracuse is placed in the year 212 B.C. On his tombstone was placed a cylinder, with a sphere inscribed in it, thereby to immortalize his discovery of their mutual relation, on which he set particular value. Cicero, who was appointed quaestor over Sicily, found this monument in a thicket which concealed it. Of the works of Archimedes there are extant a treatise on 'Equiponderants and Centres of Gravity,' in which the theory of the lever and other mechanical problems are treated; on the 'Quadrature of the Parabola'; on the 'Sphere and Cylinder'; on the 'Dimensions of the Circle'; on 'Spirals'; on 'Conoids and Spheroids'; the 'Arenarius,' a speculative treatise intended to refute the popular notion that the number of grains of sand on the seashore is infinite by showing that a definite number might be assigned to a quantity of grains sufficient to fill the sphere of the fixed stars, remarkable as containing an anticipation of the modern discovery of logarithms; on 'Floating Bodies'; a treatise called 'Lemmata,' of doubtful authenticity, on plane geometry. A very complete and splendid edition of the works of Archimedes issued from the Clarendon Press, at Oxford, in 1792. Other editions appeared in 1881 and 1897.

ARCHIMEDES, Principle of. See ARCHIMEDES.

ARCHIMEDES' SCREW, a machine invented by Archimedes while studying in Egypt. Observing the difficulty of raising water from the Nile he is said to have designed this screw as a means of overcoming the obstacle. It consists of a pipe twisted in a spiral form around a cylinder, which, when at work, is supported in an inclined position. The lower end of the pipe is immersed in water, and when the cylinder is made to revolve on its own axis, the

water is raised from bend to bend in the spiral pipe until it flows out at the top. The Archimedian screw is still used in Holland for raising water and draining low grounds. The Dutch water-screws are mostly of large size, and are moved by the wind, one windmill furnishing sufficient motive power to keep several screws going at once.

ARCHIPELAGO, *är'ki-pél'a-gō*, a term originally applied to the Ægean, the sea lying between Greece and Asia Minor, then to the numerous islands situated therein and latterly to any cluster of islands. In the Grecian Archipelago the islands nearest the European coast lie together almost in a circle, and for this reason are called the Cyclades (*Gr. kyklos*, a circle); those nearest the Asiatic, being farther from one another, the Sporades ("scattered"). (See these articles, and CYPRUS; EUBÆA; RHODES; SAMOS; SCIO, etc.). The Malay, Indian or Eastern Archipelago, on the east of Asia, includes Borneo, Sumatra and other large islands. See MALAY ARCHIPELAGO.

ARCHITECTURE. Architecture is the art of building wisely and, as the embodied philosophy of man's community ideals, is the complete index of the civilization of each age. Beauty in architecture involves such a disposition of the structural elements demanded by a problem as will give to each a maximum value in the given situation. The development, growth, and change that characterize architectural expression in different climates, countries, and ages determine historic styles. No style is the result of chance, but is always the concrete representation of the humanities, a reflection of intellectual, social, religious, military, and political conditions. Architectural styles are identified by the means employed to cover enclosed spaces; first, by the characteristic forms of the supports; and secondly, by the decorative embellishment of the elements of the structural form.

Prehistoric Monuments.—Geographically and chronologically, the earliest construction forms are the Lake Dwellings which have been discovered at the bottom of some of the Swiss lakes. These lake dwellings were very primitive houses or huts erected on piles. These hut villages were built over the water for protection. They were known to writers of antiquity, and Assyrian reliefs picture them. They date back to the Paleolithic Age. More important from the standpoint of architecture are the Megalithic remains of Europe and Asia. They are widely distributed and probably were erected as religious or funerary monuments. Upright stones without lintels are called Menhirs; tomb chambers consisting of upright stones carrying a lintel are termed Dolmens. The circles of stones, the Cromlechs, the most famous of which is at Stonehenge, near Salisbury, in England, has a religious significance. While it is true that the earliest human works known, found in the caves of the provinces of Dordogne, France, and Santander, Spain, show various decorative treatments, no evidences of structural art appear. There is every reason to believe that the state of civilization marked by these finds in the caves of Western Europe typify an era of the Stone Age, during which the South of Europe was populated. This being true, it is possible to establish as an approximate

date for the inception of prehistoric styles, a date of 25,000 or 30,000 years before Christ.

Egypt.—The Valley of the Nile was peopled as long ago as 7000 B.C. with a race highly skilled in prehistoric arts. Dr. Petrie's discoveries between Nagada and Ballos have shown that a flint working people in the Palaeolithic era dwelt in this region. Their technique, judged from the knives and bracelets that have been found, was more advanced than in any other country where relics of the stone age have been exhumed. These finds characterize an art that must have been developed over a vast series of years, and the remarkable skill in manipulating stone exhibited in the Pyramids and structures of the dynastic periods is directly traceable to these Stone Age ancestors. The works, major and minor, of the historic Egyptians from the time of the ancient Empire through the Roman period are characterized by a lavish use of color. The presence of this chromatic element indicates the persistent influence of a race whose art was developed out of the clay industries, for the evolution of the pottery art brought into use, necessarily, constant and various methods of color decoration. The question as to the origin of this color influence is satisfactorily answered by the examination of the development of the arts of Mesopotamia. The absence of the color feature before the time of the early Memphitic dynasties and its lavish use subsequent to that time indicates that the historic Egyptians combined a Nilo-Prehistoric and a Mesopotamian race, and the art of the Valley of the Nile, hitherto considered simple and elemental, is in reality a composite of earlier totally opposite origins. A general survey of the entire field of Egyptian architecture develops five notable characteristics. First, the colossal character of the monuments; second, the evolution of the proto-Doric and the proto-Corinthian columns and capitals; third, the development of the clerestory and its effect upon the problems of scale and ornament; fourth, the Egyptian temple, containing as it does the elements of the Greek temple and the later Christian Basilica, from which was subsequently developed the form of the Romanesque churches and Gothic cathedrals; fifth, architectural refinements, by which certain optical illusions were counteracted and vigor of aspect was added to the monuments. Five distinct periods marked the history of Egyptian architecture. The ancient empire is characterized by sepulchral works and includes the most ancient monumental buildings of which we have any remains. The period is terminated by the 10th dynasty, 3000 B.C., and the centre of the constructive activity was Memphis. The most typical works of the era, the Pyramids, number over a hundred, and in six groups extended from Abu Rôash in the north to Médum in the south. They were all tombs, and housing the requirements of the religious ideal of the Egyptians contained a sepulchral chamber, together with a dependency votive chapel built separate from but adjacent to the pyramid. As the cardinal point in the religious doctrine of the Egyptians was the belief in a future state of existence,—that at some distant time the body would be revived,—so every effort was directed to the preservation of the embalmed body to insure the comfort of the soul. The stupendous pyramids and numerous mastabas

and rock-cut tombs were lavishly decorated with scenes depicting surroundings and conditions of the life of the deceased. Each fresco wall is a page from the history of the civilization that flourished 5000 years ago. The Gizeh group, three in number, presents the most perfect type of pyramid construction. The works of the Middle Empire (3000 to 2100 B.C.) were almost entirely sepulchral in character, although the rock-cut tombs hewn in the limestone cliffs at Beni-Hassan for the great vassal princes of the 11th and 12th dynasties furnish, in their disposition and decoration, an indestructible record of the domestic habitations of the period. Likewise they register the experimentations in the civil architecture of the age. The first evidences of temple architecture that occur in Egyptian history belong to this middle period, dating probably from the 12th dynasty, about 2000 B.C. From these remains, both at Bubastis and Karnak, it is certain that structural stone columns as well as monolithic stone columns were used as elements of Egyptian architecture. It can be definitely assumed that the philosophy of the whole architectural system of the new empire, and subsequently of the historic columnar eras in Europe, had their origins in the age of the Middle Empire. There was an interruption in the current of Egyptian art history for some five centuries following the fall of the Middle Empire. The re-establishment of the Theban supremacy in the 18th dynasty marked the inception of an extraordinary series of religious and funerary monuments. In the development of these structures the column formed an important part. This period, comprising the 18th to the 20th dynasties, 1700–1000 B.C., was characterized by the great temple constructions at Karnak, Luxor, and a magnificent series of tombs, some of which were structural and others excavated, the most magnificent of which were those of Queen Hatasu at Deir-El-Bahari and that of Rameses II and Rameses III, erected on the west bank of the Nile opposite Thebes. During this period columnar architecture was magnified to an extraordinary scale and the planning of the tremendous temple halls, the roofs of which were upheld by numerous massive columns, brought to the designer a new problem, the solution of which was destined to find its most notable expression thousands of years later in the noble cathedrals of Northern Europe. The problem presented by these Egyptian architects of the Theban supremacy was one of lighting the interior parts of the far extending temple halls. The difficulty was solved by lifting the central part of the hypostyle roof (a roof resting on columns) clear above the roof of the sides of the hall. The part of the hall which, higher than the parts adjoining, admits light through traceried openings is called a clerestory. A most important architectural result of this solution of the lighting problem was the development of a great central nave which for its proper construction necessitated details proportionate to its height and width. Larger shafts called for increased capitals. The bell-shaped or campaniform capital was used to meet the conditions of scale imposed by the new problem. The form was not a new one. It appears in the wall decorations of the earliest dynasties, and in the sanctuary area of the great Ammon Ra, Karnak, we find it cut in exquisitely

executed relief upon a monolith that belonged to an older temple of the 12th dynasty. The bell shape accorded with the imagery of religious tradition, recalling either the papyrus or the lotus and it afforded profiles that solved effectively the problem of scale and surfaces, that, under the peculiar conditions of illumination would, to the best advantage, carry a curved and colored decoration. The artistic consistency of the Egyptian decorator is shown by the careful adjustment of his decorative lines to the profile of the embellished objects. The abacus block, borrowed originally from the proto-doric order, was retained as part of the calyx or bell capital. There being no connection between the vertical lines of this block and the flowering curves of the bell, an æsthetic discord resulted which the Egyptian artists were never able to obviate. The Greeks received this calyx order as an artistic heritage from the older civilization and developed a form, to-day called the Corinthian, which, in a mechanized Roman adaptation, appears frequently in modern architecture. The splendor of the Theban period was followed by a decadence that continued through the Saitic period (1000-324 B.C.) During the Revival (324 B.C.-330 A.D.) an epoch comprising Ptolemaic and Roman dominations foreign influence brought certain changes. While there was no attempt to create a new architecture, the eclecticism of the Greek and his love of light caused the innovation of a screen wall in place of the sombre pylons of the Pharonic temple. The simple decorated inverted bell capital of the former period was replaced by a variety of liberally carved modifications. The Greek influence is most typically expressed at Phylæ and Dendera, while the mechanization of Rome is shown at Koum Ombos and Edfu. The temple form in its general divisions underwent great change through all of the various eras of Egyptian history. Its origins are lost in the mists of antiquity. Undoubtedly the early nature worshippers of Egypt did homage to a sacred stone or shaft. The holy object at first was unprotected, but in time an enclosing wall or wooden palisade more practically isolated it, creating a Temenos, or sacred enclosure. Early, too, a shelter was provided. Because the huts of the chiefs or leaders of the aborigines had been marked by wooden posts or stone shafts, this custom was employed to dignify the entrance to the simple shrine. In historic temples this procedure is reflected in the obelisks and great votive statues that were used to flank the entrances to the sacred edifice. As the temple, in the course of time, was looked upon not as a place of meeting for worshippers, but as a dwelling place for deity, whose presence was indicated by a consecrated effigy, provision had to be made for the people. To this end an antespace, an hypostyle hall was added to the shrine.

The progress of a race from a state of barbarism to one of enlightenment is always a slow and involved one, so that the simple temple, consisting of Temenos, hypostyle hall, and shrine must have been the result of a normal development extending over a period of thousands of years. With the increase of power and wealth on the part of the priests, and the development of a complex ritual, the shrine was divided into a number of chambers, the

innermost of which, the *sekos*, enclosed the effigy or symbol of the god. The adjacent chambers were planned to contain the treasures of the sanctuary and in certain instances to be used in carrying out the intricate ceremonies of initiation into the secrets of the priesthood. The hypostyle hall was really a great ceremonial chamber. The title employed in the hieroglyphic inscription, the Hall of Appearance, clearly indicates its intention. Entrance to the *sekos* portion of the edifice was restricted to the superior priests and the king. At the celebration of religious rites the inferior priests would await the appearance of the emblem, a statue of the god, in the hall of the columns. In the earlier temples this feature was of modest size. In the southern temple of Karnak, but eight columns were required to support the hypostyle roof, but in the great temple of Ammon Ra, Karnak, 134 columns, arranged in 16 rows, were employed. Here the shafts supporting the clere-story ceiling were of colossal size—113/5 feet in diameter and 69 feet in height. The fact that it would require six men, with outstretched arms to span one of the huge columns will convey an idea of their bulk. This Hall of Assembly was separated from both the sanctuary and atrium or fore court by huge pylons. The ceremonial procession being marshalled, it advanced into the atrium, an hypæthral or open court, with colonnades upon two or three of its sides, seldom toward the entrance. As in the case of the Mohammedan mosques, the atrium served also as a place of instruction. Here, seated about their hieratic teachers, the Egyptian youth would pursue a curriculum that was unequalled in the ancient world. An enormous masonry screen, the pro-pylon, formed the façade of this court. This feature was generally composed of three parts, a central doorway and two flanking, truncated pyramidal towers. Its corners were decoratively strengthened with three-quarter round mouldings, and the summits of the three elements were crowned with the cavetto cornices. Recesses were built into the front to provide for masts, from which pennons were displayed. Provision was made in the interior for stairways and chambers, the purpose of which is unknown. The external and accessory parts of the temple scheme were the temenos, the sacred lake, and the Dromos. The elaborate ceremonies at the sacred lake made necessary an extensive fore-yard, an area hidden from the inquisitive eyes of the people. Before the mummy of the Egyptian, poor or rich, could be borne to its final resting place in the necropolis, it had to pass the ordeal, known as "the judgment of the dead." This trial was held upon the shore of the sacred lake, before a tribunal impersonating Osiris and his coadjutors. Proof of an evil life condemned the soul of the unworthy one to wander for 100 years in the world of the dead, and burial place for the mummy in the sacred precincts of the necropolis was refused.

Necessarily a large area was required for the enacting of this complex ritual, and the Temenos so used formed an important adjunct to the temple. It was enclosed with a wall 40 feet high and 33 feet thick, pierced by a monumental entrance. A paved causeway, the Dromos, formed the approach to this gateway.

It was decorated with sphinxes or kriosphinxes. The Dromos leading from Luxor to Karnak was 76 feet wide and was bordered with 500 kriosphinxes on each side of it.

As the hieratic imagery dictated in great measure the general plan of the Temple, so, too, the details were in many points subjectively treated. When the English architect, John Penne-thorne, in 1833 made a tour of Egypt he discovered that in the atrium of the temple of Medinet Habou, erected by Rameses III, that the cornices were not constructed plumb and straight but were arranged horizontally as segments of circles. It is a notable fact that, whereas the Greek curves are traced in vertical planes, these Egyptian arcs are constructed in horizontal planes.

In 1890 Prof. W. H. Goodyear of the Brooklyn Institute found these curves to exist also in the Temple of Edfu, and the author in 1897 verified them by surveys at both Medinet Habou and Edfu. The reasons underlying the use of these curves are complex. It is evident that "all architectural lines that are curved in horizontal planes, convex to the position of the spectator, produce the effect of curves in elevation." Curves so formed exaggerate the effects of curvilinear perspective and the observer gets the effect of a building appreciably larger than the facts record. A mathematically straight line above the plane of the eye appears always as slightly concave, for the intersection of the plan of rays, that convey the line to the eye, with the hemispherical retina is a curve, and in all cases, not consciously corrected, is registered in the brain as a curve. If the reader will notice the way in which the cornice line of a block of houses gradually dips until in the distance it meets the plane of the street which in its turn has bent slightly upward, he will have an example of this phenomenon. In the case of the level street and the straight cornice we know that there is no actual curvature, but in the registration or perception of these distances the effect of a curve is produced. If, then, in experience, one finds that a long line above the eye is registered as a curve, how natural it would be if a shorter straight line above the eye were actually curved, to give to the shorter line thus curved the distance quality that would exist in a straight line that produced the illusion of an equal curve. The architects of Egypt had observed this curiosity of optics and with great care built the cornices of certain of their temples so that the cornices were actually curved as explained above. Then, too, under certain conditions a line, above the level of the eye, will appear concave, a result that is architecturally unpleasant. In order to overcome this disagreeable illusion, the ancient designers at times substituted a convex curve for a straight line. This last condition always results when the horizontal straight line is intersected by slanting lines. Thus the sloping planes of the pylons of the Egyptian temples being in the field of sight of a person observing the cornices of the forecourt, would tend to make the cornice lines of these courts appear concave unless these lines were really curved in the opposite or convex direction to overcome the illusion. As a matter of fact, to the modern traveler, the cornice lines of these temple courts appear straight and the courts

in area seem to be greater than they actually are. In the wonders of Greek architecture these corrective methods were developed to a degree unthought of in Egypt. Many new conditions, material and subjective, were responsible for the system of Ictinus in the Parthenon at Athens. Another refinement in the Egyptian technique is found in the treatment of the four faces of the obelisks. These surfaces are curved outward both in the vertical and horizontal planes. This curvature was without doubt to correct the illusion of concavity resulting from the use of straight planes. Entasis, the slight bowing out of the shaft, was given to columns and pilasters for the same reason.

Chaldaean and Assyrian.—The civilization that was contemporary with Egypt was that of the Tigro-Euphrates Valley. Civilization of Chaldæa and Assyria alternately ruled in this valley until the conquest by the Persians. Its art and architecture was predominately royal. Extravagance and splendor marked the construction of palaces, especially those of Assyria, and the temples were comparatively moderate compared with the hieratic monuments of Egypt. Scarcity of timber and the difficulty of obtaining good stone for structural use forced the Mesopotamian monarchs to evolve a structural system adapted to the use of the available material. The solution of their structural problem developed the arch. To roof corridors or rooms, baked clay bricks were assembled on a curved form of wood. The bricks being inelastic material and in compression exerted lateral pressure or thrusts which were ultimately transmitted to walls or abutments. The thickness of the wall is proportionate to the amount of the arch thrust, and in the case of the Mesopotamian edifices, these superimposed weights were very great, hence the walls that held the load in check had to be enormously thick. The repetition of the arch, *i.e.* continuous arch formed a vault and the vault upon the circular base produced the dome. The column did not appear in Mesopotamian architecture as a constructive element. Palace architecture at Nineveh, Koyvndjic, Khorsabad and Nimroud exemplify the character of the Chaldæo-Assyrian palace. The religious architecture, exemplified by the ruins at Mugheir, Warka and Nippur, indicate terraced temples constructed with crude brick faced with burnt brick carefully set and often coated with enamel. Sculpture and relief, together with tile decoration, were used in the embellishment of the constructions of Chaldæa and Assyria. Winged bulls carved in high relief appear frequently as decorations of the jambs of arched gateways. Wall slabs of alabaster exquisitely carved in relief depicting subjects of war and hunting or of the king doing worship to his gods ornamented the state apartments of the palaces. Individuality in design and ornamentation is lacking. The architecture throughout has the sombre stamp of officialdom. Expressing as it did the civilization with which Greece, Rome and Byzantium were in sympathy, Mesopotamian art became a fountain head of inspiration and influence for the arts of the Occident. That miracle of Justinian, the Church of Hagia Sophia in Constantinople had its origin in Mesopotamia.

Persia.—The mountain races of Persia,

previous to Cyrus, developed no architectural monuments. From the latter part of the 6th century, however, until the conquest of the Persian Empire by Alexander, 334 B.C., an architecture of terraced palaces and columned halls, laid out upon terraces and platforms, served to splendidly house the royal court and dependencies of the Persian monarchs, Cyrus the Great and his Achæmemidæ successors. At Pasargadae, Persepolis and Susa, are ruins scarcely yielding in point of decorative magnificence and impressive monumentality to the master works of Assyria and Chaldæa. The notable detail of Persian architecture is the capital and shaft, perhaps best expressed in the form employed in the palace at Persepolis. This capital was composed of the head and forelegs of recumbent bulls or lions between whose arched heads rested the beam that supported a timber roof. While it is a notable fact that the Persian bull kept his place unique in the history of architecture and is without derivatives, the supported entablature, developed after the wooden prototypes used by the ancestors of the Persians in constructing their huts, gave us the elements of the classic Ionic and Corinthian entablatures.

Hittites.—The source of many oft-repeated motifs in Egyptian, Mesopotamian and Minoan arts, certainly not originated by these civilizations, was the Hittites, from whose capitals at Kadesh and Carchemish, Western Asia and the Ægæan were controlled. The power of the race was overshadowed by the conquering arms of the Assyrians in the 8th century B. C. The architecture and art forms of this people are hardly known to us as yet. The curious pictorial records found in many places of Asia Minor are still the subject of much study by the Oriental philologist. It is certain, however, that many forms that appeared in the architecture of Mediæval and Renaissance times had their origins in the building activities of this race. At Senjirli extensive ruins of a fortified palace have been excavated. The gateway was planned as a portico. A guard room, the ceiling of which was supported by columns, intervened between the moat and the keep. The lower part of the walls of this room was decorated with reliefs of hunting scenes, and figures of gods, unmistakably Hittite. The columns were supported upon the backs of animal grotesques. In a relief at Boghaz-Keny the deities are represented as being supported by the symbols of temporal and mystic power. The lion, the king of beasts, represents in the most satisfactory way the idea of physical superiority. The double-headed eagle presents the idea of supernatural control. The two heads indicates the ability to gather all experience from the past and to forecast the future, in fine, a pictograph of omniscience. The persistency of artistic tradition is well illustrated in the way these Hittite forms have been transmitted from nation to nation, long ago having lost their significance in imagery, but ever striking in effect. The column carried upon the backs of animals was carved by the Assyrians in their decorative reliefs and the Etruscans carried the motif to Italy. The portal of the Romanesque cathedral at Verona exhibits its employment. In both the lower and upper colonnades of the entrance broadly treated grotesques support

small Corinthianesque columns. All through northern and eastern Italy this imported Hittite motif was used. In designing ecclesiastical furniture this seemingly popular form was used continually. The Prior's Door of Ely cathedral, England, illustrates the introduction of the Hittite column form into English Norman work. In Italy, again, the pulpit that Nicolas Pisano carved for the Baptistry of Pisa, gave Renaissance expression to the ancient Hittite theme. So far researches among the scattered fragments in the rubbish heaps of Asia Minor oblige us to look upon the Hittites as the originators of an individual and vigorous art, the effect of which has been lasting and widespread. Art history, in part, must be rewritten and a place made for this virile nation. Important as their original contributions were, the greatest credit of the Hittites was in the fact that they were the principal mediating influence between Mesopotamia and Egypt in the East, and Greece, Etruria and Rome in the West.

Phœnicia and Cyprus.—Lesser intermediaries between Asiatic peoples, the Egyptians and the Greeks were the Cypriotes, Phœnicians and Lycians. It is possible that from Cyprus the Greeks borrowed the volute form in Ionic architecture, for it appears in the decorative patterns of pottery and Steles from Cyprus. The Phœnicians were purveyors of art. They developed that which was merchantable and produced quantities of objects, bronze, gold, terra cotta, glass and textiles. Little remains to-day of the military, civil or religious construction of this people. The military and civil constructions by which their cities were rendered almost impregnable seem to have been inspired by the Hittites, and the temple form, the general scheme of which constituted a cella divided into two parts and surrounded by a Temenos, was adapted from Egyptian sanctuaries, through the Hebrew mediation. The Hebrews did not originate a new style of architecture, and being prohibited by their religion from making graven images, "never developed a sculptural proficiency." They, nevertheless, occupy a most noteworthy place in the history of the world's art because the plans for their places of worship form the link between the temples of Egypt and the shrines of Greece.

Lycia.—Lycia developed a serious art, in its earlier forms, constructed in wood; in its later phase these earlier types were translated into stone. Typical Lycian examples entirely of a mortuary character are to be found at Antiphellus, Myra and Telmissus in Asia Minor.

Phrygia.—The Phrygian Empire was at its height about 700 B.C. and occupied the plateau of Asia Minor. Many of the monuments that have been characterized as Phrygian are either original Hittite works or Phrygian constructions designed in the manner and style of the earlier art. Among the Phrygians, semi-barbaric wanderers and dwellers in tents, was the desire to fashion their tombs in the form of their earthly domiciles. This led to the representation of the patterned tent covering as a tomb façade decoration. The most interesting example of this design is known as the Tomb of Midas near Sivrihissar.

Lydia.—It is probable that the early Lydians were a division of the Phrygians. In Lydia as well as Caria the conical tumulus is

the characteristic form for monumental tombs. Developed in Asia Minor and transmitted through the medium of the Etruscans, Rome utilized the tumulus as the chief element for some of her most monumental efforts. The original inspiration for the Roman form which achieved its greatest expression in the noble Pantheon, the wonder of Roman construction, is to be found in the tumulus constructions erected by the early inhabitants of Thrace and Asia Minor.

Ægean.—While the early civilizations of the Egyptians and Hittites were developing, about the eastern Mediterranean there was formally established a great controlling empire which we have come to know as the Minoan. Recent explorations at Cnossus and Phæstus in Crete, and exploration of the Ionian Islands and the islands of the Ægean, various parts of the Peloponnesus and northern parts of Greece, have established the fact that Crete was the centre of the civilization whose wide ramifications extended from Egypt and Mesopotamia to the west shores of the Adriatic, Sardinia, Sicily and Spain. Ægean or Minoan art is divided into three periods, the first or early Minoan period comprised a semi-barbaric stone age civilization and a bronze age period. The close of the era is believed to have been about 2000 B.C. The middle Minoan period (2200-1400 B.C.) was the age of the early palace building. Wall painting was developed and the manufacture of fine faience was established. The first palaces at Cnossus and Phæstus were destroyed previous to 1850 B.C. The later palaces at these two sites were rebuilt and remodelled previous to 1400 B.C. There seems to have been no architectural group arrangement for the Minoan palace plan. Expediency and utility characterize the general arrangement. Numerous courts and confusedly arranged passages occur. In some portions one story was superimposed on another. A remarkable feature is the great staircase running through three stories. What appears to have been a theatrical area, a paved court with banks of steps on two sides for the use of spectators, is a notable feature. The employment of a monumental stairway by the Minoans initiated a monumental structural feature that does not appear again until the Roman era. A knowledge of sanitary construction is evidenced by the exhumation of pottery drain tile. The appreciation of structural and sanitary systems, adapted to the needs of the Minoan civilization, established the existence of an architectural style which, for utility, was remarkable and in every way was superior to the clumsy experimentations of the dark ages which intervened between its use and the establishment of the classic periods of Greece and Rome. The late Minoan period reached its culmination about the time of the 18th dynasty of the new Egyptian Empire and is remarkable for a widespread building activity throughout the Ægean. The citadel palaces at Mycenæ and Tiryns belong to this period. The arch in its true form was not used by the Minoans but corbeled walls were used for the passages in the enclosing ramparts of the Tiryns citadel and the corbeled vault in circular form was employed in several tombs at Mycenæ and Orchomenos. At times the Minoan builders relieved stone lintels of superimposed weight by constructing above

the lintel a false arch. The Gate of the Lions at Mycenæ is an instance of this construction.

Greece.—About 1100 B.C. the Ægean civilization succumbed to the age of iron, and on its ruins developed historic Greece. The experimental period closed with the victory over the Persians, 479 B.C., which established a consciousness of power that found its highest expression in the presentation of civic and religious ideals. This abstract conception was translated through the medium of the arts into terms intelligible to the mass of the people. The real secret of the perfection of Greek architecture is to be found in the fact that to the Greek mind religion and life were indissolubly interwoven. Their architecture was entirely a public architecture and the nucleus of this was the temple. Their early itinerary existence was filled with warlike struggle and religious worship. The shrine of beneficent deity served as the depository for their wealth and battle trophies. It was natural, therefore, in the development of the race, to base their subsequent public types upon those evolved in the perfection of the temple, a form that in each detail expressed the highest æsthetic and utilitarian value, effectually representing, in a concrete way, the Hellenic ideal of power. The earliest temples were mere rectangular enclosures devoid of ornament and without architectural pretense; selected because of the existence of some natural phenomenon, which appeared to indicate the presence of the gods or because the site had from primeval times been the place of worship of personifications of the forces of nature. In the archaic temple of Apollo, at Delos, there are two important parts, the cella and the space about the cella used for the performance of certain rites. These two elements that appear in this prehistoric example were retained by the builders of all Greek temples in more or less modified form. In no other place in Greece has an original primitive sanctuary been preserved. In the less sacred localities, the early cellas, we may suppose, were rudely constructed of timber. The first departure from the simple cella was the addition of an entrance porch. In front of and between the projecting side walls were placed piers or columns, similar to the scheme used at Beni Hassan in Egypt. This plan was the natural outcome of a more complex liturgy. There is every reason to believe that Doric architecture was the natural outcome of the problem of adapting the primitive wood superstructure, translated into stone, to the exigencies of a design in which columns were used for a porch in front of the temple. In course of time the idea of entirely surrounding the temple with columns suggested itself. The natural inference is that the peristyle entirely surrounding the edifice simply continued the tradition of the sacred area which originally surrounded the primitive temples. The great temples of Greece with few exceptions were designed in the Doric style, the elements of that order being best adapted to produce the effect of monumental equipoise and æsthetic concord. For the examples illustrating the experimental phases of the Doric style one must look to the archaic temples of Magna Græcia and Sicily, for the temples erected in Greece proper, during the 6th century B.C., have disappeared; in many cases, possibly along with

the Athena temple on the Acropolis, they were destroyed by the Persians; in the enthusiasm after Salamis the archaic edifices were felt to be unworthy of the gods who helped the Greeks to glorious victory, and they were replaced with more pretentious monuments. The northern temple of Selinus, 610-590 B.C., is heavy in detail and lacks the evident refinements of the works of later periods. The ideal of beauty was intimately associated with the religion of the Greeks and it was the constant effort of her artists to achieve a perfection of form and proportion. It follows that each shrine that was erected presented an opportunity to overcome any defects in composition that had become apparent in an earlier edifice. Thus each part of the architectural mass was carefully studied, the purpose being to produce an effect of absolute unity upon the observer. The transitional period (500-460 B.C.) exhibits in the temple of Zeus at Olympia and the Aphæa temple on the island of Ægina, a great advance in harmony of proportion and delicacy of detail. Sicilian temples of Segesta at Agrigento and upon the acropolis and eastern plateau of Selinus, offer particularly striking contrasts to the archaic types. The final solution of the Peripteral temple arrangement was achieved during the Periclean era (460-400 B.C.) in the Parthenon (438 B.C.), the shrine of Athena Parthenos, the world's architectural masterpiece. In addition to the Parthenon the two great monuments of this age of Greek architecture were the Propylæa, the monumental gateway to the Acropolis of Athens, and the temple of Apollo Epicurius, at Phigalæa (Bassæ); in the former many of the Parthenon refinements appear, but the latter, although attributed to Ictinius, the architect of the Parthenon, was wholly devoid of the wonderful subtleties of the Attic masterpiece. The Greek Ionic style, developed under the influence of Asiatic types, was not generally used in Greece until late in the 5th century when the Naval Confederacy brought Asia Minor and Continental Greece into relations. The style was universal in Ionic and Æolian territory, there being but a single Doric temple in Asia Minor. During the period of Pericles the Ionic order was used in the temple of Niké Apteros and the Erechtheion and the interior of the Propylæa on the Acropolis, Athens. The desire to simplify the execution of the various elements of the Doric style and reduce the time and cost of execution, led, during the Alexandrian (400-300 B.C.) and Decadent (300-100 B.C.) eras, to various debasements. Straight lines and geometric curves replaced the delicate refinements of the Periclean period. The capital from the portico of Philip 360 B.C., upon the Island of Delos, illustrates the dry and characterless appearance of the late Doric style. During the Periclean age a capital form of foreign origin made its appearance. On account of its florid gorgeousness of detail the innovation was called Corinthian. The type in a marked manner was an index to the national spirit of the period succeeding the Peloponnesian wars. The individual had asserted himself—no longer was the state and its glories uppermost in the minds of men. The pursuit of wealth, luxury and pleasure, caused the change in character and art and reflected the new conditions in the more sensuous styles of the Ionic and Corin-

thian. The Corinthian form never achieved the distinctiveness of an independent order in Greece. It was throughout a foreign element engrafted upon the Ionic style. It was only in Roman times that a Corinthian canon or rule was established. The Choragic monument of Lysicrates, at Athens, erected (325 B.C.) by Lysicrates, exhibits the possibilities of the Greek Corinthian style. While secular monuments propylæa, colonnades, stoæ, theatres, and odeons were constructed with architectural care and embellished with elaborate detail, little importance was given to domestic architecture and our knowledge of the Greek houses is principally derived from description. In general arrangement the domiciles must have resembled the houses of Pompeii.

Rome.—The situation at Rome was particularly advantageous for its work as an organizer. Her citizens had a special aptitude for government, but had neither the time nor inclination to evolve a new decorative style. Rome was adjoined by nations the value of whose art is still evidenced by remains of great monumental and engineering interest. The southern portion of Magna Græcia and Sicily was rich in examples of the Greek columnar styles erected by the Doric colonists who settled these districts during the 8th and 7th centuries B.C. To the north were the Etruscans, a people of Turanian origin, who migrated, according to conjecture, from Asia in the 13th century B.C. The Etruscans from the remotest antiquity possessed knowledge of the arch and simple vault construction. In their rectangular and circular temples we find the origins of the religious types of the Roman Empire. In the history of art, Roman architecture is of the greatest importance, because it is the fountain head out of which the styles of the Early Christian, Mediæval, Renaissance, and Modern eras were developed. It forms the connecting link between the practise of subsequent ages and the experimentations and perfections of the various peoples with whom the Romans came into contact. It must not be thought that Rome served as an artistic clearing house for the early arts and was wholly devoid of originality. As inventors they contributed to the resources of the designer the groined vault and dome, derivatives of the arch which revolutionized the science of planning, making possible the substitution of vast open interiors for the column encumbered halls of Egypt and the narrow structures of Greece, for in all of these earlier constructions the unobstructed areas were limited by the restriction of the lintel. The Etruscans employed the arch principle in the construction of barrelled vaults (a continuous arch roofing the space between parallel walls). The preservation of the Eternal City is due to a vaulted work of this kind. The Great Sewer, by which name the Cloaca Maxima is known, was built by the Etruscan tyrant, Tarquinius Superbus (500 B.C.). Symmetry was the dominant law of Roman composition, and in its employment the design was certain to achieve results that everyone could understand. Horizontal dual symmetry has an æsthetic value in that designs laid out in deference to its laws make an immediate appeal to all people. To the Roman, with his ideas of organization, simple symmetry was the best method of portraying his racial characteristic.

Architecturally, the most important vaulted building was the Pantheon built by Hadrian between the years 117-138 A.D. The study of this monument inspired in the Florentine renaissance architect, Brunelleschi, the idea which he executed in the construction of the dome of Santa Maria del Fiore of Florence. With the Romans, the building of a great monument comprised two distinct operations, first, the fabrication of the ossature or core, and secondly, the envelope or decoration which was as independent of the construction as clothing is independent of the man. The necessity of rapid building and the availability of numerous unskilled laborers, drawn from the population of slaves and soldiers, rendered essential the development of a new constructive process. The solution of the problem was found in the use of concrete, not only for the walls, but also for the vaults and domes of their innumerable architectural undertakings. Great quantities of lime and cement rock are found in Italy, so that concrete of a fine grade was possible with a minimum of labor and cost. Skilled engineers would carefully plot out the lines of the foundations and walls and test the bearing power of the ground upon which the great vault supports were to stand. Hundreds of unskilled workmen excavated for the foundations and mixed the ingredients for the concrete. Chosen artisans laid up rough brick wall faces; the space between them was filled with concrete as fast as the faces were carried up. Then in a short time, the supporting walls would be raised to the height where the vaults were to commence. Temporary centres, or forms of wood, were then erected upon which the laborers moulded vaults. At times, in order to obviate the labor and expense of enormous timber centering, a light slat centre was used, upon which a vault of thin tiles set in hydraulic cement was laid. Upon this shell the concrete was heaped to the required thickness, rarely less than 6 feet over the thinnest part. When the core of the monument was thus completed the task of decorating it was undertaken. Artists and precious materials were commandeered without regard to cost. The vaulted ceilings were embellished with moulded stock, lavishly painted and gilded, and the roof walls were covered with marble veneering, columns and entablatures. The decorative procedure of enveloping their arcuated masonry masses with columns and their accompanying accessories confronted the Roman architects with the problems of harmonizing in the same design the conflicting forms of the lintels and the arch. In the older arts, where the two constructive principles were used together, the arch had been placed above the lintel to relieve that weaker member from the weight of the superimposed mass (entrance to Pyramid of Cheops, Egypt). In the Imperial system the orders were introduced merely as ornamental features without constructive functions and the salient horizontal lines of the entablatures were designed to mark the division of the stories or the place of springing of great vaults. The columnar forms engaged to the masonry mass between the arches were introduced to give apparent support to the entablature. This arrangement inverted the position of the lintel and the arch as hitherto

used, placing the weaker member above the stronger, and has been criticised as a reprehensible departure from structural propriety. The contention is not valid, however, for two obvious reasons; first, engaged columns necessitated an overhanging entablature whose projection beyond the face of the arch masonry indicated very clearly its introduction as an applied and not a structural feature, and secondly, through the contrast of the straight lines of the "Order" with the curves of the arches a pleasing variety was obtained, the popular value of which has been attested by the adoption and use of the Roman Arcade scheme in all subsequent styles even to our day. The columnar forms, as placed by the Romans, fulfilled, too, an æsthetic function in that they emphasized the constructional divisions and elements of the building and gave to the monuments a sparkle and play of light and shadow that added greatly to their appearance. The Romans being an essentially commercial people and their chief interests directed to the extension of their power, religious observations and its accompanying architecture were relegated to a subordinate place. Great halls for the transaction of business and the dispensing of justice assumed a far more important position. Luxury and the desire upon the part of the rulers to popularize their régimes necessitated the erection of fora, amphitheatres, baths, palaces, triumphal arches and a host of constructions such as aqueducts, roads, bridges, etc. The temples were of two types, rectangular and circular. The plans of both classes were of Etruscan origin. The rectangular shrine comprised of a deep porch led to the cella in which the statue of the deity was placed. Monumental stairways approached the porch. The circular temple plan achieved its most monumental results in Rome itself, although throughout the Latin world many minor monuments of this class were built. With the development of vaulting it was possible to greatly enlarge this type of structure until finally the imposing rotunda of the Pantheon was produced. The Roman basilica was a form adapted from the Greek royal house for the transaction of judicial and commercial business. Oblong in shape, it consisted of a broad and lofty central nave separated from double or single side aisles by colonnades. The roof of the nave was carried above the level of that of the side aisle forming a clere-story, which was pierced with windows. To the time of Constantine these structures were covered with wooden roofs, and it was that Emperor who completed the edifice commenced by Maxentius who first endowed the Basilica with a vaulted, fireproof covering. These basilicas are of especial importance because of the controlling influence that they exerted upon the later architectural styles of the Basilican, Byzantine, and Romanesque styles.

Early Christian or Romano-Christian.—The Emperor Constantine (328 A.D.) made christianity legal. Throughout the preceding four centuries Christian art had been slowly developing. Hidden and secret, its early forms were domestic or sepulchral. With the freedom of worship possible under the enlightened Constantine, the Christians appropriated for their religious edifices all that was adaptable in Roman architecture. The early Christians

translated in their liturgical forms the organization that they had become habituated to in the conduct of Roman affairs; thus the Basilica in which the business of the Empire had been transacted served as a basis for a proper housing for the performance of the public rites of Christians. The broad and lofty nave of the basilica with its single or double aisles, provided ample space for worshippers. Above the nave columns rose the lofty clerestory walls pierced with windows. Immense wooden trusses carried the roof of the nave. At the far end was the apse with seats for the clergy, and in front of the apse was the altar. Generally, a forecourt, surrounded by a covered arcade, preceded the basilica proper. This was connected with the church by a porch. One of the most impressive places of worship in the world to-day is the rebuilt basilica of Saint Paul without the walls at Rome, erected in 386 A.D. by Theodosius. In the general survey of architecture this edifice is of peculiar importance because the arches of the nave arcade are turned from column to column without the use of an intervening entablature between the capital of the column and the spring of the arch. The first known case of such use of columns as arch bearers was in the palace of Diocletian at Spalato. This nave arcade motif, modified by the structural changes of the Romanesque and Gothic periods finally flowered into the wonderful nave arcade conceptions of the ecclesiastical masterpieces of Amiens and Rheims.

Byzantine.—Under Constantine, the Greek city Byzantium, renamed Constantinople, became the chief city of Christendom. Under Justinian, 527 to 565 A.D., the structural undertakings of the Eastern Empire developed an extraordinary activity especially in the building of churches. Syria, Dalmatia, Macedonia and Ravenna were scenes of architectural industry, for the most part under the direction of Asiatic Greeks. Engrafted upon the Latin type of church—the basilica with its three aisles and wooden roof—were certain traditional vaulting methods in brick and stone of Asiatic origin. The most notable characteristic of this structural method is the central dome on pendentives, a device by which a circular vault can be erected upon a series of isolated supports. By this scheme of dome construction polygonal chambers were built which could be monumentally roofed and would permit the floor plan to be extended indefinitely in any direction. The Byzantine plans are of great variety and enable the designer to achieve results which for propriety of scale and effectiveness of decoration have never been excelled. The great masterpiece of the style is Hagia Sophia, often called "Saint Sophia," built under the orders of Justinian, 532-538 A.D., to replace an earlier Basilican building. This huge church, one of the greatest of the world's art masterpieces, marks the culmination of the style. It was followed by a long and gradual decline in artistic value. Some five centuries later a re-rediscovery of the style appears in the church of Saint Mark at Venice (1047-71), where a combination of Greek and Italian artists produced a masterpiece of great beauty which subsequently influenced the plan of the Romanesque church of Saint Front at Périgueux,

France. The Romanesque cathedral of Cahors, France, was probably inspired by the Justinian church of the Holy Peace, Hagia Irené. All church building, even the latest and richest Gothic has the exterior for its chief splendor. The Byzantines apparently gave little thought to the embellishment of the exterior of their buildings, and lavished all of their decorative effort upon the interior. This style, invented in practically a single effort, a result not known to have been achieved anywhere else in the history of art, has prevailed ever since throughout the lands extending from the Red Sea northward through Russia.

Sasanian and Mohammedan.—Contemporaneous with the development of Roman and Byzantine rule under the Sasanian dynasties (227-641 A.D.) an art was developed in Western Asia based upon Hellenistic columnar precedent, combined with vaulted methods, the knowledge of which had its origin in the subterranean vaults and fragment domes of Mesopotamia. The royal palace at Ctesiphon, with its great elliptically arched hall, is a monumental example of the remarkable tenacity with which these Oriental peoples held fast to their own artistic traditions. The two Oriental lines of architectural influence lead, one toward the Far East, expressing itself in the types found in India and China; and the other in the Levant, embracing practically all of the countries which ultimately came under the faith of Islam. The architectural styles that followed in the wake of the Mohammedan conquests were marked by certain common characteristics which differentiate them from the contemporary Christian styles. The decorative consideration was ever controlling. Construction was relegated to a secondary place. Restricted by the Mohammedan canon there is an absence of illustrative decoration and sculpture throughout Arabic, Persian, Turkish and Indian buildings. The profuse conventional decoration that necessarily took the place of humanistic representation showed a great love for minute surface ornament. The mosque and tombs throughout the Arabic countries of the Mediterranean exhibit frequently a remarkable degree of decorative elegance. In northern Africa, the Arabs restricted construction and gave free play to decorative license. This particular phase of architectural expression is known as the Moresque style, horseshoe cusped arches were substituted for the simpler and structural architectural forms. Plaster relief entirely took the place of more enduring materials. Arabic architecture attained a remarkable splendor, curiously enough, not in Africa, but in Spain, the southern portion of which was overrun by the Moors, 710-713 A.D.; where petty kingdoms were developed most important of which were Granada, Seville and Toledo; until the capture of Granada in 1492 when the Moorish rule in Spain was ended, there was an extraordinary activity in building. Mosques, castles, aqueducts were reared and the climax of the style was reached in the construction of the great mosque at Cordova, the Giralda at Seville and the Alhambra at Granada, the latter universally considered to be the masterpiece of Hispano-Moresque art.

Persian architecture, after the Arab conquest was strongly influenced by the Sasanian

palaces. The dome and vault, the colossal portal-arches and the use of brick and tile evidence the Mesopotamian origin carried to Persia through the medium of Sasanian design. From Persia, the Mohammedan architecture of India received its inspiration and beginning in the 11th century there appears the growth of an Indo-Moslem architectural style characterized by a grandeur and amplitude of disposition and a symmetry and monumental dignity which, contrasted with the Moresque style of the Arabs, awards every advantage to Indian work. The dome on a square plan was almost universal. The Byzantine pendentive was not used, but in its place original combinations of vaulting surfaces of corbeling and ribs appear. Artistic settings for the monuments of this type are noted, and in the greatest of the Indian monuments, the Taj Mahal at Agra, the style possesses a production in which constructive science combined with noble proportions and exquisite beauty is unsurpassed by any of the greatest architectural triumphs of the world. After the conquest of Constantinople in 1453, the Christian church of Hagia Sophia was occupied as the chief mosque and served as an official type to control Turkish mosque design in plan and constructive principle. Thus, out of the Justinian edifice, was developed a style of architecture less decorative and voluptuous than the style of Persia, Africa, or India, but nevertheless of great dignity. The Turkish mosque, the Suleimaniyeh (1553), with its soaring minarets, serves as a Turkish type that governs to the present day.

Romanesque.—The Dark Ages that followed the fall of Rome (476 A.D.) constituted an experimental period during which the peoples of Europe were being Christianized and the influence of the Church was being established. Nations and individuals were groping for truth in government, religion and in life, and throughout Northern Italy, the Rhine Provinces, Ile de France, Southern France, Normandy, and Norman England, art in its various departments was called upon to express each stage of advance. Roman monuments existed in all parts of the Christianized regions, and these monuments of antiquity, serving as constructive models, inspired a new architecture, modified by the liturgical requirements of the early Christians. This architecture, primarily based upon the Roman, varying in each province according to the exigencies of climate, and the registration of racial characteristics in decorative form and structural inventiveness, is known under the generic title of the Romanesque Style. In Tuscany, the churches were Basilican in plan with timbered ceilings and high clere-story. In Lombardy, in the 11th and 12th centuries the Basilican plans of classic Italy were translated into stone. Variations in plan resulted from the necessities of the lithic problems. The naves were narrowed and instead of rows of columns carrying a high clere-story wall, as used in the Tuscan Romanesque churches, heavy piers connected by wide-spreading nave arches supported the heavy ribs of the roof vaulting as in S. Ambrogio, Milan. During the 11th and 12th centuries in Northern and Western Europe, the church builders labored to adapt, like the Lombards in Italy, the Basili-

can plan to the requirements of vaulted construction. Throughout France, Western Germany, England and Belgium, the designers were constantly in trouble, caused by the difficulty of building the round arched vault over the several portions of the churches. The thrusts of the clumsy vaults used to roof the nave were inadequately resisted by half barreled vaults over the side aisles, through the medium of which the strains of the great central vaults were transmitted to enormously heavy side walls. In these cases the clere-story necessarily disappeared and the lighting problem, which did not amount to much in the southern provinces, became a serious consideration in the cloudy regions of the north. There it was necessary to raise the nave vault higher in order to introduce clere-story windows. To accomplish the introduction of the clere-story windows groined vaults replaced the barreled vault. The introduction of the groined vault made possible the concentration of the roof thrusts upon a series of isolated supports or clustered piers. The groined vaults were of two forms, four-part and six-part. The *four-part vault* is perhaps best typified in the church at Vézelay, France. The *six-part vault* was used in Normandy in the Abbaye aux Hommes and the Abbaye aux Dames built in the time of William the Conqueror. The use of the six-part vault in these churches, while making possible a higher clere-story, was an awkward expedient, for the division of the square vaulting bay into six parts by the diagonal groinings and a middle transverse rib, necessitated two narrow skew vaults meeting at the centre of the vaulting bay. Although an unsatisfactory device, this vaulting scheme was retained for a hundred years or more, and even after the adoption of the pointed arch form, it was common in the 12th century churches, both in France and in England. In constructing these vaults, the various ribs were erected independently of the vaulting surfaces, a principle of construction which the Romans had used in their concrete vaults. The buttressing necessary to support the various vaulted roofs was mainly internal and unsatisfactory. Subsequent to the Norman conquest, 1066, church and abbey building was greatly stimulated. Typical of the period in England and expressing the two various phases of the Norman style in England, are the cathedrals of Durham (1096) and Ely (1107). The original vaulting scheme of Durham was borrowed from the six-part vault method employed in Normandy. The instability of the six-part Norman construction is evidenced by the fact that the early vaults at Durham were replaced by four-part Romanesque construction. The English churches differ from the Continental edifices in two particulars. First, a huge tower was usually erected over the crossing of the nave and the transept, and secondly, the western portals were not emphasized. At Ely there appears a notable variant from the Durham Norman style, due conjecturally, to the influence of the Tuscan Romanesque. At Ely a basilican church was designed in which the graceful and elegant details of the Italian Pisan churches was replaced by the heavy forms of the Norman art used not in a structure but, a wholly decorative manner. A timber ceiling was used instead of stone vaults. This

Cathedral of Notre Dame, Paris

phase of the English Norman is practically nothing more than the Italian Basilica with a Norman envelope. In Germany a few churches dating back to the 9th century, in great part rebuilt, express the character of this period in that region. The church at Aix-la-Chapelle in Prussia has been greatly altered, but it was without a doubt inspired by that of San Vitale at Ravenna. The Byzantine type here shown was repeated in a number of later churches. The conventual church at Hechingen, near Stuttgart, and at Quedlinburg, Saxony, exhibited quasi-classical sculpture with scroll work and elaborate mouldings. Groined vaults, low and narrow, are used. The same timidity and lack of stability in vault construction is apparent here as in other parts of Europe. The great cathedral of Speyer, Bavaria, and the church at Gernrode belong to the 12th century, as do the church of Saint Michael at Hildesheim, the cathedral of Mayence, and the cathedral at Worms. These churches have been practically unchanged since the time of their building, and exhibit perhaps the most efficient examples of the Romanesque style. The Romanesque influence expresses itself in the far north in the cathedral of Lund in Sweden with the characteristics of the architecture of the period. The Scandinavian Peninsula depended for the most part upon timber for its construction and upon elaborate carving for its decoration. In Spain the Moors dominated the larger part of that country during the Romanesque era, but after the capture of Toledo (1062) by the Christians, there was a recession of Moorish influence, and in the northern provinces of Spain a number of important churches were erected which reflected the influence of French Romanesque models. The Church of Saint Iago at Compostella is typical of these Spanish Romanesque edifices. Barrel vaults over the nave, groin vaulting over the side aisles, follow the precedents of France. In the employment of a dome or cupola, as in the old cathedral at Salamanca, over the crossing of the nave and transepts is exhibited a characteristic departure from the French types.

Gothic.—The practical difficulties encountered by the Romanesque builders found a structural solution during the 12th century, when, under the influences of a firmly established state and a supremacy of episcopacy over monastic provincialism, ecclesiastical architecture assumed a foremost place in the social organization of the time. The basic principles of the Gothic styles were, first, *the concentration of thrusts upon isolated points of support*, a method adopted by the late Romanesque designers in their substitution of groined for barrel vaults, and, second, *balanced thrusts*, by which the strain weights exerted by the stone vaults were opposed by counter-thrusts, until these various thrusts were concentrated into a final resultant pressure which was transmitted by flying half-arches to external buttresses. The natural corollaries, whose development was forced through the application of those two principles, were *ribbed vaulting* and the *pointed arch*. This latter feature had been used in the Romanesque period, but it remained for the Gothic creators to appreciate its full structural possibilities. They built their groin ribs of semi-circular or pointed form, but the wall ribs were, without exception, pointed arches of such curvature as would bring the apex of each

nearly to the level of the groin intersection. The pointed arch, thus introduced as a structural device for the vaulting ribs, necessarily determined the profiles of the windows and nave arches. The advance in constructive science made possible the enlargement of the windows and the suppression of enclosing walls, conditions which promoted the use of stained glass and the necessary tracery for the support of the glass. The constructive supports were carefully moulded and buttresses were terminated with pinnacles—structural propriety was emphasized by decorative embellishment until there was produced a complex of constructive beauty which in its mystery and vivacity harmoniously presented the great ethical ideal of deity. The various styles of Gothic are universally differentiated by the character of the window tracery. The *formative era* is known as the *Early Pointed Period* (1160-1275). The simplicity and conventional treatment of structure and detail of this period gradually underwent change. In the *Middle Pointed Period* (1275-1375), knowledge of construction brought perfection in vaulting, and skill, resulting from training, developed a school of sculptors who delighted in the expression of naturalistic forms of mature foliage. The tracery, with its slender moulded bars and geometric combinations reflected the varieties of the achieved structural science. Skill and fancy finally suppressed the decorous art of the Middle Pointed Period, and *flowing* or *flamboyant* tracery in France and *perpendicular* bars and four centred arches in England and "*branch-tracery*" in Germany characterized the final or *Floric Gothic* (1375-1525).

The masterpieces of cathedral design are Notre Dame, Paris, Amiens, Rheims, in France; Canterbury, Lincoln and Salisbury in England; Strassburg and Cologne in Germany; the Cathedral of Antwerp in Belgium and the noble structures at Toledo and Burgos in Spain. In Italy civic pride expressed itself typically in the imposing edifice at Milan and Santa Maria del Fiore at Florence.

Renaissance.—During the Mediæval period arbitrary authority and ecclesiastical organization had inhibited the individual expression of human intellect and will. During the 12th and 13th centuries in Italy, the restrictions of dogmatism and centralized arbitrary authority and artificial union gradually gave way before the tide of Humanism, a movement that was related to every phase of life and expressed itself sympathetically in a reapplication of classic methods and an adaptation of antique art to the requirements of the period of the Rebirth, or Renaissance. Back, almost in the Dark Ages, may be found the beginnings of this movement. Classicism had never lost its influence among the scholars of the East and in mediæval times the intellectual centres of Italy were continually influenced by the teachings of visiting Greeks from Constantinople. The living examples of Roman and Greek art that showed their types of studied beauty continually before their eyes could not fail to affect the literature and art of Italy. A group of men who laid the foundation for the registering of the exultant awakening of modern thought and life, were Petrarch; Giotto (the architect-sculptor); the Pizani; Brunelleschi (architect and structural inventor); Donatello (sculptor), and Masaccio (the

apostle of individualism). The entire gamut of nature forms and the whole fundament of Roman structural possibilities and decorative individualism was made plain to the world in the teachings of the masterpieces produced by them. As the result of foreign invasion and commercial intercourse, the Humanistic styles of Italy came early in contact with France, the Netherlands, Germany, England and Spain. In Italy, "although the new architecture began with the colossal dome of the Cathedral of Florence and culminated with the stupendous church of Saint Peter, at Rome, it was predominantly an architecture of palaces and villas, of façades and decorative display. Constructive difficulties were reduced to their lowest terms and the constructive framework was concealed, not emphasized by the decorative apparel of the design." Among the masterpieces of the Renaissance are many buildings of small dimensions, such as gates, chapels, tombs and fountains. In these, the individual fancy had full sway and produced surprising results by the beauty of carved detail. While the general styles of the Renaissance in all countries may be divided into the *formative period*, the *classic period*, the *decline* and the *rococo period*, nevertheless on account of the personal expression of the styles, the real name that should be assigned to a given period should be the name of the great master of an era. The architectural *motifs* instituted by Brunelleschi in the construction of the dome of Santa Maria del Fiore in Florence (1420), and the Pazzi Chapel (1429); the Church of Santa Maria Novella (1456) and the Strozzi (1490) and Rucellai (1460), Palaces, Florence by Alberti; the Cancelleria (1500), the "Tempietto" (1500), at San Pietro in Montorio by Bramante in Rome; the Farnese palace (1520), by San Gallo; the Massimi palace (1531), Rome, by Peruzzi, the dome of Saint Peter's (1564), at Rome by Michelangelo; the Palace Pompeii (1530), Verona, by Sanmicheli; the Basilica, Vicenza (1560), by Palladio; the Palace Caprarola (1530), by Vignola; the Palace Grimani (1535), Venice, by Sanmicheli; the Library of Saint Mark (1536), by Sansovino, Venice, and Santa Maria della Salute (1631), by Longhena, Venice, are types establishing styles of architectural composition and decoration that continued strong in their influence from the time of their creation to the present day. These edifices are true indices characteristic of the Humanesque civilization in Italy. They are essentially products of adaptation, and, involving no new principles of construction, did not have inherent in their styles the germ of a new architecture. The Italian campaigns of Charles VIII (1489), Louis XII (1499), and Francis I (1515), resulted in the introduction of Italian culture into France. The personal contact made possible by these military activities emphasized a developing love for the luxurious facilities for living and the new mental bearing toward life resulting from an understanding of the æsthetic classic attitude. The structural character of the early French Renaissance was feudal. In the Royal Chateaux the military structural character compromised with Italian decorative styles and evolved a *formative Renaissance art* distinguished for its picturesqueness and the free and exuberant use of classic detail.

This *blending period* occupied practically the entire era of the Valois rule and covers the styles of the transition (1483 to 1515), the style of Francis I (1520-47), and the style of the advanced Renaissance (1547-89), by which time the classic methods of design had replaced the delicacy, richness and picturesqueness of the Formative period. *The Classic era*, with the fulsome, florid styles of Henry IV, Louis XIV followed, succeeded in 1715 by the extravagances and capriciousness of the *Rococo period*. Several edifices reflect in the broadest artistic sense the stylistic peculiarities of these three eras of the French Renaissance. The Chateaux at Blois, begun by Louis XII depicts all of the variations of the Blending or Formative period. The increasing use of the orders of architecture and the restrictive following of antique precedents exhibited in the Luxembourg Palace, the monumental colonnade of the Louvre, the Hotel des Invalides, and the Place Vendôme exhibit the stage of development under the Bourbons. License overcame, under Louis XV, the monumental observations of formal principles of classic design. The notable exceptions to this general trend of capriciousness is found in the works of the Ecole Militaire, originally terminating the Champ de Mars, and the two imposing edifices, adorned with monumental colonnades, of the Place de la Concorde, Paris, planned by the gifted Gabriel, which are the great architectural achievements of the period of the Decline, and, while the style of Louis XV itself was a style that characteristically avoided the formality that distinguishes classic design, these particular works have served as inspiring examples for all subsequent architects. The style of the Decline was halted by the revival of interest in things of classic origin during the period of reaction under Louis XV and the Empire, when in the Panthéon and the Madeleine and the Arc de l'Etoile there was a registration of the conviction that the translation of grandeur was possible only through the expression in architectural forms of classic Roman canon. The artistic history of the Louvre is an epitome of the entire history of French architectural development. Commenced under Francis I (1546), the beginning exhibits an Italian character. The work associated with the reigns of Henry II, Charles IX and Henry III (1547 to 1589), characterize the developing Renaissance. The additions made during the reigns of Henry IV, Louis XIII and Louis XIV exhibit the development of the orders and matured Renaissance method, while the colonnade under Louis XIV types the high water mark of Classicism. Napoleon I added his quota, and under Napoleon III, the Empire found its expression in what is now known as the New Louvre, two wings projecting from the old palace.

In England, The Netherlands and Germany, during the time contemporaneous with the Valois era in France, the great country mansions, manor houses and palaces were the first to receive and show Italian influence. The Renaissance in England makes its first feeble appearance in a decorative way during the Tudor period, a debased Gothic style. There followed during the Elizabethan period (1566-1603), by Dutch and Italian artists, a curious mixture of Gothic and Italian forms, which is

ARCHITECTURE

well exemplified in the Burghley House. Details of freely treated classic forms, which came into use during the reign of James I (1603-25), illustrate the Jacobean style. This style in reality was the introduction to the Classic period in which, under Inigo Jones (1572-1652) and Sir Christopher Wren, (1632-1723), correctly proportioned and monumentally conceived public works were erected. The palace at Whitehall (Jones) and Saint Paul's Cathedral (Wren) summarize the achievements of this period. Under the Georges a revival of Roman precedents, due to the genius of Robert Adam (1728-92), took place. With the idea that the architect should control all phases of his design, including even interior decorations and furniture, the name of Adam became synonymous with an English decorative school that produced results showing a rare taste in combining classic motifs with fertile fancy. The abandonment during the late Georgian period of the stiffness of the earlier era marks the characteristic of the style that served as the fountain head from which the American colonies borrowed models of their earliest architecture. The American churches were adapted from the Wren-Gibbs precedents (Saint Paul's, New York 1766). The drawings of Adam and his associates affected all phases of the domestic design. The translations into wood and brick of the Georgian stone *motifs* distinguished the early American style to which the name Colonial has been applied. (Mt. Vernon, the Home of General Washington).

The same general progression that marked the development of the Renaissance styles in France occurred in Germany, although the periods are not as definitely established. Beginning late (1555) the change from Gothic to Classic was rapid. Unlike France, the chief examples of the various periods are for the most part confined to secular architecture. In castles, town halls and corporation houses, irregularity of plan and a tendency to distribute ornament freely over façades, feature the German Renaissance. The orderly character of the French and Italian designer is replaced by the personal preferences of the German carver. The highest achievement of the era is the Castle of Heidelberg (1601) and its climax is reached in the degraded use of Rococo ornament in the Zwinger Palace, Dresden.

In Spain skill in metal work and delicate carving characterize a free and joyous application of Italian Renaissance forms to constructions of the early 16th century. This style, known as the *Plateresque* (1556), was widespread throughout Spain. The portal of the University at Salamanca and the Church of San Domingo at Salamanca are excellent examples of the style. The artistic barrenness of the reign of Philip II was followed by a cold classic era—*Griego-Romano*—whose masterpiece was the Escorial, completed by the great Herrera. The palace of Charles V, adjoining the Alhambra, Granada, by Beruguete exhibits the Spanish adaptation of the Italian-Paladian style. Toward the end of the 17th century a period of decadence set in during which debased taste and the throwing aside of all architectural restraint gave rise to the style *Churrigueresque*.

The Netherlands were late in re-acting to

the influence of Humanism and, in general, tended toward florid and unrestricted combinations of Italian, Spanish and French precedents.

Modern.—During the latter half of the 18th century a great activity in archæological research took place. Scientific examination of classic and pre-classic monuments and sites was undertaken, which procedure, with increasing enthusiasm, has continued to the present day. Academic theory and fanciful classic idealism gave way to definite and rational understanding of Roman and Greek methods of construction. The first effect of the publication of archæological research inspired the ambition upon the part of designers in various countries to design and construct after the form of the classic prototypes. This structural interest gave rise during the first half of the 19th century to the Greek and Roman classic revivals. The works of Piranesi, Lord Burlington, the illustrated description of the excavations at Pompeii, Herculaneum, Palmyra and Baalbek and Spalato, stimulated a Roman revival which in France expressed itself structurally in the Panthéon (1759-90) in which the dome and the porch of the Pantheon in Rome was the prototype. Napoleon commissioned Vignon (1807) to erect the Church of the Madeleine, a design whose interior is based upon the Roman *Thermæ* and its exterior a monumental peristyle of Roman Corinthian columns. The column of Trajan in Rome inspired the Napoleonic column of the Place Vendôme, and the various monumental arches of triumph re-echo the Roman triumph forms.

The publications of Greek archæological research, the antiquities of Athens by Stuart and Revett, Paestum by Major, the practical interest of Lord Elgin, and particularly the history of art by Winckelman, issued synchronously with the works of Stuart and Revett, in which the enunciation of the principle that a canonical relation between a whole and the various parts of a structure was necessary to produce an harmonious and balanced result forced the acceptance by many of the belief that the prototypes of a perfect architecture were to be found not in Roman examples but in Hellenic. Many buildings were therefore erected in England, Germany, France and America in the style of the Greek revival, in which Greek Ionic and Doric columns and details were used in profusion. While monumentality and dignity were obtained, the failure to appreciate the interdependence of the functions of Greek sculpture and Greek architecture with its then unknown refinements, resulted for the most part in an architectural style that was lacking in animation and national character. In Germany, the Greek revival was frequently modified to meet the needs of modern conditions, and while archæological correctness was to a degree subordinate, the more rational use of the Greek forms achieved a better style than in England. The style in England is exemplified by the Bank of England (1788), the British Museum (1823), Saint George's Hall, Liverpool (1815), and in Germany by the Brandenburg Gate, Berlin (1784), the Old Museum, Berlin, and the Propylæa, Munich, and in America is best expressed in the

Treasury, Washington, the old Custom House, New York, Girard College, Philadelphia, and the State House, Albany.

The results shown in the architectural monuments of the period in Germany, England and America were disappointing, for architecture to be completely successful must reflect the conditions of the civilization whose activities it is planned to house. The impossibility of instilling into modern life the conditioning causes of a dead civilization, made it impossible for the structural forms that were employed to reflect the functioning of the civilization of today.

In France the enthusiasm that resulted from the Greek revival stimulated an ambition for added refinement and purity. The delicacy of detail and the spirit of spontaneity that marks the Library of the École des Beaux-Arts and the Library of St. Genevieve exhibit well the possibilities of the æsthetic influence of Greek types.

Contemporaneous with the Roman and Greek revivals due to the influence of scholars and artists who travelled in the Far East, a pseudo-Chinese design became the vogue for many porticoes, pavilions and landscape accessories throughout France and England. The novelty and decorative possibilities of this Oriental influence, although for years imperfectly understood, have markedly influenced sportive and landscape design to the present day.

In Great Britain, about the middle of the 19th century, there appeared a revival founded upon the national Gothic architecture. The movement known as *Victorian Gothic* had its beginning in an archæological enthusiasm in which the decorative possibilities of English Gothic caused many misapplications of the Insular Gothic forms. Subsequent to 1850, archæological method gave way to an intelligent effort to adapt the Gothic principles to modern requirements, as the result of which activity there arose a number of monuments imposing in mass and refined in detail, the most successful of which is the building that houses Parliament at Westminster, London. The influence of this style extended to America during the last 40 years, but having no deep foundation in national requirements it has fallen into disuse and, like the Greek and Roman styles, has been replaced by designs founded upon Renaissance principles. In France, the 19th century Gothic revival very slightly affected the development of the modern Renaissance. The few buildings that were erected are generally superior to the English examples resulting from the same influence, in that the structural side of the problem has been scientifically dealt with; for the English and American interiors of the pseudo-Gothic style, for the most part completed with plaster-work, compared unfavorably with the French constructions in that, in France, the vaultings and dependent details are executed in masonry. Among the various nations in Europe, *eclecticism* made itself apparent during the last quarter of the 19th century. In modern times, the desire for truth and logic through structural form has appeared in a number of successful buildings in France, Germany and England. Perhaps the most remarkable example of eclecticism is the Trocadéro, Paris. It is im-

possible to classify this edifice according to architectural styles, but fulfilling its functions as a great **Expositional Building**, it is typical of the possibilities of a structurally trained architectural mind, in which license and extravagance are restrained by a knowledge of stylistic precedents.

The United States.—It has been the experience of all civilizations that a national art is not attained until there has been developed a suitable centralized authority, possible only with the establishment of a political and commercial independence. A nation achieves such a position after a long struggle, and, from the time of primitive conditions each step in the formation of an effective national life is marked by architectural and constructive methods which punctuate the epochs of the country's advance. Commercial conditions, utilitarian requirements and scientific discovery necessitate modifications in structural procedure and types of plan and mass composition adapted to new and local requirements. Dependence upon historic antecedents is continually evident. The historic development of the architecture of the United States aptly illustrates the conditions that must surround and control the evolution of architecture and its dependent arts in a growing and virile nation. From the time of the colonization of America, until the first half of the 18th century, building was confined almost entirely to sheltering and utility structures. During the period from 1725 to 1776, increase in wealth and population brought about a style based upon that in vogue in England at the time. Trained architects were not to be had in the colonies and the models which set the colonial fashion, due to lack of training of America's builders in classic traditions and the necessity of alterations caused by the use of brick and wood instead of stone, produced an architecture, which, while interesting, had no truly monumental character. In churches in New England and the Middle States, the English designs by Wren and Gibbs obviously served as prototypes and the influence of Adam and Sheraton is patent. Craigie House, Cambridge; Independence Hall at Philadelphia and the Old State House at Boston, while refined in mass and detail are not monumentally striking. In the West, influenced by Spanish types, were built picturesque mission buildings, and a few churches and secular buildings which exhibited a translated phase of the Spanish Churrigueresque. The era between 1776 to 1812 following the growth of the national government and the development of Federal strength, a characteristic monumentality became evident as is well exemplified in the central portion of the present Capitol at Washington, the City Hall, New York, and the State House at Boston. The enthusiasm which resulted from the archæological discoveries in classic lands spread to the United States, and previous to 1850 resulted in an architectural classic revival. The chaotic conditions surrounding the Civil War seriously impeded structural progress from 1850 to 1876. However a few monumental undertakings belong to this otherwise constructively poor era. The Capitol at Albany, the dome of the Capitol at Washington, Saint Patrick's Cathedral in New York, belong to this period. Due to a variety of causes, the opening up of the West, the great conflagrations

in Boston and Chicago, and the return from Europe of Hunt and Richardson, men thoroughly trained by European study, a revival in architectural spirit and production of the most powerful nature made itself felt throughout the country during the last quarter of the 19th century. With the Romanesque style as his vehicle, Richardson left an artistic imprint upon the nation's art that continues to the present day. Structural verity and dignity of mass mark his works (Trinity Church, Boston; County buildings in Pittsburgh). Hunt, with his great faculty for organization and his thorough founding in the principles of the Renaissance, formally established the Renaissance style. The Marble House, the Breakers at Newport and the Metropolitan Museum of Art in New York exhibit his genius for organized plan and standardization of style. The demand for great commercial buildings in which height was a necessary component on account of the problem of housing multifarious activities in restricted areas, caused the development of new structural form. The introduction of elevators, the invention of various methods of fireproof construction, the inauguration of a skeleton steel fabric and the solution of problems of lighting, heating and sanitation made possible the rearing of great "sky scrapers," the most notable example of which is the Woolworth Building, New York. In spite of the great advances that have been made in the development of architectural science in the United States, no style can be said to have developed that is new and characteristic. Commercial requirements, the demand for speed in design and construction and the experimental conditionings that restrict the modern designer have discouraged the evolution of a typical national style. In works of a public and commercial character the necessity for a co-operative understanding between the architect and the engineer is increasingly felt. It is only when a unified resultant combining the efforts of the architect and the engineer has been achieved—a resultant in which plan and detail shall adequately and truly function with the discoveries of modern science, that a new American style will appear.

LEWIS F. PILCHER.
State Architect of New York.

ARCHITECTURE, Education in. Training.—The ideal architect is an artist who employs structure as his medium of expression,—whose function it is to produce beautiful buildings.

That this ideal is realized by relatively few of those who are called architects in our day is due to the fact that its embodiment under modern conditions involves the correlation of activities of very diverse nature; and few there are who display in just proportion the capacities these diverse activities involve. These may be placed in three great groups, and the architect's training may be considered under three headings, namely, his artistic education, his technical education, his business education.

The student who hopes to be an artist-architect must train himself somewhat as do all artists in all other fields. Yet he cannot with his own hands bring into existence the building his imagination pictures; he is compelled, as no other artist is, to rely upon the work of others

in the realization of his artistic creations. Hence it becomes very important for him to gain a very special technical training in order (1) that he may learn how to indicate to his artisan helpers the nature of the work to be done, and (2) that he may become acquainted with the methods proper to these artisans in the accomplishment of their several tasks.

But beyond this the architect who would reach the highest goal should prepare himself for a business career. For unlike other artists he is usually unable to express himself in his chosen medium unless others entrust to him the expenditure of large sums of money. And if he is to be thus trusted he must exhibit executive ability, a knowledge of men and capacity to manage them, and at the same time he must possess unquestioned reliability and business sagacity.

In this connection it may perhaps be well to note that in our time there are not a few men who are counted as successful architects who are really merely good business men working in a special field, men without high artistic ideals or susceptibilities, and who gain such success as they attain by the mere direction of hired designers, and by the careful management of the business of their clients. The education of such men involves only such general training as is required by other business men, with the addition of such studies as will give them a knowledge of the architectural forms current in our time, and such a superficial acquaintance with the principles of architectural design as will enable them to choose as employees designers whose work will satisfy the average taste of their clients.

We need not concern ourselves, however, with business men of this type, for they will not be looked upon as architects by those to follow us unless they combine with their business skill the other qualities demanded of the ideal architect, to the consideration of whose training we may now turn our attention.

Apprentice System.—As is indicated by the etymology of his name, the architect was originally a master workman; one who had arisen from the ranks because he had evinced skill and imagination in guiding the construction of buildings after the methods current in his time, and who through the exercise of this skill and imagination had produced buildings which were looked upon as beautiful by his fellows.

The methods employed by the architects of antiquity are little known to us, yet as the work under their control became more complicated they must have found it necessary to employ assistants who at first were without doubt merely trade apprentices, and from among these the architects of the next generation would most naturally be chosen.

In modern times, as the use of complicated drawings has become more and more important, the architect has found it necessary to use his assistants on special work which does not involve the skill acquired by artisans in construction; and thus the type of man serving as the architect's apprentice has changed. While not an artisan himself he has learned his master's methods, and presently we find men thus trained assuming the function of the architect without any preliminary practice as constructors.

The apprentice system of education for the architect as thus developed was not unlike that adopted in the earlier days in the training of artists in other fields, and with such modifications as are natural in relation to the complexity of modern life it has persisted even to our day in many lands. In England a large proportion of the eminent architects of the day have been educated in this manner, and until within a generation in this country no other system of training for the architect was available.

A similar apprentice system obtained in the training of lawyers and doctors until a late period when special schools of law and medicine became established. The success of these schools called attention to the fact that, from a certain point of view, the architect is as clearly a professional man as the doctor or lawyer, and that the weaknesses in the training of doctors and lawyers under the apprentice system, which had led to the establishment of their special schools, existed also in connection with the study of architecture.

These weaknesses need but to be stated to be apparent to all. Evidently the teaching a busy architect can give to his pupil must vary greatly in quality and amount as the demands of his practice vary. Evidently his teaching is likely to be unsystematic; and it is certain to be biased by his individual taste, a matter which is of importance in relation to certain subjects, to be referred to below, where the broadest catholicity is of importance.

Thus following the example set in other professions, there have been established schools of architecture in which an effort is made to give the student a systematic training which shall not vary in quality and amount from year to year, and which shall avoid the unfortunate influences which are liable to obtain under the apprentice system. It will be generally conceded that the schools as a rule have been reasonably successful in this effort, if general results are considered, if particular instances are not overemphasized.

But the abandonment of the apprentice system of training in the law and medicine carried with it a loss which was generally overlooked. The newer method tended to minimize if not to eliminate the inspiration which comes to the student as the result of contact with the living master in the active practice of his profession. Nowadays students in law and medicine appreciate this loss and are supplementing their school training with practice under the guidance of men of reputation in their special fields.

But the loss to the student of architecture who fails to come under the influence of a practising master can scarcely be overstated. For the artist such an influence is of vital importance; under it he will absorb, as it were, stores of lore peculiar to his art which can never be expressed in the alien words of the lecturer, or upon the pages of a textbook. Fortunately the architects themselves are beginning to see that in one way or another the architectural student must be brought to feel this influence. What was valuable in the apprentice method of education, and has been in many cases lost, must be regained. In no inconsiderable measure it has been regained in the atelier system as developed in the Ecole

des Beaux Arts in Paris, and fortunately a distinct movement in the same direction is noted in the later developments of the schools existing in this country.

Granting then that there is a vital something of supreme importance to the architectural student which the school training cannot give, let us ask what he can gain in the schools, with economy of his time and labor, in connection with the training which we have seen to be desirable in the three directions above spoken of, which for convenience we shall treat in reverse order.

Business Training.—The architect's business training cannot be materially advanced in the architectural school. The general education, and the influences which produce the reliable, accurate and farseeing business man, can best be gained quite apart from the school course, in the practising architect's studio. In this connection it may be noted that, while the artistic side of the architect's life must always be first considered, it is easy to underestimate the importance of his business career. The student fresh from the schools too often thinks that he may at once undertake important commissions without the business experience which a long-established practice brings. He will tell you that this can be purchased ready made by the employment of others to attend to this drudgery so repugnant to a man of artistic temperament.

But in this view there lurks a hidden danger to the art of architecture itself. As has been said above, the confidence of the client must be obtained by the man who is to spend the client's money, and if the skilled designer is not one who inspires this confidence the control of great constructions will surely go to men of less artistic ability, and the skilled designer will find himself directed, rather than the director of the work necessary to the embodiment in solid form of the ideas which his imagination creates. Nothing can be more dangerous to progress in architecture as an art than the establishment of a belief that the architect's function ends with the creation of designs on paper; his art product is in the constructed building, and if effective artistic result is to be gained he should actually direct the construction in all particulars and to the very end, and should train himself to assume all the labor and responsibilities this direction involves.

Technical Training.—We may now turn to the consideration of the architect's technical training, which in the first place must result in the mastery of methods of representing his conceptions so that they may be understood by his clients, and comprehended by the workmen who are to be employed to embody them in material form. This means in the main the attainment of skill in technical draughting; and this can very clearly be better and more quickly gained by the concentrated effort possible in a school than in the course of the routine work in an architect's office. The student should be warned, however, that a danger is connected with the attainment of this skill if he comes to look upon his drawings, which are no more than tools of his trade, as works of art in themselves; for these drawings are necessarily on plane surfaces, and if he gives too much thought to their perfection he is liable to over-

look the importance for him as an architect of thinking in solid dimensions.

The general principles governing the representation of details of, and the writing of specifications descriptive of, the work to be done can also be learned in the schools, but little more than these general principles; the student must not hope to gain facility in these important matters without the experience of actual office practice.

Artistic Training.—It is true of all artists, as it is of poets in particular, that they are born and not made; and surely unless all opportunity is lacking the born architect of genius will show his power whatever his training may be. Nevertheless there are certain matters which even the genius must learn by his own often bitter experience, or else from those who have practised his art before him; and these matters may in some particulars be learned most quickly and surely in a school. It will be agreed for instance that each artist should understand well the nature of the medium in which he is to express his measure of genius. The medium of the artist-architect is construction in masonry, in iron and in wood; and a thorough knowledge of the principles of construction is most important to his progress. This knowledge is the ground work of engineering, and clearly can best be gained in a school. In relation to this special study it may be said, on the one hand, that the most thorough training in engineering cannot injure an architect provided it does not take from the time to be given to other equally important matters to be referred to below. On the other hand it must not be forgotten that the architect's function is not merely building as such, but building in a manner that shall stimulate in his fellows the sense of beauty. This molding of constructional forms into shapes which are beautiful is a matter of difficulty which has been attained by architects in the past only through numberless trials, with their failures and successes; through the elimination of the ugly, and the repetition with ever increasing improvement of that which has shown itself to be pleasing. The architect has thus always worked with, and upon, established modes of construction, and he always will; and this distinguishes his work from that of the engineer, whose function it is to devise special modes of structure to meet special structural demands. It is apparent then that the training of the architect in relation to his structural medium differs from that to be given to the engineer, in that the architect does not need to gain more than a thorough understanding of the principles of structure which he is to use in his work, and this does not necessarily involve so prolonged or detailed a study of the sciences as is needful for the engineer.

The Architect as a Designer.—We may now turn to the consideration of what is of the highest importance to the architect, namely, his training as a designer. As we have suggested above, no amount of training can give to a man that measure of genius which constitutes him an artist. None the less the greatest genius will gain much if he learn the lessons taught by the experience of the masters of the past, and the man who is less than a genius were stupid if he did not welcome this teaching. The masters of architecture of the

past have left us a record of the forms and relations of parts which after long series of studies and experiments they have found to be most beautiful. This record is not found in written word, but in the great monuments which have been left to us; and the study of these monuments after a certain method constitutes the history of architecture. The student should gain as thorough a knowledge as possible of this history, with especial reference to the vital development of the various greater and lesser styles, giving particular attention to those forms in which the highest perfection has been attained in the past, and making a special study of those forms which appeal to him as most likely to be of service to him under the conditions which surround him. He should also gain a considerable acquaintance with the other arts, especially with those most closely related with architecture, namely, sculpture and painting.

It must be apparent to the reader from what has preceded this that no student should undertake the practice of architecture without facing the fact that he has before him a long road, and a life of arduous efforts. Evidently a large part of the information just referred to can be gained through textbooks and illustrated lectures given in the schools. But as clearly is it important for the architect to study the art products themselves, and this can only be done satisfactorily by travel in the Old World, where the great architectural monuments of the past exist. Where such travel is impossible, he may gain something approximating to it by studying such models of masterpieces of the past as are available in museums, and by the thoughtful use of photographs of existing masterpieces.

Conclusions.—The conclusions reached may now be summarized in a few words. Beyond such general culture as he may be able to gain, the most desirable special training for an architectural student will be given by certain studies which can best be taken in established architectural schools, supplemented by careful observations of monuments of architecture in the course of travel in Europe, and by work in the studio and business office of a skilled practitioner who is a masterful artist.

It were well if life were so ordered that the acquisition of technical facility, and the study of design under a master, could begin in early youth, and continuing could fill the leisure hours of the student while gathering the store of general information which tends to broaden his life; but under existing conditions such an order of work is difficult to arrange.

If choice is to be made among the architectural schools, the one chosen should if possible be one situated in a city where building operations are proceeding on a large scale, and especially one in which design is taught by masters of architecture who are in active practice.

Finally the student would do well who could manage to obtain a position in the draughting room and business office of some architect in active practice during a large proportion of the long school vacations so generally given during the summer season. See PAINTING, EDUCATION IN; SCULPTURE, EDUCATION IN.

HENRY RUTGERS MARSHALL.

ARCHITRAVE, är'ki-träv, in classical architecture and imitations of it, the part of an entablature which rests immediately on the heads of the columns, being the lowest of its three principal divisions; also the molded enrichment on the faces of the jambs and lintels of a doorway or window, this being a part of the entablature carried around the opening and mitred at the upper corners.

ARCHIVES, är'kivz (Latin *archivum*), a room or building in which are kept the records, charters and other papers belonging to any State, community or family. Very frequently the name is applied to the documents themselves. The archives of the United States are now superintended by the heads of departments.

ARCHIVES, Imperial Russian. This term ("archives") appears in Russian legislation for the first time during the reign of Peter the Great, but the idea of conserving the important acts is very old in Russia, in fact it dates from the earliest period of Russian literacy. Besides the earliest "doskas" (i.e., tablets) which were exchanged between the government of the old Novgorod and the German statesmen in their diplomatic negotiations, there are written acts from the 14th century preserved under the name, 'History of the Russian Civil Code' (I, § 45). Churches and monasteries had, at the time of Peter the Great, well-kept archives not only relating to ecclesiastical matters but also to state affairs: but the great reformer was not satisfied with them and he ordered all the ministries to use the official acts only for three years and after the expiration of that period to place them in the care of an archivist specially appointed by the Emperor. During the reign of Empress Katharine II her archives were left in the custody of a special institution which passed over to the Ministry of Justice. Later, however, that Empress, in the pursuit of her reforms, abolished many institutions and for the custody of documents and acts she ordered two historic archives to be established: one in St. Petersburg and the other in Moscow. The most important archives in the Russian empire are the following: (1) *The Archives of the Imperial Council* which were kept, until 1886, together with the archives of the Senate in the building of the Senate but since that time they have been moved to a magnificent palace in the "Millionaya" street in Petrograd. (2) *The State Archives* which are kept in the Ministry for Foreign Affairs at Petrograd. Those archives contain, among other important diplomatic documents, the secret papers of the Cabinet of Empress Katharine II, as also those relative to the death of Emperor Alexander I and the succession to the throne of Emperor Nikolai I and the documents of the Supreme Court. (3) *The Central Archives of Moscow*, which is the richest storehouse of the most important historic documents in Russia. Established by Peter the Great those archives contain most of the documents of the Russian Embassies abroad and it was impossible for a long time to separate them and transfer them to the Ministry of Foreign Affairs, to which institution they rightly belong. (4) *The Archives of the Holy Synod*, kept in the palace of the Synod, contain several documents previous to 1721 (i.e., two documents from the 16th century, 15 from

the 17th century and 70 from the 18th century) relative to important historic events and to the archives of the Synod itself. (5) *The Moscow Archives of the Ministry of Justice*, containing documents relative to the affairs of the State Senate as also some of the oldest records of judicial proceedings from the 13th to the 18th century. (6) In the Ministry of Public Education there are two important historic archives: (a) *Archives of Kief*, established by Imperial decree in 1852 in the building of the University of Saint Vladimir for the purpose of keeping the ancient documents of the governments of Kievskaya, Podolskaya and Volynskaya; (b) *The Central Archives of Vilenskaya*, established at the same time as the Archives of Kief, for the purpose of keeping the documents belonging until that time to the various institutions in the governments: Vilenskaya, Grodnenskaya, Kovenskaya and Minskaya. Besides those there are the following archives of minor importance: (1) *The Central Archives of Vitebskaya*; (2) *The Military-Scientific Archives of the Imperial Russian General Staff*; (3) *The Archives of the Imperial Russian Admiralty*; (4) *Historic Archives of the various governments, etc.*

ARCHIVOLT, är'ki-völt, in architecture, the ornamental band, often of moldings, on the face of an arch and following its contour.

ARCHONS, är'könz, the highest magistrates in Athens. There was for a long period only one archon, who possessed for life all the power and dignity of a king, and was chosen from the royal race of Codrus. In 752 B.C. a change was introduced, and the tenure of the archonship was restricted to 10 years, the person appointed being still a member of the royal race. In 714 the latter condition was abolished and the archonship thrown open to all the Eupatrids or nobles; and in 683 a still greater change was introduced, the office being now made annual and its functions distributed among a body of nine. The reforms of Solon threw the archonship open to all who possessed a certain amount of property, whether noble by birth or not; and in 477 Aristides made it accessible to all Athenian citizens, without distinction. Until 508 the mode of election was by suffrage of the nobles; election by lot was then introduced, and the person elected had to undergo a scrutiny before the Senate and before the Agora in order to show that his ancestors had been citizens for three generations, and had to swear to obey the laws. The first of the nine archons was called "the archon," and sometimes the Archon Eponymus, because he gave his name to the year in all public records. He had the care of minors and orphans, and had to superintend some of the festivals. The second archon was called the King Archon. Upon him chiefly devolved the care of the religious concerns of the people, in connection with which he had to act as prosecutor of murderers and offenders against religion. The third archon had the name of Polemarch, and was originally entrusted with the superintendence of military matters, though in later times his duties were chiefly confined to the protection and superintendence of the resident aliens. The rest of the archons were called Thesmothetæ, and exercised a general supervision over the laws of the state.

ARCHYTAS, *är-křtäs*, an ancient Greek, a native of Tarentum, a famous Pythagorean philosopher, renowned also as a truly wise man, a great mathematician, statesman and general. He was the contemporary of Plato whose life he is reputed to have saved by his influence with Dionysius, and flourished about 400-365 b.c., but the dates of his birth and death are unknown. The invention of the analytic method in mathematics is ascribed to him, as well as the solution of many geometrical and mechanical problems. He constructed various machines and automata, among the most celebrated of which was his flying pigeon. He is credited also with the invention of the pulley. He taught that the earth is a sphere rotating on its axis every 24 hours and that the heavenly bodies move around it. Plato is said to have borrowed some of his opinions from Archytas and Aristotle also is said to have been indebted to him for the idea of his categories and some of his ethical opinions. These opinions, however, appear to depend on spurious writings, the real philosophical remains of Archytas being of inconsiderable value. Horace mentions him in one of his poems (*Carm. i, 28*) as having been drowned on the coast of Apulia. For his mathematical fragments consult Blass, '*Mélanges Graux*' (Paris 1884). The fragments attributed to him which relate to logic, physics and ethics are to be found in Mullach, '*Philosophorum Græcorum Fragmenta*' (Vol. I, Paris 1860-81).

ARCIFERA (Latin, *arcus*, bow, + *ferre*, to bear, carry), a division of Anura, including the toads.

ARCIS-SUR-AUBE, *är'se'su'röb'*, France, a town of the department of Aube on the river Aube. It is the birthplace of Danton, to whom a monument was erected here in 1886. In 1814 a battle was fought here between Napoleon and the allies in which the latter, with a much superior force, had the advantage and afterward marched to Paris. Pop. 2,841.

ARCO, Austria, a town in the Tyrol, not far from the Lake of Garda, on account of its situation and mild climate a favorite winter resort of invalids. Pop. 3,782.

ARCOLE, *är'kö-lä*, a village in north Italy, in the province and 15 miles southeast of the town of Verona, on the left bank of the Alpone, celebrated for the battles of 15, 16 and 17 Nov. 1796, fought between the French under Bonaparte and the Austrians in which the latter were defeated with great slaughter.

ARÇON, *är-sön*, Jean Claude Eléonore d', a French military engineer: b. Pontarlier 1733; d. 1 July 1800. He was received into the military school at Mézières, 1754, and in the Seven Years' War he highly distinguished himself, particularly at the defense of Cassel in 1761. In 1780 he invented the floating batteries for the attack of Gibraltar, which, however, were destroyed by the red-hot shot of the besieged. At the invasion of Holland under Dumouriez (in 1793) he took several places, including Breda. He then went into retirement, where he wrote his important '*Considérations Militaires et Politiques sur les Fortifications*' (1795).

ARCONA. See **ARKONA**.

ARCOS DE LA FRONTERA, *är'kö's dä lä fröntä'ra*, a town in Spain in the province of

Cadiz, on the right bank of the Guadalete, which is here crossed by a stone bridge. The sandstone rock on which the town, in form of a bow, is placed, rises 570 feet above the level of the river, which surrounds it on three sides. The houses are mean looking; the streets paved, but generally steep and narrow; and the ancient walls and defenses are in a ruinous state. On the highest part of the rock stands the castle of the dukes of Arcos, partly in ruins. Pop. (1900) 15,700.

ARCOT, *är-köt'*, the name of two districts and a town of India within the presidency of Madras. North Arcot is an inland district with an area of 7,256 square miles. The country is partly flat and partly mountainous. Pop. 1,817,814. South Arcot lies on the Bay of Bengal, and has two seaports, Cuddalor and Porto Novo. Pop. 1,814,738. The town of Arcot is in North Arcot, on the Palar, about 70 miles west-by-south of Madras. There is a military cantonment three miles distant. The town contains handsome mosques, a Nawab's palace in ruins and the remains of an extensive fort. Arcot played an important part in the wars which resulted in the ascendancy of the British in India. It was taken by Clive, 31 Aug. 1751, and heroically defended by him against an overwhelming force under Rajah Sahib. Pop. 11,000.

ARCTIC, a term applied to the North Pole, or the pole raised above our horizon, from the proximity of the constellation of the Bear, in Greek called *arktos*. The Arctic Circle is an imaginary circle on the globe, parallel to the equator, and 23° 28' distant from the North Pole, from whence its name. This and its opposite, the Antarctic, are called the polar circles. Within these circles the sun does not set during a part of the year, and during a corresponding part does not rise.

ARCTIC CHARR. See **TROUT**.

ARCTIC EXPLORATION. See **POLAR RESEARCH**.

ARCTIC REGION, the name given to the region of land and water surrounding the North Pole, reaching on all sides to lat. 66° 32' N. The Arctic or North Polar Circle touches the northern headlands of Iceland; cuts off the southern and narrowest portion of Greenland; crosses Fox Strait north of Hudson Bay, whence it goes over the American continent to Bering Strait. Thence it runs to Obdorsk at the mouth of the Obi; then, crossing northern Russia, the White Sea and the Scandinavian peninsula, returns to Iceland.

Climate.—The most important facts now ascertained respecting the climate of the Arctic regions are, that the main line of extreme cold extends across the Polar Sea from the meridian of 90° W. to that of 130° E., reaching much farther on the Asiatic than on the American side, so that the winter temperature of Yakutsk (lat. 62° 2') is 7° F. lower than that of Rensselaer harbor, in Smith Sound (lat. 78° 37'). But the American limit of cold oscillates much less than the Asiatic, the summer temperature at Rensselaer harbor being but 62°, while at Yakutsk it is 95° F. above that of winter. This difference is due to the absorption of summer heat by the comparatively dry plains of Siberia,

while on the North American continent the numerous lakes and inlets moderate the climate throughout the year. To this it may perhaps be added that Greenland, owing to its peculiar constitution and position, is to North America a source of refrigeration which has no counterpart in the eastern continent. This circumstance, and the humid atmosphere maintained by the numerous lakes, somewhat moderates the severity of the cold, but at the same time renders it somewhat more constant.

Arctic Ocean.—In its widest sense that portion of the ocean which extends from the Arctic Circle (lat. 66° 32' N.) to the North Pole, or more restrictedly from about lat. 70° N. Assuming the former limit, the Arctic Ocean is found entering deeply, in the form of gulfs, bays, etc., into the northern parts of the continents of Europe, Asia and America. The principal of these indentations are the White Sea in Europe; Kara Sea, Gulfs of Obi and Yenisei in Siberia; and Baffin Bay in North America. It is united to the Pacific by Bering Strait, and to the Atlantic by a wide stretch of sea extending from Greenland to Norway. Among the principal islands of the Arctic Ocean are Greenland (at last proved to be an island) and east of Greenland the extensive group known under the name of Spitzbergen, the small island of Jan Mayen, and Iceland. West of Greenland and divided from it by Davis Strait and Baffin Bay there are a considerable number of islands of great size but little interest. North of Europe are the islands of Nova Zembla; and north from these Franz Josef Land, an archipelago as yet imperfectly known. The water of the Arctic Ocean is extremely pure, shells being distinctly visible at a great depth; it also presents rapid transitions of color, chiefly from ultramarine to olive-green, the latter variations of color being produced by myriads of minute animals belonging for the most part to the *Coelenterata* and *Mollusca* classes. Many have adopted the belief in the existence of an open polar sea about the North Pole. But this belief is not supported by any positive evidence. Ice is nearly constant everywhere between Spitzbergen and the southern point of Greenland. This is called the main north ice. East of Spitzbergen and near Nova Zembla the sea is always beset, if not completely barred, by ice. In Baffin Bay and thence west to Bering Strait numerous expeditions have had a perpetual struggle with ice. The expedition of 1875-76 under Captain Nares, members of which reached a point 30 miles farther north than had ever previously been attained, proceeding by way of Baffin Bay and Smith Sound, found no indications of an open polar sea. On the contrary the explorers found north of 82° 27' a sea consisting of one unbroken sheet of old ice of immense thickness, which effectually barred the further progress of the vessels, while the ruggedness of the ice rendered it impossible to reach the pole by sledge. Nansen more recently found abundance of ice in the tract of sea crossed by him.

Arctic Current.—It seems certain that a current sets into the polar basin along the coasts of Norway and Lapland. It is probably the effect of prevalent southwest winds, though some call it a branch of the Gulf Stream. There is also a strong current running in at

Bering Strait. On the other hand, along the east coast of Greenland and in Baffin Bay the movement is generally south. In the numerous channels between Baffin Bay and Bering Strait the tides are regular but feeble; indeed, it seems possible to trace across Barrow Strait the line of neutralized or no tide, and this, there is reason to suspect, is also the line of comparatively permanent ice.

Minerals.—Valuable minerals, fossils, etc., have been discovered within these Arctic regions. In the archipelago north of the American continent excellent coal frequently occurs. The mineral cryolite is mined in Greenland and carried to the United States. Among other fossils the remains of large saurians are found in the Lias, which extends widely over the northern archipelago, and ammonites collected in abundance prove that in lat. 73° N. there was once a tropical temperature. The group of islands opposite the mouth of the Lena, in lat. 73°, are little more than accumulations of fossil remains carried down by the river and are annually visited for the purpose of digging fossil ivory.

Vegetation.—The plants peculiar to the frigid zone are stunted more by the dry winter winds than by short growing seasons and long winters. The reduction is confined to the limbs, as roots are as long and penetrate as far as in more temperate climates. The vegetation is widely distributed, the species found in North America being practically the same as those found in Europe and Asia, and since trees become more and more scarce as the Pole is approached, the prevalence of the tundra formation is characteristic of the region. In respect to distribution, Arctic plants differ from Alpine plants (q.v.) which, though otherwise similar, especially in the census of cushion and rosette plants and plants with thick-skinned evergreen leaves, include many endemic species. Arctic perennials are noted for the high percentage of species that develop winter-time flowering buds which burst into bloom early in the spring. In the Arctic zone, less than 2,000 species have been described, among them very few trees. These are mostly stunted willows, junipers and birches, and beyond their northern limits flowering plants, grasses, mosses and lichens extend to the most northern land seen by man. Commonest among the flowering species are crowfoots, potentillas, poppies, saxifrages, whitlow grass (*Draba*) and scurvy grass (*Cochlearia*). Thyme and angelica, growing in sheltered spots, are the only perfume-bearers.

The English expedition of 1875-76 found 20 or 30 species of phanerogamous plants between lat. 82° and 83°. From Churchill River on the west side of Hudson Bay (lat. 53°), the line limiting the forest runs constantly to the north of west till it reaches Norton Sound, a little south of Bering Strait, larch and poplar making their appearance as we go west. In Siberia, where the summer heat is greater, woods flourish to a much higher latitude within the Polar Circle. In the Scandinavian peninsula the red pine reaches lat. 69°, the Scotch fir 70°, the birch 71°. Animal life is by no means deficient within the Polar Circle. Species indeed are few, but the individuals are extremely numerous. The proof of this is to be found in the immense number

of skins of fur-bearing animals, eider ducks, seals, walrus, etc., annually supplied to commerce. Recent expeditions have found the usual Arctic quadrupeds and birds as far north as the land extended. How far north the cetaceans reach is doubtful.

Notwithstanding this apparent abundance, the human being has in general a severe struggle for subsistence beyond 64° north latitude, although traces of Eskimos have been found as far north as 81° 52'. The Eskimos who inhabit Greenland and the extreme north of America have a hard life of it, often pressed, and not seldom cut off, by famine. Under their rigorous skies the resources derivable from the surrounding abundance of animal life can support only a handful of men. Even in Siberia, where the reindeer trained to the sledge and the great rivers frozen throughout the winter add so greatly to the facilities of intercourse or emigration, whole communities are frequently cut off by famine or disease. Yet we see Europeans settled under the parallel of 73° at Upernavik in Greenland, of 72° 2' at Ustyarsk in Siberia, and of 70° 40' at Hammerfest in Norway, and explorers have wintered far north of this. The settlements in Greenland, northern Siberia, Kamchatka and the Hudson Bay territories are all more or less connected by trade with southern countries, whence they derive their power of endurance; and from the constant care required in order to guard against the consequences of the severe climate it is evident that to man the support of life within the Polar Circle must ever be difficult and precarious. Nevertheless, owing to the abundance of lower animal life, men have visited these regions for centuries to gather the exceedingly rich harvests of furs and oil.

Following are the farthest points of north latitude reached previous to the discovery of the Pole by Peary in 1909: 1607, Hudson, 80° 23'; 1773, Phipps, 80° 48'; 1806, Scoresby, 81° 12' 42"; 1827, Parry, 82° 50'; 1874, Meyer (on land), 82°; 1875, Markham and Parr (Nares' expedition), 83° 20' 26"; 1876, Payer, 83° 7'; 1884, Lockwood, 83° 24'; 1896, Nansen, 86° 14'; 1900, Abruzzi, 86° 33'; 1906, Peary, 87° 6'.

JOHN B. McDONNELL.

Editorial Staff of The Americana.

ARCTURUS, a fixed star of the first magnitude in the constellation of Boötes, and thought by some to be one of the largest of the

fixed stars. It has a large proper motion, and is a noticeable object in the northern heavens.

ARCUS SENILIS, a term applied to a white or grayish white rim on the outer edge of the cornea, due to the infiltration of a finely granular hyaline substance, heretofore thought to be a form of fatty degeneration. This is probably not the case, since the infiltration material has no relation to the corneal cells. It is more probably a condition due to changes in the blood vessels of the cornea and is frequently a result of old age. It is a normal phenomenon, however, occurring sometimes in perfectly healthy people, and there is no invariable relationship to fatty degeneration of the blood vessels, heart, or other organ.

ARDAHAN, är'da-hän', village in the portion of Turkish Armenia ceded in 1878 to Russia, 35 miles northwest of Kars. Its position gives it strategic importance. Its fortress was dismantled by the Russians in the war of 1854-56; in 1878 the Berlin Congress sanctioned the cession to Russia of Ardahan, which had been captured early in the war.

ARDEIDÆ, a family of wading-birds (*Order Ciconiiformes*) including the herons, egrets, night herons, bitterns and some African forms related to the shoe-billed stork (qq.v.). They differ from other families of the order in holding the head drawn by an S-curve of the neck when flying. This family is represented in all the warmer parts of the world.

ARDITI, är-dé'te, Luigi, Italian musician and composer: b. Piedmont, 16 July 1822; d. Hove, Sussex, 1 May 1903. Famous first as a violinist, then as a conductor, he went to London in 1857, and from that year till 1878 was musical director at Her Majesty's Theatre. He has conducted Italian opera and concerts in places as remote from one another as New York and Constantinople; has published the operas 'I Briganti' (1841); and 'La Spia' (1856); and is known as author of much popular music—songs, violin duets and waltzes, such as 'Il Bacio.' He published his 'Reminiscences' in 1896.

ARDMORE, Okla., city and county seat of Carter County, 100 miles south of Oklahoma City, on the Gulf, Colorado & Santa Fé, C. R. I. & Pacific, Saint Louis & San Francisco, and O., N. M. & Pacific railways. The soil is well adapted to fruits, cotton, corn, cereals and forage crops. There are only three months in the year when range cattle must be fed, the climate, abundant rainfall and the fine grass making ideal conditions for stock raising. The production of gas is becoming more and more extensive and important. The Healdton oil field, as reported 8 Aug. 1915, has a total of 311 wells with a production of over 85,000 barrels of oil daily. The gas production of the same field shows 300,000,000 cubic feet a day. Ardmore's industries include a cottonseed oil mill, cotton compress, an ice plant, machine shops, brick plant, mattress factory, electric light and power plant, two planing mills, oil refinery, flouring mill, cotton gins, cigar factory, paint factory, bottling works, paving plant and asphalt brick plant. The machine shops of the Rock Island and Frisco railroads are located here, and Ardmore is the general headquarters of the Oklahoma, New Mexico and Pacific

Railway. The city has three national banks and one State bank, with a combined capitalization, surplus and profits of nearly \$4,000,000, an increase of \$1,850,000 since 1 Oct. 1915. Ardmore has 12 churches for whites and 4 for negroes. The public school system is especially well organized and intelligently administered. The school population totals about 2,500, the enrolment 2,343, and the average daily attendance 2,048. The high school, costing \$150,000, is a handsome structure and the pride of the city. There is also a fine Catholic parish school, and the government school for Indians is located here. The city is under the commission form of government the officials being a mayor and four commissioners. The annual income of the city is \$140,000. An artificial lake, covering 300 acres, furnishes Ardmore's water supply. The entire plant, including 1,400 acres of land, is owned by the city. Pop. (1916) 12,500.

ARECA, the designation of a genus of palms, possessing pinnate leaves and a fruit consisting of a one-seeded berry or drupe, with a fibrous rind. To this genus belongs the betelnut (*A. Catechu*), a native of the East Indies, and cultivated there in many varieties. It is a very beautiful palm, with a slender stem often 40 feet high. Its nuts, called betel-nuts, are rolled into a leaf of the betel-pepper along with a little lime, and are then chewed. The nut contains at least four alkaloids, Arecoline, Arecaidine, Arecaine and Guvacine, the former alone having known active properties. Arecoline is an active taeniocide and widely used in veterinary practice for the treatment of tapeworms. It is also an active cathartic and mydriatic. In the latter case it is extensively used as a stimulant.

ARECIBO, *ā'rā-sē'bō*, Porto Rico, important commercial town on the northern coast, facing the Atlantic Ocean, 50 miles west of San Juan. It resembles ordinary Spanish towns in having a plaza, surrounded by the church and other public buildings, in the centre, with streets running from it in right angles, forming regular squares. The buildings are of wood and brick. The harbor is poor, being exposed to the full force of the ocean.

ARENACEOUS ROCKS, the name applied to a petrographic division including loose sands and gravels, sandstone, conglomerate, quartzites and such rocks as are mainly composed of quartz particles. They are of mechanical origin, being derived from disintegration of pre-existing strata and removal and deposition of the materials by wind or water. The grains are generally waterworn and rounded; in some cases, however, they are more or less angular, or rounded and angular grains occur commingled. In older deposits the grains of sand are bound together by silicious, calcareous, argillaceous, or ferruginous cements. It is seldom that a rock is composed of quartzose materials alone; grains or particles of other mineral substances are frequently mingled with the grains of quartz. Silvery flakes of mica are seldom absent; often occurring in layers parallel to the planes of stratification, thus causing the rock to split into thin slabs, and exposing a glittering surface. These are called micaceous sandstones. When grains of feldspar occur, the rock is a feldspathic sandstone. Often large quantities of calcareous matter, either as cement

or as distinct grains, occur; and these are called calcareous sandstones. In like manner we have silicious and ferruginous sandstones, when silica and oxide of iron are conspicuously present as cementing or binding materials. Clay and carbonaceous matter, when plentifully diffused through the rock, give rise to argillaceous, carbonaceous and bituminous sandstones. Greensand, or glauconitic sandstone, is a rock containing abundant grains of the dirty greenish mineral called glauconite. Arkose is a sandstone composed of disintegrated granite; volcanic sandstone, trappean sandstone, etc., being composed of disintegrated igneous rocks. The presence of lime can always be detected by the effervescence which takes place on the application of hydrochloric or other acid. A sandstone of homogeneous composition, which may be worked freely in any direction, is called freestone or liver rock. Flagstone is a sandstone capable of being split into thin beds or flags along the planes of deposition. When the sandstone is coarse-grained, it is usually called grit. If it contain, more or less abundantly, grains large enough to be called pebbles, the sandstone is said to be conglomeratic; and if the pebbles or stones be angular, the rock is described as a brecciaform sandstone. Coarse-grained grits and pebbly or conglomeratic sandstones pass into conglomerate or puddingstone, which consists of a mass of various sized water-worn stones. Brecciaform sandstones frequently pass into breccia, an aggregate of angular and sub-angular fragments. Graywacke is an argillaceous sandstone, more or less altered and sometimes semi-crystalline, met with among palæozoic formations. Limestones and shales containing much sand are said to be arenaceous.

ARENARIA, the name given to a genus of plants of the *Asteraceæ* or chickweed family. They number upward of 200 species, and are usually low-tufted herbs with white flowers. Many species occur in the United States, and others are found nearly everywhere except in tropical regions.

ARENBERG, or **AREMBERG**, August Maria Raimund, PRINCE, also known as COUNT LA MARCK, Belgian soldier and writer, brother of the Duke of Arenberg: b. Brussels, 23 Aug. 1753; d. there, 26 Sept. 1833. Began his career as a cadet in the military service of the Duke Charles von Lothringen. Served under the French in India and against the English in America from 1780 to 1782. During the French Revolution he became intimately associated with the famous leader, Mirabeau. His chief literary work, of much value for the light it throws on French history during the Revolution, is 'Correspondance entre le comte de Mirabeau et le comte de La Marck' (edited by Vacourt, 2 vols., Brussels 1851).

ARENBERG, or **AREMBERG**, Leopold Philipp Karl Joseph, Duke of, Austrian soldier: b. Brussels, Belgium, 1690; d. Löwen 1754. He began his career as a soldier as a mere child and at the age of 16 was already colonel. Gaining the favor of Archduke Charles, who later became Emperor Charles VI, he served him as Councillor of State. In 1709 he became grand bailiff of Hainault. In 1716 he went to Hungary and served under Prince Eugene and especially distinguished

himself at the battle of Belgrade. Subsequently he attained the rank of field marshal and was commander-in-chief of the Imperial forces in the Netherlands and as such commanded the operations at the battle of Dettingen. In 1747 he became president of the commission governing the Netherlands. Aside from his military interests, he was an ardent patron of learning and a close friend and patron of Jean Jacques Rousseau. He maintained an intimate correspondence with Frederick the Great and Voltaire. Consult Gachard (in the 'Biographie Nationale,' published by the Royal Academy of Belgium).

ARENBERG, or **AREMBERG**, formerly a German duchy, between Jülich and Cologne, now incorporated in the Prussian administrative district of Coblenz. Its rulers played a part of some importance in German history of the 12th century, but in 1280 the male line died out. One of the female descendants married the Count de La Marck, the younger of whose two sons became the Lord of Aremburg. In 1547 the male line again died out, but the heiress married into the Ligne family and her husband was made a count of the empire by Charles V. Because of the services rendered by him and his sons to the Emperor, his title was raised to that of duke. See **ARENBERG**, DUKE OF.

ARENDAL, Norway, a town at the mouth of the Nid Elf, in the Bay of Christiania. It is sometimes called "the little Venice," because of the fact that many of its houses are built over the water on piles. The harbor is well protected by the island of Tromö, which has favored the development of the town as a commercial port. The principal exports are timber, wood pulp and iron ore from the mines nearby. Pop. (1910) 10,315.

ARENDT, *ä'rent*, **Otto**, German economist: b. Berlin, 10 Oct. 1854. He studied, first law, then economics, in the universities of Leipzig and Freiburg. In 1882 he was one of the founders of a society for the promotion of a movement for international bimetalism, which evolved into a political party, of which he was the chief. In 1885 he was elected to the Prussian House of Representatives. In 1888 he became editor of the *Deutsches Wochenblatt*, a publication that advocated a strong colonial policy. His works are 'Die vertragsmässige Doppelwährung' (1880); 'Leitfaden der Währungsfrage' (17th ed., 1895); 'Die Ursache der Silberentwertung' (1899); 'Die parlamentarischen Studienreisen nach West- und Ost-Afrika' (1906); 'Geld, Bank, Börse' (1907).

ARENDT, **Rudolf**, German chemist: b. Frankfurt-on-the-Oder 1828; d. 1902. After graduating from the University of Leipzig he became a teacher in a business college in his native town. Later he was editor of the *Chemisches Centralblatt*, a position he held for many years. His chief works on chemistry are 'Technik der Experimental Chemie' (2 vols., 1881); 'Anschauungsunterricht in der Naturlehre' (4th ed., 1886); 'Leitfaden für den Unterricht in der Chemie' (7th ed., 1899); 'Grundzüge der Chemie' (8th ed., 1903).

ARÈNE, *ä'ren'*, **Paul Auguste**, French poet: b. Sisteron 1843; d. Antibes 1896. He

was successively director of the Lyceum at Marseilles and the Lyceum at Vanves. In 1865 he attracted wide attention by the production of a one-act comedy, in verse, 'Pierrot héritier.' His other works are dramas, 'Jean des figues' (1870); 'Les comédiens errants' (1873); 'Le duel aux lanternes' (1875); prose fiction, 'Au bon soleil' (1879); 'Le canot des six capitaines' (1888); descriptive travel, 'Vingt jours en Tunisie' (1884). Consult Armand Silvestre in preface to 'Poésies' (Paris 1900); 'Lorenz Petry' (Halle 1910).

ARENG PALM, the name of a palm, *Arenga saccharifera*. It grows wild in the islands of southern Asia and is cultivated in India. The sap furnishes "arenga sugar" and the black fibre of the leaf bases, known as gomuta fibre, is used in filters and for calking ships.

ARENSKI, *ä-rën'skë*, **Anton Stepanowitch**, Russian composer: b. Novgorod, 30 July 1861; d. Tarioki, Finland, 25 Feb. 1906. He graduated 1882 from the Conservatory at St. Petersburg, where he had been a pupil of Rimski-Korsakoff. The following year he was appointed professor of composition at the Imperial Conservatory in Moscow, where he first began to attract general attention. In 1895 he succeeded Balakireff as conductor of the Imperial Court chorus. His most noted compositions are operas, 'Dream on the Volga' (1892); 'Raphaël' (1894); 'Nala and Damayanti' (1899); orchestral music, two symphonies; concerto for piano; concerto for the violin; a fantasia for piano and orchestra; chamber music, string quartets, trios, quintets. His written works are 'Treatise on Harmony'; 'Handbook of Musical Forms.'

ARENTS, *ä'rents*, **Albert**, German-American metallurgist: b. Klausthal, Germany, 14 March 1840. After studying mining engineering in Berlin he came to America, in 1865, and went to the lead mines in Hampton County, Mass. Later he went west, where he acted as engineer for various mining enterprises. He is chiefly known for his inventions, among which is a siphon tap for lead blast furnaces.

ARENTZEN, *ä'rentz-ën*, **Kristian August Emil**, Danish poet: b. Copenhagen, 10 Nov. 1823; d. there January 1900. After making a tour of Iceland and Italy, he became professor of aesthetics at the University of Copenhagen. In 1872 he was granted a pension by the government to enable him to devote himself exclusively to his literary work. Among his works are dramas, 'Gunlög Ormetunge' (1852); 'Knud den Hellige' (1853); a volume of collected poems, 'Digte' (1854), republished as 'Ny Dygtsamling' (1867); a critical work, 'Baggesen og Ohlenschläger' (8 vols., 1878).

AREOIS, *ä'rä-ö'ëz*, a society of natives of Tahiti, of a semi-religious nature. The nearest parallel to the character of this peculiar native institution is found in the orgies of some of the Greek mysteries of antiquity. The members exalted the sex pleasures, the women being compelled by the oaths of initiation to renounce all desire for maternity. Dancing, singing and the representation of stirring events of the past, by a sort of pageantry, were also a part of their practices.

AREOMETER. See **HYDROMETER**.

AREOPAGITICA, the best-known of the prose works of John Milton. The full title runs 'Areopagitica: a Speech of Mr. John Milton for the Liberty of Unlicenc'd Printing, to the Parliament of England.' These words recall Isocrates and Mars Hill, and illustrate Milton's erudition, as well as his predilection for what he terms "the old and elegant humanity of Greece." They indicate also that his plea was made, not so much for full liberty of the press and toleration of opinion—although splendidly high-minded and liberal he was not prepared to tolerate "Popery and open superstition"—as for the abolition of that system of licensing books and tracts, the stupidity and inconvenience of which he could expose and denounce from personal experience and with weighty arguments drawn from an extraordinarily wide reading of history and literature.

The tract, for it is a speech in form only, appeared in November 1644 after Milton had caused to be printed without license two pamphlets on divorce, which had occasioned much scandal and had involved him, not seriously as it turned out, in trouble with the House of Commons. It is needless to add that the 'Areopagitica' was itself unlicensed, and it is pleasant to know that although shortly after it was published there seemed to be a chance that the House of Lords would call its author to account, he did not suffer for his boldness (consult for full details Masson, Vol. III, pp. 262-97, and the most elaborate edition, that of T. Holt White, 1819).

Its subject matter still possessing widespread interest and great importance, and its style being more equable and less cumbersome than that of Milton's other prose works, the 'Areopagitica' has naturally surpassed them in permanent influence and, if the word may be employed in connection with Milton, in popularity. More wonderfully eloquent passages may be found in other tracts, as well as a larger number of indispensable autobiographical details, but Milton the "lord of language," as Tennyson called Virgil, and Milton the noble patriot and man are perhaps nowhere else in the prose works so accessible to the latter-day reader. How Milton towers above other mortals is well perceived by anyone who examines the pamphlets on the freedom of the press published in some quantity two generations later, to which such authors as Tindal and Defoe contributed; but one need not search outside the 'Areopagitica' itself for proofs of Milton's superiority as a man and a writer. Take for example the famous passages on killing a good book, on "a fugitive and cloistered Virtue," and "our sage and serious Poet *Spencer*," on the essential intelligence of the people,—the roots of democracy were in this intellectual aristocrat—on the visit to Galileo, on the dismemberment of "the Virgin Truth," on England, "a nation not slow and dull," which later he sees "as an Eagle muing her mighty youth." Eloquence and personal dignity and learning are here in full measure, but the 'Areopagitica' is also notably practical, and its sarcasm is rendered more than usually effective and even agreeable by a vein of genuine though grim humor, which perhaps only once is unintelligible save to the student of Latin. Barring the almost ludicrous depreciation of Aristophanes, the tract is but

slightly amenable to hostile criticism, and one is not surprised to find that two poets, Thomson of 'The Seasons' and Lowell, have written introductions to it, and that on the eve of the French Revolution Mirabeau appears to have abridged it in 'Sur la Liberté de la Presse, Imitée de l'Anglois de Milton.'

WILLIAM P. TRENT,
Professor of English Literature, Columbia University.

AREOPAGUS, the designation of the oldest Athenian court of justice. It obtained its name from its place of meeting, on the Hill of Ares (Mars), near the citadel. Its establishment is ascribed by some to Cecrops, by others to Solon; from the latter, however, it seems to have only received a better constitution and more important privileges, and it is probable that it existed from very remote times. Of how many members it consisted is not now known. A seat in it was held for life. The members were men who in their former capacity of archons had rendered themselves worthy of this honor by the honest and diligent execution of their office, and whose character and conduct had been subjected to a particular examination. Aristides called the Areopagus the most sacred tribunal of Greece, and Demosthenes assures us that they never passed a sentence in which both parties did not concur. Crimes tried before the tribunal were wilful murder, poisoning, robbery, arson, dissoluteness of morals and innovations in the state and in religion; at the same time it took care of helpless orphans. The other states of Greece sometimes submitted their disputes to the judgment of the Areopagus. Its meetings were held in the open air and in the night time. After the investigation of a case the votes were collected. In the time of Pericles its political influence was materially lessened, but it continued a much venerated assemblage, and in Roman times its decisions still commanded respect. The Apostle Paul is sometimes thought to have been brought before this ancient court, but it is more likely that his famous address on Mars Hill was before an assemblage of philosophers there. Consult Botsford, 'The Athenian Constitution' (1893); Busolt, 'Handbuch' (Nördlingen 1887); Philippi, 'Areopag und Epheten' (Berlin 1874); Schömann, 'Griechische Alterthümer' (ib. 1897); Meier and Schömann, 'Der attische Prozess' (Berlin 1883-87).

AREQUIPA, ä'rā-ké'pa, Peru, city and capital of a department of the same name. It is situated in a fertile valley 200 miles south of Cuzco, at the height of 7,550 feet above the sea. Prior to the earthquake of 13 Aug. 1868, which did not leave a single house habitable, it was one of the best-built towns of South America. Beside it rise lofty mountains, El Misti, Omati, Ubinas and Pichu Pichu. It contains a cathedral, university, hospital, nunneries, convents, etc. Near at hand Harvard University has an observatory, at an altitude of over 8,000 feet. It is subject to frequent earthquakes, but this evil seems to be overbalanced by the mildness of the climate and the beauty and fertility of portions of the country round about. Islay was formerly the provincial port, but it has been superseded by the neighboring Mollendo, connected by railway with Arequipa and the highlands beyond. The industrial products of

the city are varied, including cotton and woolen textiles, leather, gold- and silver-smiths' work, etc. The engineering shops of the Southern Railway are at a short distance from the central plaza. The inhabitants number about 35,000. See the description of the department AREQUIPA.

AREQUIPA, Peru, a coast department estimated to contain 21,947 square miles; bounded on the north by Ica, Ayacucho and Cuzco; on the east by Puno and Moquegua; and by the Pacific on the southwest. Its most important port is Mollendo, which the Southern Railway of Peru connects first with the capital of the department and then with Cuzco, Puno and other cities or towns of the highlands. The provinces are Arequipa (capital Arequipa), Cailloma (capital Cailloma), Camaná (capital Camaná), Castilla (capital Aplao), Condesuyos (capital Chuquibamba), Islay (capital Mollendo) and La Union (capital Cotahuasi). Olives, grapes, sugar and cotton are grown in the valleys, and the uplands produce cereals, potatoes, etc. Minerals found in the department are gold, silver, copper, lead, coal, sulphur, manganese, rock-salt, borax, gypsum and kaolin clay. In the Desert of Islay, through which runs the above-mentioned railway, are the migrating, crescent-shaped sand dunes, remarkable for beauty of form and the impressiveness of the landscape in which they are seen. Pop. 172,000.

ARETÆ'US, physician of ancient Greece: b. in Cappadocia. He lived in Rome during the latter half of the 1st century and the beginning of the 2d century A.D. Next to Hippocrates he has been considered the best physician of his period. He left behind a monumental work, written in Ionic, the first four books of which are devoted to the diagnosis of acute and chronic diseases; the latter four volumes treat of their cure. The finest edition of the original is the one edited by J. Wigan (Oxford 1723). An excellent German translation has also been published (Vienna 1790-1802). The best English translation is by T. F. Reynolds (London 1837).

ARETAS, King of the Nabatæan Arabs. Originally his name was Æneas but he assumed the name Aretas. He gained the city of Damascus, probably as a gift from Caligula, about the time Paul the Apostle was there. Aretas attacked and defeated Herod Antipas about 28 A.D., partly because of the divorce of his daughter by Herod. He lived until about 40 A.D. Under him the kingdom of Nabatæa stretched from the Euphrates to the Red Sea. By the year 106 the whole kingdom was annexed by the Romans and was known as the province of Arabia. Damascus had been regained as early as 62.

ARETHAS, Byzantine theological writer and scholar: b. Patræ about 860. He became archbishop of Cæsarea under Emperor Leo VI and as such was next in rank to the patriarch of Constantinople. He must have lived to a good old age, as we have a manuscript letter of his to the Emperor Romanus. He was a defender of Orthodoxy as it was understood by Photius. He was the author of a Greek commentary on the Apocalypse, avowedly based on that of Andrew, his predecessor in the archbishopric. In spite of its author's modest esti-

mate, Arethas' work is by no means a slavish compilation; it contains additions from other sources and especial care has been taken in verifying the references. His interest extended beyond theological literature. He annotated the margins of his classical texts with numerous scholia, and had several manuscripts copied at his own expense, among them the 'Codex Clarkianus' of Plato (brought to England from the monastery of Saint John in Patmos) and the Dorvillian manuscript of Euclid, now at Oxford. Text of his commentary is in Migne, 'Patrologia Græca' (Vol. CVI, pp. 487-786) and Cramer, 'Catena Græcorum patrum in Novum Testamentum' (Vol. VIII, pp. 176-582, Oxford 1844). Consult Gebhardt, O., and Harnack, A., 'Texte und Untersuchungen zur Geschichte der altchristlichen Litt.' (Vol. I, pp. 36-46, 1882), and 'Vita Euthymii' (ed. C. E. de Boor, 1888); Wace, H., 'Dictionary of Christian Biography' (Vol. I); Krumbacher, C., 'Geschichte der byzantinischen Litteratur' (1897).

ARETHUSA. See ALPHEUS.

ARETINO, ā'rā-tē'nō, Carlo, properly CARLO MARSUPPINI, Italian scholar: b. Arezzo 1399; d. 1453. He obtained a finished classical education at Florence, being at one time a pupil of Giovanni da Ravenna and Manuel Chrysoloras. The profound knowledge of the classic writers he showed in his lectures won him immediate fame. He finally became first apostolic secretary, then, in 1444, was appointed chancellor of the republic of Florence. He translated the first book of the 'Iliad' and the 'Batrachomyomachia' into Latin. His tomb in the Church of Santa Croce, at Florence, is one of the finest examples of the sculptural art of the Renaissance yet to be seen in that city. Consult Nisard, 'Les gladiateurs de la république des lettres aux XV^e, XVI^e et XVII^e siècles' (Paris 1860).

ARETINO, Guido, or GUIDO D'AREZZO, Benedictine monk and reformer of music: b. probably near Paris, about 995; d. probably at Avellano, 1050. For a long time it was believed that he was born at Arezzo but Dom Germain Morin found evidence that Guido had received his education at the monastery of Saint Maur des Fossés, near Paris, a fact which adds to the probability of his having been born near Paris. He is supposed to have first reduced the science of music to a fixed system and to have been the inventor of the monosyllables of the *Solfeggio* — *ut, re, mi, fa, sol, la*, drawn from the words of a Latin hymn. The monosyllable *si*, for the seventh of the scale, is a later invention. The syllables *ut, re, mi, etc.*, are taken from a Latin hymn in honor of Saint John, composed in 770:

<i>Ut</i> queant laxis	<i>Re-sonare</i> fibris
<i>Mi-ra</i> gestorum	<i>Fa-muli</i> tuorum.
<i>Sol-ve</i> polluti	<i>La-bii</i> reatum.

It is narrated that on one occasion, while chanting this hymn, Guido noticed the gradual and regularly ascending tones of the first syllables of each hemistich in the three verses given above and promptly systematized and fitted these to his system of solfeggio. The fame of this system spread afar and Guido was subjected to much jealousy and ill-will both in his own and other monasteries, but

also attracted the favorable attention of Pope John XIX, who invited him to Rome. Guido was well received at the papal court, and taught the Pope his new system, which the latter helped to spread. In 1029 Guido was appointed prior of Avellano, where he probably remained until his death. The introduction of the four-line staff is ascribed to him. Guido wrote much in explanation of his musical doctrines, of which the most important are the 'Microlologus' and the 'Argumentum Novi Cantus Inveniendi.' Consult Michael, 'Geschichte des deutschen Volkes vom 13 Jahrhundert bis zum Ausgang des Mittelalters' (Vol. IV. p. 338, 1906).

ARETINO, Pietro, Italian writer and poet: b. Arezzo, 20 April 1492; d. Venice, 21 Oct. 1557. Aretino's life and character find almost a complete parallel in the career of the better known French profligate poet and criminal François Villon, of whom he was a contemporary. He was the natural son of one Luigi Bacci, a gentleman of the town. Early in life he went to Perugia, where he worked as a bookbinder. In 1517 he went to Rome, where he obtained a minor position at the Vatican. Here he began attracting attention by his verse and even obtained the favor of Pope Leo X and Cardinal Giulio de Medici, but soon lost it through the licentious character of some sonnets he wrote. Finally, in 1527, he went to Venice, where he gained powerful and influential friends, and there he spent most of his later life. Among his patrons were Francis I and Charles V, who made him rich gifts of jewelry and even allowed him pensions, all of which enabled him to live a luxurious life. Aretino's talents were most remarkable in the production of satirical verse, which he could make so biting that at one time he was feared by most of the public men of Italy. On the strength of this fear he worked to his own advantage, exercising a sort of blackmail over prominent personages. Aside from his poetry he wrote some comedies and one tragedy, the latter, 'Orazio,' showing a fair measure of talent. Of his comedies only 'Cortigiana' and 'Talanta' are of any merit. Consult Van Dyke, 'Renaissance Portraits' (New York 1905).

AREZZO, a-rèt'-sò, Italy, city and capital of a province of the same name in Tuscany. In ancient times it was known as Arretium, when it was one of the most prosperous cities of Italy. During the 3d and 4th centuries B.C. it was bitterly opposed to Rome, but on the occasion of Hannibal's invasion it supported the Romans. Later, when the Gauls began invading Italy it sought the support of the Romans. At that time it was famous for its pottery. It was the birthplace of a number of famous men, among them Petrarch, Leonardo Aretino, the historian, Cesalpino, the botanist, Pope Julius II and Vascari. It is still a city of some attractions, having broad, well-paved streets, a museum, a library, several convents and a cathedral built in the 13th century. It is surrounded by a fertile country producing grain, olives, wines and fruits. In the city are located a number of industrial plants in which are manufactured silk fabrics, leather goods and textiles. Pop. (1911) 48,170.

ARGALL, Sir Samuel, navigator and American colonial official: b. Walthamstow,

Essex, England, about 1580; d. 24 Jan. 1626. He was a type of the founders of English colonial dominion — energetic, resourceful and masterful; his further repute as a sort of unprincipled buccaneer and tyrant is due to sentiment and partisanship. In May 1609, he was sent with a small barque to the new settlement at Jamestown, Va., to trade and fish on behalf of the owner. He seems to have found a shorter route than usual, and soon established a reputation for unprecedentedly quick passages. The next year he took out Lord Delawarr to Jamestown, arriving just in time to prevent the entire colony, with the governor, Sir Thomas Dale, leaving for Newfoundland to avoid starvation. He was sent to the Bermudas for swine to replace those the colonists had eaten, but was driven by storms to Cape Cod where he found good fishing and returned in August; established a corn trade with the Indians above Jamestown, and early in 1611 returned to England with Delawarr, whose health was bad. In September 1621, he was again at Jamestown after the then swift passage of 51 days, and the rest of the year he and Dale spent in corn hunting among the Indians. Powhatan had a number of English prisoners in his hands and a quantity of weapons and implements, and Argall hearing that the chieftain's daughter Pocahontas was with her uncle "Powtownec" (Potomac), had the happy thought of securing her to exchange against them, a feat accomplished by threats and the offer of a copper kettle to her uncle. The stock denunciation of him for this "nefarious treachery" is best answered by the fact that no one was harmed, all parties were benefited and a most desirable aim was achieved. Pocahontas herself considered it a piece of rare good fortune, would not leave the whites and soon after married one of them, while the prisoners were released and peace restored to the colony. Argall handed her over to Sir Thomas Gates and explored the east shore of Chesapeake Bay, fishing and trading. Later in the year he was sent with a vessel of 14 guns to destroy the French settlements on the north coast, regarded as infringing on the Virginia patent. He captured Mount Desert, Saint Croix and Port Royal (N. S.), carried off the settlers as prisoners to Jamestown, and on the way forced the commandant at New Amsterdam to recognize English suzerainty by hauling down the Dutch flag and running up the English. In 1614 he sailed for England, and was put on his defense for these high-handed acts, but completely justified himself. In May 1617, he was made deputy governor of Virginia, and remained two years in a broil with part of the citizens, but justified by others. He was accused of illegal trade with the West Indies, and repeatedly ordered to return to England for trial, a command which he ignored for a time, possibly in reliance on the Earl of Warwick, who is supposed to have financed and shared his ventures. In 1620 he served against the Algerine pirates with a 24-gun merchant vessel, under Sir Robert Mansell. He was knighted in 1622. In 1625 he was admiral of a squadron cruising after a hostile Dunkirk fleet, and took some prizes. On 3 October of that year he embarked with the squadron in the expedition against Cadiz under Lord Wimbledon, with Lord Essex on board as vice-admiral and com-

mander of land forces; Argall's flagship was the *Swiftsure*. He reported the fortress too strong to be taken without a siege, the merchant vessels were ill supplied and unpaid, and after waiting till December for relief from Charles I they went home. Argall died the next month, it was said from a broken heart because the captain of the *Swiftsure* was "very backward and cross" to him. (Argall's own narrative comes down to 12 May 1613).

ARGAND, är'gän, Aimé, Swiss-Italian inventor: b. Geneva 1775; d. London, 24 Oct. 1803. He is principally known as the inventor of the lamp burner which still bears his name, though he was also a mathematician of some note. The idea of the burner, the steadying of the flame by a current of air coming up through a hollow centre, was stolen from him by a French pharmacist, Quinquet, when he, Argand, became involved in difficulties during the French Revolution. Brooding over this caused him to lose his reason. He was also the inventor of a pneumatic machine of some value. He wrote 'Découverte des lampes à courant d'air et à cylindre' (1785).

ARGELANDER, är'gë-län'dër, Friedrich Wilhelm August, German astronomer: b. Memel, Prussia, 22 March 1799; d. Bonn, 17 Feb. 1875. His first interests as a student at Königsberg were in economics, but after attending several lectures on astronomy by Bessel he decided to devote himself to astronomy. In 1820 he was made Bessel's assistant in the Königsberg Observatory; three years later he became astronomer at the observatory in Abo, Finland. It was here that he began those observations which later made him one of the most noted astronomers of his time, though later the destruction of the observatory by a fire compelled him to continue his work at Helsingfors. In 1837 he became professor of astronomy at Bonn. Argelander has added much to the knowledge of the progressive motion through space of the solar system. His chief work is the 'Atlas des nördlichen gestirnten Himmels' (Bonn 1857).

ARGENIS, a romance written in Latin by John Barclay, published in 1621. Like 'Gulliver's Travels,' it is really a commentary on current historical events, thinly veneered by its fictional form. But even as a piece of fiction it has some merits, for Cowper said of it that it was "the most amusing romance that was ever written." Fénelon's 'Télémaque' is said to have been suggested by it. Cardinal Richelieu also prized it very highly and is supposed to have been inspired in his diplomacy by its suggestive character. The characters in the romance represent Henry IV, Queen Elizabeth and Philip II of Spain.

ARGENSOLA, Bartolomé Leonardo de, Spanish poet: b. Barbastro, Aragon, 26 Aug. 1562; d. Saragossa, 26 Feb. 1631. Until 1610 he lived in Salamanca, when he accompanied the Count de Lemos to Naples (see ARGENSOLA, LUPERCIO), together with his brother. On the death of the latter, in 1613, he returned to Spain, where he succeeded to his brother's position as historiographer of Aragon. Here he took up his brother's unfinished work, a continuation of Zurita's 'Annals of Aragon.' The collected poems of the two brothers were published by Lupercio's son after their death,

under the title 'Rimas' (1634). The best modern edition of their works is that which was edited by the Count de la Viñaza and in the 'Colección de escritores castellanos' (1889). In this also is included two plays by Lupercio, 'Isabela' and 'Alejandra.'

ARGENSOLA, Lupercio Leonardo de, Spanish poet: b. Barbastro, Aragon, 14 Dec. 1559; d. Naples, March 1613. He and his younger brother, Bartolomé (q.v.), have sometimes been called the "Spanish Horaces." Both brothers enjoyed the special protection and favor of Maria, widow of Emperor Maximilian II of Austria. After having served her as secretary for some time, Lupercio was appointed official historian of Aragon by Philip III. In 1610 he accompanied the Spanish viceroy, Count de Lemos, to Naples, where he filled the position of State Secretary until his death three years later. Before leaving Spain he had written for the Count de Lemos, who was then president of the Indian Council, 'Conquista de las Islas Molucas' (1609). Consult Crawford, 'Notes on the Tragedies of Lupercio Leonardo de Argensola' (in the *Romanic Review*, Vol. IV, 1913).

ARGENSON, är'-zhän'-sôn', Marc Pierre de Voyer, COUNT D', French statesman, brother of René Louis de Voyer d'Argenson (q.v.): b. Paris, 16 Aug. 1696; d. there, 22 Aug. 1764. At the age of 24 he was lieutenant-general of the provincial gendarmerie. In 1742 he succeeded de Breteuil in the war office and after the death of Cardinal Fleury, in 1743, found himself supreme chief of the French war operations. To his energy and administrative ability is due in no small measure the final success of the French arms against the Austrians, who had threatened the very existence of the nation and had already invaded Alsace and Lorraine. After the favorable termination of the war, with the Treaty of Aix-la-Chapelle in 1748, Argenson continued his work in the war office with a general reorganization of the French armies, one of his reforms being the establishment of the Ecole Militaire in 1751. How he stood in the world of arts and letters may be judged from the fact that Voltaire wrote his 'Siècle de Louis XIV' largely from material supplied him by Argenson, and the famous 'Encyclopédie' was dedicated to him by its illustrious editors, Diderot and D'Alembert.

ARGENSON, Marc René, MARQUIS D', French statesman: b. Venice, Italy, 4 Nov. 1652; d. Paris, 8 May 1721. He was for some years chief of the Paris gendarmerie, but in 1718 was made Keeper of the Seal and, two years later, Minister of State. But the mad schemes for the financial regeneration of the treasury which John Law was then involving the king in caused Argenson soon to resign. He was a very generous patron of letters and arts and was made a member of the Academy.

ARGENSON, René Louis de Voyer, MARQUIS D', French writer: b. 18 Oct. 1694; d. 10 Jan. 1757. While Minister of Foreign Affairs under Louis XV, from 1744 to 1747, he foiled the intrigues of the Spanish Court in certain diplomatic negotiations of a delicate nature. But Spanish influence still remained strong enough in the French Court to cause his resignation, whereupon he retired to private life

and followed the life of a student and a man of letters. He was a close friend of Voltaire. His chief works are 'Considérations sur le gouvernement ancien et présent de la France' (1764); his 'Memoirs' (9 vols., 1861-67); 'La France au milieu du XVIII^e siècle' (1898). Consult Ogle, 'The Marquis d'Argenson' (1893).

ARGENTA, är-gen'ta, Ark., city in Pulaski County, on the Arkansas River, opposite Little Rock and on the Saint Louis Southwestern, the Saint Louis, Iron Mountain and Southern and the Chicago, Rock Island and Pacific railroads. It is in the centre of a fertile agricultural region producing corn and other grains. Natural gas is available and is utilized by a number of manufacturing plants, including extensive railroad repair shops, four cotton oil mills and a boiler and iron works. The municipality owns and operates its own electric lighting plant. Pop. (1910) 11,138.

ARGENTEUIL, är'zhän-té'y', France, a town on the right bank of the Seine, seven miles northwest of Paris in the department of Seine-et-Oise. It supplies much wine, fruit and vegetables for the Parisian market. Excellent asparagus is produced in the vicinity. Alcohol, files, pasteboard, and watches are manufactured. The famous Héloïse was abbess of its now ruined priory from 1120. This priory was founded by Charlemagne in the 7th century, and his daughter Theodada was its abbess. The town grew up about the priory. Pop. (1911) 24,282.

ARGENTINA, OR THE ARGENTINE REPUBLIC. A federal republic, the second largest of South America, situated in the southern extremity of South America, between the 22d and 55th parallels of south latitude and between the meridians of 54° 20' and 73° 30' of longitude west of Greenwich, the greater part of the territory thus lying within the temperate zone. It is bounded on the north by Bolivia, Paraguay and Brazil, on the east by Uruguay and on the west by Chile. Its eastern boundary is composed entirely of maritime or fluvial coasts, in direct contact with the world's commerce by means of numerous ports of easy access. Its area is 1,153,119 square miles. The history and political and industrial development of Argentina are treated under the following headings:

- | | |

1. PHYSIOGRAPHY. 1. A notable characteristic is found in the Pampas which cover more than three-fourths of the country. The plains, however, can be further divided into four great sections: (1) The Chaco plains, between the rivers Pilcomayo, Paraná, and Salado del Norte, comprising the eastern portion of Jujuy, Salta, and Tucuman, the territory of the Chaco, part of the province of Santiago del Estero and the north of Santa Fé; all of it being warm, thickly wooded and rich in excellent timber. Here preference is given to the cultivation of sugar-cane, cotton-growing and

quebracho-cutting. (2) The pampas properly so called, most notable on account of the uniformity of level and the almost total absence of trees, but covered by excellent pastures in which gramineous grasses preponderate. This region is gradually being devoted to agricultural purposes such as the cultivation of wheat, linseed and corn, after having first served for cattle-feeding. (3) Between the last two regions the saline plains extend from the range of Aconquija to that of Córdoba and reach to the Salado River. This region derives its name from the great amount of salt covering the soil. (4) The southern plains, south of the 38th parallel, and popularly known as Patagonia, comprise the territories of Rio Negro, Chubut, Santa Cruz and Tierra del Fuego, sloping down from the Andes in three successive inclines. "Stock farming, especially sheep farming, dominates in this field, yielding large profits," says Mr. Marrion Wilcox, an American expert on Latin-American countries, adding: "New port works, extension of the sheep industry, plans for rendering navigable the Patagonian rivers, the production of minerals in the Cordillera and the Far South—all these forms of activity show that in a commercial sense Patagonia is to be regarded as a land of the future." (In *Bulletin of the American Geographical Society*, Vol. XLII, No. 12, pp. 903, seq.).

II. The Argentine Mesopotamia lies between the rivers Paraná and Uruguay and comprises the provinces of Entre Rios and Corrientes and the national territory of Misiones. At its southern extremity the rich alluvial soil covering the numberless islands forming the delta of the Paraná River has helped the development of a luxuriant vegetation. Toward the north a network of streams intersect an undulating land where tree-clad hill slopes alternate with rich meadows. At Corrientes the soil is damp and marshy but rises again in Misiones, where it becomes hilly.

III. The mountains belong to four separate systems, of which the most important is the Andean system. The coasts are 1,500 miles in length and are generally low and sandy from Buenos Aires to Rio Negro. South of this point they are higher, often rising in bluffs and cliffs forming innumerable gulfs and bays. In the Plata estuary the most interesting island is Martin Garcia, which commands the mouth of the rivers Paraná and Uruguay. About 400 miles off the shores of Santa Cruz are the Malvinas Islands, which the Argentine government claims as part of its territory although England has occupied them since 1833, having named them Falkland Islands.

Tierra del Fuego is also an island, belonging half to Argentina and half to Chile. Staten Island, separated from Tierra del Fuego by the Lemair Strait, is used as a place of deportation for criminals. There are several other islands of lesser importance.

Omitting all minor differences, the Argentine Republic may be divided into three great sections: the central plains, the river region on the eastern side, and the mountain systems.

The Cordillera of the Andes which runs throughout the whole extent of the Argentine Republic and forms its western limit is the most important mountain system of the country. Commencing at the extreme south of the

republic in the shape of low ranges of hills, isolated by the waters of the Pacific which, in addition, have invaded its valleys, forming an immense number of picturesque channels, it little by little became of greater height and breadth until it forms in the north the elevated tablelands of Atacama and Jujuy, with a mean height of 13,000 feet above sea-level. The abundant vegetation which covers its lower slopes in the south disappears on passing beyond the 37° of latitude, and in the same manner the snow, in the north, has only a permanent character on the summits of the most elevated peaks, such as the Aconcagua, Mercedario, Tupungato, and Juenal. Another interesting feature of the southern part of the Cordillera is the existence of deep gullies which run through it and allow the passage of important rivers formed by the waters of the eastern slopes, which otherwise would have found an outlet toward the Atlantic Ocean. Besides the Andean system there is a central system formed by three parallel ranges known by the general name of Córdoba and San Luis ranges; the Buenos Aires system formed by two isolated ranges and the Misiones system formed by the western extremity of two mountain ranges entering the Argentine territory from Brazil and forming a letter Y by their joining together.

In regard to the hydrographic system of the country, we may divide it into four systems: the system formed by the rivers within the Plata basin; the central system, the Patagonian system formed by the basins of the rivers flowing from the eastern slope of the Andes, and lastly, the system of the province of Buenos Aires.

The basin of the Plata, which includes most of the territory of Argentina and part of those of Brazil, Uruguay and Paraguay, is drained by the river Plata, justly considered as the entrance gate to South America; the rivers Uruguay and Paraná which debouch into the Plata after a course of 900 miles in the first case and of 2,000 in the second; the river Paraguay, which forms the axis of the system and joins the Paraná at 1,200 miles from its source; the Pilcomayo and Bermejo rivers which rise in Bolivia and fall into the Paraguay after having crossed the territory of the Chaco; the Salado del Norte River which runs through the provinces of Santiago del Estero and Santa Fé to discharge into the Paraná near the city of Santa Fé; the river Carcarañá, another affluent of the Paraná formed by the union of the Tercero and Cuarto rivers which have their sources in the Córdoba range; and in addition other rivers of less importance, all of which rise in the province of Buenos Aires and are affluents of the river Paraná and the river Plata.

Mr. E. L. Corthell, an American engineer, says that "the Paraná has a larger discharge than the Mississippi; its annual flow is double that of the Ganges, three times that of the Saint Lawrence, four times that of the Danube and five times that of the Nile. There are records of 608 cubic miles in one year." The Paraná River is one of South America's great waterways. Transatlantic steamers of 10,000 tons drawing 23 feet can enter the river up to Rosario, 240 miles from Buenos Aires. Those of 6,000 tons can reach the ports of Paraná and

Colastiné. Specially constructed vessels can go farther, to Corrientes, 640 miles above Buenos Aires. At Corrientes the Paraguay River flows into the Paraná which at this point makes a sharp turn toward the south. From the point of view of navigation the Paraguay River is a natural continuance of the Paraná. Steamers drawing 13 feet ply from Buenos Aires or Corrientes to Asunción, on the Paraguay River, during nine months of the year.

The upper Paraná, from Corrientes toward the east, is navigable by large boats only to the falls of Apipé, 145 miles above Corrientes. But smaller steamers ply regularly beyond Apipé up to Posadas and still smaller craft up to near Iguazú Falls, on the boundary line between Argentina, Paraguay and Brazil.

The river Uruguay is navigable by large steamers up to Concordia which is an important agricultural and commercial centre. But during the floods the river is everywhere navigable. These floods are quite sudden but not long continued. The floods of the Paraná are much longer continued, because its source is in the tropical and rainy regions of Brazil and it receives also, through the Paraguay, the waters from the flanks of the Andes. At the confluence of the latter river with the Paraná at Corrientes, the rise of the floods is about 33 feet; at Rosario it is from 19.7 to 23.5 feet.

Of the other rivers belonging naturally to the Plata system, such as the Pilcomayo, the Bermejo and the Salado, none at present is of economic importance. Further south the Paraná River receives the Carcarañá, formed by the confluence of the Tercero and Cuarto rivers which drain the southeastern part of Córdoba. These rivers are used for irrigation purposes and the Argentine government has entered into an extensive program of irrigation works contemplating the reclamation of large tracts of land along the valleys of these rivers and also of the Quinto, which more properly belongs to the central system.

The central hydrographic basin is formed by a vast depression that in its lowest part is occupied by the lakes of Porongos and Mar Chiquita into which several rivers such as the Dulce and the Primero and Segundo fall. Irrigation works in these rivers have been going forward on a large scale. The Rio Primero dam holds 260,000,000 cubic metres and the Segundo River dam 350,000,000 cubic metres.

The hydrographic basin of the Colorado River commences in the north of Rioja with several rivers which, after forming the Bermejo, are lost in the lagunes of Huanacache, together with the rivers San Juan and Mendoza; and in succession to these we have the streams that run from north to south, which join the waters with the Desaguadero or, as we may call it, the channel for the discharge of the lakes of Huanacache, and this conjunction flows on toward the south under the names of Salado, Chadileuvú, and Curico until it falls into the Colorado, having on its course southward formed many lakes and marshes; and lastly the Grande and Barrancas that in combination form the Colorado River, which having traversed the pampas from east to west debouches into the Atlantic Ocean a little to the south of the estuary of Bahía Blanca.

Most of these rivers are used for irrigating the grape and fruit districts of Mendoza and

San Juan, as well as the pasture lands of San Luis.

The basin of the Rio Negro is also of great importance, being formed by the streams which flow down from the Cordillera of the Andes between 37° and 41° south latitude. This basin, like all the others that are found further south, has the peculiarity of encircling within it a large number of lakes which, while constituting one of the principal attractions of the Cordillera of the Andes, have a beneficial influence on the regulation of the waters. There are several other lakes whose natural drainage is the river Limay which, together with the Neuquén, forms the Rio Negro, the mouth of the main river on the Atlantic being a little to the south of the Rio Colorado. The island of Choel-Choel, renowned for its great fertility, is about midway between the confluence of the Limay and Neuquén and the sea, but nearer to the former.

Extensive irrigation works are being completed at Negro River, with the purpose of irrigating the barren pampas stretching between that river and the Colorado, as well as the lands south of the Negro. The Patagonian rivers are also navigable to a certain extent. Flat boats have to be used, however.

The drainage of the remaining lakes of the Cordillera is effected by means of the river Senguier, an affluent of the Chubut; the beautiful lakes of Buenos Aires and San Martín, whose waters make their way through the Cordillera of the Andes to fall into the Pacific in the same manner as do those of the lake Lacar and many others farther north; the Argentine and Viedma lakes whose drainage forms the river Santa Cruz, one of the most important in Patagonia, which, with the Deseado and the Gallegos, completes the hydrographic system of this region.

The most important rivers of the province of Buenos Aires are the Salado del Sur, whose valley is considered as being only a continuation of that of the Rio Quinto, which flows down from the "Sierras" of San Luis. This river gives rise to important lagunes and receives, before falling into the bay of San Borombón, the superfluity of waters of many others.

The remaining rivers of that province which debouch directly into the ocean are the San Borombón, Quequén Grande, Quequén Salado, Napostá, Sauce Grande and Sauce Chico.

As regards the Argentine Mesopotamia, it is, on account of the impermeability of its soil, a region traversed by numerous rivers and streams which flow into the Paraná and Uruguay. The province of Corrientes, in particular, contains the immense lagunes of Iberá and Maloya, up to the present almost unexplored.

To conclude this hydrographic sketch of the republic we may call attention to the existence of a certain number of depressions, occupied by salt lakes and deposits of salt, that constitute so many additional basins into which there flow streams of brackish water, which, on evaporation, deposit the salt they held in solution, forming real natural salt pans, some of them being worked to supply the requirements of the inhabitants of the interior. In the high tablelands of Atacama and Jujuy are other deposits which are doubly interesting on account of the deposits of borax which they contain. There are, also, distributed throughout the whole

Andine region, numerous water-courses, which are taken advantage of near their sources for the irrigation of the soil but which, their course being through immense zones of permeable land, are quickly lost in the subsoil. Among these we may mention, as examples, the rivers Tala, the Valle, and the Paclín, which give life to the beautiful valley of Catamarca, and to the city of that name. Irrigation works are also prominent in some of these rivers.

Climate.—Almost any desired climate, from tropical to frigid, may be had in a country that extends through more than 34 degrees of latitude, or more than 2,300 miles, from latitude 22° to 56° south, and is in places 800 miles wide. Conditions vary widely in the same latitude. Rainfall diminishes from the east to the west until the very base of the Andes is reached. Temperature is highest in the central part of the country, falling rapidly in the Andean region to a point many degrees below the temperature of localities due east. Temperature also diminishes toward the south.

In the northern part of Argentina the transition from the rainy to the dry season is very marked. A four-season climate prevails in Corrientes, Entre Rios, Santa Fé, Córdoba, Buenos Aires, Mendoza, San Luis and the remaining country lying south. However, there is always a prevalence of rains from October to April. In the provinces of Corrientes, Salta, Jujuy, Catamarca and Santiago del Estero and the territories of Chaco, Formosa, Andes and Misiones, climatic conditions are those of sub-tropical countries. In Buenos Aires, Santa Fé, Entre Rios, La Rioja, San Juan and San Luis, south of Corrientes, Santiago and Catamarca and territories of La Pampa Neuquén and Rio Negro, the climate is temperate. In Santa Cruz, Tierra del Fuego and Chubut, the climate is cold but not so severe as to prevent these southeastern regions from being habitable.

The highest recorded temperature, 120°, was during the hot wave of February 1900, in the province of Catamarca at the extreme north, and the lowest recorded temperature was 3°, in the southern extremity of the continent, a range of 117° of temperature in 33 degrees of latitude. The Argentine weather bureau states, however, that lower temperatures are probably experienced in the interior of the territory of Santa Cruz. In the northern part of the Litoral the ordinary range of temperature is from 41° to 106° and in the southern section of the Litoral the usual limits are from 32° to 102°. This is the territory in which most of the corn is raised, and the summer temperature averages from 72° to 77° and is rarely above 96°.

The meteorological system of Argentina consists of 200 meteorological and 1,600 rain-gauge stations. Besides, the Argentine Weather Service receives information from 12 Brazilian, 10 Chilean and six Uruguayan stations. The Argentine weather map issued daily shows conditions reigning from Pará (Brazil) to the southernmost limit of the continent. At the South Orkney station (lat. 61° S.) there is a fully equipped meteorological and magnetic station. The hydrometric service has established nearly 150 river gauges and information is published in the daily weather map as to the depth of the water at the principal ports and shallow passes of the navigable rivers as well

as timely warnings of the approach of the freshets in the rivers. The magnetic service is well equipped for the observation of the solar spots and spectroscopic observations, atmospheric electricity, kite work and the preparation of the isogonic chart of the country.

Geology.—In the Tertiary period the uplifting of the Cordilleras and of the Andes was effected, and the leveling of the Pampas, giving to the country the physical aspect of to-day. The Pampean system is characterized by the abundance of deposits of an argillaceous sand of great fineness, of gray color peculiar to deposits of sand and clay or alumina, the first of which encompasses the slopes of the Sierras, while the second is found along the margin of the Plata. The Pampean system is characterized, moreover, by an abundant and marvelous fauna of fossil mammals.

The works of Florentino Ameghino, who collected hundreds of fossil specimens on the banks of Patagonian rivers, will help in clearing up many points related to the origin and distribution of mammals, man included. The fact that most of the fossils appear in formations older than those in which the same species are to be found in the northern hemisphere is leading some palæontologists to assign man an antiquity not hitherto suspected. In this connection the finding in 1914 by a commission from the Buenos Aires Museum of Natural History of an arrowhead—evidently the work of man—embedded in a bone of *Toxodon* remains one of the most sensational palæontological discoveries of the age. To comprehend the abundance of fossil mammals in Pampean soil it is necessary to remember that in the Cretaceous epoch the southern hemisphere contained relatively more land than water; while in the northern hemisphere the contrary condition existed. This naturally greatly favored the deposit of a varied fauna of mammalia.

The Cretaceous epoch is represented in Argentina by the Chubutian and Guaranitic formations, which belong respectively to the lower and upper Cretaceous. The former extends over the territory of Chubut, occupying the most central part, and is characterized by a very hard sand of very marked color. Both land and marine fossils are found in it. The latter formation is found in Corrientes and Misiones, reappearing in the Rio Negro and also in Chubut, resting upon the former.

The period of the Tertiary epoch is represented along the coast of Patagonia and sea-shore region from Puerto Madryn to the bottom of the Gulf of Nuevo, as far as the mouth of the Santa Cruz River, where it disappears under the Atlantic. The fossils are marine on the coast, and land toward the west. To the south of Patagonia, between the rivers Chico and Gallegos, there extend other formations of the same period.

The Oligocene period is represented by a succession of layers principally of marine origin, which appear in the province of Entre Rios along the whole length of the Paraná River. The same layers reappear farther south at the mouth of the river Negro and extend along the Patagonian coast as far as the Gulf of Nuevo.

Remains of the Miocene period cover the central and southwestern Pampas, as well as

a portion of Catamarca and Tucumán. To this period belongs the immense quantity of rounded gravel which covers the whole surface of Patagonia from the river Negro to the south.

Of the Pliocene period may be found representations in the Pampean formation, or in the great deposit of lime and reddish gray clay which covers the province of Buenos Aires.

Representations of the Quaternary and recent epochs are met with in isolated deposits throughout the length of the republic.

Flora.—According to Professors Holmberg, Spégazzini, and Gallardo, the Argentine flora represents almost one-tenth of the flora of the world. Professor Stuckert claims to have studied and classified as many as 8,000 phanerogamous and vascular cryptogamous plants. The number of known plants among the cryptogamous alone is calculated at 3,000 species. Only a fourth of the phanerogamous and less than a tenth of the cryptogamous plants have been classified. The microscopic flora is almost entirely unknown. The province of Buenos Aires is almost devoid of trees; the only part where they are found is along the coast, but they are small and consist principally of mimosæ, which make excellent fuel. Calden is to be found in the west. In part of Santa Fé, the Chaco, Santiago del Estero, Entre Rios, Corrientes, Misiones, Tucumán, etc., there are immense forests of the finest and most useful classes of trees, from the easily worked cedar to the quebraco (axe breaker) used for railway sleepers, flandubay for fencing posts, lapacho, algarroba and numerous varieties of wood for shipbuilding and furniture. The ombú is useless as timber, and is not even suitable for firewood, but is valued for its shade, while the ceibo bears an extremely beautiful flower of a deep crimson color.

Fauna.—Very few species of animals pertain exclusively to Argentina. Among the mammals are recognized two, the vizcachá, which is not found outside of the Pampas, and the hare of Patagonia. Among birds may be numbered two species characteristic of Argentina; the marineta, a bird of the heron family, and the gallito, or small cock, which also live on the Pampas, but farther south than the two species first named. Most of the animal species which live in Argentina are met beyond the frontiers of the country in Brazil, in Bolivia and in Chile. Some of these are also common to the Antilles and to North America.

There is a great variety and diversity in the fauna, according to the region studied, since the animals of the east or of the north differ considerably from those of the west and the south. Dr. Lahille has divided southern South America into three regions: (1) The Andean, which comprises the whole of Chile, all of Patagonia and the greater part of the Andean provinces; (2) the central region, formed by the basin of the Paraná River; (3) the Brazilian, which comprises the territories of Misiones, a part of the province of Corrientes, and also the northern part of the republic of Uruguay. In the eastern zone of Argentina live the animals that have emigrated from the tablelands of Brazil.

The wild animals are numerous, being the jaguar (tiger), puma (leon) and various kinds of wild cats, the aguara-guazu (fox of Paraguay), an animal of a reddish color with a

black stripe along the back; gray and red foxes, various kinds of weasels, otters, skunks or polecats, nutria, a rodent which is called an otter but is *Myopotamis Copyus*, having a tail like a rat; seals, opossums, raccoons, vicuña, huanaco, elamas and alpacas, the last two said to be the domesticated varieties of the preceding two, various kinds of deer varying in size from that of the red deer of Europe down to 18 inches in height; armadillos of four varieties, the wild guinea pig, the pampa hare, which is not a hare but *Dolichotis Patagonica*, and several monkeys, carpincho or water hog, vizcacha or prairie dog, tapir, peccari, ant-eaters. The vizcacha was some years ago very numerous, but is not now to be found on the inside camps, that is land that has been stocked for many years, as a war of extermination was waged against them some 25 or 30 years back. Birds are also numerous, the more notable being the vultures, hawks, ostrich (rhea or fiandu), eagles, owls, parrots, woodpeckers, ovenbuilders, humming birds, ibis, flamingo, spoonbill, swallows, pigeons, doves, egrets, storks, wood turkeys, partridges of various kinds, snipe, plovers, ducks, swan, geese, gulls, bustard and in the far south the penguin and other sea birds. The house sparrow was introduced some years ago and has now become a thorough nuisance, as are also the descendants of imported hares in Santa Fé and the north of Buenos Aires.

The best fish are the pejerrey (a kind of trout), dorado (something like salmon but of a golden color), corvina, palometa, pacú, anchoa (a large fish not a bit like an anchovy), flatfish, zurubi, an immense yellow and black spotted catfish. The only fish we know that will take the artificial fly are the pejerrey, dorado and the mojarra, a small fish very like a sardine. Alligators are still to be found in the upper Paraná and Paraguay; iguanas are to be found in the northern provinces and lizards throughout the country.

Snakes are numerous but the only dangerous ones are the rattlesnake and the vibora de la cruz; possibly some of the large water boas may be so, but no instance has been reported of man being attacked by them.

Some years ago it was successfully demonstrated that oysters could be brought from the favored localities of the United States and placed in the bays of the Atlantic coast of this republic and there multiply, grow and fatten.

ERNESTO NELSON,

Director-General of Secondary, Commercial and Industrial Education of the Argentine Republic.

2. POLITICAL DIVISIONS, POPULATION AND IMMIGRATION.

The Argentine Republic consists of 14 provinces, 10 territories and a federal district. These, with their areas and populations, are as follows:

PROVINCES	Area (in square miles)	Population
Buenos Aires (Federal District)...	72	1,594,170
Buenos Aires.....	117,777	2,155,118
Santa Fé.....	50,713	922,406
Córdoba.....	66,912	598,545
Entre Ríos.....	29,241	423,100
Corrientes.....	33,545	365,434
San Luis.....	29,035	126,895
Santiago del Fuego.....	10,422	247,004
Tucumán.....	55,385	348,582
Mendoza.....	56,502	296,553
San Juan.....	37,865	130,412
La Rioja.....	37,839	104,550
Catamarca.....	36,800	112,995
Salta.....	48,302	161,150
Jujuy.....	14,802	73,062
TERRITORIES		
Misiones.....	11,511	52,603
Formosa.....	41,402	27,902
Chaco.....	52,741	49,500
Pampa Central.....	56,320	98,841
Neuquén.....	40,530	30,085
Rio Negro.....	79,805	37,302
Chubut.....	93,427	23,143
Santa Cruz.....	109,142	8,630
Tierra del Fuego.....	8,299	2,420
Los Andes.....	34,740	2,552
Total.....	1,153,119	7,979,259

The returns of the 1914 census, published in September 1916, gave 7,885,237 inhabitants as the total population on 1 June 1914. The 'Argentine Year Book,' 1915-16, gives, as the estimated population for 1915 (a calculation by the National Statistical Office), 7,979,259. The estimates 9,000,000 or 10,000,000 frequently given appear to be based upon the growth of cities, with which the rural population does not keep pace. The urban population, constituting 42.8 per cent of the total population of Argentina in 1895, increases from year to year out of all proportion to the rural; and the movement toward the cities, especially Buenos Aires, has been marked in the decade 1908-17.

Of the total population of the republic about 2,000,000 are foreigners, or more than 25 per cent as against 10 per cent in the rest of South America and 13 per cent in the United States. About one-fifth of the entire population of the country is in the capital city, of which about 40 per cent are foreigners. This shows that an undue proportion of immigrants remains in Buenos Aires, while the sparsely settled country districts have received a minority of them. To counteract this tendency the Immigration Bureau now offers free lodging during 10 days in the agricultural centres to all those immigrants willing to go there. Transportation to those districts is also free to the immigrant, his family and baggage.

Only second and third class passengers are considered immigrants by Argentine law. Immigration regulations are very strict regarding health of immigrants and the hygienic and safe conditions of steamers carrying them. On their arrival at Buenos Aires immigrants are provided with board and lodging, valid for five

days, which term may be renewed in case of sickness. The Immigrants' Hotel is a model establishment offering accommodations for 1,000 persons at a time. Dormitory buildings, dining hall, lecture-rooms, lavatories and hot and cold baths and swimming pools are the chief features. There are also immigrants' hotels at Rosario and Bahía Blanca. The National Labor Bureaus use every means to find a situation for the immigrant in the art, craft or industry in which he wishes to apply himself. Since the country was opened to immigrants in 1854 about 4,750,000 immigrants have entered Argentina, of which number 30 per cent have returned to their native land. In 1913, the year before the European War, 302,047 immigrants entered Argentina. The immigrants have come in great numbers from Italy and Spain, and lately from Russia and the Balkans. The immigrants can acquire rich government land without being subjected to nationalization. Provision is also made for the supply of the necessary funds to furnish the colonist with implements and other equipment to enable him to begin work immediately.

One of the drawbacks the country has had to contend with is that the feudal land system instituted by Spain was continued under the republic. The conquered land in the provinces was already mostly held in private estates. The remnant was won by degrees from the Indians. After conquering from them the rich lands of southern Argentina in 1885, land was sold off in blocks with a square league (6,250 acres) as a unit at a nominal price. The army received a vast grant of these lands in payment of the work accomplished. All these tended to create vast latifundia which, fortunately, are being gradually broken up. From 1905 to 1915 the number of holdings of less than 12,000 acres has increased in the proportion of 100 to 171, while the number of big holdings of 12,000 acres upward has diminished in the proportion of 100 to 56.

3. HISTORY. Exploration Period.—

Spain, not being satisfied with the discoveries and conquests which she had effected in America, was made ambitious by her rival, Portugal,

regarding the known riches of the Molucca Islands, in the Malay Archipelago. To possess herself of these she looked for a channel between the Atlantic and Pacific oceans traversing the new continent, and the mission of finding this was entrusted to the most able mariner of the day, Capt. Juan de Solís, who in 1515 A.D., navigating with two boats along the coast of America, arrived at 35° S. latitude. He proceeded along what is now known as the river Plata (Rio de la Plata) until he reached the mouth of the Uruguay River, and anchored his vessels there, in front of a little island which he named Martín García, in honor of the second commander of the expedition.

Solís and some of his companions went to the eastern bank of the river, but they had hardly disembarked when they were killed by the Charrúa Indians. Deprived of their leader the company did not venture to begin the exploration of the newly-discovered country, and returned to Spain. This dismal failure disheartened the Spanish government until 15 years later, when the discovery of Brazil and the conquests of the Portuguese revived the ambition of Spain. In 1526 the Spanish government sent nearly simultaneously two expeditions to the south, one under the command of Diego García, with the intention of stopping the advance of the Portuguese, and the other in charge of the English captain Sebastian Cabot, with the object of finding an interoceanic passage. The lack of provisions and a mutiny among the sailors prevented Cabot from carrying out his designs, and unfortunately while navigating in the river discovered by Solís, and following the Uruguay River, the detachment that disembarked to explore the region had no better fate than that of Solís and perished at the hands of the Charrúas. Cabot therefore changed his route and discovered the mouth of the Paraná. Here he established in the delta the first European port in the region of the Rio de la Plata, the fort Espíritu Santo. Ascending the Paraná to its junction with the Paraguay, Cabot began trading with various tribes of Indians, whom he found using many silver ornaments and utensils. This excited the cupidity of the explorer, who, thinking he had discovered a region of silver mines, named the estuary then known as Rio de Solís the Rio de la Plata, or Silver River.

By chance the expedition of Diego García, which, as previously stated, had been sent out to stop the advance of the Portuguese, arrived at the mouth of the river Plata. Quarrels broke out between the two commanders which obliged Diego García to return to Spain, and fearing the decision of the government at Madrid would be unfavorable to himself, Cabot returned to Europe, leaving large supplies in the fort Espíritu Santo, which was soon assaulted in an unexpected way and burned to the ground by the Timbu Indians, who up to this time had maintained friendly relations with the Spaniards.

These early discoveries in the Rio de la Plata led to a great deal of jealousy and desire for territorial expansion on the part of European monarchs. Carlos V, King of Spain and Emperor of Austria, who was at war with Francis I of France, not being able to disband his army nor to give much attention to the conquest of America, decided to send out explor-

ing parties to annex definitely the territory of the river Plata. A rich Spanish noble, Don Pedro de Mendoza, arranged with his government to equip at his own cost an expedition, on condition that he was to be named governor over all the territories which he discovered or conquered. The Mendoza expedition consisted of a fleet of 14 vessels and about 2,000 men, many of whom were Germans. This force entered the river Plata 20 Feb. 1535, and landed on the spot where now stands the capital of the Argentine Republic. There a town site was chosen, Mendoza giving it the name of Santa Maria de Buenos Aires, which means Saint Mary of the Good Breezes. Subsequently the little town was destroyed by the Querandí Indians who inhabited the region. The expedition escaped to the Espíritu Santo fort, leaving seven horses and five mares, the first herd of horses in Argentina. From Espíritu Santo Mendoza sent his principal lieutenant, Don Juan de Ayolas, to explore the Paraná River. After numerous fights with the various Indian tribes Ayolas occupied the land and founded the town of Asunción in 1537. He intended later to penetrate as far as Lima in Peru. Mendoza, sick and discouraged, started to return to Spain, but died on the way. Ayolas succeeded him in command of the Spaniards on the Plata.

From Asunción, Ayolas went on an expedition to Peru, and upon his return was killed by the Indians. This expedition brought from Peru some ewes which had been imported from Spain via Panama. These ewes constituted the nucleus of the Argentine flocks. Several years before this seven cows and one bull, the first cattle in the river Plata territory, had arrived at Asunción.

All the people who did not care to follow Ayolas on his unfortunate expedition across the unknown continent remained in Asunción. Among them were many Germans and some French, Belgians, and Italians. They elected Domingo Martínez de Irala as governor, and formed the first autonomic government of South America, organizing the first colony and entering into friendly relations with the neighboring tribes of Indians.

The polygamous condition of these tribes made easy the multiplication of the colonials, thus originating the half-breed type, who in their turn joining with the Europeans gave the racial character of the new population of the region. D'Orbigny thus describes the Mestizo, or mixed blend of people: "The mixture of the Spaniards with the Guaranies produces men of large form, nearly white, and having beautiful faces even from the first generation; large eyes, clear complexion, and nose generally like the Spaniards. As a rule they have scanty beards until the third generation, when it becomes as thick as the white man's."

During the second half of the 16th century, while they were founding and organizing the governments of Paraguay and Rio de la Plata, other expeditions leaving Peru by land explored and settled the interior territory of the Plata. In this way were founded the cities of Estero, Tucumán, Córdoba, Salta, Rioja and Jujuy. Other conquerors, coming from the general headquarters in Chile, took possession of the Cuyo region and founded the cities of San Juan, Mendoza and San Luis.

The inefficiency of the military conquest of

the Indians and their continued insubordination decided the government at Asunción to try to bring them into submission through the medium of church missions, which they commissioned the Jesuit Fathers, already established in Peru, to undertake. The missionaries founded their schools in Salta, Córdoba, and Santa Fé. Others went to unexplored sections and established missions with the most perfect theocratic government among the Guaranies.

The government of Spain, after the death of Irala, sent out Don Juan de Garay as governor of Paraguay. Needing a fortified position nearer to the ocean, Garay descended from Asunción resolved to reconquer the site occupied by Mendoza in 1536, and succeeded in re-establishing, 11 June 1580, the abandoned colony of Buenos Aires. Plans were made for the laying out of the town which the Indians again tried to destroy. The first inhabitants of Buenos Aires were 19 Spanish and 50 Creoles. With the founding of Buenos Aires the period of conquest in the region now comprising the Argentine Republic may be said to have finally closed, to be followed by the colonial régime.

The desire to secure communication between Buenos Aires and Asunción necessitated the foundation of various forts and colonies along the Paraná River in the region which to-day constitutes the provinces of Santa Fé, Entre Rios, and Corrientes.

During this time the Portuguese were advancing their explorations south along the Atlantic coast, arriving at the left margin of the Rio de la Plata. This alarmed the Spanish government, which, being powerless to quell the internal anarchy of the colonies while in the midst of the fight with rebellious tribes of Indians, separated Buenos Aires from the government of Paraguay, instituting the province of Rio de la Plata dependent on the viceroy of Peru, and named for governor-general Bruno de Zabala, who, in 1726, founded the city of Montevideo, now the capital of the republic of Uruguay.

The Spanish government did not permit commercial importation through the port of Buenos Aires and the colonists of this region were obliged to resort to troublesome trans-continental traffic to reach Lima, the capital of the viceroyalty, the only market of importation which they could count on. But as Paraguay received direct importations in freight boats for the official agents of the Spanish government, and the traffic necessarily had to pass near to Buenos Aires, the inhabitants of this city devised methods to organize a trade with Cadiz, from which place there were secretly sent to Buenos Aires books that the Spanish government did not permit to circulate even in Spain, which contained comments on the American Revolution and philosophical writings such as preceded the French Revolution. One can understand that these books found eager readers, since the cultured class of Buenos Aires had been recruited from liberals, who, fleeing from persecution in Spain, preferred as a refuge the modest city on the banks of the Rio de la Plata to the brilliant capital of Peru, centre of military and ecclesiastical prestige and head of an aristocracy formed from descendants of successful adventurers. The liberal ideas of this class separated them somewhat from the theocratic and military influence

which ruled the interior, but during the next two centuries Buenos Aires received only such liberal literature as could be smuggled from Europe.

Colonial Period.—In the middle of the 18th century Spain was engaged in war with Portugal, which, allied with England, sent a fleet to the Rio de la Plata and took possession of a small port on the left bank of Buenos Aires. The government sent forces which repelled the invasion and, in view of the fact that the river la Plata required more safeguards, reorganized the colonial administration, constituting the viceroyalty of Buenos Aires with its jurisdiction in the territories now occupied by the republics of Uruguay, Paraguay, Bolivia and Argentina, and opening in 1776 the ports of the river Plata to importation.

The first viceroy, Zeballos, explored part of the coast of Patagonia. His successor, Juan José de Vertiz, a Mexican of excellent antecedents, dedicated himself to the advancement of the city of Buenos Aires, using for this object the property confiscated from the Jesuits by Carlos III. Buenos Aires at that time, 1778, contained 22,000 white inhabitants, of whom 15,000 were European Spaniards. The total population of the country was 300,000, of whom 10 per cent were negroes or mulattoes. The buildings were almost exclusively of unbaked bricks, roofed with straw. The increase of the horses, abandoned by Mendoza, that had scattered themselves through the pampas, had modified the traits of the Indians of the region, who, becoming horsemen, fled from the harsh treatment of their conquerors.

The facility with which a colonist could make himself a large landed proprietor, and the impossibility of inducing the natives to work, promoted the importation of negroes as slaves, and in 1715 the government had conceded to an English company the monopoly of importing 1,200 negroes a year, which concession, however, was abolished in 1728, although the importation continued in a very light proportion till the beginning of the 19th century.

At this time it was the custom of the wealthy class in these colonies to send their studious young men to complete their education in the schools and colleges of Europe. The unliberal spirit which ruled in the University of Córdoba in the centre of the country did not attract the young men of Buenos Aires.

In 1806 an English expedition, returning from the conquest of the Boer colonies at Cape Town, South Africa, crossed the Atlantic and invaded Buenos Aires. The viceroy, Sobremonte, fled to the interior of the country, leaving the defense of the city to the Spanish residents and natives. The English assault was repelled, all being made prisoners, although taking advantage of the confusion, the invaders seized \$1,500,000, which was in the fiscal treasury and which they sent to England. This produced an extraordinary effect in London in regard to the riches of the Rio de la Plata region and induced the English government to send another and better equipped expedition, consisting of 60 boats and 12,000 men, to take possession of Buenos Aires. This second attempt, however, had no better success than the first and many English prisoners remained in the country where they eventually intermar-

ried with the natives. The authorities and the Spanish residents accused the masses of sympathy with the invaders; nevertheless the English were freed and received by the first families, thus helping to constitute the liberal element which was later to have the direction of the revolution of independence.

The Republic.—The government of Spain, alarmed at the projects of Napoleon, could not extricate itself from warring elements and had refused to send aid for the defense of the river Plata. The citizens of Buenos Aires, proud of their triumphs and dissatisfied with the viceroy, Sobremonte, deposed him and named as his successor Liniers, a French captain who had helped them in the first defense against the English; but the Spanish government denounced this act and appointed as viceroy a Spanish marshal, Cisneros. At this time, because of Napoleon's domination over Spain, the authority of the Spanish viceroy was not recognized and fresh germs of independence were sown. With this impetus some of the patriots met and announced a government Junta. This assembly took place 25 May 1810, the date which the Argentine Republic celebrates as its birthday. This congress invited all the authorities of the viceroyalty to join the movement, and founded a periodical of revolutionary tendencies called *The Buenos Aires Gazette*; for it was evident that the power of Spain could only be broken by united effort of the patriots who were scattered throughout the southern portion of the continent, and that Buenos Aires was the natural leader in such an enterprise. The colonial authorities, however, refused the invitation and, supported by the loyal colonists, repelled the revolutionary expeditions which were later sent from Buenos Aires to overthrow the Spanish authorities.

For seven years the success of the insurrection remained in doubt. The Argentines suffered defeats in Paraguay and in Upper Peru (now Bolivia), and the Spanish held unconquered the fort of Montevideo at the mouth of the river Plata. During this time the enthusiastic propaganda for liberty and equality, and the revolutionary documents sent out from Buenos Aires to all the colonies, had awakened fanciful ambitions and uneasy repinings among the natives and illiterate semi-barbarous half-breeds, who during the progress of seven generations—more than two centuries—had submissively considered themselves inferior to the whites. So when the Argentines had once conquered the Spanish forts of Montevideo and Asunción, the provinces of Paraguay and Uruguay declared themselves independent.

By 1815 the leaders having sown anarchy in all the colonies, the revolutionary government of Buenos Aires saw itself beset by the danger of invasion of the territory of the provinces of the Plata by the forces under the command of the Viceroy of Peru, and on the borders of the Plata River by the Spanish fleet. In such emergencies the larger part of the directors of the revolutionary movement felt powerless to follow the model of the republic established by the English colonies in North America and discussed a monarchical government (one of the leaders even proposed annexation to the British empire) in order to link the provinces of Rio de la Plata with

European countries, and to silence the resentments of Spain. At the same time they would submit to the insurgents who were breaking up the country by encouraging the passions of the half-breeds, and stimulating their narrow clannishness which they disguised under the name of federalism. To bring about a crisis the revolutionary government convoked a congress of representatives from all the provinces united with Buenos Aires. This congress met in the city of Tucumán 9 July 1816, and pledged itself to a Declaration of Independence for the United Provinces of Rio de la Plata, a date which the Argentines celebrate as a national holiday. The Congress of Tucumán, where the local element predominated, decided also that the form of the government should be democratic-republican-federal, by which title the Congress exalted the elements of anarchy and diminished the prestige of the active industrial class which produced the independent movement whose centre was Buenos Aires.

England and the United States, the former to limit the political power of Spain, the latter to remove from the American continent the other great powers, were the first nations to recognize the independence of the Argentines. It was then that President Monroe proclaimed the doctrine, "America for the Americans." However, the Spanish rule was not ended in America, but maintained itself firmly in the rest of the colonies. It was the destiny of Argentina to fulfil her mission as Liberator.

Lima, the capital of Peru, was the centre of the Spanish power which extended through the latter country, Chile, and the northern part of South America, Central America, and Mexico. Besides, the Spaniards still held the city of Montevideo, which was their bulwark on the Atlantic coast.

To reach Lima by land was a task beyond the bounds of possibility, on account of the geographical conditions which favored the Spanish troops by offering them a safe position within easy reach of their headquarters. The Argentine Congress had the good fortune, however, to find a soldier of genius to whom they confided this new undertaking. His name was San Martín. Realizing the risk of meeting the Spanish forces on land, he conceived the project of crossing the Andes to drive out the Spaniards from Chile and to reach Lima by sea. This bold enterprise was secretly preparing for two years, and in 1817 General San Martín led across the Andes an army of 5,000 Argentine soldiers, largely recruited from the hardy plainsmen and cowboys. This little force of rough-riders, by defeating the Spanish troops in the battle of Chacabuco, gave independence to the Chilean people. San Martín was also successful against the Spaniards in Peru, entering Lima as a liberator in 1821. Though urged to take the civil government of the countries he had freed, this soldier of splendid quality refused the rewards, honors and offices of civil life, which men fulfilling similar missions in other countries have almost without exception consented to receive.

While the patriotic army gloriously ended their campaign on the Pacific, ambitious leaders had converted the country at home into various feudal dependencies, which were at war with one another. The government, being powerless to contend with the factions, dis-

solved, leaving the provinces to take care of themselves. This picture of savagery discouraged San Martín, who, upon his return from his campaign, despairing of seeing the return of order and peace in the new communities, retired to France, where he died some years later.

The province of Buenos Aires had, no doubt, an exemplary government. The soul of it was Bernardino Rivadavia, a mulatto, who, as secretary of the government, completed commercial treaties with England and other countries, and obtained in London, through the Baring Bank, a loan of £1,000,000 at 6 per cent interest, which was totally covered at the fixed rate of 70 per cent. He also interested some small English capitalists in the enterprise of sending over the first herds of fine cattle.

Rivadavia also founded a bank of discount and for the issue of paper money, which began its operations with an issue of \$290,000, the first Argentine currency.

But the half-civilized conditions continued in the rest of the country, though the leaders of emancipation tried to reunite the provinces under national control, naming Rivadavia as President. Here we encounter the origin of the two great political parties in the history of the Argentine Republic, one being the Unitary, which favored a strong central government, in opposition to the localism of the Federals, or State-Rights party.

Rivadavia advanced his epoch, and to him Argentina owes many progressive ideas, among others the governmental ownership of the land and the natural sources of wealth. He carried on great works of public utility, employing the funds obtained from Baring Bank to found schools, universities, a national bank, hospitals and other benevolent institutions. However, he could not triumph over the local rivalries and, discouraged, like San Martín, gave up the government, which dissolved immediately, having been unable to crush out anarchy, which now broke out more furiously than ever. The discount bank of the province of Buenos Aires had been changed to a national bank, and its issue of paper money now rose to \$2,700,000, yet the payment of the debt to Baring Bank had not even been commenced.

The new Empire of Brazil, heir to the Portuguese policy in South America, expected to reach the river Plata and to dominate Montevideo, the capital of the republic of Uruguay. Buenos Aires, which had inherited at the same time the Spanish secular views, notwithstanding that it was itself menaced by anarchy, aided the Republic of Uruguay to obtain its independence from Brazil in a war which lasted three years and whose chief purpose was to drive out the Brazilians from the Plata (1828).

The anarchical wars had reduced considerably the masculine part of the population, which in 1810 numbered half a million, the fourth part of which were quadroons descended from half-breeds, mulattoes, and negroes. A leader unbalanced and fierce, Juan Manuel de Rozas, chief of the federals, now assumed command, and pleased himself with collecting the savage negroes of the population, some 40,000, recently emancipated slaves, nearly all in the province of Buenos Aires, and

bringing about the exile of the cultivated and industrious elements, who took refuge mostly in the republic of Uruguay and in Chile. The reckless spirit that during 25 years reigned in all the local military dictatorships had ended in destroying the mining and wine-making industries that the Spanish colonies had started in the interior.

The diplomats of Europe, acknowledging the Monroe Doctrine, hastened to recognize the self-styled republic. In 1829 England recognized the independence of the new country and entered into diplomatic relations with the tyrant Rozas. The final recognition of it by Spain in 1842 completed the assurance of the leaders, who, confident of their independence, had now no other idea but to destroy each other.

Of all the old provinces of the ancient viceroyalty of Buenos Aires, the only one which prospered through these years was the new republic of Paraguay, in reality an absolute kingdom at the mercy of the powerful will of the tyrant dictator Francia. Its independence was recognized by Europe and Brazil but not by Buenos Aires, and this made it impossible for Paraguay to enlarge its outside commerce, as its only outlet to the sea was by way of sailing 850 miles on the rivers Paraná and Plata. This obliged them to pass in front of Buenos Aires with all their export and import traffic.

Because Rozas at Buenos Aires could close the natural channels and hinder the traffic of Paraguay with Brazil and Europe, the English and French governments decided in 1845 to establish a blockade of Buenos Aires and open to free navigation the Paraná, and thus assure international communication with Paraguay. This blockade lasted two years, and in 1847 the English fleet abandoned the waters of the Plata. During these two years the English officials tried to excite the settlers of Buenos Aires to rise against the tyrant Rozas, but they were weak and timid and did not think they could free themselves without the help of the exiled patriots and their allies. Various attempts had been made to expel Rozas but without success until, understanding that the problem was not local but national, they united with the expatriated from other provinces, and counting on the help of the dictator who ruled the province of Entre Rios (separated from Buenos Aires by the Paraná River) and with the aid of the troops sent by the Empire of Brazil, they deposed Rozas and instituted the national government with its capital in the city of Paraná, province of Entre Rios. Then, taught by experience, the people resolved to safeguard their rights and privileges for the future. On 25 May 1853, a Constitution closely resembling that of the United States was formed, with some modifications, particularly in regard to civil legislation which is national and not provincial, and the United Provinces of Rio de la Plata took the name of Argentine Republic (from the Latin *Argentum*, silver).

Constitutional Consolidation.—Here began a period of national reconstruction and the normalization of the provincial autonomies. The country entered into commercial treaties with various European countries and with Brazil, and began to pay the Baring Bank of Lon-

don the accumulated interest and collateral on the loan obtained by Rivadavia 25 years before. The national bank, founded by Rivadavia and converted into a mint by Rozas, became the Provincial Bank of Buenos Aires.

The ensuing years witnessed some practical advances, such as the inter-provincial telegraph, the construction of the first railroad, and communications by steamboat between the Rio de la Plata and Europe, reducing to 40 or 50 days the passage which up to this time had taken three or four months by sailing vessels.

But the incipient economic interests had not yet much political representation. Personal rivalries among the commanders of the army, and the troublesome pride of Buenos Aires, jealous at seeing the national capital in the city of Paraná, separated that province from the rest of the confederacy, and civil war began once more, hindering the steps of real progress which had been taken. After various bloody battles, in 1861, the hegemony of Buenos Aires threatened the integrity of the rest of the country and the provisional capital was moved to that city. But the aggressions of the tyrant Solano Lopez, dictator of Paraguay, a country which had been formed under the fiercest of the dictatorships which the people of the south had been subjected to, had forced Brazil to war. The invasions into the Argentine territory by Paraguayan armies, which moved toward the republic of Uruguay with a view to assuring an outlet to the ocean, provoked the offensive and defensive alliance of Brazil with the republics of Uruguay and Argentina, which brought on a devastating war that lasted five years, and in which 70,000 combatants took part. Its outcome was the complete overthrow of Paraguay, whose male population was reduced to one-tenth.

Already the Argentine government had become suspicious of the policy of Chile, a country less democratic than its neighbors, who found themselves exhausted by civil and other wars. Chile manifested a strong inclination to obtain ports on the Atlantic side of Patagonia. Notwithstanding the complete victory over Paraguay, the Argentine government asserted the doctrine that "victory does not give rights," and offered to submit to the arbitration of President Hayes of the United States the question of the boundaries of Paraguay, thus making an honorable precedent in international policy.

The costs of the war with Paraguay were defrayed by a loan contracted with the Bank of London. The honorable arrangement which in 1854 the government had proposed to the Baring Bank to pay the debt made in 1825 had aroused English capitalists, who not only covered the loan for the war but also organized railroad and marine transportation companies.

The continuous issue of fiat money had depreciated the currency to an extreme limit so that the rate of exchange was 27 pesos to one gold dollar. In 1867 the Provincial Bank established the rate of exchange at the fixed point of one dollar gold for 25 paper, and vice-versa.

The war, notwithstanding its epidemics and miseries, did not wholly check the progress of civilization. The struggle with the foreigner united the confederate provinces against Buenos Aires, which, though politically allied

to the rest of the country, socially still felt itself aloof. At the same time the influx of British capital and the entrance of some thousands of immigrants changed this feeling a little. Meanwhile citizens who were enthusiastic admirers of the republic of the United States endeavored to make this the general opinion, and in 1868 a pacific presidential election took place in Argentina, resulting in the choice of Domingo Sarmiento, who was at that time the Argentine Minister in Washington. He was devoted to the progress of civilization in South America, through schools and industries. He established throughout the country compulsory and free public schools, and inviting normal teachers and scientists from the United States and Germany, he founded institutions of scientific and general culture and strengthened the sway of the national Lyceums, instituted by his predecessor, General Mitre, and established in all the provinces. Sarmiento obtained from the Bank of London \$5,200,000 gold, which he employed in public works.

Faith in the progress of the country had grown much firmer through the fact of the peaceful presidential election. People trusted in personal and property guarantees, and the rural industries, using wire fences to enclose pastures, passed from the nomadic and route systems which the cowboy had opened up to civilization. But the adventurous element of the low class, result of the mixed races, and composed of uncultured men, asserted their rights to political equality, stirred up provincial revolutions and uprisings in the city of Buenos Aires, placing again in constant uncertainty industry and commerce and checking immigration. Yet through it all the new modes of communication and the work of Sarmiento little by little made stable the growth of civilization.

As a result of wars and revolutions the scourge of cholera for two years decimated the country and an epidemic of yellow fever, brought from Brazil, in its turn for a third time destroyed the population on the banks of the Plata, whose death rate remained for years about 45 per thousand. In 1873 the population of the city of Buenos Aires was about 220,000, almost all whites; the whole population of the country was about 2,000,000, nearly a third part of them half-breeds. Stability of money was impossible, and the Provincial Bank closed its office of exchange. The wars of independence, revolutions and uprisings during the period of anarchy and tyranny, the war with Paraguay and the civil wars had reduced considerably the masculine part among the creoles half-breeds, and negroes, so that the feminine element made alliances with the European immigrants.

But the foreigner, who was indifferent to the quarrels of the political leaders and to the depreciation of paper money, which had fallen to the ratio of 30 to 1, entered heartily into agriculture which had recently shown unusual results, and the political leaders became uncertain of a field for their propaganda, warlike and personal.

Withal they had to solve the problem of the capital, up to that date provisionally located in the city of Buenos Aires, which was also the capital of the province of the same name. In 1880, because of the presidential election,

the national government, which was beginning to organize its small army in the conquest of the desert, reducing the nomadic tribes which existed in those regions, and which had extended the railroads to the distant provinces, and increased the schools, was violently expelled by the government of the province of Buenos Aires, which, with the help of the party preponderant in the city of Buenos Aires, headed by ex-President Mitre, resisted the entrance of the national forces. After many bloody combats, however, the national forces triumphed and fixed forever the national capital at Buenos Aires.

The government of Buenos Aires province removed its capital in 1882, founding the city of La Plata on the banks of the river of that name, 57 kilometres from the city of Buenos Aires. The founding of this city of La Plata cost \$30,000,000.

After the Paraguay War the two political parties ceased to exist. This gave rise to the founding of personalistic parties named for their leaders. After having lost the city of Buenos Aires in 1880 the party of Mitre retreated from the electoral struggle, and their chief, General Mitre, devoted himself to literature and high politics, becoming a famous figure in the nation, and popular with the masses, on account of his daily paper *La Nacion*, which united the characteristics of the English daily and French review. The electoral withdrawal of the Mitristas gave opportunity to the party of Federal origin, which was under the control of General Boca, who was then President of the republic, to take possession of all government positions, both national and provincial.

Chile, having defeated Peru and taken from it the provinces of Tacna and Arica, now raised the question of the boundaries along the ridge of the Andes. Being short of squadrons and provisions to defend the desert coast of Patagonia and the valleys of the Andes, the Argentine government ceded a part and recognized the claim of Chile to part of Patagonia and Tierra del Fuego; and by common agreement both governments left out the surveying of the boundaries of the land, thus allaying fears of a new war.

Although in the hands of the party of Federal origin and under a Federal Constitution, the national government adopted as its own the program of centralization laid down by Rivadavia, the founder of the Unitary party, and continued somewhat the work of progress begun by Sarmiento. It secured another loan from the Baring Bank for \$12,000,000 gold, at the rate of 90 per cent and at 1 per cent interest, to be used in railroad extension. Two years later, in 1882, it obtained another loan of \$9,000,000, gold, at the rate of 84 per cent and 5 per cent interest, to found a national bank, and immediately Parliament authorized another loan of \$20,000,000, gold, for public schools.

The conquest of the desert and the reduction of the Indian tribes was followed by great prosperity, enriching the government by the possession of millions of square miles of excellent ground for pasture. These most valuable regions were divided among the military who had made the campaign of the desert, and government politicians. The increase of immi-

gration, which was now about 100,000 a year, in most part northern Spaniards and northern Italians, attracted by the advertisements of free lands and the advantages offered by the government, and the investments of foreign capital in railroad companies and public improvements in the cities of La Plata and Buenos Aires, inflated considerably the price of land in the hands of the military and government leaders. In less than one year it doubled in price. The national government continued to ask for loans from the Bank of London, and again obtained \$20,000,000, gold, at 6 per cent interest, for the construction of the port at Buenos Aires. In 1886 another loan was made of \$42,000,000, gold, at 80 per cent rate and at 5 per cent interest, to unify diverse loans for public works.

In these conditions the military, in great part made up of half-breeds and quadroons, enriched by the gain of their desert conquests, and by the prodigality with which the London bankers loaned money to the government, outshone the old, cultured and quiet well-to-do people of Buenos Aires and other centres. The latter were descendants of the patriots of the War of Independence, and of the exiled patriots, yet they were overshadowed by the new military plutocracy, who had no thought but ostentation, and were destitute of all idea of duty, civic and social. They simply centred in Buenos Aires to enjoy life in pseudo-Parisian style.

In 1886 the government, hindered by the difficulty of obtaining more loans in London, abolished the law of "conversion," and began again to issue millions of fiat money, thus giving a chance to stock jobbing and producing an extreme instability of currency, which in 1889 had a relation of five pesos to one gold dollar. At that time the fiat money reached the sum of \$80,200,000. The London bankers had not only been beguiled into loaning money to the national government, but had also made loans to provincial and municipal governments to the extent of \$80,000,000 in gold, which was largely embezzled by the intermediaries in Europe and the retainers of the authorities of those centres.

Recent History.—In the Pan-American Congress held at Washington in 1889, the Argentine representatives, fearing the interpretation Mr. Blaine gave to the Monroe Doctrine, "America for the Americans," would be ratified by the Congress, declared as the Argentine sentiment, "America for Humanity," expressing the Argentine inheritance of blood and of interests through the mixtures of the Spanish, English, French and Italian races, and its independence of the rest of the American continent outside of its own boundaries.

Argentina now had more than \$500,000,000 English capital invested in the country and more than a half a million Italian citizens. Political and administrative corruption, however, seemed to know no bounds. Fiat money reached \$197,000,000, making the national dollar less than 30 cents, gold, and the credit of the country was compromised in loans of more than \$300,000,000, gold, covered by mortgages on its inalienable property and interests, which amounted to more than 40 per cent of its estimated wealth.

The inaction of public opinion and the lack of any party of opposition moved the young

men of the universities and those in active business to form a protesting party—"The National Civic Union,"—which in a few months after its founding conspired with some of the chiefs and officials of the army and navy, and incited mutinies and mobs which drove the President, in 1890, to resign his position. The Vice-President, Dr. Pellegrini, a man of great energy and capacity, but lacking political tact, remained in office and partly quelled the provincial revolutions. Meanwhile, the personalist leaders, reviving the traditions of the old parties, Federal and Unitary, separated the elements which formed the young party of the Civic Union.

The national government had to ask delay from the European banks, and finally the National Bank with the Provincial Bank of Buenos Aires failed. The Argentine credit was completely lost, immigration ceased as well as the coming in of foreign capital; public service became uncertain. Money was wanted to prosecute public improvements and education. The country found itself exhausted, and again threatened by Chile, which had recently come out of a cruel civil war, the only one in its history, and had been cleverly militarized under the direction of German officials. Now Chile wanted the boundaries on the Andean frontier to be made at once. As the interests of English and Italians were great in Argentina the danger of war opened again an opportunity for credit to improve the national defense, and the government spent more than \$100,000,000, gold, in forming a modern navy, making strategic lines and military posts, and purchasing military supplies. During this time agriculture and stock-raising prospered and in a few years doubled the exportation.

The government in 1891 founded the Bank of the Nation and offered to the public a subscription for \$250,000,000, to be used as its capital. The public did not respond to any extent and the government only saved the situation by resorting again to the issue of fiat money. In 1892 the government founded the "Caja de Conversion" (Exchange office) and in 1899 modified its organization, forming a reserve fund to change the bills in circulation at the price fixed by law of 44 cents, gold, to one peso, and pledging itself to set aside gold corresponding to this price for each new issue. See BANKING AND FINANCE.

Disquietude over the boundaries of Chile and the costs occasioned by it did not disappear till 1902, when the differences were referred to and settled by the King of England, followed by a treaty of partial disarmament, signed in Buenos Aires, in 1904, the only instance of the kind in the history of peace, and which reflected great honor on both peoples.

The hard experience during a decade of complicity between some national and local leaders and European bankers which endangered and discredited the country, and another decade of anxieties and expenses for the national defense, moved Argentine opinion to sustain the Calvo doctrine, proposed by Drago and upheld by the Argentine representative, in the Pan-American Congress at Rio de Janeiro, 1906, according to which the new nations have a right to repudiate the debts contracted with foreign banks which enter into treaties and plots with the reckless heads of government.

This was opposed to the Roosevelt doctrine according to which payments of debts contracted by the agents of those in authority are to be coerced from the defrauded people.

The rare coincidence of the almost simultaneous disappearance of men who were most prominent in politics—ex-President Gen. Bartolomé Mitre, ex-President Dr. Carlos Pellegrini, President Dr. Manuel Quintana, ex-Gov. Dr. Barnardo Trigoyen—whose deaths occurred in 1906, left the party of opposition without leaders, and the old political Unitary organization changed its name, substituting for it "The National Autonomistic Party," directed by ex-President Julio A. Roca.

In 1906 Dr. Figueroa Alcorta was elected President. Serious disturbances occurred during the first week of May 1909, in consequence of labor troubles and anarchist agitation. On 13 March 1910 Dr. Roque Sáenz Peña was the successful candidate for the presidency. Two months later Buenos Aires was thrown into great confusion by an attempt to call out a general strike. The 100th anniversary of the birth of the nation was celebrated 25 May. Diplomatic relations between Argentina and Bolivia, which had been interrupted as a result of boundary disputes, were resumed in January 1911, through the good offices of the United States. In November 1913 Colonel Roosevelt, ex-President of the United States, visited the Argentine Republic. On 9 Feb. 1914 the ministry resigned, after President Sáenz Peña, who had been ill for a long time, turned over his functions to the Vice-President, Dr. Victorino de la Plaza. On 25 April, four days after the United States had inaugurated hostilities at Vera Cruz, diplomatic representatives at Washington, D. C., of the "A. B. C." powers, Argentina, Brazil, and Chile, offered to act as mediators between the American and Mexican governments. (See MEXICO—HISTORY).

In 1915 the first actual treaty between Argentina, Brazil, and Chile, signed at Buenos Aires 25 May, provided for five years of peace between the three nations, during which time each of said nations was pledged not to make war on either of the others until the causes of conflict should have been investigated and reported upon by an impartial commission. Independence Day was celebrated with special ceremonies—that being the centenary—on 9 July 1916. Argentina, after more than 80 years of distracted political life hindering its development, has succeeded in the last 25 years in establishing its prominence among the young nations, and in bringing to itself immigrants from the European races. On 12 June 1916 Hipolito Irigoyen was elected to the Presidency. His administration was at once confronted with a national problem, which arose from the sinking of Argentine vessels by Germany. On 16 April 1917 a mob attacked the German Legation and Consulate and the offices of German journals in Buenos Aires in retaliation for the ruthless destruction of Argentine shipping and commerce. A protest was made by Germany which was answered in a conciliatory tone by Argentina, who at the same time sought guarantees for the safety of her merchant shipping in the war zone. Many times in the course of the following months diplomatic relations were strained to the breaking point, but a crisis was reached in September 1917, when the Depart-

ment of State of the United States made public dispatches from Count Luxburg, German Minister at Buenos Aires, to his government, in which he advised "sinking without leaving a trace" of Argentine vessels. The Argentine people, now thoroughly aroused, demanded the prompt severing of relations with Germany and late in September the lower house by a substantial majority and the Senate almost unanimously (23 to 1) voted to sever diplomatic relations with Germany. Meanwhile Germany recalled Luxburg and he was given his passports. For subsequent developments see LATIN AMERICA AND THE WAR.

JUAN A. SEÑILLOSA,

Former Argentine Consul-General to Canada.

4. GOVERNMENT. The form of government of Argentina is a representative republican-federal one, modeled after that of the United States of North America, and in accordance with its historical antecedents every province keeps its own peculiar autonomy, drawing up its own constitution, fixing the number of its magistrates, the organization of its municipalities, and administering its property without the intervention of the national government.

The executive power is vested in an officer bearing the title of President of the Nation. The terms of office of the President and Vice-President are six years, and they cannot be re-elected until after the passing of a presidential period. The Ministers are eight: Interior, Foreign Relations and Worship, Treasury, Justice and Public Instruction, War, Navy, Public Works, and Agriculture, Industry and Commerce.

The legislative power is vested in two bodies or chambers, that of the deputies and that of the senators. The former are elected by a majority of the votes of the people, and the latter by the legislatures of the provinces, thus ensuring two senators for each Federal State and two senators for the capital elected by the people.

The judiciary is vested in the Supreme Court of Justice, Federal Chambers of Appeal in the capital and also in the cities Córdoba, Paraná and La Plata; Federal courts in the capital and throughout the provinces and territories; Chambers of Appeal in the capital for civil, commercial, criminal and correctional cases. Each province has its own judicial system with a Supreme Court and several minor courts. Penal, civil, commercial and military laws are national laws, uniform throughout the republic and codified under national codes. The provinces can only enact such laws of procedure as do not affect the national laws.

The seat of the national government is Buenos Aires, the Federal capital of the Republic. The national territories are ruled by governors appointed by the Executive Power, with the consent of the Senate.

The governors of the provinces are elected by the people. Foreign citizens can hold real estate.

Article 14 of the Constitution provides for the absolute freedom of the people of the nation in the exercise of their religious faith.

There is no state religion though in accordance with the Constitution the state contributes to the support of the Roman Catholic religion, the expenses of which are about \$1,000,000 in gold per year; but it likewise contributes aid for the support of educational or charitable institutions established by other denominations. In 1884 civil marriage was established.

The ecclesiastical government consists of an archdiocese and seven dioceses, under the patronage of the national government which authorizes or prohibits the carrying out of papal decrees.

ERNESTO NELSON,
Director-General of Secondary, Commercial and Industrial Education of the Argentine Republic.

5. EDUCATION. As reformed in March 1916, this comprises six divisions: Primary (four years), Intermediate (two years), Secondary (five years), Normal (four and seven years), and Higher education (from five to seven years). The sixth division includes Industrial, Commercial and Education of the Abnormals and is called Special Education. Agricultural education is partly controlled by the universities and partly by the Department of Agriculture. Public education is free throughout.

Primary.—Primary schools are the concern of state (provincial) authorities. The exceptions are: the control of the primary schools of the Federal city of Buenos Aires by the National Board of Education, and a system of subsidies by the Federal government for the benefit of certain provinces whose finances are not equal to the needs of primary education. In 1894 there were 3,000 primary schools, public and private, which increased during the next 20 years to 7,877 schools; likewise did the teaching force of these schools grow from 7,800 to over 26,000 teachers, 80 per cent of whom are women. The pupils attending the primary schools in 1894 numbered 280,000, whereas in 1914 the attendance increased to 900,000 pupils. The expenditures incurred for the maintenance of the schools rose sixfold. Population increased less than twofold during that period.

Secondary.—Secondary education was originally shaped after European models, but the schools are already responding to the modern demands of democracy. From mere preparatory institutions for the university they are fast becoming schools of advanced education to an increasing number of men and women. In 1894 the students in secondary colleges numbered 3,000, which number rose to 10,000 in 1914, the expenses being increased from \$400,000 to \$2,500,000. There are 33 of such lycées (16 in 1894) eight of which are in the city of Buenos Aires (only one in 1894). Secondary education is not compulsory.

Normal.—Normal schools are for primary teachers and for secondary teachers. There are also special institutions for teachers of

modern languages and of physical training. Normal schools for primary teachers numbered 70 in 1914 (10 of which were in the city of Buenos Aires) with an enrolment of 8,970 students, about six times those enrolled 20 years before. They offer a four-year general course followed by a three-year special course leading to the professor's diploma. Teachers graduating from normal schools are eligible for positions of \$900 a year. Principals get from \$1,250 to \$1,500. After 25 years teachers may retire with 95 per cent of their salary, provided it has been earned during four years and also that the candidate is more than 45 years old. Normal schools for secondary teachers offer courses in different specialties besides the general courses. Graduates who secure positions as teachers in secondary schools get from \$800 to \$3,600. Salaries of principals vary from \$2,500 to \$4,000 a year. Both teachers and principals also retire with the 95 per cent of their last salary, but only after 30 years' work the remaining conditions being equal.

Minor terms of special study are required for qualification for the professions of chemist, midwife, dental surgeon, surveyor and architect.

The University of Córdoba is composed of the school of medicine, the school of engineering and the school of law, in connection with the National Academy of Sciences.

In order to follow his profession in the country, the professional graduate of a foreign university is obliged to prove his ability by means of an examination before some Argentine university.

Technical.—Technical education also is encouraged by the national and provincial governments. Prominent among those of the first category are the national industrial schools, similar in type to the manual training high schools in the United States, although the courses cover six years and afford specialization in engineering, architecture, chemistry and mechanics. Other technical schools of a vocational type provide training in the various trades. There are about 15 trade schools for girls also under the control of the national government giving instruction in dressmaking, embroidery, millinery, flower, lace and glove making, metal work, telegraph operating, drawing, painting and industrial arts. Several provinces also have established schools similar to these.

Agricultural.—Agricultural education is of a two-fold type, special and general. Special or so-called regional schools look toward the education of future workers in special fields, such as the sugar industries of Tucumán, the wine industries of Mendoza, the lumber industry of Misiones, the dairy industry of the Plata Valley, the fruit industry of San Juan and several other regional activities. Other schools provide for the thorough scientific instruction underlying all agricultural occupations, and they are of a type similar to the agricultural colleges in the United States.

Commercial Schools.—Commercial schools for men and women offer courses in commercial practice (five years), bookkeeping (four years) leading to the degree of public accountant (three more years). A more recent addition to the scope of the commercial schools is the degree of doctor for advanced work in economics.

Other Educational Interests.—Besides

national schools for abnormal children, deaf, dumb and blind, the government is establishing a number of special schools for weak children in need of fresh air as well as mountain or seaside climate. In connection with such provisions for the health of children it is interesting to mention here that every school child in the city of Buenos Aires is given a glass of milk at the noon hour. After 15 years of such practice milk drinking has become a habit among all classes of the population, thereby reducing the consumption of intoxicating liquors.

The National Academy of Fine Arts gives free instruction in drawing, painting, decorative and industrial arts.

Popular interest in education is shown by the number of organizations established either with the purpose of studying educational problems, helping the schools or conducting educational centres. The working classes themselves, through the Socialistic party, have done considerable good in organizing lectures, educational excursions and other elements of self-improvement.

Education of women has made great progress in Argentina. In certain districts primary and secondary schools are co-educational. Also some of the normal schools and all the universities. Pedagogical departments are well patronized by women who also are pre-eminent in medical studies. Women take an active interest in social work, notably through the remarkable Philanthropic Association, which although recognized and endowed by the national government is practically under the management of a woman's board. Women are active in education and have also done much to bring the child-saving agencies to the present state of efficiency.

The national government, as well as some of the provinces, maintains numerous scholarships to support Argentine students in England, the United States, Canada, Italy, France and Germany. Those in the United States number about 50, and as many more are supported by their own means or enjoy private scholarships; they are principally engaged in studying engineering, agriculture and commerce.

No fewer than 300 young Argentinos are attending courses in Europe, the great majority of them paying their own expenses.

ERNESTO NELSON,
Director-General of Secondary, Commercial and Industrial Education of the Argentine Republic.

6. AGRICULTURE. Under this title we shall endeavor to treat of Argentine agriculture as the great importance of the subject deserves, in the broadest sense of the word, with such economic, geographic and even historic implications as are, for the sincerity and thoroughness of our study, really indispensable.

The area of land under cultivation is more than 95,000 square miles, and its chief products are as follows: Wheat, more than 105,000,000 bushels; oats, 61,000,000 bushels; maize, 190,000,000 bushels; linseed, 40,000,000 bushels; sugar, more than 280,000 tons. Analyzing the statistics for recent years we find that between 16,000,000 and 17,000,000 acres are devoted to wheat, about 16,000,000 acres to alfalfa, 10,000,000 to 11,000,000 acres to Indian corn (maize), over 4,000,000 acres to linseed, and over 3,000,000 acres to oats, the other crops being barley,

sugar cane, grapes, rice, potatoes, cotton, tobacco, etc. But the fact is to be noted that of the somewhat more than 1,000,000 square miles embraced in the republic more than one-third (about 334,000) are arable. In other words, 241,000 square miles of the arable regions remain to be brought under cultivation. It is therefore proper to regard the present output of cereals, despite its unquestionable importance, as only a promise of the vastly greater crops which will be secured when the limit of Argentina's potential productivity has been even approximately attained. Moreover the agricultural system accepted and practised in Argentina at the present time is as far as possible removed from the intensive system, its aim being simply and frankly, and perhaps with over-emphasis of facility, to obtain the maximum of profit with a minimum of capital and labor. Compare it with the agricultural system of Canada. We may call the former "extensive," the latter intensive. Thus, in Canada the farms of less than 200 acres constitute 88 per cent of the total of holdings of rural property; in Argentina the holdings are relatively large and it appears that farms which best respond to the present conditions of agriculture there are those of 500 to 750 acres. The capital required for farming operations in Canada is \$59.25 gold per hectare (2.47 acres) including the value of the land, buildings and machinery; in Argentina, \$27.70 gold per hectare. The amount produced in a given area by the Argentine farmer can be greatly increased whenever it becomes more profitable to cultivate intensely than simply to extend the margin of cultivation.

In addition to the arable regions we have to consider a second one-third part of the entire area of the republic—roughly speaking 333,000 to 335,000 square miles that can be utilized for sheep or cattle and to a large extent already have been assigned to the stock-raising industry. In fact live-stock has been, from the early years of Spanish colonization, one of the two principal sources from which the wealth of the inhabitants has been derived; and the figures given in a recent census are, for the entire country: 80,000,000 sheep, 29,500,000 bovine cattle, 9,700,000 horses, 452,000 goats, 3,050,000 pigs and 920,000 asses and mules—the estimated total value being \$700,000,000 gold. The nucleus of the supply of live-stock was derived mainly from Peru and Spain in the 16th and 17th centuries.

The remaining areas are commonly assumed to be (in the agricultural sense) unproductive; and as an illustration or the most striking example of the worthless section, it has been customary in the past to mention Argentine Patagonia. But in the light of recent investigations and practical experiments we are enabled to correct that erroneous impression; and it is reasonable to expect that the whole subject of Argentine agricultural expansion will be revised when essential new facts, which would have been called heresies even a decade or so ago, are arrayed against very old but wholly unwarranted prejudice. Our task at the moment is to set forth such essential facts.

Agricultural Patagonia.—Argentine Patagonia is divided into five parts, namely, the territories of Rio Negro, Neuquén, Chubut, Santa Cruz and Tierra del Fuego, whose combined areas (about 775,000 square kilometres or

ARGENTINA

THE HARBOR OF RIO

MAY AVENUE, BUENOS AIRES

The Government House is in the distance

302,250 square miles) exceed the total area of Chile, and constitute between one-third and one-fourth of the entire area of the republic of Argentina, or nearly one-twentieth of the continent of South America. A comparatively small portion of the Patagonian regions belongs to Chile, and forms the Chilean territory of Magallanes. In view of the circumstance that its climate, ranging from temperate to cold (since it extends, roughly speaking, between lat. 40° S. and lat. 55° S.), favors the development of vigorous communities, we note with special interest records of Patagonia's agricultural achievements which demonstrate the fertility of the soil, accessibility of the interior districts, facilities for irrigation, etc. The question whether this distinctly habitable one-twentieth of South America possesses such elements of substantial prosperity has entered a new phase; and it is obviously a very large question. The 18th century witnessed a race between England and Spain for the control of this region. In 1774 the Jesuit, Thomas Faulkner, having penetrated to the heart of the country, found the interior so unexpectedly desirable that he urged England to undertake its conquest. The Spanish government, when this project became known, hastened to take formal possession of the coast by establishing forts there. On 15 Dec. 1778, an expedition was sent from Montevideo, and, after a voyage of 22 days, a landing was made on the north shore of Valdez Peninsula. The bay (a portion of the Gulf of San Matias) where this landing was effected received the name of San José. Spanish settlements were established there and at Puerto Deseado—the latter in what is to-day the territory of Santa Cruz. When Spain was on the point of losing forever her control over Argentina, England decided to strike, but aiming first at the capital, neglected to put sufficient force into the blow—and the captured English regimental flags are still to be seen in frames and under glass on the pillars of San Domingo Church at Buenos Aires. A quarter of a century passed. Argentina, distressed by war and political dissensions, was shunned by nearly all Europeans excepting soldiers of fortune. Then, after 1832, the world received from one of its greatest men extremely unfavorable impressions in regard to this portion of the far south. When Captain Fitzroy on the *Beagle* was devoting his attention to Patagonian hydrography, Charles Darwin, as the naturalist accompanying the expedition, pursued his investigations on land. But inasmuch as Darwin's studies were in the main confined to the dreary repellent wastes of the littoral, he of course depicted the land in darkest colors on account of its lack of vegetation. To this condemnatory judgment was due, in part, the delay in colonizing central and southern Patagonia. Genuine colonization of central Patagonia—the Chubut territory—began in the year 1865. In 1862 an important emigration society had been formed in England with the object of establishing colonies in Patagonia. Two representatives had examined Chubut Valley and subsequently applied to the Argentine Minister of the Interior, Dr. Rawson, for an assignment of national government lands. In the name of the government the minister stated that he was

ready to give to each family of immigrants an adequate portion of the national land. On 28 July 1865, a ship arrived from Liverpool with 153 Welshmen on board, and in September of the same year Colonel Murga, thereto commissioned by the government, came to point out to the immigrants the land assigned to them in Chubut Valley. On 16 September the colony was formally established. The Argentine flag was hoisted and the place received the name of the Minister of the Interior, Rawson. From the very beginning a lack of means of subsistence occasioned great suffering. Forty-eight newcomers abandoned the community, and the government, whose energies were absorbed by the war with Paraguay, could extend no aid. Fortunately the starving Welshmen obtained a little food from the Tehuelche Indians. The second harvest was a failure because the rainfall was insufficient. When the colonists abandoned their settlement and betook themselves to the neighborhood of the port of Madryn, Dr. Rawson promised support to the poor people and requested them to remain one year longer in the colony. Thereupon irrigation canals were cut. At one stroke the situation changed. Splendid crops of wheat were produced. From the year 1867 onward the harvests were good, but communication with the outside world was very imperfect. Application was made to the national government for assistance in exporting wheat. New bands of Welsh immigrants came in 1874 and 1875. Chubut wheat was then sent to Buenos Aires and the Falkland Islands. The colonists established a species of autonomous government, electing for this purpose a council which consisted of 12 members and which promoted the public interests and discouraged private quarrels. This council of 12 elected a president. Thus matters stood until 1876, when a commissioner was appointed to represent the national administration. In 1881 the inhabitants of Chubut Valley numbered 1,000. The law of 16 Oct. 1884 relating to the national territory prescribed for Chubut the following boundaries: On the north, lat. 42° S., on the east, the Atlantic Ocean, on the south, lat. 46° S., and the Chilean frontier on the west. Under this law a governor, a Federal judge and other officials were assigned to each territory. The first governor of Chubut, L. J. Fontana, installed the territorial administration at Rawson. Governor Fontana promptly realized that he knew nothing about the 10,000 square leagues constituting his realm. Therefore, in the spring of the year 1885 he set out with 30 men to explore the Andean valleys. The entire outfit—provisions, a large number of cattle, etc.—had been supplied by the participants themselves; and the reason why so many colonists undertook the journey was that certain friendly Indians had told them about the fruitfulness and beauty of the Cordillera valleys, and the agreeable climate prevailing there had been the subject of much praise. The interior of Chubut had, indeed, been studied at certain points by foreign geologists and botanists but not a word had been said about the agricultural possibilities of the hinterland; and in Buenos Aires the commercial world knew probably less about the southern territories than did the people of Europe.

Fontana's expedition reached the foot of

the Cordilleras after a journey of three months, and there the wanderers discovered a beautiful wide valley which their leader, in honor of the day on which the territorial divisions had been decreed, named Valle 16 de Octubre. A stock-farming colony was founded there. Fontana has characterized the newly discovered regions in the south as follows: "There were 30 of us and we belonged to four different nationalities, yet all declared to me unanimously that they had seen no other spot on earth where nature had combined on such a liberal scale whatever is necessary for the welfare of mankind."

A word of explanation is necessary in regard to conflicting accounts of certain portions of the Patagonian territories. The Rio Negro Valley and Limay region have been described by some writers as very fertile, while other writers have represented them to be entirely worthless for agriculture. If a visitor happened to come at the close of a rainy season he found luxuriant vegetation; whereas another visitor arriving in time of drought could scarcely obtain fodder for his horse. The facts that the wheat grown in the valley of the Rio Negro is as good as or better than the Chubut wheat, and that both are superior to the wheat grown in the warm northern provinces, deserve to be kept in mind.

Increase of Agricultural Resources.—The assertion has been made that the Rio Negro Valley in many respects is like the Nile Valley. Its total length, from the point where the Neuquén and Limay rivers unite to form the Rio Negro to the disembogement of the latter in the Atlantic, is about 275 miles, and the average width about four miles. Great Britain's old ambition to which we have referred has in our own times manifested itself in the construction of railways and the investment of very large sums of money in the development of the country. On 1 June 1899 the railway connecting Bahía Blanca and Buenos Aires with Neuquén was opened, and this gave ready access to regions which formerly were reached by long stage-coach journeys. The English spirit of daring which undertook the extension of the great system of the Southern Railroad merits recognition. The region to be crossed was in part so poor that the prospect of good financial returns was frankly admitted to be remote, and no colonization could be expected to follow except in the Rio Negro Valley. But English capitalists looked far beyond the present and saw in the line connecting Bahía Blanca with Neuquén only the first half of the great Trans-Andean route, which should supply, for the products of south Argentina and south Chile, an outlet at that point (Bahía Blanca) which has, as its most valuable asset, a natural harbor, much deeper and better for large vessels than the harbor of any other place in the extreme southeast. As evidence of the interest that the Argentine government takes in the southern territories, we may mention the construction of the Patagonian Railroad, which was begun in 1908. The discovery of petroleum about 1907 near Comodoro Rivadavia is another factor in the growing prosperity of southern or Patagonian Argentina. It is to be noted also that the cultivation of cereals, with all its promise, is not the most important source of wealth. Stock-farming, es-

pecially sheep-farming, dominates here; in fact, this region sustains a relation to the provinces on the Rio de la Plata analogous to that which the Southwest and West in the United States held to the Middle and Eastern States just after the Mexican War. The progress made in recent years proves that these territories can at least produce all that is requisite for the continuance of prosperity. The territory of Neuquén made gains in the matter of population (white and Indian in the proportion of three to one) to such an extent that it had recently about 30,000 white inhabitants, most of whom were Chileans, and about 10,000 Indians; and it was recorded that these 40,000 individuals possessed or were in the employ of those who possessed 195,000 cattle, 105,000 horses, 676,000 sheep, 170,000 goats and 7,000 mules. Considering only one item, we note that there were 16.9 sheep for each man, woman and child. Some progress has been made in the plans for rendering navigable the Santa Cruz River. In 1909 a steamer carrying many passengers and a cargo of 80 tons succeeded in going up against the rapid current of that stream as far as the Rincon Chico region, which was formerly regarded as inaccessible. The feasibility of plans for river improvement which shall enable larger vessels to come and go between the wide interior zone and the outside world has to be conceded. It is of highest importance to consider the agricultural possibilities of these very extensive regions, situated in latitudes that favor their development by the more vigorous classes of immigrants. The observation has quite recently been made that Argentina's expansion into the temperate southern regions of the South American continent is in its own way not less truly interesting than are the similar westward movements in the United States and Canada, the eastward one in Russia or the northward one of South Africa. This is Argentina's wide and deep frontier, the borderland in which pioneer conditions give place to rapidly growing settlements, and scientific methods convert supposedly useless areas into sources of economic wealth.

Argentina's Chief Agricultural Products.—At this point it is desirable to form correct and very distinct impressions in respect to each of the items that stand at the head of the list of agricultural products. We begin with the wheat. It will be seen that wheat, representing 57 per cent of all cereals produced in the republic, covers approximately 17,000,000 acres of land; but if labor were available no less than 80,000,000 acres could at once be brought under the plow for its cultivation. There is a decided tendency to increase the area of wheat-sown lands toward the south, where the climatic conditions are even more favorable—a tendency attributable to the new shipping facilities at Bahía Blanca.

With the steady encroachments of tillage upon the pasture the need for opening up fresh areas is making itself felt. The vast available tracts of unoccupied lands could, of course, be utilized for stock-raising, but the indigenous grasses are too coarse and unpalatable for forage purposes. These coarse grasses will have to be replaced by the fine short grasses growing in the lowlands, and gradually superseded by alfalfa, rye, barley and oats. These changes

cannot be effected without a considerable outlay of capital, which may in turn enhance the already high prices of cattle.

The fertile region lying north of the province of Buenos Aires, close to the banks of the Paraná—is at one time the realm of herds and flocks—is to-day the principal centre of maize cultivation. Levee work is in progress on one of the islands in the Paraná River near Rosario with a view to preventing inundation at the period of floods. Should the venture prove successful considerable land will be reclaimed on this and on other islands where the soil is very fertile. It is estimated that these reclaimed lands are worth \$100 per acre.

A recent issue of 'The Argentine Year Book' contains the statement that improvement in the grade of cattle has been brought about by the importation of pedigree animals valued at \$8,000,000 in about 13 years. The essentially cattle-breeding zones are now to be found in the provinces of Entre Ríos and Corrientes. Here the climate, the pastures and the water-courses are ideal features that have insured the lasting prosperity of this pastoral zone, in which the old meat-packing industry still survives the advent of the large modern factories. The pastoral industry is, as we have said, extending into Patagonia, which is already being covered from the Cordillera to the Atlantic, with flocks that promise to be the best in the republic. The Argentine Republic annually produces in the neighborhood of 300,000,000 pounds of wool, 75 per cent of which comes from white-faced, long-wool sheep, Lincolns and Leicesters, and is known in the world markets as Argentine crossbred. When sorted, this wool grades largely into coarse and medium crossbred, corresponding to domestic commons and domestic one-fourth bloods in the United States. The fine crossbred of Argentina is known in the United States as domestic three-eighths blood. Merino fleeces form 20 per cent of the yearly total, producing wool that is graded as domestic fine in the United States. The remaining 5 per cent is wool of black-faced and domestic sheep. The average weight of the fleece is 5.3 pounds. Previous to the war France and Germany were the principal buyers of the wool crop, but the United States has now become the principal purchaser, taking 152,330 bales (925 pounds) of the 298,939 bales exported in the year ending 30 Sept. 1916. This industry in Santa Cruz is represented by 5,000,000 sheep, which yield 12,000 metric tons (2,204.6 pounds) of wool, all of which is exported. Within the last 30 years the area devoted to linseed has increased 20 fold. Argentina is to-day the largest linseed producer in the world. Although the plant can be grown in nearly any part of the republic, its cultivation is confined mainly to the territory of Pampa Central and to the provinces of Buenos Aires, Santa Fé, Entre Ríos and Córdoba.

The richest alfalfa fields are to be found on the immense pampa plains. The cultivation of alfalfa has assumed vast proportions, as will be seen from the following figures: 1872, 264,500 acres; 1888, 585,000 acres; 1895, 1,780,000 acres; 1912, 13,501,500 acres; 1914, 16,725,250 acres. This forage plant, which is displacing the native grasses, grows so rapidly when

favoured by the weather that three or four crops are easily obtained. Its yield is six to eight tons per acre. Formerly all the alfalfa grown was consumed in the country, but it is now being exported to Brazil.

Large tracts of land in the northwestern section of the country are well adapted to cotton, but the crop has made little progress. Most of the cotton grown comes from the territory of Chaco. It is also grown in Córdoba, Santa Fé and Corrientes. The annual production is about 1,230,000 pounds, of which about 60 per cent is exported. About 71,536 acres were planted under beans in 1914, but although a primarily agricultural country, Argentina is dependent to a large extent on imports for its supply of beans, peas and chick-peas. Rice is produced to the extent of 15,000,000 pounds annually, which is only 14 per cent of the rice consumed in the republic.

When discussing the general outlook in a year (1914) of depression in the land market, the 'South American Year Book' for 1915 published the following:

"As a general rule, land values in the Argentine are below those current in other countries less favorably situated as regards fertility, climatic conditions and accessibility to markets, and that being so, it would be only a matter of time when prices would revert to their old level. Every year the land is becoming more and more closely settled and its productive power increased and the country is in the happy position of having a practically unlimited market for its staple commodities."

If we desire to found our opinions in regard to the permanence of the agricultural prosperity of a large country even in part upon the statistics of production (a procedure always attended by risk of error), we must at least examine the figures that relate to long periods of time and to years in which fairly normal conditions prevailed, rather than to a single year, or to two or three recent years alone, in which the conditions may have been exceptional. With this rule in mind we may now revert to the Canadian-Argentine comparison, and may mention the suggestive and somewhat propagandist statistics prepared by Señor Lahitte, chief of the Bureau of Agricultural Statistics and Rural Economy for the Ministry of Agriculture of the Argentine Republic, which show that the increase in land farmed in Canada between 1871 and 1891 was 75 per cent; the increase in the area devoted exclusively to the cultivation of cereals in Argentina between 1895 and 1909 was 284 per cent. Such figures arrest attention, especially because the inhabitants of the two countries compared are about equal in number. The increase in the number of hectares (one hectare = 2.47 acres) of cultivated land in Argentina since the first year of independence is shown as follows: From 1810 to 1888, only 2,300,000 hectares; from 1888 to 1910, nearly 17,000,000 hectares. Exported products of stock farming alone were valued at only \$3,300,000 in 1822 and at \$71,075,955 in 1888, but in 1915 their value was \$218,780,485. From statistics prepared in the year 1914 (Department of Agriculture, Argentine Republic; Ricardo Pillardo, Director-General, Commerce and Industry) we extract the returns of the

four principal products of the arable regions, showing that Argentina exported as follows:

	In 1904
Wheat.....	\$66,947,891 gold
Maize.....	44,391,196 gold
Linseed.....	28,359,923 gold
Oats.....	541,973 gold
	In 1913
Wheat.....	\$102,631,143 gold
Maize.....	112,292,394 gold
Linseed.....	49,910,201 gold
Oats.....	20,447,278 gold

Summarized, the value of exports of these four products increased during that decade from \$140,240,983 gold in 1904 to \$285,281,016 gold in 1913. In 1916 there were 16,088,963 acres under wheat, 3,207,411 acres under linseed and 2,525,402 acres under oats. The official estimate, published 17 Dec. 1916, places the wheat yield for 1916 at 77,393,258 bushels, linseed 5,280,071 bushels and oats at 33,610,157 bushels. Exports of linseed from 1 Jan. to 7 Dec. 1916 amounted to 619,210 tons, of which the United States took 209,337 tons.

Another comparison was suggested to the writer in the course of studies he made in the province of Buenos Aires and in the Paraguay-Paraná-La Plata regions between Asunción and the city of Buenos Aires, namely, the comparison with the pastoral industry of Australia, that country which rivals Argentina in flocks and herds, as clearly appears from the fact that Australia at the close of 1904 possessed 65,822,918 sheep, 7,868,520 cattle, 1,595,256 horses, etc.; and, thanks to the characteristic Australian rapidity of increase at the end of 1911 the number of sheep in the commonwealth was 93,003,521; of cattle 11,828,954, and of horses 2,279,027. In regard to this matter the writer was glad to avail himself of the testimony of those who have engaged in this industry on a large scale in both countries; and there seems to be no doubt that, tested by such practical experience, the conditions in southern and central Argentina are found to be unsurpassed.

Unquestionably the main support, and a very substantial one, of Argentina's leadership in varied or mixed agriculture is her possession of good, fertile soils, in flat or nearly level areas of vast extent, grass-grown and not covered with forests that have to be cleared away, easy of access, lying open and ready for the plough in regions so temperate, as a rule, that agricultural work can proceed almost without interruption throughout the entire year and cattle can be kept always in the open and at pasture. Invasions of locusts occur and in the past have proved to be exceedingly destructive; but preventive measures can in the long run so reduce the injury from this source that it will become a negligible quantity. Irrigation is required in many sections, though it is true that in the rich alluvial central basin of the valley of the Rio de la Plata the annual rainfall averages 30 inches; but it is demonstrable that irrigation constitutes a better and much safer reliance for the farmer than mere rainfall in every region not mountainous and not occupying an exceptional position with respect to permanent air and water currents. From Rio Negro to Misiones, in the sub-tropical northeast, and to Jujuy and Catamarca, in the Andean Northwest, soils of excellent quality and

great or sufficient depth have been known, or cultivated successfully without knowledge, for many years; and, as we have seen, we are at liberty to entertain a favorable opinion in regard to soils in the Argentine Patagonian territories.

MARRION WILCOX.

7. COMMERCE. In the year 1915 Argentina's imports amounted to \$218,951,000 and exports to \$539,000,000, while in 1916 the value of imports was \$211,310,688 and of exports \$453,841,507. In 1914 the total foreign trade, exclusive of coin and bullion, was \$602,439,880 (U. S. gold), that being the sum of imports to the value of \$263,663,363 and exports, \$338,776,517. More nearly normal was the year 1913, the last wholly normal year before the European War, in which, according to the official report of the statistical office, the total foreign trade of the republic was \$877,711,376 (U. S. gold, equivalent to 904,857,089 pesos), that being the sum of imports valued at \$408,711,966 (421,352,542 pesos) and exports \$468,999,410 (483,504,547 pesos). In 1913 the imports from Great Britain were valued at \$126,959,989; from Germany, \$69,172,279; from the United States, \$60,171,867; from France, \$36,933,537. To Great Britain in the same year the exports were, in value, \$11,756,777; to Germany, \$56,178,368; to France, \$36,586,981; to the United States, \$22,207,965. The chief imports are: Food products, textiles and allied products, manufactured articles of iron and steel, railway supplies, agricultural implements, electric apparatus, glass and chinaware, chemicals, building materials, manufactured articles of hides and skins, oils and beverages. The chief exports are products of agricultural and pastoral industry, of the forests and of the mines.

During the decade 1904-13, commercial progress on the part of Argentina, Uruguay, Chile and Brazil has been especially noteworthy; and we learn by consultation of the official data that the percentages of increase are as follows: Argentina, slightly more than 108 per cent increase; Uruguay, 104 per cent increase; Chile, slightly more than 94 per cent increase; Brazil, 54 per cent increase. Argentine exports (with values in gold dollars) in a single year preceding the outbreak of the war in Europe are listed as follows: Live-stock, \$8,770,045; meat, hides, wool, etc., \$136,336,218; manufactured animal products, \$18,124,419; by-products, \$2,569,451; agricultural products (in the restricted sense, products of tillage or of the field and garden), including raw material, manufactured and by-products, \$301,267,094; woodland products, \$10,617,985; products of the chase, \$1,816,911; mineral products, \$194,690; other products, \$3,807,734.

Of the cereals, Argentina exported 592,797 tons of oats in 1915, 74,899 tons of barley, 4,921 tons of rye, 4,330,594 tons of corn, 2,511,514 tons of wheat and 116,049 tons of corn meal. The exports of frozen beef reached a record figure in 1916, while the exports of mutton were less than in any year in the last five-year period. The shipments of chilled and frozen beef in 1916 were 47 per cent more than in the last normal year, 1913.

Argentine imports, value in gold dollars, during the same year were: Live-stock, \$1,419,290; animal foods, \$6,572,463; vegetable foods and fruits, \$2,583,251; spices and condiments, \$8,098,967; vegetables and cereals, \$6,727,848; substances for infusions, etc., \$9,517,360; flour, macaroni, bread, etc., \$1,434,066; tobacco and manufactures of, \$7,038,055; wines, \$9,866,310; spirits and liquors, \$3,022,088; other drinks, \$1,153,760; textiles, raw and manufactured, \$89,560,214 (this includes silk, \$7,080,063; wool, \$16,751,832; cotton, \$41,407,338, and sundries, \$24,320,981); vegetable and mineral oils, \$23,778,916; chemical, medicinal and pharmaceutical substances and products, \$15,193,658; paints and dyes, \$2,535,437; timber in bulk, \$4,252,600; timber worked, \$6,576,339; paper and pasteboard, \$6,011,345; sundry paper manufactures, \$3,890,640; leather and manufactures of, \$4,610,560; iron (raw material), \$24,149,251; iron and steel manufactures, \$25,891,054; other metals unwrought or manufactured, \$14,257,919; agricultural machinery, sacking, seeds, etc., \$9,124,632; railway material, vehicles of all classes, etc., \$37,223,336; stone, clay, glass, \$36,577,913 (including raw material, \$31,640,937, and manufactured, \$4,936,994); building material, \$35,775,580; electrical supplies, \$10,110,088; sundry articles and manufactures, \$14,399,584. The foreign trade of Argentina in 1916 amounted to 760,755,161 gold pesos (\$733,748,324), of which imports represented 217,409,322 pesos (\$202,940,400) and exports 543,345,839 pesos (\$524,057,350). This gives the country an apparent favorable balance of trade of 325,936,517 pesos (\$314,365,752).

Commerce with the United States.—In 1915 the exports from the United States to Argentina were valued at \$53,912,544. The record of Argentina's commerce with the United States during 20 years (1895 to 1914, inclusive) shows a very marked preponderance of imports over exports, except in the first and

last of those years. Thus, in 1895 Argentina imported from the United States goods valued at \$6,419,519, and exported to the United States goods valued at \$8,589,278; and in 1914 the figures were \$35,585,913 for imports and \$41,680,985 for exports. But in the years that intervened the balance of trade in favor of the United States was conspicuously large. The importance of the Argentine market will be most readily appreciated when we ascertain, from a study of the records for the year 1913, that the value of merchandise exported from the United States to Argentina was nearly (within \$7,430) as great as the value of merchandise exported from the United States to Brazil, Uruguay, Paraguay and Ecuador combined; and that it was \$12,543,939 greater than the sum of exports from the United States to Chile, Colombia, Peru, Venezuela, British Guiana, Bolivia, Dutch Guiana, French Guiana and the Falkland Islands. In brief, Argentina received 36.2 per cent of the total exports from the United States to South America. The principal articles thus supplied by the United States to Argentina were: Iron and steel, raw material and manufactures of 33.4 per cent of total supplied by the United States to South America; wood and manufactures, 62 per cent of total; oils—animal, mineral and vegetable, 39.8 per cent of total; agricultural implements, 82 per cent of total; cars, carriages, other vehicles and parts of, 35.8 per cent of total; leather and manufactures of, 42.5 per cent of total; fibres, vegetables and manufactures of, 74 per cent of total; engines, locomotives and railway material, 21.1 per cent of total; aeroplanes, automobiles, bicycles, motor and other cycles, 38.5 per cent of total; chemicals, drugs, dyes and medicines, 36 per cent of total; naval stores, 36.4 per cent of total; paper and manufactures of 44.6 per cent of total; other goods of minor importance, 14.9 per cent of total. According to the Argentine commercial statistics of 1913 goods to the value of \$22,135,215 from the United States were received duty free. It is necessary, however, to emphasize in this connection the fact that among the seven nations that lead in exports to Argentina, the United States took only a third position, surpassed by Great Britain and Germany and followed by France, Italy, Belgium and Spain, until there came the enormous increase that characterized the years 1913-17, inclusive, and which was due to the vast decrease in production of the European countries because of the war.

In 1916 the United States imported from Argentina articles valued at \$100,000,000, approximately, and the value of exports from the United States to Argentina in 1916 was about \$65,000,000. Consult *Americas, The* (New York, published monthly, 1914 et seq.); 'Argentine International Trade' (Panama-Pacific Int. Exp., 1915, Buenos Aires, Department of Agriculture, 1914).

MARRION WILCOX.

8. MINING AND MANUFACTURING INDUSTRIES. Although it is true that gold, silver and copper have been mined in a small way from early times, the mining industry in Argentina has not been developed to any great extent. It is often said that the main reason is the total lack of manual labor; that the mineral outcrops are found in the Andean

region where labor is scarce; that the mineral zone has an area of 48,000 square miles and is inhabited by only 20,000 people, living mostly in or near the town of San Rafael; and that a large area is altogether unpopulated. The means of communication (as stated in consular reports, etc.) are insufficient, and on those lines that do exist a prohibitive freight is exacted. Writers mention districts "reported to contain" copper, petroleum, silver, iron, borax, sulphur, gold and tin. But it is quite safe to say that districts which are with certainty known to contain such things in paying quantities do not remain unpopulated or wholly unprovided with manual labor. Means of communication are provided readily enough in any part of the republic that particularly requires and can make uncommonly good use of them; in fact, the capitalists interested in Argentine railway development are especially alert. The conclusion is that mines which are referred to in such terms are not of sufficient value to attract capital and labor for their development. But in Córdoba province (which has a large population and railways) copper, silver, gold, marble and lime are found. Jujuy has mines of gold, silver, copper, mercury, borax, salt and asphalt. Other mining districts are those of the province of Salta, which have kaolin, beside the minerals found in Jujuy. Similarly the provinces of Catamarca, Rioja and San Juan have mineral products. Mining of marble and wolfram is the principal industry of San Luis; Chubut and Mendoza produce coal and petroleum. In 1915 there were 15 petroleum wells; petroleum is exploited by the government and eight private companies; gold is found in Tierra del Fuego, Santa Cruz and Chubut. See COMMERCE (Article 7).

Nearly all the important branches of human industry are represented in the period of development that began after the year 1875. Manufacturing establishments at the present time produce standard varieties of food, clothing, building material, furniture, etc., to a limited extent; but the republic, agriculturally so powerful, is both willing and able to continue to be a purchaser of such manufactured articles as can be produced more correctly and at less cost in the United States and in Europe. Naturally the preparation of products of agricultural and pastoral industries for domestic and foreign markets increases rapidly, favored by wholly exceptional conditions. Flour and sugar mills are in vigorous and profitable operation, and the dairies have increased remarkably. There are 525 creameries, 16 butter factories, 129 cheese factories, etc., a total of 1,259 establishments connected with dairies. During the last reported year over 35,000,000 pounds of cream were produced, 20,000,000 pounds of butter, and 12,000,000 of cheese. The estimated value of these products was about \$8,000,000. The production of sugar and wine tends to increase, the annual output now exceeding 230,000 tons of the former and 500,000,000 quarts of the latter. Tucumán has 72 per cent of the registered sugar mills of the republic. Mendoza is the centre of the wine district. Important also are the tanneries (about 200 in number), the manufactories of cigars and cigarettes, of furniture, etc. But it is a mistake to speak of Argentine manufactures and mining as though they ranked with

Argentine agriculture. They do not; and their attainment of such rank in the near future is highly improbable. According to the last industrial census, there were 31,988 factories in Argentina, employing a total of 329,490 persons. The total capital was \$727,591,135, and the output was valued at \$1,227,549,196.

According to an industrial census taken in 1914, Buenos Aires at that time had 437 shoe manufactories, which gave employment to 9,970 workmen and consumed raw material valued at \$8,460,418, of which \$5,854,172 worth was domestic and \$2,606,246 imported. The combined annual sales of these factories amounted to \$16,448,514. It is estimated that the industry in Buenos Aires represents approximately 75 per cent of the total for the country.

MARRION WILCOX.

9. BANKING AND FINANCE. The first important operation of credit made by Argentina was a loan negotiated with Messrs. Baring Bros. & Co., of London, in the year 1823, bearing interest at the rate of 6 per cent and 2½ per cent amortization, issued at 90 per cent. Shortly after this operation, internal political troubles caused the suspension of interest; and not until many years after, during the administration of President Mitre, did the republic resume the service on its debt. Eventually the stockholders of the bonds received their full capital and interest in new bonds. During the years 1883 to 1885 many of the Argentine provinces issued loans in order to assist in establishing national banks under a special national law. A number of these provinces negotiated their loans in Europe, principal with French bankers. Unfortunately, owing to the crisis in 1890, the provinces suspended service of interest on these loans, the country suffering at the same time a great crisis; and although the national government, during the presidency of Dr. Pellegrini, who is remembered as an able statesman, endeavored to continue the service in cash, it could not do so. At that time Dr. Victorino de la Plaza (subsequently President of the republic) transmitted to Buenos Aires sound financial views prevailing in London, and by his counsel the funding loan was issued to pay service in bonds instead of cash for five years. Before the expiration of that time the country renewed the normal service in cash of its entire debt. Soon afterward the national government decided, in the interest of the credit of the country, to make arrangements to assume the loans created by the provinces, giving national bonds in exchange for the provincial bonds; and thus the loans issued by the different provinces, as we have mentioned above, were withdrawn. The same thing was done with the railway guaranties, under national laws, given for the construction and equipment of lines. In consequence of the financial crisis of 1890, these guaranties were not punctually paid, and it was decided to treat this question in a radical way by computing the value of each guaranty and giving to the railway 4 per cent national bonds. Fifty million dollars assigned to this purpose are known as national railway bonds. The credit of the Argentine Republic, thus completely re-established, has been maintained during a long period without an interruption, notwithstanding the difficult moments experienced

in the years 1914-16 over all the world in consequence of the European War. It is but just and right to mention in this connection the able manner in which the President, Dr. de la Plaza, controlled the finances of the country.

Aid Extended by British and American Bankers.—Nearly all the loans made by the Argentine Republic were issued under the auspices of Messrs. Baring Bros. & Co., who have been the friends and bankers of the country from the beginning, and have won the respect and the sympathy of all the Argentine people. Many of the principal loans of the republic were issued solely for the construction of railways, water and drainage, port-works, and other improvements, all of which belong to the national government and earn enough to pay the service.

American bankers have had until quite recently little direct negotiation with Argentina. Messrs. J. S. Morgan & Co., of London, issued a loan jointly with Messrs. Baring Bros. & Co., in 1886-87; again, but on this occasion unaided, issued the funding loan of 1890; and also organized and retained a large interest in one of the railway companies, the Argentine Great Western Railway, now known as the Pacific Railways. The only direct loan contracted with American bankers was one for \$10,000,000 made by the province of Buenos Aires in 1882 with Messrs. Morton, Bliss & Co., who took the whole amount. This loan, according to the statement in Don Pedro Agote's book on finance, was the first Argentine loan issued at par, and was brought out in the London market. The same firm, afterwards the Morton Trust Co., now the Guaranty Trust Co., of New York, has maintained intelligent interest in and continued its friendly relations and financial connections with Argentina. Compare the memorandum on the finances of Argentina submitted by Dr. Samuel Hale Pearson, in Proceedings of the First Pan-American Financial Conference (Washington 1915).

Since the loan of 1882, the first financial operation of marked and conspicuous importance negotiated with the banks of the United States was an advance for a short period of \$15,000,000 made in 1914 by the National City Bank of New York and its associates. Its sequel was the new issue made in 1915 by the same bank and its associates for a further amount of \$25,000,000, the object of the second issue being the retirement of the first advance of \$15,000,000; and it must be understood that the issue by the National City Bank and its associates was part of a loan of \$50,000,000 of which Messrs. Baring Bros. & Co., of London, issued the other half in London. With this loan for five years, a number of small advances have been retired.

La Caja de Conversión was created by national law in the year 1896. Its duties have relation to the exchange of used notes for new; the receipts of gold and issuance of paper money for its legal value (44¢ gold, per dollar), or, vice versa, the conversion of paper into gold at the same rate; the exclusive control of the printing and issuing of the currency of the country, etc. When the Caja de Conversión was created the circulation of currency in the republic was about \$300,000,000, but to-day it is about \$600,000,000; the gold value is about \$425,000,000, and against this

there is in the vault nearly \$300,000,000, or about 70 per cent of the notes issued.

Development of Argentine Banking.—And now a few words in regard to the Argentine banking system. During the early years of the independence of the country a number of banks were established, although the old Bank of the Province of Buenos Aires, founded in the year 1802, continued to lead them all. This was a bank of issue, having fiscal privileges, and became a very powerful institution. It was, indeed, the pioneer and founder of the wealth of the country, its useful practice being to loan its money at low interest, with a 5 per cent amortization each three months, to the farmers and owners of land, enabling them to improve and develop the ranches. By such means did the principal land owners of Argentina make their fortunes. This bank had close relations with Messrs. Baring Bros. & Co., and became very powerful, having large credits in London and controlling the exchange market for many years; nevertheless the financial and political crisis of 1890 caused its suspension, and years passed before it was reorganized with a capital of \$30,000,000. To-day it is half-owned by the province of Buenos Aires and half by private shareholders. In the year 1873 a group of wealthy citizens organized a national bank, the government contributing half of the capital, and for many years this was a powerful institution, helping the development of Argentine industries, such as the sugar in Tucumán, the wine industry in the provinces of Mendoza and San Juan, and agriculture in the province of Santa Fé. This institution also experienced financial difficulties in the crisis of the year 1890. During Dr. Pellegrini's administration, in the year 1891, the Banco de la Nacion Argentina was created, with a capital of \$50,000,000 currency (this bank taking over the liquidation of the Banco Nacional). It is an entirely official bank, and one of the articles of its "law of creation" contains the provision that all the net profits are to be applied to the increase of its capital. To-day that capital has reached the sum of \$128,000,000 paper, equivalent to over \$60,000,000, currency of the United States, and the bank has besides a reserve fund of \$14,500,000 in gold. The management does not sustain such relations of dependence upon the national government as the circumstances that the directors are named by the President of the republic, and their nominations require confirmation by the national Senate, would seem to indicate. It has over 150 branches in Argentina and is constantly increasing the number, following the growth of the nation. It has no agencies abroad, although its financial relations with the principal banks and bankers of the world are being increased every year, and it now has very friendly relations with some of the principal banks of the United States. Its deposits have reached over \$300,000,000 gold, and during the universal financial difficulties of 1915 it helped the commerce and industry of the republic, which would otherwise have suffered more severely from the restriction of credits caused by the war.

Beside the Bank of the Nation and the banks of the province of Buenos Aires to which we have referred, there are several private banks, formed solely with Argentine capital,

which are very prosperous institutions and have been created as the requirements of the country demanded, such as the Banco Español and Banco de Italia del Rio de la Plata, whose combined capital is over \$80,000,000 (gold). There are also several foreign banks which have aided materially in the development of the trade of the country. One of the first of these was the Bank of Maua (now liquidated), established in Buenos Aires and Montevideo about 1855. The very important London and River Plate Bank was founded in the year 1862. Since that date the following have been established: The London and Brazilian Bank, The British Bank, Anglo-South American Bank, two German and several other banks, including Italian, Spanish and Dutch, with a total capital of about \$300,000,000. The most recently established is the agency of the National City Bank of New York.

The National Mortgage Bank is strictly a governmental institution managed by a board of directors appointed by the President of the Republic and confirmed by the Senate. This bank issues national cédulas (real estate mortgage bonds). The transaction must not in amount exceed 50 per cent of the value of the lands. Loans are limited to \$250,000 to any one person. These cédulas bear either 5 or 6 per cent interest, and, because this bank is a national institution, have the guaranty of the Argentine Republic. Some of the first issues were of 7 per cent, but all have 1 per cent amortization. They were principally held in Belgium, having been one of the favorite investments of the Belgian public. The total amount of cédulas issued is in the neighborhood of \$200,000,000.

Argentine finances suffered from a crisis that began in 1913 and went on with increasing stress until the end of 1914 and the early months of 1915, when conditions began to improve. The European War was, of course, a tremendous shock, which further unsettled the financial structure of the country, but which offered some compensating advantages in the form of increased demand and higher prices for the food products which Argentina was so abundantly able to supply. The situation in 1915 improved rapidly, and in 1916 decidedly favorable tendencies prevailed.

The national finances, collection of customs, stamp taxes, disbursements, and the service of the public debt are entrusted to the Department of Finance; and the conversion office (Caja de Conversión) is charged with the maintenance, as we have said above, of the proper relation between gold and paper money, besides having in its care the national archives, the bureau of statistics, the national chemical office (established to enforce the national pure food law), the custom-houses, ports, and all banks.

The basis of the monetary system of Argentina is the gold standard. The unit is a gold peso, divided into 100 centavos, weighing 1.6129 grammes of gold .900 fine, or, say, 1.4516 grammes fine gold. Its par value, expressed in terms of United States currency, is \$0.96475. The parity of \$1 United States currency in terms of Argentine gold pesos is \$1.0365. The actual currency of Argentina is government notes, to which a value of 44 per cent of the gold peso has been assigned by the government.

This parity of 44 per cent is maintained through the medium of a conversion fund which exchanges gold for paper, and vice versa, on the basis of \$44 gold for \$100 paper, or \$227.27 paper for \$100 gold. Therefore, since the value of the paper peso is fixed by governmental decree and is maintained through the conversion fund, the paper peso represents 0.6387 grammes of fine gold, and its parity expressed in terms of United States currency is \$0.4245. The parity of \$1 United States currency in terms of Argentine paper pesos is \$2.35576 *curso legal* (paper currency). Bills of exchange on foreign countries are quoted in both paper and gold, but usually they are quoted in gold. When Buenos Aires quotes New York exchange on the basis of paper currency, the quotation represents the equivalent in United States currency of \$1 paper peso. Thus, 42.50 means that \$0.4250 United States currency is the equivalent of \$1 peso, paper. When Buenos Aires quotes New York exchange on the basis of the gold peso, the quotation is expressed in gold pesos; thus, "New York sight \$1.0375" means that \$1.0375 Argentine gold pesos equal \$1 United States currency.

The trade balance in favor of Argentina in 1915 was noteworthy: 331,000,000 Argentine gold pesos. Failures in the republic during the recent period of financial crisis are summarized as follows: Year 1912, assets \$95,000,000 and liabilities \$82,000,000; year 1913, assets \$200,000,000 and liabilities \$173,000,000; year 1914, assets \$603,800,000 and liabilities \$422,800,000; year 1915, assets \$233,500,000 and liabilities \$178,000,000. These figures, supplied to us by the courtesy of the National City Bank of New York, clearly demonstrate both the stress and the recovery mentioned above. The budgets at hand give us: Total estimated ordinary revenue for the year 1913, \$342,292,894.54 *curso legal*; and for the year 1914, \$361,773,132. The new budget, signed 22 Feb. 1917, appropriates the same amount as in 1916, namely, 381,000,000 paper pesos (\$161,772,600). The latter proved to be excessive. The income for custom houses and port services during 1916 amounted to \$118,587,979, against \$108,929,011 for 1915, and \$133,352,488 for 1914. The total debt of the republic, 31 Dec. 1911 was \$526,540,088 gold; at the end of 1912 it was \$532,398,699 gold; on 31 Dec. 1913 it amounted to \$544,820,000 gold; and on 31 Dec. 1914 it was \$545,023,470 gold. We must add to the total for 1913 about \$100,000,000 gold in order to approximate the amount of the public debt in 1915 and 1916.

2 Theatre Colon, Opera House in Buenos Aires

million paper pesos in 1916, or \$14,546,796,000 (American currency), as against the small sum of only \$2,740,600,000, the estimate of the census of 1895 which appears to have been somewhat incorrect.

Property of a private character, owned by the state, is valued at \$1,126,000,000, showing an increase of nearly \$850,000,000, as compared with 1888. The industrial property of the state was estimated at \$480,000,000 in 1914, as against \$53,000,000 in 1884. It consisted of the following items in 1914: Sanitary works, \$145,000,000; State railways, \$136,000,000; port works, \$168,000,000; irrigation works, \$15,000,000; hydraulic works, \$12,000,000; telegraphs, \$4,000,000. In 1888 the government lands were valued at \$104,000,000 (301,000,000 acres at 34.4 cents per acre). By 1914 their value had increased to \$220,000,000, although their area in the meantime had been reduced to 205,000,000 acres, the value per acre evidently being estimated at \$1.07.

The bulk of the people's wealth is represented by agricultural property, the value of which is estimated at \$7,218,200,000. Industrial, factory and shop properties are estimated at \$758,760,000. It is noted that 75 per cent of the raw materials employed by the industries is of domestic origin. Argentine industries supply 71 per cent of the demand for manufactured articles. Reckoning the population at close to 9,000,000, and the aggregate wealth at \$14,546,796,000, the wealth per capita — statistical average — is \$1,616.

Another estimate of the national wealth was made in 1917 by Dr. Alejandro E. Bunge, director general of the National Bureau of Statistics. He gives the following estimates of Argentina's national wealth for the years 1908 and 1916:

Form of wealth	1908	1916
Lands and grounds.....	\$2,758,000,000	\$4,510,000,000
Fixed investments.....	267,000,000	456,000,000
Cities and villages.....	2,547,000,000	2,887,000,000
Personal and household effects.....	637,000,000	722,000,000
Live stock.....	628,000,000	1,360,000,000
Agricultural products.....	530,000,000	530,000,000
Industrial products.....	637,000,000	700,000,000
Agricultural implements and machinery.....	78,000,000	172,000,000
Industrial machinery.....	170,000,000	187,000,000
Stock of gold.....	168,000,000	338,000,000
Railways.....	890,000,000	1,433,000,000
Street railways, telegraphs, telephones, electricity, and gas works.....	255,000,000	290,000,000
Port works, canals ships..	255,000,000	280,000,000
Total.....	\$9,820,000,000	\$13,865,000,000

The difference in the valuation of lands and grounds for the year 1916 and that for 1908, amounting to \$1,752,000,000, or 63.5 per cent, does not represent a real increase in the value of land. No such increase in land values has taken place. The difference is to be explained by the difference in the methods of estimating values employed for the two censuses. The same holds true in regard to the valuation of live stock, the value of which is estimated at \$628,000,000 for 1908 and \$1,360,000,000 for 1916. The difference of \$732,000,000 would represent an increase of 116.5 per cent.

For the purpose of comparing the national wealth of Argentina with that of other nations the following table is submitted, showing the aggregate and the per capita wealth of the principal nations:

Country	Year	National wealth	Population	Wealth per capita
Argentina...	{ 1908	\$9,820,000,000	6,050,000	\$1,623
	{ 1916	13,805,000,000	8,070,000	1,718
France.....	1908	55,391,000,000	39,280,000	1,410
Germany...	1908	83,300,000,000	62,800,000	1,325
United Kingdom	1908	67,012,000,000	44,500,000	1,506
United States....	{ 1904	107,104,000,000	81,200,000	1,318
	{ 1912	187,739,000,000	95,540,000	1,965

It should be noted, however, that these figures are not directly comparable. The purchasing power of money differs in different countries and, moreover, if the real economic power of a country is to be measured correctly it is necessary, in addition to the property existing within the boundaries of the country, to consider also the investments placed in foreign countries. The European nations in particular have enormous investments abroad, with considerable returns in the form of interest and dividends. This fact must be taken into account, particularly if a comparison of the taxable wealth of different countries is attempted. Argentina's foreign investments are nil, while millions of dollars have been invested by foreigners in her various public and private enterprises. Consult 'Tercero Censo de la República Argentina de 1914' (Buenos Aires 1916), and 'Commerce Reports,' issue of 29 Sept. 1917 (Bureau of Foreign and Domestic Commerce, Washington, D. C.).

Editorial Staff of *The Americana*.

11. TRANSPORTATION AND COMMUNICATION. Shipping.—We shall first consider the shipping at the ports of the river system (La Plata, Paraná, etc.); and the magnitude of British trading interests in Argentina is one of the facts that will claim our attention immediately. The preponderating share of the United Kingdom in the sea-borne commerce of the Paraná-La Plata River system, as the 'South American Year Book' suggests, may be summed up in a single sentence: the number and tonnage of British shipping in Argentine waters exceeds that of all the other nations put together. So important is the sea-carrying trade of the British flag, and so keen has become the competition of foreign shipping, that even so slight a fall in the relative position of British shipping as one-half per cent before the European War began was commented upon by British writers as a not altogether propitious sign. Taking the shipping of all the ports of the river Plata as a whole, the tonnage of the vessels owned by British subjects represented in 1912 no less than 3,557,700 tons, or 60½ per cent of the total shipping, but compared with 1911 there was a falling-off of 97,000 tons to be recorded. In the year last mentioned the British tonnage attained 3,654,700 tons, or 61 per cent of the tonnage of all nations. Germany took the

second place with 661,400 tons, followed by Italy with 426,500 tons, and France with 400,000 tons. Germany and France were credited with an increase of 16,300 and 46,990 tons respectively; the Italian flag showing the considerable decrease of 140,300 tons, as a result of the utilization of liners as transports. Under the Argentine flag we find 78 steam vessels with 43,001 tons, and 9 sailing vessels with 7,052 tons. At the Atlantic port of Bahía Blanca, during the normal period before August 1914, the number and tonnage of British vessels nearly doubled in the short space of a single year. Practically all the important shipments here were made in British vessels, notwithstanding the efforts of Germany to secure a footing in this trade. Rapid travel has become a necessity in Argentina as elsewhere. Competition between the various steamship companies for fast services between Argentine ports and Europe has become keener than ever.

The efforts of the government to foster the Argentine coasting trade have accomplished, unfortunately, very little. As for river communication, some progress is now being made and the communications with Paraguay by the Paraná River are gradually improving. There is a service of rather light-draft steamers from Buenos Aires as far as Asunción, while transit by water between the capital and Rosario, to which port on the Paraná River ocean-going steamships ascend, is beginning to compete advantageously with the railways. From a handbook prepared by the Pan American Union ('Argentine Republic,' Washington, D. C., 1916) we quote as follows: "Austrian, Belgian, Brazilian, British, Danish, Dutch, French, German, Italian, Spanish and Swedish steamers arrive and depart regularly from the ports of Argentina to all quarters of the earth. There are 50 lines with agencies in Buenos Aires. Regular passenger service is maintained to the various ports of Europe and steamers leave or arrive several times a week. To New York, while there are not so many steamers, opportunity is offered at least once in a fortnight for the traveler to take a direct steamer." Argentine official statistics show that since the year 1900 the total tonnage (entrances and clearings to and from ports of the Argentine Republic) have increased 124.2 per cent. In March 1917 a regular line of cargo steamers was inaugurated between Japan and Argentina and Brazil.

Railway Postal and Telegraph Services.—Argentine railways have at least one characteristic which distinguishes them from those of the other South American countries; each is part of a system designed to promote the development of the entire republic.

For a number of years practically all imports were sent to Buenos Aires, and thence forwarded to the centres of consumption. That made necessary the joining of Buenos Aires with all the interior districts by a number of radiating main lines. These help to develop the agricultural districts they influence, which in turn give them a large amount of traffic. Secondary lines are then interconnected and the points where such lines cross the original lines become in turn new centres. Subsequently, radiating lines were constructed from other important places also, such as

Bahía Blanca, Rosario and Santa Fé, the shipping facilities of these foci being increased to accommodate the growing traffic. The result is seen in the present logically developed system which is uncommonly efficient and capable of almost indefinite expansion. Up to the beginning of the year 1914 there had been constructed and, as a rule, very well equipped, 20,502 miles of railways. Of these, 6,226 miles were of narrow gauge; 1,611 miles of standard gauge and 12,967 miles of broad gauge. Private corporations owned 17,351 miles, while 3,454 miles belonged to the state. The railway system was extended 391 miles during the year 1913. In 1915 there were open 22,688 miles of railways, of which 4,136 miles belong to the state. This railway expansion places Argentina in the ninth position, with respect to length of railways, among the countries of the world; more extensive systems exist only in the United States, Germany, Russia, France, India, Great Britain, Austria-Hungary and Canada. "The nation has realized," says the 'Argentine Handbook,' "that to have a population to develop the rich soil of the country, the railway must go in advance of settlement. Surveys have therefore been encouraged and actual construction has been hastened into regions practically unvisited by man until then." A phase of the railway development during 1913 was the practical completion of the line westward from the Port of San Antonio, in Rio Negro Territory, to Lake Nahuel Huapé; the plan being to extend this road into Chile through the neighboring Cordillera. The Southern Railway also has continued construction from Neuquén toward the Andes, and the intention is to cross into Chile not far from Valdivia.

The provinces of Buenos Aires, Santa Fé and Córdoba excel in the development of their railway systems; but each large political subdivision, except Los Andes and Tierra del Fuego, has at least some line built or building. The government by its plan of extension has carried its own lines into Jujuy, and thus to the Bolivian frontier, where connection is to be established with La Paz. Of international interest also was the inauguration and operation (1913) of a through passenger and freight service between Buenos Aires and Asunción, the capital of Paraguay. A law passed by the Argentine Congress in 1915 provides for the collection of a pension fund for railway employees. In 1912 a law was passed providing for the canalization of the Upper Uruguay; the work to be carried out jointly by Argentina, Brazil and Uruguay. A ferry boat service was also projected between Paraguay and Argentina at Posadas and Encarnación.

The so-called Mitre law, which went into effect 1 April 1908, is of great importance to investors in Argentine railways. Article 8 of that law states, with regard to railways:

The materials and articles for construction and operation which are imported into the country shall be exempt from import taxes, and this exemption shall be effective until 1 Jan. 1947. The company shall pay, during the same period, regardless of the date of its concession, a single contribution [tax] equivalent to 3 per cent of the net earnings of its lines, being exempted during same period

from all other national, provincial, or municipal taxes.

In 1906 the national Supreme Court decided that this law exempted the railway companies from the payment of any tax except the 3 per cent of their net earnings, the net earnings being assumed to be 40 per cent of the gross earnings; but it has recently revised its decision, and the municipalities are now attempting to compel the railway companies to pay several years' back taxes for paving, lighting, etc. Some of the railway companies are paying the municipal taxes under protest. The principal railway companies operating in the republic have asked Congress to pass a resolution enjoining the municipalities and provinces from collecting these taxes, and it is expected that the present Congress will decide definitely what interpretation is to be placed on the law.

The 3 per cent tax is expended on improvement to highways leading to the stations of the railway paying the tax.

The organization of posts and telegraphs was established by law in 1878. Argentina is a member of the Universal Postal Union, and the parcel-post convention with the United States was signed in September 1915. The mails receive systematic attention, and delivery is made to every place in the country. The number of permanent employees is about 13,500 and about 1,250,000,000 pieces are carried annually by railways, steamers, stage-coaches and mounted messengers. In May 1913, there were 43,202 miles of telegraph, with about 2,600 telegraph offices, employing more than 10,000 persons in the service. The revenue of the Postal Department was \$4,967,910 for 1914-15. The government owns about one-half of the telegraph system and the provinces of Buenos Aires and Entre Ríos have lines. Cable service between Argentina and other countries is chiefly in the hands of private companies. By agreement with Bolivia, Paraguay and Uruguay, the charges to those countries are the same as the Argentine inland rates. Argentina was the first of South American states to adopt wireless telegraphy. There are 12 stations for wireless telegraphy. All ships with a crew of over 50 and touching at Argentine ports are compelled by law to be provided with wireless equipment.

MARRION WILCOX.

12. ARMY AND NAVY. Military service is compulsory to all Argentine citizens for the nominal term of 25 years, between the ages of 20 and 45. By means of an annual drawing of lots conscripts of 20 years of age are designated to serve for one year (army) or two years (navy). Conscripts who can not read and write are taught during the term of military service. Those joining the army are also given instruction in agriculture. After the conscription service the citizens do not receive military training although they belong to the active army (first 10 years), then make up the national guard (following 10 years), and lastly the territorial guard (remaining five years).

There is also provision for soldiers enlisting under contract, for citizens serving as a punishment for breach of the Military Law, and for voluntarily enlisted musicians. The standing army has 20 infantry battalions of three companies each, nine cavalry regiments of four squadrons each, five regiments of field artillery, each having four 6-gun batteries, one regiment of howitzers, some mountain artillery and heavy artillery, six battalions of engineers of two companies each, cyclist, administrative companies, etc. The army expenditure in 1915 was \$28,334,556 paper.

The total establishment of the standing army was about 22,000 in 1916. The compulsory service was created in 1901 and since that time nearly 200,000 men have been trained.

All officers in the army are graduates from the military school at San Martin. Besides there are a Superior Military School, a Cavalry School, a school for petty officers, a school for marksmen, another for gunsmiths and an Aviation School.

In the navy the two-year conscription system provides the men for ordinary duties of the navy while officers are selected from the Naval School at Rio Santiago. In addition there are special training schools for mechanics, electricians, artillerymen, torpedo crews, stokers, clerks, wireless operators, pilots, sailors and ship boys. The entire fleet is mobilized for four months in every year and during that period a number of reserve men are called up for service. The reserve force consists of 12,000, of whom one-half belongs to the first reserve and the other half to the second. Before graduating as midshipmen the students of the Naval School spend the last year of instruction on board of a training ship making a cruise around the world. The war navy consists of 2 dreadnaughts, 2 pre-dreadnaughts, 4 armored cruisers, 3 protected cruisers, 2 armored gunboats, 2 torpedo gunboats, 15 destroyers, 8 torpedo boats and some miscellaneous craft.

MARRION WILCOX.

ARGENTINE, Kansas, formerly a city in Wyandotte County on the Atchison, Topeka and Santa Fe Railroad; annexed to Kansas City in 1910. It has extensive smelting interests, a structural steel company, zinc and chemical works, an ice plant, railroad repair shops and several grain elevators. Pop. at time of annexation, about 6,200.

ARGENTINE, the name of a group of small smelt-like fishes, living in the open seas of the north temperate zone, and distinguished by the brilliant, silvery appearance of their scales. Some ascend rivers to deposit their spawn, where they are caught in large quantities and eaten as a delicacy. This group is also famed for the abundance of nacre, the substance used in making artificial pearls, which is attached to their air bladders in the form of a coat of silvery fibres.

ARGENTITE (from the Latin, *argentum*, "silver"), a native sulphide of silver, belonging in the galena group, crystallizing in the isometric system and having the formula Ag_2S . It is opaque and has a metallic lustre and a dark, leaden gray color. Its hardness is from 2 to 2.5, and its specific gravity is about 7.3. Argentite occurs in many countries and when

found in quantity is a valuable ore of silver. It occurs in crystals (often distorted), massive, in crusts, and in thread-like aggregates. Choice specimens occur in the silver mines of Joachimsthal, Bohemia and Freiberg, Saxony; in Bolivia, Chile and Peru, and notably at Batopilas, Mexico; also in many silver mines in Colorado, Nevada, and elsewhere in the United States. Argentite is often called "silver glance" by miners.

ARGENTORATUM, an Old Celtic word, meaning "stones of Argantos," the old Roman name for Strassburg.

AR'GILLA'CEOUS ROCKS, a petrographic division including those rocks that are largely composed of clay. They owe their origin to the disintegration and decomposition of other rocks and hence are always of secondary nature. Among the common varieties belonging to this class are ordinary brick-clay, fire-clay, potter's-clay, kaolin, mudstone, shale and marl (qq.v.). Clay rocks are easily influenced by metamorphic agencies, yielding shale, micascist, graywacke and other hard rocks. See **SEDIMENTARY ROCKS**.

ARGINUSÆ, är'ji-nū'sē, the name of several small islands southeast of the Island of Mitylene (Lesbos), now belonging to Greece. In their vicinity the Athenians, under Conon, 406 B.C., defeated the Spartans under Callistrates, in a hard-contested naval battle.

ARGIVES, or **ARGIVI**, the inhabitants of Argos; a term used by Homer and other ancient authors as a generic appellation for all Greeks.

ARGO, the important southern constellation of the Ship, which is nearly 75 degrees in length, and contains over 800 stars visible to the naked eye. It has been subdivided into the smaller constellations: Puppis (the Poop), Vela (the Sails) and Carina (the Keel). Canopus, a star of the first magnitude, is its chief ornament. It is invisible in the northern and central United States. The variable star, N. Argus, has deeply interested astronomers, because of its great changes in brightness.

ARGO. See **ARGONAUTS**.

ARGOB, the name of a district in Bashan, referred to in Deut. iii, 4, as the kingdom of Og, and containing threescore walled cities. Its precise location has not been determined. In this connection consult De Vogüé, 'Syrie Centrale (Paris 1869); Porter, 'Five Years in Damascus' (London 1870); 'Giant Cities of Bashan' (ib. 1869) all interesting if not very reliable. Consult also the careful description given in Wetzstein, J. G., 'Reisebericht über Hauran und die Trachonen' (Berlin 1860).

ARGOL (origin of the word unknown), a term applied to the crude acid tartrate (or bitartrate) of potassium, as deposited on the sides of the vats in which wine is fermenting. It exists in the grapes from which the wine is made, but is precipitated from solution in the vats by the alcohol formed during the fermentation. Like many other precipitates, argol brings down more or less of the coloring matter in the solution from which it is deposited, and it is white or red, according to the color of the wine from which it is formed. When purified by re-crystallization from its solution in hot water, argol is known in commerce as "cream

of tartar." The purified salt is extensively used in baking powders and to a lesser extent in medicine. It is used in its crude state in metallurgy as a reducing agent in fire assaying.

ARGOLIS, a peninsular state of ancient Greece; between the bays of Nauplia and Ægina, now forming with Corinth, a nome or department. Argolis was the eastern region of Peloponnesus, and its inhabitants were often called Argives. According to the monuments of Greek mythology, Argolis was peculiarly rich, and early cultivated. Here reigned Pelops, an emigrant from Asia Minor, from whom the peninsula derives its name. It was afterward the seat of government of Atreus and Agamemnon, Adrastus, Eurystheus and Diomedes. In the earliest times it was divided into the small kingdoms of Argos, Mycenæ, Tiryns, Troezen, Hermione and Epidaurus, which afterward formed free states. The chief city, Argos, has retained its name since 1800 B.C. Its inhabitants were renowned for their love of the fine arts, particularly of music. Some vestiges remain of its ancient splendor, and it has at present about 9,000 inhabitants. Near it is the modern capital of Argolis, Nauplia or Napoli di Romania, with an excellent harbor, and the most important fortress of the peninsula. Pop. of the nome of Argolis and Corinth (1907) 153,172.

ARGON (Greek, "inactive," in allusion to its entire lack of chemical affinity), a gaseous substance, presumably an element, discovered in the earth's atmosphere in 1894 by Lord Rayleigh and Prof. William Ramsay. For some years previous to this discovery, Lord Rayleigh had been engaged in a careful determination of the densities of certain gases, and consistent results had been obtained for all of them save nitrogen. This gas, when prepared from air by the abstraction of all other known components, was found to be heavier, by about one part in 200, than the nitrogen prepared from ammonia. There could be no doubt about the reality of the difference, because the same experimental methods, when applied to other gases, gave results that were consistent with one another to about one part in 10,000. In studying the cause of the discrepancy, Lord Rayleigh prepared nitrogen from ammonium nitrite, from urea, and from nitric and nitrous oxides; and found that all specimens of the gas that were prepared from nitrogen compound agree with one another in density, but that the specimens of nitrogen that he prepared from air were uniformly and consistently heavier, by the same constant amount of one part in 200. Provisionally, therefore, he recognized two kinds of nitrogen, which he called "chemical nitrogen" and "atmospheric nitrogen," respectively, to indicate the sources whence they were obtained. He then published a letter in *Nature*, narrating these facts, and calling for suggestions from chemists as to the cause of the systematic difference in density. No ideas of value were elicited. The possibility that "chemical" nitrogen might be contaminated with hydrogen, and that the experimental methods failed to eliminate the last traces of this very light gas, was tested by adding hydrogen to "atmospheric" nitrogen, and then submitting the mixture to the same process employed for

removing any hydrogen that might have existed in the "chemical" nitrogen. If the hydrogen theory of the discrepancy had been true, it would have been found that "atmospheric" nitrogen, when treated in this way, would ultimately agree in density with "chemical" nitrogen; but the test showed that "atmospheric" nitrogen, after the addition and subsequent removal of hydrogen, returned to its original state of higher density, thus proving the adequacy of the experimental methods, and disproving the hypothesis that the difference in density was due to hydrogen. The suggestion was also made that the "atmospheric" nitrogen had partly polymerized into an allotropic state analogous to ozone, or that the "chemical" nitrogen had partially dissociated into monatomic molecules. These possibilities were tested by subjecting both kinds of nitrogen to the action of the silent electric discharge, in an apparatus designed for the production of ozone from oxygen. It would certainly be expected that the difference in density would partially or wholly disappear under this treatment if there were any basis to the polymerization or dissociation hypotheses; but it was found that both kinds of nitrogen retained their initial densities, so that the original difference persisted undiminished in amount. Furthermore, if the lightness of "chemical" nitrogen were due to a partial dissociation induced by the method of preparation, it would be reasonable to expect that the molecules would recombine in time with a resulting return of the density to that observed in "atmospheric" nitrogen. Specimens of "chemical" nitrogen that were allowed to stand for eight months, however, were found to retain their characteristic lightness. At this stage in the investigation, Professor Ramsay asked permission to cooperate in the investigation, and his services were gladly accepted. The hypothesis was made that "chemical" nitrogen contains an unknown gas, *lighter* than true nitrogen; or that "atmospheric" nitrogen contains some similar gas that is *heavier* than true nitrogen. In spite of the many analyses that had been made of the air, it was thought more probable that the unknown gas would be found in "atmospheric" than in "chemical" nitrogen; and hence the experimenters turned their attention to the problem of removing "true" nitrogen from the "atmospheric" nitrogen, with the idea of obtaining a possible residuum, which would at least contain the unknown gas in concentrated form. For this purpose it was proposed to take advantage of the known fact that at a red heat nitrogen will combine with metallic magnesium, with the formation of magnesium nitride. "Atmospheric" nitrogen, carefully freed from all known impurities, was therefore passed through a long tube of hard glass filled with magnesium shavings and heated in a furnace. The first experiment of this sort was made in May 1894, and gave encouraging results, the "atmospheric" nitrogen showing a slight but unmistakable increase in density. A more elaborate experiment of the same sort followed, in which "atmospheric" nitrogen was caused to pass over hot magnesium for more than two weeks. By this means its density, originally about 14 (that of hydrogen being 1), was increased to 19.09, and the bulk of the gas under examination was diminished until not much

more than 1 per cent of it remained. Plainly a great concentration of the unknown gas had been effected. To remove the last traces of true nitrogen, pure oxygen was next added, and the mixture exposed to a rain of electric sparks in the presence of caustic soda. When so treated the experimental gas contracted, indicating that the nitrogen was being withdrawn in the form of nitrate of sodium. When contraction was no longer noted, the nitrate of sodium and the excess of oxygen were removed, and it was found that the remaining gas had a density about 20 times as great as that of hydrogen. When subjected to the electric spark and examined by the spectroscope, this residual gas was found to exhibit certain characteristic groups of red and green lines that did not correspond to any element previously known. The experimenters, therefore, felt reasonably sure that a new element had been discovered, and this conclusion has been borne out by all subsequent investigations. The discovery of this element (to which the name "argon" and the chemical symbol "A" have been assigned), was formally announced to the public in August 1895, and for it Lord Rayleigh and Professor Ramsay were awarded the Hodgkins prize and also the grand prize of the Smithsonian Institution. See AIR.

As it was found that air contains 0.933 of 1 per cent (by volume) of argon, it is natural to ask why the new element had escaped detection in the vast number of air-analyses that have been made in the past. The answer is that argon shows no chemical affinity whatever, and as nitrogen is also inert in comparison with most elements, the two were very easily confused. Chemists have almost invariably estimated the nitrogen of the air "by difference"; that is, by removing all such constituents as oxygen, carbon dioxide and ammonia, and taking it for granted that the inert remainder is nitrogen. It might be thought that the spectroscope would betray the presence of argon, when the spectra of "atmospheric" and "chemical" nitrogen were compared; but the curious fact has been established that when argon and nitrogen are mixed, the argon does not reveal itself to the spectroscope unless the mixture contains at least 37 per cent of argon. Upon looking over the work that had been previously done upon air, it was found that Cavendish had isolated nearly pure argon as long ago as 1785, but without recognizing its real nature. Thus, knowing that air contains a considerable quantity of nitrogen, he raised the question whether all of the apparently nitrogenous part of the air "could be reduced to nitrous acid, or whether there was not a part of a different nature from the rest which would refuse to undergo that change." To decide this point he added excess of oxygen to air and passed electric sparks through the mixture (precisely as Rayleigh and Ramsay did) until no further diminution of volume occurred. He then removed the excess of oxygen, together with the oxides of nitrogen that had been formed, and found that only a small bubble remained unabsorbed, which, he says, was not more than one one-hundred and twentieth of the bulk of the original nitrogen. The bubble that he thus obtained and whose nature he did not further question must have been nearly pure argon.

Argon having been discovered, chemists at once undertook to ascertain its chemical properties, but here they met with an obstacle that has not yet been overcome, and which constitutes one of the strangest facts known to chemistry. It was found, namely, that argon cannot be made to enter into chemical combination with any substance whatsoever. Thus Rayleigh and Ramsay have stated that "argon does not combine with oxygen in presence of alkali under the influence of the electric discharge, nor with hydrogen in presence of acid or alkali, nor when sparked, nor with phosphorus at a bright red heat, nor with sulphur. Tellurium may be distilled in it and also sodium and potassium. Red hot sodium peroxid has no effect. Persulphids of sodium and calcium have no effect at a red heat. Platinum sponge does not absorb it. Aqua regia, bromine water, bromine and alkali, and potassium permanganate are all without influence. Mixtures of metallic sodium and silica, or of sodium and boric acid, are likewise without influence, and hence also nascent silicon and boron." Moissan further found that fluorin does not act upon it at any temperature. In short, it may be said that every reagent that the previous experience of chemists indicated as likely to combine with argon has been tried without success, and hence the chemical properties of the element (if, indeed, it has any such properties), are as yet quite unknown. Several announcements of the existence of compounds of argon have been made, but no really convincing evidence of such combination has been given. For example, Berthollet subjected a mixture of argon and benzene to the action of the silent electric discharge for a long time, and observed a diminution in the volume of the argon, which he attributed to its combination with the benzene. Benzene when treated in this way forms a resinous mass, which coats the walls of the tube, and it is not improbable that the small quantity of argon which disappears is held mechanically by the gummy deposit, either in solution or by absorption. At all events the original quantity of argon is restored, unchanged, by heating the resin. It cannot be positively affirmed that no compound of argon exists, but there is no previously known element (not even the metals of the platinum group) that could withstand the action of the substances whose activity has been exerted without effect upon argon. Until some compound can be formed we shall therefore have to infer the atomic weight of argon from determinations of the density of the gas, taken in connection with Avogadro's law. The best determinations made up to the present time indicate that the density of argon is 19.942 times that of hydrogen. If the molecules of argon are diatomic, then 19.94 is the atomic weight of the element, but if they are monatomic, we must double this estimate and conclude that the atomic weight is 39.88 (see ATOMIC THEORY; also GASES, KINETIC THEORY OF). To settle this doubtful point experiments were made to find the ratio of the two specific heats of the gas, and it was found that the specific heat of argon at constant pressure is about 1.644 times as great as the specific heat at constant volume. This indicates that the molecule of the gas contains but one atom, and hence it is necessary to conclude that the atomic

weight of argon is 39.88, the atomic weight of hydrogen being taken as 1. Argon has been liquefied and solidified. Its critical temperature is 179.3° F. below zero, and its critical pressure is about 52.9 atmospheres. Liquid argon boils (under ordinary atmospheric pressure) at about 303° F. below zero, and at about 309.3° below zero it freezes. The density of liquid argon is about 1.4046 at its boiling point. Four other elements, associated with argon in the air and closely resembling it in properties, have been discovered as the result of researches suggested by the discovery of argon. They are called, respectively, helium, neon, krypton and xenon (qq.v.). Hundreds of papers dealing with argon and the other gases just mentioned have appeared in the scientific periodicals, so that no bibliography of the subject can be attempted here. Ramsay's book, 'The Gases of the Atmosphere' (1896) gives an excellent account of the chemistry of the air, from the earliest times down to 1896. It must be remembered, however, that our knowledge of argon and its allies is growing rapidly, so that some of the statements that Ramsay makes can be no longer admitted to be true. For example, he states that helium (which had already been discovered when his book was written) does not occur in the air, but it has since been shown that it is a component of the air, forming from one to two one-millionths of its bulk. (See GASES, COMPRESSED). Travers' 'The Experimental Study of Gases' may also be consulted with advantage.

A. D. RISTEEN.

ARGONAUT, the appellation of an eight-armed oceanic cephalopod, closely allied to the octopus, and having the same power of swimming backward by forcing water through its funnel. Though called "paper nautilus" it is entirely different from the true nautilus (q.v.), and although, since the earliest days, it has been said to sail upon the surface of the ocean, in its shell as a boat, with two web-like arms spread for sails, this belief is pure fable. Argonauts remain in deep water except in spawning season, and then come to the surface only at night. The male is a naked octopod, and the "boat" of the female has no organic connection with her body, but is a mere receptacle for holding eggs, retained in place by the two dorsal arms, which are membranous and secrete it from their inner surfaces. It is not chambered like that of the true nautilus, but has a radially fluted, semi-transparent spiral shell, enveloping the body as far as the base of the tentacles, increasing in size with the growth of the animal, and attaining a length of six inches. The male is only about an inch in length; one of its very short arms is specialized into an organ of generation, called a "hectocotyle," which detaches itself from the male body, and, having independent locomotory powers, attaches itself to the female, and in some manner unknown fertilizes the eggs. Only a single species is known (*A. hians*), representing the family *Argonautida*. See NAUTILUS; OCTOPUS.

ARGONAUTS, the name given in Greek legends to the sailors, who, in a ship called the *Argo*, made a hazardous voyage to Colchis under the leadership of Jason, in quest of the golden fleece. Jason's uncle Pelias had usurped

the kingdom of Iolcos and would resign it only on condition that Jason should first bring from Colchis the golden fleece suspended in a consecrated grove at Colchis. Among Jason's companions were Hercules, Castor and Pollux, Peleus, Admetus, Meleager, Orpheus, Telamon, Theseus, and his friend Pirithous, Hylas and Lynceus. Having sailed from the promontory of Magnesia, in Thessaly, they reached the harbor of Lemnos, where they remained two years. The women of Lemnos, instigated by the offended Aphrodite (Venus), had slain all the males among them, except Thoas, and they detained among them the welcome strangers. At length they proceeded to the Troad, where Hylas and Hercules were left behind. After various adventures they approached the dreaded Symplegades, rocks which closed together and dashed in pieces vessels passing through them. According to instructions previously received, they caused a dove to fly through before them, and followed, rowing with all their strength, while Orpheus played on his lyre. The rocks stood firm, and the danger was escaped. The last adventure awaited them at the Island of Aretias. Here they found the Stymphalides, birds which shot their feathers like arrows, and from which the heroes could only protect themselves by a violent clashing of weapons. On their arrival at Colchis King Æetes did not refuse absolutely to deliver the golden fleece, but charged Jason with three dangerous labors, thus hoping to destroy him. Jason was to yoke the two fire-breathing bulls of Hephæstus to a ploughshare of adamant, and to plough with them four acres of land consecrated to Ares (Mars), and never before turned up. He was then to sow in the furrows the remaining serpents' teeth of Cadmus, in the possession of Æetes, and to kill the armed heroes which they produced; at last, to fight with and slay the dragon that guarded the golden fleece. All three labors he was to accomplish in a single day. With the help of Medea, the daughter of Æetes, these tasks were accomplished and the fleece obtained. Jason then fled with Medea, but the fugitives were pursued and on the point of being overtaken when Medea averted the danger by killing her brother Apsyrtus, and strewing on the road his mangled limbs. The unhappy father quitted the pursuit to collect the bloody limbs of his son and the fugitives escaped. The return of the Argonauts is variously told, but after many perils they reached Iolcos and gave the fleece to Pelias. Whatever the origin of the story, it was certainly developed under the influence of the great period of Greek colonization in the 8th and 7th centuries B.C., when the adventures of the navigators and explorers of the western Mediterranean and the Black sea were told of gods and heroes. The story is scattered through nearly all the literature of Greece. Apollonius of Rhodes first gathered the mass of material into a connected consistent narrative.

ARGONAUTS OF '49, a literary name (the colloquial one being "Forty-niners") applied to the California pioneers. The first discovery of gold was in January 1848, but it was not generally realized till April; from thence till the following winter California itself (recently obtained by the United States from Mexico) was partially depopulated outside the

mining camps, even soldiers and sailors deserting in great numbers and rushing to the mines, while executive authority was paralyzed. These local changes of place, however, did not constitute a "voyage for the Golden Fleece" from far distant regions, which is what the term implies. The excitement, spread by official reports, and intensified by journalistic inventions, had fully roused the east by winter; from January onward the great sea routes were thronged. By the end of the year the new province (it never was organized as a Territory, entering the Union as a State from a condition of legal nullity or permitted trespass) contained toward 100,000 people. The imperfect State census of 1852 showed 264,435, nearly all Argonauts proper.

Much the greater portion came by sea; the favored route being by the Isthmus of Panama. The passengers landed at Chagres, took boat up that river to Cruces, then crossed over by horse or mule conveyance to Panama, where they took such coasting steamers or sailing craft as came along. The crowds which flocked thither by all sorts of Atlantic vessels far outran the Pacific fleet's capacity, and large numbers had to wait many weary weeks for a passage. At one time 3,000 were collected at Panama, so wild with impatience that several small companies unsuccessfully attempted to make the voyage to San Francisco in the natives' log canoes. An assemblage of several hundred to a thousand was common; and at one time they enlivened the tedium by issuing a newspaper. But a far more terrible foe than ennui had to be faced: the cholera and Panama fever, which carried off great numbers of the emigrants and a quarter of the inhabitants of Panama. Before the excitement had begun, two new steamers, the *California* and *Oregon*, were assigned to this route to run monthly. The fare was \$300, and the competition for space was so great that double price was sometimes paid. The *California* reached San Francisco on her first trip 28 Feb. 1849. When she came up the west coast after rounding the Horn to reach Panama, the gold fever had just reached Peru, and 75 Peruvians took passage. This preoccupation of space so enraged the 1,000 or so of waiting Americans that they induced the commandant of the United States forces in California, who was waiting with them, to issue a proclamation ejecting the Peruvians as intending trespassers on United States public lands not yet opened for settlement. As they refused to go, however, no one dared use force. In one case some 300 intending passengers drew lots for the 52 steamer tickets on sale. Many gold-seekers crossed at Nicaragua, at the Isthmus of Tehuantepec, or at central Mexico. Many thousands, however, chose the cheaper and unbroken but time-wasting sailing voyage of several months around Cape Horn. The vessels on this route were miscellaneous and often unfit and ill manned; the food was poor and insufficient, and the voyage full of hardship. There was also a large overland emigration across the plains, through the Great Basin and its alkali deserts, and over the Coast Range. This journey, too, was full of suffering from lack of food, lack of water, lost trails, and exhaustion; and sometimes after a summer of endurance to the last gasp, the pilgrims saw the snows

close up the mountain passes before them, and either wintered or died on the eastern flank, or lost themselves trying to penetrate through the snow. This overland body had two strongly distinguishing marks from the immigrants by sea. First, it contained nearly all the families among the Argonauts, as distinguished from the solitary masculine adventurers; and therefore nearly all the women. Second, it was nearly all a Northern and free-labor element—an important point in the struggle to make new States free or slave then going on between the sections.

The characteristics of the Argonauts as a body were these: First, they were mostly men, with a few low-caste women, and their moral sense was not therefore quickened by the presence and needs of family life; though families and reputable women were by no means so utterly absent as the exaggerated myths of the old-timers would make it appear. Second, few intended to remain longer than was needed to acquire a fortune and return East. This did not make their settlement in the least less enduring or desirable, but with the paucity of family life, it prevented them for some time from feeling a proper responsibility for public order and the creation of solid institutions, and spasms of illegal violence were expected to do the work of steady legality. Third, they were from all sections of the country, at a time when North and South were daily becoming hostile races. Though the free-State people were largely in the ascendant, the Southerners were the political leaders and the State was steadily Democratic. Yet the former class had no idea of letting sectional politics rule their general action; home issues were too pressing and national ones too academic; and while California as a free State sympathized with and furnished splendid help to the Union, her politics have never been affected by the issues either of slavery or of reconstruction. Fourth, along with men of character and ability, since prominent as business and professional men, State officials, editors, etc., there were of course great numbers of blacklegs, desperadoes, and refugees from justice. These not only defied all law in their relations with each other, but frequently outraged, plundered and murdered the native Spanish inhabitants, and required an amount of time and effort to keep them in order, which the decent element—who were in a great majority—were unwilling to give. Hence society again and again seemed on the verge of being dominated wholly by its criminal classes, and the fear of an occasional uprising of the orderly element did not countervail its being only occasional and the chance of escaping it (see *VIGILANCE COMMITTEES*). But the best praise which can be given to the essential soundness of the Argonauts is that in a remarkably short time they rose to the same sense of their responsibilities as older commonwealths, and the California of 1860 was not inferior to any of its companions. Consult Audubon, 'Western Journal' (Cleveland 1906); Bret Harte, 'Tales of the Argonauts' (Boston 1875); Royce, 'History of California' (1891); Bancroft, H. H., 'History of California' (4 vols., San Francisco 1884-90); id., 'California inter Pocola' (San Francisco 1888); Shinn, 'Mining Camps' (1885); Taylor, Bayard,

ARGONNE, är'gün', France, a hilly rock and forest covered district of the northeastern region, on the borders of Lorraine and Champagne, now contained in the departments of Marne, Meuse and Ardennes. The forest of Argonne over 30 miles long and from one to 8 miles wide, is celebrated for the Campaign of Dumouriez against the Prussians in 1792, and was also the scene of several events in the Franco-Prussian War, 1871-72, and in the great European War, 1914-17.

ARGOS, an important city of ancient Greece. The conquest of Argos by the Dorians forms the first really authenticated event in its history. Argos was now a Doric city, though it retained with part of its Achæan population some of its ancient habits, particularly the worship of Hera (Juno). It had also a temple of peculiar sacredness to Apollo. It was long the first Dorian city in Greece, Sparta being the second, and Messene the third. From the time of the ascendancy of Sparta, Argos was divided between a democratic and an oligarchic party, the former of which inclined to the Athenian, the latter to the Spartan alliance; but the general spirit of the city tended toward enmity to Sparta. In 362 Argos fought with Thebes against Sparta and Athens. The celebrated Pyrrhus was killed in an invasion of Argos in 272. In 229 Argos joined the Achaian League, to which it continued to adhere till its overthrow by the Romans. The town of Argos is a straggling modern place, with houses mostly surrounded by gardens, and few buildings of importance. The chief relic of the ancient city is the theatre. There is an acropolis, 1,000 feet high, crowned by a ruined castle. Pop. about 9,000.

ARGOS, Ind., town of Marshall County, eight miles south of Plymouth, the county-seat, on the Dixie Highway and on the New York, Chicago and Saint Louis and the Lake Erie and Western railroads. It contains a saw mill, bending factory, printing establishment, two grain elevators and three banks with combined resources of \$200,000. It is the headquarters of the National Retail Hardware Association. The value of its taxable property is estimated at \$525,745. It has a high school. Pop. 1,200.

ARGOSTOLI, är'gös-tö'le, an important city of the Ionian Islands, the capital of Cephalonia. Its harbor is considered the best in the Ionian Islands, and there are excellent quays. The town is the residence of a Greek bishop. Wine, oil, melons and currants are exported. Several mills here are driven by a current of sea water flowing through an artificial channel and then disappearing through fissures in the rocks. A naval school has been established here. Pop. about 14,000.

ARGOSY (a corruption, by transposition of letters, of the name of the seaport Ragusa), the term originally for a carrack or merchant ship from Ragusa and other Adriatic ports, now used poetically of any vessel carrying rich merchandise. In English writings of the 16th century the seaport named is variously written

Ragusa, Aragouse or Aragosa, and ships coming thence were named Ragusyes, Arguzes and Argosies; the last form surviving and passing into literature. The incorrect derivation from Jason's ship, the *Argo*, is of modern origin.

ARGOUT, *är'goo'*, **Antoine Maurice Apollinaire**, Count *d'*, a French statesman and financier: b. Isère 1782; d. 1858. In 1810 he was auditor to the Council of State, was made prefect of Gard in 1817 and peer of France in 1819. In July 1830 he acted as mediator between Charles X and the popular leaders. He obtained several concessions from the former, but these came too late. In the same year Argout became Minister of Marine and in 1833 Minister of the Interior. He was governor of the Bank of France, after 1834, except for a time in 1836 when he was Minister of Finance.

ARGUELLES, *är-gwä'lyäs*, **Agustín**, Spanish statesman: b. Rivadisella, Asturias, 1776; d. Madrid, 23 March 1844. On the outbreak of the war of independence in 1808 he attached himself to the patriotic party, and, as representative of his native province in the Cortes, gained a high reputation for eloquence (1812-14). On the restoration of Ferdinand VII, Arguelles was arrested, and suffered several years' imprisonment in the galleys till the revolution of 1820 restored him to freedom. He became Minister of the Interior, but soon resigned, being displeased with the narrow bigotry of the court. On the fall of the Constitution (1823) he fled to England, where he remained till the amnesty of 1832. On his return to Spain, being nominated to the Cortes, he was repeatedly made president and vice-president of the Chamber of Deputies, and always showed himself a moderate but unwavering reformer. In 1841 he opposed all concordats with the Pope. He was guardian of the young Queen Isabella during the regency of Espartero. To the last he displayed those remarkable oratorical gifts which in his youth earned for him the sobriquet of "Spanish Cicero." Consult Evaristo San Miguel, (*Vida de D. A. Argüelles*) (Madrid 1851).

ARGUMENT, a term sometimes employed as synonymous with the subject of a discourse, but more frequently appropriated to any kind of method employed for the purpose of confuting or at least silencing an opponent. Logicians have reduced arguments to several distinct heads, of which the only one that can be said to have truth only for its object is the *argumentum ad iudicium*, founded on proof and addressed to the judgment. See ARGUMENTATION; LOGIC.

ARGUMENTATION is the process of proving or attempting to prove a given proposition the truth of which is doubtful or disputed. It is, in many respects, the converse of the process of inference which is reasoning from premises to a conclusion. In arguing, the conclusion becomes a thesis and the facts or premises from which it was inferred become the reasons by which it is proved. Inference is a forward movement from the premises to the conclusion; arguing is a backward movement, or reference, from the thesis to the grounds which support it. Inference is the process by which we ourselves reach a conclusion or belief; arguing is the process by which we seek to induce belief in others.

Proof requires that the proposition to be proved be brought within the scope of an accepted law or principle, a law or principle being defined as every general proposition that includes, or may be applied to, unascertained cases. This may be done by setting forth evidence, that is, facts observed by those sought to be convinced, or established to their satisfaction, which show the relation between the two. In practice argumentation is usually elliptical. The whole of the proof is seldom stated in full. The advocate is usually content to state one or more facts, leaving it to those addressed to supply the presuppositions in the light of which alone such facts may be interpreted. Implications which may be readily supplied are usually omitted. Thus, if it be argued that "Congress is in session" for the reason that "the flag is flying over the Capitol," it is clear that the assertor relies not only on the fact given as a reason but also on an implied assumption which may be expressed as a general proposition: "Whenever the flag is flying over the Capitol, Congress is in session." Every valid argument, then, when fully expressed, consists of a proposition to be proved which may be called the Thesis, and two proving propositions usually called the reasons or the proof, one of which is a general proposition and may be called the Principle, and the other is a statement of evidence and may be called for distinction the Reason, and shows that the thesis is brought within the scope of the principle. A thesis is said to be proved: (1) if the reason and the principle are known or admitted to be true, and (2) if the thesis is contained, involved or implied in them. An argument may be compared to a lever; the thesis is the weight to be lifted, the principle is the fulcrum and the reason, the power. The first requirement of proof has reference to those sought to be convinced. The advocate must found his thesis on something which they recognize to be true. If the reason or principle be not accepted, the proof remains incomplete until the disputed proposition is itself proved by reference to another reason and principle, and so on until some holding ground is reached, some reason and principle which will be unchallenged. The second requirement is concerned with the relation of the thesis to the other propositions of the argument. If the principle and the reason are both expressed, the question whether or not they imply the thesis is manifest in most cases on simple inspection.

Proof may be either conclusive or probable. To prove a proposition means strictly to establish its truth conclusively and beyond all doubt. In practice, however, a proposition is said to be proved when its truth is shown to be probable or highly probable, or so probable that we do not hesitate to act as if it were true. Thus, in a criminal trial a prisoner's guilt is said to be proved if it be established beyond a reasonable doubt; and in a civil trial the plaintiff's case is said to be proved if there is a mere preponderance of evidence in its favor. There are many principles that cannot be asserted or accepted as true universally, but only generally, or in most cases, and when such a principle is relied on as the foundation of an argument the thesis can only be asserted as probably true. So if the reason can only be asserted as probable, the thesis can have no higher certainty. In most

cases it is only possible to establish a disputed question with more or less probability, to afford a presumption of its truth, and to shift the burden of proof on him who maintains the contrary.

Proof is said to be direct when the reasons directly imply the thesis, and indirect when they imply the falsity of all possible alternatives, and hence indirectly imply the truth of the thesis. Thus, if we argue that a given straight line, AB, is equal to another given straight line, CD, we employ the indirect mode of proof if we show that AB is not greater than CD, and that it is not less. The only possible alternative is that AB is equal to CD.

Argumentation includes also the processes of disproof and of refutation which, however, are fundamentally processes of proof, since disproof consists in proving that a given thesis is false, and refutation consists in proving that a thesis for which reasons have been given is not proved by them, having regard to the requirements of proof.

Principles may be divided according to their source into two general classes, namely, those derived from Experience and those derived from Authority. Principles derived from Experience include the laws of nature, scientific truths and, in short, all general propositions which are suggested or confirmed by experience, as for example, "all men are mortal"; the air has weight"; "unsupported bodies fall to the ground"; "division of labor increases its efficiency."

Principles derived from Authority include civil laws, rules of action and other general propositions, declared, enacted or promulgated, usually for the guidance or government of a class or community, by a legislature, church, judge, lawgiver, teacher, inspired writers or by any man or body of men having or assuming authority, as for example: "every person who, being a witness in a judicial proceeding, makes a statement under oath which he knows to be false is guilty of perjury and is liable to a penalty"; "it is wrong to commit murder"; "all men are created free and equal"; "all who believe will be saved."

Arguments may be divided into two general classes, according as the principle on which they are based is derived from Authority or from Experience. This division is similar to that adopted by lawyers when they speak of issues of law and issues of fact. The following is an example of an argument where the principle is an enacted law:

Thesis: This prisoner is guilty of perjury and is liable to a penalty.

Reason: Because being a witness in a judicial proceeding he made a statement under oath which he knew to be false.

Principle: Because every person who, being a witness in a judicial proceeding, makes a statement under oath which he knows to be false, is guilty of perjury and is liable to penalty.

Arguments based on principles derived from Experience may be conveniently divided into eight general classes, namely: arguments to prove facts of Causation, arguments from Example, from Analogy, from Cause to Effect, from Effect to Cause, from Testimony, from Sign and from Circumstantial Evidence.

Facts of Causation.—That one thing is

the cause or the effect of another may be proved by reference to one of the five principles first formulated by John Stuart Mill, which are as follows:

(a) *Agreement.*—When two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.

(b) *Difference.*—If an instance in which the phenomenon under investigation occurs and an instance in which it does not occur have every circumstance in common save one, that one occurring only in the former, the circumstance in which alone the two instances differ is the effect or the cause or an indispensable part of the cause of the phenomenon.

(c) *Joint Method.*—If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two sets of instances differ is the effect or the cause or an indispensable part of the cause of the phenomenon.

(d) *Residues.*—Subduct from any phenomenon such part as previous induction has shown to be the effect of certain antecedents and the residue of the phenomenon is the effect of the remaining antecedents.

(e) *Concomitant Variations.*—Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner is either a cause or an effect of that phenomenon or is connected with it through some fact of causation.

These five principles may be reduced to two, which are: negatively, that none of the antecedents of an effect that can be dispensed with without preventing the effect is the cause, and positively, that every antecedent of an effect that cannot be dispensed with without preventing the effect is the cause or part of the cause. These principles may be proved by reference to two principles which are the ultimate foundation of all arguments from Experience. These are the law of Universal Causation which may be expressed by saying that "Every event has a cause," and the law of the Uniformity of Causes which may be expressed by saying that "Like causes produce like effects in like circumstances."

It is in accordance with these principles that investigations are carried on in every branch of science that has to do with tracing the relation of cause and effect, and establishing principles based thereon.

Example.—We use the argument from Example when we cite as a reason for the truth of a general proposition a number of observed or known facts similar to those summed up in the thesis, the facts set forth being examples of the general truth they are cited to prove. Thus, we argue that all horned animals are ruminant because the ox, the sheep, the deer and other horned animals are ruminant. In an argument of this kind the reason is seldom stated in full and the principle is seldom stated at all. When the proposition to be proved is universal, the advocate relies on the implied assumptions that no negative example has been found and that the search has

been exhaustive. He is usually content to state one or more positive instances and shift on his opponent the burden of showing an exception, or that the search has not been complete. The argument may be stated in full as follows: Thesis: All horned animals are ruminant; Reason: Because A, B, C and a number of other horned animals are ruminant and no horned animal has been found, after due search, that is not ruminant; Principle: Whatever has been found to be true in a number of instances of a phenomenon and never found to be false, after due search, in any, is true of all.

In like manner we may argue that all men are mortal, that unsupported bodies fall to the ground, that food is necessary to animal life, that the price of protected manufactures tends to decline.

Analogy.—In an argument from Analogy points of resemblance between two things are relied on to prove that the resemblance extends further than is actually known or observed. Thus, when we argue that a given specimen of handwriting was written by a particular person because it resembles handwriting that is known to have been written by that person, we employ an argument from Analogy. The principle upon which this argument is based may be stated as follows: "Whatever is true of a thing is true of what essentially resembles it." It is sometimes said that no thesis can be proved conclusively by analogical evidence, but if essential resemblance can be shown, if, in other words, the analogy is complete, the argument may be as conclusive as any other. In many cases in which the argument from analogy is employed it is impossible to show essential resemblance, and, of course, the thesis cannot be asserted as more than probably true. Thus, in the argument that Mars is inhabited because of its many points of resemblance to the earth it is impossible to say that the thesis is even probably true, since there are so many points of essential difference and so many essential points as to which it is unknown whether Mars resembles the earth or not. To justify a probable conclusion there must be more points of resemblance than of difference and the points as to which we do not know whether the two things compared agree or differ should be considered as points of difference. Moreover, of all possible points of resemblance and of difference only those should be considered which are essential, that is to say, which have a direct bearing on the question to be proved. The principle upon which we rely in using a probable argument from analogy may be stated as follows: "When two things resemble each other in a preponderating number of essential particulars what is true of one is probably true of the other."

The arguments from Example and from Analogy depend in the last analysis upon causation. The uniformity of the facts in the one case and the essential similarity of the facts in the other lead us to infer a cause which, although not known, is assumed to exist to account for the fact or class of facts to be proved.

Cause to Effect.—An argument from Cause to Effect is one in which the existence of a known cause is given as a reason to prove an effect, as when we argue that a man will die because he is afflicted with a particular

disease. Such an argument may be only probable since the action of every cause is liable to be frustrated by other agencies, and it approaches to conclusiveness in so far as it can be shown that no other agency is operating or will operate to prevent the effect. When an argument of this kind is employed the assumptions relied on are that the circumstance given as a reason has been found to be adequate to produce the alleged effect, that its action cannot be frustrated and that it will be followed by its effect in this case as in the former case or cases, or in other words, that like causes produce like effects. The argument may be expressed in full as follows: T: A will die; R: Because he is afflicted with X, a cause of death that cannot be frustrated; P: Every cause that cannot be frustrated will be followed by its effect. The argument may be stated more simply by using as a principle the law of the particular effect: T: A will die; R: Because he is afflicted with X; P: Because all who are afflicted with X die. In like manner we may argue from motives to actions which they tend to produce.

Effect to Cause.—An argument from Effect to Cause is one in which the existence of an effect is given as a reason to prove a cause that is known to be adequate to produce that effect. Such an argument may only be probable since the same effect may be produced by two or more causes, and it approaches to conclusiveness in so far as all the causes but one can be shown not to be operative. Thus, when we argue that it has rained because the streets are wet we use an argument from an effect (the wet street) to a cause (rain), and it is conclusive in so far as we show that no other cause operated which might produce the effect, as for example, a heavy dew, melting snow, the sprinkling cart, the bursting of a water main, etc.

The principle relied on in arguments of this kind may be stated as follows: when any circumstance is known to be adequate to produce a given effect, that effect having appeared and no other cause having operated to produce it, the effect in question was preceded by that circumstance.

Testimony.—An argument from Testimony may be regarded as an argument from an effect to a condition, the giving of the testimony being the effect and the reality of the fact testified to being a more or less probable condition of the effect; in other words we argue that the testimony would not have been given if the fact testified to were not true. The assumption relied on in every argument from testimony is that the witness is trustworthy, and the principle on which we rely is: what a trustworthy witness testifies to is true. An argument from testimony may be stated formally thus: T: A assaulted B; R: Because C, a trustworthy witness, testifies that he saw him do it; P: Because what a trustworthy witness testifies to is true. It is assumed both in the courts of justice as well as in the ordinary affairs of life that a witness is trustworthy unless the contrary is shown, in much the same way that an accused person is presumed to be innocent until he is proved to be guilty, and the burden of showing that he is not trustworthy is usually upon him who asserts his untrustworthiness.

Sign.—An argument from Sign is one in which the fact to be proved and the fact cited as a reason, although not related as cause and effect, are associated through some fact of causation, usually as joint effects of a common cause either known or assumed to exist. Thus, when we argue that it will rain because the mercury is falling in the barometer, or that this animal is a ruminant because it is horned, or that Congress is in session because the flag is flying over the Capitol, we use arguments from sign. Arguments from testimony, from cause to effect and from effect to cause, are also sometimes called arguments from sign, but it is convenient to use the term in the sense above indicated. In a wide sense all arguments are arguments from sign since sign is only another name for evidence. The principle relied on in this argument is usually a law already established by the argument from Example.

Circumstantial Evidence.—In this argument the reason consists of a number of facts or circumstances any one of which taken by itself may have little evidential force, but which taken together form a body of evidence that is often stronger than the direct testimony of witnesses. It is in the nature of an argument from cause to effect or from effect to cause or from sign, or it may contain elements of all three. An example of the establishment of a thesis by circumstantial evidence may be taken from almost any criminal trial. In one case the house of a license inspector, who had aroused the hostility of liquor sellers by a strict enforcement of the law, was wrecked by some explosive. Shortly after the explosion, which happened about one o'clock in the morning, marks of footsteps in the fresh snow were found leading from the place of the explosion to one of the hotels, not by the most direct route, but circuitously around a block and through a back alley to the rear entrance of the hotel. In one of the rooms was found a pair of boots which coincided with the footmarks made in the snow, and under the mattress of the bed there were two sticks of dynamite and an unused dynamite fuse. The owner of the boots who occupied that room was unable to give any satisfactory explanation of these facts, and he was tried and convicted of the crime. The reason in an argument of this kind is seldom stated in full. The advocate relies on an implied assumption that the facts stated as evidence cannot be accounted for in any reasonable way except on the truth of the thesis. The proof of incriminating facts has the effect of shifting upon the accused the burden of showing that the facts can be explained or accounted for in some other way. The principle upon which an argument of this kind is based may be stated as follows: "Every thesis that is exclusively sufficient to explain a given set of facts is true," and the whole argument may be stated formally as follows: T: A caused the death of B; R: Because that thesis is exclusively sufficient to explain the facts A, B, C, D, etc.; P: Every thesis that is exclusively sufficient to explain a given set of facts is true. The same kind of argument is employed in a great variety of other cases, as for example in proving the existence of a glacial epoch in prehistoric times, or that Sir Philip Francis wrote the letters of Junius.

Arguments from example, from analogy

and to prove facts of causation are usually classed as inductive arguments and all others as deductive. For the distinction between inductive and deductive see the article on Logic.

Disproof, like proof, may be direct or indirect. It is direct when the reasons directly imply the falsity of the thesis, and it is indirect when the reasons imply the truth of any one alternative, or of any fact inconsistent with the truth of the thesis. Thus, the thesis in a criminal trial that the prisoner at such a time and place committed a certain offense may be disproved indirectly by the proof that the prisoner at that time was elsewhere, usually called proving an *alibi*. A general proposition may be disproved indirectly in two ways, first, by proving exceptions called *exceptive disproof*; secondly, by showing that a proposition manifestly absurd is logically deducible from it, called a *reductio ad absurdum*.

Refutation consists in showing the fallacy of an argument having regard to the requirements of proof. This may be done in two ways, first, by showing that the reason or the principle relied on, whether express or implied, is untrue. Thus, an argument from Testimony may be refuted by showing that the witness is untrustworthy, as for example, that he lacked the means or opportunity for accurately observing the facts testified to, that he was biased by interest or hostility, that his testimony is inconsistent with itself or with other facts better known or better established, that his memory is defective, that he is known to be untruthful, etc. An argument from Example may be refuted by showing exceptions to the general law sought to be proved, or by showing that the search for negative examples has not been exhaustive. An argument from Analogy may be refuted by showing points of essential difference between the things compared; an argument from Cause to Effect, by showing the operation of other causes to prevent the effect; and an argument from Effect to Cause, by showing the operation of other causes to produce the same effect. The common fallacy committed in arguments to prove facts of causation is to argue that one thing is the effect of another merely because it follows that other—*post hoc ergo propter hoc*—other antecedents of the effect besides the alleged cause being overlooked. In an argument from circumstantial evidence there is an implied assumption that the facts given as a reason cannot be explained or accounted for in any reasonable way except on the supposition that the thesis is true. The argument may be refuted by showing that the facts may be otherwise explained. The so-called "theory of the defense" in a criminal trial is usually a thesis by which the facts may be accounted for consistently with the prisoner's innocence.

Secondly, an argument may be refuted by showing that the principle and the reason, even if true, do not imply the thesis. Fallacies of this kind all involve some form of irrelevancy. Thus, in the fallacy of "evading the issue," the reasons imply an irrelevant conclusion, or in other words, the conclusion proved is not the question in dispute, but is either (1) a thesis that is like it and is intended to be mistaken for it; or (2) a thesis that is entirely different from the question at issue, the argument being often employed to distract attention from the

real issue, or as it is sometimes expressed, "to draw a herring across the trail." The argument *ad hominem* which is addressed, not to the merits of the case, but to the character, principles or conduct of an opponent; the argument *ad populum* or *ad captandum*, which consists in making an improper appeal to the feelings of those addressed; the argument *ad verecundiam* (reverence) which invokes the authority of a great name as concluding the question; the *tu quoque* argument—are all forms of the fallacy of evading the issue, as opposed to the argument *ad rem*, which is addressed to the matter in dispute. This fallacy is often committed in refutation when our opponent by way of answer elaborately disproves a proposition which we never maintained, a process which is sometimes called "setting a straw man up only to knock him down." In like manner the reason or the principle or both may be irrelevant through ambiguity of language or otherwise.

The fallacy of "begging the question" consists in attempting to prove a thesis by itself which in the course of the argument is either tacitly assumed to be true or, if expressed as a reason, is disguised in an equivalent form of words.

The fallacy of *non sequitur* (it does not follow) really includes all the foregoing fallacies of the second class, but the name is usually restricted to loosely constructed arguments, for which no appropriate name has been found. Professor DeMorgan gives the following example: "Episcopacy is of Scripture origin; the Church of England is the only Episcopal Church in England; therefore, the Church established is the Church that should be supported."

EDWIN BELL,

Member of the Canadian Bar.

ARGUNOV, ăr-goo'noff, Ivan P., Russian painter: b. 1727; was a serf of Count Sheremetyev (A. Matvyeyev's relation) and became a pupil of G. H. Grot. The date of his death is not positively known. That event occurred, we think, not in 1797, as sometimes stated, but probably later by a year or more. Despite the researches of S. Dyagilen, he still remains, as A. Benois says in 'The Russian School of Painting' (New York 1916), a somewhat obscure figure; indeed the obscurity or lack of

certainty extends to the authorship of some of the paintings usually attributed to him, one reason for such uncertainty being traceable to the circumstance that he did not hesitate to sign portraits copied from other artists' originals—in this respect adopting a practice too common among his contemporaries. Benois observes that such "mixing of copies with original work makes the estimation of his talent a difficult task. Thus it is to be regretted that we cannot be certain of Argunov's authorship in regard to one of the best productions of 18th century Russian painting, the portrait of Countess Barbara Alexeyevna Sheremetyev, which can bear comparison with the portraits of Tocqué, Rotari and Van Loo. Of course all the interest of this characteristic and soundly realistic portrait would be lost if the work proved to be Argunov's copy from the forgotten original by one of these masters." Other meritorious portraits are those of Count P. Sheremetyev, Field Marshal Boris Petrovich Sheremetyev and Countess V. P. Razumovsky. Engravings of the foregoing, with the exception of the last mentioned, were made by P. Antipiev. Almost incomparably inferior are, as a rule, other portraits of the Argunov series; yet even in the poorer work we find, besides the mere charm of the past and of interesting costumes and poses, many fine qualities, not a little purely pictorial merit—fairly good painting and sufficiently correct design. We mention finally, as by him, the 'Cleopatra' (1750) in the Roumientsef Museum at Moscow; on the Sheremetyev estate portraits of Prince Michael Golitzin (engraved by A. Radigues) and of Prince A. M. Tscherkaski; on the Ostankina estate a full-length portrait of Czar Paul I. Still other portraits attributed to him are in the Trétiakof or Tretyakov Museum at Moscow.

ARGUS, (1) a personage represented in Greek mythology as having 100 eyes, or as having his whole body covered with eyes, half of these being always awake while the rest were closed in sleep. The jealous Hera made him keeper of the unhappy Io; but Hermes lulled him to sleep with the sound of his flute and cut off his head. Hera afterward took his eyes to adorn the tail of the peacock. (2) The son of Zeus and Niobe and mythical ancestor of the Argives, and founder of Argos. (3) The builder of the ship *Argo*. See ARGONAUTS. (4) Argus, the dog of Odysseus, who recognized his master after 20 years' absence, and died of joy. (5) In Homer, the kingdom of Agamemnon, the Peloponnesus and even all Greece. Also the name of several Greek cities and towns of which Argos, capital of Argolis, was the most renowned.

ARGUS AND PELICAN, Battle of the. In the War of 1812 Capt. William H. Allen (q.v.) in the sloop-of-war *Argus* (rated as a 16 but carrying 18 24's and two long 12's) had wrought great havoc among British merchantmen in the English Channel, in a single month destroying more than 20 ships valued at \$2,000,000. Accordingly the British admiralty sent ships in pursuit, one of which, the *Pelican* (16 32's, four long 12's and one short 12), Capt. John F. Maples, overtook the American ship on 14 Aug. 1813 in the Irish Channel, off the Welsh coast. At first the *Argus*, having

the advantage of position, raked the *Pelican*, but her guns were so poorly served and so badly aimed that the *Pelican* was almost uninjured. On the other hand, the British gunnery was excellent, and soon the rigging of the *Argus* was in such condition that she became unmanageable, whereupon the *Pelican* for 20 minutes raked her at close range from the starboard quarter without receiving a single shot in return. After 43 minutes of fighting the British prepared to board the *Argus*, but the latter struck her colors, having lost six killed and 17 wounded, while the British loss was only seven killed and wounded. Allen was mortally wounded and died in a hospital at Plymouth, England. As Allen was responsible for the high degree of excellence attained by the gunners of the frigate *United States* (q.v.), the poor marksmanship of the *Argus* crew seems inexplicable unless, as some have stated, part of the crew was drunk, a brig from Oporto, laden with wine, having been captured the night before the battle. S., 'History of the Navy' (Vol. I, pp. 523-29); Roosevelt, 'Naval War of 1812' (pp. 205-09); Adams, 'United States' (Vol. VII, pp. 303-08); Mahan, A. T., 'War of 1812' (Vol. II, p. 217 et seq.); James, William, 'Naval Actions' (pp. 74-78); Wiley and Rines, 'The United States' (Vol. V, pp. 475-77); Bowen, Abel, 'Naval Monument' (pp. 69-77); Spears, J. R., 'History of Our Navy' (Vol. II, pp. 356-71).

ARGYLE, ä-r-gil', **Campbells of**, the designation of a distinguished Scottish family. Among its most noted representatives are: ARCHIBALD the 2d Earl, who was killed at the battle of Flodden, 1513. ARCHIBALD, 5th Earl, attached himself to the party of Guise, and was the means of averting a collision between the reformers and the French troops in 1559. He was commissioner of regency after Mary's abdication, but afterward commanded her troops at the battle of Langside, and died in 1575. ARCHIBALD, 8th Earl and Marquis, b. 1598, was a zealous partisan of the Covenanters, and was created a marquis by Charles I. It was by his persuasion that Charles II visited Scotland and was crowned at Scone in 1651. At the restoration he was committed to the Tower, and afterward sent to Scotland, where he was tried for high treason, and beheaded in 1661. ARCHIBALD, 9th Earl, son of the preceding, served the King with great bravery at the battle of Dunbar and was accordingly excluded from the general pardon by Cromwell in 1654. On the passing of the Test Act in 1681 he refused to take the required oath except with a reservation. For this he was tried and sentenced to death. He, however, escaped to Holland, whence he returned with a view to aiding the Duke of Monmouth. His plan failed, and he was taken and conveyed to Edinburgh, where he was beheaded in 1685. ARCHIBALD, 10th Earl and 1st Duke, son of the preceding, died in 1703. He took an active part in the revolution of 1688-89 which placed William and Mary on the throne, and was rewarded by several important appointments and the title of duke. JOHN, 2d Duke, and Duke of Greenwich, son of the above, was born in 1680 and died in 1743. He served under Marlborough at the battles of Ramillies, Oudenarde and

Malplaquet, and assisted at the sieges of Lisle and Ghent. In 1715 he fought an indecisive battle with the Earl of Mar's forces at Sheriffmuir, near Dunblane, and forced the pretender to quit the kingdom. GEORGE JOHN DOUGLAS CAMPBELL, 8th Duke, Baron Sundridge and Hamilton, was born in 1823 and died 24 April 1900. He early took a part in politics, especially in discussions regarding the Presbyterian Church of Scotland. In 1852 he became Lord Privy Seal under Lord Aberdeen, and again under Lord Palmerston, in 1859; Postmaster-General in 1860; Secretary for India from 1868 to 1874; again Lord Privy Seal in 1880, but retired, being unable to agree with his colleagues on their Irish policy. He was the author of 'The Reign of Law' (1866); 'Primeval Man' (1869); 'The Burdens of Belief' (1894); 'Organic Evolution' (1898). SIR JOHN DOUGLASS SUTHERLAND CAMPBELL, 9th Duke of Argyll in the peerage of Scotland and 2d in that of the United Kingdom, hereditary chief of the Clan Campbell, Knight of the Most Noble Order of the Garter, K. T., G. C. M. G.: b. 6 Aug. 1845; d. 2 May 1914. He was probably better known by his former title of Marquis of Lorne. He married, 21 March 1871, Princess Louise, daughter of Queen Victoria; was educated Edinburgh Academy, Eton, Saint Andrew's University and Trinity College, Cambridge. Represented Argyllshire as a Liberal 1868-78. When his father was Secretary of State for India (1868-71) he was his private secretary; he was made a privy councillor in 1875, and was governor-general of Canada 1878-83. In the Home Rule split of 1886 he separated from the Liberal party and contested Central Bradford as a Unionist in 1892. Three years later he was returned for South Manchester and sat in Parliament till 1900, when he succeeded his father in the dukedom. King Edward VII appointed him chancellor of the order of Saint Michael and Saint George; he was hereditary master of the King's household in Scotland, and at the last two English coronations he carried the sceptre and the garter. He was an honorary colonel of the Argyll and Sutherland Highlanders, the London Scottish and several other regiments. The Duke was a many-sided man, intensely Scottish and endowed with high literary talent. He wrote poetry, books on travel, imperial politics and Scottish social history. Among his best-known works are 'A Trip to the Tropics and Home Through America' (1867); 'Guido and Lita' (1875); 'Imperial Federation' (1885); 'Life of Palmerston' (1892); 'The Life and Times of Queen Victoria' (1901); 'Passages from the Past' (1907); and 'Yesterday and Tomorrow in Canada' (1910). As he left no heir the title devolved upon his nephew, Niall Diarmaid Campbell.

ARGYLLSHIRE, ä-r-gil'shîr, Scotland, a west midland county bordering on the Atlantic Ocean and the Irish Sea. It consists partly of mainland and partly of islands belonging to the Hebrides group. Total area is 3,230 square miles, including area of islets, 616 square miles. The greatest length of mainland is about 115 miles, the greatest width 55 miles. From the windings of the numerous bays and creeks with which the land is everywhere indented it has more than 2,200 miles of sea-coast. The chief towns are the capital, Inverary, Campbeltown,

Oban, Dunoon, Lochgilphead and Tobermory. The chief articles of export are sheep, cattle, horses, fish, slate and granite. One of the most important branches of industry besides sheep-grazing is the fishing of herring, cod and ling. The principal manufactures are whisky and coarse woollens. Argyllshire was anciently ruled by the Macdonalds of the isles and later by the Campbells, whose present representatives, the Duke of Argyll and the Marquis of Breadalbane, are the chief landed proprietors. Among the antiquities of Argyllshire are the celebrated monastery of Iona and the remains of a Cistercian priory in Oronsay. The most noted of its natural curiosities are the basaltic columns and cave of Staffa (q.v.). Pop. 71,000.

ARGY'RIA, or **SILVER POISONING**. See TOXICOLOGY.

ARGYR'ODITE (Greek, "like silver"), a mineral first observed at Freiberg, Saxony, and found upon analysis to contain a previously unknown metallic element, to which the name "germanium" has been given. Argyrodite has the formula $4\text{Ag}_2\text{S}\cdot\text{GeS}_2$, and crystallizes in the isometric system. It has a hardness 2.5 and a specific gravity varying from 6.08 to 6.26. It has a metallic lustre, and fresh fractures show a gray color tinged with red or violet. Its crystals are usually small and it also occurs massive. Large crystals have been found in Bolivia.

ARI THORGISSON, á-rę-tór-gęł-són, the father of Icelandic literature: b. 1067; d. 1148. He was the first Icelfander to use his mother tongue as a literary medium. His 'Islendingabók,' a concise history of Iceland from its settlement (about 870) until 1120 is preserved only in an abstract. Later Icelandic writers modeled their style upon his.

ARIA, á-rę-ą or á-ria (Ital. for "air"), musical term, equivalent to the English "air," signifying a melody apart from the harmony, but especially a musical composition for a single voice or instrument, with an accompaniment of other voices or instruments.

A'RIAD'NE, the daughter of Minos, King of Crete, who, having fallen in love with Theseus when engaged in his attempt to destroy the Minotaur, gave him a clue of thread, which served to guide him out of the labyrinth after having slain the monster. Theseus, on leaving the island, took with him Ariadne, but deserted her on the Isle of Naxos. Dionysus found Ariadne and made her his bride. Ariadne's fortunes have been a favorite subject with artists.

ARIANISM is the name given to the doctrine of the person of Christ advocated by Arius and his followers. It contained nothing essentially new, but it crystallized certain modes and tendencies of thought which had been more or less prevalent in the Church for three or four generations. (See CHRISTOLOGY). The views of Arius and the strict Arian party may be summarized as follows: (1) The Son was created out of nothing and is therefore *different in essence* from the Father. He is Logos, Wisdom, Son of God, but so only by the *grace* of God and not in and of himself. (2) There was (before time began) when he was not; that is, he is a finite being. (3) He was created before everything else, and through him the universe was created and is administered.

(4) The Logos became the soul of the historical Christ, and the human elements in the character of Jesus belonged to the Logos. (5) Although the incarnate Logos is finite and hence is not God, he is to be worshipped, since he is exalted far above all other creatures, and is both Ruler and Redeemer.

The discussions at the Nicene Council revealed the fact that there were three parties present: the strict Arians, the semi-Arians and the Alexander-Athanasian party. The latter party, with the help of Constantine and the Western bishops, secured the adoption of a creed (see CREEDS) which no strict Arian could subscribe to, since it declared that the Son is *identical in essence (homoousian)* with the Father. The semi-Arians, although they maintained that the Son was not *identical in essence*, but of *similar essence (homoiousian)* with the Father, were finally constrained to sign the document. Soon after the closing of the council the semi-Arians began to assail the Nicene creed, and finally, through the influence of Eusebius (q.v.), they secured the recall of Arius and his companions and the deposition and banishment of Athanasius. The sons of Constantine continued to favor the semi-Arian party, which included a large majority of the Eastern bishops; but the Western churches generally adhered to the Nicene creed. But the death of Constantius II in 361 and the accession of Julian left the Arian party without imperial support and Athanasius and his followers regained considerable influence in the east. The accession of Valens in 363, however, reversed the governmental policy and led to the fanatical persecution of the Nicenes. But the distracted condition of the Orient, due to the war with Persia, and the demoralized state of many of the bishoprics under Arian leadership, made it relatively easy for Theodosius the Great to espouse and support the Nicene party. A second oecumenical council held at Constantinople in 381 reaffirmed the Nicene creed with slight additions and curtailments, thus completing the victory of Nicara in favor of the full deity of the Son. Arianism was soon suppressed within the empire, but it continued for a long time to prevail among the barbarians. The conversion of Clovis, King of the Franks, to the orthodox faith in 496 was followed by a rapid decline of Arianism among the Teutonic peoples. (See ARIUS). Consult Gwatkin, H. M., 'Arianism' (in 'Cambridge Medieval History,' Cambridge 1911); Newman, J. H., 'The Arians of the Fourth Century' (5th ed., London 1888).

EDWIN KNOX MITCHELL.

ARIANO, á-rę-á-nō, Italy, town in the province of Avellino, 44 miles northeast of Naples, in one of the most frequented passes of the Apennines. In the limestone cliffs of the neighborhood caves have been hollowed out and serve as dwellings for many of the poorer classes. Earthenware is the chief manufacture. It is the seat of a bishop and contains a handsome cathedral. Pop. (1901) 17,650.

ARIAS, á-ri-ás, **Montanus Benedictus**, Spanish Orientalist and editor of the Antwerp *Polyglot*: b. Fregenal de la Sierra, Estremadura, 1527; d. Seville 1598. He was educated at Seville and at Alcalá, where he became distinguished for his proficiency in the Semitic

languages. He traveled through France, Italy, Germany, England and Holland and thus became acquainted with several modern tongues. About 1559 he took orders and attended the Council of Trent as consulting theologian to the bishop of Segovia. On his return he secluded himself in a cloister among the mountains of Andalusia in order to give his whole time to literature. Philip II drew him forth from his seclusion in 1568 and persuaded him to go to Antwerp to superintend and edit the 'Polyglot Bible,' projected in that city by the celebrated printer, Christopher Plantin. The work appeared in eight volumes folio between 1568 and 1573. Only 500 sets were printed and the greater part of them were lost at sea, on the way to Spain. The work was well received by all except the Jesuits, to whom Arias was strenuously opposed. Léon de Castro, a professor at Salamanca, brought charges of heresy against Arias because he had included much rabbinical matter in the work and the latter journeyed to Rome in 1575-76 to clear himself and was acquitted. Philip gave him a pension and made him court chaplain. He wrote several works dealing with the Bible, Jewish antiquities, etc., and also a history of nature and several Latin poems. The best known is his 'Jewish Antiquities,' attached to the 'Polyglot,' and also published separately. Consult Gorris, 'Vie d'Arias Montano' (Brussels 1842) and 'Memorias de la real Academia de la Historia' (Vol. II, Madrid 1832).

ARICA, a-rē'ka, Chile, seaport in lat. 18° 29' S. It is connected by rail with Tacna, capital of the province of that name, 45 miles distant, and so with La Paz, Bolivia; also with Valparaiso, 987 miles away. During the war between Chile and Peru it was bombarded by the Chilean forces and it passed into the possession of Chile in 1883. The chief exports were formerly silver and silver ore, copper, bark, chinchilla skins and alpaca wool; at present it is of importance as the only port in the province of Tacna and the terminus of the Arica-La Paz Railway, which carries by far the greater share of the outward and inward trade of Bolivia (q.v.). Loading and unloading is effected by lighterage, and there is safe anchorage in eight to nine fathoms behind the island of Alacran, which protects the roadstead. There are telegraphic stations, both cable and wireless. The shipping movement in normal years amounts to 400 or 500 overseas steamers and 200 to 300 coasters. Pop. (1916) about 6,000.

ARICHAT, ā-rē-shāt', Nova Scotia, seat of Richmond County. It is situated on Madame Island and is a seaport of some importance, being the centre of quite an extensive fishing and canning industry. Ships of all sizes find accommodation in its harbor, the commerce being important enough to warrant a United States consular agent. The town is the see of a Roman Catholic episcopate. Pop. about 2,500.

ARICI, ā-rē'chē, Cesare, Italian poet: b. Brescia, 2 July 1782; d. there, 2 July 1836. Under Bonaparte he was secretary of the departmental court in his native city. In 1810 he was appointed professor of elocution in the Brescia Lyceum. Later he became professor of history and literature and then professor of Latin. His chief works are 'La coltivazione

degli olivi' (1808); 'La pastorizia' (1814); 'Il campo santo di Brescia.' A collection of his works was published under the title 'Opere' (6 vols., Padua 1858).

ARICIA, or **ARICCIA**, Italy, town 16 miles from Rome, on the famous Appian Way. It is one of the most ancient communities now surviving from classical times. Its name figures in history as early as 338 B.C., when it was conquered by C. Mænius. It has an old church, built by Vernini in 1664 near where once had stood a magnificent temple to Diana.

ARID LANDS. See **DESERTS**.

ARIEGE, ā-rē-āzh', France, inland department, bounded on the south by Spain, west and north by the department of Haute-Garonne, northeast and east by Aude. It has an area of 1,893 square miles and is for the most part mountainous. The climate is mild in the south, but naturally very severe among the mountains. Wheat, maize and potatoes are the chief crops. Good vineyards and market gardens are found in the north. Flax and hemp are also cultivated. The mountains afford excellent pasture, and a considerable number of cattle, sheep and swine are reared. Poultry- and bee-farming flourish. Forests cover more than one-third of the department and harbor wild boars and even bears. Game, birds of prey and fish are plentiful. There is abundance of minerals, including lead, copper, manganese and especially iron. Iron founding and forging are the principal industries. Flour-milling, paper-making and cloth-weaving may also be mentioned. The capital is Foix. Pop. (1911) 198,725.

ARIES, a-rī-ēz, ("The Ram"), in astronomy, the first sign of the Zodiac, denoted by the sign Υ , in imitation of a ram's head. The name is probably to be associated with the fact that when the sun is in this part of the heavens (in spring) sheep bring forth their young; this finds a parallel in "Aquarius," when there is much rain. It includes the first 30° of the ecliptic, beginning from the vernal equinox. The vernal equinox, sometimes called the first point of Aries, continually changes its position among the fixed stars because of the procession of the equinoxes, moving 50.2" westward each year. For this reason the sign Aries has ceased to correspond with the constellation of the same name, as it did 20 centuries ago, when the ecliptic was divided into its 12 parts, each represented by a sign which was named after the group of stars through which it passed. At the present time the sign Aries is in the constellation Pisces, 30° westward of the original sign. It will require 24,000 years before the sign and the constellation again correspond.

ARIMATHÆA, a town in Judea and according to Saint Jerome, not far from Lydda. It is mentioned in the Gospels as the home of Joseph, a member of the Sanhedrin, who had the honor of giving the burial place for the body of the crucified Christ. Joseph of Arimathea is also mentioned in Arthurian legends as having brought the Holy Grail from Jerusalem. Its site is not definitely known, but was probably Ramah, the home of Samuel in the hill country, the modern *Er Râm*, 19 miles north-west of Jerusalem.

ARIMINUM. See **RIMINI**.

ARION, a lute player of ancient Greece, native of Lesbos. He lived about 600 B.C. Herodotus tells the story that Arion was sent by Periander, tyrant of Corinth, to Italy to compete there in a great competition for musicians and singers. Arion went and so enchanted the judges with his playing that he won all the prizes. As he was returning home on a Corinthian ship, with all his rich prizes, Apollo appeared to him in a dream and warned him that the sailors were plotting to murder him. Whereupon he asked the sailors that he be permitted to play his lute once more. This request being granted, he stood on deck and began playing, whereupon the dolphins, fascinated by his sweet music, gathered thickly about the vessel. Then as the sailors were about to slay him, he leaped overboard. One of the dolphins lifted him up on its back and swam ashore with him, landing him safely on the promontory of Tænarius, from which place he journeyed to Corinth. When the sailors arrived at Corinth they assured Periander that Arion was dead, whereupon they were confronted by him and then crucified. As proof of the truth of this story Herodotus points to the fact that there existed at Tænarus a bronze statue of Arion riding on the dolphin's back. The lute and the dolphin were raised to the constellations and the story became a tradition among the Greeks. It was said that Arion was the inventor of the dithyramb. A. W. Schlegel recites the story of Arion in one of his best poems.

ARIOSTO, *är-yōs'-tō*, **Ludovico**, an Italian poet: *b.* Reggio, 8 Sept. 1474; *d.* Ferrara, 6 June 1533. His father, who was commander of the citadel of Reggio, proposed that he should study law, but, as he showed no indication of being fitted for this profession, he was finally permitted to follow his own inclinations. These led him to the study of literature, especially the classics, and he soon developed so much ability as a poet that, as early as 1495, he wrote several comedies. Two of them were acted about 1512, and they attracted the attention of Cardinal Ippolito d'Este, who sent him as an ambassador to the court of Pope Julius II. In 1517 he offended the cardinal by refusing to accompany him to Hungary, but he immediately entered the service of Alfonso, Duke of Ferrara, by whom he was appointed governor of Garfagnana, a position which he filled successfully for several years. The last years of his life were spent in writing comedies and in completing his principal work, a romantic epic, 'Orlando Furioso,' which has been called "the greatest poem of its kind in any language." His 'Satires' in the Horatian style were not published until after his death. His last days were spent in a modest home of his own in Ferrara. It has been carefully preserved. Recent editions of 'Orlando Furioso' are those by Casella (Florence 1877), and Popini (*ib.* 1903). His minor works were edited by Polidori (2 vols., Florence 1891) under the title 'Opere minori in verso e in prosa.' The best English translations are those by Sir John Harrington (London 1591), by Hoole (*ib.* 1783), and by W. Stewart Rose (*ib.* 1823). Consult the biography by A. Cappelli, in his collection of Ariosto's 'Letters' (Milan 1887); Giosuè Carducci, 'Studi su Ludovico Ariosto e Torquato Tasso' (Bologna 1905); Gardner

'The King of Court Poets: Ludovic Ariosto' (New York 1906), and De Sanctis 'Storia della Letteratura Italiana,' edited by B. Croce (Vol. II, Bari 1912). See ORLANDO FURIOSO.

ARISTÆ'US, a divinity of ancient Greece widely worshipped, but of whom few details are known. From what is known of the few fragments of the traditions of the period surviving in historic records, he was supposed to be the son of Apollo and Cyrene, the latter being the granddaughter of the river god Peneus. She was delivered to Aristæus on the coast of Libya. Another record has him born in Thessaly where he became the pupil of Chiron, the centaur. Numerous such stories survive, each probably representing a local tradition. Aristæus was the protector of the hunters and herdsmen and also was credited with having taught bee-keeping and the spinning of wool. All the traditions assign to him good qualities, as his name signifies.

ARISTAG'ORAS, *satrap* of Miletus. He was the son-in-law of Histæus, whose influence at the Persian court obtained for him his position, in about the year 500 B.C. He attempted to conquer Naxos for the Persians, but failed. Anticipating punishment for his failure, he made a tour of the Ionian cities and persuaded them to join a general revolt against the rule of the Persians. He next appealed to Sparta, without success, but the Athenians came to his assistance with 25 ships and an army. At the head of the Greek allies, he attacked Sardis, 499 B.C. and burned it. But the Persians finally defeated him and he fled to Thrace, where he was put to death by the Edonians.

ARISTAR'CHUS, ancient astronomer, native of Samos, who lived in about the middle of the 3d century B.C. He was known as the chief exponent of the heliocentric theory of the universe; that the sun stood still and the earth and the rest of the universe revolved around it. Because of this he was accused of heresy. He was supposed to have written extensively on his science, but all that survives is a short essay on the sizes of the sun and the moon and his estimates of their distances from each other and from the earth. He was the first to attempt to work out this problem by trigonometry, but on account of not having accurate instruments for measuring his estimates were inaccurate, though his theory was sound enough. This essay was first published by Valla, in Latin (1498). Later it was issued in Greek and Latin by Wallis (1688). Consult Heath, 'Aristarchus of Samos, the Ancient Copernicus' (Oxford 1913).

ARIS'TEAS, a fabulous character of the ancient Greeks, sometimes styled the "Wandering Jew" of ancient Greece. He was accredited with supernatural powers, one of his practices being to leave his body and re-enter it at his own free will. It is therefore not surprising that he has been reported to have lived at various times over a period covering several centuries. His first appearance is as the teacher of Homer. Then, some generations afterward, he is born on Proconnesus, an island in the Sea of Marmora. Next he pays a visit to the Hyperboreans. On his return he dies. But a traveler reports having met him some time afterward and being accosted by

him. Seven years later he appears in the rôle of an author, and during this incarnation he composes an epic poem called 'Arimaspiæ,' which was copied by Herodotus and other writers of a later period. Over 300 years later he reappears in Metapontum, in southern Italy, where he advises the people to build an altar to Apollo, assuring them that Apollo had founded the city, for he had been present in the form of a raven and assisted at the ceremony. Consult Rohde, 'Der griechische Roman' (Leipzig 1900).

ARISTEAS, an official of Ptolemy Philadelphus, who is said to have sent him to Jerusalem, 273 B.C. with the mission of obtaining from the high priest there, Eleazar, a copy of the Pentateuch. Consult Schürer, 'Geschichte des jüdischen Volkes' (Vol. II, p. 819, 1886).

ARISTIDES, ár'is-tí-déz, Ælius, ancient Greek orator: b. Hadrianoi Mysia, 129; d. Smyrna, 189 A.D. His father was Eudemon, a priest in the temple of Zeus. He was a pupil of the most famous rhetoricians of the period, among his teachers being Herodes Atticus of Athens and Aristocles of Pergamus. Having finished his education he made a journey through foreign countries, visiting Asia and Egypt and Italy. In Rome he gained the favor of the Emperor, Marcus Aurelius, over whom he maintained so powerful an influence that he was able to persuade him to rebuild Smyrna at Roman expense, the city having been destroyed by an earthquake. There are extant two rhetorical treatises and over 50 speeches ascribed to him, among the latter being six 'Sacred Speeches,' reporting the words of Æsculapius through his priests. The speeches of Aristides are often quoted as samples of Attic style. The writings ascribed to him have been edited by Dindorf (3 vols., Leipzig 1829). Consult Sandys, 'A History of Classical Scholarship' (Vol. I, Cambridge 1906).

ARISTIDES, Quintilianus, a famous Greek grammarian probably of the 3d century A.D., whose treatise on music is esteemed the most valuable of all ancient writings upon that theme. It was printed by Meibomius in his 'Antiquæ Musicæ Auctores Septem' (Amsterdam 1652) and was edited by Jahn in 1882. Consult Cäsar, 'Die Grundzüge der griechischen Rythmik im Anschluss an Aristeides' (Marburg 1861); Goodell, T. D., 'Chapters on Greek Metric' (New York 1902); Pauly-Wissowa, 'Realencyclopädie' (Vol. II, 894).

ARISTIDES, Saint, famous Greek convert to Christianity, who lived in about the 2d century A.D. In 1889 Dr. J. R. Harris found a complete copy of an 'Apology' for the Christian faith, written by Aristides, on Mount Sinai. It was a Syriac version of the original and was addressed to the Emperor Titus Hadrianus Antonius Augustus Pius. Previously only a fragment of this writing had been in existence, published in Venice (1878). Consult Harris, 'The Apology of Aristides' (in his 'Text and Studies,' 1891).

ARISTIDES, of Thebes, ancient Greek painter, who lived in about the middle of the 4th century B.C. He learned his art from his father, Nicomachus. His works brought very high prices. One of his most famous pictures was a great battle scene, showing over a hundred figures. His power of expression was

best shown in the picture of a woman, lying wounded on a battlefield, fearfully attempting to hide the blood on her breast from her nursing child.

ARISTIDES THE JUST, an Athenian statesman: b. near the middle of the 6th century B.C.; d. about 468 B.C. He was the son of Lysimachus and belonged to one of the great Athenian families. He was one of the 10 generals of the Athenians when they fought against the Persians at Marathon, 490 B.C. According to the usual arrangement the command of the army was held by each of the generals in rotation for one day. But Aristides prevailed on his colleagues each to give up his day to Miltiades; and to this, in a great measure, must be ascribed the victory of the Greeks. In the following year he was elected chief archon. His policy aimed at constituting Athens as a land power and this brought him into direct conflict with Themistocles who advocated a naval policy. The conflict ended in the ostracism of Aristides about 485 B.C. A story is told that on the day of the voting, an ignorant voter asked Aristides himself to write the name "Aristides" upon his ostrakon. The latter asked him if Aristides had wronged him; to which the voter replied that he did not even know Aristides, but was irritated to hear him everywhere called "the Just." In 480 a general amnesty was decreed at Athens because of the threatening Persian invasion and Aristides returned to Athens and was elected strategus for 480-79. He loyally supported Themistocles in the Salamis campaign and annihilated the Persian garrison on the island of Psyttaleia. In the following year he commanded the Athenian forces at Plataea and arranged for the celebration of the victory over the Persians. About 477 Aristides commanded the Athenian fleet off Byzantium and, after the Ionian allies revolted from Pausanias, was offered the chief command and given full powers to fix the contributions of the newly-founded Delian League. His assessment was deemed most equitable and it is probably from this that he gained the title of "the Just." Soon afterward he yielded his command to his friend Cimon and returned to Athens where he continued to occupy a prominent place. Many ancient writers have represented Aristides as a democratic reformer, but there appears little justification for this as the period during which he shaped the national policy was one of conservative tendency. His estate suffered during the Persian invasions and he died poor, not leaving enough money to pay the expenses of his burial. A son and two daughters survived him and received state pensions. He was buried at Phalerum. Consult Herodotus VIII, 79-81, 95; IX, 28 Plutarch, 'Aristides' (translated by B. Perrin, New York 1901); Nepos, Cornelius, 'Vita Aristidis'; Meyer, E., 'Geschichte des Altertums' (Stuttgart 1901).

ARISTIDES, Apology of, a popular Christian theology written by Marcianus Aristides, an Athenian philosopher, in the 2d century A.D. (according to Eusebius, Hist. eccl. IV, 3). Little was known of the work until 1891 when Harris and Robinson published a complete Syriac version and proved at the same time that the greater part of the apology is contained in the legend of Barlaam and Joso-

phat extant in many Greek manuscripts and numerous translations. Since that time much attention has been paid to the work. It is addressed to Antonius Pius and has points of contact with the 'Kerygma' of Peter, the 'Shepherd' of Hermas, the 'Didache' and Justin, but more especially with the letter to Diognetus. After speaking of the true idea of God (chap. I) it takes up the origin of those nations which followed error and those which followed truth. The barbarians are treated in Chapters III-VII; the errors of the Hellenes in VIII-XIII, with an excursus on the Egyptians (XII). Chapter XIV is devoted to the Jews; and XV-XVII speak of the Christians, especially of their life and customs, in an attractive and instructive manner. Through the 'Apology' the name of Aristides gained a certain literary popularity among the Armenians. A homily 'On the Call of the Thief and the Answer of the Crucified' (Luke xxiii, 42-43) and a fragment of a letter 'To All Philosophers' are ascribed to him. Other names from the old Christian literature besides that of Aristides were applied to the literary frauds in Armenia from the 5th to the 7th century (cf. Conybeare, F. C., in *The Guardian*, 18 July 1894). The Greek and Syriac texts (the latter from a manuscript of Mount Sinai) were published by Harris and Robinson in 'Texts and Studies' (Vol. I, Cambridge 1891), translation of which appeared by Kay, D. M., in 'Ante-Nicene Fathers' (Vol. IX, pp. 259-79), and the Armenian text by the Mechitarists at Venice in 1878). Consult Harnack, 'Litteratur' (Vol. I, p. 96, 1893); Harris, J. R., 'The Newly Recovered Apology of Aristides, its Doctrine and Ethics' (London 1891); Picard, M., 'L'Apologie d'Aristide' (Paris 1892); Seeburg, R., 'Der Apologet Aristides' (Erlangen 1894); Robinson, J. A., 'Apology of Aristides' (Edinburgh 1896); Krüger, 'History.'

ARISTIPPUS, a disciple of Socrates, and founder of a philosophical school among the Greeks, which was called the Cyrenaic, from his native city Cyrênê, in Africa; flourished 380 B.C. His moral philosophy differed widely from that of Socrates, and was a science of refined voluptuousness. His fundamental principles were that all human sensations may be reduced to two, pleasure and pain. Pleasure is a gentle, and pain a violent, emotion. All living beings seek the former and avoid the latter. Happiness is nothing but a continued pleasure, composed of separate gratifications.

ARISTOBULUS, Jew of Alexandria, who lived about 180 B.C., in the time of Ptolemy VII, whose teacher he was supposed to have claimed to have been. The work which brings his name down to modern times and of which only parts are still in existence was a commentary on the Pentateuch, in which he attempted to prove his theory that much of the literature of ancient Greece had been borrowed from that book. To uphold his view he quoted copiously from works supposed to have been written by Homer, Orpheus, Linus and Hesiod. He has been the subject of much controversy, many scholars, including Renan, Eichhorn, Wendland and others, contending that his work was not genuine. Their arguments are mainly based on the peculiar forms of the quotations and the supposed claim of Aristobulus to be the teacher of Ptolemy. On the other hand

such authorities as Vlackenaer, Freudenthal, Clemen, Schlatter and Schürer maintain that Aristobulus may have taken his Greek quotations from some older Jewish writer, which would account for the similarity of their style to the Old Testament. A full discussion of the subject, together with a bibliography, is given in Schurer's 'Geschichte des jüdischen Volkes' (Vol. III, p. 512, 4th ed., 1909).

ARISTOBULUS I, prince of Judæa, son of John Hyrcanus, the high priest, whom he succeeded 104 B.C. His mother had been given the royal title, but on his father's death Aristobulus threw her into prison and allowed her to starve to death. He then assumed the kingly office as well as that of high priest. He was very much disliked by his people on account of his brutality, not only against his mother but his brothers as well, whom he caused to be murdered at the behest of Queen Salome. It is said that he was strongly inclined toward the Greek pagan worship, but on the other hand Josephus declares that he conquered a great deal of Iturean territory and forced the people to accept the Jewish faith. His reign lasted not over a year, when he died of an acute disease. Consult Welhausen, 'Israelitische und jüdische Geschichte' (p. 256, 3d ed., 1901).

ARISTOBULUS II, Jewish priest and ruler, son of Alexander Jannæus and Salome Alexandra, the widow of Aristobulus I (q.v.). He lived during the 1st century B.C., dying in the year 49. His brother, Hyrcanus II, was the rightful ruler and high priest, but Aristobulus succeeded in ousting him from both offices and installing himself, 69 B.C. The deposed brother appealed to Pompey, and after much indecision and intriguing Pompey finally declared himself against the usurper. In 63 B.C. Aristobulus' resistance was overcome and he himself was taken a prisoner to Rome. Seven years later he escaped, returned to Judæa and again raised an army against Rome. Again he was defeated and taken prisoner to Rome. Cæsar released him in 49 and sent him with the Roman troops to Judæa against Pompey, but some months later he was murdered by adherents of Pompey by means of poison.

ARISTOBULUS OF CASSANDRIA, ancient Greek historian; b. Chalcidice, about the middle of the 4th century B.C. In about 316 B.C. he went to Cassandria and became a citizen there. He accompanied Alexander the Great on his campaign into Asia. With this experience as a basis he wrote an historical work, the title of which remains unknown. Its text is preserved through the quotations of later writers, among them being Strabo, Plutarch and Arrian.

ARISTOCRACY.—(Greek ἀριστοκρατία from ἀριστος best, and κράτος, power). Etymologically, the rule of the best, but in its more usual significance, any system of government in which the right to govern is vested in a few; an oligarchy. From its strict political meaning and the fact that most aristocracies have been hereditary, it has taken on the secondary significance of any hereditary caste which has claimed or has been accorded a superior rank in social matters. The ancient Spartan state, the Athenian state before the Persian wars, the Roman republic are good

examples of communities where the aristocratic tendencies predominated. Though mediæval feudalism involved the existence of privileged classes, the dominating aspect of the system was a graduated hierarchy of absolute monarchs. It is on the break-up of feudalism and the origin of the Italian city-state or the subordination of the French and British petty lords to the king that we see the nobles again assume power by virtue of their membership of a privileged class and not by virtue of their territorial rule. When a weak monarch or dynasty came on the throne, as was the case with the house of Valois in France or the four Georges in England, it became easy for vigorous noble families to assume the real control of the state. At present the aristocratic system of rule survives in greatest measure in Germany and Austria-Hungary; in Great Britain the aristocracy has political power not so much through its constitutional position in the House of Lords as through the custom in many noble families of standing as candidates for seats in the House of Commons and the political prestige which attaches to their rank. See GOVERNMENT.

ARISTOLOCHIA, *ar-is'tō-lo-ki'ā*, a genus of plants of the family *Aristolochiaceæ*, consisting of 180 species, mostly climbing, natives of tropical regions, a few occurring in temperate countries. The plants are remarkable for their curious flowers, the corolla-like calyx of which is tubular and usually variously bent and often showy. Many of them are cultivated, the best known being the Dutchman's pipe (*A. macrophylla*), a native of the southeastern United States, and the goose-flower, pelican-flower or swan-flower (*A. grandiflora*), native of tropical America, whose flowers bear a singular resemblance to a bird. The roots of some species are used in medicine, for example those of *A. serpentaria*, Virginia snake-root, native of the eastern United States, and of *A. clematitis*, birthwort, a European species.

ARISTOPHANES. Modern comedy derives by way of Plautus, Terence, and Molière from the so-called New Comedy of Menander and his contemporaries. The so-called old comedy, of which Aristophanes is the only surviving representative, flourished 100 years earlier at the time of that Peloponnesian War which shook Greek civilization as the European War shakes that of Europe. There is no good single modern analogue of the old comedy. It is a blend of Shakespeare's 'Midsummer Night's Dream' with Bernard Shaw, musical comedy and a *revue de fin d'année*. It is extravaganza combined with the dramatic criticism of ideas and set off with occasional flights of true poetry and wood notes wild. So at least it appears in Aristophanes, who in native genius and spontaneous mastery of expression ranks with the four or five supreme poets of Greece. Though Aristophanes was easily the foremost representative of the old comedy, the extant fragments of his contemporaries, Eupolis, Cratinus and others, indicate that he found this comedy an already established literary form. It was presumably, like everything else in the world, an evolution. The performance of comedies at the winter and spring festivals of the wine god, Dionysus (the Lenæa and the Greater Dionysia) was for the Athenians a ceremony of the state religion. But modern attempts to

trace the processes of the origin of comedy in primitive rites, revels and superstitions, and its development in imitation of tragedy are, in the absence of evidence, merely conjecture masking as science. They distract our attention from the broadly human literary aspects of that comedy and throw into false perspective the life, thought, politics and civilization of Periclean Athens, which were its real shaping environment.

Apart from his 11 extant plays little is known of Aristophanes' life. His first play, the lost 'Banqueters,' was produced in the year 427, like other of the earlier plays under the name of another comedian because, as Aristophanes tells us, in 'The Clouds' and in 'The Wasps' he was still too young to woo public favor in his own name. Whether this is literally and historically true or not it implies that he was a young man in 427 and may have been born between 448 and 455. His last extant play dates from 388 and he is supposed to have died between 385 and 375. An obscure jest in his 'Knights' implies that he was in some way connected with the island of Ægina, recently conquered by Athens—possibly because his father held an allotment of land there. The praise of country life and the pictures of rustic types in his plays indicate familiarity with the rural life of Attica and perhaps sympathy with the sturdy farming class, the backbone of sane, conservative democracy. But until the siege penned them within the long walls many Athenian families lived by preference on their country estates, and we need not assume that the lover of the country was himself a farmer or a bidder for the farmer's vote. In any case, Aristophanes is no less familiar with the city and the life and gossip of the young bloods about town. Plato in the 'Symposium' depicts him as dining with Agathon and in the company of that Socrates whom he had lampooned in his 'Clouds.'

His criticism of life and that of the old comedy generally is on the whole conservative, with many lapses into irresponsible and inconsistent buffoonery. He satirizes in strangely modern style the new thought, the new education, the new music, the new poetry, the new liberal theology, the new radical democracy and its demagogues. Modern critics, in reaction against naive older interpretations, warn us not to take too seriously the criticism of life of one whose main purpose was to make the people laugh. The psychology of the possible mixture of motives is ingeniously analyzed in Browning's 'Aristophanes Apology.' The predominating conservatism of Aristophanes may be due in part to the natural tendency of comedy to satirize the newness and in part to a genuine conviction that the progressives were moving too fast and that "Athens was dying of the triumph of the liberal party." It was not sympathy with the reactionary plots of the young aristocrats with whom Plato shows him in familiar association. Aristophanes was a true patriot and a sincere if critical democrat.

The first extant play, 'The Acharnians,' 425, turns on the fancy of a militant pacifist's establishing a private peace for himself while the state is at war. This happy thought is hotly debated in the first half of the play, and in the second half illustrated by farcical scenes of contrast between the riotous living of the

pacifist and the bread ticket diet of the war party. This way of composition gives the formula of many Aristophanic comedies. 'The Knights' (424), named from its chorus, is an open assault on the demagogue, Cleon, who is outfaced by a still more scurrilous ruffian who fights fire with fire. Aristophanes elsewhere informs us that Cleon dragged him or the poet who produced his lost 'Babylonians' into court on a charge of treason.

'The Clouds' (423, 2d. ed., 422) is a gross caricature of Socrates treated as representative of sophistry, the new education, atheism, and the new science of nature. The chorus of clouds symbolizes the mists of the new thought. In the second edition Aristophanes bitterly reproaches the audience for not giving the prize to this cleverest of his comedies. See CLOUDS, THE.

The happy thought of 'The Wasps' (422) is the institution of a court in a private house to satisfy the litigious mania of an old professional jurymen, Love-Cleon, whose dashing son Hate-Cleon has vainly attempted all other means of restraint. The first case brought before the court is the trial of the house dog for stealing a Sicilian cheese, a motive borrowed by Ben Jonson. The chorus of wasps symbolizes jurymen and native children of the soil as they explain:

"Do you wonder, O spectators, thus to see me
applied and braced,
Like a wasp in form and figure, tapering inwards
at the waist?
We on whom this stern-appendage, this
portentous tail is found,
Are the genuine old Autochthons, native children
of the ground!" (Rogers)

Many of the scenes are pure farce. In its larger purport the play may be a conservative satire on that palladium of advanced democracy, the huge popular courts in which from 500 to 2,000 jurymen as judges of both law and fact gave irresponsible decisions according to their own good pleasure and the plausibility of the orators.

'The Peace' (421) develops still further the motive of protest against the Peloponnesian War. Poor Peace has been buried out of sight, but the farmers and other men of good will with a long pull and a strong pull all together draw her forth and celebrate with wild revels her nuptials with their worthy leader Trygæus, who had sailed not across the ocean, but up to heaven on a black beetle in order to find out how to get the boys out of the trenches.

After 'The Birds' (414) the year 411 yields two comedies with similar motives. In 'The Lysistrata' the women of all Greece plot to enforce a peace by divorce from bed and board. In 'The Thesmophoriazusaë,' a licentious picture of the women celebrating the festival of Demeter is converted into a literary satire of Euripides, whom the women condemn for his well-known misogynism and whose representative caught spying upon them, they arrest and hold as a hostage. After 'The Frogs' (405), 'The Ecclesiazusaë' or 'Ladies in Parliament' (393) portrays the women of Athens seizing the reins of government and establishing a communism and community of wives, the relation of which to Plato's 'Republic' has been endlessly discussed. 'The Ploutos' (388) in its present form presents a tamed and subdued comedy of transition shorn of the

chorus. The blind god of wealth recovers his sight by incubation in the temple of Æsculapius and the consequences are portrayed in scenes which caused the play to be much used as an edifying school book in the Renaissance and after. An earlier edition of 'The Ploutos' (408) is supposed to have been charged with political allusions to the restoration of wealth to Athens by the victories of Alcibiades. See BIRDS, THE; FROGS, THE.

The best complete translation of Aristophanes is that which accompanies the separate plays in Roger's edition. Convenient and accessible is the reprint in Morley's Library of Frere's racy rendering of 'The Acharnians,' 'The Knights' and 'The Birds.' Murray's translation of 'The Frogs' is masterly. No formal and printable translation can recreate the atmosphere of an Aristophanic comedy—the cumulative hilarity of the exuberant rush of puns, surprises, local hits and topical song allusions. Only an impressionistic viva voce version, compact of up-to-date analogies and equivalents, could approximate to that effect, and such a rendering, if printed, would lose its flavor and become more obsolete than Aristophanes himself in a decade. All histories of Greek literature give a chapter to Aristophanes. Croiset's 'Aristophanes and the Political Parties at Athens,' translated by James Loeb (London and New York 1909) is an admirable and very readable monograph. Consult also Conybeare, F. C., 'A Message from Aristophanes' (*Open Court*, Vol. XXX, pp. 41-59, Chicago 1916); Courtney, W. L., 'Aristophanes, the Pacifist' (*Fortnightly Review*, New York 1916); Petrie, R., 'Aristophanes and Socrates' (*Mind*, London 1911); Todd, O. J., 'Quo Modo Aristophanes Rem Temporalem in Fabulis Suis Tractaverit' (Harvard Studies in Classical Philology, Cambridge, Mass., 1915).

PAUL SHOREY,

Greek Department, University of Chicago.

ARISTOPHANES, The English, a name frequently applied to Samuel Foote (q.v.), also called "The Modern Aristophanes," because of his abundant good spirits and skill in unsparing ridicule. Garrick was a common object of his wit.

ARISTOPHANES, The French, a name sometimes applied to the French dramatist, J. B. P. Molière (q.v.).

ARISTOPHANES' APOLOGY, a poem by Robert Browning (q.v.), published in 1875; the title being in full, 'Aristophanes' Apology; Including a Transcript from Euripides: Being the Last Adventure of Balaustion.' It is a sequel to the poem 'Balaustion's Adventure.' A long work in blank verse, it commemorates the defense made by Aristophanes of his comic art, on learning through Sophocles of the death of Euripides, the tragedian. An extensive article on it may be found in Berdoe's 'Browning Cyclopædia' (1892), with a glossary of terms, etc.

ARISTOPHANES OF BYZANTIUM, Greek grammarian: b. about 262 B.C.; d. about 185. He was educated under Zenodotus at Alexandria, and became the chief librarian of the great Alexandrian library. Ancient critics rank him among the most celebrated critics and grammarians. He deserves great credit for his services to the Greek language and litera-

ture. With Aristarchus, he was the principal expert in determining the so-called Alexandrian canon of the classical writers of Greece. He invented a series of critical signs, and greatly improved the notation employed in prosody, including accent, quantity and breathing. His publications include important critical editions of Greek writers, particularly of Homer—the first of its kind—Hesiod and the lyricists Alcæus and Pindar. For the plays of the tragic and comic poets he wrote introductions. Little of what he wrote is extant, save fragments in the scholia of the poets, some *argumenta* to the dramatic writers, and a part of the *Λέξεις* ('Glossary'). Consult Nauck, 'Aristophanis Byzantii Fragmenta' (1848); Sandys, 'A History of Classical Scholarship' (Vol. I, pp. 126–131, Cambridge 1906).

ARISTOTELIANISM. Aristotle is the first philosophical writer to make a strict separation of the branches of philosophy. His writings, in terms of their subject matter, fall into the following groups: Logic, Metaphysics, Physics, Ethics, Politics and the Philosophy of Art. A classification made by Aristotle, but not applied to the arrangement of his writings, is: (1) theoretic philosophy; (2) philosophy of conduct; (3) philosophy of production, that is, of art. The analysis of the problems and subject matter of philosophy and science begins with him. In Plato's writings the various problems are fused together and treated integrally and synthetically in an ethico-metaphysical system.

Logic.—For Aristotle logic is a methodology of science, a propædeutic to the other disciplines. It is not strictly a science, because science has some essence or aspect of reality for its subject matter, while logic is concerned with the forms of knowing. Formal logic was founded by Aristotle and almost completely developed by him. Its chief feature is the doctrine of the syllogism, the process of reaching scientific or apodictic conclusions. The syllogistic process is a deductive process, that is, it derives particular conclusions from general principles or accepted premises. The possibility of deriving such conclusions rests upon the axiomatic principles of contradiction and the excluded middle, that is, two contradictories cannot at the same time and in the same reference be true; and of two contradictory propositions, one must be true and the other false, and a third intermediate proposition is excluded. The logical treatises were grouped together by Aristotle's successors and called the *Organon* or instrument of science. The several treatises consist of the *Categories*, the *Hermeneutics*, the *Analytics* and the *Topics*. The *Categories* discuss simple terms; the *Hermeneutics* discuss the combination of terms with a predicate, that is, the judgment or proposition; and the *Analytics* and *Topics* discuss the combination of propositions in the syllogism. The syllogistic conclusion is the derivation of one judgment from another by means of a middle term. The notion, judgment and conclusion are the three elements with which formal logic operates. The categories, or general notions under which reality is viewed, are enumerated by Aristotle as substance, quantity, quality, relation, place, time, position, possession, action, passion. These ten categories are

evidently not derived from any single principle and are neither exhaustive nor mutually exclusive. Aristotle's main interest is in the syllogism; simple terms or notions and the judgment are scantily treated. His treatment of the syllogism is practically exhaustive. Modern logic has supplemented his work by adding to his theory of the categorical conclusion, which was his chief interest, the theory of hypothetical and disjunctive conclusions; further, by adding a fourth figure to his three, and lastly by developing the theory of inductive logic and the method of the sciences. Aristotle regards deductive logic as the only method that can furnish demonstration or apodictic conclusions. Science, however, would not be possible with syllogistic demonstration alone, for if all our premises had to be proved we should be forced into an endless regress. Therefore, science must accept certain fundamental principles as its axiomatic postulates. From these accepted postulates scientific proof proceeds by deduction. In addition to this Aristotle mentions the further method of induction without elaborating it, saying, however, that universal principles are secured by it from particular instances and that it has the advantage over deduction by being nearer to our sense experience and therefore more generally intelligible. On the other hand, he insists that a complete knowledge of particulars is necessary to a completely certain induction, and this, owing to the multiplicity of particulars, being rarely possible, induction lacks in its conclusions the cogency of the deductive syllogism.

Metaphysics.—First Philosophy (the term *Metaphysics* is not used by Aristotle, but is a word applied to the First Philosophy on account of its being placed after the treatises on Physics by the early editor of the works) is the philosophy of first principles as such; second philosophy or physics is the philosophy of these principles applied to concrete phenomena, the phenomena of motion and matter. Aristotle is a disciple of Plato and, like his master, he viewed the world from the standpoint of teleology. The cosmic processes are determined by final causes. He makes more of facts than Plato does, has a much larger mass of empirical data for his constructions and is more catholic in his scientific interests. His metaphysics, however, like Plato's, is based on high speculative ideas and he explains the world-order by means of these general and ultimate principles, so that he is not a realist in the sense of confining reality merely to particular facts. Like Plato, he sought the essence of phenomena in the concept and law, but unlike Plato he sought it in a concept given in the phenomena as their inner principle of development and not in a transcendent principle. If there is no concept or universal there can be no scientific knowledge. The concept is not, however, an idea isolated from particular things, but as the universal reality it is immanent in particulars (*universalia in re not ante rem*), the individual being the only self-existent real. Against Plato's doctrine of ideas Aristotle brings the following criticisms: (1) The Platonists furnish no adequate proof of the existence of ideas as hypostasized entities; (2) The Platonic ideas, because transcendent, cannot explain the phenomenal world, which is left without a principle of motion; (3) The world of ideas

is only a reduplication of the world of sense in its generic aspect; (4) The explanation of the relation of the ideal to the sensible world by the terms archetype, pattern, image, etc., is only metaphorical. The universal is real as the formative principle in things, giving to them their generic character, while matter is the principle of individuality. Form and matter are explanatory of genus and individual. In every particular thing, with the exception of God or the Prime Mover (who is pure form), the two principles of form and matter are present; form making the classification of things and scientific knowledge possible, and matter making possible the concreteness of objects. Form and matter are two aspects of individual things and are not really, but only notionally, separable. Everything is both form and substrate, idea and matter, significance and stuff, soul and body, with the single exception of the Supreme Being. Form is the moving principle of development and matter is the passive potentiality. Plastic stuff or matter is molded after generic patterns. In nature's processes Aristotle calls them energy and potentiality. The real is an explication of a prior potential. The transition of a thing from a condition of potentiality to a condition of actuality is accomplished by some form of motion. Motion in turn (which is of several kinds: spatial, that is, locomotion; qualitative, that is, transmutation of substances; quantitative, that is, growth) implies a moving cause, and any given moving cause an antecedent cause and so the causal regress would be endless, were we not to posit a Prime Mover or uncaused First Cause. The First Cause is the origin and source of all motion and life. As motion is eternal, so the Prime Mover is eternal; it is also immaterial, passionless and motionless, for the Prime Mover causes motion merely as an ideal toward which matter strives in the processes of nature, analogously to the power of attraction in beauty. The activity of God is pure thought or thought turned upon itself, which theoretic life is for Aristotle the perfect type of life. Between God, as pure form, and matter, as formless stuff—the extreme cosmic principles—Aristotle places the world of natural phenomena, which are all composites of the two principles. His doctrine of the Prime Mover is a direct product of his philosophy and is the first attempt to found a theistic theory on a philosophical basis. Aristotle specifies as the four causes operative in nature the formal, final, efficient, and material. But as form contains within itself the principles of efficiency, purpose and meaning, these four causes are reducible to his dualism of form and matter. As an example of his application of the four causes, a statue presupposes: (1) matter, for example, clay, wood or marble; (2) a form or idea in the artist's mind; (3) an efficient cause, such as the energy applied to tools; (4) a motive or purpose.

Physics.—While the metaphysics treats of being as such, of the unconditioned, of the ultimate principles explanatory of reality, Physics treats of the contingent, the conditioned and of the quantitative and qualitative relations of things. In the philosophy of nature's phenomena, the concept of motion plays the chief rôle, effecting the transition of potentiality to actuality and having its ultimate source in the

Prime Mover. The whole of growth and development proceeds from one form of being to another form of being, but not from nothing to something, or from non-existence to existence. For Aristotle as for all the Greek philosophers the maxim holds: *ex nihilo nihil fit*. Inert matter is the most formless element in nature and man is the stage in which the highest form manifests itself. Between these nature exhibits a graded scale of development, that is, from the most inorganic to the highest organism. This scale itself is static and not a scale of evolution in the modern sense. The scale of beings is a fixed cosmic hierarchy, not determined by protoplasmic conditions plus environment. The Aristotelian world is a teleological system, the eternal forms working themselves out in plastic and contingent matter with reference to fixed final goals, the whole exhibiting plan, not planless, as Aristotle says, "like a bad tragedy." As the Prime Mover is perfect so the world shows that degree of perfection which is possible with the contingency and imperfection of matter. God is both *in* the world and *outside* of it as the transcendent cause of its order, just as the discipline of an army is in the army and outside of it in the person of the general. The universe is conceived by Aristotle to be spherical in form, not infinite. Its periphery consists of the region of the fixed stars, which revolve in a perfectly circular motion. They do not move freely in space, but are attached to the ethereal body of the outer heaven and move as a rider in a chariot. Their motion is caused immediately by the Prime Mover and being nearest to him, their motion is most perfect. The earth is at the centre of the universe and is fixed. Between the centre and the circumference are the seven planets, including the sun and moon. The motion of these, although concentric with the circumference, is less perfect, deviating from an exact circle. The earth is the region of rectilinear motion. The general presuppositions of motion are space and time. Space is, in Aristotle's conception, strictly speaking, only place, that is, it is the room occupied by body, and time is the measure of motion with reference to earlier and later. Motion being endless, time as the measure of its discrete moments is infinite. Space is finite, for there is no space outside the corporeal world. The elements in the cosmos are fire, earth, air, water and ether. Of these the first four are sublimatory. The celestial spheres consist of pure ether.

Psychology.—Aristotle defines soul as the "complete realization of a body endowed with the capacity of life." Every body, therefore, that has life, has soul, and psychology in the narrow sense would be a branch of biology. The physical world, according to Aristotle, is divided into two realms, the inorganic and the organic. The characteristic mark of the latter is the possession of life, or "soul." Soul is synonymous with the principle of life, by virtue of which a thing is endowed with the power of self-movement. Life is the universal form of organic activity, feeling and reason are specific forms of the same power. The highest manifestation of psychical activity is rational thought. There are four main forms in which life manifests itself: (1) Nutrition, growth, decay and the power in things to reproduce,

each after its kind, whereby the continuity of life is maintained; (2) locomotion; (3) sensation; (4) reason. These various types of life are forms of self-movement. The first form is found in the plant world as well as in the animal world, the last three only in the animal world. Soul as life is found in every part of the body, to which it is related as form to matter. The heart as the anatomical and physiological centre is also the life-centre. The heart, therefore, and not the brain, is the organ of consciousness, for consciousness is one of the forms of life. The processes of knowing or conscious life are developed in these stages: (1) sensation; (2) imagination, the power of using images of absent objects, combined with memory; (3) rational thought. Reason, according to Aristotle, is two-fold, creative and passive. All knowledge, in the last analysis, is derived from sense-perception. The mass of sense-perceptions which are held together by memory and stored in the central sense (*sensorium*) are the passive reason, that is, they constitute the matter which the creative reason transforms into conceptual knowledge. The two stand related to each other, therefore, as form to matter, actuality to potentiality.

Ethics.—The ethics of Aristotle consists mainly in a theory of the final end of conduct or the *summum bonum* and an account of the individual virtues. The chief good is happiness (well-being), which is defined as "activity of the reason in accordance with virtue in a complete life." This conception of happiness as consisting in theoretic activity is based on the peculiar function of man. Reason being the differential mark of man, his peculiar good should be discoverable in the activity of reason. Further, the good consists in the realization of the rational self in an ethical life that is complete and not of fragmentary duration, for "one swallow does not make spring." The virtues of an individual are divided into ethical and dianoëtic. The ethical virtues are liberality, temperance, justice, courage, friendship, high-mindedness, gentleness, veracity. The dianoëtic virtues are wisdom, art, insight, cleverness and such excellencies as attach to the theoretic activity, while the moral virtues are reasonableness expressed in action. Virtue is the power or persistent quality in an individual which enables him to perform his function well. Aristotle otherwise defines it as a "moral habit based on a life of deliberation, and expressed in the observance of a rational mean." The connecting link between ethics and politics is found in the social virtue of friendship.

Politics.—Aristotle gave to politics the position of an independent science, which he based on the study of over 150 actual constitutions. Politics, as the architectonic science, considers the complete good of man, for it is only in the state that man's full realization is attained, and man is by nature a "political animal." Ethics is, therefore, a branch of politics. Although the state is notionally prior to the household and village, it is preceded by them in the order of development. The state is such an aggregation of households and villages as to be self-sufficient. While it comes into being primarily for the sake of life, its growth is determined by the interests of a good and complete life. The individual is not self-sufficient. The end of the state is not power, or the protection of

life, property or industry, but the promotion of noble life in its citizens and the happiness that springs from such life. The function of the state is educational and moral. One has to keep in mind that the Aristotelian state is a city-state and not an empire. The various forms of good constitutions are: royalty (rule of one), aristocracy (rule of few), polity (rule of the entire people). The corresponding corrupt forms are tyranny, oligarchy and democracy. The best constitution under most actual conditions is the polity, a constitutional democracy, which more than any form of government embodies the principle of the mean and on the average best meets the demands of the greatest number. Under completely ideal conditions monarchy is the best form of government.

Art.—Art has for its function partly the supplementing of nature and partly the imitation of nature. Nature has left man naked and defenseless, but provided him with the "tool of tools," a hand. The useful arts serve the interests of life; imitative and decorative arts serve the ends of noble pleasure and relaxation. The Aristotelian exposition of the philosophy of art is confined almost entirely to the extant fragment of the 'Poetics,' in which scarcely more than the theory of tragedy has survived. The function of tragedy is described as catharsis. The conclusion of a tragic representation that is true to the principles of art has the cathartic effect on the spectator of purifying his emotions by the instruments of pity and fear.

History of Aristotelianism.—Aristotelianism was continued in the peripatetic school (the name "peripatetic" came from Aristotle's method of giving instruction while walking, or from the walks—*περιπατος*—in the Lyceum's grounds) down to 529 A.D., when the Emperor Justinian closed all the Athenian schools. During the early Middle Ages it was kept alive by the works of Boëthius and the 'Isagoge' of Porphyry. Later by its fusion with the theology of Thomas Aquinas it became practically the official philosophy of Roman Catholicism, which it still continues to be. The Arabs in Spain were the bearers of Aristotelianism to mediæval Europe, and by 1220 almost all of Aristotle's works had been translated from the Arabic into Latin. A little later, by the efforts of Thomas Aquinas, they were translated from Greek originals, and Aristotle's authority in science became well-nigh absolute. With the rise of Humanism Aristotelianism began to wane, and with the development of modern science and the Cartesian philosophy his influence outside the Catholic Church was to a large extent nullified. Within the Church, however, during the last quarter of the 19th century, through the efforts of Leo XIII, the influence of Thomism and Aristotelianism increased.

WILLIAM A. HAMMOND,

Sage Professor of Ancient Philosophy, Cornell University.

ARISTOTLE, Greek philosopher, and one of the greatest thinkers and scientific investigators and organizers the world has ever seen.

Life.—Aristotle was born in 384 and died 322 B.C. His birthplace was Stagira (hence he is often called "the Stagirite"), a city on the Thracian peninsula known as Chalcidice, which was at that time thoroughly Hellenic country, enjoying all the advantages of Greek culture. His father, Nicomachus, was the court physician and friend of the Macedonian King Amyntas. The medical profession is said to have been hereditary in his family, and the scientific and medical atmosphere in which he grew up probably helped to form his mind in those habits of accuracy and exactness for which he is famous. Both parents having died, his education was directed by Proxenus of Atarneus. In 367 B.C., when in his 18th year, Aristotle came to Athens, and became a member of the Academy, the school of Plato (q.v.). Here he remained until the death of Plato, 20 years later. Before this time, he had become renowned for his scholarship and brilliant writings, as well as through his public lectures on rhetoric. Doubtless he had also already developed to some extent his own philosophical views. There seems to be no truth in the charges that were brought against Aristotle by later writers, that he was guilty of ingratitude and active hostility toward his teacher, Plato. As we have seen, he remained a member of the Academy until Plato's death, and in his later writings, although criticising with keen insight certain Platonic doctrines, he speaks of his master with the greatest reverence and affection (cf. Zeller, 'Aristotle and the Earlier Peripatetics,' Vol. I, Chap. I).

After Plato's death, Aristotle resided for three years at the court of Hermias, ruler of Atarneus, who had been at one time a member of the Academy, marrying there Pythias, the niece, or, as some say, the daughter of the Prince. Hermias, however, was treacherously put to death by the Persians, and Aristotle withdrew to Mitylene. Soon after (343) Aristotle was called by Philip of Macedon to undertake the education of his son Alexander, the future conqueror of the world, then a boy of 13 years. Nothing is known regarding the nature of the education which Aristotle gave to his distinguished pupil. The regular instruction of the Prince must have ceased three years later when he was made regent by his father and entrusted with military duties. Aristotle remained in the north engaged in scientific work, though probably still retaining some connection with the Prince and the Macedonian court. When Alexander set out upon his campaign in Asia, Aristotle went to Athens and founded there his school. Its place of meeting

was the Lyceum, a gymnasium attached to the temple of the Lyceian Apollo. He was accustomed to talk to his pupils as he walked to and fro in the gardens of the Lyceum, and from this custom the school became known as the "Peripatetic" (*περιπατεῖν*, to walk up and down).

Here Aristotle taught and directed the various scientific activities of the school for 12 years (335-323). This school was not merely an institution for imparting instruction. It was also an intimate association of scientific workers, many of them, like Theophrastus (who succeeded Aristotle in the leadership), mature men and ripe scholars. The organization and direction of the investigation as well as the fruitful utilization of materials and synthesis of results were, however, the work of the master. During these years, Aristotle systematized the knowledge of the past, and thus defined the limits and laid the foundations of the sciences of the western nations. But he did more. He carried on investigations and extended the boundaries of knowledge in almost every field. In logic, metaphysics, ethics and politics, he reached conclusions that are of great and permanent significance for all time. Moreover, in psychology, zoology, physics, astronomy, æsthetics, and also in his historical investigations, his work is of the greatest value and importance for all the subsequent development of these sciences. See **ARISTOTELIANISM**.

After the death of Alexander the Great, the Greek states, with Athens at their head, attempted to free themselves from the Macedonian power. Aristotle's former relation to Alexander, and his friendship for Antipater, the Macedonian governor, made him at once an object of attack. The charge of Atheism was brought against him, as it had formerly been brought against Anaxagoras and Socrates and he retired to Chalcis in Eubœa, where, in the following year (322), he died.

Writings.—The writings that have come down to us under the name of Aristotle do not by any means represent his complete literary activity. It is moreover known that the writings of Aristotle which were lost included: (1) Certain popular works published by Aristotle probably during the time of his connection with the Academy. He himself refers to these as the "exoteric," or popular writings. They were written generally in dialogue form, and modeled, both in subject matter and style, after the works of Plato. (2) Compilations of scientific, historical, and political materials, which were used by Aristotle as data in the preparation of his theoretical works. To this class belongs the 'Constitution of Athens,' fortunately discovered in nearly complete form a few years ago and published in 1891 (English translations, by F. G. Kenyon and E. Poste, both London, 1891).

The works which have survived are those which set forth Aristotle's system in more complete and systematic form, and which were used within the school. The writings which have been known to tradition as those of Aristotle appear to have come essentially from the edition of Aristotle's works prepared and arranged by Andronicus of Rhodes about the middle of the 1st century B.C. Of present-day editions of Aristotle's works that of the Berlin Academy

(1831-70) may be mentioned. These writings may be classified in the following way:

(a) *Treatises on Logic*.—These were later collected under the title of the 'Organon.' This included the 'Categories,' 'De Interpretatione' (on the parts and kinds of propositions); the 'Analytics,' prior and posterior (consisting of two books each, and developing the doctrine of the syllogism and dealing with scientific methods in general); the 'Topics' (dealing with probable conclusions); and on 'Sophistical Elenchi' (which discusses certain fallacies and the ways of refuting them). The Bohn Library gives an English translation of these works in two volumes by O. F. Owen.

(b) *The 'Rhetoric' and the 'Poetics'*.—The former consists of three books, of which only the first two are regarded as genuine. (English translation by T. Buckley in Bohn Library). The 'Poetics' has been preserved only in a very incomplete and fragmentary condition. An English translation is given in S. H. Butcher's 'Aristotle's Theory of Poetry and the Fine Arts' (3d ed., 1902). See POETICS, THE.

(c) *The Work 'On the First Philosophy'*—our 'Metaphysics'—which Zeller describes as a torso arbitrarily bound up with a number of other fragments, some genuine, some spurious. (English translation in Bohn Library, by J. H. McMahon, 1889).

(d) *The Works on Natural Science*.—To this class belong (1) the 'Physics,' with the connected works, 'On the Heavens,' 'On Growth and Decay,' and the 'Meteorology'; and (2) the zoological treatises, 'The History of Animals,' 'On the Parts of Animals,' 'On the Movement of Animals,' and 'On the Generation of Animals'; (3) the psychological writings, including the 'De Anima,' and the smaller treatises known as the 'Parva Naturalia.' Of these works 'The History of Animals' is translated by W. Cresswell in the Bohn Library; 'On the Parts of Animals' by J. Ogle (1882); the 'De Anima' by E. Wallace (1882), and W. A. Hammond (1902). The latter writer under the title 'Aristotle's Psychology' has given also a translation of the 'Parva Naturalia.'

(e) *The Ethics and Politics*.—Aristotle's treatise on ethics is known as the 'Nicomachean Ethics.' It has 10 books, of which books V to VII are largely made up of additions from the 'Eudemian Ethics.' This latter work is a revision of the Aristotelian ethics by Eudemus, of which only a part has been preserved. The 'Nicomachean Ethics' has often been translated into English. Two of the most recent and best translations are those of F. H. Peters (4th ed., 1891), and J. E. C. Weldon (1892). The 'Politics,' in eight books, was left in an incomplete and fragmentary condition. (English translations by B. Jowett and J. E. C. Weldon). See ARISTOTELIANISM and consult works there referred to.

JAMES E. CREIGHTON,

Professor of Philosophy, Cornell University.

ARISTOTLE'S LANTERN, the complex dentary apparatus or oral skeleton and associate soft parts of a sea-urchin (q.v.). The oral skeleton attains its highest development in the *Echinidea* in the Aristotle's lantern of the sea-urchins. The lantern is composed of 20 principal pieces—five teeth, five alveoli, five

rotulae and five radii—of which the alveoli are again divided into four pieces each, and the radii into two, thus making a total of 40 pieces. This complex apparatus has, beside the inter-alveolar muscles, protractor, oblique, transverse, and retractor muscles. A somewhat similar but less complicated oral skeleton is found in the *Clypeastroida*.

ARISTOXENUS, Greek musician and philosopher of Tarentum, flourished about 350-324 B.C. He was one of the oldest writers, and probably was the greatest of Greek students of the science of music and all its branches. He was a son of Spintharus, who taught him music, having himself studied under Socrates and being possessed of a great knowledge of musical matters. After having received his elementary education he went to study music under Lamprus of Erythrae, and later became a student of philosophy under the Pythagorean Xenophilus of Chalcedice. He afterward went to Athens to study philosophy under Aristotle, and made such rapid strides that, upon the death of Aristotle, he aspired to be his successor and head of the philosophical school; Theophrastus was, however, appointed in his stead. He founded a school of musicians, who were called, after him, Aristoxeneans. The main difference between the systems of the Pythagoreans and the Aristoxeneans lay in the fact that the latter judged of the notes in the diatonic scale exclusively by the ear, while the former determined these mathematically. The only one of his works of any value now extant is a treatise on music, 'The Elements of Harmony.' It was published in three volumes by Meursius in 1616. There is an English translation by Marcran (Oxford 1902). The best edition is that by Marquard (Berlin 1868). Consult Goodell, T. D., 'Chapters on Greek Metric' (New York 1902); Laloy, 'Aristoxène de Tarente et la musique de l'antiquité' (Paris 1904); Westphal, 'Melik und Rhythmik' (Leipzig 1893); Mahme, W. L., 'Diatribes de Aristoxeno' (Amsterdam 1793).

ARISUGAWA, ā'rě-soo-gā'wa, the title of a noble Japanese family founded in the 17th century and prominent in civil and military affairs. This ancient family was founded by the seventh son of the Mikado Go-Yozei, during his reign from 1587 to 1611. The members of the family did not, however, attain much prominence until January 1868, when Arisugawa Taruhito (b. Kioto, 1835; d. 1886), who was the uncle of the Mikado, was appointed supreme administrator and commander-in-chief of the army. It was at this time that the duarchy of Mikado and Shogun was abolished and the present form of government established, with the Emperor Mutsuhito as dictator with undivided power. Upon taking office he at once reorganized the army to put down the rebellion in the north, led the imperial troops against the rebels, completely routing them and saving Yedo from destruction. After this he began military operations in the north, and by his skillful manœuvres soon brought the rebels to terms and the war to a quick conclusion. The next year, in 1869, he returned the sword of justice and the brocade banner, which he had received at the beginning of his campaign against the rebels, to the Emperor, thus signifying that he had brought the

ARISTOTLE

empire to a state of complete subjugation. In 1875 he became president of the senate, and again in 1877 was placed in command of the forces sent to suppress the Satsuma rebellion, under the leadership of Saigo Takamori. This was a long and severe test of his military ability, and his success, though won only after seven months of hard fighting and the sacrifice of 20,000 soldiers and \$50,000,000, showed him to be a leader born of the highest order of military genius. For this great service the Emperor decorated Arisugawa with the Order of the Chrysanthemum and appointed him field-marshal and junior Prime Minister. A superb bronze equestrian statue of Arisugawa Taruhito on a lofty granite pedestal stands in Tokio.

ARISUGAWA Takehito, b. 1862; d. 6 July 1913; brother of the above, was adopted by him as his heir and was also heir presumptive to the throne till 1879, when a son was born to the Emperor. He served three years in the British navy, commanded a cruiser in the war with China (1894-95) and later served as superintendent of the naval base at Yokosuka. He was guardian of the person of the Crown Prince in 1902-03, represented the Emperor at the marriage of the German Crown Prince in 1905 and later visited England as the guest of Edward VII. Takehito's only son died in 1895 while serving as a naval cadet. In the ordinary course the house would become extinct, but in view of the special relation of the house to the court, the Emperor ordered his third son, Prince Nobuhito Terunomiya (b. 3 Jan. 1905) to become, on attaining his majority, the head of the Arisugawa House.

ARITA, *a-rē'tā*, a Japanese town in the western part of Kyushu, famous for its pottery works, dating from the end of the 16th century. The Arita porcelain is highly esteemed.

ARITHMETIC. This word has been and still is used in two quite distinct senses. It formerly signified merely the science of numbers (see ARITHMETIC, HISTORY OF), and treated such numeral properties as seemed mysterious or peculiar. With the invention of algebra it was often taken to include such portions of that science as referred to the operations and to the number theory. In this sense it is still used in Germany and France to-day, the art of computation being indicated by the names *Rechnung* and *Calcul*. In English, however, the term early came to be applied to both the science of numbers and the art of computation. As the former branch developed the advanced portion was given the distinctive name of Theory of Numbers (q.v.), leaving the name Arithmetic to apply to calculation and its application to business problems. With the recent relegation of the progressions and the roots to algebra, this is the sense in which the word is used in the United States to-day. With this understanding of the term, the leading topics relating to the subject will be considered.

I. Notation and Numeration.—The former referring to the number of symbols is from the mediæval Latin *notæ*, meaning the numeral characters (see NUMERALS), and the latter, referring to number names, is from *numerus*, number. The distinction between the terms is

coming, however, to be less marked than formerly, the word numeration being used for both. The writing and reading of numbers generally refers to positive integers, common fractions (or vulgar fractions, so called to distinguish them from the *fractiones physicae* or *astronomicae*, the old sexagesimal fractions still met in angle measure), decimal fractions, compound numbers and surd numbers. Of these the positive integers are known as natural numbers, the others as artificial numbers. Negative numbers, also belonging to the artificial group, have until recently been excluded from arithmetic. They have, however, so many practical applications that they are beginning to find a place, and in time they will probably be treated in arithmetic so far as necessary for cases involving numbers of opposite nature, like debit and credit, opposed forces, and contrary directions.

The distinctive feature of our present numeral system (see NUMERALS) is its place value. The characters for 5 and 1, written in juxtaposition, indicate addition in the Roman system (VI); but in the Arab-Hindu notation (51) they indicate 5 tens and 1 unit, the 5 having a place value showing that it represents tens. Thus by means of only 10 characters we are able to write numbers of any desired magnitude, and by means of the simple device of decimal fractions we are also able to represent any numbers, however small.

II. Scales.—Because man has a natural counting apparatus in his 10 fingers (see FINGER NOTATION) the world has come to write numbers on a scale of 10, and to give them names based upon a decimal system. We might use other scales, and the duodecimal (scale of 12) would be better on several accounts, although a change is not practicable. There has always been some tendency to use the scale of 12, as is seen in such tables as 12 inch=1 ft., 12 oz.=1 lb. troy. The superiority of the duodecimal over the decimal scale lies in the fact that 12 has more exact divisors than 10 has. Therefore the fractions most commonly employed could better be represented on the scale of 12, as is here shown:

	Scale of 10	Scale of 12
.....	0.5	0.6
.....	0.333...	0.4
.....	0.666...	0.8
.....	0.25	0.3
.....	0.75	0.9
.....	0.125	0.15
.....	0.08333...	0.1

In the tables of denominate numbers the tendency formerly was to adopt a varying scale, but at present it is entirely toward a uniform scale, as in the metric system (q.v.):

Uniform scale	Varying scale
10 mills=1 cent	2 pints=1 quart
10 cents=1 dime	8 quarts=1 peck
10 dimes=1 dollar	4 pecks=1 bushel

III. The Fundamental Operations.—These are now commonly considered as four in number, although formerly as many as nine *species*, *atti*, or *passioni*, as they were called, were given. They sometimes included doubling (*duplicatio*), because a common method of multiplication was by successive duplications. They also included halving (*mediatio*), this operation being often used in effecting a division. The Rule of Three, Evolution, and Progressions were also

commonly included. The fundamental operations may more scientifically be classified as follows, each direct process having two inverses:

Direct	Inverse
Addition: $2+3=5$.	Subtraction: $5-2=3$.
	$5-3=2$.
Multiplication: $2 \times \$3 = \6 .	Division: $\$6 \div 2 = \3 .
	$\$6 \div \$3 = 2$.
Involution: $2^3=8$.	Evolution: $8=2^3$.
	Logarithms: $3=\log_2 8$.

Of these the primitive one is addition, multiplication by a positive integer arising when the addenda are equal, and involution to a positive integral power arising from multiplication when the factors are equal. Arbitrarily, elementary arithmetic has usually excluded evolution beyond the cube root, and logarithms. It is now tending to relegate cube root to algebra on account of its difficulty and lack of applications. The exclusion of logarithms (q.v.) is due to their relatively late invention, since, if the theory of their computation is excluded, the subject is simple of presentation and valuable in application.

From the primary operations with natural numbers have been derived operations, designated by the same names and subject to the same laws, involving the artificial numbers. For example, $2 \times \$3 = \6 means that \$3 is taken twice as an addendum, thus: $\$3 + \3 . But $\frac{2}{3} \times \frac{3}{4}$ cannot mean that $\frac{3}{4}$ is taken as an addend $\frac{2}{3}$ of a time. It means that $\frac{2}{3}$ of $\frac{3}{4}$ is taken, or that $\frac{1}{8}$ of $\frac{3}{4}$ is taken 2 times. It is, however, convenient to broaden the definitions so as to use the same phraseology and symbols as in the case of positive integers. Similar considerations fix a meaning for $-2 \times -3 = +6$, $\sqrt{2} \times \sqrt{3} = \sqrt{6}$, and $\sqrt{-2} \times \sqrt{-3} = -\sqrt{6}$. For the justification of these usages, see ALGEBRA, DEFINITIONS and FUNDAMENTAL CONCEPT. In certain cases an operation is so difficult that it is more convenient to substitute for it another which gives the same result. This is seen in the case of the division of fractions, where to divide $\frac{2}{3}$ by $\frac{3}{4}$ it is easier to multiply $\frac{2}{3}$ by $\frac{4}{3}$ than to reduce to a common denominator as was formerly done, and then divide, thus: $\frac{2}{3} \div \frac{3}{4} = \frac{2}{3} \div \frac{3}{4} = \frac{2}{3} \times \frac{4}{3} = \frac{8}{9}$.

Of the four common operations, addition is the simplest of comprehension, although not in actual work. In fractions it is usually easier to multiply than to add, as in the case of $\frac{3}{4} \times \frac{1}{27}$ compared with $\frac{3}{4} + \frac{1}{27}$. With integers, both addition and multiplication require the learning of 45 combinations of numbers ($1+2, 1+3, \dots, 1 \times 2, 1 \times 3, \dots$), and the mere memorizing of these facts is as easy in one operation as the other. Subtraction does not require memorizing a table, since it is merely the inverse of addition, and if taught by the "making change" method it uses the addition table, as division uses that of multiplication.

IV. Checks.—An important consideration in all computations is the checking of the work, to be reasonably sure that no error enters. Checks should be applied at every opportunity so that an error may be discovered as soon as it is made, and not vitiate the further work. The most important check in addition is the repeating of the work in the opposite direction, adding downward if the first addition was upward. The psychological reason for this is that like stimuli tend to produce like reactions, and if an

error has been made it is liable to be made again if the numbers are soon met in the same order. Hence the order is reversed to counteract this tendency. In subtraction the best check is that of adding the subtrahend and remainder. If the remainder was obtained by the "Austrian" or "making change" method, this addition should be performed in the opposite direction as in the check for addition. The best check for multiplication and division is that of "casting out nines." This ancient Oriental method was of especial value when the sand-board form of the abacus (q.v.) was used, since the numbers were so frequently erased as to render a general review of the work impossible. This check has gone out of use in American schools, but it is so simple and valuable that it will probably be revived. The check depends upon two propositions: (1) The excess of 9's in a number (that is, the remainder arising from dividing a number by 9) is the same as the excess in the sum of the digits. In the case of 1247 the sum of the digits is 14, and this divided by 9 gives a remainder of 5. It is customary to cast out the 9's as the digits are added, thus: $7+4=11$; cast out 9 and 2 is left; $2+2+1=5$, the excess.

(2) The excess of 9's in the product equals the excess in the product of the excesses of the factors.

1247			
21			
1247			
2494	3	6	5
26187	3	6	5

In the case here given, the excesses in the factors are 5 and 3, indicated in the right and left angles of the cross. The excess in their product (15) is 6, indicated in the upper angle. The excess in the product, 26187 is 6, indicated in the lower angle. The upper and lower numbers in the cross are the same, showing that the result is probably correct. In division, the excess of 9's in the dividend equals the excess in the product of the excesses of the divisor and the quotient, plus that in the remainder. Of course, the check of 9's fails to detect an error involving a multiple of 9. There is a somewhat similar check by casting out 11's requiring slightly longer time, but in some respects more liable to detect errors.

V. Short Processes.—There are numerous short processes of performing operations, or rather of securing results by substituting simpler operations than those to be performed. Thus to multiply by $12\frac{1}{2}$ it is often easier to annex two zeros (or move the decimal point two places to the right) and divide by 8. In the same way it is easier to multiply by 100 and divide by 4 than to multiply by 25. Such processes depend upon simple number relations of the following kind: $12\frac{1}{2} = \frac{25}{2}$, $25 = \frac{100}{4}$, $33\frac{1}{3} = \frac{100}{3}$, $125 = \frac{500}{4}$, $75\% = \frac{3}{4}$, $125\% = 1\frac{1}{4}$, $66\frac{2}{3}\% = \frac{2}{3}$. The publication of extensive tables and the perfecting of calculating machines (q.v.) have rendered obsolete most of the short processes involving other kinds of multipliers and divisors.

VI. Compound Numbers.—The four fundamental processes with compound numbers were formerly considered of much importance, since before the introduction of decimal fractions most tables of denominate numbers were on a varying scale. Within a century, however, the metric system (q.v.) and various monetary tables have so decimalized denominate numbers as to take from compound numbers most of their former importance. The only case in which several denominations are commonly used in writing a number to-day is that of English

money. In most countries the whole subject is obsolete. The United States still uses the British system except in the monetary table, but it has greatly simplified it, rarely using more than two denominations in the same number. Indeed, within a single generation the metric system has come to be used exclusively in this country in scientific laboratories, and the efforts now being made to secure a large foreign trade will make the system more and more known in commercial and industrial affairs.

VII. Methods of Solving Problems.—

There are five general methods of attacking an applied problem, as follows:

(1) We may study typical problems and thus acquire the habit of solving others of the same nature. This is the oldest method, and was practically the only one in use before the 17th century. At present it is coming into renewed prominence in American schools, the type problem being attended (as was not formerly the case) by a large number of exercises.

(2) We may commit to memory rules for all general classes of problems liable to be met. Historically, this is the second method of attack, and it characterizes the American textbooks until nearly the close of the 19th century. The rules were usually inductively inferred from type problems, and pupils committed them to memory. Since in practical life we never depend upon a verbatim rule, this method is rapidly becoming obsolete. In mediæval times there was much effort expended in searching for a general rule that would solve all arithmetical problems. Hence arose the Rule of Three (see ARITHMETIC, HISTORY OF), the Rule of False Position, and other rules of less importance, all of which lost their chief value when algebraic symbolism was invented. Of these general rules only the Rule of Three has survived, being now recognized in the form of proportion.

(3) We may learn formulas instead of rules. This method was received with some favor for a time, but it has been discarded as a general plan. It has all of the defects of the method of rules, with the added difficulty of an unnecessarily confusing algebraic symbolism.

(4) We may analyze each problem as it arises, simply applying common sense to the solution. When problems are, as they always should be, properly graded to the understanding of the pupils, this plan is better than any of the preceding ones. It establishes a habit of independence and of confidence that is wholly wanting in the older methods.

(5) We may bring to the aid of analysis the representation of the unknown quantity by the familiar algebraic symbol x . This materially simplifies the analysis, and most writers on arithmetic at the present time advocate the plan. The concept of the linear equation with one unknown quantity is a very simple one, and it greatly clarifies the analysis in many cases.

VIII. Nature of the Problems in Arithmetic.—The interests of the ancient and mediæval philosophers were not at all commercial. These men were attracted rather by considerations of the properties of numbers and by puzzles which were imagined to sharpen the wit. The rise of commerce in the later Middle Ages and at the time of the Renaissance, brought into the science a large number of

applied problems representing actual business conditions. Principles of conservatism have tended to keep these ancient problems from generation to generation, strengthened by the feeling that mental discipline was as well secured from an obsolete as from a modern problem. It is therefore only recently that the question has arisen: What should be the nature of the problems set for children studying arithmetic? In answer to this question teachers seem to be tending to observe the following principles:

(1) A problem that pretends to set forth a business custom should state the real business conditions of the present. This excludes obsolete business problems, it being the opinion that better mental discipline can be secured from a question relating to genuine commercial matters of the present, than from one relating solely to forgotten customs.

(2) Problems should appeal to the interests and understanding of the children in their respective school years. Arithmetic was formerly taught only to boys who could read and write and who were preparing for business. When the subject found its way into the earlier school years it carried many difficult problems of business down to immature minds. The modern tendency is to replace such problems by others that relate to children's interests. Thus in the primary grades there should be the study of home purchases, of the application of number to the large interests of the country, especially such as appeal to a child's love of nature and of the heroic, and such as relate to the sources of food and clothing. Later, the problems should refer to the more detailed features of the national and world life, to the great industries, trades and transportation facilities. Finally they should relate to the details of the industrial and commercial life, thus preparing both the boy and the girl for earning a livelihood. In all this there should be an effort to make arithmetic interesting, since when the interest of the pupil is secured the work is prosecuted with more zeal and is attended with better and more permanent results.

(3) In the effort to modernize the problems care must be taken to avoid the extreme of withdrawing from arithmetic all topics involving effort, thus making the subject insipid from its very lack of fibre.

IX. Sequence of Topics.—Formerly arithmetic was taught from a single book, each important topic being met but once. Then came the two-book series, the second book covering the ground of the first, but with more difficult examples, thus forming a spiral of two revolutions. In this way there arose the so-called Spiral Method of treatment, which certain devotees have carried to the extreme of returning to each topic every few days. Between the topical method and the radical spiral method there has been much strife. Advocates of the latter said that the former encouraged forgetfulness through lack of review, while advocates of the former said that the latter gave the pupil no feeling of mastery of any subject. The result has been a compromise, seen in all modern American courses. Such important topics as percentage are treated several times, with progressive difficulty, applications like simple interest offering new features on each succeeding occasion. On the other hand, such

relatively unimportant chapters as that on longitude and time (semi-geographical) are met but once. In the same spirit, the fundamental operations with integers, decimal fractions, and those common fractions often met in business, are frequently reviewed, while compound numbers and fractions involving unusual numerators and denominators are less emphasized. The technicalities of business, including the study of investments, insurance, banking and exchange, are reserved until the last years of the grammar school, when a child beginning to look forward to being self-supporting is prepared to understand them.

X. Methods.—Various methods have been suggested for presenting arithmetic to children, especially in the primary grades. The serious consideration of this phase of the subject began toward the close of the 18th century, particularly in Germany and Switzerland. With it are connected such names as Trapp, von Busse, Kranckes, Pestalozzi, Tillich, Grube, Tanck, Knilling and Kaselitz. Each of these writers stood for some principle which he carried to such an extreme as to render the method generally unusable. Pestalozzi, for example, did great good in his judicious use of objective illustration, but he went to an unwarranted extreme in his emphasis of the unit and in his devotion to abstract work. Tillich suggested a valuable set of number blocks, but his followers went to the extreme of eliminating all other material. Grube wrote a condensed manual for teachers, and systematically treated numbers in concentric circles of progressive difficulty, but he went to several extremes that made the system so absurd that it is now nearly forgotten. On the other hand, every prominent writer of this class has usually suggested some slight improvement which has gradually worked its way into the schools. It has been the universal experience that no advocate of a single method has been able to impress this method on any considerable number of followers. The best teacher has been the one who, being interested in the subject, has imparted that interest to the pupils, who has not been limited to any one set of objects or to any peculiar device, who has made arithmetic modern in its applications, and who has followed the best curricula of the day.

XI. Time Required for the Subject in the Schools.—There has been a gradual diminution in the time allowed to arithmetic in American schools for a number of years past, on account of the demands of more modern studies for a place in the curriculum. As a result there has been decreased attention to the subject, there is less ability on the part of pupils to grapple with problems, and the question has arisen as to the amount of time necessary to secure a reasonable facility in the arithmetical processes. Although the textbooks and the teaching have both improved, the curtailment of time and the scattering of the pupils' attention over more subjects have left the results far from satisfactory. It has even been urged that arithmetic be not taught before the third or after the seventh school year, thus allowing five instead of eight years to the subject. But although it is true that the necessary parts of arithmetic can be covered in five school years, it is equally true that the child has as much delight in his work with numbers in his first school year as

he has in the other subjects studied, and quite as much need for this work. It is also true that the number facts are more easily impressed on the memory if the work is begun, as Pestalozzi advised, when a child first enters school. It is therefore better to allow arithmetic to extend throughout the elementary grades, combining with it, if the class is well advanced, some constructive geometry and the first steps in algebra in the eighth school year.

Columbia University, New York.

ARITHMETIC, History of. Among the ancients there were two distinct sciences now called by the name arithmetic. One had to do with the science of numbers and the other with the art of computation. The former was called, by the Greeks, *arithmetikē* (ἀριθμητική), and the latter *logistikē* (λογιστική). Logistic was taught to boys going into trade and among the most ancient peoples it probably involved the use of the abacus (q.v.) and commercial rules relating to rents, loans, exchange and the settlement of accounts. The nature of the problems being simple, and abacus computation depending largely upon manual training, the instruction in this art seems to have been entirely oral. On this account no ancient work upon the subject is extant, and our knowledge concerning it is derived from such sources as the Babylonian cylinders, early Cretan remains, certain fragments of Egyptian papyri and the occasional references of literary writers. In the Middle Ages the instruction offered by the Church schools was so meagre from the commercial standpoint that arithmetic schools (*Rechenschulen*) were established, and in these logistic (*Rechnung*) was taught. A number of manuscripts of the 13th, 14th and 15th centuries are extant showing the nature of the problems then considered necessary, but extant treatises on counter reckoning (see **ABACUS**) are mostly confined to the first century of printing. Not a few of the problems of importance at that time still survive in the arithmetics of to-day, although substantially obsolete from the commercial standpoint.

The Greek *arithmetikē*, or theory of numbers, begins with Pythagoras (q.v.), about 530 B.C., who taught their mystic properties, and to whose school is probably due most of their ancient classification. The fundamental division of numbers seems to have been into odd (*ἀρτιοί*) and even (*περιττοί*), the former being masculine, divine, lucky, and the latter feminine, earthly, unlucky. The expression "There is luck in odd numbers," appears in Virgil as "*Numero Deus impare gaudet*," and probably goes back to the Pythagoreans. The odd numbers were, on account of their geometric representations, also called *gnomons* (γνώμονες), and it was well known that the sum of the first *n* of these gnomons, including

1 (which was not generally considered a number until the 17th century), was a square *τετράγωνος*). The side (*πλευρά*) of the square was called by the later writers *radix* (*root*, whence *radical*). It is therefore evident that the Greeks looked upon arithmetic from the standpoint of geometry. Following out this plan, they studied triangular numbers, formed by arranging dots in the form of a triangle, as in the case of 3 (\cdot), 6, 10, etc., and also pentagonal and other *figurate numbers*, solid as well as plane. Many other classifications were suggested by the Greeks, some of which have remained in our school books until quite recently. Such, for example, included *perfect numbers* (*τέλειοι*), which are equal to the sum of all possible factors, including 1 (for example, $28 = 1 + 2 + 4 + 7 + 14$), and *amicable numbers* (*φίλοι*), each of which equals the sum of the possible factors of the other, including 1 (for example, 220 and 284). Euclid (q.v.) (c. 300 B.C.) emphasized the ancient arithmetic in his books II, V, VII, VIII, IX and X, although II, V and X are nominally geometric. Soon after, Eratosthenes (q.v.) (c. 225 B.C.) made a particular study of primes, and invented a "sieve" (*κόσκινον*), which bears his name, for the purpose of sifting out the composite numbers. In the next century Hypsicles (c. 180 B.C.) made a more extensive study of progressions than had before been attempted. It is, however, to Nicomachus (q.v.) (c. 100 A.D.) that we owe the first great treatise on arithmetic (*Εἰσαγωγή ἀριθμητική*), a work which sought to do for that subject what Euclid had done for geometry, and which actually succeeded in turning the attention of the later Greeks from the science of form to the science of number. The next great arithmetician was Diophantus, who wrote probably in the 4th century. His arithmetic (*Ἀριθμητικά*) professes to be in 13 books, but only six (seven in one Vatican MS.) are extant. In the main, however, this treatise relates rather to algebra.

The greatest difficulty of the ancient arithmeticians and calculators lay in the treatment of fractions. This is seen in the oldest mathematical treatise of any note as yet deciphered, a papyrus copied by one Ahmes, an Egyptian scribe of c. 1700 B.C., from an earlier MS., probably dating from c. 2300 B.C. Here all of the fractions, save $\frac{2}{3}$, have 1 as a numerator. For example, $\frac{1}{2}$ was written, in hieratic characters, as $\overset{\cdot}{\Delta}$ $\overset{\cdot}{\Delta}$ $\overset{\cdot}{\Delta}$, this meaning that the sum of these unit fractions equals $\frac{1}{2}$. The Akhmin papyrus, written more than 3,000 years after the original of the Ahmes work, gives the same treatment of fractions, thus testifying to the difficulty of the subject. While the Greeks and Romans simplified the subject and improved the symbolism, it is to the Hindus and Arabs that we are indebted for our present convenient forms.

The Romans contributed but little to the theory of numbers, although their mercantile spirit doubtless led them to improve the abacus. Their only writer of prominence was Boëthius (q.v.), who, early in the 6th century, did much to make the ideas of Nicomachus known in western Europe, and whose treatise was the standard in the Church schools for many centuries.

Of the early Hindu arithmeticians but little is known. There are, however, several works extant that set forth the theory and practice

of numbers in the period following the introduction of the zero and the consequent perfecting of the system of place value. (See NUMERALS). It is in this period that the foundations for our common arithmetical operations were laid. From the Hindus the Arabs of the Bagdad school (c. 800 A.D.) drew their inspiration. The earliest Arab writer to make extensive use of the Hindu numerals, in a textbook on arithmetic, was Al Khowarazmi (q.v.). So prominent was his treatise that his name became a synonym for the Hindu arithmetic, even as Euclid became synonymous with geometry. The early Latin translations, one of which was made by Adelard of Bath (q.v.) (c. 1120 A.D.), went by such names as 'Liber Algoritmi' ('The Book of Al Khowarazmi'), whence comes our word *algorism* (*algorithm*, in Chaucer *augrim*), a name for a long time used to mean the arithmetic of the Hindu numerals.

The Arab arithmetic became known in Christian Europe chiefly through the 'Liber abaci' of Leonardo Fibonacci of Pisa (q.v.), in 1202. In the 13th century the great rivalry of trade brought into prominence the commercial aspect of the subject, and from this time on the theoretical treatment as exemplified in the works of Nicomachus and Boëthius gradually lost ground.

The first printed arithmetic appeared anonymously at Treviso, in Italy, in 1478. In Germany the first one to appear from the press was published at Bamberg in 1482. The commercial supremacy of Italy and Germany was such that their works for the next century were largely mercantile, the arithmetic of the Boëthian type being published more often in Paris than elsewhere. It was quite late in the 16th century before France produced many commercial arithmetics, and when these did appear the tendency to unite some of the features of the Boëthian arithmetic gave their books considerable influence. The first arithmetic to be printed in England was the prolix theoretical work of Bishop Tonstall (1522), and it was not until about the middle of the century that *Recorde* (q.v.) began to publish his popular commercial textbook. Owing to the great mercantile activity of Holland between 1575 and 1650, a large number of arithmetics appeared in that country early in the 17th century, and materially influenced the textbooks of England. To this creative period of arithmetic is due a large amount of matter once of importance but now quite obsolete. An extended treatment of compound numbers and of certain forms of exchange was more necessary then than now; barter was of great importance; partnership accounts were settled by a process quite different from that of to-day; alligation was of real use in the numerous mints then existing; proportion (usually in the form of the Rule of Three, *Regula de tre*, *Regeldetri*) was much more often used in practice than at present. The first arithmetic to be printed in America was Hodder's popular English work, which was republished in Boston in 1719.

The symbolism of arithmetic amounted to very little before the 19th century, when the symbols invented for algebra (q.v.) between 1550 and 1650 were rather injudiciously adopted in elementary arithmetic. The greatest advance since 1600 has been the invention of decimal fractions, a feature which revolution-

ized business arithmetic, making percentage simple and common, and rendering tables practicable.

The operations of arithmetic were formerly performed on some kind of abacus (q.v.) At the time of the invention of printing our present forms of addition and subtraction were quite common. There were, however, several methods of multiplication, although our present form was already in favor. The present method of division did not come into general use until the 17th century, although it appears in rare cases in the 15th.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College,
Columbia University, New York.

ARIUS, an Alexandrian theologian and controversialist, the father of Arianism (q.v.): b. in Libya, north Africa, about 256 A.D.; d. Constantinople, 336. He was educated under Lucien at Antioch and later went to Alexandria, where several years afterward he so severely suffered from the Diocletian persecution. He was ordained deacon by Peter, Bishop of Alexandria, whom he had joined in the Meletian Schism; then joined the schismatics and in consequence was excommunicated; later repented and was restored to his former good standing; and about 311 was advanced to the priesthood and placed in charge of a suburban church.

In 318 Arius became involved in a controversy with Alexander, Bishop of Alexandria, about the doctrine of the person of Christ, the latter contending that there was only a single essence, whereas Arius denied that Christ was unoriginated being, but was created out of nothing and therefore *in essence* must be different from the Father. He also affirmed that though Christ were the Son of God, he was not so in and of himself, but only so by the *grace* of God the Father; and that, were he in the truest sense a son, he must have come *after* the Father, therefore the time obviously was when he was not, and hence he was a *finite* being. These doctrines, emanating from a man of so great personal popularity and so highly regarded as a presbyter, though they contained nothing essentially new or original in thought and had been more or less prevalent in the Church for three or four generations, soon gained many adherents. Alexander, fearing the spread of the so-called heresy, in 321 called a council of 100 Egyptian and Libyan bishops, and Arius was immediately excommunicated.

Arius then retired to Nicomedia, under the protection of one of his supporters, Eusebius, Bishop of Nicomedia, who, notwithstanding

Alexander's exhortations to exclude the heretic, absolved him, and at a local synod in 323 brought about an endorsement of his opinions and actions. The dispute soon attracted the attention of Constantine, who had become emperor in 323. Thinking to avert further controversy he sent his ecclesiastical adviser, Hosius, Bishop of Cordova, to Alexandria, in an effort to arrange, through concessions by both parties, a doctrine to which both would subscribe. This attempt at reconciliation being barren of results, Constantine in 325 called a general council of all the bishops of the Church at Nicæa, in Bithynia, Asia Minor. This was the first œcumenical council and the attendance has been variously estimated. Gibbon places the number of bishops at 318; Eusebius at 250; and others at 300 and 320. About 2,000 other representatives of the Church throughout the East also attended the sessions. The Eastern bishops attended in person; the Western Church was represented by seven delegates, the most important of whom was Hosius, Bishop of Cordova, who presided over the sittings, which continued for about two months.

The conference developed into three distinct parties: (1) The strict Arians, led by Arius himself, who claimed that Christ was a pre-existent, divine, finite being and was different *in essence* (*heteroousios*) from the Father; that he was created by the Father out of nothing, but that he himself was the creator of the world and the incarnate Saviour; (2) The semi-Arians, who maintained that Christ was not *identical in essence*, but was of *similar essence* (*homoiousios*) with the Father; and (3) the Athanasians, led by Athanasius (q.v.), a young deacon of Alexandria, as Alexander's personal representative, who contended that the Son was *identical in essence* (*homoousios*). There were two other parties present, those of Eusebius of Nicomedia, and those of Eusebius of Cæsarea, the latter of which formulated a compromise creed, which was not, however, adopted. These two favored Arius and were classed as heretical, but later both signed the creed as adopted. After much discussion of the doctrines of Arius, his creed was torn in pieces and he himself ejected from the council, and the Athanasians succeeded, with the help of Constantine and the Western bishops, in securing the adoption of a creed to which the Arians would not subscribe. The council declared that it was and always had been the teaching of the Church Apostolic, in conformity with the apostolic tradition in all the churches, that Jesus Christ was "consubstantial"—*in essence* the same—with the Father. Thus in the Nicene Creed will be found the words *consubstantialis patri*, an exact rendering of the Athanasian claim *homoousios*. The creed reads: "We believe in the God, the Father Almighty, maker of all things visible and invisible; and in one Lord Jesus Christ the only-begotten Son of God, begotten of the Father (that is of the *essence* of the Father) before all worlds God of God, Light of Light, Very God of Very God, begotten, not made, being one substance (*homoousios*) with the Father," etc. This was somewhat abridged in the Nicæno-Constantinopolitan creed of 381 A.D. In consequence of refusing to sign the creed as adopted, Arius and two of his companions were excommunicated and banished to Illyria.

Soon after the Nicene Council had concluded its work, the semi-Arians began to assail the creed, and during the next few years Arius himself carried on propaganda work against it, corresponding with several prominent bishops, with the result that in 331, through the influence of Eusebius and Constantia, sister of the Emperor, Arius was recalled to court. Constantine, upon being convinced that the creeds of Arius and Athanasius were substantially alike, ordered Athanasius to receive Arius into the communion of the Church. Athanasius refused, was deposed by a synod of bishops at Tyre in 335, and sent to Gaul. A second synod, convened at Jerusalem in the same year, remitted the decree of excommunication against Arius and his followers, but even this did not establish him in his former exalted position nor cause his doctrines to be accepted by the followers of Athanasius. Disappointed and disheartened, Arius in 336 returned to Constantinople, where, again convincing Constantine of his orthodoxy, orders were issued to Alexander, Bishop of Constantinople, to administer the holy communion to him the following Sunday, but on the Saturday preceding his expected restoration, he was suddenly taken ill and died. See **ARIANISM**; **CHRISTOLOGY**; **COUNCIL**; **CREEDS**; **EUSEBIUS OF NICOMEDIA**; **EUSEBIUS OF CÆSAREA**; **INCARNATION**; **NICÆA, COUNCIL OF**; **NICENE CREED**.

ARIZONA (from the former Papago locality of *Arizonac*, or *Arizonaca*, probably meaning "place of small springs," a few miles from the present Nogales, where some celebrated nuggets of silver were discovered in 1736-41. It has no connection with "arid zone," etc.). A State of the United States (Western or Pacific group), bounded by Utah and Nevada on the north, New Mexico on the east, Mexico on the south, Nevada, California and Lower California on the west. It extends from lat. 31° 20' to 37° N. and from long. 109° 2' to 114° 35' W. Land area, 113,810 square miles (72,838,400 acres), thus ranking fifth in size among the States. Pop. (1910) 204,354, (1917, est.) 263,788; males, 58.4 per cent. The capital is Phoenix.

Topography and Geology.—Topographically Arizona presents two great divisions: a plateau region in the north, made up of approximately horizontal strata; and the mountainous region in the south, consisting of uplifted strata plicated and folded with mineral rocks and intrusive veins. These mountain ranges are numerous and have a general northwest and southeast trend, with intermediate broad valleys often 20 to 30 miles wide. The chief mountain masses are the Castle Dome, Big Horn, Eagletail, Chocolate, Dome Rock, Palomas, Harquahala and Harcuvar in the southwest; the Aquarius and Colorado in the west; the great plateaus rising in what are sometimes called the Northside Mountains in the northwest; the San Francisco and Black in the north central; the Carrizo, Lukachukai and Tunicha in the northeast; the Zuñi, White, Mogollon and Apache in the east; the Gila, Peloncillo, Pinaleno, Dragoon, Galiuro, Santa Catalina, Huachuca and Baboquivari in the southeast and south. The isolated volcanic San Francisco Mountains above Flagstaff are the highest of all, rising in their greatest height to 12,794 feet, and in Humphrey Peak to

12,562 feet. The other important peaks in the State are Thomas, 11,496 feet; Escudillo, 10,691; Graham, 10,516; Ord, 10,266; and Greens, 10,115, while many others exceed 5,000 feet. To the south the surface falls sharply to low ridges, mostly volcanic; thence by terraced mesas to a great desert plain little above sea-level, cut by gullied stream-beds drawing the occasional rainfall to the broad and shallow Gila. The great northern plateau, or series of plateaus, range in altitude from 5,000 to 7,500 feet; rising from them are numerous mountain spurs, buttes and the cones of extinct volcanoes, while the Colorado River has cut through 6,000 feet of strata, exposing formations down to Carboniferous and Tertiary marine strata, underlying Tertiary lake sediments and later alluvium; indeed it has been said that every period of the world's history since the dawn of life is represented in the geology of Arizona. The surface of the land as it lies was formed by a huge Eocene uplift, the water action afterward cutting the gorges and shaping the mesas and buttes; another took place in the Miocene, with eruptive volcanoes. Near Holbrook, Navajo County, is a wonderful chalcidony forest (see **FOREST, PETRIFIED**), with prostrate trunks four feet thick cracked into exquisitely colored blocks. Everywhere a feature of the landscape in the northern section is the great isolated mesas of sandstone with scarped and pinnacled sides, often more than 1,000 feet in sheer height. Most of the stream courses are dry save in the rainy season, and even then their flow is sometimes swallowed by the sands. The one considerable river is the Colorado (q.v.) which flows generally southwest from Utah for 400 miles through the famous Grand Cañon of Arizona (q.v.), one of the wonders of the world, then turning south, forming the western boundary of the State until shortly before it reaches the Gulf of California. Its chief affluent in the State is the Gila, which flows entirely across its southern portion; other tributaries are the Virgin, which crosses the extreme northwest corner; the Colorado Chiquito or Little Colorado in the north, and Bill Williams fork in the west. Important tributaries of the Gila are the Salado, or Salt, and the Verde from the north and the San Pedro from the south.

Climate.—Arizona is entirely within the arid region, but owing to the difference in altitude of the northern and southern portions there is a wide range in temperature, as likewise in precipitation between the two sections. The average annual precipitation at Flagstaff since 1850 averaged 24.65 inches, that of Yuma 2.84 inches; while the mean temperature is 45° in the north and 69° in the south. The sandy plains of the southwestern part are the hottest region north of the Isthmus of Panama, 120° in the shade being frequent in summer; but even in this lower area, owing to the dryness of the atmosphere, the heat is not very oppressive in summer, while the winter climate is usually delightful. Heavy snows occur in the mountainous country of the north and sharp frosts are frequent even in the Salt and Gila valleys; but nowhere are the mountains perpetually snow-capped. In recent years Arizona has become a popular resort for those suffering from pulmonary tuberculosis and catarrhal ailments, but notwithstanding the deaths of

those who settle in Arizona when seriously afflicted with tuberculosis, the total death rate in 1914 was only 14.98. In 1913, out of 779 deaths from this cause, 538 cases had their origin outside the State.

Minerals and Mines.—Arizona is rich in minerals and its mining industry is of prime importance. In 1915 it was first among the States in copper production, 459,972,295 pounds having been mined; it was fifth in silver (5,649,020 fine ounces, commercial value \$2,864,053), and fifth also in gold (201,531 fine ounces, commercial value \$4,166,025). Of lead, 21,738,969 pounds were produced, valued at \$1,021,732, and of zinc (spelter) 8,428,526 pounds. There are also deposits of coal (as yet but little worked), fluorspar, mica, molybdenum, nickel ores, limestone, marble, granite, sandstone in limitless quantities, chalcodony, tungsten, turquoise, vanadium, garnet (pyrope) and other minerals, and there are numerous hot and mineral springs. In 1915 Arizona ranked seventh in mineral products, the value being \$91,541,403.

Soil, Agriculture, Forestry.—Of the 72,838,400 acres in Arizona, 1,935,327 acres were cultivated in 1900 and 1,246,613 acres in 1910, a decrease of 35.6 per cent; farm property, however, increased in value from \$29,993,847 to \$75,123,970 during the decade, while the number of farms increased from 4,985 to 8,203, of which latter number 7,038 farms were free from mortgage. Only 1.7 per cent of the total land area was in farms in 1910. The valley lands are marvelously fertile, experiment demonstrating that in the southern part, under favorable conditions, the yield per acre is 2,150 pounds for wheat, 4,000 to 5,000 pounds for potatoes, 12,300 pounds for tomatoes, 5,000 pounds for strawberries, 27,000 pounds for melons and 1,735 pounds for corn. Lack of water has been more or less a hindrance to the development of the agricultural sections, but with the construction of storage reservoirs in recent years by the government, it is estimated that a total of 10,000,000 acres will be reclaimed. In 1910, 320,051 acres were under irrigation. The staple crops are alfalfa, barley, corn, wheat, sugar beets, green vegetables and orchard fruits and grapes. Experiments in the cultivation of Egyptian cotton have proved successful, 6,500 acres having been picked in 1916; and tracts of alkali lands in the south, hitherto believed to be waste, are now being utilized largely by the State for date culture.

The mountains and mesas of the northern part are generally covered with nutritious grasses, forming excellent pasturage for cattle and sheep, while irrigated pastures in the south afford means of fattening for market. In 1910 there were 833,458 cattle, 1,227,864 sheep, 114,609 horses, 5,284 mules, 9,982 asses, 259,396 goats and 18,512 swine. Fowls were valued at \$1,545,966, bees at \$104,374, and dairy products at \$909,411. The wool production in 1909 was valued at \$983,761 and mohair at \$63,120. Of the total value of crops in the same year, 46.4 per cent was in hay and forage (\$2,553,228), and 28.6 per cent in cereals (\$1,570,853). The value of all crops was \$5,496,872, an increase of 122 per cent in 10 years.

The southern plains and parts of the north have a dress of sagebrush, greasewood, yucca, cactus and other desert growths. Cottonwoods

line almost every stream. Mesquite, the giant cactus or saguaro, palo verde, ironwood, Jerusalem thorn and other trees are indigenous to the southern plains, and vast mountain areas throughout Arizona are covered with pine, cedar, juniper and other valuable timber. An important lumbering industry has been developed in the vicinity of the San Francisco Mountains, but vast tracts of timber in this and other sections have been set aside by the government in the Kaibab, Coconino, Dixie, Prescott, Sitgreaves, Tonto, Apache, Coronado, Garcés, Chiricahua and other forest reserves.

Industry, Commerce.—Mining is the chief industry of Arizona and copper the chief metal mined, although considerable gold, silver and lead are also produced. (See above). In manufacturing Arizona holds no important place, ranking 42d among the States, but gaining an increase of 27.5 per cent in value of products in five years. In 1914 it had 321 manufacturing establishments, representing an investment of \$40,282,000, a product worth \$64,068,000, and wage-earners numbering 6,888, with wages amounting to \$6,221,000. In 1909 there were 251 producing mines and quarries, with 16,917 wage-earners and with products valued a \$34,217,651, of which sum \$31,614,116 was in copper.

Finance.—The total receipts for the fiscal year 1915 were \$2,953,291 and the expenditures \$3,127,929. On 30 June 1915 there was an unexpended balance in the State treasury of \$579,183, while the gross debt amounted to \$3,319,048 (\$13.65 per capita). The assessed valuation of all properties amounting to \$408,540,283, the general levy rate being \$4.48. The same year the number of National banks was 13 and of State banks 47, with a capitalization of \$3,046,452, and total deposits amounting to \$30,093,522.

Railroads.—The railroad mileage in 1916 was 2,404 and was valued for assessment at \$93,147,822; of the mileage 69.88 miles, valued at \$1,165,200, were exempt from taxation until 1919.

Defense.—In 1915 the national guard of Arizona numbered 883 men; in addition there were 12 civilian rifle clubs with a membership nearly equalling that of the organized militia. The only armory in the State was erected at Tucson in 1915 at a cost of \$28,000. In 1913 Arizona's rifle team won 10th place among 45 competitive teams at Camp Perry; and in 1914, at Fort Riley, with matches open to entries from the United States army and western and southwestern States, the Arizona marksmen received first awards in all of the eight matches with the exception of two, establishing a State record.

Education.—Arizona has a good public school system and is energetic in extending its facilities to its children despite the scattered population. Education is compulsory. The school population in 1914 was 53,845; the estimated number of children of school age (5 to 18 years) being 57,491. The value of school real and personal property was \$501,852,186; teachers employed, 154 men (average salary, \$113.87), 942 women (average salary, \$85.59). In teachers' salaries Arizona is exceeded by only six States. Cost of maintenance, 1885, \$138,164; in 1914, \$2,135,549. There is a State University at Tucson (308 pupils), normal schools at

Tempe and Flagstaff and 17 high schools. There are also numerous private and sectarian schools. The government and various sectarian organizations maintain 59 boarding and day schools for Indians among the various tribes and there are also government non-reservation schools at Phoenix and Fort Mohave. In 1916 these had a capacity of 5,275 pupils, a total enrolment of 5,076 and an average attendance of 4,159.

Religious.—Owing to the large number of persons of Spanish descent, locally known as "Mexicans," and to the activities of the early Jesuit and Franciscan missionaries, more than half the communicants in the State are of the Roman Catholic faith, followed in order by the Latter Day Saints (Mormons), Presbyterians and Methodists. So far as the statistics are available, the Roman Catholics and the Methodists have an almost equal number of church organizations, and the Roman Catholics and Episcopalians an equal number of church buildings. In value of church property the Catholics exceed the Methodists only slightly, while in indebtedness the Catholic churches greatly exceed that of any other denomination. The Methodists have a greater number of Sunday-schools than any other religious organization, followed by the Catholics and the Latter Day Saints respectively; while in Sunday-school pupils the order is Latter Day Saints, Methodists, Catholics, Presbyterians, and Baptists.

Charitable, Penal.—The State maintains an asylum for the insane near Phoenix, a home for aged and infirm pioneers at Prescott, the Florence Crittenden Home and Children's Home at Phoenix, a penitentiary at Florence and an industrial school for juvenile offenders on the site of Fort Grant near Willcox. The University of Arizona maintains a department for the deaf.

Population and Divisions.—The first separate census was taken in 1870, giving, exclusive of Indians, 9,658; in 1880, 40,440; in 1890, 88,243 (including Indian lands and reservations); in 1900, 122,931; in 1910, 204,354; in 1917 (est.), 263,788. The principal Indian tribes are: Navajo (partly in New Mexico), 21,763; Papago, 7,112; Pima, 4,892; San Carlos Apache, 2,584; White Mountain Apache, 2,384; other Apache, 646; Mohave, 584; Hopi, 2,476; Walapai, 470; Maricopa, 269; Chemehuevi, 1,002; Havasupai, 170; Paiute, 285. There are 14 counties in the State, as follows, with their county seats, population, etc.:

In addition to towns named in table, the following contained more than 1,000 inhabitants in 1910: Bisbee, 9,019; Douglas, 6,937; Jerome, 2,393; Winslow, 2,381.

Government.—Sessions of the legislature are held biennially, commencing on the second Monday of January next after the election of members of the legislature. By constitutional provision the people reserve the power and privileges of initiative and referendum. Women were granted full suffrage in 1912 and in 1914 the State declared for absolute prohibition against the manufacture, sale or transportation of intoxicants. The hours of labor for women in laundries, bakeries, mercantile establishments, hotels and restaurants and also in telegraph and telephone offices in which more than three women are employed shall not exceed eight hours per day or 56 hours a week; for females under 18, the maximum is 48 hours a week. For females under 18, night work is prohibited from 7 P.M. to 7 A.M. The law provides also that seats shall be furnished in mills, factories, mercantile establishments, laundries and offices. Mothers are provided pensions under certain conditions. Eight hours constitute a lawful day's work in all employment by or in behalf of the State or any political subdivision thereof, and also in most cases the same length of day is provided for all workers in mines, smelters, etc. No child under 14 years of age shall be employed in any gainful occupation during school hours and no child under 16 years of age shall be employed in a mine or in any other injurious or hazardous occupation, or in any occupation at night. Female labor in or about any mine, quarry or coal-breaker is prohibited. Provision is made for employers' liability and for compulsory compensation applicable to workmen engaged in dangerous occupations. The minimum wage for females (except family domestics) is \$10 per week.

Archæology.—Practically throughout the State are the remains of innumerable structures, the homes of Indian tribes in former times. The more celebrated of these are Casa Grande, the main building of a large group of similar structures near Florence; the cliff-dwellings of the Navajo National Monument within the Navajo Indian Reservation in the extreme northern part of the State; Montezuma Castle on Beaver Creek near old Camp Verde; the cliff-dwellings of Walnut Canyon near Flagstaff and near the Roosevelt Dam. Many others are situated along the water-courses,

and indeed in many instances away from any present water supply. These remains for the greater part are probably at least a thousand years old, but others show evidence of having been inhabited not very long before the discovery of America, while still others were doubtless occupied within the historic period.

History.—The first white men to enter Arizona were probably Juan de la Asunción and Pedro Nadal, two friars of whom little is known, who penetrated the region in 1538. Fray Marcos of Niza and his negro companion Estevanico, in 1539, journeyed from Mexico to the sources of the Rio San Pedro, thence across the southeastern part of the present State to the province of Cibola. (See New Mexico). In the following year Niza served as guide to Francisco Vasquez Coronado, who, with a considerable force, visited Cibola and sent two small expeditions which discovered the Hopi villages (called Tusayan) and the Grand Cañon of the Colorado. Meanwhile other parties went from the settlement which Coronado established on the Rio Sonora in northwestern Mexico, explored the region, later known as the Papagueria (from the Papago Indians), to the mouth of the Colorado, where letters had been buried by Hernando de Alarcon who commanded a joint expedition by sea and went up the Colorado for 85 leagues. Antonio de Espejo visited the Hopi villages in the north-eastern part in 1583, as did Juan de Oñate, the first governor and colonizer of New Mexico, in 1598, the latter also passing entirely across the State to the mouth of the Colorado and back in 1604-05. The first missions were established among the Hopi by Franciscans in the summer of 1629, which, barring the killing of some of the missionaries by the Indians, were successfully continued until August 1680, when, in a general uprising of the Pueblos, the missionaries were murdered and little effort made thenceforth to introduce Christianity. From 1687 the Jesuits, particularly Padre Eusebio Kino, made various journeys into southern Arizona, establishing the missions of San Xavier del Bac in 1699 or 1700, and that of Guevavi in 1732. The present church of San Xavier was begun about 1783 and finished in 1797. In 1752 a presidio was established at Tubac, but in 1776 it was removed to a rancharia of about 80 families of Pima, Papago, and Sobaipuri Indians, known as San Augustin de Tucson (the present Tucson) a few miles northward, at which a few Spaniards may also have settled after 1763. Another mission of importance, the walls of whose fine church are still standing, was that of San José Tumacacori, erected in 1752. The missions and their *visitas* led a precarious existence after 1750-53, during which years the Pima were at war against the Spaniards, killing several priests and plundering the missions, including that of San Xavier. The Jesuits were expelled in 1767 and were followed by Franciscans, who rehabilitated the mission settlements and conducted explorations in unknown or forgotten regions. For many years before and after, the Apache tribes were at almost constant war with the more sedentary Indians of southern Arizona, raiding their settlements, killing the men and carrying off the women; nor did the white settlements fare much better, notwithstanding the presence of

presidios. At the time of the conquest of New Mexico in 1846 by Gen. S. W. Kearny, Arizona formed a part of that territory. By the Treaty of Guadalupe Hidalgo in 1848 the section north of the Gila was ceded by Mexico to the United States, while that south of the river was obtained through the Gadsden Purchase (q.v.), approved in 1854. Raids continued, various military expeditions were conducted and outposts established, and rich mineral deposits were discovered during the next few years. By act of Congress approved 24 Feb. 1863, Arizona was erected into a separate Territory, and on 29 December it was formally organized at Navajo Springs. The withdrawal of troops from the frontier at the beginning of the Civil War left the country practically at the mercy of Apaches, who continued their depredations; mines were abandoned and settlements deserted, but with the re-establishment of the military posts the development of the Territory was renewed and has since continued.

In June 1910 Congress passed an act to enable Arizona and New Mexico to form State constitutions and governments and to be admitted to the Union. In December of that year a proposed State constitution for Arizona was adopted by a convention held at Phoenix and was ratified by the people in February 1911. This constitution received the conditional approval of the Federal government in August 1911 and was referred to the people of the Territory for amendment. On 14 Feb. 1912 the Territory became a State of the Union.

The Territorial and State governors have been:

Bibliography.—Although among the youngest of the States, the literature of Arizona is voluminous. For a list of writings on the subject, consult Hector Alliot, 'Bibliography of Arizona, (Los Angeles 1914). The publications of the Federal government cover a very wide range of subjects and are embodied in the reports and bulletins of the Bureau of American Ethnology of the Smithsonian Institution, the Bureau of the Census and the War Department (especially the reports and narrations of various engineer officers of the army in the forties and fifties); the Mineral Resources of the United States, published by the Geological Survey, the reports of the governors of Arizona published by the United States Department of the Interior during the territorial government of Arizona; the bulletins of the United States Bureau of Labor Statistics, the circulars of the Children's Bureau, etc. For more general information on various topics

regarding Arizona, consult Bancroft, H. H., 'History of Arizona and New Mexico' (San Francisco 1889); Benavides, Fray Alonso, 'Memorial' (trans. by Mrs. E. E. Ayer; annotated by F. W. Hodge and C. F. Lummis, Chicago 1916); Bolton, H. E., 'Spanish Exploration in the Southwest, 1542-1706' (New York 1916); Bourke, J. G., 'The Snake-Dance of the Moquis of Arizona' (ib. 1884); id., 'An Apache Campaign' (ib. 1886); id., 'On the Border with Crook' (ib. 1891); Coues, E., 'On the Trail of a Spanish Pioneer; The Diary and Itinerary of Francisco Garcés' (ib. 1900); Dellenbaugh, F. S., 'Romance of the Colorado River' (ib. 1903); DeLong, S. R., 'History of Arizona' (San Francisco 1905); Farish, T. E., 'History of Arizona' (Phoenix 1915); Hough, Walter, 'Archeological Field Work in North-eastern Arizona' (Washington 1903); id., 'Culture of the Ancient Pueblos of the Upper Gila' (ib. 1914); id., 'The Hopi Indians' (Cedar Rapids 1915); James, G. W., 'In and Around the Grand Canyon' (Boston 1900); id., 'Arizona the Wonderland' (ib. 1917); McClintock, J. H., 'Arizona, Prehistoric, Aboriginal, Pioneer, Modern' (Chicago 1916); Powell, J. W., 'Report of Explorations of the Colorado of the West' (Washington 1874); Prudden, T. M., 'On the Great American Plateau' (New York 1906).

F. W. HODGE,
Smithsonian Institution, Washington, D. C.

ARIZONA, University of, State institution, established by the legislature in 1885 and opened in 1891 at Tucson, Ariz. Its buildings and grounds are valued at about \$500,000. The United States government appropriates annually \$50,000 to the institution and the State appropriation amounts to \$120,000. The library contains 23,000 volumes and in 1917 there were in the institution 52 professors and instructors and 450 students. The departments are those of agriculture, civil, electric, mechanical and mining engineering, commerce, liberal arts, and economics.

ARK, (1) the box made of bulrushes in which Pharaoh's daughter found the infant Moses. (2) The great vessel or ship in which Noah took refuge during the deluge. According to the story in Genesis, Noah's ark was large enough to contain his family and representatives of each kind of animal. Its dimensions were 450 feet long, 75 feet broad and 45 feet high. It was made of "gopher" wood, which has been variously identified with cypress, pine, and cedar. Until the advent of "the higher criticism" there were many theories as to the number of animals and the space necessary for their reception. Modern criticism and the surrender of attempts to square scientific facts with a literal interpretation of the Bible are indicated by the following suggestion of Bishop Stillingfleet, approved by many eminent authorities: "The insuperable difficulties connected with the belief that all the existing species of animals were provided for in the ark, are obviated if we assume that the deluge did not extend beyond the region of the earth then inhabited, and that only the animals of that region were preserved in the ark." (3) A chest or cupboard in the Jewish synagogue in which are placed the scrolls of the Torah. It is placed against or in the wall in the direc-

tion of Jerusalem. (4) The Ark of the Covenant, Ark of the Revelation, Ark of the Testimony, are the full names of the sacred chest of acacia wood, overlaid with gold, which the Israelites took with them on their journey into Palestine. It was an oblong box three feet nine inches in length, two feet three inches broad and the same in height. It was lined within and without with gold, and through four golden rings were placed staves of acacia wood, by means of which it was carried. In it were preserved the tables of the law. It was borne by the Levites, often at the head of a battle host, and had an eventful history before it was finally placed in the city of Jerusalem by David. Later its importance was apparently merged with that of the Temple which Solomon erected. There is no record of when or how it finally disappeared, but there are many popular legends regarding it, one of which speaks of its translation to heaven until the coming of the Messiah.

ARKADELPHIA, Ark., county-seat of Clark County, 65 miles southwest from Little Rock. It is situated on the banks of Ouachita River, on the Saint Louis, Iron Mountain and Southern Railroad. Its industries include cotton mills, a foundry, machine shops and a roller mill. A Baptist and a Methodist college are located here, and there is a Presbyterian school for negro children. Pop. 2,745.

ARKANSAS, ăr'kăn-să, the "Bear State." A south-central State of the United States, bounded on the north by Missouri, on the east by Missouri and the Mississippi River, on the south by Louisiana and Texas, on the west by Texas and Oklahoma. It measures about 250 miles north and south and from 175 to 275 east and west. Area, 52,525 square miles of land, 810 of water. Capital, Little Rock (q.v.).
Topography.—About one-fourth of the State is mountainous. In the northwest are the Ozark Mountains (q.v.), a continuation of that system from Missouri. The most extensive ranges are the Boston Mountains north of the Arkansas River and the Ouachita south. The highest peak is Magazine Mountain, 2,785 feet, in Logan County. Several others approach 2,000 feet. There are several unexplored caves of large dimensions, notably in Newton and Washington counties. Broken ranges extend eastward on the north as far as Sharpe and Independence counties and to Pulaski, Pike and Howard on the south. East and south of a line connecting these counties is a considerable tract of hilly country sloping east and south. Beyond this and extending to the Mississippi are the alluvial lands, swamps, lakes and bayous of the river "bottoms" 40 to 50 miles wide. The elevation of this region ranges from 350 feet along the border of the uplands to 100 feet in the extreme southeast. Much of it, excepting the prairie lands of Lonoke, Prairie and Arkansas counties, is still subject to overflow, though a considerable area has been recovered by a splendid system of drainage ditches and levees.

Hydrography.—Except for a few miles on the north the Mississippi touches the State on its entire eastern border. Four large tributaries flow through the State. The Saint Francis (450 miles long) parallels the Mississippi from the Missouri border to a short dis-

tance above Helena. The region between the two is full of swamps and lakes, but is dotted with thriving settlements. The White River (800 miles) rises in Arkansas, passes into Missouri, re-enters the State, receives the Black (400 miles) at Jacksonport, the Cache near Clarendon, and enters the Mississippi in Arkansas County. The Arkansas River (q.v.), bisects the State from northwest to southeast and enters the Mississippi just below the White. It has no considerable tributaries. The Red River crosses the southwestern corner and receives the Ouachita (500 miles), which leaves the State through Union County. An incomplete survey of the streams in the northwest showed 525,000 horse-power. The total in the State probably amounts to 1,000,000.

Climate and Sanitary Conditions.—The mean temperature is 60.8; for the winter 41.6, summer 78.9; lowest on record —32 (1862), highest 112. The variation between the northern and southern part of the State is about 5 degrees. The average rainfall is 46.7; it is somewhat higher in the eastern and southern part. Severe droughts are unknown. Floods are common in the river sections. The eastern and southern river bottoms are hot and malarial, but drainage has improved conditions greatly and a beginning has been made of the destruction of the mosquito. The uplands are healthful and the Ozark region is much frequented as a summer resort.

Geology.—Several distinct periods of geological formation are represented in the State. The oldest is the Ordovician, found in several counties between the White River and the Missouri boundary and a narrow strip extending westward from Pulaski County. The next oldest belongs to the Lower Carboniferous age and extends in general from east to west along the crest of the Ozark Mountains. Most of the region between 34° and 36°, and extending east to meridian 93 on the south and 91 on the north is Middle and Upper Carboniferous. Just below this is a small patch of Cretaceous. The rest eastward to the Mississippi is Tertiary and Quaternary.

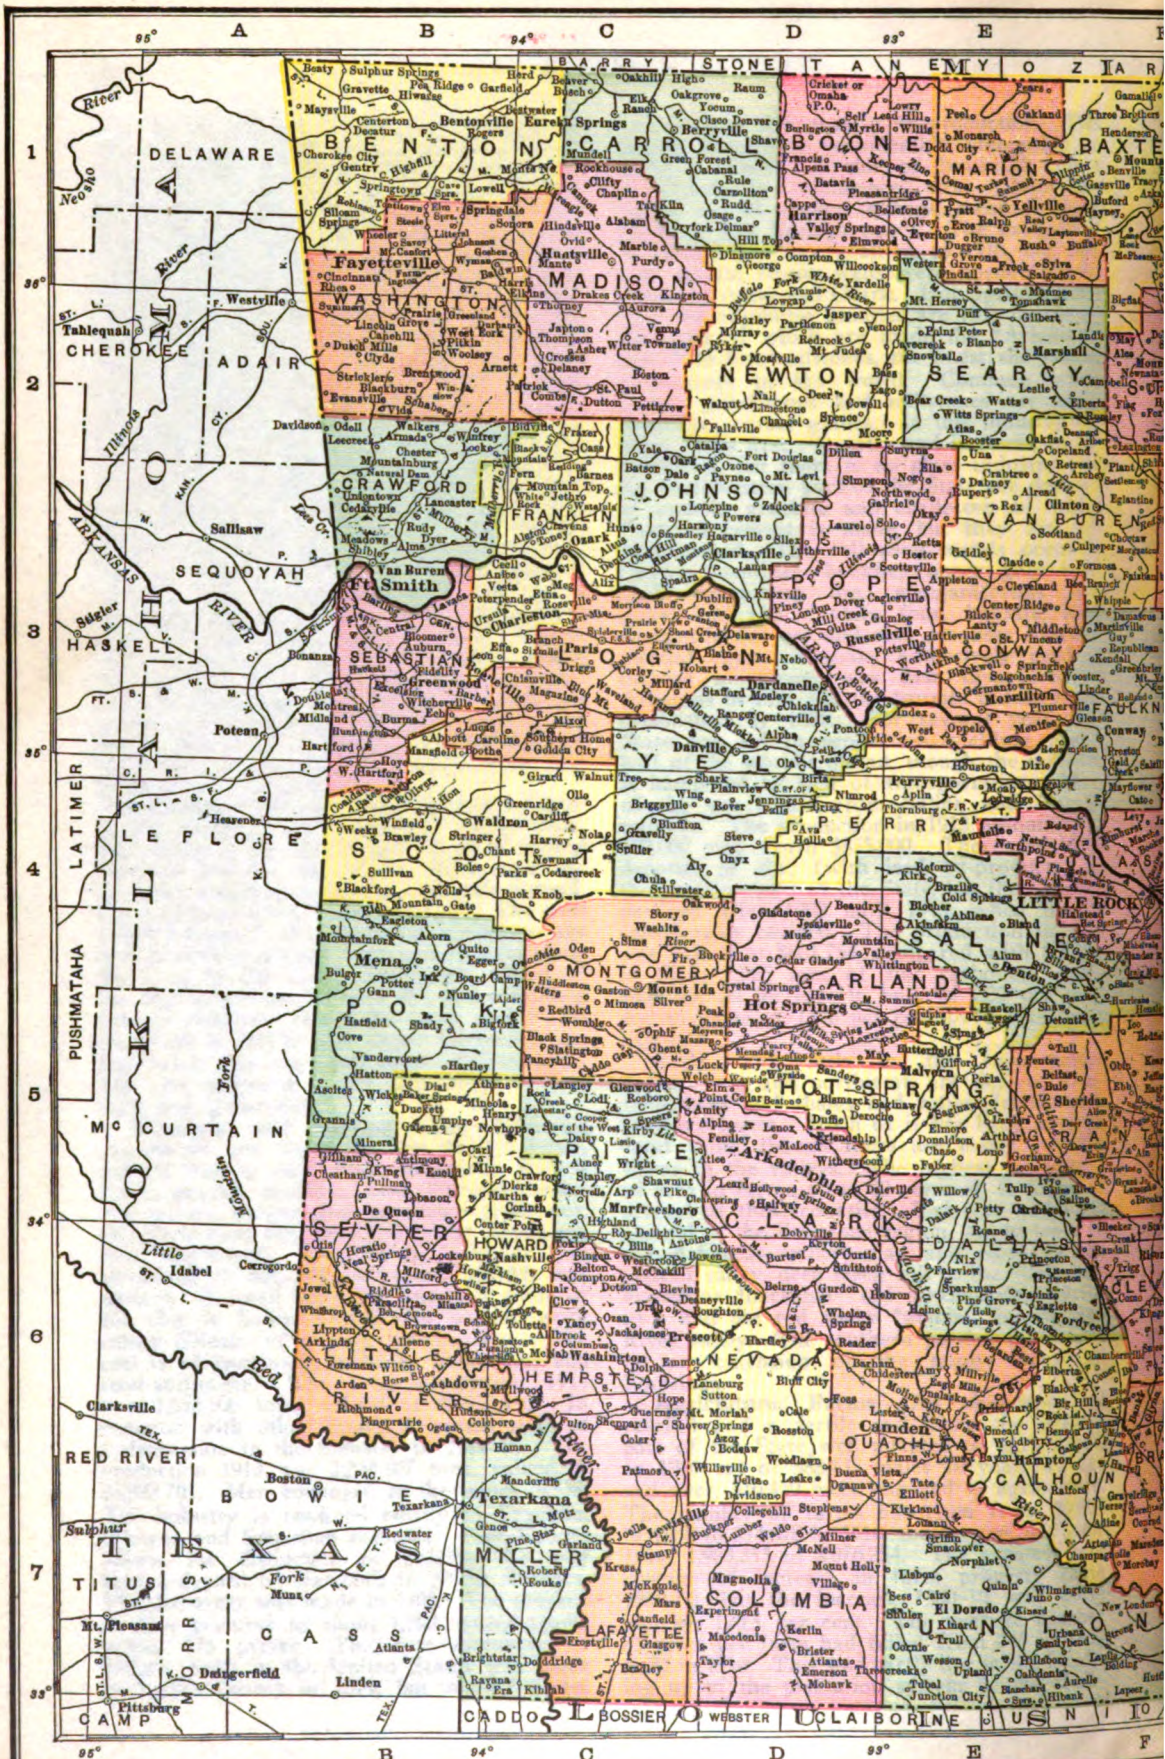

Minerals and Mining.—The following non-metals are found in the State: Agate, asphalt, basalt, clay, coal, diamonds, fuller's earth, granite, graphite, lime, limestone, mineral waters, natural gas, novaculite (oilstone), phosphate rock, salt, sand and gravel, sandstone, slate, and tripoli. The clay products for 1914 amounted to \$451,986, of which \$19,400 was pottery. A small beginning has been made of the clay in Saline County for pottery work called Niloak, of a very artistic type. The coal is of two kinds, ordinary bituminous and semi-anthracite. The total production 1915 was 1,652,106 tons, valued at \$2,950,456. In common with other States Arkansas suffered a depression in the industry in 1914-15. The production 1913 was 2,234,107 tons, valued at \$3,923,701. Men employed in the mines, 4,339. The industry is confined mostly to Franklin, Johnson and Sebastian counties. Pike County enjoys the distinction of holding the only known deposit of diamonds in North America. The discovery was made in 1906. The product to date amounts to about 1,700 stones aggregating 575 carats. The first discovery of fuller's earth in the United States was made in Saline County in 1891, but several States

now surpass Arkansas in its production. The granite industry is considerable, amounting to \$378,110 (1913). Marble of beautiful colors is found in abundance near Batesville. There are 18 mineral springs, most of them found at Hot Springs (q.v.). The production of natural gas was small up to 1916, but that year several strong wells were opened in the region of Alma and Ozark. Hot Springs, Garland and adjoining counties are rich in novaculite, out of which are made the "Arkansas" and "Ouachita" oilstones, the finest sharpening instruments in the world. Common whetstones, grindstones and millstones are made from the coarser grades. In this industry the State ranks first. Quartz sand is found in the northwest, but there is no glass industry. In the southwestern part of the State are deposits of asphalt, graphite and chalk out of which Portland cement is made, but they are still undeveloped. The following metals occur in varying quantities: bauxite, copper, gold, iron, lead, manganese ore, manganiferous ore, nickel and zinc. Only four, bauxite, lead, manganiferous ore and zinc are now of commercial value. Bauxite, extensively used in making aluminum, was first discovered in Arkansas in 1891 and the bauxite industry was established by 1896. For several years the State has led in production, yielding nearly half of the world's output, though the industry is hampered by lack of transportation. Most of the ore comes from Saline and Pulaski counties. The production in 1913 amounted to 180,000 tons worth \$855,000. There are large deposits of zinc (with lead by-products) in the northern part of the State, but the industry declined after 1908 until 1915, when it was considerably revived. The production in 1915 was valued at \$801,754, compared with \$65,214 in 1914; 7,925 tons of zinc carbonate, value \$408,079, an increase in bulk of 700 per cent, and in value of 1500 per cent over 1914, were exported.

Soils.—The soils in the mountainous region, west and northwest, are derived from sandstones and shales and range from sandy to heavy loams. Much of it has little agricultural value, though there are many valuable farms in the valleys. The highest percentage of area in farms, 60 to 80 per cent, is found in several of these counties. Red clay and loam abound in the limestone region, sandy loam in the Arkansas valley, clay and sand in the eastern valley, deep black soil in the "bottoms" known as "buckshot" (of inexhaustible fertility), and the red sticky "gumbo" in the Red River valley. The southern portion is covered by an extension of the sandy loams of Louisiana.

Agriculture, Farms.—An abundance of rainfall and a fertile soil make the greater part of the State well adapted to agriculture. In 1910 out of 588,133 males 10 years of age and over, 510,410 were engaged in agriculture. The number of farms has risen from 39,004 in 1860 to 214,678 in 1910, the acreage in farms from 1,983,313 to 8,076,254. The greatest percentage of increase in farm property came 1850-60, but the increase 1900-10 was noteworthy, 120.5 per cent. The average number of acres per farm had fallen from 245 in 1860 to 81 in 1910. This was partly due to the breaking up of the plantation system or the aboli-

tion of slavery. There are still several large holdings in the cotton region. The average value per farm in 1910 was \$1,864, the total value for the State being \$400,089,303. The average value per acre of the farm is \$14.38, but it varies greatly in different counties, ranging from \$5 in some to \$50 in others. The farms are equally divided between tenants and owners. However, 75.8 per cent of the land farmed by whites was in the hands of owners, while 54.4 of the lands operated by negroes was in the hands of tenants. The percentage of tenants is increasing. Twenty-two thousand three hundred and seventy-four farms were (1910) under mortgage.

Agricultural Products.—Agriculture is the leading industry and cotton is the chief product. The acreage devoted to cotton advanced steadily from 1870 to 1913, when it reached 2,502,000 and the product was 1,073,000 bales. The yield per acre is slightly above the average, as also the price. The former is due to the rich bottom lands, the latter to the superior grade of cotton, approaching the long staple variety. The low price in 1914 led to a regular campaign for diversified farming and the result was the product dropped to 785,000 bales in 1915. The same year the corn crop increased 20,000,000 bushels, or about 50 per cent and several other crops in like proportion, especially hay and oats. One of the most striking things is the development of the rice industry, which was introduced in 1904. In five years the acreage had risen to 27,419, in another five years to 100,000. The yield is 12 bushels above the average for the United States and the price 2.5 cents higher. The product in 1915 was 4,840,000 bushels worth \$4,598,000. Cultivation is confined mainly to Lonoke, Prairie and Arkansas counties. Since 1909 Arkansas has risen from rank 13 among the States in production of apples to rank three, and from rank three in peaches to rank two. By far the larger part of the apples is grown in the three northwestern counties, the peaches in the western and southwestern counties below the Ozarks. One peach orchard in Pike County contains 5,000 acres, said to be the largest in the world. The berry crop is large in the eastern and central region. Large quantities of cantaloupes and strawberries are grown in the western counties, and strawberries in White County. The State ranked fourth in acreage devoted to vineyards (1915). The following table gives the amount and value of the chief products in 1916:

	Acreage	Production	Value
Cotton.....	2,635,000	1,145,000 (bales)	\$107,430,000
Corn.....	2,550,000	45,135,000 (bu.)	44,232,000
Hay.....	375,000	469,000 (tons)	5,862,000
Oats.....	350,000	7,350,000 (bu.)	4,998,000
Rice.....	125,000	6,312,000	6,060,000
Potatoes.....	25,000	1,625,000	3,088,000
Wheat.....	255,000	2,040,000	3,325,000

The total value of the crops for 1916 was \$175,057,000, an increase of \$59,101,300 over that of 1915. More attention is being given to live stock and within the last few years there has been a notable improvement in the breed of cattle, yet the dairy industry, to which the State is so well adapted, is still in its infancy. In 1916 there were 1,589,000 hogs worth \$8,581,000; 270,000 horses worth \$22,140,000; 240,000 mules worth \$24,480,000; 402,000 milch cows worth \$15,276,000.

Forests and Forest Products.—The forested part of the State covers nearly three-fourths of its area. The area of national forest lands in 1916 was 916,919 acres. More than 100 varieties of wood are found, but only a few appear in considerable quantities. The leading variety is pine (chiefly short leaf yellow), which covers the southern part of the State. Several varieties of oak, hickory, ash, gum, maple and elm are scattered widely over the State. Cypress abounds in the swamps of the Saint Francis and Mississippi valleys. Red cedar and cotton wood are found in the Arkansas valley. The estimated stand of timber in 1909 was 81,600,000,000 board feet, which was exceeded by only two Southern States. Of this amount all but 2,900,000,000 was privately owned. All but 300,000,000 feet of this was in two National forests, the Arkansas, 680,000 acres, and the Ozark, 488,949 acres. In 1916, 240,000 acres in these forests were thrown open to homestead. Since 1909 the cut has amounted to about 14,000,000,000 feet, leaving 67,500,000,000 in 1916. In 1909, 2,060 mills were cutting 1,313,668,000 feet of pine, 358,556,000 of oak and other varieties in amounts bringing the total up to 2,111,300,000 feet worth \$31,839,283. This does not include cross ties, poles, staves and firewood or whole logs shipped out of the State. Since 1909 the annual cut has decreased. In 1915, 1,150 mills produced 1,800,000,000 feet. A great part of this, both soft and hard, is dressed or used for manufactures within the State.

Manufactures.—Arkansas is still a distinctly agricultural State, but there is a steady increase of manufactures. The number of establishments rose from 1,746 in 1899 to 2,925 in 1909; the number of wage earners from 31,525 to 44,982; the value of the products from \$39,888,000 to \$74,916,000. The following table shows the standing of the leading industries in 1909:

	No. of establishments	Wage earners	Value of products	Value added by manufacture
Lumber and timber products, 1909..	1,697	32,923	\$40,640,000	\$26,340,000
Oil, cotton seed and cake.....	44	1,086	7,789,000	1,784,000

Printing and publishing.....	295	981	2,082,000	1,546,000
Furniture and refrigerators.....	20	680	975,000	496,000
All others.....	740	5,751	13,661,000	6,664,000
Total.....	2,925	44,982	\$74,916,000	\$39,981,000

While in 1914 the number of establishments and wage-earners had decreased, capital invested, wages, and output had increased, as shown in the following table:

Number of establishments.....	2,604
Number of wage-earners.....	41,979
Capital invested.....	\$77,162,000
Wages.....	20,752,000
Value of materials used.....	44,907,000
Value of products.....	83,940,000

The manufacture of lumber is easily the leading industry, employing 73.2 per cent of the wage earners and contributing over half to the value of products. While the number of

establishments is large compared with the amount of products the tendency toward large scale production is easily apparent. Of the 1,697 lumber and timber companies, 97 employed 17,300 wage earners and produced \$22,848,000, while the other 1,600 employed 15,632 wage earners and produced \$17,792,000. In the oil, cotton seed and cake industry 30 establishments employed 920 wage earners and produced \$6,819,000 while 14 employed 166 and produced \$969,000. The industries are centred mainly in five cities, Little Rock, Argenta, Fort Smith, Pine Bluff and Hot Springs. The legislature of 1915 passed a law requiring railroads to make repairs within the State.

Transportation and Commerce.—Though bountifully supplied with rivers the State has little water transportation of much value except that of the Mississippi. This stream gives deep water communication with other States and with the Gulf. New Orleans is the port for Arkansas and through this large quantities of lumber and cotton are exported. The Arkansas River is navigable a part of the year for boats of light draft from the eastern to the western border, a distance of about 400 miles, the White to Jacksonport, about 250 miles; also the Red and Ouachita for short distances, but the tonnage on all of them is very small. The main reliance is upon railroads. In 1861 railway construction had just begun. In 1870 there were only 256 miles in the State. By 1890 the mileage had risen to 2,203, in 1900 to 3,082 and in 1916 to 5,407, or one to every 10 square miles of territory. A railroad commission was created in 1909. Farmers still labor under great difficulties in getting their produce to the railroads. The State maintains a highway commission which aids counties and localities in construction of roads. There are about 36,500 miles of road in the State, of which 1,185 are improved. Seven lines of electric street railways operate 134 miles of track.

Banks.—There were 59 National banks in Arkansas (1915) with capital of \$5,301,000; surplus and undivided profits, \$3,331,121; resources, \$34,641,315. There are 404 State banks (five private, 46 trust companies included), surplus and undivided profits, \$5,457,353; capital, \$13,763,892; resources, \$61,989,094. Only seven National banks have ever failed in the State, two of these in 1915 (one of which was restored to solvency), and one in 1916. In 1915, five State banks failed, assets \$78,450, liabilities \$127,847. The office of State bank commissioner was created in 1913. There are very few savings banks separately organized, but most State banks run a savings department, paying 4 per cent. Their savings accounts amount to \$3,719,007. There are 41 loan and trust companies, capital \$4,741,875. Five private banks report \$105,000 of capital.

Finances.—The assessed valuation increased from \$299,730,877 (\$199,331,562 real, \$100,399,315 personal) in 1905, to \$447,020,270 in 1915. A good part of the increase was due to the activity of the State tax commission, created in 1909. The total revenue collected in 1905 was \$5,037,665; in 1915, nearly \$7,000,000. The poll tax amounted to about \$260,000, of which \$190,000 is paid by whites. Another large item for non-property taxes was for liquor licenses. This amounted to \$93,000 in 1913, \$69,540 in

1914, \$54,550 in 1915 and was entirely cut off by the "dry" law of 1916. The insurance companies paid \$60,000 in fees and \$112,412 in taxes. The return from the inheritance tax law was small, though the law is drastic in form. The only recognized bonded debt is that of \$1,134,500 borrowed from the permanent school fund many years ago and \$116,000 taken in like manner from the University endowment. On these the State pays 3 per cent. In 1917, the legislature authorized the issuance of \$750,000, short term notes, to take up outstanding warrants of several years' accumulation. Education, Confederate pensioners, charitable institution and officers' and employees' salaries constitute the chief subjects for expenditures.

Education.—The educational conditions in Arkansas are not the best, neither are they the worst. A very decided improvement has been made in the last few years. In 1909 counties were authorized to elect superintendents and 25 counties now have this officer. In 1911 a State board of education (eight) was created with considerable administrative powers to be exercised with the State superintendent. Provision was made for the consolidation of weak districts and \$50,000 was appropriated to aid high schools. The latter was declared unconstitutional in 1915 because the appropriation was made from the school fund. The legislature of 1917 provided aid for rural high schools, also funds necessary to receive the Federal grant under the Smith-Lever Act. A State supervisor of high schools, a State supervisor of rural schools and a school improvement organizer are supported by the general education board. A compulsory attendance law was passed in 1909 (amended twice since), but 28 counties are exempt and it is not well enforced. A child labor law was adopted by popular vote in 1914. State uniformity of textbooks was provided in 1917.

The school revenue is derived almost wholly from taxation. In 1907 the State levy was raised from 2 mills to 3 mills and school districts were authorized to vote 7 mills instead of 5. In November 1916, the people adopted an amendment raising the latter limit to 12 mills. The total expenditures in 1915 were \$4,454,737 as compared with \$3,187,083 in 1909 and \$1,369,810 in 1900. The value of all school property in 1915 was \$12,660,849 as compared with \$6,939,000 in 1909 and \$2,500,000 in 1900.

The census of 1910 showed 142,954 illiterates, or 12.6 per cent of the population, as against 20.4 per cent in 1900. The percentage for whites was 7.1, negroes 26.4 as against 11.6 per cent and 43 per cent in 1900. The percentage of illiterates 10 to 14 years of age was 8.2 per cent in 1910, 16.2 per cent in 1900. The school population in 1916 was 649,083, of whom 460,145 were white, 188,938 colored. The enrolment was 332,914 white, 114,812 colored, total 447,725. About 6,250 were enrolled in private schools. The percentage of the school population enrolled in the public schools is higher than in any State east of the Mississippi. The average length of the term is 134.9 days, the average daily attendance 304,401. The average salary of teachers is \$51.50, or about \$325 a year; \$65 monthly for male teachers, \$50 for female teachers. The number of teachers was, male, 4,982; female, 6,080. Arkan-

sas ranks first in the percentage of revenue paid to teachers. There are 145 schools giving high school instruction, but only 82 maintain a four years' course. The enrolment in public high schools is 9,505, private 1,356. Four agricultural high schools (at Jonesboro, Russellville, Magnolia and Monticello) and one normal (at Conway) are supported out of the general revenue. Also a "Branch Normal" for negroes at Pine Bluff. The University of Arkansas (Fayetteville 1872) has a total annual revenue of about \$300,000. In 1917, it was put on a millage basis. The enrolment is about 800. A medical department at Little Rock was added in 1911. Besides these there are the following private institutions: Arkansas College (Presbyterian, Batesville 1872); Hendrix College (Methodist, Conway 1884); Ouachita College (Baptist, Arkadelphia 1886); Henderson-Brown (Methodist, Arkadelphia 1890); Arkansas Cumberland College (Presbyterian, Clarksville 1891); Galloway Female College (Methodist, Searcy); Central Baptist College for Women (Conway); and Crescent College (Eureka Springs).

Churches.—The Baptists and Methodists are the leading denominations in membership and influence. Catholics, Disciples of Christ, Presbyterians and Episcopalians have growing memberships in the order given.

Charitable and Penal Institutions.—There are 27 benevolent institutions in the State. The following are maintained by the State in or near Little Rock: School for the blind, school for deaf mutes, hospital for nervous diseases, reform school and home for Confederate soldiers. The State also pays \$1,000,000 a year in pensions to ex-Confederates. The tuberculosis sanatorium is located at Booneville. The State prison is located at Little Rock, the State penal farm for whites in Jefferson County, for negroes in Lincoln County. At the last census the number of dependent paupers was 534, or 33.9 per 100,000 of the population. Criminals amounted to 1,307, or 83 per 100,000 of the population.

Population.—The growth of population is indicated by the following figures: 1820, 14,270; 1830, 30,388; 1840, 97,574; 1850, 209,897; 1860, 435,450; 1870, 484,471; 1880, 802,525; 1890, 1,128,179; 1900, 1,311,564; 1910, 1,574,449; 1916 (est.), 1,753,033. The State lost heavily to Oklahoma when that State was opened to settlement. Of the total population, 71.8 per cent are whites, 28.1 per cent are colored. In 14 of the 75 counties over half the population are colored, but in 26 counties the whites make up 95 per cent. The foreign population is 46,909 or 1.4 per cent, though native whites of foreign parentage make up 2.3 per cent. Of these the Germans contributed 34.4 per cent. In 1910 there were only 28 incorporated places of more than 2,500 population and these contained only 12.9 per cent of the total population. There were 395,842 males, 21 years of age in 1910, and 263,055 qualified voters (who had paid the poll tax) in 1915. The leading cities are Little Rock, 45,941; Fort Smith, 23,975; Pine Bluff, 15,102; Hot Springs, 14,434; Argenta 11,138.

Government.—The constitution, in effect since 1874, has undergone few material changes. Suffrage depends on a year's residence and the payment of a poll tax. The Governor

and other State officers hold office for two years. The salary of the Governor is \$4,000 a year plus \$1,000 for house rent. His veto may be overridden by a simple majority. He has an extensive power of appointment. If the office becomes vacant within the first year, a new election is held; if later, the President of the Senate fills out the term. The legislature meets biennially. The members of the House of Representatives (100) are elected every two years, of the Senate (35) for four. The per diem (\$6) is limited to 60 days, after which the legislature may sit without pay. Special sessions are limited to 15 days. The Supreme Court has five members elected for eight years. There are 18 circuit and 12 chancery courts; also municipal courts and the usual county and probate courts and justices of the peace. Three cities have commission government, one the city manager. There is an optional primary election law. A corrupt practices act applies to all elections.

The following is a list of Territorial and State governors to date:

State Militia.—There are 24 companies with 1,850 enlisted men (June 1916).

Representatives in Congress.—There are two senators and seven representatives.

Politics.—The State has been democratic since 1874, generally by large majorities and a solid delegation in Congress.

History.—De Soto was the first white man to set foot in the State; the French explorers, Marquette and Joliet, came down the Mississippi in 1673 and found near the mouth of the Arkansas river a tribe of Indians, the Arkansas, from whom the State and river were named. The first settlement was made under direction of De Tonti at Arkansas Post in 1686 a few miles above the mouth of the Arkansas river. But settlement was slow and inhabitants were very few in 1803 when the United States acquired the territory as a part of Louisiana. In 1812 it was separated from Louisiana as a part

of Missouri. In 1819 Arkansas Territory, including what is now Oklahoma, was organized. It was admitted as a slave State 15 June 1836. Though settled chiefly by the southern people it was greatly divided on the question of secession and the convention adjourned without passing an ordinance, but President Lincoln's call for troops led to the reassembling of the convention and the ordinance of secession was adopted 6 May 1861. Several battles took place in the State, but it did not suffer from military operations like the others. By 1863 a large part of the State had been recovered by the Union and a loyal State government was established in 1864, with Isaac Murphy, governor. However the State had to undergo reconstruction and was not readmitted to the Union until 23 June 1868. The anarchy of the carpet-bag régime reached its climax in 1872 in an armed conflict between Brooks and Baxter for the governorship. The Democrats supported Baxter, Republican, and he held until 1874. A new constitution was adopted that year and the Democrats recovered the State government, which they have held ever since.

The constitution of 1874, which was somewhat reactionary in type, is still in force, though 13 amendments have been added. The most radical is that providing for the initiative and referendum (1910). In recent years the legislature has passed some progressive and a few radical measures. The attempt to regulate freight and passenger rates on railroads (1907) was taken into the Federal courts, along with like attempts in Minnesota and Missouri. After a long delay the action of the State was sustained in part, but soon overruled by new suits and decisions. A drastic anti-trust act (1905) drove the insurance companies and some other concerns out of the State for a while, but it was amended and the companies returned. The 'fellow servants' rule was abolished after a long drawn-out fight. The convict lease system has been greatly improved and virtually abolished. The legislature of 1915 passed a State-wide prohibition law, though a similar law originated by petition had been rejected in 1912, a drastic inheritance tax law, and a minimum wage law. In 1917 the ballot was conferred on women in primary elections; the tax laws were revised; an amendment was submitted authorizing the State to issue \$9,000,000 of bonds to loan to farmers for the purchase of lands; and a convention was called to revise the constitution. The convention met, appointed committees, and adjourned to July, 1918.

The first opportunity to use the initiative and referendum came in 1912. One legislative act was referred by petition and three other acts originated under the initiative. The first was a revenue law, the others related to prohibition, elections and uniform and free textbooks. All were rejected. Five amendments were voted on, two submitted by the legislature and three under the initiative. One, the "grandfather clause," was defeated. All the others received a majority of the votes cast on them, but the Supreme Court held that only three could be submitted at one time and that a majority of the total vote cast was required for adoption. This cut out all initiated amendments except the one limiting the legislature to 60 days. In 1914 two acts were sub-

mitted under the initiative, a child labor law after the preceding legislature had refused to pass one, and a "publicity" act, which subsidizes the press through public advertising. Both were adopted. An amendment (by petition, 1916) providing for good roads received a majority of the vote cast on it, but not a majority of the total vote. A primary election law, the repeal of the prohibition law and two amendments originated by petition were submitted in 1916. The first was adopted. Also the amendment raising the limit of the school tax to 12 mills. The others failed.

DAVID Y. THOMAS,
Professor of History and Political Science,
University of Arkansas.

ARKANSAS, University of, a State institution founded in 1871 at Fayetteville, Ark. It comprises a college of liberal arts and sciences, colleges of engineering and agriculture, an agricultural experiment station and a department of education. The medical and law faculties are located at Little Rock and at Pine Bluff there is a branch normal college for negroes. The annual income is about \$250,000, derived from Federal and State endowments and appropriation. The university plant and grounds are valued at more than \$1,000,000. The library contains 25,000 volumes. The State appropriates \$20,000 annually to the medical school. Tuition is free in all departments except in the professional schools. In 1917 the institution had 70 instructors and 814 students.

ARKANSAS CITY, Kan., city of Cowley County, 50 miles southeast of Wichita, near the southern border of the State, on Arkansas River, near the Walnut River, and furnished with water power by a canal uniting them. It was settled as Greswell in 1870, and incorporated under its present name in 1872. It is on the Atchison, Topeka and Santa Fe, the Missouri Pacific, the St. Louis and San Francisco, the Midland Valley and Kansas S. W. railways, and manufactures agricultural implements, windmills, wire mattresses, flour and lumber. The new western oil fields around have added largely to its prosperity and it has a large trade with Indian posts and agencies in Oklahoma and Indian Territory. It contains a United States Indian School; operates municipal water works; and since 1912 is governed by commission. Pop. 8,500.

ARKANSAS POST, Ark., village in Arkansas County; on the Arkansas River, 117 miles southeast of Little Rock. It is on a high bluff and was the site of the first settlement made within the present limits of Arkansas by French missionaries in 1685. Its elevated location gave it considerable military importance during the Civil War. The Confederates established strong works here, which were re-

duced by a combined assault of a portion of the Federal army, under General McClernand, and a naval command under Admiral Porter, on 11 Jan. 1863.

ARKANSAS RIVER, the largest affluent of the Mississippi save the Missouri; length, nearly 2,000 miles; area of basin, 189,000 square miles; mean discharge, 63,000 cubic feet. It rises in central Colorado; flows east with a rapid current through deep, narrow cañons, and over a rocky bed till it emerges on the naked, arid plains of eastern Colorado and western Kansas; runs east several hundred miles in Kansas, and turning southeast leaves it near Arkansas City. It then cuts a cante off Oklahoma,—where it receives the Cimarron and the broad shallow Canadian from the west, with the Verdigris and Neosho from the north,—and becomes navigable 650 miles to its mouth in Arkansas (which it bisects). In Fremont County, Colo., it flows through the Royal Gorge, one of the deepest cañons in the United States.

ARKANSAS STONE, a name given to the oilstones made from two grades of novaculite quarried in Hot Springs, Garland County, and also in adjoining counties in Arkansas. The rocks cover a large area and yield the finest whetstones. From them the highest grades of both whetstones and razor hones are made.

ARKLOW, Ireland, seaport town of county Wicklow, 14 miles southwest of the town of that name, on the right bank and just above the mouth of the Avoca, here crossed by a bridge of 19 arches. Fishing is the chief industry, gunpowder is manufactured, and copper and lead are exported. There are remains of an old monastery, and of the castle of the Ormonds, the latter destroyed by Cromwell in 1649. Here in 1798 the United Irishmen suffered a defeat. Pop. 5,000.

ARKONA, the northeast promontory of the German island of Rügen, in the Baltic. Its chalk cliffs rise to a height of 177 feet, topped with a lighthouse, built in 1827, from which the Danish island of Møen, 33 miles northwest, can be seen. Here stood the famous fortification (Slavonic, *Urkan*) so long impregnable, and the temple of the Wend deity Swantewit, the most sacred sanctuary of the Slavs of northern Germany.

ARKOSE, är-kös', a variety of sandstone that contains many fragments of feldspar. Arkose commonly results from the incomplete, or mechanical weathering of a granite, so that the grains of quartz and feldspar fall apart into what is called a feldspathic sand or arkose sand. The feldspar grains remain unweathered. This type of weathering is common where frost or great heat without much moisture is the agent, as on high mountains or in deserts. By cementing together of this feldspathic sand an arkose results.

ARKWRIGHT, SIR Richard, English inventor: b. Preston, Lancashire, 23 Dec. 1732; d. 3 Aug. 1792. He was the youngest of 13 children, and was bred to the trade of a barber. His residence in a cotton-spinning district (Bolton) drew his attention to the operations of that manufacture; but he was 35 before he devoted himself to consideration of the subject.

The *spinning-jenny*, invented in 1767 by Hargreaves, gave the means of spinning 20 or 30 threads at once with no more labor than had previously been required to spin a single thread; but the thread spun by the jenny, could not, however, be used as warp, being destitute of the firmness required. Arkwright supplied this deficiency by the invention of the *spinning-frame*, which spins a vast number of threads of any degree of fineness and hardness, leaving the operator merely to feed the machine with cotton and to join the threads when they happen to break. His invention introduced the system of spinning by rollers, the carding or *roving* as it is technically termed (that is, the soft, loose strip of cotton) passing through one pair of rollers and being received by a second pair, which are made to revolve with three, four or five times the velocity of the first pair. By this contrivance the roving is drawn out into a thread of the desired degree of tenuity, a twist being given to it by the adaptation of the spindle and fly of the old flaxwheel to the machinery. The precise date of his invention is not known, but it is most probable that the idea of spinning by rollers had occurred to his mind as early as the period when Hargreaves was engaged in the invention of the jenny. He removed to Nottingham in 1768, in order to avoid the attacks of the lawless rabble who thought his machines would deprive many workmen of a livelihood. Arkwright erected his first mill, which was driven by horses, at Nottingham, and took out a patent for spinning by rollers, in 1769. He built a second factory on a much larger scale at Cromford, in Derbyshire, in 1771, the machinery being turned by a waterwheel, and having made several additional discoveries and improvements, took out a fresh patent for the whole in 1775, thus completing a series of ingenious and complicated machinery. When the importance of his inventions became known efforts were made to have the patent set aside, and in 1781 Arkwright brought actions against a number of persons for invading his patent. Only one cause was tried, that against Colonel Mordaunt in the Court of King's Bench in July 1781; and in that the verdict went against Arkwright on the ground of defective specification. In February 1785, a second action was tried in the court of common pleas, in which Arkwright brought a number of persons to prove that they could make machines from his specifications, in consequence of which he obtained a verdict in his favor. This producing great alarm among many who had erected machines for cotton spinning, and from whom a royalty was demanded, in order to settle the dispute a suit was brought against Arkwright in the Court of King's Bench, in which the whole question was argued, not only as to the intelligibility of his specification, but on the less technical and more important ground of his not being himself the inventor of the machines for which he had obtained a patent. After a long and ably-conducted trial a verdict was given against Arkwright, and in November 1785 the patent was canceled. None of Arkwright's most intimate friends, or those best acquainted with his character, ever had the slightest doubt with respect to the originality of his invention. In 1786 Arkwright received the honor of knighthood from George III, and unlike many inventors, he amassed a large fortune

by his inventions. Consult Baines, 'History of Cotton Manufacture' (London 1861), and Ure, 'The Cotton Manufacture of Great Britain' (London).

ARLBERG. a mountain pass between the Rhetian and the Lech Alps, in the west of Tyrol; between Tyrol and Vorarlberg, pierced by one of the longest railway tunnels in the world. It is six and one-half miles long, was finished in November 1883 and connects the valley of the Inn with that of the Rhine, and the Austrian railway system with the Swiss railways. In 1786 a road was constructed across the pass and was for a long time the only means of communication between Vorarlberg and the rest of the country.

ARLES, *ār*, (ancient, *Arelate*), France, town on the Rhone, about 25 miles from its mouth, in the department of Bouches-du-Rhône. A canal has been cut which connects it with the Mediterranean. It stands on a rocky limestone eminence, sloping to the river, and has irregular streets, presenting many interesting features. In a large square is an ancient granite monolith, and among other remarkable objects are the Romanesque cathedral of Saint Trophimus, with a fine portal and some good paintings and sculptures; and especially numerous ancient remains, of which the most conspicuous are those of a Roman amphitheatre which accommodated 24,000 spectators, and those of a Roman theatre. It has railway workshops, manufactures silk, hats, flour, etc., and forms a market for the productions of the surrounding country. It possesses a college, a naval school, a public library and several museums. Arles was founded several centuries before the Christian era and was the chief colony of Massilia (Marseilles). In the 4th and 5th centuries several church councils met here. From 897 to 1150 it was the capital of a kingdom bearing its name. Pop. (1911) 16,746.

ARLINGTON, Mass., town in Middlesex County, about seven miles northwest of Boston, on the Boston & Maine Railroad. It contains several fine buildings, among which is a library given to the town by Mrs. Eli Robbins at a cost of \$200,000. The town has electric lights and car service to Boston, of which it is practically an attractive residential suburb. Local industries include flower and market gardening, chrome works, piano case and wire factories. The United States census of 1914 recorded 19 manufacturing establishments of factory grade, employing 303 persons, of whom 246 were wage earners, receiving a total of \$185,000 annually in wages. The capital invested amounted to \$1,056,000 and the year's output was valued at \$641,000. As Menotomy, Arlington was settled about 1650; in 1807 it was renamed West Cambridge, and received its present name in 1867. Pop. 12,000.

ARLINGTON, Wash., town in the northern part of Snohomish County, at the confluence of the forks of the Stilliguamish River, and on the Northern Pacific Railroad, 60 miles north of Seattle and 22 miles northeast of Everett, the county-seat. It has saw mills, a shingle mill, a creamery and pasteurizing plant, cannery, machine shops, blacksmith and carpenter shops, two banks, a post-office, two hospitals and a weekly newspaper. It has a graded school system, with a fully accredited

high school, and six churches representing the leading denominations. The principal agricultural industries are dairying, grain-growing, bush-fruit growing, etc. Poultry raising is also important. The lumber industry is extensive. The two banks have resources aggregating \$600,000. The assessed valuation of the town is \$450,000, said to represent but 33 per cent of the actual value. The annual expenses amount to about \$8,000, of which about \$1,000 are raised otherwise than by direct taxes. The government is vested in a mayor and council. Pop. 1,500.

ARLINGTON CONFEDERATE MONUMENT ASSOCIATION. During the administration of President McKinley the Confederate dead buried in the city of Washington, D. C., and vicinity were removed to the National Cemetery at Arlington, Va., the old home of Robert E. Lee, where they were reinterred in a plot of ground set apart by the President for that purpose and designated "The Confederate Section." The Arlington Confederate Monument Association was formed for the purpose of erecting in this section a suitable monument to the dead there buried and to stand, in a larger sense, as a memorial to all those who lost their lives in defense of the Confederacy, as well as to the cause they represented.

ARLON, *ār'lôn*, Belgium, the capital of the province of Luxembourg, in the midst of the woods and mountain ridges of the Ardennes. It is a thriving place, with manufactures of ironware, leather, tobacco, earthenware and clay pipes. It appears in the Antonine Itinerary, and from the coins, inscriptions and other antiquities found, must have possessed some importance even in the time of the Romans. It is mentioned under its present name in 870, in connection with the partition of Lorraine. It has suffered much in the various wars which swept across this part of Europe. From 1684 to 1697 it was in the hands of the French. It was ceded to Belgium in 1831. Pop. (1910) 12,012.

ARM, a term technically applied to that portion of the upper extremity of the body extending from the shoulder joint to the elbow, but popularly used to denote both arm and forearm. The arm proper has one large and strong bone, the humerus, covered by strong muscles, which protect the blood vessels and nerves. The upper end of the humerus fits into the head of the scapula and with the clavicle forms the shoulder joint. The head of the humerus is held in the joint partly by ligaments, but mainly by the muscles attached to it. The motions of the arm are many. Those muscles that move the arm inward toward the chest are known as the abductors. These are the pectoralis major, coraco brachialis, which also flex the arm, and the latissimus dorsi and teres major, which also extend the arm. The arm is moved away from the body by the deltoid, a large muscle on the outer side, and the supraspinatus, a smaller muscle going from the scapula. The arm is rotated outward by the infraspinatus and the teres minor, and rotated inward by the subscapularis: All of these muscles are fastened about the upper part of the humerus. The greater mass of the muscles of the arm are those that go to the forearm and that move

SIR RICHARD ARKWRIGHT
Famous for Inventions in Cotton Spinning

that member. Those that flex the forearm, or bend the elbow, are the biceps, the brachiales and the brachio-radials, the former being the most important. It also aids in turning the forearm palm downward. The muscles that extend or stretch the forearm are the triceps and the anconeus. There are other movements of the forearm. The arm having two bones, the radius and ulna, one turns on the other and the movements of pronation and supination are produced. Pronation is accomplished by two muscles, the pronator teres and the pronator quadratus; the supinator makes the movement outward. The movements of flexion and extension take place in the elbow joint, which is hinged like those of pronation and supination, just below the elbow joint, the radius moving on the ulna. The union of the radius and ulna with the bones of the wrist make a hinge-like joint, the wrist joint. Movements at the wrist are in four directions, flexion and extension, abduction and adduction. These movements, as well as those of the fingers, are made by a large group of muscles some 20 in number. There are in all 48 muscles concerned in the movements of the arm, forearm and hand. The blood supply of the arm is derived from the brachiocephalic of the right side and from the arch of the aorta on the left (see AORTA) in a single main trunk that divides at the bend of the elbow. The first portion is called the subclavian and is not in the arm proper; the axillary, or second portion, begins at the outer border of the first rib and becomes the brachial just about the armpit where it may be felt and compressed. The brachial artery is the great trunk of the arm. It may be felt just inside the inner edge of the biceps muscle about the middle and there may be readily compressed in case of hæmorrhage. At the bend of the elbow the brachial artery divides into the radial and ulnar, which supply the outer and inner sides of the forearm respectively. The radial artery is the one most frequently felt in determining the pulse; the ulnar may be used but as it lies deeper it is felt less easily. In the hand these arterial branches anastomose to form a superficial and a deep palmar arch from which branches go to supply the fingers. Hæmorrhages in the palm of the hand can be controlled therefore only by controlling both radial and ulnar arteries, or better by controlling the brachial just above the bifurcation in the elbow. This may be done by strongly flexing the forearm or by something held against the artery. The principal veins of the forearm are the ulnar, the median and the radial; of the arm the cephalic and basilic. These empty into the axillary vein and this into the sub-clavian. The nerve supply of the arm is derived from the spinal cord from the fifth, sixth, seventh and eighth cervical, and the first, second and third thoracic nerves. These form a complex plexus, the brachial plexus. The main branches going to the different muscles and supplying the skin areas are the median, ulnar, musculo spiral, musculo cutaneous and circumflex. Their distribution is extremely complex. See JOINT, DISEASES OF.

ARMADA, ār-mā'dā or ār-mā'dā, the Spanish name for any armed force, especially a naval force. The term *Spanish Armada* is applied to that great naval armament which Philip II, in 1588, fitted out under the command of the Duke of Medina-Sidonia and Martinez

de Recaldo, against Queen Elizabeth, with the view of conquering England. The fleet consisted of 131 great and many smaller ships of war, and carried 19,000 marines and 8,000 sailors. The ships had scarcely left Lisbon on 29 May 1588 when they were scattered by a storm and had to be refitted in Corunna. Advancing in the form of a half-moon of seven miles in extent, it came in sight, off Plymouth, of the English fleet, scarcely numbering 80 sail, and commanded by Lord Howard, who, endeavored by dexterous seamanship and the discharge of well-directed volleys of shot at alternately long and short distances, to damage the vessels of the enemy. Some of these, including the galleon laden with treasure, fell into the hands of the English or were destroyed. Arrived at length off Dunkirk, on the 7 August the armada was becalmed and thrown into such confusion by the arrival in the fleet of eight fire-ships sent by the English admiral, that on the morning of the 8th Lord Howard was enabled to attack it on several sides. Notwithstanding a brave resistance, many of the Spanish vessels were destroyed or fell into the hands of the English and Dutch, and in consequence the Duke of Medina-Sidonia resolved to abandon the enterprise, conceiving the idea of conveying his fleet to Spain by a voyage round the north of Great Britain. A hurricane which now broke forth with tremendous violence on the already dispirited Spaniards, scattered their ships in all directions. Some went down on the cliffs of Norway, others in the open sea and still others on the Scottish coast. About 30 vessels reached the Atlantic Ocean, and of these several were driven by a west wind on the coast of Ireland and wrecked. In all, the armada is said to have lost in the open sea 72 large vessels, exclusive of smaller craft, and 10,185 men, while every family of distinction in Spain had to mourn the loss of one or more of its members. Only about 50 vessels reached Spain on the return voyage.

Bibliography.—Corbett, 'Drake and the Tudor Navy'; Creasy, 'Fifteen Decisive Battles'; Froude, 'The Spanish Story of the Armada' (London 1892); Gardiner, 'Historical Biographies: Drake'; Green, 'History of the English People'; Motley, 'History of the United Netherlands'; Laughton, J. K. (ed.), 'State Papers Relating to the Defeat of the Spanish Armada' (London 1894).

ARMADALE, the title of a novel by Wilkie Collins (1866). The plot of this, like that of 'The New Magdalen' and others of its author's later novels, is a gauntlet of defiance to the critics who had asserted that all the interest of his stories lay in the suspension of knowledge as to the dénouement. The machinery is in full view, yet in spite of this disclosure, the reader's attention is held until he knows whether the villain or her victims will come out victorious.

ARMADILLO (Sp. dim. of *armada*, armed, referring to its bony shell). 1. *A. edentate*, mammal of the family *Dasypodida*, found in South and Central America and notable for its defensive armor. This armor consists of small roundish bony plates, ossified within the skin, and united to form solid shields, one over the shoulders, one over the haunches, and, between these two, transverse bands of movable plates, which protect, but

leave freedom of motion, to the trunk of the body. These plates are overlaid by a thin, horny pellicle, and between them grow hairs varying in length and amount with the species, from almost none in some to a coat in others, hiding the shell; and the unarmored central surface is also hairy. The head is provided with a shield entirely separate from that of the shoulders, and in some species even the tail is protected by bands of plates. The various forms of armadillos are distinguished largely by the number of movable thin bands of plates lying between the large fixed anterior and posterior shields, up to as many as a dozen in the cabassous (*Xenurus*). This armor serves the purpose of defense, and some of the tribe (only those of the genus *Tolypeutes*, however), increase its value by exercising the power of rolling themselves up into a ball so that the tender under parts of the body may be completely protected. This ability depends upon the number of bands in the central portion of the armor-case. Although true edentates, these animals have a few small, useless teeth, without true roots; the tongue is covered with a sticky fluid like that secreted by the tongue of an ant-eater, but it is not protrusible.

The armadillos are timid, nocturnal animals, living on insects, carrion and vegetable matter; their legs and claws are adapted to burrowing, and, when pursued, they usually bury themselves more quickly than the pursuer can follow them. Only one species (*Dasyus villosus*) is sufficiently adaptable to hold its own when a wild region is settled; the others soon disappear. One of the most interesting of them all is the pichichago (*Chlamyphorus truncatus*), found in Argentina, which lives entirely underground like a mole, and exhibits a peculiar structure in many ways, the body having an appearance of truncation, as if the hinder part had been cut squarely off, instead of ending in curved lines. It is very small, only five to six inches long, while the giant armadillo (*Priodon gigas*) measures three feet, exclusive of the tail. Some of the armadillos range north and south as far as Texas and Argentina; among these is the peba, or nine-banded armadillo (*Tatusia novemcincta*). The family is divided into several genera and the species are numerous and are known as peludos, cabassous, apars, etc., elsewhere described. They are eaten by the South Americans and even esteemed delicate, but their flesh is usually so flavored by the insects and decayed matter which they eat that only a few vegetable-eating species are inoffensive to an unaccustomed palate.

Many forms of fossil armadillos are known from both North and South America, a fossil species of *Dasyus* having been six feet long. Another genus was *Eutatus*, which had a shield formed of 36 distinct bands, of which the last 12 were soldered together. These lead back to the large group *Gravigrada*. (See GLYPTODON; MYLONON.) Good accounts of the armadillos are given in both the 'Standard' and the 'New (Royal)' Natural Histories. Consult also Hudson, 'Naturalist on the La Plata' (1892); Alston's 'Biologia Americana Central'; 'Mammals' (1879-82), with colored plates; Azara's 'Historia Natural de los Paxaros del Paraguay' (Madrid 1805); 'Mammals of Uruguay' in the *Proceedings* of the Zoological So-

ciety of London for 1894; Newman 'The American Naturalist' (September 1913).

ARMADILLO, in entomology. See WOOD-LOUSE.

ARMAGEDDON, är-mä-gëd'dön, the great battlefield where occurred the chief conflicts between the Israelites and their enemies. The name was applied to the tableland of Esdraelon in Galilee and Samaria, in the centre of which stood the town Megiddo, on the site of the modern Lejjun; used figuratively in the Apocalypse to signify the place of "the battle of the great day of God." From the applications of the word Armageddon to the great battle at the end of time it has come to be used for any great slaughter or conflict.

— **ARMAGH**, är-mä', Ireland, a county in the province of Ulster. Its area is about 500 square miles. The northern part of the county, bordering on Lough Neagh, consists principally of extensive bogs of great depth, with a remarkably black soil. Oats, potatoes, wheat, fruit, flax and turnips are the principal crops. Cattle, hogs and sheep are raised. The manufacture of linen is carried on very extensively. The chief towns are Armagh, Lurgan, Portadown. Armagh is the county town. Pop. (1901) 125,238; (1911) 120,291.

ARMAGH, Ireland, city and capital of the county of Armagh. It contains two cathedrals, a Protestant and a Roman Catholic; county court-house, prison, infirmary, lunatic asylum, linen hall, music hall, a public library and an observatory. In the Middle Ages Armagh was an extensive and populous city, and celebrated for its learning, having at one period 7,000 students at its college. There is a modern college, a barracks, an observatory and a large library. Among its benevolent institutions are an infirmary, fever hospital and lunatic asylum. Linen weaving is the chief industry. Not far from Armagh was the palace of Emania, the royal residence from the 5th to the 9th century. Between 839 and 1092 the Danes sacked the town five times. Armagh was again a battleground in the religious struggle between the English and Irish. Pop. (1911) 7,356. Consult Stuart, J., 'Historical Memoirs of Armagh' (Dublin 1900).

ARMAGNAC, är'mä-nyäk', Counts of, an ancient French family, said to have sprung from a branch of the Merovingians. Many of its members hold a prominent place in the history of France. One of the most celebrated was Bernard VII, son of John II, surnamed the Hunchback. He succeeded his brother, John III, in 1391, and greatly extended his territories by the most unscrupulous means, putting several of his relations to death because they stood in the way of his ambitious schemes. Another of the family, John V, grandson of the above, who succeeded his father, John IV, in 1450, made himself notorious for his crimes. On a pretended dispensation from the Pope he married his own sister, by whom he had three children. Charles VII took his possessions, but they were restored by Louis XI. By joining the "League for the Public Weal" he was driven into Aragon and had his estate forfeited. Armagnac was slain by the King's soldiers.

ARMAGNAC, the title of a former district of France now included in the department

ARMADILLOS AND ANT-EATERS

1 Pangolin (*Manis pentadactyla*)
2 Three-banded Armadillo (*Tolypeutes tricinctus*)
3 Aard-Vark (*Orycteropus afra*)

4 Pichicigo (*Chlamyphorus truncatus*)
5 Tamandua (*Tamandua tetradactyla*)
6 Great Ant-Eater (*Myrmecophaga jubata*)

of Gers. Its inhabitants figured largely in the wars of the Middle Ages, one of their contests being known as the "Armagnac War," in which the Armagnac mercenaries of the Emperor Frederick III were defeated by the Swiss, 26 Aug. 1444. See Berthault's 'L'Armagnac' (1899).

ARMAGNAC WAR, The, (*Bellum Armeniacum*; in German called frequently *Armegeckenkrieg*), the struggle between the Swiss and the Armagnac mercenaries of Frederick III in 1444. The war was concluded by the defeat of the Armagnacs at Saint Jacob on the Birs 26 Aug. 1444. See ARMAGNACS, THE.

ARMAGNACS, The, mercenary bands, derived chiefly from the district of Armagnac in southern France, and largely trained in the army recruited in 1410 by Count Bernard of Armagnac for his contest with the Duke of Burgundy. They made themselves extremely oppressive in France through their plundering; and when the Emperor Frederick III requested auxiliary troops from Charles VII, to assist in the conquest of the Swiss, the latter gladly dispatched the Armagnacs. Doubtless the King believed he might at the same time be able to gain control of territory on the left bank of the upper Rhine. What is known as the Armagnac War ensued. In Germany the word Armagnac was converted into *armer Geck* ("poor fool"), and the war frequently styled *Armegeckenkrieg*. On band of 20,000 Armagnacs proceeded by way of Lorraine, another of 30,000 to southern Alsace, whence it marched against the Swiss. At Saint Jacob on the Birs, 26 Aug. 1444, it was badly defeated, with a loss of 6,000, by 2,000 Swiss. It then retired to Alsace, and on 28 October a treaty (that of Ensisheim) was concluded between France and the Swiss Confederation. The Armagnacs continued for a time to work havoc in Alsace and Swabia, where the peasantry retaliated by condemning to death an Armagnac whenever they caught one. In 1445 the remnant was in part dismissed by Charles VII, in part incorporated with other companies of soldiery. Consult the article by Barthold in Raumer's 'Historisches Taschenbuch' (2d series, Vol. III, 1842); Wülcken, 'Urkunden und Schreiber, betreffend den Zug der Armagnaken' (Frankfort 1873); Chevalier, U., 'Répertoire des sources historiques du moyen âge' (Montbéliard 1894); Dognon, Paul, 'Les Armagnacs,' etc., in *Annales du Midi* (1889); Witte, 'Die Armagnaken im Elsass, 1439-1445' (Strassburg 1889).

ARMAMENT, a term used in its broader sense to designate the military and naval equipments or forces of a nation; in its more technical meaning it is used to designate the weapons with which these forces are supplied, such as ammunition and gun mountings, torpedoes, torpedo tubes, etc. See AMMUNITION; ARMY; ARMS AND ARMOR; NAVAL GUNS; WARSHIPS, etc.

ARMAMENT DISTRICT. For the maintenance and improvement of the mobile and seacoast artillery and accessories, armament districts are established in orders from the War Department, and the assignment of armament officers to the charge of these districts is made by the chief of ordnance. These officers keep themselves informed of the condition of

the material by inspections and by direct correspondence with the various district and post commanders. The former are authorized to make the necessary repairs to material in their districts, but no alterations can be made without the authority of the chief of ordnance. Where repairs indicate improper handling or neglect of material, the circumstances are reported to the chief of ordnance. When mechanics employed by an armament officer are on duty at a post or in a district, they, in the absence of the armament officer, are under the supervision of the post or district commander. When a part of or an accessory to an article constituting a portion of the armament of a district becomes obsolete and is replaced, the obsolete part or accessory is transferred by the district commander to an arsenal to be designated by the armament officer.

ARMAND, är'män, Charles Tiffin, (MARQUIS DE LA ROUARIE), French soldier: b. 1753; d. 1793. He was dismissed from the French army for fighting a duel about an actress. Coming to America in 1777, he was given a colonel's commission in the American army, succeeded Pulaski in command of the "Pulaski Legion," in 1779, soon renamed "Armand's Partisan Corps," and became a brigadier-general in 1783. Returning to France he was active on the Royalist side in the French Revolution. Consult the 'Memoir' by Townshend Ward (in *Pennsylvania Magazine of History and Biography*, Philadelphia 1878).

ARMANDE, an elder sister of Henriette in Molière's 'Les Femmes Savantes.'

ARMANSPERG, är'mans-perg, Joseph Ludwig, Count von, Bavarian statesman: b. 1787; d. 1853. He became Bavarian minister of foreign affairs in 1826, and later of the interior and finances. His opposition to the claims of Rome drew upon him the hatred of the Catholic clergy and contributed to bring about his dismissal. He accompanied King Otho to Greece in 1830. He was president of the regency of Greece, 1833-35, and chancellor of state, 1835-37.

ARMATOLES, är'mä-tölz, bodies of Greek militia inhabiting districts in the mountains of Greece assigned to a *capitani* for protection before Greece became independent of Turkey. To these fastnesses fled the independent part of the Greeks, in order to continue the war under leaders called *capitanis*. A *capitani* collected generally a troop of from 50 to 200 men, who remained true to him through every variety of fortune, and attacked the enemy everywhere. Thus involved in an endless struggle with their oppressors, these Greeks were apt to degenerate and become little better than bandits. A large number of them were careful to confine their depredations to Mussulmans; but many instances occurred in which Greeks were attacked when the booty expected was considerable. The Turkish pashas, unable to subdue the armatoles, treated with them; and the *capitanis* received, on condition of remaining quiet, money, stores or other perquisites. They thus became a sort of rural police, having custody of the highways. The Turks disliked their growing power and after 1739 sought to weaken the organization by restricting the privileges and introducing Mohammedan Albanians into the companies, or *armatoliks*. The armatoles aided Ali Pasha

considerably in 1820-22, and greatly aided their countrymen during the Greek war of independence.

ARMATURE, a term applied to the piece of soft iron placed across the poles of permanent or electro-magnets to receive and concentrate the attractive force. In the case of permanent magnets it is also important for preserving their magnetism when not in use, and hence it is sometimes termed the keeper. It produces this effect in virtue of the well-known law of induction, by which the armature, when placed near or across the poles of the magnet, is itself converted into a temporary magnet with reversed poles, and these, reacting upon the permanent magnet, keep its particles in a state of constant magnetic tension, or, in other words, in that constrained position supposed to constitute magnetism. A horseshoe magnet should therefore never be laid aside without its armature; and in the case of straight bar-magnets, two should be placed parallel to each other, with poles reversed, and a keeper or armature across them at both ends. The term armature is also applied to the core and coil of the electro-magnet, which revolves before the poles of the permanent magnet in the magneto-electric machine, and to a part of the telegraph sounder. It is also very generally applied to the part which is revolved between the poles of the field magnets of a dynamo or motor. The iron cores on which the coils are wound afford a magnetic connection between the poles. Consult Cramp, 'Armature Windings' (London 1906); Kinzbrunner, 'Continuous Current Armatures' (New York 1906).

ARMED NEUTRALITY. The term "armed neutrality" has been applied to the collective action of the neutral states which employ their armed strength for the purpose of compelling belligerents to respect their rights. There have been two well known examples of armed neutralities, namely those of 1780 and 1800. Both were formed mainly for the purpose of bringing pressure to bear upon Great Britain to compel her to respect the rights of neutral powers during the war in which she was then engaged and for placing a check upon her exaggerated assertion of belligerent claims. Neutrals complained that in consequence of her naval supremacy she committed unwarranted aggressions upon neutral commerce, in particular that she seized enemy non-contraband property in neutral ships, extended the doctrine of contraband beyond all reason and maintained blockades which were illegal because of their ineffectiveness. Among the parties to the first armed neutrality were Russia, Sweden, Denmark, Spain, France, Holland, Prussia, Austria, Portugal and the two Sicilies.

It adopted a declaration that enemy goods in neutral vessels, contraband of war excepted, were not liable to capture; that a blockade to be legal must be effective, that is to say, vessels of the blockading squadron must be placed sufficiently near the blockaded port to make entrance to it dangerous; and other similar rules in the interest of neutrals were laid down.

The second armed neutrality of 1800 was a similar arrangement for similar purposes. The objects of both were partially realized but it is significant that when the parties became bel-

ligerents themselves, as most of them did shortly afterward, they abandoned for the most part the principles which as neutrals they had striven to enforce. See NEUTRALITY.

JAMES W. GARNER.

ARMED SHIP, a term applied to a ship formerly which had been granted a letter of marque by government authority and which entitled it to the privilege of mounting guns and attacking an enemy's commerce, such vessels being more commonly known as privateers. The term now applies more to commercial ships which are utilized by the government in time of war, in part or wholly, and are armed at the government expense. Special significance has been attached to the term during the great European War, on account of the tendency of the commanders of German submarines to sink all vessels without warning, the United States government contending that all unarmed ships should first be warned and the crew and passengers be given time to leave.

ARMED SOLDIER OF DEMOCRACY, a term occasionally applied to Napoleon Bonaparte because of his supposed expression of the ideals following the French Revolution.

ARMENIA, a mountainous region of western Asia with an area of about 140,000 square miles. It is now partitioned among Turkey, Persia and Russia, their boundaries meeting at Little Ararat.

The plateau of which Armenia chiefly consists is a continuation of the Great Iranian plateau. It is bounded on the north by the Black Sea, descends abruptly to the lowlands of Mesopotamia on the south and more gradually on the east and west to the plateaus of Persia and Asia Minor. It has a mean elevation of about 6,000 feet and is mountainous and volcanic. The ridges, of which there are four principal, are generally parallel to each other, running, with sundry deviations, east and west, and between them are broad valleys; that of the Aras, at Mount Ararat, being 2,890 feet and many others 5,000 to 7,000 feet above the sea-level. The mountains are mainly composed of stratified rocks, with slate, limestone, etc., appearing on the sides of the chains. Granite is also met with but is not frequent; and in the north Palæozoic and in the south later sedimentary rocks are superimposed on archaic rocks. Its volcanoes are all quiescent, unless we except Ararat, of which an eruption took place in 1840, accompanied by a disastrous earthquake. A few mountains, as Ararat, 17,000 feet, Alaghez and Bingöl Dagh, rise above the line of perpetual snow but this is not generally the case; and there are no passes but such as can be crossed in a single day. Saltpetre, lead, iron and copper are found in the mountains; and the last two have to some extent been wrought in modern times. Rock salt is plentiful and is exported in considerable quantities to Persia and elsewhere. Mineral waters abound but little or nothing is known of their qualities. Several important rivers take their rise in Armenia, namely the Kur or Cyrus, and its tributary the Aras or Araxes, flowing east to the Caspian Sea; the Churuk Su, or Tchörak and the Halys or Kelkid Irmak, flowing north to the Black Sea; and the Tigris and

Euphrates, which flow into the Persian Gulf. There are also several minor tributary streams. The only considerable lakes are those of Van, in Turkish Armenia, 78 miles in length and about 32 in breadth; Goukcha or Sevan north-east of Erivan, in Russian Armenia, about 40 miles long by 15 broad; and Urumiyah or Urmia, in Persian Armenia, 80 miles long and 24 broad. It is abnormally salty, while Lake Van is heavily charged with soda.

The climate of Armenia is very severe, presenting a marked contrast to that of the warm regions of the Lower Euphrates and to the mildness prevalent on the shores of the Black Sea. Winter in Armenia continues from October to May, spring and harvest a month each, and the change to the summer is very rapid. The heat, especially in the valleys during summer, is great and rain seldom falls. In Erivan, which is a degree of latitude south from Trebizond, the thermometer in winter falls 36° F. lower than it does in the latter; and in summer it rises 24° F. higher. On the plateaus of Erzerum, Gumri, etc., the difference is still greater; indeed, in the town of Erzeroom the snow lies in the streets for eight months of the year. East and southeast winds in summer, west winds in spring and northeast storm winds in winter, are most prevalent. The soil of Armenia is reckoned on the whole productive, though in many places it would be quite barren were it not for the great care taken to irrigate it. Wheat, barley, tobacco, hemp, grapes and cotton are raised; and in some of the valleys apricots, peaches, mulberries and walnuts are grown. From the nature of the country the rearing of stock is carried on to a greater extent than agriculture. The horses are spirited, fleet and fiery. Pines, birches, poplars and beeches flourish but there are no thick forests except in the northern parts of the country. The flora is not so varied as might be expected in such an Alpine country; in several respects it resembles the vegetation of the Alps of Tyrol and Switzerland.

The inhabitants of Turkish Armenia number about 2,470,000. Besides those of the genuine Armenian stock, in consequence of the repeated subjugation of the country, various other races have obtained a footing. Of these the principal are the Turks and the predatory Kurds; on the Tchorak, Georgians; and throughout the whole country, Greeks, Jews and Gypsies. Before the European War the total number of Armenians was estimated at over 2,500,000, of whom about 650,000 were in Turkish Armenia; about 576,000 in the rest of Asiatic Turkey; about 400,000 in European Turkey; about 1,119,000 in Russian Transcaucasia; and 100,000 in Persia. Since the outbreak of the war, however, an appallingly large number have been exterminated in Turkey. The remainder, like the Jews, are scattered over various countries, and being strongly addicted to commerce, play an important part as merchants. Of late years many have emigrated to America and they are also to be found in Hungary, Italy, Africa and India, chiefly in the great marts, Bombay, Madras and Calcutta. Everywhere they are engaged in banking and trading. Their eyes and hair are black, their looks lively, noses aquiline and their complexion somewhat

swarthy. The women are remarkable for the delicacy and regularity of their features. Like the Jews, whom in many respects they resemble, their ruling passion appears to be an inordinate love of gain, but they are generally esteemed honest. Their mental capacity is good and those who are educated are distinguished by superior cultivation and refined manners; but the mass of the people inhabiting their native country, in consequence of centuries of neglect, are grossly ignorant and superstitious.

History.—The legendary history of Armenia begins with Haik, son of Togarmah, the great grandson of Noah, mentioned in Gen. x, 3. He is said to have taken refuge in Armenia from the tyranny of Belus, King of Babylon, who was slain in pursuit of him. The seventh king in descent from Haik was killed in battle with Semiramis and the country became tributary to Assyria. From Haik the country derived the name Haikistan, and from Armenak, one of his successors, that of Armenia. Armenia continued subject to Assyria under its own princes till the revolt of the Medes and Babylonians against Sardanapalus, when Barbak, the King of Armenia, joined these powers and recovered his independence. Tigranes I is said to have been the ally of Cyrus against Astyages and to have built the city of Tigranocerta. His successor, Vhakin, the legendary hero of Armenia, was deified after his death. Vahi, the last of the dynasty of Haik, was killed in fighting against Alexander the Great as the ally or vassal of Darius. The duration of the dynasty was about 1,800 years. Armenia was now incorporated with the kingdom of Syria. It recovered its independence under Ardvates, 317 B.C., during the dissension among the successors of Alexander, but on his death submitted to the Seleucidæ. About 190 B.C. Artaxias and Zariadres, two Armenian nobles, freed themselves from the dominion of Antiochus the Great and established the kingdoms of Armenia Major and Armenia Minor. Armenia Major was reconquered from Artaxias II by Antiochus Epiphanes. About 149 B.C. Mithridates, or Arsaces VI, King of Parthia, whose dominion extended over Media, Persia and Babylonia, placed his brother Wagher-shag or Valarsaces on the throne of Armenia and introduced the dynasty of the Arsacidæ into the country. He built cities and organized the defenses of the country. His great grandson, Tigranes II, whose long reign appears to have begun about 96 B.C., conquered Artenes, King of Sophene or Armenia Minor, and united all Armenia under his sway. He was successful in war against the Parthians and made himself master of the whole Syrian monarchy. He is also said to have founded or built Tigranocerta, the origin of which is likewise attributed to his probably mythical predecessor. Being the son-in-law of Mithridates, King of Pontus, while Mithridates was preparing to renew his war with the Romans after the death of Sulla, he invaded Cappadocia at his instigation and carried away much spoil and many prisoners. Mithridates, after his defeat, took refuge with Tigranes, who does not seem to have been disposed to render him active assistance; but Lucullus made a peremptory demand through Appius Clodius

for his surrender, which left Tigranes no alternative but a declaration of war, 69 B.C. Disregarding an invasion of Cilicia, Lucullus at once carried the war into Armenia, defeated the numerous forces of Tigranes and captured Tigranocerta. Antiochus Eusebes was reinstated on the throne of Syria, and other dependents of Tigranes revolted. Tigranes in the meantime, with the assistance of Mithridates, collected another army which was again defeated by Lucullus. Favored by disaffection among the Roman troops, however, Tigranes recovered the greater part of Armenia and defeated Fannius, the lieutenant of Lucullus. Pompey, who arrived in 66 B.C., after overthrowing Mithridates, who had also recovered his dominions, advanced to Armenia, which was at the same time invaded by the Parthians, instigated by the revolted son of Tigranes. The Parthians speedily withdrew and young Tigranes fled to Pompey. At this critical juncture the elder Tigranes hastened to make his submission to the Roman general, who left him in possession of his kingdom, but deprived him of the provinces of Sophene and Gordyene, which he erected into a kingdom for the younger Tigranes. The elder Tigranes continued faithful to the Roman alliance, and Gordyene, which had been seized by the Parthians, was soon after restored to him. Tigranes died about 55 B.C. His son Artavasdes was made prisoner by Antony and carried to Egypt where he was put to death by Cleopatra in 30 B.C. Armenia, lying between the Roman and Parthian empires, became a battlefield where they disputed for mastery, and with difficulty maintained its independence under princes from the family of the Arsacidæ till the time of Trajan, who made it a province. It was given up by Hadrian and again ruled by the Arsacidæ. Chosroes defended it during a long reign against the power of Persia, which had recently re-established its monarchy on the ruins of the Parthian empire; but about 258-59 A.D. Sapor, King of Persia, unable to subdue Chosroes by force of arms, caused him to be assassinated, and his son Tiridates being an infant, took possession of the country. Tiridates was restored by the Romans in 286, the third year of Diocletian. At the beginning of his reign he persecuted the Christians, who were numerous in Armenia, but was himself converted to Christianity, it is said, by Gregory the Illuminator. Armenia was thus the first country which officially embraced Christianity. On the defeat of Galerius by the Persians in 296 Tiridates, who fought valiantly as the ally of the Romans, was compelled to follow the retreat of his protectors; but the succeeding campaign restored him and his dominions were extended in the peace with Persia which followed. By the treaty into which Jovian, the successor of Julius, entered with Sapor II, 363 A.D., the Romans were compelled to abandon the protection of Armenia. It was speedily reduced to a Persian province, but after the death of Sapor its independence was restored in a new treaty of peace made with Theodosius in 384. The country long oppressed by the contentions between the Romans and Persians, soon fell into division through the attraction of these rival powers (387). A Persian king or gov-

ernor, Chosroes, was set up over the eastern, and a Roman, Arsaces, over the western portion of the country, both being of the royal house of Armenia. On the death of Arsaces the Romans suppressed the form of royalty and annexed their portion of the country to the empire under the military command of a count of the Armenian frontier. This occurred in the reign of Theodosius II. On the death of Artasires or Ardashir, the successor of Chosroes, Bahram V of Persia (about 428) annexed the Persian portion under the name of Persarmenia. The Persians exerted themselves to extirpate Christianity but failed to do so; and on the fall of Sasanidæ (632) the country was united again under the Greek empire. After the Arab invasion in 637 it became the scene of incessant struggles between the declining empire and the rising Mohammedan power and as it was persecuted by the emperors for its adoption of the Monophysite heresy its sympathies were not always with the former. The dynasty of the Pagratids or Bagratidæ was established by the arms and influence of the caliphs. It was a family of Jewish origin and appears to have risen gradually to influence in the country. The date of its elevation to royalty is usually given as 885, but a much earlier date is sometimes assigned. It lasted till 1079, when the country again became dependent on the Greek empire. During this period several other dynasties which it is not necessary specifically to notice reigned simultaneously in different parts of the country. On the fall of the Pagratidæ, Rhupen or Ruben, a relative of the last king, founded a small kingdom in the north of Cilicia, which gradually extended to the Mediterranean and was known as Lesser Armenia. It rendered valuable assistance to the Crusaders, and its later rulers were of the house of Lusignan, styled Kings of Cyprus, Jerusalem and Armenia, the last of whom, Leon VI, was taken prisoner when the country was conquered by the Mamelukes in 1375. Armenia formed part of the empires of Genghis Khan and Tamerlane and a great part of it was conquered by Selim II in 1522. Henceforth it was shared between the Turks and Persians, the former having the greater part of it. In 1828 Russia obtained a considerable portion of Persian Armenia and this was augmented in 1878 by the Turkish possessions of Batum, Ardahan and Kars, ceded by the treaty of Berlin. Russian Armenia includes the governments of Erivan and Elizabethpol, the territory of Kars, etc., with the important towns of Tiflis, Kars and Erivan. Persian Armenia forms part of the province of Azerbaijan. Turkish Armenia, which includes most of Kurdistan, is composed of the vilayets of Erzerum, Mamuret-ul-Aziz, Diarbahr, Bitlis and Van, with an area of 71,990 square miles.

Armenian Question.—The so-called "Armenian Question" began after the Russo-Turkish War of 1877-78. By the treaty of Berlin the Sultan promised much needed reforms for his Armenian subjects to the great Powers, particularly Great Britain and Russia. After 1884, however, Russia's policy toward the Armenians changed, the reforms were not effected and revolutionary movements, in imitation of the Russian Nihilist propaganda,

started among the oppressed Armenians. The Turkish government called upon the Kurds to police the country, sanguinary conflicts ensued, and in 1895-96 brutal and atrocious massacres by the Kurds, aided by Turkish soldiers, occurred at Trebizond, Van, Bitlis and in many other parts of the country and entire Armenian communities were wiped out. England, France and Russia protested, the Sultan promised reform and reparation, a commission of investigation was formed, but the massacres continued, and in August 1896 from 4,000 to 6,000 Armenians perished in the streets of Constantinople at the hands of the mob, in retaliation for the seizure of the Ottoman bank by Armenian insurgents. Revolutionary propaganda and minor massacres continued until the Young Turk Revolution of 1908, at first enthusiastically supported by the Armenians. A year later, however, at Adana and throughout Cilicia and northern Syria another massacre on a large scale occurred and 30,000 Armenians were killed. In April 1915, after the outbreak of the European War, the Turkish government started to put into execution what seemed a systematic plan for the extermination of the Armenian race, and it has been estimated that nearly a million Armenians have perished.

Art.—The only important ruins of the Roman period are at Karni. After the country had become Christian many churches were built, possessing much architectural character. The oldest of these still surviving is probably the Church of Saint Ripsima at Vagashabad (618), but the most interesting is the cathedral at Ani, built about 1010, while of nearly equal importance is the cathedral of Kiutas, on the basilican plan. A church with a striking dome and five naves, belonging to the same century, is found at Mowki and there are many others remarkable for the delicacy of decorative details. The most richly ornamented of these is that at Mtzkhet in Georgia, belonging to the 15th century. The Armenian architects and artists were much given to the employment of decorative inscriptions, as were their Mohammedan neighbors, and in their use of animal and decorative sculpture, especially for wall panels and for broad bands surrounding windows they showed great artistic sense and originality. Carving in wood and ivory was much practised but the Armenians especially excelled in the production of cloisonné enamel and in the employment of geometric ornament applied to buildings as well as to small objects, such as the sacred vessels of the church and toilet articles. Wall-painting was also an Armenian accomplishment and one in which not a little independence of Byzantine influence was exhibited. Illuminated Mss. were brought to great perfection in the 13th century. Fine collections of them are preserved in the Armenian Library in Venice and in the monastery of Etchmiadzin in Russian Caucasus, the national sanctuary of the Armenian church.

Armenian Church.—The Armenians received Christianity as early as the 3d century. During the Monophysitic disputes, being dissatisfied with the decisions of the Council of Chalcedon (451), they separated from the Greek Church in the year 536 and called themselves the Gregorian Church, after Greg-

ory the Illuminator. The Popes have at different times attempted to gain them over to the Roman Catholic faith but have not been able to unite them permanently and generally with the Roman Church. There are, however, at present about 100,000 United Armenians scattered in Russia, Poland, Galicia, Persia and Italy who acknowledge the spiritual supremacy of the Pope; they agree in their doctrines with the Catholics but retain their peculiar ceremonies and discipline. At different times force has been used to make the Gregorian Armenians conform to the religion of Mohammed; but the far greater part are yet Monophysites and in spite of fierce persecutions have remained faithful to their old religion and worship. Their doctrine differs from the orthodox chiefly in their admitting only one nature in Christ and believing the Holy Spirit to issue from the Father alone. In their seven sacraments, which they call mysteries, there are these peculiarities, that in baptism they sprinkle thrice and dip thrice, and this is immediately followed by confirmation; that in the Lord's Supper they mix no water with the wine and use leavened bread, which they distribute dipped in wine; and that they allow extreme unction only to divines immediately after their death. They adore saints and their images, but do not believe in purgatory. In fasting they surpass the Greeks. Their feasts are fewer than those of the Greeks but they celebrate them more devoutly. They worship, in Turkey mostly in the night time; the mass is said in the ancient Armenian, the sermon is preached in the modern. Their hierarchy differs little from that of the Greeks. The *catholicus* or head of the church has his seat at Etchmiadzin, a monastery near Erivan, the capital of the Russian Armenia, on Mount Ararat. The holy oil, which he prepares and sells to the clergy and the frequent pilgrimages of the Armenians to Etchmiadzin, supply him with means for the support of a magnificent style of worship and of establishments for education. He maintains in his residence a seminary for the education of divines. There is here also a printing press. When the office of *catholicus* is vacant two candidates are elected by the people, through their representatives in each diocese, and the Tsar chooses between them. The patriarchs of Constantinople and Jerusalem, the bishops and archbishops are invested by the *Catholicus* and every three years confirmed in their offices or recalled. In Turkey the Patriarch of Constantinople is the official as well as the real ecclesiastical head of the nation and presides over the National Assembly which includes two administrative bodies: the committee for civil affairs and the committee for ecclesiastical affairs. The remainder of the clergy are often ignorant but generally respected and resemble the priests of the orthodox church in rank and duties. The monks follow the rule of Saint Basil. The *varabets*, who live like monks, cultivate the sciences, take degrees, which may be compared with the usual academic honors and are the vicars of the bishops, form a class of divines peculiar to the Armenian Church. The secular priests must be married once, but are not allowed to take a second wife. Armenian churches have

been established in the United States wherever a considerable body of Armenian refugees have settled.

Language and Literature.—The Armenian language is, according to H. Hubschmann, one of the main divisions of the Indo-Germanic group of languages though formerly considered a dialect of the Iranic branch. The Old Armenian or Haikan language, which is still the literary and ecclesiastical language, is distinguished from the New Armenian, the ordinary spoken language, which contains a large intermixture of Persian and Turkish elements. The most learned Armenian antiquaries do not pretend to trace their literature further back than about 150 years before the Christian era when Marbas Catina wrote a history of Armenia, and earned for himself the title of the Armenian Herodotus. He was followed by some half dozen historians and mythologists, but all these early productions are lost, though they have not been quite valueless, inasmuch as they were the sources whence later Armenian writers compiled work still extant. The authors who lived in the 4th century of the Christian era are the first whose writings have been preserved. Christianity then prevailed in Armenia, and her authors were princes and prelates. The 5th century was the golden age of Haikan literature. This century was fruitful in authors, and was further distinguished by two events important to the progress of learning. The Armenians till then had had no alphabet of their own, indifferently using Greek, Syriac, and Persian characters. Early in the 5th century Mesrop Masdoty invented a Haikan alphabet of 36 letters, still called, in honor of the inventor, Mesropian, and now employed as capitals, since others of more convenient form have supplanted them in common use. About the same time schools were instituted throughout Armenia, and the scholars there trained exerted themselves in producing Haikan versions of the Bible, the earliest of which was completed by 412, and of the masterpieces of Greece and Rome. One of the most distinguished authors who now appeared was Archbishop Moses Chorenensis or Moses of Chorene. Besides innumerable translations, he wrote a history of Armenia, and a treatise on rhetoric—all of which, together with some homilies, have been preserved as well as some hymns still habitually sung in the Armenian Church service. A treatise on geography also ascribed to him dates probably from the 7th century. His 'History of Armenia' was published in London in 1736, with a Latin translation, by the celebrated W. Whiston and his son George. It was published at Venice in 1752, 1827, 1865 and 1881; was translated into French by Levaillant de Florival in 1841, and into German by Lauer (Regensburg 1869). Other celebrated Armenian authors of the golden age are Eznik of Golp; Korune, the biographer of the learned Mesrop; Elisaeus, author of a history of the Vardanants; Lazar of Parpi; Agathangelos, and the historian Faustus of Byzantium, who probably wrote in Greek. In the 6th century Haikan literature first remained stationary, and then began to decline. It revived somewhat in the 12th century but after the 14th declined steadily until the 17th. During this period authors abounded, but in a literary sense their pro-

ductions were worthless. A few histories, however, national, Tartar, Arab etc., some of them in verse deserve esteem for the information they contain. In the 17th century Armenian schools and colleges arose in the East and in the West, Armenian printing presses were set up in various towns, and Armenian literature began to revive. In the 18th century the revival was complete, very much owing to the zealous and judicious exertions of Petro Mechitar, a Catholic Armenian, who in 1701 founded a religious society at Constantinople for the purpose of elevating the Armenians by diffusing among them a knowledge of their ancient literature and language. Being persecuted by the opposite sect he fled with his adherents to the Morea, then under the Venetians, and established a monastery and academy at Modon. The Morea reverting to the Ottoman sceptre, Mechitar transferred his institution to the small island of San Lazaro at Venice, where it has ever since remained and prospered. Abbot Mechitar, during the remainder of his life (he died in 1749) successfully exerted himself to render his monastic college the chief seat of Armenian erudition and education. The best Armenian press extant is the Mechitarist, from which issues a newspaper that circulates widely in the Levant. Here many of the classical works of England, France, Italy, and Germany have been translated into Armenian. There is also a Mechitarist college in Vienna, and a branch in Munich. Wherever any extensive community of Armenians have settled they have set up a printing press, as in Amsterdam, Leghorn, Moscow, Venice, Astrakhan, Constantinople, Smyrna, Tiflis, Saint Petersburg, Madras, Calcutta, etc., and at several of these places periodicals are published. The founder and greatest master of modern Armenian literature is the novelist Raffi (1837-1888). A splendid dictionary of the Armenian language with Latin and Greek equivalents for each word was published by the Mechitarist press at Venice in 1836. The best Armenian dictionaries for foreigners are the Armenian-French one published at Venice in 1812; the Armenian-Italian of Emmanuel Tchaktchak (Venice 1837); the Armenian-English of Aucher as improved by Bedrossian (Venice 1868-79, both Armenian-English and English-Armenian); and the French-Armenian of Norayr (Constantinople 1884).

ARMENTIERES, *ār'mān'tyār'* (Latin, *Armentaria*), France, town on the Belgian frontier, 10 miles west-northwest of Lille, on the Lys. The town has a communal college and factories for spinning flax, hemp and cotton yarn. There are also manufactories of woolen cloth, table linen, calicoes, lace, thread, beet-root sugar and tobacco; bleachfields, distilleries, soap-works, tanneries and salt-refineries, with a considerable trade in grain, brandy, iron, tobacco, soap, etc. Bricks are made in the neighborhood in large quantities. Armentieres was occupied by the German armies in their offensive against Paris in 1914. In the several offensives during the war it was the scene of much hard fighting. Pop. (1911) 28,625.

ARMFELT, *Gustav Mauritz*, Swedish courtier and diplomat: b. Finland, 31 March 1757; d. Tsarskoe-Selo, 19 Aug. 1814. His amiability, brilliant social gifts and unwavering loyalty commended him to Gustavus III, who entrusted him with important negotiations. In 1783 he took part in the negotiations with Catherine II, with the Danish government in 1787 and during the Russian war of 1788-90 was one of the most active counselors. He displayed great bravery in the field and concluded the peace of Verela in 1790. By the will of Gustavus III, who was assassinated in 1792, Armfelt was appointed to care for the infant son of Gustavus and made a member of the council of the regent, Charles, Duke of Suder-

mania. The latter found means to destroy the will and Armfelt was sent as an ambassador to Naples to be out of the regent's way. From Naples he wrote to Catherine II, urging her to help overthrow the regency and induce the states to proclaim Gustavus IV of age. The regent's spies discovered the plot and Armfelt only escaped from the war vessel sent to Naples to seize him, through the aid of Queen Caroline. He fled to Russia, and at home was condemned to confiscation of property and death as a traitor. When Gustavus IV reached his majority in 1799 Armfelt was restored to all his honors. He was sent as ambassador to Vienna in 1802, but was obliged to quit this post for attacking the Austrian policy in relation to Napoleon I. In 1805-07 he commanded the Swedish forces in Pomerania and there he displayed remarkable ability. When Gustavus IV was deposed in 1809 Armfelt would not treat with the revolutionary leaders. He was among the most courageous supporters of the Crown Prince Gustavus, and when Bernadotte was placed at the head of the nation Armfelt decided to remove to Finland. In 1811 he was expelled as a conspirator. On retiring to Finland he was held in high esteem by Alexander I. The grand-duchy of Finland was erected into an autonomous state and Armfelt was its first governor-general. He was made a count and appointed chancellor of the University of Abo, and member of the Russian senate. Consult Bain, R. N., 'Gustavus III' (Vol. II, London 1895), and Tegner, Elof, 'Gustaf Mauritz Armfelt' (Stockholm 1887).

ARMIDA, a grand heroic opera by Christoph W. Gluck (1714-87); libretto by Philippe Quinault, a 17th century poet, who had written it for another composer, Lully. It is founded on an episode from Tasso's "Gerusalemme liberata," and was utilized by Gluck nearly 100 years after the libretto had been written. The music he composed to it is sublime in grandeur and is regarded as a classic of the highest type. Armida, the Queen and enchantress, dwells in a magnificent palace in Damascus; the period is the 11th century. The gallant knights crusaders fall under the charm of Armida; but not so Rinaldo, the famous hero in Godfrey de Bouillon's army. Unjustly accused of a misdemeanor, Rinaldo has been expelled from the army and wanders alone in the forest. He has been warned against the wiles of Armida, but he scoffs at the idea of any woman compelling his love. But the sorcery of Armida is at work; languorous music overcomes him and he falls asleep in a green valley. Enraged at his scornful indifference, Armida has decided to kill him, but love conquers hate and the dagger falls from her hand. Though she strives against her tender passion, she succeeds in entrancing him with her display of devotion. Meanwhile de Bouillon has dispatched two knights to recall Rinaldo—a Danish warrior and the knight Ubalt. These two also fall victims to Armida's witchery. The Dane meets a demon who has assumed his bride's face and tenderly calls him, but Ubalt breaks the spell and both reach Armida and Rinaldo. The call of duty and honor awakens Rinaldo from his love dream and he resolves to return with his companions. Armida's passionate entreaties

fail to shake his resolution; he departs, and in despair she curses her love and him who provoked it, and turns her palace and gardens into a wilderness. In the sequel Armida becomes a Christian. Aside from the ones already named, the story has been made the subject of operas by Cherubini (1784), Zingarelli (1786), and Rossini (1816). Consult Beloni, 'Gli epigoni della Gerusalemme liberata' (Padova 1893).

ARMIDALE, Australia, town in Sandon County, New South Wales, 313 miles north of Sydney. It lies at an elevation of 3,313 feet, in a picturesque mountainous district, for the most part pastoral and agricultural, though it contains some alluvial gold diggings. Antimony is found in large quantities near the town. It has two fine cathedrals, its schools include the New England Girls' School, Saint Patrick's College, the high school, the Ursuline Convent and state schools. Armidale became a municipality in 1863. Pop. 4,250.

ARMINIANISM, a term applied to a certain phase of Protestant theology. In the Netherlands early in the 17th century there was a revolt against the doctrine of unconditional election as taught by the rigid Calvinists. The most important person, though not the first one, in this revolt was Jacob Arminius (q.v.) A controversy was carried on between him and Gomarus over the question of predestination, and, after the death of Arminius, with increased vigor by their followers. In 1610 the Arminians set forth their views in a 'Remonstrance' covering the points in controversy which in substance was as follows:

(1) God decreed to save through Christ those who believe in his Son and who persevere in faith and obedience through life, but he leaves in sin those who are not believers. (2) Christ died for all, but no one except the believer has remission of sins. (3) Man can neither do nor think anything truly good until he is born again through the Holy Spirit. (4) All good in the regenerate man is brought about by the grace of God, but this grace is not irresistible. (5) Those who are truly converted have power given them through the Holy Spirit and the help of Christ, so that if they desire his aid and are not inactive, no power can take them away from Christ.

In 1618 the Synod of Dort met and condemned the five articles, and many of the remonstrant ministers were deposed, but in 1630 they were granted religious liberty. They have continued to the present as one of the smaller religious sects of Holland with a presbyterial organization and a theological seminary at Amsterdam. The present importance of Arminianism is due to the fact that the founders of Methodism (q.v.) incorporated into their system the teachings of Arminius and his immediate followers. This is the belief of the Methodist Church to-day, as well as that of many individuals belonging to churches nominally Calvinistic. Consult Annan, W., 'The Difficulties of Arminian Methodism' (Philadelphia 1860); Blok, 'History of the People of the Netherlands' (Part III, trans. Putnam, New York 1900); Gill, J., 'The Cause of God and Truth: Being an Examination of the Principal Passages of Scripture made use of by the Ar-

minians in Favour of Their Scheme' (4 vols., London 1735-38); 'The Works of Arminius' (trans. 2 vols., Buffalo 1853).

ARMINIUS, the German national hero celebrated by his fellow-countrymen as their deliverer from the Roman yoke: b. 17 B.C.; d. 21 A.D. He was the son of Segimer, a prince of the Cherusci, a tribe inhabiting parts of what is to-day Brunswick and Hanover. His early life was spent in the Roman army where he served with distinction and attained the rank of *equus*. This period was one of great peril for Germany. The Romans had advanced far into the territory of the Teutonic tribes and had erected a series of strong fortresses in order to keep the more turbulent districts in subjection. From 9 B.C. to about 4 A.D. Drusus and Tiberius had campaigned against the Germans; Tiberius proceeded with great circumspection, however, and induced the Germans to live on good terms with the Romans, to adopt Roman habits and mode of living, etc. Arminius, during his years of service with the Roman legions had acquired a knowledge of Latin and also gained an insight into the art of war as practised by the Romans. Returning home in 7 A.D. he found his people secretly chafing under the Roman governor, Quintilius Varus, and resolved to deliver his countrymen from Roman rule.

With this object he secretly organized all the tribes as far as the Elbe, induced Varus to scatter his forces, and in 9 A.D. decoyed Varus with three legions into the fastnesses of the Teutoburg Forest, probably between the modern towns of Detmold and Wiederbruck and near the headwaters of the Ems and the Weser. Arminius fell upon the legions unexpectedly and virtually annihilated them. The news of the disaster caused consternation in Rome and gave rise to the Emperor's despairing utterance: "Varus, restore to me my legions." The Germans did not follow up their victory, however, and both sides maintained peace until 15 A.D., when Germanicus Cæsar led the Romans against Arminius and reduced the latter to great straits, capturing his wife, Thusnelda. In 17 A.D. he was recalled by Tiberius and the results of his two years' campaign against Arminius were lost. After this time no Roman army ever penetrated to the heart of Germany. Arminius' later years were troubled with the internal feuds which broke out among the several tribes, his chief opponent being Marbod, prince of the Marcomanni. By aiming to found a powerful kingdom Arminius drew upon himself the hatred of his countrymen and he was assassinated in 21 A.D. Of him Tacitus says ('Annalia'): "Arminius fought with the vicissitudes of fortune, and fell at last by the treachery of his own relatives; a man of warlike genius, and beyond all question the liberator of Germany." In 1875 a great monument to Arminius was completed. It was by Bandel and was erected on the Grotenburg Mountain, near Detmold. The exploits of Arminius have furnished material for the dramas of Klopstock and others. Consult Dünzelmann, E., 'Der Schauplatz der Varusschlacht' (1889); Fischer, F. W., 'Armin und die Römer' (1893); Kemmer, O., 'Arminius' (1893); Meyer, E., 'Untersuchungen über die Schlacht im Teutoburger Walde' (1893); Uhl, W., 'Das Porträt des

Arminius' (1898); Wilms, A., 'Die Schlacht im Teutoburger Walde' (1899).

ARMINIUS, Jacobus, or JACOB HARMENSEN, the founder of Arminianism (q.v.); b. Oudewater, Holland, 10 Oct. 1560; d. Leyden, 19 Oct. 1609. He early showed marked promise as a scholar, and entered the University of Leyden at the age of 15. His ability was so apparent that certain officials of Amsterdam undertook the expense of his education for the service of the Church. This enabled him to study at Geneva, where Beza was at the height of his influence and by whom Arminius was greatly influenced. He also studied at Basel and Padua and visited Rome, returning to Holland he was ordained in 1588 and became pastor of the Reformed Church at Amsterdam. At that time he was a rigid Calvinist, but milder views of predestination than those which he had learned from Beza having made their way into Holland, Arminius was called upon for a defense of Calvinism. He made a more careful examination of the disputed points and as a result modified his own views, though still holding to predestination. In spite of the opposition which arose because of his changed opinions he was offered and accepted a professorship in the University of Leyden in 1603. A controversy soon broke out between him and his colleague, Gomarus, a zealous and extreme Calvinist. Two parties were formed in and beyond the university, and the controversy was kept up till his death in 1609. See ARMINIANISM. Consult 'J. Arminii Opera Theologica' (Leyden 1629), 'The Works of Arminius' (English translation, Buffalo 1853); and Nichols, 'Life of Jacobus Arminius' (London 1843).

ARMISTICE, a suspension of hostilities between two belligerent powers or two armies by mutual agreement. It may either be for a definite period or until its termination is proclaimed. An armistice throughout the whole theatre of war can be concluded only by the belligerent governments, and does not take full effect until it has been ratified. A partial armistice may, however, be concluded by the commanders of individual armies or army corps, and such an armistice requires no ratification, although it may be disapproved and abolished by the government. An armistice is often concluded for only a few hours to bury the slain, remove the wounded, and exchange prisoners, and also sometimes to allow of a parley between the opposing generals. A breach of an armistice is regarded as a violation of the law of nations. Sometimes a regular armistice is preceded by an actual suspension of hostilities. If the conditions on which an armistice was agreed upon, as that while it lasted all preparations for attack or defense should cease, are violated by either side, the enemy is entitled to resume hostilities at once. A general armistice is usually the preliminary of a peace, and can only be proclaimed by the commanders-in-chief or their home governments.

ARMITAGE, Edward, English historical and mural painter: b. London, 20 May 1817; d. 1896. He studied in Paris, where, 1842, he exhibited his first independent work. In the following year his 'Landing of Cæsar' gained a prize of \$1,500 in London; and in 1845 and

1847 he carried off prizes of \$1,000 and \$2,500. He was made a fellow of the Royal Academy in 1872, and in 1875 was appointed lecturer on painting there. His mural paintings include a series of noble figures of Christ and the 12 apostles, executed for Saint John's Roman Catholic Church in London. His 'Lectures on Paintings,' to the students of the Royal Academy, were published 1883 and another volume, 'Pictures and Drawings' was issued 1898.

ARMITAGE, Thomas, American clergyman: b. Pontefract, England, 2 Aug. 1819; d. Yonkers, N. Y., 20 Jan. 1896. He prepared himself for the ministry and preached his first sermon when 16 years old. Coming to New York city in 1838, he was actively engaged in the ministry of the Methodist Church until 1848, when he became a Baptist, and was pastor of the Norfolk Street Church (later the Fifth Avenue Baptist Church). In 1890 he was made pastor emeritus, given a residence in Yonkers. He was one of the founders of the American Bible Union. He advocated the revision of the Bible, especially in regard to the correct interpretation of the words therein relating to baptism. He published 'Jesus: His Self-Introspection' (1878); 'Lectures on Preaching' (1880) 'History of the Baptists' (1886).

ARMOR-PIERCING PROJECTILES.

Projectiles intended for practice at objects composed of wood, masonry, or earth are made of cast-iron; but since the introduction of iron for the defense of ships and for fortifications, a material possessing greater hardness than ordinary cast-iron is required to overcome the resistance opposed by thick wrought-iron plates. Both elongated and spherical projectiles for use against armor should be of the hardest and toughest material possible. The power of a projectile to stand up to its work and deliver its full blow on the target depends on the *shape* as much as on the *quality* of the metal of which it is composed.

The flat-ended form of *elongated* projectiles possesses a peculiar advantage as regards the projectile, and another as concerns the plate. As to the projectiles, in direct impact the whole of the resistance of the target acts in lines parallel to the projectile's axis, which direction is the most favorable to the projectile retaining its mass and delivering its full blow on the target; and, again, if the target is to be punched by actual shearing, the flat head is the form best adapted to effect it. The flat head would probably be best in the case of direct firing against plates composed of hard iron, for it is easy to conceive of a hard material offering very great resistance to the forcing open of a pointed head, which might be punched by the clean shearing of a flat-headed projectile. The power given by rotation of keeping the same portion of a projectile presented to the front is of peculiar value in punching armor plates; it enables the head of the projectile to be made of any desired form, while the power of reducing the calibre of projectile in proportion to its weight, which is perhaps the principal advantage obtained by rifling, is also

most important here, the depth of penetration being in inverse proportion to the circumference. In shells, however, this stability of the axis of rotation tells more fully, for it enables

SIX-INCH RIBBED CAVITY ARMOR-PIERCING SHELL.

Projectile was loaded with 2 pounds of black charcoal powder and fused with magazine fuse. Fired at 6-inch Krupp hard-faced armor plate. Shell burst about 8 feet to rear of plate after penetrating the same. Weight of largest fragment recovered 10½ pounds. Average weight of fragments 2 ¼ ounces. Total number of pieces recovered, 650.

every part of the projectile to be made of such proportions as will give the maximum power at the moment of impact. The walls of an elongated shell being chiefly subjected to a longitudinal strain, an interior hollow may be made without entailing the great weakness existing in spherical shells as compared with solid shot. Hence it follows that while smooth-bore shells have seldom or never been fired at armor, rifled shells have proved very successful.

There are two causes which contribute to give shells peculiar power against iron plates. The first is that it is not necessary to weaken the head of a shell by making a fusehole in it, because no fuse occurs, the heat generated on the impact of a projectile against the armor being sufficient to fire the bursting-charge. To such an extent is light as well as heat generated, that on firing at a target after dark a pale flash is seen to follow the impact. The second cause that operates to favor the action of shells is the fact that when the shell has penetrated to a depth of even a few inches before rupture occurs, the sides are supported by the armor around them, and the explosion, being confined at the sides, acts to the front with greatly increased force.

In a conical head the normal pressures throughout form a zone of compression acting as a wedge toward the body of the projectile, whose angle is the supplement of that of the

cone of the head. This is better than that formed in the spherical head, because the angle is less acute, and because the apex of the wedge, instead of being a fixed point throughout (the centre of the sphere) moves along the axis of the projectile as it enters deeper and deeper into the target. In the ogival head it will easily be seen how much superior is the action. In this the wedge is at the commencement slightly acute, but then the resistance acts on a small surface and is comparatively small, and the angle increases, till, at the junction of head and body, it becomes 180°, or a straight line, so that we then have the body of the projectile in much the same condition as the flat-headed bolt driving before it an ogival wedge, which opens the armor by wedging rather than by clipping or punching. As the softer and more plastic natures of plate-iron have been found to hold their bolts the best, and stand the longest, and so have been universally adopted, the ogival has become obviously the correct form of head.

The effect of hardening projectiles is probably much greater than is generally supposed, that is, the amount of work gained is much greater than the increase of strength of the projectile. It is well known that a very small force may under certain circumstances determine the performance or non-performance of a very large amount of work. In like manner a very slight addition to the rigidity of a projectile, by hardening or otherwise, may determine whether a very large amount of work shall be wasted upon the projectile or expended upon the plate. Another means of increasing the work done upon the armor plate in comparison with that done upon the projectile is by increasing the velocity of the latter. That is, a projectile moving at a low velocity may be smashed up or flattened against the plate, while the same projectile fired at a higher velocity may go through the same plate almost uninjured. On this principle a lead shot may be fired through an iron plate, or a tallow candle through a pine board.

ARMOR-PIERCING PROJECTILES CAPPED AND UNCAPPED.

The projectiles shown are a 3-inch capped, a 4-inch capped, a 5-inch and a 6-inch uncapped, 8-inch uncapped and capped, 10-inch uncapped and capped and 12-inch capped.

Numerous trials have shown a superiority of steel projectiles over those made of chilled cast-iron; and although the former are somewhat more expensive than the latter, it would

be misplaced economy to leave any means unavailed of to increase the penetrating power of projectiles. The quality of chilled projectiles, from the nature of their manufacture, is necessarily unreliable; whereas this is not the case with hammered cast-steel, or at least not to the same extent by far, even when large masses are produced, and the difficulty of manufacture increases with the calibre. The most essential difference in the behavior of steel and chilled projectiles on striking the target consists in the reaction on the projectile showing itself in the latter by breaking up, while the former are only set up. As the breaking up of the chilled shells may take place before the bursting-charge comes into operation, whereby the rending effect is considerably prejudiced, this material appears far less adapted for shells than steel. The superiority of steel in this respect is still further increased by the fact that the steel shell can have thinner walls, consequently a larger chamber, and can thus hold a larger bursting-charge than the chilled metal. SEE ARMOR PLATE; PROJECTILES.

ARMOR PLATE. The idea of protecting ships of war and the fronts of fortifications by means of armor plate dates from about the middle of the 19th century. In 1842 experiments were conducted with iron plates made by riveting together plates three-eighths of an inch in thickness to a total thickness of six inches. Those plates did not successfully resist 8-inch guns or heavy 32-pounders at 400 yards; so some modifications were introduced and further experiments made in 1850. In 1853 the French constructed floating batteries which carried four inches of iron armor.

While the European ships were, for the most part, modifications of existing types, the American ships were constructed from new designs, or railway iron and the like was attached to existing vessels. The old *Monitor* and *Merrimac* are the first examples; but with the improvements in gun manufacture, it became apparent that the wrought iron plates as first used could not withstand heavy gun fire. As a result a compound armor plate was developed in England and an all steel plate in France. In 1889 nickel was introduced in steel and a plate of great toughness and resistance was produced. This type of armor proved superior to the old and from then onward the march of progress has increased. In 1890 the Harvey process was advanced and met with great success, followed in 1895 by the Krupp process. These two processes are essentially the same in principle and represent the highest development of the compound type of armor.

Formerly this kind of armor was manufactured by taking a wrought iron plate as a backing and casting upon its face a plate of steel, the former being so heated as to produce as perfect a union as possible. This operation was based on the theory that a plate to resist the powerful energy of a projectile must have a hard face to resist penetration and a tough back to prevent shattering on impact. Difficulty, however, was experienced with the flaking of the steel face, so that the homogeneous nickel-steel plate really superseded this type.

Harvey Process.—Compound armor held the record against shell until the invention of Harveyized plates, introduced in the United States in 1891. A solid steel plate was cemented

on the face and then water-hardened, a glass-hard face with a tough backing being thus provided. This invention at once raised the resisting power of armor by at least 50 per cent. When Harvey adopted the method of hardening the surface of plates with a powdered cementing material, Messrs. Schneider invented a process of cementing by means of hydro-carbon gas, followed by water hardening, and this superseded the Harveyizing system. The Harvey plate was faulty in respect of the back not being sufficiently tough to resist the racking effects of the projectiles. The addition of chromium to the nickel-steel and differential treatment in hardening (variation in degree of hardness imparted to front and back), provided the necessary toughness. Nickel-chrome steel is carbonized and hardened on the outer face, gas being used for carbonizing and a water spray for hardening.

Krupp Process.—The manufacture of Krupp armor plate consists of a series of distinct operations requiring great care and attention and covers a period of from four to nine months, depending on the thickness of the plate. The composition of the plate having been determined upon, the necessary elements are melted together in an open hearth furnace. When ready for tapping, the ingot mould having been prepared, the metal is run into a large ladle, from which it is poured into the mould through a gate on the outside, which connects with the interior of the mould at the bottom. The ingot is bottom poured so as to get a more perfect ingot and the large projection on the upper end the sink-head, is an aid in handling. The mould is made up of cast iron sections bolted together to facilitate the stripping of the ingot. After the ingot has cooled it is stripped, that is, it is removed from the mould. Usually 24 hours suffice for the ingot to solidify and cool sufficiently to permit its being stripped, and then the ingot is sent to the heating furnaces preparatory to forging. The ingot after being heated for about 24 hours is taken out of the furnace and receives its first forging. This operation is one of the most wonderful sights in a steel plant: to see a red hot mass of metal, weighing in the neighborhood of 80 tons, being handled entirely by mechanical means with the ease that one would handle a pencil. The ingot is placed on a die under a 14,500-ton hydraulic press and there forged to within a few inches of its finished thickness. At each working of the press the metal is decreased about three inches in thickness, the ingot being moved along until its whole length has been forged. Of course, the length and breadth are increased, the metal under such great pressure flowing evenly in all directions, and this operation is repeated until the required dimensions are obtained.

Schneider Process.—Armored plates are cemented on the surface in furnaces designed for that special purpose. At the Creusot works hydro-carbon gas is used, introduced through pipes. At a dark red heat the hydro-carbons separate, and the liberated carbon penetrates the surface of the steel. The furnaces are fitted with movable hearths on wheels. The plates, having been already molded to their curves by templet, are placed one above another, with spaces between them, into which the gas is introduced. Each space is enclosed

by a cast-steel frame inserted between adjacent plates and rendered gas-tight with an asbestos strand. The sides of the frame are drilled to receive the rows of gas pipes. The pipes, which are water-cooled, contain passages for the gas inlet, the water outlet and the gas escape. The furnace is fired from each side, with blast. The deposition of the carbon goes on until, by a certain appearance of the flame given by the ignition of the escaping gas, the progress of the cementing operation is estimated when the admission of the gas is stopped for a while to permit of equal saturation of the opposed faces. It is then turned on again for a time and these stages are repeated until the cementation is equalized and completed. The temperature of the furnaces is regulated in such a way as to effect the maximum of cementation without risk of melting the surfaces of the plates. The plates cool down in the furnaces to be reheated and hardened subsequently. They are reheated in the vertical position in furnaces and for the water-hardening they are suspended vertically in tanks, through which jets of water are sprinkled on the surfaces of the plates. The rates of cooling can be varied by altering the distances between the plates and walls.

Cementation Process.—It has been the practice of some manufacturers of armor plate to use a series of rolls instead of a press, but it has been proved that the forging of a plate under a hydraulic press effects a more uniform working of the metal and produces a finished plate far superior to one which has been rolled. This statement is borne out by the fact that many of the plants which had installed a costly set of rolls have had the same removed and replaced by powerful hydraulic presses. After forging, the sink-head is cut off and the plate allowed to cool a little in air before annealing. From the annealing furnace the plate is taken to be scaled by pneumatic hammers preparatory to carbonizing. This process consists essentially of heating the plate in the presence of dry carbon or in a gas-carbonizing furnace.

Dry-Carbon Process.—In this process a special dry-carbon furnace is employed; coal is used in the furnace as fuel and the flame passes over the plates, down in front and back under again to the smoke-stack. Usually several plates are carbonized at the same time, the plates being arranged in pairs. The faces to be carbonized are placed together, separated only by a layer of finely powdered wood and animal charcoal. The edges are well sealed and the plates are placed in the furnace through the top and lowered on a bed of sand; the whole is then well covered with sand and if more than one pair are carbonized at the same time they are treated in like manner and placed on top of the first. When all are well protected from contact with the flame the furnace top is closed and the furnace brought up to heat. The heat is maintained at a uniform temperature for a considerable length of time, this time depending on the amount of carbon to be absorbed by the plates and then the furnace allowed to cool. Almost a month is employed in this process from the time the plate is charged until it is taken from the furnace.

Gas-Carbonizing Process.—In the employment of this process the plate, with the face to be carbonized exposed, is placed on a bed of

sand in a furnace which is heated by some highly carbonized gas. The flues for the flame entry are built on each side of the furnace and so arranged that they can be used alternately, while a deflector causes the flame to first strike the top of the furnace and then pass downward. After the furnace has been raised to heat, coal gas or one rich in hydrocarbons, is passed along the surface of the plate and the intense heat causes this to be broken up, depositing carbon on the face of the plate. The plate is left in the furnace until the required degree of carbonization is attained. The plate is again scaled and reheated for its second or final forging to bring it to gauge. This forging also serves to smooth up any roughness on the surface. After forging it is again annealed and from the annealing furnace goes to the machine shop, for such machining as can be done preparatory to bending. On return from the machine shop the plate is heated preparatory to bending and this operation requires the greatest skill and experience in order to prevent cracking to a degree which would result in the condemnation of the plate. An allowance, too, must be made for any slight distortion which may occur in the next operation, that of tempering and water hardening. The plate is heated to the required temperature and then subjected to a cold water spray. The bath is of a special design and is arranged to give a pressure of about 15 pounds per square inch.

Manufacture.—The process of manufacture in every detail is of scientific nicety. The melted steel is drawn off into ladles, transported by electric cranes capable of lifting 120 tons and poured into massive ingot moulds, some of which weigh 60 tons without the steel. Some of the ingots weigh 50 tons and are 36 inches thick. They are reheated and rolled out in an immense mill. One of these mills at Messrs. Vickers' works has rolls 36 inches in diameter and 12 feet in length. An ingot 36 inches thick can be rolled down to six inches within half an hour. The thickness after rolling is equal, but the edges are rough and irregular. At this stage the first portion of the cementing process is performed. The plates are laid one on top of another in specially constructed furnaces. Powdered charcoal is sprinkled between the opposed surfaces and the plates remain in the furnaces from 10 to 12 days, the temperature being regulated by pyrometers. During that period the charcoal is absorbed by the plates, increasing the quantity of carbon at and near the surfaces. This does not harden the surface of the plate, but it prepares it for the subsequent hardening which is done at a later stage, after the bending in the case of those plates which have to be curved, and after the planing off of the rough edges in the case of all plates. Both operations involve the use of much massive machinery and careful handling.

Bending and Planing.—The bending is done in hydraulic presses. Messrs. Vickers have two of 8,000 tons power, which will bend plates up to 21 feet long and 11 feet wide. The pressure exerted is three tons to each square inch of the rams. Each weighs 600 tons. The bending of the thickest plates under the powerful persuasion of these presses is easily and quickly accomplished. In the next stage the surfaces are planed on machines which will

carry a plate weighing 30 tons on a moving table, weighing as much, and will reciprocate it under the cutting tools, which cut in both directions. The plate moves at a rate of about 11 feet a minute. In other types of machines the plate is fixed in a pit below and the cutting tools are traversed over it. It is necessary to plane the surfaces of the plates smoothly, for, although they have been rolled and are smooth, the thicknesses are not so uniform as they should be to enable them to be fitted perfectly in their places. Afterward the very rough and irregular edges are planed in machines of a totally different design. Many plates must have their edges beveled and provision is made for dealing with these by means of hinged tool holders. When a large quantity of metal has to be removed the edges are cut or parted with circular saws.

Hardening.—The hardening process comprises two stages—the moderate hardening of the plate right through, which might be more correctly termed tempering, and the intense hardening of the outer face. The first is done with oil, the second with water. In the first stage the plate is reheated in a furnace to an exact temperature and dropped suddenly into a bath of cottonseed oil, large enough to temper the entire plate without becoming itself sensibly overheated. The result is that the plate is hardened or toughened throughout without being rendered brittle. It is both stronger and tougher than it was before immersion, but it would not resist a modern soft-nosed shell. Afterward the surface, which has been saturated with carbon to a depth of from two and a half to three inches, is rendered of excessive hardness by a chilling process. A series of jets of cold water are directed under pressure against the highly carbonized surface, the plate having been heated first. This is continued during two or three hours, by which time the surface to a depth as far as the carbon has penetrated has become of glasslike hardness.

The finished plate is made ready for the inspector who goes carefully over the whole carbonized face, testing every square foot for hardness. The punch must be dulled and the surface of the plate show practically no mark. If this test is satisfactory the *coupon*, which has been previously cut in the machine shop, is broken off to show the structure of the plate by its fracture. Then follows the drill test to show the depth of chill and if the plate passes this test, bars are taken to show its physical characteristics, that is, tensile strength, elastic limit and extension.

Final Test.—After the above tests are completed the ballistic plate is picked—that is, a plate to be fired at and which represents a group of plates. The armor for a battleship is divided into groups of from 400 to 600 tons, as determined by the department. This test is the most important and on its acceptance or rejection hangs the fate of the whole group of armor; as a result the inspector usually picks that plate of a group, which in his opinion is the least likely to pass. Of course, he has a record of all the plates, and going over these most carefully, he chooses the one which for some slight reason or other is not as perfect as the others, assuming that if the plate in question can pass the severe test required of

it, the other plates of the group most assuredly can.

The plate having been decided on, it is sent to the proving ground for test. Here it is attached to a structure, braced from the rear and bolted in the same manner as armor on shipboard. When in readiness three shots are fired at it, the actual thickness of the plate determining the gun to be used and the initial velocity. Approximately a gun of the same calibre in inches as the armor in thickness is used and no projectile or fragment thereof shall get entirely through the plate, nor shall any through crack develop to an edge of the plate or to another impact. The plate having successfully passed test, the group is accepted and the remaining plates are finished machined; a replacing plate is substituted for the ballistic one.

EDWARD S. FARROW,
Consulting Civil and Military Engineer.

ARMORED TRACTORS. As the result of experiments conducted in November 1915, at Fort Sill, under the direction of the Field Artillery Board, with caterpillar tractors as motive power for field artillery, and other experiments conducted both at Fort Sill and the Rock Island Arsenal with motor trucks as transports for the same arm of the service, the United States Army has its newest Field Artillery regiment moved by motor power completely. Thus it would appear that the United States was in the lead in establishing practical applications to military use of American commercial engines; and that when the editor of the *Field Artillery Journal* wrote the caption beneath a photograph of a tractor "Artillery Horse of the Future" he was nearer to the truth than such glimpses into the future usually are.

The American built caterpillar tractors, heavily armored, made their appearance from behind the British lines in the battle of the Somme and were revealed as armored motor cars capable of advancing over the rough terrain resulting from the terrific bombardment by high-powered explosive shells. The car or tractor resembles an enormous armadillo. The crew is protected by varying numbers of armored plates, any one of which is impervious to machine gun or rifle fire as well as shrapnel bullets. It is asserted that only a direct hit from a gun of large caliber could put one of these monsters out of action. The car completes the work of the artillery bombardment on the enemy trenches before the infantry advances. Its chief work on the Somme front was to locate the German machine gunners and blow them out of their positions so that they could not mow down the advancing infantry. This done, the infantry could occupy the abandoned enemy positions with comparative ease.

The completed car, as employed by the British, is made simply by enlarging the platform on the tractor so that it extends over most of the machinery and furnishes room for machine guns and their crews and by covering the whole with a tortoise shell of steel armor.

The machine has a fore wheel which is used only for guiding purposes. No weight rests on this wheel and it could be removed altogether without causing the frame of the tractor to dip more than a few inches. The weight is

carried on the two caterpillars. These consist of two belts with corrugated surfaces, on the inside of each of which are two lines of steel rails, jointed in short sections and operated by sprocket wheels. As the endless belt turns with the progression of the machine the forward sprocket wheel lays down the track and the rear one picks it up again.

Each of the caterpillars is under independent control and by starting one while the other is motionless the entire machine can be turned in its own length—a characteristic which would account for some of the strange manoeuvres which led observers to describe the "tanks" as wallowing about, "eating houses and pawing the debris under their bellies" and so on.

The pressure on the ground under the caterpillar—the string of steel plates seven feet long and two feet wide on which the entire weight of the machine is supported—is less than that caused by the foot of a horse or even of a man. And owing to the construction and location of the engines, the centre of gravity of the whole machine is near the back of the caterpillar and not more than 18 inches off the ground. For this reason the machine can roll along without danger of tipping over on an almost incredible slope and it can run considerably more than half its length forward over a chasm without any support at all.

When it moves across a trench the front wheel, on which normally no weight rests, crosses first. The forward end of the caterpillar would then move forward over the open part of the trench and the machine be supported by the rear of the caterpillar, where most of the weight was concentrated, on one side with the guide wheel forward to act as a steadier in front. Then by the time the rear part of the caterpillar had reached the edge of the trench the forward part would already be across and there would be very little displacement of the machine. In this way the machine could cross a trench almost as wide as the ground length of the caterpillar.

ARMORER, a term formerly applied to a maker of arms and armor, a very important handicraftsman in the Middle Ages and down to the end of the 16th century and even later. (See ARMS AND ARMOR). At the present day the term denotes persons employed to keep the arms of the soldiers in repair, or the custodian of an armory. On board a man-of-war the armorer is a petty officer appointed to keep the small arms in complete condition for service.

ARMORICA, the country of the Armorici. The name was formed from two Celtic words signifying "upon the sea," and was apparently applied in ancient times to the whole northern and western coast of Gaul. It was afterward confined to the province of Brittany.

ARMORY, a building, or military station appropriated to the storage of arms, or the use of troops. In the United States the term is generally applied to the headquarters of the local militia, and signifies almost the equivalent of a club house, to which is added a drill shed, for military manoeuvres. Many of these are fine examples of military architecture and are equipped with every modern convenience. In Europe the term is often applied to a museum of military antiquities, but is used more gen-

erally of the part of an arsenal, barracks, etc., set apart for the armorer and his assistants or where arms and equipment are stored.

ARMOUR, Herman Ossian, American merchant: b. Stockbridge, N. Y., 1837; d. 1901. After several years spent in the grain commission business in Chicago he became in 1865 the New York representative of the Milwaukee firm of Armour, Plankinton & Co., which retained the firm name of H. O. Armour & Co. until 1870. The name was then altered to Armour & Co., which is now the most important provision firm in the world.

ARMOUR, John Douglas, Canadian judge: b. 1830; d. 1903. Educated at Upper Canada College and Toronto University, he was called to the bar in 1853. Appointed a judge of Queen's Bench of Ontario, 1877; was chief justice 1887-90; president of the Court of Appeal 1890-1902; and judge of the Supreme Court 1902-03. He was one of the Canadian representatives on the Alaska Boundary Commission in 1903.

ARMOUR, J. Ogden, American capitalist and packer: b. in Milwaukee, Wis., 11 Nov. 1863, the son of Philip Danforth Armour and Malvina Belle Armour. His mother was a daughter of Jonathan Ogden, a prominent merchant of Cincinnati, and his father, Philip Danforth Armour, was a pioneer in the meat packing industry in America and also widely known for his philanthropy. He endowed the Armour Institute of Technology and the Armour Mission in Chicago, giving them a total of over \$2,500,000. J. Ogden Armour was educated at the Harvard School, Chicago, and at Yale University. He did not complete the course at the latter institution, but yielded to the request of his father that he should return to Chicago and relieve him of some of his business cares. Consequently he entered the business house of Armour & Co. in 1883. Beginning as a subordinate, he soon became a partner and later, upon the incorporation of the firm in 1900, was made a director and vice-president. Upon the death of his father in 1901 he became president of Armour & Co. Under his direction the steady and vigorous growth of the firm and its subsidiaries has been maintained. He finds his greatest satisfaction in having successfully carried on, extended and developed the industrial activities and the philanthropic enterprises bequeathed him by his father. Mr. Armour married Lolita, daughter of Martin J. Sheldon, retired capitalist of Suffield, Conn. Mr. Armour is a director in various corporations, including the Chicago, Milwaukee and Saint Paul Railway Co., the National City Bank of New York, the Fort Worth Stock Yards Co., the Stock Yards National Bank, South Omaha, the Continental and Commercial National Bank, the Northwestern National Insurance Co., the Continental and Commercial Trust and Savings Bank, etc. He is also a member of the Illinois State Council of Defense and has published 'The Packers and the People' (1906).

ARMOUR, Philip Danforth, American merchant and philanthropist: b. Stockbridge, N. Y., 16 May 1832; d. 6 Jan. 1901. He was a miner in California in 1852-56, but engaged in the commission business in Milwaukee in 1856-63; and later became the head of the pork

packing firm of Armour, Plankinton & Co., which was transferred to Chicago in 1870 and reorganized under the firm name of Armour & Co. Its business increased rapidly and it exported its products to every land. It also invested in the refrigerator car service and in the storage and handling of grain. Armour became noted for his philanthropy as well as for his astonishing business ability. He founded the Armour Mission and the Armour Institute of Technology (q.v.), both in Chicago; the former at a cost of about \$250,000 and the latter with an endowment of \$1,500,000, subsequently increased. His philanthropic work has been carried on and extended by his son, Jonathan Ogden Armour (q.v.).

ARMOUR INSTITUTE OF TECHNOLOGY.—This institution was founded in 1892 by Mr. Philip Danforth Armour of Chicago. The work of instruction was begun in September 1893. The aim of the Institute was expressed in its first public announcement as follows: "This institution is founded for the purpose of giving to young men an opportunity to secure a liberal education. It is hoped that its benefits may reach all classes. It is not intended for the poor or the rich, as sections of society, but for any and all who are earnestly seeking technical education. Its aim is broadly philanthropic. Profoundly realizing the importance of self-reliance as a factor in the development of character, the founder has conditioned his benefactions in such a way as to emphasize both their value and the student's self-respect. The Institute is not a free school; but its charges for instruction are in harmony with the spirit which animates alike the founder, the trustees and the faculty; namely, the desire to help those who wish to help themselves." Four-year courses in mechanical and electrical engineering were first organized. A union was effected with the Art Institute of Chicago for the purpose of developing the course in architecture which that institution had successfully maintained since 1889. The result was the establishment in 1895 of the Chicago School of Architecture. In 1899 the course in civil engineering was added; in 1901, the course in chemical engineering; in 1903, the course in fire protection engineering, and in 1911, the course in industrial arts. The courses now offered in mechanical engineering, electrical engineering, civil engineering, chemical engineering, fire protection engineering, architecture and industrial arts, all lead to the degree of Bachelor of Science.

ARMS. History.—When the naked savage found himself face to face with the wild beast, hungry and fierce, but not within striking distance, he swiftly seized a jagged fragment of rock from the ground and hurled it with all his force at the blazing eyes before him; then another and another, until the beast, dazed from the unexpected blows, fell back and gave him a chance to escape. At that moment the savage had invented arms and ammunition. He had found a way to strike a harder blow than the blow of his fist, at a greater distance than the length of his arm, and his brain showed him how to do it. The cave man and his descendants learned the valuable lesson of stone-throwing and it made hunters of them, and so it went on for cen-

turies. At last, however, there appeared a great inventor—a nameless Edison of his day. He took his girdle of skin and placed a stone in its centre, holding both ends with his right hand. He whirled the girdle twice around his head, then released one end so that the leather strip flew out and the stone shot straight forward. Here was the first slingman in action. A little practice made expert marksmen, and most of the early races used it for hunting and in war. We find it shown in pictures made many thousands of years ago in ancient Egypt and Assyria. We find it in the Roman army, where the slingman was called a "funditor." We find it in the Bible, where it is written of the tribe of Benjamin: "Among all these people there were 700 chosen men left-handed; every one could sling a stone at an hair breadth and not miss." Likewise the story of David and Goliath is remembered, when the young shepherd "prevailed over the Philistine with a sling and with a stone." Slings were used in European armies until nearly 100 years after America was discovered.

A little later we find man armed with his "bow and arrow" as an instrument of war. The cross-bow, the Chinese repeating cross-bow, the ballista and catapult, all played their parts up to the invention of gunpowder, when firearms were born, and we have the rapid development of the cannon, the petronel, the hand-culverin, the match-lock, the serpent, the harquebus, the wheel-lock, the Monk's gun and flint-lock.

It is doubtful at what time guns were first used as sporting arms; but early French and Italian works seem to indicate the close of the 14th century. We find a curious illustration in an old manuscript entitled, "Ye Gonne and How to Use It," dated 1446. This curious sketch is evidently a caricature; but it is sufficient to show that all firearms were used for game shooting in the early part of the 15th century. We have notices of the same in several records of that century, and by the close of the 16th century the gun seems to have become so general a sporting weapon as to necessitate special regulations in several European countries. About 1580, an Italian work informs us, shooting at birds flying and animals in motion was first practiced; but this could not have been to any great extent. It was not until the close of the 18th century that shooting on the wing became at all common. Since that time it has been so universally practised as to make shooting at any fixed object with a shot-gun unsportsmanlike.

Breech-Loaders.—Sporting arms may be classed as shot-guns, pistols, carbines and rifles. Muzzle-loaders are but little used at the present time. Most breech-loaders employ the metallic case cartridge, and are divided into simple breech-loaders and repeaters. The essential parts of all such arms are the barrel, the chamber, the breech-mechanism, the lock, the stock, the sights and the mountings, and in repeaters, the magazine. If the chamber be made in the piece which closes the breech, commonly called the breech-block, the arm is said to have a movable chamber. The latter has great advantages and is generally used. With the fixed chamber the interior of the barrel is divided into two distinct parts, viz., the bore proper or space through which the projectile moves

under the influence of the powder and the chamber in which the charge is deposited. The principal parts peculiar to breech-loaders are: (1) The movable breech-block, by which the chamber is opened and closed; (2) the breech-frame, upon which the breech-block is mounted and united to the barrel; (3) the chamber, with its recess, to receive the rim of the cartridge; (4) the firing-pin, which transmits the blow of the hammer to the cartridge; (5) the extractor, by which the empty case is removed after firing.

The foregoing named parts may be said to be essential to all breech-loading arms in which the metallic cartridge is used; the different ways in which they are combined mark the systems. These combinations have reference chiefly to the modes of operating and locking the breech-lock. The different systems may be classified into: (1) those with a fixed chamber; (2) those with a movable chamber. The latter have now become obsolete. The first class have (1) a movable barrel; (2) a movable breech-block. With each the motion may be sliding, in which case it moves in grooves; rotating when it swings on a hinge; or sliding and rotating combined. The greater number of systems belong to the class of a "movable breech-block rotating about an axis." In arms of this class the axis of motion may be parallel to the axis of the barrel, and above, below, or to one side of it; or perpendicular to that axis, being vertical or horizontal, and lying in or out of the plane of the axis. The position of the hinge has an important influence on the facility of operating the block, inserting the cartridge, and extracting the empty shell; the most suitable position is deemed to be in front of the centre of the block. In this case the motion of opening and closing the block is natural and easy; the cartridge is pushed into its place by the block, and a very simple retractor serves to withdraw the empty shell after firing. The most serious defect found in breech-loading arms was the escape of the flame through the joint, which not only incommoded the shooter, but, by fouling the machinery, seriously interfered with its operation. At present this is entirely overcome by the elastic metallic case of the cartridge. The advantages of breech-loading over muzzle-loading arms are (1) greater certainty and rapidity of fire; (2) greater security from accidents and loading; (3) the impossibility of getting more than one cartridge into the piece at the same time; (4) greater facility of loading under all circumstances, and particularly when the soldier is mounted, lying on the ground or firing from behind any cover.

The Barrel.—There are certain functions performed by, and certain important conditions to be fulfilled in the construction of, the different portions of a small-arm. The barrel is by far the most important part, its office being to concentrate the force of a charge of powder on a projectile, and give it proper initial velocity and direction; for these purposes, and for the safety of the firer, it should be made of the best material and with the greatest care. In determining the exterior form, it is not only necessary to give such thickness to the different parts as will best resist the explosion effect of the charge, but such as

will prevent it from being bent when subject to rough usage. Weight, to a certain extent is necessary to limit recoil, to give steadiness to the barrel in aiming, and to prevent it from "springing" in firing. The latter defect generally arises from bad workmanship, whereby there is a greater thickness of metal and consequently less expansion on one side of the bore than on the other.

Calibre.—Three points are to be considered in determining the calibre of small arms: (1) it should be as small as possible to enable the hunter or soldier to carry the greatest number of cartridges; (2) to diminish the amount of ammunition required, and to prevent the confusion liable to arise from a variety of calibres, there should not be more than two for all arms of the same service, viz., one for the rifle and the carbine, and one for the pistol; (3) this point relates to the force and accuracy of the projectile, and to the flatness of its trajectory. The introduction of the elongated projectiles afforded the means of increasing the accuracy and range of firearms, without increasing the weight of the projectile, simply by reducing the calibre, which diminished the surface, opposed to the air. Too great reduction of calibre, however, gives a very long and weak projectile; and besides, the effect of a projectile on an animate object depends not only on its penetration, but also on the shock communicated by it to the nervous system, or upon the surface of contact. These considerations have led to a general reduction of calibre of rifles.

Grooves.—The grooves being for the purpose of communicating a rotary motion to the projectile around an axis coincident with its flight, their construction will depend upon the form, dimension and material of the projectile, charge of powder, and angle of fire. The points to be considered in determining the form of grooves for arms are range, accuracy of fire, endurance, and facility of cleaning the bore. Experiment has shown that for breech-loaders these points are best attained by making the grooves broad and shallow, and with a rapid twist. The chamber being a receptacle for the charge, its shape is made to conform to that of the cartridge. Its diameter is made a little larger, and that of the bore a little smaller than that of the projectile. This facilitates the insertion of the charge, and causes the projectile to be compressed and held firmly by the bands in its passage through the bore. The bottom of the grooves and the surface of the chamber are generally continuous.

Breech-Mechanism.—The breech-mechanism comprises the principal parts that are peculiar to arms loading at the breech. The functions of these parts are the opening, closing, and locking of the breech, firing the charge and removing the empty cartridge shell. These are the objects for the accomplishment of which the different systems are variously contrived, and with which alone they are concerned. The most important conditions to be fulfilled in the arrangement of this mechanism are: (1) the number of parts should be as few as possible, and all should be of the simplest construction; (2) the strength and union of the parts should be such as not only to resist repeated discharges, but the bursting

ARMS AND ARMOR

Armor for Man and Horse, Italian, 1575

Burgonet, French, 1550

of a cartridge case, which sometimes occurs from defective material or workmanship; (3) the locking of the breech-block should not only be secure, but all the parts by which it is effected should work freely without sticking; (4) the parts should be so arranged that the hammer cannot strike the firing-pin until the breech-block is properly locked; (5) the hammer should not necessarily rest on the firing-pin when the piece is carried loaded; (6) the breech should be unlocked without the hammer being brought necessarily to full cock; (7) the working parts should, as far as possible, be covered from dust and water; (8) the extractor should be so arranged as to require no cuts or openings in that part of the chamber which surrounds the body of the cartridge case.

The Lock.—The lock is the machine by which the charge in the cartridge is ignited. Those of the present day belong to the percussion class, in which fire is produced by a blow upon the fulminating powder, contained in the cartridge case. Locks are divided into side and centre locks, depending upon the position occupied in the stock; each of these may be either front action, wherein the main-spring is in front of the tumbler or back-action, where the spring is in rear of the tumbler. The mortise, which forms a bed for the lock of the latter construction, seriously affects the strength of the stock at the handle, and for this reason the front-action lock is generally preferred for all arms, except revolvers. The conditions to be fulfilled in the construction of a lock are simplicity, strength, certainty of action, and freedom from such accidental motion of the parts as might produce explosion of the charge in the barrel.

The Stock.—The stock is the wooden part of the firearm, to which all the parts are assembled; it is preferable that it should be in one piece. The material should be light, strong, and well seasoned. The butt, the part intended to rest against the shoulder and to support the recoil of the piece, should be of such length and shape as will enable it to transmit the recoil with the least inconvenience to the sportsman. The longer it is, to a certain extent, the more firmly will it be pressed against the shoulder, and the effect of the recoil will be a push rather than a blow. The stock is crooked at the handle for convenience in aiming, and for the purpose of diminishing the direct-action of the recoil. Changing the direction of the recoil in this manner causes the piece to rotate around the shoulder; but if the stock be made too crooked, the butt will be liable to fly up and strike the face.

The Sights.—The sights are guides by which the piece is given the elevation and direction necessary to hit the object. They are two: called front and rear sights. The front sight is fixed to the barrel near the muzzle. The fineness of its point is regulated by the length of the barrel, or distance from the eye, and the size and distance of the object generally aimed at. It is made coarser in military than in sporting arms, to prevent injury. The rear sight is attached to the barrel a short distance from the breech; it has a movable part, capable of being adjusted for different elevations of the barrel. A sight

should satisfy the following conditions, viz. (1) it should be easily adjusted for all distances within effective range; (2) the form of the notch should permit the eye to catch the object quickly; (3) it should not be easily deranged by accidents. Globe and telescopic sights are used for very accurate sporting arms, but they are too delicate in their structure and too slow in their operations for general purposes.

The Mountings.—The mountings may be divided into two classes, viz. (1) those which serve to connect the principal parts, generally bands and screws; (2) those which protect from wear or strengthen the stock at certain points, as the butt-plate, guard-plate, tup; (3) the minor parts which secure the different parts (including the mountings proper), in their place, consisting of springs, screws, rivets, pins, washers and nuts.

Modern Instruments.—Trench warfare has created absolutely new conditions and has brought into use new weapons, revived old ones, and brought forth new methods in their use. The use of cover in connection with increased fire effect has greatly increased the power of the defense. The attack will not succeed unless the defense has first been completely shaken. Never before has human ingenuity been so taxed to devise and supply so many murderous instruments of combat.

The modern sabre, bayonet and lance are the successors of the ancient instruments of a similar nature appearing in the Stone, and later in the Bronze and Iron ages. Scottish regiments have used the dagger; Indian troops, the throwing knife, a successor to the javelin. The modern rifle represents the culmination of the same idea found in the sling-shot, later in the bow and arrow, and in the cross-bow. Another variation is the aero-arrow used by the French and English. The revolver is the successor of the pistol. The flat trajectory of the modern rifle has brought about the use of new means to reach troops under cover. The ancients used the ballista and the catapult. The first mortars used also fired stone projectiles. The modern howitzers resemble in their ballistic properties the first guns that were used. Large calibre mortars have been developed, such as the 42 centimetre mortars. Their life is very short. The machine gun is the successor to the Gatling gun. The use of trench mortars and hand grenades dates back to the 16th century. The Japanese were the first to revive their use. See **ARMS AND ARMOR; ARTILLERY; CANNON AND SMALL ARMS.**

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMS, Stand of, the outfit of arms necessary for the equipment of a single soldier including rifle, bayonet, cartridge box and belt. The term is fast becoming obsolete.

ARMS AND ARMOR. The earliest arms were everywhere made of stone. Stone was succeeded by bronze in the manufacture of weapons of war. The commonest warlike relics of the bronze age that have come down to us are daggers and spear-heads. From the descriptions of Homer we know that almost all the Grecian armor, defensive and offensive, in his time was bronze, although it is evident that iron was sometimes used in the time of Homer for making weapons, from the fact that

he occasionally uses the Greek word for iron (*sideros*) for a sword. Not the sword, however, but the lance, spear and javelin, were the principal weapons of this age among the Greeks. The bow is not often mentioned, although a bow belonging to Pandarus is described in the Iliad, and in the Odyssey, Ulysses is represented as very expert in the use of this weapon. Among the most ancient nations the Egyptians seem to have been most accustomed to the use of the bow, which was the principal weapon of the Egyptian infantry. The Egyptian bow was somewhat shorter than the height of a man; the arrow was usually made of reed, the head of bronze, but sometimes of flint. Peculiar to the Egyptians was a defensive weapon the object of which was to catch and break the sword of the enemy. With the Assyrians also the bow was a favorite weapon; but with them lances, spears and javelins were in more common use than with the Egyptians. Most of the large engines of war, chariots with scythes projecting at each side from the axle, catapults, and ballistæ, seem to have been of Assyrian origin. All of those mentioned can at any rate be traced back to the Assyrians, to whom the invention of the catapult and the ballista was attributed by classical writers. During the historical age of Greece the characteristic weapon was a heavy spear from 21 to 24 feet in length. The sword used by the Greeks was short, and was worn on the right side. The Roman sword was of Spanish origin, from 22 to 24 inches in length, straight, two-edged, and obtusely pointed, and as by the Greeks was worn on the right side. It was used principally as a stabbing weapon. On the Trajan column, belonging to 114 A.D., the sword appears considerably longer than that used at an earlier period. The Roman sword was originally of bronze, but like all other offensive weapons among the Romans was always of iron in the time of Polybius (2d century B.C.), when bronze continued in use only for defensive armor. The characteristic weapon of the Roman soldier was the pilum, a kind of pike or javelin, about five or six feet in length, with a wooden shaft and an iron head, the latter of which was about one third of the length of the whole. The pilum was sometimes used at close quarters both as an offensive weapon and as a means of parrying blows, but more commonly it was thrown along with the other javelin, which every Roman spearman (*hastarius*) carried when within 10 or 15 paces of the enemy. The pilum, when thrown from this distance, would fix itself in the enemy's shield, whereupon the Romans would rush up, and seizing hold of the shafts of their pila draw down the shields in which they were fixed, and follow up the attack with their swords. In addition to the large engines of war that have been already mentioned as of Assyrian origin (scythes, chariots, catapults, and ballistæ) the Romans made use of battering-rams for making breaches in the walls of fortified places. The Greeks are said to have used a sort of cannon made on the principle of the modern air-gun. The Romans also employed caltrops to embarrass the movements of an enemy's cavalry.

The principal pieces of defensive armor used by the ancients were shields, helmets, cuirasses, and greaves. No shields were car-

ried by the Egyptian archers; but the Egyptian spearmen had large shields, rectangular below and semi-circular at the top, and with a round sight-hole in this semicircular part. In the heroic age of Greece the shield is described as of immense size, so as to be capable of defending the whole body. In the early monuments the shield is still large, though not so large as it appears to have been in the heroic age. In shape it is round or oval, with a very considerable degree of convexity. At the time of the Peloponnesian War a still smaller shield came into use. The Romans had two sorts of shields—the *scutum*, a large, oblong, rectangular, highly convex shield, carried by the legionaries—and the *parma*, a small, round or oval, flat shield, carried by the light-armed troops and the cavalry. In the declining days of Rome the shields became larger and more varied in form. The helmet was a characteristic piece of armor among the Assyrians, Greeks, Etruscans, and Romans. Like all other body armor it was usually made of bronze. The Assyrian helmet was frequently conical. Sometimes it had the form of a truncated cone, and sometimes the pointed extremity was curved forward. The helmet of the historical age of Greece was distinguished by its lofty crest, which tapered downward to the back of the neck. The Etruscan helmet was also very high crested and sometimes had a wing rising to a considerable height on either side from points near the summit. The Roman helmet in the time of the early emperors fitted close to the head and had a hollow neck-guard and hinged cheek-pieces fastened under the chin, and a small bar across the face for a visor. The neck-guard and cheek-pieces were not peculiar to the Roman helmet, but were in common use wherever the helmet was worn. In later days the helmet of the Romans had a higher crown than that of the early emperors. The cuirasses of the Assyrians were close-fitting tunics made of several layers of flax plaited or interwoven and glued together. This kind of cuirass was introduced into Greece during the Peloponnesian War and was sometimes used even by the Romans. Before the Peloponnesian War the Greeks had the upper part of their body defended by bronze cuirasses. The defensive body armor of the Egyptian archers consisted of a quilted coat. The Egyptian spearmen had cuirasses of bronze scales or quilted with bands of metal. Under the Roman republic all the legionaries wore a bronze cuirass, consisting of a breast and back plate, with a border of pendent leather straps defending the lower part of the body. On the columns of Trajan and Antonine this cuirass is given only to officers, the legionaries wearing at that period only leather or linen cuirasses, on which circular plates of metal and metal shoulder-pieces were sewed, and to the lower border of which were attached oblong plates which served the purpose of the leather straps of the other cuirass. In the time of Trajan and Septimius Severus a flexible cuirass was added to the equipment of the Roman knight or horseman. This was made either of scales (*lorica squamata*) or of chains (*lorica hamata*). One of the latter kind has been found at Avenches in Switzerland, and is there exhibited. Greaves do not seem to have been worn by any of the eastern nations

except the Persians, whose defensive armor resembled pretty closely that of the Middle Ages. The greaves of the Greeks (*knetides*) were made in two pieces which were fastened together by clasps. The Roman greaves (*ocrea*) were made in one piece and were often worn only on one leg. The Samnite practice was to wear the greave upon the left leg, which is the leg advanced in fighting with a shield on the left arm; but Vegetius mentions that the greave was worn by the Roman legionaries upon the right leg. The greave reached only from the knee to the ankle. The Roman soldiers had their feet protected by shoes set with nails (*caligae*).

The favorite weapons of the Germanic races, by which the ancient civilization of Rome was to a large extent overthrown, were the battle-axe, the lance or dart, and the sword. Their defensive armor consisted almost exclusively of a shield made of plaited osier covered with leather and generally eight feet by two inches in size. Afterwards it was made round and bound with iron, and had several prominent bosses on its surface. The Frankish form of the German battle-axe was called *francisca* (francisque), and was the characteristic weapon of that tribe. It had a broad single-edged blade and a short haft, and was often used as a missile. The lance or dart of the Franks, called *angon*, closely resembled and was used exactly in the same way as the Roman pilum. The sword among the Franks was only a horseman's weapon. The shield of the Franks was round. Hardly any body armor (scarcely even a helmet) was used by them until the Carolingian days. Swords belonging to the early iron age in Scandinavia are frequently found in the marshes of Schleswig. They are long, straight, two-edged, and often richly damascened. Shields belonging to the same district and epoch were made of wood, and were flat, round, and from 22½ to 44 inches in diameter. They were bossed and otherwise mounted, generally in bronze, sometimes in iron. The common arms of the Anglo-Saxon infantry were a spear, and axe, and a scramasaxe (a heavy single-edged knife). With the Anglo-Saxons as with the Franks the sword was especially a horseman's weapon, being carried by none under the rank of thane. The sword carried by them was three feet long, broad in the blade, and round at the point. The Saxon shield was round or oval, made of wood covered with leather, and furnished with a high conical boss.

The arms and armor both of the Normans and Anglo-Saxons, but especially of the former, at the time of the Norman conquest of England are pretty fully illustrated by the Bayeux tapestry. On this work the horsemen appear armed with long lances as well as swords. The Normans are represented as well furnished with archers and cavalry, of which arms the Saxons do not seem to have had any. Maces, clubs, axes with shafts from four to five feet long, are seen in the hands of both. The shields are long, rounded above and tapering to a point at the bottom. The body-armor consists of a long hauberk ringed or trellised. The helmet is conical and has a sort of tongue in front which comes down over the nose.

Chain armor of interlinked rings came into use at the time of the Crusades and continued

in use till the beginning of the 14th century. From the latter date to early in the 15th century mixed chains and plate armor was in use, and from about the year 1410 to the beginning of the next century the body armor was entirely of plate, and complete suits of plate armor did not altogether go out of use for another century. Below the waist the body was protected by taces, a series of narrow overlapping plates attached to a lining of leather. After the introduction of complete suits of plate armor the chief modifications consisted in the strengthening of the weakest parts, especially on the right side. By the end of the 15th century plate armor had attained its highest development, even the horses at that period being protected by plate armor everywhere except on the legs. By this time, in fact, the fabrication of armor had reached such a degree of perfection that it was scarcely possible for men-at-arms engaged in combat to find any spot where the armor of their antagonist could be pierced. Combatants equipped in this manner aimed accordingly less at wounding than at unhorsing one another, for a man-at-arms unhorsed was at the mercy of his antagonist, who, if he could not find any weak point where he could pierce the armor of his fallen foe, might beat him to death with the heavy mace with which he was armed. Many savage encounters of this nature are recorded by the chroniclers of the time. Usually, however, a man-at-arms when unhorsed became the prisoner of his conqueror, and many battles were decided, especially in the wars between the states of Italy, carried on by means of mercenaries, almost or altogether without the shedding of blood either on the side of the vanquisher or the vanquished. When body-armor had come to be manufactured with such perfection shields were almost entirely discarded. In England, indeed, no effigy has been found representing a man-at-arms bearing a shield of later date than the last quarter of the 14th century, from which it would seem that that defense had gone out of use even before the adoption of complete suits of plate armor. Perhaps the most characteristic portion of the body-armor of the 15th century was that which protected the feet. The coverings for the feet during this period were laminated *sollerets* (as they were called), actually pointed or rounded off at the toes. In the following century these were succeeded by *sabbatons*, cut off square at the toes. In this century the armor gradually became less rigid and cumbersome, and often consisted of small plates of metal quilted within linen or other tissues. As the century advanced the manufacture of body-armor declined, and after the close of the century armor was worn as much for show as for real service. Metal cuirasses gave place, as a rule, to buff suits and jerkins, although the former armor is not entirely disused even at the present day. The principal weapons of the man-at-arms were the lance, sword, battle-axe, and mace, all of which were remarkable for their massiveness, as might be expected from the resistance they had to meet. The lance (see LANCE and TOURNAMENT) was the weapon which he used to unhorse his antagonist if he could not wound him with it. Two-handed swords were in common use in the 16th century. The sword-breaker, consisting of a deeply notched blade

about 15 inches in length, and intended to catch and break the sword of an antagonist, belongs to the same period.

During all the time that the use of heavy armor prevailed, the horsemen, who alone were so armed, formed the principal strength of armies; and so much was this the case that infantry were generally regarded as of hardly any account. An exception must, however, be made in the case of England; the archers of which were almost at all times, before the invention of gunpowder, an important and sometimes the chief force in the army. It has been already mentioned that the Bayeux tapestry furnishes us with evidence of the fact that the Normans were provided with archers at the time of the conquest. The bows used by them were small, being little more than a yard in length. The deadly weapon afterward used by the English archers was from five to six feet in length, and the arrow discharged from it was itself a yard long. The bow used in Germany as well as that used in Italy (where steel was the material of which it was usually made) was about a yard and a half long. There is no evidence of the cross-bow having been used before the 11th century. Its use against Christians was forbidden by the Council of the Lateran in 1139. The long-bow continued in general use in England till the end of the reign of Elizabeth, and even as late as 1627 there was a body of English archers in the pay of Richelieu at the siege of La Rochelle. The cross-bow did not go out of use in the French army till the 17th century. Among the other hand-arms in use before the invention of gunpowder were the sling and the fustibale, which was nothing else than a sling with a handle to it. The large engines of war used in the Middle Ages were the same as those that had been employed by the Romans, with only slight modifications. A coat made of leather or quilted stuff, called in French *gambouison* or *gambeson*, was almost the only defensive armor of the foot-soldier during the greater part of the period of which we are now treating.

The use of gunpowder as a means of discharging projectiles and the gradual improvement of firearms effected in course of time a complete change in all the methods and accessories of warfare. Details regarding the construction and recent improvements of large and small firearms and projectiles will be found under BOMB, BULLET, CANNON, GUN, MUSKET, RIFLE, SHELL, etc. Gunpowder was not used in Europe to discharge projectiles till the beginning of the 14th century. Cannon are first mentioned in England in 1338, and there seems no doubt that they were used by the English at the siege of Cambrai in 1339. All early cannon were breech-loaders. In the oldest form the breech consists of wedges of wood or metal and this form was succeeded by cannons with movable breech-piece. The projectiles first used for cannon were of stone. Field-guns were introduced in the course of the 15th century. A rifled cannon of the 15th century is to be seen in the museum of The Hague. Mortars were introduced into the French army in 1634. Hand firearms date from the 15th century. The Swiss at the battle of Morat in 1476 are said to have been provided with 6,000 arms of this kind. In England the yeomen of the guard

were armed with them in 1485. At first they required two men to serve them, and it was necessary to rest the muzzle on a stand in aiming and firing. Lighter hand-firearms called petronels seem to have been first used by cavalry. Hand-firearms were at first fired in the same way as cannon, by means of a slow match carried in the hand and applied to the powder at the touchhole. The first improvement was the invention of the matchlock about 1476. In the matchlock the slow match was held at the end of one arm of a bent lever attached to the side of the piece in such a manner that by the action of a trigger it could be brought down upon the powder in the pan at the touchhole. This kind of lock was superseded by two others, the wheel-lock and the snaphance, that seem to have been invented about the same time early in the 16th century, although the matchlock continued in use long after that date, and indeed was not altogether abandoned till the beginning of the 18th century. The wheel-lock is generally said to have been invented at Nürnberg, and was largely used in Germany. It consisted of a steel wheel which was made to revolve by a spring, and in revolving struck fire from a flint, and at the same time lifted a cap which kept the powder in the pan from being wet by rain or blown away by the wind. The chief objection to it was that it was slow in its operation, as the spring had to be wound up every time it was used. The snaphance was largely used in the Spanish dominions. It was the immediate predecessor of the flintlock, from which it differed only in making the flint strike against a fixed upright piece of iron in front of the powder-pan, while in the flintlock this upright piece was attached to another piece that covered the pan and which turned on a hinge, so that when the flint descended and struck sparks from the iron it at the same time uncovered the pan. The flintlock was invented in France about 1640, and gradually came into universal use, until it was itself superseded by the percussion-lock. This last was patented by a Scotch clergyman named Alexander Forsyth in 1807, and had been adopted everywhere by the year 1820. The first model of the needle-gun was made in 1827 by J. N. Dreyse of Erfurt. It was first made breech-loading in 1836. The only important weapon not a firearm that has been invented since the introduction of gunpowder is the bayonet, which is believed to have been invented about 1650. The socket-bayonet, fitted round the muzzle of the gun, was introduced into the French army by Vauban.

The earliest collection of arms and armor was that made by Louis XII, at Amboise in 1502. There is a fine collection at Dresden, begun in 1553. Among others may be mentioned the collection in the Metropolitan Museum, New York, recently augmented by the acquisition of the celebrated Riggs collection, which makes the New York collection one of the finest in the world. The Riggs lot contains about 2,500 separate pieces, many of historic interest as well as of artistic importance; the Ambras collection, commenced in 1570, now at Vienna, and those at Turin, Sigmaringen, Tsarsko-selo, Petrograd, Madrid and in the Tower of London. The last mentioned was classified by Dr. Meyrick and catalogued by J. Hewitt. The Antiquarian Museum of Edin-

ARMOR

1 French Foot Soldier, Eighth Century
 2 Polish Knight, end of Fifteenth Century
 3 French Soldier, about 1120 A. D.
 4 Battle of Askalon (1099) from a Window in the Church of St. Louis, Paris

5-6 German Full Armor, of the time of Maximilian I
 A Mottled or Striped Armor. B Ringed Armor. C Fettered Armor. D Shield Ornament. E Plate Armor. F Chain Armor

burgh is rich in weapons of the stone and bronze periods, but has few specimens of arms and armor of more modern times. Of works specially devoted to the subject of arms and armor the most worthy of mention are Grose, 'Treatise on Ancient Armor and Weapons' (1785-86; Supp. 1789; afterward annexed to the second edition of the same author's 'Military Antiquities,' 1801), and Meyrick, 'Critical Inquiry into Ancient Armor as it existed in Europe, but particularly in England, from the Norman Conquest to the reign of King Charles II' (1824). An excellent compendium on the subject by Auguste Demmin was published in 1869 in French, English and German. The title of the English edition is 'Weapons of War'; it gives a history of arms and armor from the earliest period to the present time. Consult also Dean Bashford in 'Bulletin of the Metropolitan Museum' (Vol. IX, New York 1914); id., 'Arms and Armor' (ib. 1915).

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMSTEAD, Henry Hugh, English sculptor and worker in metals: b. in London 1828; d. 1905. He studied at the School of Design and later in the Royal Academy Schools, Somerset House, and at first was much influenced by the elegance of his instructor, E. H. Bailey. He presently exhibited greater insight and was employed by Sir Gilbert Scott to execute portions of the Albert Memorial, London. A noted portrait statue sculptured by him is that of Bishop Wilberforce in the north transept of Winchester Cathedral. Other marble effigies by him will be found in Westminster Abbey. Consult biography by his daughter (1906).

ARMSTRONG, Andrew Campbell, American educator: b. New York City, 22 Aug. 1860. After graduating from Princeton University in 1881 he entered Princeton Theological Seminary. Having finished his four-years' course he went to Berlin, there to take a post-graduate course in Berlin University. He was then appointed associate professor of ecclesiastical history at Princeton Seminary. Two years later he became instructor in history at Princeton College, but a year later was called to Wesleyan University. From 1904 to 1909 he was co-operating editor of the *Psychological Review*. Aside from his many articles on psychological and philosophical subjects, he has written 'Transitional Eras in Thought' (1904), and has translated Falckenberg's 'History of Modern Philosophy' (1903).

ARMSTRONG, David Maitland, American artist: b. Newburgh, N. Y., 15 April 1836. He was graduated from Trinity College, Hartford, A.B.A.M. 1858, was a member of the New York Bar, practised law in New York six years, and studied art in Rome and Paris. He was a pupil of Luc Olivier Merson, United States Consul General for Italy at Rome 1869-72, Director of American Art Department, Paris Exposition, 1878 and Chevalier of the Legion of Honor of France. He is associate member of National Academy of Design, of the Architectural League and other art societies, National Society of Mural Painters, Century Club, Trustee New York Society Library. He

and his wife constitute the heads of the firm of Maitland Armstrong & Co., designers and makers of stained glass. Many hundred important memorial and other windows in various parts of the United States and Canada have been designed by them.

ARMSTRONG, Edward, English educator and historian: b. Grahamstown, South Africa, 3 March 1846. He is a graduate of Exeter College, Oxford, where he took his final examinations in 1869. During the following year he served as tutor at Queen's College, when he was appointed assistant master at Rugby. In 1873 he returned to Oxford. From 1878 to 1911 he was bursar at Queen's College and lecturer on modern history; while in the university he was lecturer on foreign history and a member of the board of finance. Since 1910 he has been warden of Bradfield College. Among other positions he held was that of curator of the Taylor Institute and the Botanic Gardens. His writings in book form are 'Elisabeth Farnese' (1892); 'Lorenzo de' Medici' (1897); 'The Emperor Charles V' (2 vols., 1902); 'The French Wars of Religion' (2d ed., 1904).

ARMSTRONG, Edward Cooke, American educator: b. Winchester, Va., 24 Aug. 1871. Graduating from Randolph-Macon College in 1890, he took a post-graduate course at Johns Hopkins and was accorded a degree of Ph.D. in 1897. Later he took up studies at Paris and Berlin. In 1897 he became professor of the French language at Johns Hopkins, and in 1910 chairman of the Romance department.

ARMSTRONG, George, called the "Father of the United States Railway Mail Service": b. Armagh, Ireland, 27 Oct. 1822; d. Chicago 5 May 1871. His parents came to the United States when he was eight years old and settled in Baltimore. He entered the postal service in Washington when a young man, and his ability won him promotion in 1854 to assistant postmaster at Chicago. He then made a study of mail transportation, wrote exhaustively on the subject, and in July 1864 was given authority by Postmaster-General Montgomery Blair to experiment on any railroad he might select. The first trial took place on the Northwestern Railroad 28 Aug. 1864, between Chicago and Clinton, Iowa, and was a complete success. He was the head of the service from the start but was assigned to headquarters in the West with general supervision of the service in the East. In 1869 President Grant directed that a bureau be made of the railway postal service, and placed Armstrong at the head as general superintendent, a position which he held until his death two years later. A bronze statue in memory of his work was erected in the post-office building, Chicago, in May 1881. See **POSTAL SERVICE IN COMMERCE**.

ARMSTRONG, John, American soldier: b. Ireland 1725; d. Carlisle, Pa., 1795. In 1756 he was the leader of a successful campaign against the Indians at Kittanning, Pa. In 1776 he was made a brigadier-general in the Continental army. He resigned his commission after 13 months and took a similar rank in the militia of Pennsylvania. He commanded this force at Brandywine (11 Sept. 1777) and at Germantown (4 Oct. 1777) and was appointed

major-general in January of the following year. He served as member of the Continental Congress in 1778-80 and in 1787-88.

ARMSTRONG, John, American author and soldier; b. Carlisle, Pa., 25 Nov. 1758; d., Red Hook, N. Y., 1 April 1843. While an undergraduate at Princeton he enlisted in the army and became aide-de-camp to General Mercer, being made a major at the same time. For a time after the close of the war he was successively Secretary of State and Attorney-General of Pennsylvania and in 1787 was sent to Congress from that State. Two years later he married, removed to New York State and in 1800-04 was United States Senator from that State. He was United States Minister to France, 1804-10, and afterward to Spain; and Secretary of War, 1813-14. The failure of the Canada expedition and the capture of Washington were the cause of his becoming very unpopular and he resigned. He wrote the 'Newburg Addresses' in 1783, anonymously, with the intent to arouse Congress to redress army grievances. He also wrote 'Notices of the War of 1812' (1836); memoirs of Generals Montgomery and Wayne in Sparks's 'American Biographies,' and prepared in part a history of the American Revolution. Consult Adams, Henry, 'History of the United States, 1801-17' (New York 1889-90).

ARMSTRONG, Paul, American playwright: b. Kidder, Mo., 25 April 1869; d. 29 Aug. 1915. From 1890 to 1895 he was a licensed master mariner, commanding steamships on the Great Lakes. In 1904 he had produced his first play, 'The Heir to the Hoorah.' Then followed 'Saint Ann' (1904); 'Salomy Jane' (1905); 'In a Blaze of Glory' (1906); 'Via Wireless' (in collaboration with Winchell Smith, 1909); 'Alias Jimmy Valentine' (1909); 'The Deep Purple' and 'The Greyhound' (in collaboration with Wilson Mizner, 1910 and 1911); 'A Romance of the Underworld' (1911); 'The Escape' (1913).

ARMSTRONG, Robert, American soldier: b. Tennessee, 1790; d. Washington, D. C., 23 Feb. 1854. He was an artillery captain in the war with the Creek Indians in 1813, being badly wounded at Taladega. At the Battle of New Orleans, 8 Jan. 1815, he was in chief command of the American artillery, and during the second Seminole War, 1835-37, he was a brigadier-general. In 1845 he was appointed United States Consul at Liverpool, where he remained for seven years, after which he returned home and became proprietor and editor of the *Washington Union*. During this period he was confidential adviser to President Polk.

ARMSTRONG, Robert Allen, American educator: b. Frenchton, Va., (now West Virginia) 23 Sept. 1860. In 1886 he graduated from the West Virginia University after which he took post-graduate courses at Chicago, Columbian (now George Washington), and Harvard universities. He was first appointed principal of the West Liberty State Normal School, during which period he also studied law and was later admitted to the bar. In 1893 he was appointed professor of English at West Virginia University, becoming head of the English department there 10 years later. From 1899 to 1909 he was secretary of the West Virginia Board of School Examiners. In 1904 he

became editor of the *West Virginia School Journal*. He is the author of 'Geography of West Virginia.—Supplement to the Natural Geography' (1899); 'Life out of Death' (1906); 'The Law of Service' (1907); 'Dramatic Interpretation of Shakespeare's Tragedies' (1907); 'Mastering the Books of the Bible' (1916).

ARMSTRONG, Samuel Chapman, an American educator: b. Wailuku, Maui, Hawaii, 30 Jan. 1839; d. Hampton, Va., 11 May 1893. He was a son of Richard Armstrong, one of the earliest American missionaries to Hawaiian Islands and founder of their educational system. The son was educated at Oahu College, Honolulu, till 1860, and graduating from Williams College in 1862, at once entered the Union army. He served till the end of the Civil War and was mustered out with the rank of brigadier-general of volunteers. In 1866 Gen. O. O. Howard, who had noted Armstrong's interest in the colored troops, induced him to take a position with the Freedman's Bureau, where he was charged with the oversight of all colored people in 10 Virginia counties. After two years of successful administration, during which he had worked out a careful plan of negro education, he enlisted the aid of the American Missionary Association and personal friends in the North, and founded the Hampton Normal and Agricultural Institute. Its object was to give the negroes practical education, to train teachers, and to render its graduates self-supporting. For 10 years the students were negroes exclusively; then (1878) the United States government, attracted by Armstrong's success, arranged to have Indian children taught there. This experiment has also proved successful. General Armstrong devoted his life to the school and made it the best known and studied one of its kind in the world. At his death it had 100 teachers and employees, 200 Indian and 600 colored students. Consult Ogden, R. C., 'Sketch of Armstrong' (New York 1894).

ARMSTRONG, Sir Walter, British writer and art critic: b. Roxburghshire, Scotland, 1850. After finishing his education at Harrow and at Exeter College, Oxford, he became art critic on the staff of the *Pall Mall Gazette*, the *Saint James' Gazette* and the *Manchester Guardian*. In 1892 he became director of the National Art Gallery, Dublin. In 1899 he was knighted. Among his works are 'The Art of Velazquez' and 'The Life of Velazquez' (1896); 'Art in Great Britain and Ireland' (1909); 'Sir Henry Raeburn' (1901); 'Sir Joshua Reynolds' (1900); 'J. M. W. Turner' (1901); 'Sir Thomas Lawrence' (1913).

ARMSTRONG, BARON, William George, an English engineer and mechanical inventor: b. Newcastle-on-Tyne, 26 Nov. 1810; d. Rothbury, 27 Dec. 1900. He was trained as a solicitor, and practised as such for some time, though his tastes scarcely lay in that direction. Among his early inventions were the hydroelectric machine, a powerful apparatus for producing frictional electricity, and the hydraulic crane. In 1847 the Elswick works, near Newcastle, were established for the manufacture of his cranes and other heavy iron machinery, and these works are now among the most extensive of their kind. It was here that the first rifled ordnance gun which bears his name

was made in 1854. His improvements in the manufacture of guns and shells led to his being appointed engineer of rifled ordnance under government, and he was knighted in 1858. This appointment came to an end in 1863, since which time his ordnance has taken a prominent place in the armaments of different countries. He was raised to the peerage as Baron Armstrong in 1887.

ARMSTRONG-HOPKINS, Saleni, American physician, author and lecturer: b. London, Ont., 21 Jan. 1855. She was educated at the high school, Blair, Neb., and at Northwestern University. She studied medicine at the Woman's Medical College, New York Infirmary and at the Woman's Medical College of Pennsylvania, where she was graduated in 1885. She engaged in social work, taking 13 small waifs from Philadelphia and Chicago to the West, and established them in the homes of farmers in Nebraska. She was one of the founders of the Park Hill Orphan Home, now the Mothers' Jewels' Home, at York, Neb. In 1886 she was sent out to India as a medical missionary by Bishop William Taylor. She was founder of Khetwadi Castle Hospital and the Khetwadi Training School for Nurses at Bombay, 1887-88. In the latter year she was elected national lecturer on heredity by the Women's Christian Temperance Union of Bombay. She was appointed by the British government physician-in-charge of the Woman's Hospital Dispensary and Training School for Nurses at Lahore, India in 1889 and later was made physician-in-charge to the Woman's Hospital Dispensary at Hyderabad, Sindh. She returned to America in 1893, bringing with her six natives of India to be educated as missionaries to their own people. In 1893-95 she was resident physician of the Armstrong-Hopkins Private Hospital for Women and Children at Omaha, Neb., and has since practised medicine and surgery, and lectured and preached in Colorado, Delaware, Virginia and New York. She has published several works, including 'Divine Call to Foreign Missionary Service'; 'Record of Daily Work'; 'Heroes and Heroines of Zion'; 'In the Zenana Homes of Indian Princes'; 'Khetwadi Castle,' etc.

ARMY. Among nations of antiquity all men capable of bearing arms were liable to be called on to serve as soldiers, with the exception of the Egyptians, Indians of Aryan race, and the Israelites. In the first two of these nations the warrior formed a separate class or caste of the community, ranking next in dignity and influence to that of the priests. In Egypt the military caste shared with the king and the priests the whole of the soil. The members of the caste were interdicted from all handicrafts. The Egyptian infantry was mainly composed of archers. Foreign auxiliaries were also employed, but kept in a strictly subordinate position, except under the last native kings of Egypt; and the different policy pursued by them was without doubt in a great measure to blame for the easy conquest of Egypt by Cambyses. In India the members of the warrior caste were called Kshatriyas, and after the complete subjugation of the non-Aryan inhabitants whom they found in the peninsula when it was invaded by them, seem generally to have lived an indolent life. Among the Israelites the only portion of the

male population exempt from military service was of the tribe of Levi. In the other tribes all men above 20 might be called upon to serve in the army when occasion required. At first the army of the Israelites consisted entirely of infantry. David introduced charioteers, and Solomon added a regiment of cavalry. In later times an Egyptian auxiliary cavalry is sometimes found serving in the Jewish armies. The beginning of a standing army was made by Saul, who raised a body-guard of 3,000 men. After the captivity a new organization developed itself under the Maccabees. John Hyrcanus raised an army of foreign soldiers, chiefly Arabs.

From the monuments found in the valleys of the Euphrates and the Tigris we learn that at an early date the Assyrians, Babylonians, and Medes possessed armies of infantry, cavalry, and charioteers and divided into light and heavy armed troops, distinguished by dress, equipment, and arms. But it was after the establishment of the Persian empire that the army system of the East attained its highest point of development. When the Persians had extended their empire over almost the whole of western Asia it was necessary to maintain a standing army to keep down conquered tribes and to guard the frontiers. The various sections of this army were each levied in the province to which it belonged, and were partly stationed in fortified towns, partly distributed over the country districts. Their pay was derived from the revenues of the province, but their commanders were wholly independent of the satraps or provincial governors. Yearly reviews were held in order to see that they were constantly kept in a state of efficiency. The troops of the standing army included a light and heavy infantry, as well as strong bodies of cavalry, part of whom were clad in armor. The subdivisions of the army (both cavalry and infantry) were according to the decimal system. Originally all the forces were Persians, but in later times Asiatics and Greeks were also enrolled. Express messengers, stationed throughout the empire at the distance of a day's journey from one another, formed the means of communication between the different parts of the army. In addition to this provincial force the king had a body-guard of 10,000 men, called the immortals, from the fact that their numbers were always kept full. When great expeditions (such as the invasions of Greece) were undertaken a levy of the whole people was made. Fifty-six nations, according to Herodotus, were represented in the levy made by Xerxes for his celebrated Greek expedition.

In the small free states of Greece the armies consisted of a civic militia, in which it was the right and duty of every freeman to serve. In times of emergency the slaves also were armed. The Greek armies often consisted exclusively of infantry. Athens never had more than 1,000 cavalry. The foot soldiers were divided into *hoplitai*, or heavy-armed, whose equipments consisted of a long lance, a sword, and a large shield; *peltastai*, armed with a short spear, and carrying a small round shield; *psiloi*, carrying no shields, and armed only with javelins, bows and arrows, or slings; and *gymnetes*, also without shields, and chiefly composed of slaves and foreigners. The age

for military service was 20 to 40 at Athens and 20 to 60 at Sparta. In Athens, however, every youth was enrolled at the age of 18, although not liable to be called on for active service till he had reached the age of 20. The command of the Athenian army was divided among 10 generals, who were elected for one year, one by each of the 10 Attic tribes, and each of whom had the chief command in turn for one day, when they were all present with the army. To obviate the manifest inconvenience of this arrangement nine of the generals were sometimes left behind, and sometimes one of the archons called the Polemarch took the field, in which case the duties of a commander-in-chief were in a great measure left to him. Until after the Peloponnesian War Athenian soldiers received no pay, but from that date a small pay was given to those in the field. At Sparta the command of the army belonged to the two kings, and usually two armies were formed, each king having the command of one of them. When only one army was formed one of the kings remained at home. Although in Sparta, as in Athens, the army consisted of the free citizens generally, yet, as in the former city it was always kept ready for war, it constituted a kind of standing army. It was divided into five *moras* or regiments, one for each tribe. After the time of the Peloponnesian War it became more and more common for all the Greek states to employ mercenary troops, and the Greeks themselves often entered into foreign service. The Macedonian standing army was created by Philip, and from the time of Alexander was composed chiefly of mercenaries. The Carthaginian armies consisted in large part, and indeed mainly, of mercenaries. The body-guard of the general, called the "sacred band," was, however, entirely made up of Carthaginians by birth, but was distinguished less by its valor than by the splendor of its equipments. In the army of Hannibal, Gauls, Iberians, and Ligurians formed the main force; Numidian cavalry hovered on the wings; Balearic slingers and elephants led by Ethiopian masters were drawn up in front. In Rome every citizen from the age of 17 to 46 was bound to serve in the army till he had made 16 (or in emergencies 20) campaigns on foot or 10 in the cavalry, and no citizen could become a candidate for any magisterial office unless he had been 10 years on foot or 5 mounted. During the best times of the Roman army the troops were selected with great care, and the discipline and training of the legions were admirable, so that the Roman infantry (of which the legions were mainly composed) was the best the world had yet seen. The Roman cavalry, on the other hand, was numerically weak, and was excelled by the Numidian, and still more so by the Parthian. Pay was given to the Roman troops from the time of the siege of Veii (406 b.c.). When the Roman empire in the West fell to pieces, in consequence of the repeated inroads and settlement within its borders of German tribes, there was an end for the time to all regular army organization in western Europe. The forces by means of which the Roman empire had been gradually dismembered consisted, like the Persian hordes that 1,000 years before had conquered western Asia, of armed nations;

but a new military organization, greatly inferior, however, to that of the Romans, grew up in process of time out of an institution common to all the German tribes. This was the practice followed by the chiefs of gathering round themselves bodies of retainers constantly ready to fight under them, in the expectation of being rewarded out of the spoils of conquest. As long as the Germans were confined to their original settlements outside the Roman empire these bodies of retainers bore a small proportion to the total strength of the armed population; but when extensive conquests of land were made within the Roman empire more or less of the conquered territory was always seized by the conquerors, and the personal retainers of the conquering chiefs were often so richly rewarded that the retinues of the chiefs were rapidly swelled by the adhesion of those who hoped for equal gain. At first these grants were looked upon simply as rewards for past services, but they soon came to be given and received as pledges of future service, every person receiving a grant being bound to serve his chief in war whenever called upon. In this way the feudal system, as it is called, gradually arose, and feudal armies finally superseded the national levies of the German tribes. When Charles Martel conquered the Saracens at Tours in 732 the transition from national to feudal armies was not yet accomplished, but it was almost completed under Charlemagne at the end of the same century. The chief strength of the feudal armies lay in the men-at-arms, who were all mounted, heavily armed, and protected by shields and defensive armor. After the introduction of firearms, shields and armor ceased to be an effectual protection, personal valor and bodily strength became of less moment, disciplined armies were found to be necessary, and the knights entered these armies as officers. The military forces of the small states that rose up in Italy from the 12th century resembled those of the states of ancient Greece in being at first nothing more than a civic militia. In later times hardly any troops were used, but mercenaries were employed, led by *condottieri*, and these at last were superseded by standing armies.

Among the countries of modern Europe the foundation of a standing army was first laid in France. In 1439 Charles VII of France issued an ordinance called the Ordinance of Orleans for the creation of a number of troops of horse (hence called *compagnies d'ordonnance* or ordinance companies), which were to be maintained by the cities and villages in war and peace. In 1448 the same king established a corresponding body of infantry called *Francs-archers*. Henceforward the feudal militia fell more and more into disrepute, and the vassals assembled their forces only on occasions of great emergency. The example of France was followed elsewhere, and during the wars of Francis I and Charles V at the beginning of the 16th century, France, Germany and Spain were all in possession of considerable standing armies. These armies were all raised mainly by voluntary enlistment, compulsory levies being resorted to only under the pressure of very exceptional circumstances. The usual practice was for the king to contract with some nobleman or gentleman

for the raising of a regiment; but in the Thirty Years' War Gustavus Adolphus set the example of raising all his troops directly for his own service. In this same war, however, a whole army was raised for the emperor by a private gentleman (the celebrated Wallenstein), the emperor engaging to give him the command of it. Gustavus Adolphus was also the author of many reforms in army organization. He established smaller divisions, introduced lighter weapons, separated the pikemen from the musketeers, who had hitherto been mixed together, and made many improvements in the artillery; by all of which changes quicker and more complicated movements became practicable. The soldier was more thoroughly drilled and reduced almost to a machine, while the responsibilities of the officers were increased. The wars of Louis XIV led to further improvements in military organization and tactics, and in a still greater degree to the increase of the size of armies. Instead of the 14,000 men maintained by Henry IV of France, Louis XIV, after the Peace of Nijmegen (1678) had on foot an army of 140,000 men. Armies were likewise increased by all the other powers of Europe except England and Holland, where the strengthening of the standing army was looked on with great jealousy, and till the time of William III continually opposed by the representatives of the people as dangerous to freedom. Among the military powers that came to the front in the next century the new Prussian monarchy was perhaps the most conspicuous. Frederick William I devoted all his energies to the creation of a strong military force, and his army of 80,000 was increased by Frederick II to 200,000. The latter introduced the system which still prevails in Prussia, and is now extended to the whole German empire, of localizing the different sections of his army. Each regiment was assigned to a certain district, which was bound to keep it at its full complement. Where voluntary enlistment did not suffice for this purpose resort was had to conscription; but this was applied only to the lowest classes of the community. The systems of drill now followed in all European armies are founded on that introduced into the Prussian army by Leopold of Dessau, who organized it under Frederick William I. Cavalry tactics were greatly improved by Frederick the Great himself, who also was the first to use horse artillery. The dividing of artillery into batteries is of about the same date, but is due to a Frenchman named Gribeauval.

Since the time of Frederick the Great a great change has taken place in the composition of armies through the reintroduction of the principle of the universal liability of all men capable of bearing arms to military service, or, in other words, through the raising of armies by a general conscription, now practised in every European country. Conscription was first adopted by France in 1798, and it was by means of it that Napoleon was able to raise the large armies with which he overran and conquered a great part of the Continent. In 1808 it was adopted by Prussia, by which power it has been applied with greater rigor than by any other. In Prussia it was combined with the short-service system, a mode of train-

ing the population to arms suggested by Napoleon's attempt in the Peace of Tilsit to limit the Prussian army to a certain strength. This system consists in requiring those serving in the active army to remain under arms for a comparatively short term (in Prussia three years), during which they become thoroughly trained soldiers ready for active service on any emergency. Every year a certain number return from the army to civil life, and are replaced by others who are subjected to military training for the same term. By this means Prussia, while never maintaining a larger active army than that prescribed by the Peace of Tilsit, was able to train its whole able-bodied male population to arms, and that without allowing the fact to be discovered until it was made manifest by the war of revenge in 1813. In other countries where the principle of conscription had been adopted its operation was greatly weakened by the numerous exemptions that might be obtained, and especially by allowing those required to serve to obtain exemption by paying for a substitute. Especially was this the case in France, where, under Napoleon III, the army had again become to all intents and purposes a professional one. In army organization the principal change that has been made since the introduction of conscription has been the establishment of army corps (*corps d'armée*), that is, divisions of an army composed of all arms (infantry, cavalry and artillery), and placed under the command of a single general. These divisions were first established by Napoleon, who placed them under the command of his marshals. The division was afterward adopted by Prussia and extended to the German empire, where the further improvement is made of localizing each army corps in a certain province or member of the empire, in which it is reunited, and in which are kept all the arms and other equipments necessary for its mobilization. In the Prussian army the cavalry are very numerous, and are used principally on the march, when they are sent in front to cover the advance of the main body of the troops, and to collect information. In all armies considerable changes in tactics have resulted from the increased range, precision and rapidity of fire of the improved artillery and musketry now in use.

In most nations, will now be found an army of reserve, intended to augment the standing army from a peace to a war strength, and consisting of two classes—those waiting an immediate call to arms, if required, and those constituting the militia—the entire effective military power of the state. It may be of interest here to mention certain distinctions in the application of the word army. A covering army is encamped for the protection of the different passes or roads which lead to the town or other place to be protected. A siege army is ranged around or in front of a fortified place, to capture it by a regular process of besieging. A blockading army, either independent of, or auxiliary to, a siege army, is intended to prevent all ingress and egress at the streets or gates of a besieged place. An army of observation takes up an advanced position, and by celerity of movement keeps a close watch on all the manœuvres of the enemy. An army of reconnaissance has a

more special duty at a particular time and place, to ascertain the strength and position of the enemy's forces. A flying column is a small army carrying all its supplies with it, so as to be able to operate quickly and in any direction, independently of its original base of operations.

EDWARD S. FARROW,
Consulting Civil and Military Engineer.

ARMY ADMINISTRATION. The administrative branch of the government, known as the War Department, and presided over by the Secretary of War, is second to none in real importance. Much of the business carried on by the Secretary of War has little or no connection with the military arm of the government, but by a process of accumulation of statutes and authorities, resulting often from the expediency of the moment, the present vast dimensions have been reached. The methods of conduct of business remain practically the same to-day as in the War of 1812, except that through a long course of years, there has grown up a system of laws and regulations fixing in great detail the complex duties of the various bureaus.

Ordinarily army administration consists in the organization and other means by which various administrative duties are performed, necessary to provide for the wants of troops, and for all the foreseen demands of a state of war, including labor and the supplies for garrisons, sieges, etc. Such duties embrace subsistence-magazines, daily rations, forage, dress, encampments, barracks, hospitals, transportation, etc., the administrative duties of engineers and of the ordnance department, estimates, accountability, payments, recruiting and in general the receipt and proper application of money. The Secretary of War, under the orders of the President, is the head of military administration in the United States. The object of such administration is to provide, through the resources placed by law at his disposition, for the constant wants, regular or accidental, of all who compose the army. Good administration embraces a foreknowledge of wants, as well as the creation, operation and watchfulness of the ways and means necessary to satisfy them; the payment of expenses, and the settlement of accounts. Army administration is divided into several branches determined by law. These different branches constitute the administrative service of an army, the operations of which should be so regulated that the Secretary of War will be always informed of the condition of each, and be able to exercise, subordinate to law, a complete financial control over each. The Adjutant-General of the army and the heads of the administrative corps have each been assigned a bureau in the War Department, under the direction of the Secretary of War, for the management of the administrative duties with which they have been respectively charged. Administration and Command are distinct. Administration is controlled by the head of an executive department of the government, under the orders of the President, by means of legally-appointed administrative agents, with or without rank; while Command, or the discipline, military control and direction of military service of officers and soldiers, can be legally exercised only by the military hierarchy, at the head of which is the constitutional commander-in-chief

of the army, navy and militia, followed by the commander of the army, and other military grades.

ARMY AVIATORS. See **MILITARY AERONAUTICS.**

ARMY BOUNTY. See **BOUNTY.**

ARMY COMMISSARY. The duties of an army or corps commissary, like those of division, brigade or regimental commissaries, are to see that all troops with or in his particular command are properly supplied with good and wholesome food; these duties for an army are, of course, on a more extended scale than for a regiment, but in general principles, forms, manner of procuring and issuing stores, in nearly all cases, the same rules will apply to the one as to the other.

The requisitions of an army commissary should always be approved by the commanding officer of the army; he should know accurately the number of troops in the command, and their different posts or stations. If the command is an extended one, there being many detached posts, he should at once ascertain the different methods of access to them, the probability of continuous or interrupted transportation, and endeavor to keep each post supplied in such a manner as to guard against any contingency arising from a lack of transportation. He should know the amount of stores on hand at any time, and the amount of stores due on any requisition. In order to facilitate his work, he should call upon all subordinate officers, particularly upon those having charge of stores in bulk, to make frequent reports (trimonthly are usually sufficient) showing the amount of stores on hand at each depot or post suitable for issue or for sale to officers. Should any stores at the different posts become damaged, or unfit for issue, he should require that they be immediately reported to him, in order that he may make the necessary arrangements for replacing them. In an extended command he should make, or if his duties will not permit of his attending to it personally, he should have at least one practical commissary to act as an inspector, who should make frequent inspections of the stores at every post, examining the stores, their condition, quantity, quality, and, above all, the manner of caring for and protecting them.

The more stores are handled from the time they leave the depot until their final distribution to the different companies of the regiment for which they were drawn, the greater is the damage and wastage, and when possible for the division commissary to draw in bulk, and issue at once on the proper returns, the damage is slight and the wastage, if any, is easily accounted for by the one officer; but if he again transfers to a brigade commissary, who, in turn, transfers to a regimental commissary, the same wastage occurs in the second and third transfer, and subsequent issues, as would occur in the first, while the proportion would be greatly reduced if but one officer had the entire charge of the issue.

ARMY CORPS. When an army is very large, three or four divisions are joined together and form an "Army Corps." The officer commanding an army corps should be of a higher grade than he who commands a division.

This grade, in the United States Army, is that of major-general. An army corps is most generally composed of all arms of service, and is, to all intents and purposes, an army complete in itself. Two or more army corps, or armies, would be under the command of the general, or of a general-in-chief. The functions of general officers are to command armies, or fractions of an army greater than a regiment, when mobilized. In time of peace, when the regiments are not formed into brigades or divisions, but are distributed over districts of country, the function of the general is to command the troops in these districts, which are then designated by the term "military departments."

ARMY DISPENSARIES. Medical officers and contract surgeons on duty attend officers, enlisted men, contract surgeons, acting dental surgeons, members of the nurse corps, prisoners of war, and other persons in military custody or confinement, and applicants for enlistment while held under observation; also, when practicable, the families of officers and enlisted men; and at stations, or in the field, where other medical attendance cannot be procured, civilian employees. Medicines are dispensed to all persons entitled to medical attendance, and hospital stores to enlisted men and hospital matrons, also to officers at posts or stations where they cannot be procured by purchase. Medical officers and contract surgeons at their stations furnish medical attendance to officers and enlisted men on the retired list, but they are not required to leave their stations for that purpose. Medicines, dressings, etc., are supplied to retired officers and enlisted men from army dispensaries on medical officers' prescriptions.

ARMY FIELD ENGINEERS SCHOOL. See **ARMY SCHOOLS.**

ARMY FIELD SERVICE SCHOOL FOR MEDICAL OFFICERS. See **ARMY SCHOOLS.**

ARMY MEDICAL BOARD. A board of at least three officers, appointed by the Secretary of War, which passes on the appointment and promotion of officers in the Medical Corps of the United States army. The preliminary examinations for commissions in the Medical Corps may also be given by other designated boards.

ARMY MEDICAL SCHOOL. A school located in Washington, D. C. Its personnel consists of the faculty, such special professors and instructors as may be assigned to temporary duty at the school, the students and such enlisted men and civilian employees as are assigned to it for duty. Its object is to train the students therein in the subjects that pertain to the duties of the medical department. It also carries on such scientific work and investigations as are directed or authorized by proper authority. The commandant, professors and assistant professors are detailed by the War Department from among the officers of the medical corps; the special professors are nominated by the faculty, with the approval of the surgeon-general, from among distinguished members of the medical reserve corps; the instructors are officers of other branches of the army detailed by the

War Department to give special courses of instruction. The faculty consists of the commandant who is its president, the professors and assistant professors. It meets at such times as the commandant deems advisable. It arranges the program of instruction, prescribes the textbooks appropriate thereto, the allotment of time to each subject, and the character and scope of the examinations, and has final determination of all questions concerning the proficiency of students, subject, however, in all respects to the express provisions of law. The adjutant is the secretary of the faculty and is chosen by the commandant from among the professors or assistant professors. He is the custodian of the records of the faculty, conducts the correspondence of the school and promulgates the orders of the commandant.

The student-body consists of officers of the medical reserve corps who are candidates for appointment in the medical corps, such medical officers of the army and of the organized militia as may be ordered or authorized to attend the school, and enlisted men of the hospital corps ordered to the school for instruction. The army field service and correspondence school for medical officers is a branch of the army service schools at Fort Leavenworth and is governed by regulations published in general orders.

ARMY AND NAVY BOUNTIES. See **BOUNTIES.**

ARMY AND NAVY GENERAL HOSPITAL. This hospital located at Hot Springs, Ark., is under the direction of the Secretary of War, and is devoted to the treatment of the officers and enlisted men of the military and naval service of the United States, cadets at the United States military and naval academies, officers of the Revenue-Cutter service, officers of the Public Health service and honorably discharged soldiers and sailors of the regular and volunteer army and navy of the United States, for such diseases as the waters of the Hot Springs of Arkansas have an established reputation in benefiting. Admission to this hospital is restricted to those of the above-named classes who require medical treatment in the following order of preference: (1) Officers and enlisted men of the army, the navy, and the marine corps on the active lists, and cadets at the United States military and naval academies; (2) Officers and enlisted men of the army, the navy and the marine corps on the retired lists; (3) Officers of the Revenue-Cutter service and of the Public Health service; (4) Honorably discharged soldiers and sailors of the regular and volunteer army and navy of the United States may also be admitted by authority of the surgeon-general when there are vacant beds in the hospital.

ARMY AND NAVY MANŒUVRES. The object of manœuvres is to train, in time of peace, the fighting forces of a nation by handling them, as far as practicable, as in time of war, the forces designated being divided for this purpose into two opposing bodies. Previous military training is presupposed. Manœuvres are of three kinds: First, Land manœuvres, taking place entirely on land; second, Naval manœuvres, where fleets manœuvre against

fleets; third, Combined army and navy manœuvres. The last two are of comparatively recent origin. Manœuvres are now annually held in all the principal countries of Europe. They are the culmination and test of the military instruction of the year. As operations in the grand manœuvres are carried on over a large extent of territory, the time fixed is after the crops are harvested so that agricultural interests are interfered with as little as possible. The annual manœuvres begin with regimental and brigade exercises for the infantry, with battalion exercises for field artillery (a battalion consists of two or more batteries) and with special manœuvres for cavalry. Manœuvres are also carried on all over the country by the army corps not participating in the grand manœuvres. The program for the grand manœuvres is carefully worked out beforehand by the general staff.

These manœuvres are of great value in training officers, especially staff officers. They also serve as a sort of examination for officers, whose work in the field comes under the observation of their superiors. Officers showing zeal and ability are marked for advancement, while those whose work does not come up to the standard are reproved or even more severely dealt with. In the United States circumstances have prevented the carrying on of army manœuvres except on a small scale, the American army being so widely scattered that a large enough force to make it worth while could not be brought together without great inconvenience and expense.

Naval Manœuvres may be tactical or strategical; the former having to do with the handling of fleets when they are within sight of each other, the latter when they are not. As all the elements, such as size and speed, character and arrangement of armor, number and power of guns, of different classes of ships, battleships, cruisers and torpedo boats, are well known, it is supposed, when they come in conflict, that the result will be a foregone conclusion, assuming the personnel to be of equal quality. The personal element, the man behind the gun, while of vital importance in war, is a factor that cannot be easily estimated in tactical manœuvres. Much more attention is therefore given to strategical manœuvres. A fleet going out for manœuvres is divided into two squadrons, one to attack, the other to defend. A passive defense is not contemplated. While the object may be the defense of a harbor, the way to accomplish it is not to wait in port for the enemy, but to go out to seek him on the open sea. Otherwise the advantage of one of the most valuable characteristics of ships, their mobility, would be lost. In the United States combined army and navy manœuvres were inaugurated in 1902. The decision as to whether the fleet or the land forces win is of minor importance. The manœuvres are of great value to both the army and navy. For the former they give instruction in the most efficient means of coast defense, including the co-ordination of all its various elements; the best system of fire control; the best location and employment of search-lights and range-finders; the best means of obtaining and transmitting information. They serve to point out any defects in the location and plans of the fortifications, and

whether the number, type and mounting of guns are the best adapted for the purpose at any particular site. For the navy they afford a test of the means of obtaining the ranges of the forts and batteries, and of conveying the information to the officers in charge of the guns. They give information as to the effect of mines and obstructions in impeding the movements of ships and the methods to be used in forcing such a passage or in removing the obstructions. They give instruction as to the best manner of approach and of manœuvring under fire, the formations to be used, the speed and the distance between ships; the method of attacking by night or in a fog; the use of the search-light for lighting the target or blinding the eyes of the enemy's gunners or range-finders. The manœuvres rouse the interest and stimulate the *esprit de corps* of the personnel of both services and teach it to make the best use of war material under conditions as nearly as possible like those of actual war.

W. A. SIMPSON,

Assistant Adjutant-General, United States Army.

ARMY AND NAVY UNION. An organization composed exclusively of men who have served in some branch of the army or navy of the United States. Its objects are "to bring together and unite in benevolent and social fellowship those who have served their country honorably; to provide for the sick and distressed; to assist in the burial of the dead, and to extend a helping hand to the family of a deceased comrade or shipmate."

ARMY NURSE CORPS. The superintendent of the nurse corps, under the direction of the surgeon-general, has general supervision of the corps, and her duties and the duties of chief nurses and nurses are as prescribed by the surgeon-general. The services of army nurses are afforded sick and wounded officers, enlisted men, and other patients in military hospitals. When traveling under orders on transports they assist in the care of sick officers and enlisted men, under the direction of the transport surgeon. Members of officers' and enlisted men's families are not entitled to the services of army nurses, but in great emergencies and for the manifest interest of the service, nurses will care for such patients when so directed by the officer in charge of the hospital, a report of the fact being made in each instance to the surgeon-general through military channels. At places where the services of trained nurses are not otherwise obtainable, a nurse may, if she so desires, and with the approval of the officer in charge of the hospital, be granted a special leave, without pay and allowances, in order to take a private case, such leaves not to exceed 60 days. The pay, allowances, and privileges of nurses are specified by law, and they are forbidden to receive presents from patients, or from the relatives or friends of patients, for services rendered when on duty.

See UNITED STATES, ARMY OF.

ARMY OF THE UNITED STATES.—

ARMY ORGANIZATION. United States.—The land forces of the United States are classified into the Regular Army, in which enlistment is for four years with the colors and

three in the unorganized Army Reserve, the Officers Reserve Corps, and the Enlisted Reserve Corps, forces called or drafted into the service of the United States, the Organized Militia of the several States, and the unorganized militia, consisting of all males between 18 and 45 who are fit to bear arms and are citizens of the United States, or have declared their intention to become citizens. The President of the United States is the Commander-in-chief of the United States Army by right of office, and he nominates for the approval of Congress such general officers of the rank of general or lieutenant-general as he deems necessary properly to officer the higher commands. The administration is carried on by the War Department under the direction of the Secretary of War, who is a member of the official cabinet of the President. For administrative purposes the following divisions are made: The *General Staff Corps* prepares all plans for national defense, for mobilization of the forces, and has a general supervision of all questions affecting the efficiency of the Army, and is under the charge of the chief of staff. The *Adjutant-General's Department* keeps all records and has charge of all correspondence, the issuing of orders, notices, bulletins and official literature, and is under the charge of the Adjutant-General. The *Inspector-General's Department* exercises general supervision over all matters that have to do with the efficiency of the Army—the conduct and discipline, condition of uniforms, equipments, supplies and expenditure of public money, and is under the charge of the Inspector-General. The *Judge-Advocate's Department* is the custodian of all legal records, has a general supervision over all courts-martial, courts of inquiry and military commissions, and is under the charge of the Judge-Advocate-General. The *Ordnance Department* supplies all arms, equipments and other fighting material and maintains the arsenal and depots for the manufacture, distribution and safe-keeping of military stores, and is under the charge of the Chief of Ordnance. The *Quartermaster Corps* takes care of all matters of supply (other than ordnance), transportation, distribution of funds and payment of troops, and is under the charge of the Quartermaster-General. The *Engineer Corps* is in charge of the construction and maintenance of all fortifications, military posts, lines of communication and rivers and harbors, as far as is necessary for their use for military or naval purposes, and is under the charge of the Chief of Engineers. The *Coast Artillery Corps* is in charge of the garrisoning of all coast fortifications and coast and harbor defense and siege work, and is commanded by the Chief of Coast Artillery. The *Signal Corps* is in charge of all methods of communication by balloons, aeroplanes, wireless telegraphy, telephones and visual signaling, and is commanded by the Chief Signal Officer. The *Medical Department* is subdivided into (a) the Medical Corps, which is in charge of the sick and wounded and the physical and sanitary condition of the army, detachments of which are known as sanitary troops when serving with other troops; (b) the Dental Corps, which is in charge of the teeth; (c) the Medical Reserve Corps, which secures a reserve of medical

officers available for military service; (d) the Hospital Corps, which renders all necessary hospital services in garrison, camp or field (including the ambulance service); (e) the Nurse Corps, from which nurses may be assigned to active duty when the emergency of the service demands. The Surgeon-General is in charge of the Medical Department and all its branches. The *Bureau of Insular Affairs* is in charge of all matters of a military nature and of the supplies that affect the colonies, and is under the control of the Chief of Insular Affairs. The *Bureau of Militia Affairs* is in charge of the affairs of the National Guard and is under the direction of the Chief of Militia Affairs.

The organization of the fighting forces of the United States in May 1917, was based on following units: A *Squad* consisting of 1 corporal, as squad commander, and 7 privates, or privates, first class: a *Platoon* consisting of 1 first lieutenant, second lieutenant or sergeant, as platoon commander, and 4 squads. The organization of the United States Army at the present time (1917) is in a state of change. Besides the scheme outlined in the "Tables of Organization" on 3 May, a new organization for overseas service was outlined in the *Official Bulletin* for 22 September. The following table is an outline of the comparative structure of the two systems (the numbers stand for officers and men combined):

In an infantry division there are

SCHEME OF 3 MAY 1917 (Maximum strength)	SCHEME OF 22 SEPTEMBER 1917
1 division headquarters under a major-general (153)	1 division headquarters under a major-general (164)
3 infantry brigades (18,579)	1 machine-gun battalion of four companies (768)
1 field-artillery brigade (4,030)	2 infantry brigades (16,420)
1 cavalry regiment (1,579)	1 field-artillery brigade (5,068)
1 field signal battalion (259)	1 field signal battalion (262)
1 regiment of engineers (1,098)	1 regiment of engineers (1,666)
1 train headquarters and military police (332)	1 train headquarters and military police (337)
1 ammunition train (702)	1 ammunition train (962)
1 supply train (332)	1 supply train (472)
1 engineer train (170)	1 engineer train (84)
1 sanitary train (927)	1 sanitary train (4 field hospital companies and 4 ambulance companies (949)
1 aero squadron (173)	
Total, 28,334	Total, 27,152

In an infantry brigade there are

1 headquarters (19)	1 headquarters (about 140)
3 infantry regiments (6,060)	2 infantry regiments (7,510)
	1 machine-gun battalion of three companies (560)
Total, 6,079	Total, 8,210

In a field artillery brigade there are

1 headquarters (19)	1 headquarters
2 regiments of 3-inch field guns (2,687)	3 regiments of 75 mm. field guns ()
1 regiment of 3 8-inch howitzers (1,337)	1 trench-mortar battery ()
Total, 3,943	Total, 5,068

An infantry regiment contains

1 headquarters and headquarters company (61)	1 headquarters and headquarters company (303)
3 battalions of four line companies each (1,842)	3 battalions of four line companies each (3,078)
1 supply company (39)	1 supply company (140)
1 machine gun company (78)	1 machine gun company (178)
1 medical detachment (38)	1 medical detachment (56)
Total, 2,958	Total, 3,755

An ordinary infantry company contains

1 captain, 1 first lieutenant, 1 second lieutenant, 1 first sergeant, 1 mess sergeant, 1 supply sergeant, 8 sergeants, 17 corporals, 2 mechanics, 3 cooks, 2 buglers, 28 privates (first class), 87 privates. Total, 3 officers, 150 men.

1 headquarters (2 officers, 18 men), 4 platoons, each including 1 headquarters (1 officer, 1 man), 2 sections riflemen (24 men), 1 section bombers and rifle grenadiers (22 men), 1 section auto riflemen (11 men, 4 guns). Total, 6 officers, 250 men.

An infantry supply company contains:

1 captain (chief supply officer), 1 second lieutenant as assistant, 3 regimental supply sergeants, 1 first sergeant, 1 mess sergeant, 1 stable sergeant, 1 corporal, 1 horseshoer, 1 saddler, 27 wagoners and 1 cook. Total, 39.

(Composition not officially published).

Total, 140

A machine-gun company contains

1 captain, 1 first lieutenant, 2 second lieutenants, 1 first sergeant, 1 supply sergeant, 1 mess sergeant, 1 stable sergeant, 7 sergeants, 8 corporals, 1 horseshoer, 2 mechanics, 2 cooks, 2 buglers, 12 privates (first class), 36 privates. Total, 4 officers, 74 men, 6 guns.

1 headquarters (3 officers and 21 men), 3 platoons (each containing one officer and 46 men), a train of 13 men, armament, 12 heavy machine guns and four spare guns. Total, 6 officers, 172 men, 16 guns.

An infantry headquarters company contains

1 captain (regimental adjutant), 1 regimental sergeant-major, 3 regimental supply sergeants, 1 first sergeant, 1 mess sergeant, 1 supply sergeant, 1 stable sergeant, 1 sergeant, 1 horseshoer, 2 cooks, 4 privates (first class), 12 privates, 28 men in band. Total, 1 officer, 56 men.

1 headquarters platoon (93 officers and men), including 1 staff section (36 officers and men), 1 orderlies' section (29), 1 band section (28 men), 1 signal platoon (77 officers and men), including 1 telephone section (51 men), 1 section with headquarters (10 men), 1 section with 3 battalions (16 officers and men), 1 sappers' and bombers' platoon, including 1 section sappers (9) for digging and special work, one section bombers (34 officers and men), 1 pioneer platoon (35 officers and men), 1 one-pounder cannon platoon (33 officers and men). Total, 7 officers, 294 men.

In addition to the units already described, the establishment of 3 May contains the following organizations: A *troop of cavalry* is organized as an infantry company with the addition of a stable sergeant, 2 horseshoers, and 7 saddlers, and with only 5 sergeants, 8 corporals, 2 cooks, 20 privates, first class, and 61 privates. A *supply troop of cavalry* is as prescribed for an infantry supply company with an extra second lieutenant and an extra corporal, an extra horseshoer, an extra saddler, an extra cook and 10 extra wagoners. A *coast artillery company* is as prescribed for a line company of infantry, except that certain enlisted men, according to their duties, are rated as follows: casemate electricians, observers first class, observers second class, plotters, chief planters, coxswains, chief loaders, gun commanders and gun pointers. A *field artillery battery* of 4 guns (3 in.) is organized as prescribed for a line company of infantry, there being in addition an extra first lieutenant, an extra second lieutenant, an extra sergeant, 3 extra corporals, a chief mechanic and an extra mechanic, 3 horseshoers, an extra bugler, 7 extra privates, first class, and 21 extra privates, the privates being sometimes called drivers and cannoners. A *pioneer company of engineers* is as prescribed

for a line company of infantry, except for an extra first lieutenant and 3 sergeants, first class. Mounted companies are organized as cavalry troops with an extra first lieutenant and 2 sergeants, first class. A *pontoon company of engineers* is as prescribed for a line company of infantry, having in addition 2 saddlers in charge of harness and equipment, 2 farriers in charge of wagons. A *signal corps radio company* consisting of 1 captain as commanding officer, 2 first lieutenants, 1 master electrician, 6 sergeants, first class, 9 sergeants, 15 corporals, 2 cooks, 1 horseshoer, 35 privates, first class, and 6 privates. A *signal corps wire company* consists of 1 captain as commanding officer, 2 first lieutenants, 1 master electrician, 5 sergeants, first class, 7 sergeants, 12 corporals, 2 cooks, 1 horseshoer, 39 privates, first class, and 8 privates. A *signal corps outpost company* consists of 1 captain as commanding officer, 4 first lieutenants, 1 master electrician, 3 sergeants, first class, 15 sergeants, 14 corporals, 2 cooks, 1 horseshoer, 37 privates, first class, and 12 privates. A *company of military police* is as prescribed for a company of infantry, with 4 less privates, first class, and 2 less privates. An *ambulance company* consists of 1 surgeon with the rank of captain as commanding officer, 4 assistant surgeons with rank of captain or first lieutenant, 2 sergeants, first class, 11 sergeants, 6 corporals, 1 mechanic, 3 cooks, 96 privates in a motor-driven company, 124 in an animal-driven company, and in addition to a horseshoer, a saddler and a farrier. An *ammunition train section* (wagon transportation) consists of 1 captain or first lieutenant as commanding officer, 1 sergeant (wagonmaster), 1 clerk, 2 sergeants (assistant wagonmasters), 1 mess sergeant, 4 sergeant horseshoers, 2 sergeant farriers, 2 sergeant saddlers, 1 sergeant mechanic, 1 sergeant agent, 4 corporals (assistant wagonmasters), 1 corporal agent, 2 cooks, 60 privates, first class (teamsters and orderly), and 12 privates (laborers). An *ammunition train section* (motor transportation) consists of 1 first lieutenant as commanding officer, 1 sergeant (truckmaster), 1 clerk, 3 sergeants (assistant truckmasters), 1 mess sergeant, 1 sergeant mechanic, 1 sergeant agent, 1 corporal agent, 2 cooks, 33 privates, first class (chauffeurs), 2 privates, first class (assistant mechanics), and 9 privates as assistant chauffeurs. A *field bakery* consists of 1 captain or lieutenant as commanding officer, 60 men, rated as cooks, and 12 bake ovens. A *battalion of infantry* consists of 1 major as battalion commander, 1 headquarters and 4 line companies. A *squadron of cavalry* corresponds to a battalion of infantry and contains 4 line troops. A *battalion of field artillery*, as prescribed, contains 1 major, 1 headquarters and 3 batteries. A *battalion of engineers* is constituted as prescribed for a battalion of infantry and contains 3 companies. A *battalion of signal corps* (field battalion) consists of 1 major as commanding officer, 1 headquarters, 1 supply section of a supply sergeant and 5 men, 1 wire company, 1 radio company and 1 outpost company. A *battalion of signal corps* (aero squadron) consists of 1 major as commanding officer, 1 headquarters section under the adjutant, containing 10 men, 1 supply section with 2 officers and 37 men, 1 engineering sec-

tion with 2 officers and 19 men, 12 aero squadrons, each containing 1 captain or first lieutenant, 1 sergeant, first class, as mechanician, 2 sergeants or corporals as mechanicians, 2 privates, first class, and 2 privates. There are attached to the squadron 1 surgeon and 4 enlisted men, medical department. For a *regiment of infantry* see the tables of the old and new establishments. A *regiment of cavalry* consists of headquarters, 3 squadrons of cavalry, a headquarters troop, a machine-gun troop and a supply troop. A *machine-gun troop*—the cavalry equivalent of a machine-gun company—contains 1 more sergeant, 1 more private, first class, and 13 more privates than its analogue. A *regiment of field artillery* contains a headquarters, 2 or 3 battalions of field artillery, a headquarters company and a supply company. A *regiment of engineers* is as prescribed for infantry without the machine-gun company and with only 2 battalions. A *regimental detachment of the medical corps* consists of 1 surgeon with the rank of major, 2 or 3 assistant surgeons with the rank of captain or first lieutenant, 2 veterinarians in mounted regiments, 1 sergeant, first class, 2 or 3 sergeants, 17–29 privates, and privates first class. A *brigade* consists of 1 brigadier-general as brigade commander and his headquarters and of 2 or 3 regiments of one arm. For the constitution of an *infantry division* see the tables of the old and new establishments. A cavalry division consists of headquarters, train headquarters and military police, much like those of an infantry division, together with 3 brigades of cavalry, 1 regiment of horse artillery, 1 mounted battalion of engineers, 1 mounted battalion of signal corps, 1 aero squadron, 1 ammunition train, 1 sanitary train and 1 supply train. A *field army*, the equivalent of the army corps of foreign countries, consists of 1 lieutenant-general or major-general as commander, the following officers, whose duties are the same as the departments and corps they represent—1 brigadier-general (chief of staff), 1 colonel (adjutant), 1 colonel (inspector), 1 colonel (judge-advocate), 1 colonel (chief quartermaster), 1 colonel (chief of engineers), 1 colonel (chief surgeon), 1 lieutenant-colonel (assistant chief surgeon), 1 lieutenant-colonel (chief of ordnance), 1 lieutenant-colonel (chief signal officer), 3 lieutenant-colonels (aides-de-camp), 2 or more divisions with additional so-called field army troops, including such troops as regiments of heavy artillery, and pontoon battalions of engineers. An army consists of such number of field armies as may be required.

The organization of the coast artillery is territorial and not by battalions or regiments. A coast artillery battery is manned by a company. Battery commands are organized into fire commands or mine commands under the charge of a major. These, together with such troops of the mobile army as may be used for purposes of support, are grouped into fort commands under majors or lieutenant-colonels. Several fort commands make a coast defense command under colonels. These again are grouped into coast artillery districts. As the coast artillery is a highly technical service, a large number of commissioned and

non-commissioned staff officers are required at every stage of organization.

Foreign Countries.—The general features of army organization are much the same throughout the world and conform very closely to the scheme adopted by the United States on 22 September 1917. The range of variation is fairly indicated by the two schemes of this table. In particular, the size of an infantry company is usually from 200 to 250 men, and that of a battalion in the neighborhood of 1,000 men. The nomenclature and administration of cavalry units in the United States army is not reproduced exactly elsewhere; the usual arrangement is by squadrons of about 150 sabres, corresponding to infantry companies and grouped into regiments of four or five squadrons. The troop in the British army corresponds to a platoon and is led by a subaltern. Artillery administration is also very variable; batteries of field artillery, however, usually consist, as in the United States, of four guns. The organization known in America as a battalion of field artillery is known abroad variously as an *Abteilung*, group, brigade, or division. The organization of the technical troops, such as the engineers, train and signal corps men, is different in each army. In general, the aviators are recognized as a separate arm and are not subordinated to the Signal Corps. The army police is usually a separate organization and not, as until recently in our army, made up by details from other troops. In the British army it contains no privates—every man ranks at least as lance-corporal. In most Continental nations part or the whole of the municipal police and fire departments receive a military organization and is regarded as part of the army.

England.—The military services in the British Empire comprise the Regular Army, the Army Reserve, the Special Reserve, the Territorials, the Indian Army and the Militia forces of the various colonies. The Regular Army is organized into an expeditionary force, serving in the British Isles, and a colonial force, serving in the various colonies and India. Enlistment is normally for 12 years, which is variously divided in different branches of the army between the Regular Army and the Army Reserve. At present the terms of enlistment for active service are the duration of the war, with a minimum term of three years. The Special Reserve, for all service, and the Territorial force, for service in the United Kingdom, correspond to the organized militia in the United States, and are organized into divisions in a way in general similar to that in the Regular Army. The native Indian Army is composed of native troops under British officers and is a distinct service from that part of the Regular Army which also serves in India. All colonies also maintain bodies of troops organized in a manner similar to that in the Regular Army. In Australia and New Zealand military service is compulsory.

The British infantry is not organized into regiments as administrative units and a regiment is a mere collection of battalions of various sorts, usually recruited within a specified area. The battalions are grouped directly into brigades. The whole artillery force is

known as the Royal Regiment of Artillery and is not divided into tactical regiments. Regiments as administrative and tactical organizations are found in the cavalry. The train and pay services are separate, whereas in the United States both are under the Quartermaster Corps.

France.—The military services in France comprise the Metropolitan Army, the Colonial Forces and the Territorial Army. Service in the Metropolitan Army is compulsory and that in the Colonial Forces is by voluntary enlistment. All males between the ages of 18 and 45 are liable to military service, which is divided into (a) that with the colors (3 years); (b) that in the Metropolitan Army Reserve (10 years); (c) that in the Territorial Army (5 years); and that (final service) in the Territorial Army Reserve (9 years). The Metropolitan Army is organized into the Army of the Interior and the Algerian-Tunisian Army. The Colonial Forces are partly French and partly native troops.

Germany.—There are two main divisions of the military service in Germany—(a) regular service; (b) service in the *Landsturm*. All males between the ages of 17 and 45 are required to perform service in one or the other of these main divisions. Men selected for the regular service serve seven years with the standing army (three with the colors and four in reserve) and then are passed into the *Landwehr*, where they continue service until their 39th year. Service from the 39th to the 45th year is in the *Landsturm*. Men who for any reason are not required to serve in the standing army are placed in the *Eratz* reserve (special reserve) for 12 years and then passed to the *Landsturm*.

Austria-Hungary.—The military service of the Austro-Hungarian empire is divided into—(a) the *Landwehr*, or National Army of Austria; (b) the *Honved*, or National Army of Hungary; (c) the *Gemeinsames Heer*, or common army of both countries; (d) the *Landsturm*, or second reserve of Austria and Hungary. All males between the ages of 19 and 42 are liable to military service, and it is decided by lot whether such service will be in a national army or in the common army. Actual service begins at the age of 21 and lasts for 12 years. Men drawing assignment to the common army serve three years with the colors and seven years in the reserve of that army. They then serve an additional two years in the reserve of a national army, and at the expiration of this service pass to the *Landsturm*. Men drawing assignment to a national army serve two years with the colors of that army and 10 years in its reserve. They then pass to the *Landsturm*.

The Austro-Hungarian army in war time is not divided into three forces as in peace, but forms one army composed of all three elements. The administrative unit is the field army, consisting of from two to four corps, and these in turn of usually three divisions. Two of these divisions are drawn from the common army and the third from the *Landwehr* or *Honved*, or from the reserves of the first line.

Italy.—Military service in Italy comprises (a) that in the standing army; (b) that in

the Mobile Militia; and (c) that in the Territorial Militia. Every adult male between the ages of 20 and 39 years is liable to service in one of these branches. In time of war the army is the grand unit of organization in the Italian service. Each army is composed of three corps, one division of cavalry and auxiliary troops.

Russia.—All male Russian subjects, with the exception of the Mohammedan native Caucasian population and the population of a few provinces, are liable to military service from the 21st to the 44th year of age. This service is divided into (a) that in the standing army and reserves, and (b) that in the Imperial Militia. At the annual levy the class of service to which a man is assigned is determined by lot.

Japan.—The military service in Japan is divided into—(a) the active army (*Genyeki*); (b) first reserve (*Yobi*); (c) second reserve (*Kobi*); (d) replacement troops (reserve of recruitment) (*Hoku*); (e) the National army, first and second parts (*Ko kumin-hei*). Service is obligatory on all males between the ages of 17 and 40. The active army is divided into divisions and reserve divisions, each of which occupies a military district and is complete in itself, not only as regards combatant troops, but as regards auxiliary troops, including the medical department. In matters of general administration, decentralization is the keynote of the Japanese army, and each division is almost autonomous. It is maintained complete in all its branches in time of peace so that it can be moved in its entirety in time of war and its place immediately taken by a reserve division. In time of war two or more divisions (usually three) are mobilized to form field armies. See *ARMY; ARTILLERY; CAVALRY; INFANTRY; RANK; TACTICS*. Consult Balck, 'Tactics' (tr. Fort Leavenworth, Kan., 1914); War Department, 'Tables of Organization' (Washington 1914 and 1917).

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMY RATION. There are three varieties of the American army ration, garrison, field and emergency. The garrison ration is given soldiers at regularly established military posts; while the field ration is issued to troops in the field in active campaign. The emergency ration is a condensed ration, in which the best and most valuable nutritive elements are combined in the smallest bulk. In composition, the garrison and field ration are almost identical. Each ration, which is supposed to keep the soldier one day, furnishing breakfast, dinner and supper, consists of 20 ounces of fresh beef or mutton, 12 ounces of bacon, 16 ounces of canned meat or canned fish, 14 ounces of dried fish or 18 ounces of pickled fish, 18 ounces of flour or 20 ounces of corn meal, either $\frac{3}{4}$ ounces of beans or peas or $1\frac{1}{2}$ ounces of rice or hominy, and either 16 ounces of potatoes or $12\frac{1}{2}$ ounces of potatoes together with $1\frac{1}{2}$ ounces of dried fruit, $1\frac{1}{2}$ ounces of coffee, and $3\frac{1}{2}$ ounces of sugar. The ration also includes small quantities of vinegar, salt, pepper, soap and candles.

Rations are usually computed by the hundred, and are issued for ten days. To a company of 100 men, would, therefore, be issued 1,000 rations. In the field, each soldier is sup-

posed to carry one regular ration and one emergency ration all the time. The emergency ration is never eaten, except in case of last resort, and the regular ration is issued every day.

The army ration, it will be seen, contains none of those things which are ordinarily considered luxuries. For instance, there is no milk included in the ration, and the soldier must take his coffee black, unless he is able to purchase a can of condensed milk from the "sales store" with his "savings." Congress has authorized the commissary to keep on hand other articles of food that are not included in the regular ration. These are kept in the "sales stores," and are issued to the mess stewards, in return for "savings" from the regular rations. Out of a company of a hundred men there are a number who do not eat all of the articles in the ration. These would be wasted if drawn by the mess steward; therefore, when the thousand rations are issued to him, he returns to the commissary that part of the various components that he thinks will not be used. This, in the language of the army, is making a "savings" on the rations.

The value of the articles returned to the commissary is computed, and the mess steward is allowed to draw from the "sales stores" a sufficient quantity of luxuries that are not in the regular issue, equal to the value of his "saving." The government, however, will not allow a "saving" to be made on certain articles in the ration. Fresh meat, dried or preserved fish, potatoes, onions, tomatoes, prunes, apples and peaches must be used; a "saving" cannot be made on these articles. They contain just the proper nutritive elements, and the quantities given are what the normal soldier should eat.

ARMY REGISTER. The official list of the United States army, published annually, showing the position, rank and duties of officers, regiments, companies, etc., with the promotions and casualties during the preceding 12 months.

ARMY REGULATIONS. The Constitution of the United States provides that "Congress shall have power to make rules for the government and regulation of the land and naval forces." The only acts of Congress in force, authorizing the President to make regulations better defining the powers and duties of officers, are contained in the 5th section of the act of 3 March 1913, and the 9th section of the act approved 26 April 1816. The first of these acts is an act for the better organization of the General Staff of the army, and the second relates (with the exception of the last section) to the same subject.

The words *regulate* and *regulation* are used in several places in the Constitution of the United States. Thus, Congress has power to "regulate" commerce, to "regulate" the value of money, to make rules for the government and "regulation" of the land and naval forces, to make "regulations" with regard to the elections of senators and representatives, to make "regulations" with reference to the jurisdiction of the Supreme Court, in certain cases, and to make needful rules and "regulations" respecting the territory and other property of the United States. In all these cases regulation is legislation.

By virtue of its power to make rules and regulations for the land and naval forces, Congress covers a large field of legislation relating to the administration of military affairs. When this is done there still remains a mass of matters appertaining to the military establishment, which it is necessary to "regulate." Legislation cannot enter into all the details of this regulation, and, if it could, it would not be desirable, because a legislative code controlling the whole subject of military administration would not have the necessary elasticity. The Constitution provides a way of supplementing this power of Congress, the President, as executive and commander-in-chief of the army, having the power to make regulations for its government.

The regulations for the transaction of the public duties and business relating to the military establishment, adopted by the President in the exercise of this power, are designated as the army regulations. They may be divided into several classes, viz.:

1. Those which have received the sanction of Congress. These cannot be altered, nor can exceptions to them be made by the executive authority unless the regulations themselves provide for it. In reality, the approval of Congress makes them legislative regulations, and they might, therefore, be more strictly classified with other statutory regulations with reference to subjects of military administration. They are, however, included under the general head of army regulations, as approved codes of executive regulations.

2. Those that are made pursuant to, or in execution of, a statute—meaning by the latter expression those that are supplemental to particular statutes, and, in the absence of sufficient legislative regulation, prescribe means for carrying them out. These, if it be not prohibited by the statute, may be modified by the executive authority, but until this is done they are binding as well on the authority that made them as on others. It has been held that a regulation of the Treasury Department, made in pursuance of an act of Congress, "becomes a part of the law, and of as binding force as if incorporated in the body of the act itself." So it has been held that the civil service rules, promulgated under the Civil Service Act, "became a part of the law," and that removal from a position placed under the act and the rules can only be made agreeably to the terms and provisions of both the act and the rules, and an army regulation made pursuant to a provision contained in an act of Congress is of the same force. Examples of regulations of this class are those relating to the examination of enlisted men for commissions, under the act of Congress of 30 July 1892, and the executive order of 30 March 1898, prescribing limits of punishment.

3. Those emanating from, and depending on, the constitutional authority of the President, as commander-in-chief of the army and as executive, and not made in supplement to particular statutes. These constitute the greater part of the army regulations. They are not only modified at will by the President, but exemptions from particular regulations are given in exceptional cases; the exercise of this power with reference to them being found necessary. "The authority which makes them (regulations)

can modify or suspend them as to any case, or class of cases, or generally."

4. Departmental regulations, made by virtue of the authority conferred by section 161, Revised Statutes, on the head of each department "to prescribe regulations not inconsistent with law, for the government of his department, the conduct of its officers and clerks, the distribution and performance of its business, and the custody, use, and preservation of its records, papers and property appertaining thereto."

Mere repetitions of legislative enactments are not included under any of these heads. A long continued practice has been held equivalent to a specific regulation.

As to the subject-matter of regulations for the government of the army, no distinct line can be drawn separating the President's constitutional power to make them from the constitutional power of Congress "to make rules for the government and regulation" of the land forces. Regulations are, when they relate to subjects within the constitutional jurisdiction of Congress, unquestionably of a legislative character; and if it were practicable for Congress completely to regulate the methods of military administration, it might, under the Constitution, do so. But it is entirely impracticable, and therefore it is in a great measure left to the President to do it. So far as Congress chooses to exercise its jurisdiction in this respect, it occupies the field, and the President cannot encroach on it. But when it does not see fit to do so, the President's power, of necessity, is called into action. It is, indeed, of the commonest occurrence for Congress to regulate a subject in part, and for the Executive to regulate some remaining part, and this without any pretense of statutory authority, but upon the broad basis of constitutional power. We thus have a legislative jurisdiction, and, subject to it, an executive jurisdiction extending over the same matter.

So, also, as between the legislative and judicial powers, Congress may regulate the procedure of the Federal courts, but in so far as it does not do it, the courts may prescribe their own regulations. And this is, in fact, the existing condition. Congress has exercised the power in part, leaving it to the courts to regulate what it has not provided for. Courts cannot exercise their jurisdiction without rules of procedure, and necessarily have the original power of adopting their own when the legislature does not prescribe them; just as the President cannot exercise his power as commander-in-chief without the power to make orders for the regulation of the army. In fact, each branch of government—the legislative, executive and judicial—has the original power of making regulations for the transaction of its business—most manifestly so when the business is of direct constitutional origin—but the legislative has sometimes a jurisdiction over the regulations of the other branches, and when this happens its jurisdiction is superior.

In speaking of the powers of Congress over the administration of the affairs of the army, it is, of course, not intended to include what would properly come under the head of the direction of military movements. This belongs to command, and neither the power of Congress to raise and support armies, nor the power to

make rules for the government and regulation of the land and naval forces, nor the power to declare war, gives it the command of the army. Here the constitutional power of the President as commander-in-chief is exclusive.

When Congress fails to make regulations with reference to a matter of military administration, but either expressly or silently leaves it to the President to do so, it does not delegate its own legislative power to him, because that would be unconstitutional, but expressly or silently gives him the opportunity to call his executive power into play. It is, perhaps, not easy to explain why, if regulations may, under the Constitution, be made both by the legislative and executive branches, one should have precedence over the other; but it is to be noticed that the power of Congress is the express one "to make rules for the government and regulation of the land and naval forces," whereas the power of the President is a *construction* of his position as executive and commander-in-chief. The legislative power, by the words quoted, covers the whole field of military administration, but it is not always certain how far the executive power may go. It is not as well defined as the legislative power, but it is undoubtedly limited to so much of the subject as is not already controlled by the latter. The jurisdiction of the executive power is not, however, within this limit, coextensive with that of the legislative power, because the legislative branch of the government has a constitutional field of operation peculiar to itself, and yet there are army regulations which seem to be of a legislative character. It is because of this that difficulty sometimes occurs, a difficulty which has in the past quite often taken the form of a difference of views between the War Department and the accounting officers of the Treasury.

An impression has existed that a peculiar "force of law" is given to regulations by their approval by Congress, but it seems to be an erroneous one. If, as above stated, the making of regulations is within the jurisdiction both of Congress and the President, but the authority of Congress is superior to that of the President, it follows that when regulations are approved by Congress they cannot be altered by him until the approval is removed. To this extent, regulations approved by Congress may be said to have a superior force of law to those not thus approved, but this is not the erroneous impression referred to. Precisely what it is, is not clear, but it seems to have been believed that the approval of regulations by Congress makes them of higher obligation. This, however, is not true. Whether approved by Congress or not, they have, so long and so far as they are in force, the force of law, and are, therefore, binding. The distinction, in this respect that has sometimes been made between regulations approved by Congress and those not thus approved is misleading. Congress has, on several occasions, given its sanction to army regulations:

1. An Act of 3 March 1813, provided, "That it shall be the duty of the Secretary of the War Department, and he is hereby authorized, to prepare general regulations, better defining and prescribing the respective duties and powers of the several officers in the adjutant-general, inspector-general, quartermaster-general and

commissary or ordnance departments, of the topographical engineers, of the aids of generals, and generally of the general and regimental staff; which regulations, when approved by the President of the United States, shall be respected and obeyed, until altered or revoked by the same authority. And the said general regulations, thus prepared and approved, shall be laid before Congress at their next session."

A system of regulations was laid before Congress as required by the act. It was published (together with the statutes relating to the military establishment) in book form, from the adjutant and inspector-general's office, 1 May 1813, and may also be found in volume I of the 'American State Papers on Military Affairs.'

2. By Act of 24 April 1816, it was prescribed "that the regulations in force before the reduction of the army be recognized, as far as the same shall be found applicable to the service, subject, however, to such alterations as the Secretary of War may adopt, with the approbation of the President." The reduction referred to was made in June 1815, pursuant to an Act of 3 March. The Act of 24 April 1816, did not relate to any particular code of army regulations, but to all the regulations which were in force.

3. On 22 Dec. 1819, the House of Representatives resolved that "the Secretary of War be instructed to cause to be prepared and laid before this House, at the next session of Congress, a system of martial law, and a system of field service and police, for the government of the Army of the United States."

On 22 Dec. 1820, the Secretary of War accordingly submitted a system of "martial law," prepared by Judge-Advocate Major Storrow (which was never adopted), and a system of field service and police, which had been prepared by General Scott, and submitted to the War Department in September 1818.

On 26 Dec. 1820, the Speaker laid them before the House. The document was in manuscript, and was ordered to be printed, and a copy laid upon the desk of each member. (It is reprinted in the third volume of the State Papers on Military Affairs.) When the book was printed, several copies were sent to General Scott, who made certain corrections, and on 20 Feb. 1821, returned a copy (of which he retained a duplicate) to the War Department for the Committee of the House. It was received by the chairman of the Military Committee on 23 Feb. 1821.

On 27 Feb. 1821, the chairman of the Military Committee of the House reported the Senate bill, "To reduce and fix the military peace establishment," with certain amendments, among which was the addition of a section approving and adopting "the system of General Regulations for the Army, compiled by Major-General Scott." The bill, including this (the 14th) section, became law 2 March 1821. Early in that month, General Scott received directions to put the book to press for the use of the army, and, having received a letter from the chairman of the Military Committee of the House, informing him that the corrected copy had been received, and section 14 added to the army bill by way of amendment, he caused the book to be

reprinted from his retained duplicate corrected copy.

4. By an Act of Congress of 28 July 1866, the Secretary of War was directed to have prepared, and to report to Congress, at its next session, a code of regulations for the government of the army and of the militia in actual service, including rules for the government of courts-martial, the existing regulations (those of 1863) to remain in force until Congress should have acted on such report.

It was said by the Court of Claims, and repeated by Attorney-General Brewster, that under the act of 1866 a report of a code of regulations for the government of the army was made but not acted on. This was evidently a mistake. A system of regulations was prepared by a board consisting of Generals Sherman, Sheridan and Augur, but it does not appear to have been submitted to Congress. A revision of the articles of war was reported, but not, it would seem, a code of regulations.

The act of 1866 was construed by the Court of Claims, the Attorney-General, the second comptroller, and Secretary of War Belknap, to have had the effect of an adoption by Congress of the regulations of 1863, but there has been little agreement as to how long the regulations so adopted remained in force. The legislation has sometimes been regarded as repealed by the repeal provisions (section 5596) of the Revised Statutes, if not already superseded by the act of 15 July 1870, which again provided for the preparation of a system of regulations, to be reported to Congress "at its next session." It has also been held that the regulations of 1863 remained in force, by virtue of the legislation of 1866, until superseded by the regulations of 1881, issued under the act of 23 July 1879, authorizing the Secretary of War to cause all the regulations of the army and general orders then in force to be codified and published. And they have been treated as in force subsequently to this.

After this no revision of the regulations appears to have been undertaken until December 1888, when a board was appointed "for the purpose of revising and condensing the regulations of the army and preparing a new edition of the same." The work of this board finally took the form of the regulations of 1889.

The general regulations, with their accompaniment of manuals, may be regarded as forming the regulations of 1895. One of these manuals—the Manual for Courts-Martial—was not, indeed, a staff manual at all, but is a general system of rules for the administration of military justice. It was the first of its kind promulgated by the War Department, and was an outgrowth and enlargement of the directions on the subject which it was formerly the practice to issue from the headquarters of military departments. Regulations, approved by the Secretary of War, had, however, before this been issued by several of the staff departments for their own government.

The regulations for the United States Military Academy also emanate from the President's constitutional power. There can be no doubt, however, that, within limits, the superintendent of the United States Military Academy, the same as any officer in control of a public institution peopled with persons whose good conduct is entrusted to his charge, may also lay

down rules or regulations. He does, in fact, exercise this power in issuing certain orders. A distinction has, indeed, been made between regulations and orders, but it cannot be said that there is any essential difference between regulations and general orders laying down general rules of action.

As a good illustration of this power, as vested in superintendents of institutions of this character, we may take the various soldiers' homes. For these, certain regulations are prescribed by statute, and others by their boards of managers, necessarily, however, leaving a very considerable residue of matters, principally relating to discipline, to be regulated by the superintendents of the institutions. It may, of course, sometimes be difficult to decide what the limit of the power is, but that the power exists seems clear. Without it, public institutions of this kind could not be controlled, and, therefore, could not be managed for the purpose for which they are established.

Commanding officers of military posts have this power in a marked degree—limited, it is true, in their cases, by statute and regulation of higher authority; but, subject to these, having a distinct, necessary and unquestioned jurisdiction. In this case, however, as also in the case of the superintendent of the Military Academy, the power is a part of an independent military system. But it is the same kind of power that is exercised by the school-teacher in the maintenance of the discipline of his school.

The army regulations issued 15 Nov. 1913, in 80 articles and 1,573 paragraphs, are endorsed as follows by the Secretary of War: "The President of the United States directs that these regulations for the army be published for the government of all concerned, and that they be strictly observed. Nothing contrary to the tenor of these regulations will be enjoined in any part of the forces of the United States by any commander whomsoever."

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMY RESERVE. The regular army reserve, established in 1916, in the United States consists of men not over 45 years of age, physically qualified, who enlist for four years. The President is authorized to assign members of the army reserve as reserves to particular organizations of the army, or to organize the reserve, or any part thereof, into units or detachments as he may prescribe, and to assign to such units and detachments officers of the regular army or of the officers' reserve corps; and he may summon the regular army reserve or any part thereof for field training for not exceeding 15 days in each year, reservists to receive travel expenses and pay at rate of their grades; and in event of actual or threatened hostilities he may mobilize the reserve, and thereafter retain it, or any part thereof, in active service for such period as he may determine conditions demand. All enlistments in the regular army, including those in the reserve, in force on date of outbreak of war, continue in force for one year, unless sooner terminated by order of the Secretary of War. Subject to such regulations as the President may prescribe for proper identification, location and physical condition, members of the

army reserve shall be paid semi-annually at the rate of \$24 a year while in the reserve.

When mobilized the reserve, while in active service, receives pay and allowances of enlisted men of like grades, including additional pay provided for second enlistments. Upon reporting for duty, and being found physically fit, members of the reserve receive \$3 per month for each month they shall have belonged to the reserve, as well as actual necessary cost of transportation and subsistence from their homes to places where they are summoned to report for duty. Service in the reserve confers no rights to retirement or retired pay. Title to pension is attained only through disability incurred on active duty.

The law contemplates that the President may cause reservists to be organized at all times in the manner indicated and that, in the discretion of the President, they may be attached, as such, to organizations of the regular army that are at maximum strength, but when so attached, they are not constituent parts of such organizations and form no part of the numbers authorized by law for such organizations.

ARMY SCHOOL OF THE LINE. See **ARMY SCHOOLS.**

ARMY SCHOOLS. New inventions and rapid progress in the development of materials cause radical changes in the methods of making war. It is necessary to have post-graduate instruction in many forms to keep pace with modern improvements. The American military educational system now comprises: The United States Military Academy; the Army War College; the Army Staff College; the Army School of the Line; the Coast Artillery School; the Engineer School; the Mounted Service School; the Army Medical School; the Army Signal School; the Army Field Engineer School; the Army Field School for Medical Officers; the School of Musketry; and the Field Artillery School of Fire. There are also schools for training bakers and cooks for the army. The educational scheme contemplates that beginning his career in the garrison school, every officer shall fit himself thoroughly for the duties of his grade while advancing to the Army School of the Line, the Army Staff College and the Army War College; and in this way it is expected that the nation will eventually have at its disposal a highly trained body of officers.

United States Military Academy.—This school was established in 1802 and designed for the practical and theoretical training of cadets for the military service. Upon completing its course satisfactorily, cadets are eligible for promotion and commission as second lieutenants in any arm or corps of the army, the duties of which they have been judged competent to perform. The supervision and charge of the academy are in the War Department under such officer or officers as the Secretary of War may assign to that duty. In conformity with the provisions of section 1331, Revised Statutes, the chief of staff is, by direction of the Secretary, charged with the supervision of matters in the War Department pertaining to the academy. See **UNITED STATES MILITARY ACADEMY.**

Army War College.—This institution at Washington, D. C., was formerly established

by General Orders 155, 27 Nov. 1901. This order provided for the executive head of the college to be an officer not below the grade of field officer, and for a War College Board to prepare regulations for the government of the college, etc. The objects of the War College are: (a) The direction and co-ordination of military education in the army and in civil schools and colleges at which officers of the army are detailed under acts of Congress and the extension of opportunities for investigation and study in the militia of the United States. (b) To provide facilities for and to promote advanced study of military subjects and to formulate the opinions of the college body on the subjects studied for the information of the chief of staff. The personnel of the Army War College is in part permanent and in part temporary. The permanent personnel consists of a president, to be assigned to that duty by the Secretary of War, and the officers for the time being of the second section, War Department General Staff. Two directors and a secretary of the college are selected from the permanent personnel of the section.

Army Staff College.—The object of this college is to train the selected graduates of the Army School of the Line for the more important staff duties with large commands in time of war. The assistant commandant of the Army Service Schools is the director of the Army Staff College. Selections of student officers are made as follows: (a) They are detailed annually, by the War Department, from the highest graduates of the latest class of the Army School of the Line who receive the recommendation of the academic board, approved by the commandant, and who desire to take the course: provided that an officer once detailed to the Army Staff College, and through sickness or War Department orders, is prevented from completing the course, may be redetailed as a member of a succeeding class, upon the recommendation of the academic board, approved by the commandant. (b) With the exceptions noted under (c) no officer of the army is detailed for instruction in the Army Staff College who has not been graduated at the Army School of the Line with a standing as high as No. 18, exclusive of militia officers, and no militia officer is eligible for admission to the college unless he has been graduated at the Army School of the Line with a percentage as high as that of the regular officer lowest in class standing who has qualified in accordance with the foregoing. No officer is detailed for instruction in the Army Staff College without the recommendation of the academic board, approved by the commandant. (c) In addition to the students who become eligible under (a) and (b) there may be detailed annually by the War Department, upon the recommendation of the academic board, approved by the commandant, not to exceed two graduates of the Army Field Engineer School, who may so desire, to receive instruction in the Army Staff College. To become eligible for such detail, graduates of the Army Field Engineer School must attain a percentage in the course in military art as high as the student officer graduating No. 18 in that course of the Army School of the Line.

The course of study is embraced in four

departments, as follows: (1) The department of military art; (2) The department of military engineering; (3) The department of military law; (4) The department of languages.

Army School of the Line.—The object of this school is the instruction of specially selected officers from the line of the army in the proper methods to be employed in the leading and care of troops in time of war, and their training in time of peace. The assistant commandant of the Army Service Schools is the director of the Army School of the Line. Selections of student officers are made as follows: (a) One officer of grade not lower than that of captain and of not less than five years' commissioned service from each regiment of cavalry, field artillery, and infantry serving within the limits of North America and the Hawaiian Islands, and such other officers as are hereinafter specified. Officers are not detailed from regiments in service, or about to serve in the Philippine Islands, but in lieu thereof additional officers may be detailed from regiments of the same arm which have most recently returned, or are about to return, from Philippine service to home stations; but not more than five officers are detailed from the field artillery for any one class. (b) The commanding officer of each regiment of cavalry, field artillery and infantry serving within the limits of North America and the Hawaiian Islands submit directly to the adjutant general of the army, not later than 1 January of each year, the names of two officers (one as principal and the other as alternate) recommended for instruction at the school. From the officers thus recommended selections are made by the Secretary of War. (c) In a similar manner, the chief signal officer of the army may annually recommend one permanent officer of his corps, with the same limitations as to grade and length of service. The course of study is embraced in three departments, as follows: (1) The department of military art; (2) The department of military engineering; (3) The department of military law.

For Coast Artillery School, School of Fire for Field Artillery, School of Musketry, School for Bakers and Cooks, Post schools for the instruction of enlisted men, Garrison schools for the instruction of officers in subjects pertaining to the performance of their ordinary duties and the military departments of civil institutions at which officers of the army are detailed under the provisions of law, see MILITARY EDUCATION.

Army Field Engineer School.—The object of this school is (1) the instruction of officers of the corps of engineers and of engineer officers of the organized militia in their military duties; (2) To furnish such instruction in military engineering as the schedules of the other schools comprising the Army Service School may call for. There is detailed a field officer of the corps of engineers to report to the commandant of the Army Service Schools for duty as director of the Army Field Engineer School. Selections of student officers will be made as follows: (a) The chief of engineers may submit to the adjutant-general of the army, not later than 1 January of each year, the names of not less

than 2 nor more than 10 officers of the corps of engineers, of grade not below that of captain, for instruction in the school. (b) There may also be detailed such engineer officers of the organized militia as may apply for entrance, subject to certain provisions. The course of study is embraced in two departments, as follows: (1) The department of military engineering, (2) The department of military art.

Army Field Service School for Medical Officers.—This school consists of two parts: (1) The Field Service School for Medical Officers, at which attendance in person for the pursuance of a graded course of study is required; (2) The Correspondence School, wherein answers and solutions to such questions and problems as may be sent to designated medical officers, at their posts or stations, are required. Its object is in the Field Service School: (a) To instruct officers of the medical corps and medical officers of the organized militia in their duties as administrative and staff officers on field service, and to make research into such subjects as may concern medical officers under field conditions. (b) To give such technical instruction to students in the other schools as the schedules of those schools, approved by the commandant, may call for. In the Correspondence School: (c) To afford opportunity for such wider elementary instruction in the methods and purposes of military plans and movements as will enable medical officers of the regular army better to fulfil their duties in the field; and to prepare them to participate to better advantage as students in actual attendance at the Field Service School for Medical Officers. There is detailed a field officer of the medical corps to report to the commandant of the Army Schools for duty as director of the Army Field Service and Correspondence School for Medical Officers. The course of study is conducted under the School for Medical Officers and covers a period of not less than six weeks between 1 April and 15 May of each year. Selection of student officers is made as follows: (a) The surgeon-general will submit to the adjutant-general of the army not later than 1 January of each year the names of not less than four nor more than eight officers of the medical corps whom he recommends for Medical officers of the organized militia who may apply for entrance and whose admission detail for construction in this school. (b) may receive the approval of the Secretary of War, not to exceed a total of six in any one session, may also be detailed for instruction in the school subject to certain provisions. The course of study is conducted under the Field Service School for Medical Officers, the Army Staff College and the Army Field Engineer School. Its details are prepared by the director of the Army Field Service and Correspondence School for Medical Officers, in co-operation with the directors of the Army Staff College and the Army Field Engineer School subject to the approval of the commandant.

Army Signal School.—The object of this school is: (1) To prepare officers of the signal corps for the better performance of the duties of their profession, to provide instruction in signal duties for such officers of the line as may be designated therefor, and to make re-

search and practical experiments in such subjects as relate to the duties of the signal corps. (2) To supplement the instruction given in the Army School of the Line and the Army Staff College along the special technical lines of the signal corps, as called for by the schedules of the latter schools, having especially in view the relation of the signal corps to the whole army and the function it fulfils in time of war. There is detailed a field officer of the signal corps to report to the commandant of the Army Service Schools for duty as director of the Army Signal School. Selections of student officers are made as follows: (a) The chief signal officer of the army may submit to the adjutant-general of the army, not later than 1 January of each year, the names of not less than two nor more than five officers holding permanent appointments in the signal corps for instruction in the school. (b) Also there may be detailed such officers of the rank of captain or first lieutenant from the army at large as may make application to the adjutant-general of the army and receive the recommendation of the commandant of the Army Service Schools, provided that the total number of officers detailed under (a) and (b), exclusive of militia officers, shall not exceed 15; also such signal officers of the organized militia as may apply for entrance, subject to certain provisions. The course of study is embraced in three departments, as follows: (1) The department of signal engineering; (2) The department of topographs; (3) The department of languages.

The whole scheme of the army schools results from a fixed policy, the object of which is to make the army as perfect as possible, not only in the performance of its own duties, but in its capacity as instructor for the hundreds of thousands of citizen soldiers necessary in any war of magnitude. See MILITARY EDUCATION.

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMY SERVICE CORPS, in the British army, is the commissariat and transport department. The corps is organized in 51 horse transport companies, 18 mechanical transport companies, 5 supply companies, and 4 remount companies. The transport companies are stationed at the various large garrisons at home and in the colonies, and all the transport services required by the troops are carried out either by these companies or by civilian transport hired from local contractors and carried out under the supervision of army corps officers. In large stations like Aldershot, where there are huge army abattoirs and bakeries, not only is the food issued, but it is actually prepared by the army service corps. The mechanical transport companies are a modern creation; they utilize three grades of motors—heavy, medium and light—drawing from one to five 4-ton trucks. The remount companies have the care of the young horses at the government depôts, and are mainly composed of men transferred from the artillery and cavalry. For active service the A.S.C. units are formed into "trains" and "supply columns," one column being attached to each division (infantry or cavalry), each brigade and each field army. The field bakery attached to each divisional train and supply column is

capable of baking bread for 26,000 men. The strain thrown upon the A.S.C. in war time is enormous. By day and night a never-ending procession of A.S.C. trucks plough along the roads and through the mud behind the firing line, often traveling great distances from the base to carry food, clothing, munitions, medicaments and innumerable other items roughly classified as "stores" to the men on the battlefield. His Royal Highness, the Duke of Connaught, is colonel of the corps.

ARMY SERVICE SCHOOLS. In addition to the Military Academy at West Point, which trains candidates for commissions in the army, certain schools are maintained for the instruction of selected officers and men in their duties after they have been admitted to the service. These are the Army War College at Washington, D. C.; the Army Staff College at Fort Leavenworth, Kan.; the Coast Artillery School at Fort Monroe, Va.; the Engineer School at Washington Barracks, D. C.; the Mounted Service School at Fort Riley, Kan.; the Army Medical School (q.v.) at Washington, D. C.; the Army Signal School at Fort Leavenworth, Kan.; the Schools for Bakers and Cooks at Washington Barracks, D. C.; the Presidio of Monterey, Cal.; Fort Sam Houston, Tex.; Fort Shafter, Hawaii; Fort Riley, Kan.; Fort William McKinley, P. I.; the Army Field Service and Correspondence School for Medical Officers, Fort Leavenworth, Kan.; the School of Fire for Field Artillery, Fort Sill, Okla.; the School of Musketry, Fort Sill, Okla.; the Signal Corps Aviation Schools at San Diego, Cal.; Mineola, New York; and near Chicago, Ill.; the United States Army Balloon School at Fort Omaha, Neb.; and the Ordnance School of Application, Sandy Hook Proving Ground, N. J. Certain of these schools are not under the command of the commander of the department in which they are situated, except in matters concerning courts-martial. Many of them have special details of enlisted men attached to them permanently. See also ARMY SCHOOLS.

ARMY SIGNAL SCHOOL. See ARMY SCHOOLS.

ARMY SIGNAL TROUPS. See MILITARY SIGNALLING AND TELEGRAPHING.

ARMY STAFF COLLEGE. See ARMY SCHOOLS.

ARMY STAFFS. The general commanding a large body of troops must have assistants to generally supervise the fighting forces under his command. These assistants form his "staff." To a certain extent, an arbitrary rule decides what portion of the latter is designated as "general staff." In some armies all the staff belongs to the general staff, but a necessity has universally been felt of having a distinct portion of the staff entrusted with planning and carrying out the movements of armies in the field, and generally distinguished by some special name.

The enormous numerical strength of modern armies, and the way they must be organized to meet the constantly changing requirements of war, render an immense amount of detail necessary in carrying out military operations even under apparently similar circumstances of time and place. Thus the higher leaders and com-

manders necessarily require the permanent support of specially selected and trained officers. But there is another case in which this necessity of assistance is felt, and which is more intimately connected with the handling of troops in action, viz., the reconnaissance of the ground and of the positions and movements of the enemy, and the observation of the state of affairs in an engagement, at a point removed from the personal observation of the general commanding.

It is now considered part of the duty of the general staff to be invariably watching over the military efficiency and material welfare of the troops. On every large staff all branches of the service are represented by certain individuals or heads of departments, and it is naturally their duty, in the first place, to see to the proper efficiency of their respective branches or departments; but being often ignorant of the general military situation, or not rightly understanding sudden changes in the state of affairs, they are unable to carry out what is expected from them. The general staff is consequently called upon to act as a directing and explaining body toward these individuals by keeping itself in constant communication with them, the chief of the general staff being at the same time regarded, in a general way, as head of the whole staff.

Officers of the general staff are invested with no military command. But even without having any command they can make themselves extremely useful in an engagement by carrying out any special and important duties that may be entrusted to them by the general commanding, in addition to devoting themselves to their general duties. Their usefulness in this respect will be found to depend not only on their fitness and ability, but on their tact and discretion as well, in rightly appreciating the position they hold, both as regards general and troops. The conditions to fulfil this, however, are not entirely one-sided. Troops very soon find out, especially in war, whether the duties of the general staff are in good hands.

The duties of the general staff in war are: 1. Working out all arrangements necessary for quarters, precautions against surprise, movements and battle; 2. Communicating the necessary orders, either verbally or in writing, at the right time and place, and in sufficient detail; 3. Obtaining, collecting and compiling in order all information concerning the nature and the military character of the theatre of war; 4. Collecting and estimating the value of information received concerning the enemy's forces; 5. Watching over the fighting condition of the troops, and being constantly informed of their efficiency in every respect; 6. Keeping journals and diaries, drawing up reports on engagements, and collecting important materials, to afterward form a history of the war.

General staff officers have to take, as a basis for carrying out their duties in all the branches that have been assigned them, the wish and determination of the general in command, in which, however, initiative on their part is by no means excluded, but rather invited. A general staff officer cannot excuse himself for any neglect on his part on the plea that no order on the subject had been given him by his general. He should only consider himself freed from responsibility when his sug-

gestion has been declined by the general. This gives rise to no small amount of constant responsibility, which rests anything but lightly on the shoulders of the general staff in war, and which obliges it to be devoted to an untiring energy.

The "great general staff," a body of general staff officers who are not attached to any corps, is entrusted, under the immediate supervision of the chief of the general staff, with drawing up and preparing schemes for the strategical concentration of the army in certain particular directions by road and rail, with collecting and estimating the strength, etc., of the various armies, with the study of the theatres of war, and with the preparation of military maps. It is also employed in promoting military science, especially military history, and in the supervision of the training of young officers.

The general staff corps, United States army, is composed of officers detailed for service in said corps for a period of four years, unless sooner relieved, under rule of selection prescribed by the President. Upon being relieved from duty in the general staff corps, officers return to the branch of the army in which they hold permanent commissions, and except in case of emergency or in time of war are not eligible to further detail therein until they have served for two years with the branch of the army in which commissioned. This ineligibility does not apply to any officer who has been relieved prior to the expiration of four years' duty with the corps; but such officer will become ineligible as soon as he shall have completed a total of four years of said duty. While serving in the general staff corps officers may be temporarily assigned to duty with any branch of the army.

The general staff corps, under the direction of the chief of staff, is charged with the duty of investigating and reporting upon all questions affecting the efficiency of the army and its state of preparation for military operations, and to this end considers and reports upon all questions relating to organization, distribution, equipment, armament and training of the military forces, proposed legislative enactments and general and special regulations affecting the army, transportation, communications, quarters and supplies; prepares projects for manœuvres; revises estimates for appropriations for the support of the army and advises as to disbursement of such appropriations; exercises supervision over inspections, military education and instruction, examinations for the appointment and promotion of officers, efficiency records, details and assignments, and all orders and instructions originating in the course of administration in any branch of the service which have relation to the efficiency of the military forces; prepares important orders and correspondence embodying the orders and instructions of the President and Secretary of War to the army; reviews the reports of examining and retiring boards, and acts upon such other matters as the Secretary of War may determine.

The general staff corps, under like direction, is further charged with the duty of preparing plans for the national defense and for the mobilization of the military forces (including the assignment to armies, corps, divisions and other headquarters of the necessary quota of

general staff and other staff officers), and incident thereto with the study of possible theatres of war and of strategic questions in general; with the collection of military information; the preparation of plans of campaign, of reports of campaigns, battles, engagements and expeditions, and of technical histories of military operations of the United States.

EDWARD S. FARROW,
Consulting Civil and Military Engineer.

ARMY TERRITORIALE. As soon as the men complete nine years service in the French army, and reserve, they are transferred for five years to the army territoriale, and after its expiration are transferred for six years to the reserve of the army territoriale, when their liability to military duty ceases. The army territoriale embraces troops of all arms and is organized substantially on the same basis as the regular army.

ARMY TRANSPORT SERVICE. At the outbreak of the war with Spain the water transportation in the possession of the United States consisted of a few small tugs, ferry-boats and launches. Suddenly confronted with the necessity of dispatching armies across the sea, it is not surprising that some confusion and delay were encountered in selecting, chartering and assembling fleets capable of transporting troops, with their guns, animals and impedimenta, to Cuba, Porto Rico and the Philippine Islands. To convert the vessels composing the several fleets from ordinary freight-ships into commodious and comfortable troop-transports required time and much outlay. The arrangement of sleeping accommodations for the men, stalls for the animals, increased water-supply and ventilation involved a practical reconstruction of the interior of every vessel. It was particularly necessary to have those vessels destined for the Philippines made safe and comfortable, for it was anticipated that the troops might pass direct from the decks to the battle-field. Hospital ships were fitted out as quickly as possible and served a useful purpose during the time of greatest need.

It was apparent at the outset that the problem of water transportation required careful and continuous study, and immediately after the surrender of Santiago de Cuba a division of transportation was created by the Secretary of War and charged with supervision and control of all rail and water transportation; with the inspection of ships with reference to charter or purchase for use as transports, and with the arrangements for sending troops by rail to and from the various ports. When it became apparent that vessels would be required for a prolonged period, and that it was a very expensive proceeding to alter chartered vessels, the department began to purchase such ships as seemed best adapted to use as transports. Aside from the mere act of affording a passage to troops across the sea, the question of furnishing them supplies after landing involved many intricate problems, each requiring a special solution. American troops submit cheerfully to any amount of necessary hardships, but consider themselves entitled to the best of everything, regardless of cost, when the emergency has passed. For supplying their needs, it was necessary to construct refrigerator com-

partments in the transports to carry fresh beef and other perishable stores to the most remote and hitherto little known islands of our new possessions.

During the first few months of the heavy demands for transportation, the quartermaster's department was much hampered because vessels of foreign register could not be employed for the service and Congress refused to grant American register to such vessels. Nevertheless, by 1 July 1898, 43 chartered vessels had been secured and fitted up for the transportation of troops, animals and supplies. The difficulties and expense attendant upon securing efficient service with chartered vessels led to the gradual substitution of transports purchased by the government and permanently fitted up as troopships. The largest and best transports averaged nearly 6,000 tons capacity; and when, after some practical experience, a general plan of fitting up had been adopted, the transport service became a prominent feature of army administration, and attracted the attention and admiration of the civilized world. The urgency of the situation on the Pacific compelled a continuance of the charter system; but a fleet of government transports was gradually put in commission on the Atlantic, and as soon as the withdrawal of the volunteer army from Cuba permitted, many of the transports were sent to Manila by way of the Suez Canal and put on the San Francisco-Manila route. The *Grant*, *Sherman* and *Sheridan* were the first vessels fitted out for this service, and their sailing from New York for Manila marked a new era in the occupation of the Philippines. The character of these transports may be comprehended by the statement that the *Grant* sailed from New York on 19 Jan. 1899, with the 4th United States infantry and one battalion of the 17th United States infantry, with a total strength of 50 officers and 1,703 enlisted men. The *Sherman* sailed on 2 February with the 3d United States infantry and one battalion of the 17th United States infantry, with a passenger list of 1,812 persons, followed by the *Sheridan* on 19 February with the 12th United States infantry and the 3d battalion, 17th infantry, with a total passenger list of 2,017 persons. These vessels made the long voyage to Manila with such success and comfort that the regiments were enabled to enter immediately upon active service. The experience of these voyages dictated some valuable suggestions, which were availed of at once in making desirable changes to perfect the transport service generally.

The large number of troops remaining in Cuba and Porto Rico after the return of the main body of regulars and volunteers necessitated the establishment of a regular line with weekly sailing dates. Advantage was taken of the regular steamship lines as far as possible for the larger movement of returning troops. The transportation to Spain of the Spanish prisoners was accomplished under contract, in accordance with stipulations under which the surrender of Santiago took place. More than 22,000 Spanish prisoners were thus returned from the eastern end of Cuba to Spain within 60 days of their surrender, in an economical and apparently satisfactory manner.

The outbreak of the insurrection in the Philippines made it necessary to hasten relief to the

volunteer regiments still held in those islands, and the presence there of the old Spanish garrisons which, under the terms of the treaty of peace, were entitled to repatriation, made it desirable that they should be returned to Spain without delay. The transport service was strained to the utmost limit, but fulfilled its part in the most gratifying manner. During its first year of existence a total of 202,587 passengers were transported across the seas by army transports without responsibility for the loss of a single life.

The question of transportation of animals was one requiring much study and experiment, for there was little experience available to guide the department in a solution of the problem of landing cavalry horses in fit condition for service after a voyage of 7,000 miles. Some discouraging losses of mules occurred at a critical moment in the campaign against the insurgents, but gradually the system was perfected and the loss of animals actually reduced below the percentage of loss from injury and disease which should be expected in the herds on shore. Nearly 20,000 animals were transported during the year ending 30 June 1901.

At a time when every effort was being put forth to meet the requirements of the military situation Porto Rico was devastated by a hurricane, and the transport service was called upon to distribute relief stores to the unfortunate inhabitants who, just released from the worries of war, found themselves threatened with famine and pestilence.

As conditions in the Philippines gradually settled down to a guerilla warfare the troops were distributed at about 400 stations, necessitating an inter-island transport service. Just as everything was becoming adjusted to the new conditions which followed the dispersal of Aguinaldo's army the unfortunate "Boxer" outbreak took place in China. The experience already obtained enabled the department to handle the transportation question in such a way as to win the admiration of all the foreign contingent composing the Chinese relief expedition which finally entered the sacred city of Peking.

Following the signing of the treaty of peace with Spain it was necessary to maintain a considerable force in Cuba during the period required to establish the new government of the island upon a reasonably stable basis. Spain had for many years garrisoned the island with a force several times as large as the entire United States army. Affairs gradually assumed a normal condition and on 30 June 1901 the transport service between the United States and the islands of Cuba and Porto Rico was discontinued.

Under the American volunteer system the men were enlisted for the war with Spain under contracts calling for two years' service or during the war. With the signing of the treaty of peace it had been necessary for Congress to authorize the enlistment of 35,000 volunteers to assist the regular army in putting down the insurrection in the Philippines and permit of the discharge of those who had enlisted for the war with Spain. In its refusal to increase the regular army and its substitution of a force of volunteers whose enlistments should not extend beyond 1 July 1901, Congress found itself confronted again with

the necessity for keeping faith with the 35,000 volunteers, and arrangements were made to transport them home before their enlistments should expire.

The records show that more than 500,000 passengers had been safely transported across the seas, in some instances as much as 11,000 miles upon single voyages, without the loss of a passenger due to the transport service.

Following the discharge of the volunteers and a reorganization of the regular army in 1901, the number of transports was reduced by disposing of the least efficient in respect to carrying capacity and economy of operation. The vessels retained in service represented the finest types of transports then in the service of any nation. They contained all the improvements suggested by several years of extended experience and were of the tonnage deemed most economical for the peculiar service required. Until very recently when Congress authorized utilization of space for non-military freight from the congested ports of the Philippines, there was little cargo on the homeward run. The space was usually utilized for coal from Nagasaki where the cheapest fuel on the Pacific shores is available. The question of fuel supply for American ships in the Pacific is a very serious one and will not be solved until the coal fields of Alaska become available. Vessels of American register are handicapped in several ways in their competition with Japanese ships and cheaper fuel than heretofore available on our Pacific coast is a maritime necessity.

The second occupation of Cuba required the restoration of the service in the Atlantic which was continued until the final evacuation of that island by American troops during the spring of 1909, concerning which the quartermaster-general reported: "The movement was made without delay or casualty and the troops arrived at their final stations in the United States in good condition. The dispatch and ease with which this movement was accomplished, without instructions from this office other than general directions for operations under the decentralization system, show conclusively the thorough efficiency with which field operations may be conducted according to that method."

Upon conclusion of this movement the small fleet of Atlantic transports was again withdrawn from service and the vessels laid up at Newport News, Va., where they remained until the conditions in Mexico brought about the concentration of the second division of the army at Galveston and Texas City with a view to meeting any emergencies. The transports were speedily put in commission and assembled in the harbor of Galveston where they remained until their services were demanded for the movement of troops to Vera Cruz, and then to maintain their connection with the base of supplies. During the continuance of the revolution in Mexico transports have been used to bring home American citizens from both Atlantic and Pacific coast ports. With the withdrawal of troops from Vera Cruz the Atlantic transports were again ordered out of commission to await the next of the recurring calls for over-sea service to which the American army has been so frequently summoned since the war

with Spain pushed the frontier of our altruistic and trade interests beyond our territorial borders.

The Pacific transports have continued a monthly schedule of sailings between San Francisco, Honolulu, Guam and Manila. Guam is maintained as a naval station and the only regular communication is by the monthly transport going to Manila. On the homeward-bound voyage the transports sail via Nagasaki and take on coal. From Nagasaki the voyage continues direct to Honolulu and San Francisco, passengers from Guam for the United States being compelled to make the long detours. The traffic has materially increased since the garrisons of Oahu and Guam have been enlarged, and averages over 2,000 passengers per month.

The Pacific fleet has continued the transportation of horses and mules on a special horse transport which has been a pronounced success from the beginning. The delivery of animals in condition for immediate service after voyages of upward of 7,000 miles continues to elicit the admiration of the army. The laying of cables has been not the least important work of the transport service in the Philippines and Alaska. A very large and seemingly growing amount of passengers and freight has been carried for the navy and civil governments of the several island dependencies. Without the accommodations afforded by the transports it would be impossible for the families of civil, military and naval officers and soldiers to follow them across the seas. The inter-island service in the Philippines has covered an enormous number of voyages since the occupation of those outposts began, and now the needs of the garrison at Tientsin, China, are supplied by those vessels having Manila for a base.

When the success of the transport service had become widely known the propriety of its continuance in competition with commercial liners was frequently under discussion and attracted the attention of Congress. The matter was settled in favor of the continuance of the transports by the enactment of legislation at the session of 1902-03, providing that the service should not be abandoned without the consent of Congress.

WILLIAM HARDING CARTER,

Major-General, United States Army.

ARMY TRANSPORTATION. The European War has made a radical change in the systems of army transportation. Both strategy and tactics have been affected by motor transport. The strategical mobility of troops has been increased, and they have been rendered less dependent upon lines of communication. The increased size of armies engaging in warfare make necessary the more rapid concentration of superior forces. While armies are being mobilized, concentrated and engaged in warfare, they must be fed, clothed and furnished with ammunition. The development of railroads has had a decided effect toward making possible the rapid mobilization and concentration of armies; but, as the locomotive is tied to the rails, it necessarily follows that it cannot always move immediately with the army. So exorbitant is the demand on the sources of supply for draft animals in any modern war that the question of mechanical

transportation has become one of great military interest, and no military man will deny the fact that the army which can mobilize and concentrate most quickly, and can most rapidly advance after concentration, will have a decided advantage over its opponent.

It is also true that the expense of carrying on a modern war is so great that no nation can neglect to take advantage of every means that will have a tendency to shorten the war and bring about a decisive conclusion. Troops must be fed and it is hardly possible that in any theatre of war in the future sufficient subsistence for hundreds of thousands of troops can be secured by means of forced contributions. Especially will this be true of the advancing army which will have to traverse the territory over which the retiring army has already passed, and which it has already devastated. The immense amount of ammunition expended in modern battles makes its supply more important and difficult. The use of heavy artillery is absolutely necessary, and the transportation of this class of artillery and the ammunition for it adds another difficulty and materially increases the demands on the transportation of an army. The extensive frontage of 50 to 100 miles occupied by large modern armies in the field makes more difficult the distribution of supplies to the smaller units. These and other considerations make it more imperative that no practical means be neglected whereby an army may more quickly and efficiently supply its parts and reduce the necessity for draft animals.

With the development of firearms has come an increase in the distance that must be observed between the parts or elements of a column on the march. With the increased size of armies has also come the necessity for the utilization of more roads in an advance or retreat, as the principle still holds that only about 30,000 men may use the same road on the same day for the purposes of a march; and thus is increased the frontage of an army on the march. This has brought about the necessity for a more effective means of communication between the parts of a column and between the different columns. As the commander of an army will often be separated from some parts of his army by a distance of 40 or 50 miles, his personal observation of the conditions existing at the front are absolutely prevented unless he employs some more effective means of travel than that furnished by the horse. The signal troops, with telephone and telegraph, have supplied the means of communicating; but even these sometimes fail, and, at most, they do not furnish to the commander of the army that detailed information and that understanding of the situation which he can get from a personal observation.

Animal Transportation.—Motor vehicles deteriorate rapidly under the service demanded in war and are very vulnerable to missiles. Beyond their limited sphere of utility, other facilities for transportation must be provided. On good roads and for long drives, the motor truck is very satisfactory. On bad roads and for short hauls, horse power is more economical and much more satisfactory. The latter must, therefore, still supply the principal means of transportation over muddy roads and ploughed fields, across streams and ditches and

up steep slopes. Experiments conducted at the University of Wisconsin have indicated that, due to the intelligence with which the horse applies his motive force, and to the flexible qualities of the latter, the efficiency of the horse as a traction agent is much higher than the horse power developed would alone indicate.

The heavy purchases of horses made by the European belligerents show clearly that experience in the field caused a renewed recognition of the important place of the horse in the work of war. The best estimates indicate that there were purchased in the United States alone, for use in the European War, about 1,000,000 horses at an average initial price of about \$170, increased by a further cost for transportation, etc., of from \$115 to \$130. This makes the average cost of the horse, landed in Europe, from \$300 to \$315. If the millions expended for horses as above did not show sufficiently their recognized importance in the face of all competition from motor vehicles, further proof of their essential place in war is found in the greatly improved arrangements, visible in all the belligerent armies, for the care and preservation of the animals and for the prompt treatment when wounded.

Railroad Transportation.—In time of war, the railroads give life to armies, provide food, clothing, materials and munitions rapidly. They give freedom and vigor in the movement of large bodies of troops, remove sick and wounded rapidly, deliver reinforcements promptly. In fact, the railroad is indispensable in utilizing a nation's forces to their greatest capacity and with the maximum effect.

Germany has a highly developed and brilliantly organized military railroad service. They had on hand in 1914 at the outbreak of hostilities all material and rolling stock necessary for the transportation and concentration of men, animals and materials. Tables for the dispatch and conduct of trains were all ready. The system for handling sick, wounded and prisoners was carefully worked out. The principal reason for the superiority of the Germans over their adversaries was that their railroad systems were perfectly organized, allowing them to mobilize much more rapidly and giving them greater mobility in operations. It might almost be said that their plans of war consisted of the judicious and intensive development of their railway systems. There are nine railroad lines, each absolutely independent of the others, operating in the province of Lorraine. Seven days was the maximum required to put all the first line troops on the frontier, and on the 10th they invaded France. On the west front, the great bases are Düsseldorf, Cologne, Coblenz, Mayence, Mannheim, Strassburg and Leopolsche. The bases on the east front are Danzig, Thorn, Posen, Ostrowa, Breslau, Myslowitz and Cracow. These great bases are linked in all their enormous extension by 800 kilometres of line separate from the nine great lines connecting the two fronts.

France had her railroad service well organized and almost all the materials and rolling stock required was on hand. The railroad service was divided into two divisions of sub-services (1) Transports over the interior system; (2) transports over the army systems. The interior system receives orders from the Minister of War and the army system receives

its orders from the commander-in-chief of the army only. To insure normal functioning of these services, "regulating stations" were established in regions of notable importance and in favorable situations. An officer of the general staff had charge of each of these stations. Having helped in the preparation of the general plans of mobilization, he had a perfect knowledge of the conditions to be met. Rapid transportation of artillery and its prompt entrance in great masses into the conflict is possible only if railway facilities exist and are used. When Paris was threatened, the French brought an entire army from the south in a few days.

Wagon Transportation.—Wagon trains are slow moving, excessively wasteful of road space and very vulnerable. The train guard must fight to save its convoy if attacked and its excessive length requires a large force to ensure its safety. A few mules dropped and the road is effectively blocked. Consider an auto train carrying the same quantity of stores. It will be about one-sixth the length of the wagon train. Its comparatively small cavalry escort, scouting well to the front and flanks, will notify it of danger in time to permit a counter-march and a retreat which will soon easily outdistance pursuit by even cavalry. A hundred shots might hit the truck without damaging the engines and a bullet-proof shield could easily be provided to protect the chauffeur. The empty wagons returning to the base are supposed to carry sick and wounded, to assist in the prompt evacuation of the field hospitals.

A brigade wagon train in service in the field will vary from 70 to 100 wagons and teams, according to the strength of the brigade, the distance from the depots or base of supplies, the character of the roads, nature of the climate or season of the year. Such a brigade train on the march, allowed to go at will, as the roads average, will take up a mile of road. For convenience of handling it, the brigade train should be divided into three parts of from 20 to 25 wagons each. These lesser divisions of the train should march slightly separated from each other. Should they have to leave the road, or halt on the march, each separate train should pull out at the same time into a field or open space, and be parked *with the mules facing the road*. In such position, all the trains can *simultaneously* pull into the road and occupy their proper space and distances without consuming time in waiting for each other. If parked with wagon tongues toward the road, the train is ready to march in either direction which necessity shall require. If the teams are parked three or four deep, that number can start simultaneously at the word.

In Europe nearly all the work of transportation from railroad is by motor. To give some idea of the extent of the transportation problem, the example of a division may be taken. This is the administrative and tactical unit and comprises 22,665 men, 4,463 horses and 2,912 mules. The daily march averages 12½ miles and the road space is 15.4 miles. The daily supplies of a division weigh 175,000 pounds. The net cargo in the supply trains of a division, exclusive of pack trains and artillery ammunition, is 2,143,000 pounds. These supplies and the regularity of renewal are essential to the well-being and morale of an army.

Lines of communication comprise the base section, where supplies are accumulated and forwarded by rail and boat; the intermediate section, comprising the transportation routes to railroad; and the advance section, where is found the great problem of the daily renewal of the supplies expended, amounting to 175,000 pounds for a division. The division supply train carries two days' food for the men and two days' forage for the animals. The division train transports supplies from the refilling point to the distributing point, whence distribution to the troops is made by the ration and field trains. On wagon transportation, capable of a daily movement of only 18 miles, a division has a very limited radius of action from railhead.

Ammunition expenditure, both artillery and small arms, is enormous, and transportation must be provided accordingly. The daily expenditure per man for small arms ammunition, formerly calculated at 240 rounds, is now calculated at 1,000 rounds per day in action. The Germans have 48 machine guns per regiment.

For efficiency in supply, proper organization must be had in the transport. In motor transport, the unit is the truck, its driver and his helper, and the best truck for general purposes appears to be the 1½-ton truck. These units must be organized into companies. Companies must be limited to the number of trucks that can be properly supervised by one man, and also to the number that can be properly served by one supply and repair truck. In addition to the supply and repair truck, arrangements must be made for shops where more extensive repairs can be made.

The most convenient and efficient division supply train is made up of two units, each comprising 60 baggage trucks, 1½ ton; three fuel supply trucks; three repair trucks; one office truck; four high-speed cars for officers; eight motorcycles. This corresponds to an organization of squads of five trucks, two squads to a section, two sections to a platoon and three platoons to a company, with a personnel of a captain, three lieutenants and 154 men.

EDWARD S. FARROW,

Consulting Civil and Military Engineer.

ARMY-WORM, the caterpillar of the moth *Leucania unipunctata*. The adult measures about one and a half inches across the expanded wings, which are dull brown, the anterior pair bearing near the centre a small white dot which has suggested the specific name. Like most moths, this species flies at night and, in seasons when they are specially abundant, are the most commonly captured insects at lights and baits of sugar or syrup, of which they are very fond. The eggs are usually concealed on herbage in fields, especially where vegetation is luxuriant, as in wheat fields. Unless checked by enemies the caterpillars quickly reach maturity, pupate a short time under ground, emerge, pair and lay eggs from which a larger brood than the first is hatched. This brood, after devouring every green thing soft enough to eat, spread destruction as they march, army-like, from the place where they were hatched to fresh feeding grounds. When full grown these larvæ pupate; some for only a short time, others until the following spring. The former lay eggs for a third brood of caterpillars which endeavor to pass the winter as
