POLK, James Knox, 11th President of the United States: b. Mecklenburg County, N. C., 2 Nov. 1795; d. Nashville, Tenn., 15 June 1849. He was of Scotch-Irish ancestry and was reared near the North Carolina frontier amid the hard, simple surroundings of plain farmers. He was graduated at the University of North Carolina in 1818 and settled in Tennessee, where he studied law under Felix Grundy, then one of the foremost public men of the West. He was admitted to the bar in 1820 and he began the practice of his profession at Columbia in middle Tennessee. Becoming a member of Congress in 1823, he at once took sides against Henry Clay and became a leader of great force. He remained in the House of Representatives 14 years, serving two terms as speaker at a time when the bitterness of the sections, as displayed in Congress, made the office one of the greatest difficulty. He was recognized as an able Jacksonian Democrat in 1840, when he was occasionally discussed as a probable candidate for the Vice-Presidency. But the evenly balanced state of politics in Tennessee and the importance of the State in national affairs caused him to become a candidate for the governorship of the State in 1839. He was elected and served two years, but was defeated in spite of all Jackson could do for him in 1841 and again in 1843. Under these rather adverse circumstances, his candidacy for the Vice-Presidency with Van Buren in 1844 was widely pressed. But the one issue which determined the nominations of that year was the proposed annexation of Texas. A group of ardent Southerners and Democrats, led by Robert J. Walker of Mississippi, was bent upon compelling Van Buren to agree to annex Texas in case he were elected. Van Buren had never been willing to make an explicit declaration of his views on the subject. He had been badly defeated for a second term in 1840, in a way which caused him and his friends to think he was entitled to a renomination in 1844. As the time for the assembling of the Democratic convention approached Senator Walker and other Southerners pressed for a declaration. Van Buren visited Jackson in April and on his return called upon Henry Clay at Lexington. On his return home late in April he gave out a public statement opposing the annexation of Texas. What made this announcement so extraordinary was the fact that on the same day Clay, then at Raleigh, N. C., made a similar public announcement. The excitement all over the South was intense. Walker and others secured the release of Southern delegates to the convention which was to meet in May from their instructions to vote for the nomination of Van Buren. In the Northwest a similar desertion of the New York leader took place. When the convention met there was great turmoil. Van Buren was, however, promptly defeated. After some manœuvring Polk was chosen as the party candidate. He was an ardent Texas man. Calhoun who was then, as always, a powerful leader in the South, supported Polk with enthusiasm and he was elected. It was one of the few cases in American history when the issue was perfectly clear and when the people understood what was to be done in the event of the success of Polk. The Democratic platform declared pointedly for the reannexation of Texas and the reoccupation of Oregon, a vast region then little known to the country but held jointly by the United States and England. Polk favored the seizure of all of Oregon, upon the giving of a year's notice of his intention to Great Britain, and it was his known opinion on this subject that secured him the hearty support of Northwestern leaders like Cass and Douglas. It was what has been called the bargain of the Baltimore convention, that is, that Southern men would support the demand for all Oregon to the southern boundary of Alaska on condition that Northwestern men would support the plan for the annexation of Texas. Polk was an avowed expansionist and he was elected upon the issue, Clay being defeated for the third and last time. George M. Dallas of Pennsylvania, a popular protectionist, was the candidate for the Vice-Presidency, notwithstanding the fact that Polk had always been known as an opponent of the principle as well as the practice of a protective tariff. In spite of the difference of opinion Polk and Dallas made an able and successful administration. James Buchanan was Secretary of State and Robert J. Walker Secretary of the Treasury. George Bancroft was also a member of this Cabinet. Clay opposed the administration most bitterly and both Webster and Calhoun, in spite of the recent friendliness of the latter, were leaders of the opposition in the Senate. Few Presidents have met with such powerful oppostion in Congress, and Van Buren, with his friends, held aloof, refusing their support at critical times. Yet Polk completed the annexation of Texas, solved the Oregon problem, but without securing all of the disputed territory, settled the long standing tariff dispute between the South and the North and established a new treasury system which continued till the outbreak of the Civil War. No other President with the exception of Wilson has placed upon the Federal statute books so many and such vital general laws. Nor was this all. Polk sought to procure by treaty certain lands claimed by Texas in the autumn of 1845 and he hoped to purchase New Mexico and California, where only a few thousand Spanish-Mexicans lived. John Slidell was sent to negotiate these delicate matters. He failed and at the same time irritated the already angry Mexicans. Meanwhile a small American army under the command of Gen. Zachary Taylor had already occupied part of the area claimed by both countries. The Mexicans attacked Taylor and war ensued. Upon the receipt of the news of victories in northern Mexico great excitement was aroused in the United States. Westerners and Southerners volunteered in great numbers. Polk pressed the war with vigor but he did not restrain army and navy men or the land hungry elements of the country from crying for the annexation of the whole of Mexico. At one time Polk himself, urged by two or three members of the Cabinet, contemplated the dismemberment of the unfortunate country. At the close of the war, not only the Texan claims but New Mexico, Arizona and California were demanded and received by the American commissioners. Polk and his group of followers were undoubtedly the most imperialistic of American leaders. The result of their policy was the annexation of about 1,000,000 square miles of fresh and valuable territory. But in the imperialistic campaign, supported by the West and the South, a part of Oregon was lost to the United States. That created ill feeling in the North toward Polk. About the same time that Polk agreed to yield to Great Britain the northern half of Oregon, he angered Northwesterners by vetoing a bill which proposed large appropriations for the improvement of harbors on the Great Lakes and for the dredging certain rivers in the same region. This was the beginning of the schism in the Democratic party for which the defeat of Van Buren in the Baltimore convention had prepared the way; Lewis Cass, a friend of Polk, could not hold his followers in line. The Wilmot proviso, a direct attack upon the President's annexationist program, was attached to important legislation and became the cause of a most bitter conflict among those who had elevated Polk to the Presidency. As the Mexican War drew to a close, Polk saw that a renomination was out of the question. He recommended the nomination of Cass by his party, but Van Buren and his friends united with the Liberty Party men and the malcontents of the Northwest to form a new party which took the name of Free Soilers. They polled votes enough to defeat Cass and the Democratic party and Polk retired chagrined if not directly defeated to his home in the spring of 1849. But his work remained. He died the following June at the capital of his State. (See MEXICO, AMERICAN DIPLOMATIC RELATIONS WITH). Consult Jenkins, J. S., 'Life of James K. Polk' (Auburn, N. Y., 1850); Tyler, L. G., 'The Times of the Tylers'; Smith, Justin H., 'The Annexation of Texas'; Reeves, Jesse S., 'The Diplomacy of Tyler and Polk'; Quaife, M. M., 'The Diary of James K. Polk' (4 vols., Chicago 1910).

WILLIAM E. DODD,
Professor of History, Chicago University.

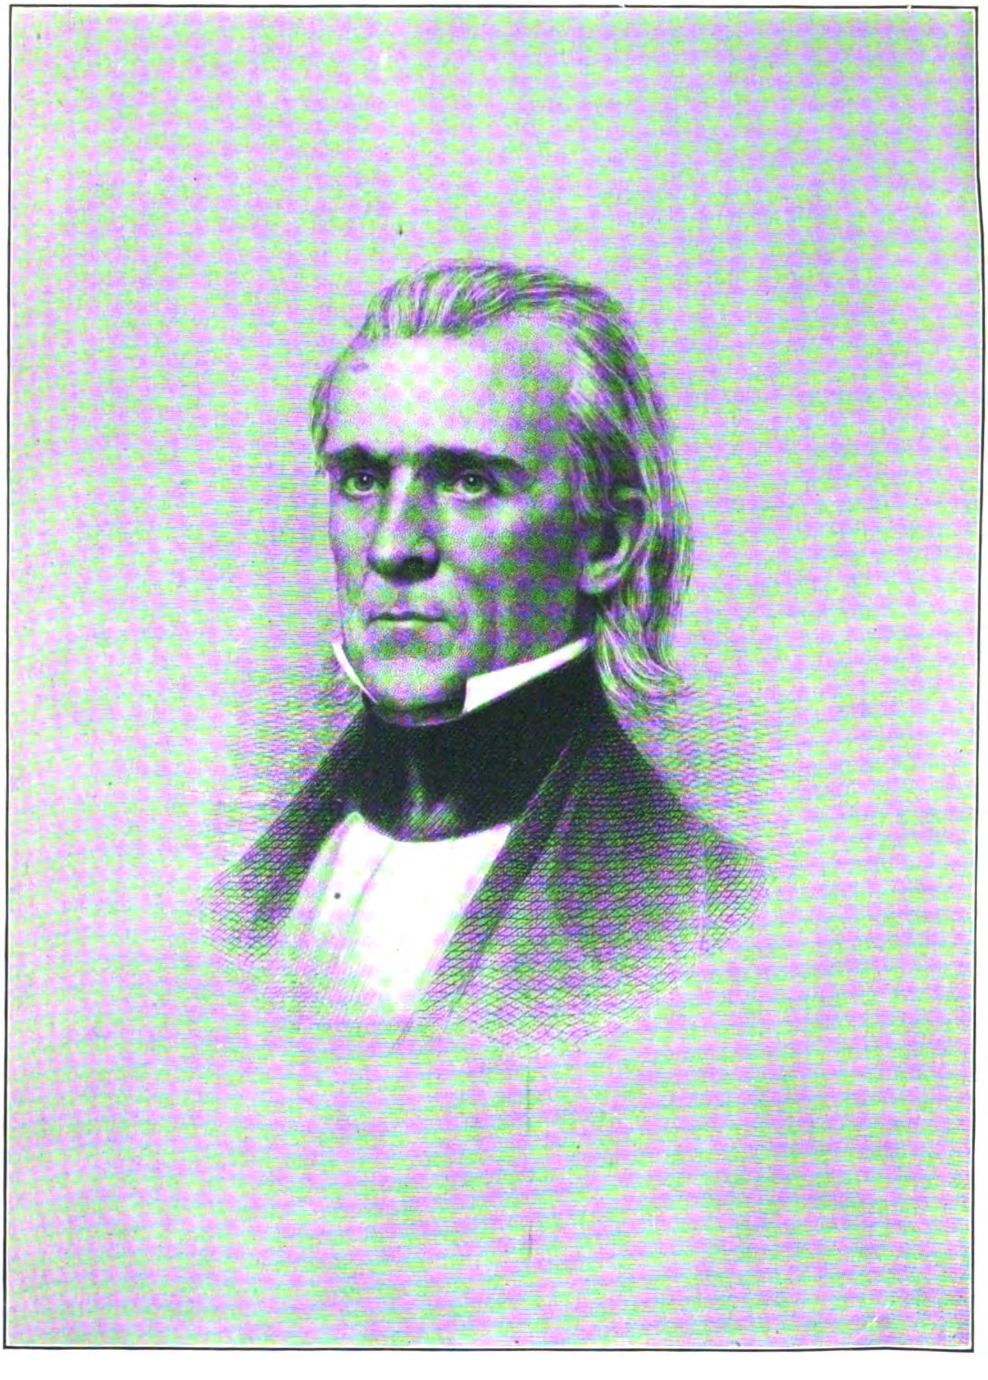
POLK, Leonidas, American general and Protestant Episcopal bishop: b. Raleigh, N. C., 10 April 1806; d. Pine Mountain, Ga., 14 June 1864. He was a cousin of President Polk (q.v.). Educated at the United States Military Academy, he subsequently studied for the ministry, and in 1831 took priest's orders in the Episcopal Church. In 1838 he was consecrated missionary bishop of the Southwest Indian Territory, Alabama, Mississippi and Louisiana. In 1841 he was appointed bishop of Louisiana, and his plan for a system of higher education in the South had its outcome in Sewanee University and the University of the South, established in 1858. He was an ardent lover of the South and soon after the outbreak of the Civil War was offered a major-generalship in the Confederate army and, accepting it, proceeded to fortify strongly strategic points on the Mississippi. At Shiloh and at Corinth he commanded the First corps; in October 1862 he was promoted to lieutenant-general, and in November conducted the retreat from Kentucky. In December 1863 he was promoted to the Department of Alabama, Mississippi and eastern Louisiana, and afterward joined Johnston in opposing Sherman's march to Atlanta. He was killed by a cannon ball while reconnoitring on Pine Mountain. Consult 'Life' by his son, W. M. Polk (1893).

POLK, William Mecklenburg, American physician, son of Leonidas Polk, the Rebel bishop: b. Ashwood, Maury County, Tenn., 15 Aug. 1844. He was graduated at the Virginia Military Institute in 1861; served in the Confederate Army under his father and rose to the rank of captain. In 1869 he was graduated at the College of Physicians and Surgeons of Columbia University, since when he has practised in New York. In 1876–79 he was professor of therapeutics at Bellevue Hospital Medical College; in 1879–98 professor of obstetrics and gynecology at New York University and since 1898 dean and professor of gynecology at Cornell University Medical College. Dr. Polk is consulting gynecologist to many hospitals in New York City.

POLKA, a dance of Bohemian or Polish origin, the name being derived from the Bohemian *pulka,* half, from the half-step that characterizes the dance, or from *Polka,* a Polish woman. Stainer and Barrett in their 'Dictionary of Music' credit the invention of the dance to Anna Slazak, a farm servant at Elbsteinitz, near Prague, about 1830. It was popularly introduced at Prague about 1835, and in 1839 was brought by a part of the musical band of the Prague sharpshooters, under the management of Pergler, to Vienna, where both the music and dance met with extraordinary acceptance. In 1840 it was received with the greatest applause at the Odéon Theatre in Paris, and was soon the favorite dance at all the public and private balls of that capital. It spread rapidly into every country of Europe, and is now common in every part of the civilized world. The music is written in two-four time, the first three quavers being generally strongly accentuated.

POLKO, pŏl'kō, **Elise Vogel,** German novelist: b. Leipzig, Germany, 31 Jan. 1822; d. Munich, 15 May 1899. She was a sister of Eduard Vogel, the African explorer, and attained considerable fame as a public singer, but retired from the stage after her marriage to Polko, a scientist, and thenceforth devoted herself to literature, in which field she won much notice. Her 'Musikalische Märchen' (1852) was translated into English, as were others of her books. She published 'Ein Frauenleben' (1854); 'Erinnerungen an Felix Mendelssohn Bartholdy' (1868); Aus dem Jahre 1870'; 'Conversations' (1872); 'Neues Märchenbuch' (1884), etc.

POLL-EVIL, a swelling followed by severe ulceration, on a horse's poll or nape of the neck, just between the ears toward the mane, which often results from a bruise, undue pressure of halter or similar injury to the flesh. As soon



JAMES K. POLK

Eleventh President of the United States

as it becomes evident that pus is forming warm poultices should be applied to hasten the process. When ripe the swelling should be lanced and kept open by a seton until thoroughly drained and clean and in condition to heal properly. Careful treatment is necessary to prevent serious injury to an animal so afflicted.

POLL-TAX. See CAPITATION; TAXATION.

POLLACK, or COALFISH, a dark green fish (*Pollachius virens*) of the cod family, a native of the Baltic, Northern and Mediterranean seas, and the name coalfish is derived from the dusky pigment which tinges the skin and which soils the fingers like moist coals. This species differs from the cod in seeking its food in shoals at the surface as well as near the bottom. In such surface excursions they pour out their spawn, which floats and quickly hatches. The flesh is highly esteemed on the British and Canadian coasts, but is not commonly known in the United States. Very similar fishes occur in the north Pacific, one of which is highly important to the Alaskan coast natives who call it beshow. All of these fishes yield a valuable liver-oil; and the eastern ones, at least, afford good sport with hook and line.

POLLAJUOLO, pŏl-lä-yoo-ō'lō, **Antonio,** Italian painter, sculptor and goldsmith: b. Florence, 1429; d. Rome, 1498. He was a pupil of Lorenzo Ghiberti and assisted him in the celebrated gates of the baptistery of San Giovanni. Chiefly known as a sculptor, his paintings, however, have a distinct place in the development of Italian art from their power in the expression of action, which quality is best exhibited in his 'Hercules Strangling Antæus' in the Uffizi, and the 'David' at Berlin. At Rome he made the monuments of Sixtus IV and of Innocent VIII. He was also a medalist and engraved several plates which are extremely scarce. His other occupations lend a certain character of hardness to his painting, which also exhibits his superior knowledge of anatomy, he being the first to study from dissection. His brother PIETRO,— b. Florence, 1443; d. there, 1496, was associated with him in all his works and did much independent painting. Pictures assigned to him are the 'Annunciation' in Berlin and a fresco of Saint Christopher in the Metropolitan Museum, New York.

POLLAJUOLO, Simone del («IL CRONACA»), Italian architect: b. Florence, 1454; d. 1509. He studied the architectural remains of antiquity at Rome for a number of years before undertaking any original work; and his constant habit of describing them to his friends, after his return to Florence, won for him the title «Il Cronaca» («The Chronicler»). His masterpiece is the cornice added to the façade of the Palazzo Strozzi, of which he had been appointed architect. He built at Florence the Palazzo Guadagni and the church of San Salvador al Monte, also the sacristy of San Spirito, the court of the Palazzo Strozzi and the great hall of the Palazzo Vecchio. He must be looked upon as one of the leading architects of the original Renaissance style in Italy. Consult Geymüller-Stegmann, 'Die Architektur der Renaissance in Toscana' (1885–96).

POLLAK, pŏl'ąk, **Gustav,** American editor: b. Vienna, 4 May 1849. After a course of study in the schools of his native city, he came to the United States in 1866, where he has devoted himself largely to editorial work. A contributor to *The Nation* from 1874, and to the New York *Evening Post* since 1881, he has written chiefly on foreign politics and literary subjects. In addition to copious work on leading encyclopedias, he has published 'The Century Book for Mothers,' in which he was joint editor with Dr. L. M. Yale; 'Franz Grillparzer and Austrian Drama'; 'The Hygiene of the Soul'; 'Michael Heilprin and His Sons'; 'International Perspective in Criticism,' and 'Fifty Years of American Idealism.'

POLLANARRUA, Ceylon, a ruined city and formerly capital of Ceylon, situated about 60 miles northeast of Kandy. There are numerous large stone figures of Buddha and remains of temples and other buildings. It flourished from the 8th to the beginning of the 13th century. It is now called Topare.

POLLARD, pŏl'ąrd, **Charles Louis,** American botanist and entomologist: b. New York, 29 March 1872. In 1893 he was graduated at Columbia University; was assistant curator of the division of botany of the United States Department of Agriculture in 1894–95, and of the United States National Museum from 1895 to 1903. From 1907 to 1913 he was curator of the Public Museum of the Staten Island Association of Arts and Sciences and from 1897 to 1913 was editor of *Plant World*. Pollard contributed many botanical terms to the Supplement to Webster's 'International Dictionary' (1900) and the 'Century Dictionary' (1903). He was the editor for botany and horticulture of Webster's 'New International Dictionary' and has written many short articles. After 1917 Pollard was special field commissioner of the Boy Scouts of America.

POLLARD, Edward Albert, American journalist and author: b. Nelson County, Va., 27 Feb. 1828; d. Lynchburg, Va., 12 Dec. 1872. He was graduated from the University of Virginia in 1849, removed to California where he engaged in journalism, and was preparing for the Episcopal ministry at the outbreak of the Civil War, throughout which he was editor of the Richmond *Examiner*. An ardent supporter of the Confederacy, he was nevertheless a bitter and active opponent of Jefferson Davis. While endeavoring to run the blockade in 1865 on his way to England he was captured and imprisoned in Fort Monroe for eight months, when he was released by General Butler. He was an able writer, but bitterly opinionated and unfair where his prejudices were concerned. Among his numerous works are 'Black Diamonds' (1859); 'Southern History of the War' (1862); 'The Lost Cause' (1866); 'The Life of Jefferson Davis' (1869).

POLLARD, Josephine, American author: b. New York City, 1842; d. there, 15 Aug. 1892. She was an editorial writer on the *Sunday School Times* from the time of its establishment in 1876, and for 20 years was connected with the Methodist Book Concern. Her books are chiefly religious works and juvenile stories. Among them are 'The Gypsy Books' (1873–74); 'A Piece of Silver' (1876); 'Decorative Sisters'

(1881); ‹Elfin Land› poems (1882); ‹Gellivor, a Christmas Legend› (1882); ‹The Boston Tea Party› (1882); ‹Vagrant Verses› (1887); ‹Favorite Birds and What Poets Sing of Them› (1888), and the hymn ‹Outside the Gate.›

POLLARD, Percival, American author: b. Pomerania, 1869; d. Baltimore, Md., 17 Dec. 1911. He came to the United States in 1885, engaged in journalism in 1891 and was afterward engaged in editorial and literary work in Chicago and New York. Among his published works are ‹The Cape of Storms› (1895); Posters in Miniature› (1896); ‹Dreams of To-day› (1897); ‹The Imitator› (1902); ‹Lingo Dan› (1903); and ‹Recollections of Oscar Wilde.› He also wrote the plays ‹Nocturne› and ‹The Ambitious Mrs. Alcott,› the latter produced at the Astor Theatre in 1908.

POLLARDING, the practice of cutting off the limbs of trees at a given height in order to make the stubs throw out numerous adventitious limbs. These latter, after being allowed to grow for three or four years, are cut for fuel and the process continued. In Holland and other parts of Europe where fuel is high-priced or scarce, the practice is very popular; but in the United States it has not come into vogue. It is also employed, like copses, for furnishing bark for tanning and withes for baskets, barrel hoops and wickerwork. Though the pollards, as they are called, are unsightly and are seemingly injured by the operation, they often become picturesque with age, and specimens still apparently thrifty are considered among the patriarchal trees of Europe. The species most used are willows, poplars, lindens, alders and certain elms and oaks.

POLLEN, John Hungerford, English clergyman and historian: b. London, 1858. He was educated at Münster, Germany, at the Oratory School, Birmingham, under Dr. (later Cardinal) Newman and at London University. In 1876 he entered the Society of Jesus and in 1891 was ordained to the priesthood. He has devoted his life principally to the study of the history of the Society of Jesus and of the lives of English, Irish and Scotch Catholics since the Reformation, and is vice-postulator for the beatification of the English martyrs. For purposes of research he has traveled in England, France and Italy. His published works are ‹Acts of the English Martyrs› (1891); ‹Life of Father John Morris› (1896); ‹The English Martyrs› (1908); ‹The Bedingfeld Papers› (1909). He edited ‹Papal Negotiations with Mary Queen of Scots› (1901); and ‹Queen Mary's Letter to Guise› (1904), both published by the Scottish History Society; ‹The Memoirs of Father Parsons› (1906–07); ‹Documents Relative to the English Martyrs› (1908), and contributions to ‹The Catholic Encyclopedia,› the *Dublin Review,* etc.

POLLICE VERSO, pŏl'lĭ-sē vėr'sō, the title of a famous picture by the French painter Gérôme. The words mean «with turned thumb,» and the artist represents the spectators in the gladiatorial games turning their thumbs down as the victorious swordsman sets his foot upon the body of his vanquished antagonist. When the thumb was turned up it meant that the vanquished swordsman was to be dispatched by the victor; it is not so plain that the down-turned thumb meant mercy.

POLLINATION. The pollen grains of seed plants are really microspores in a more or less advanced stage of germination. They are developed within anthers and, at the time of shedding, form a powdery mass which usually has a distinctly yellowish color. The pollen is the male product of the plant. The transfer of the pollen to the female structures — to the ovule of Gymnosperms and to the stigma of the ovary in Angiosperms — is called Pollination (Fig. 1).

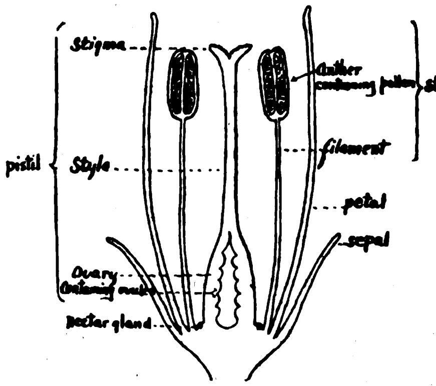


FIG. 1.— Diagrammatic section of a flower showing the various parts.

The terms pollination and fertilization are often confused, but they are very different processes; for pollination is merely the transfer of the pollen grains from the anther to the ovule or stigma, while fertilization is the union of the sperms and egg, or many would define the term more closely as union of the sperm and the egg nuclei. The confusion in the use of terms is particularly persistent because the earlier writers used both terms indiscriminately and because a widely read book by Darwin on ‹The Fertilization of Orchids by Insects› deals entirely with pollination, there being no reference whatever to the real process of fertilization.

The interval between pollination and fertilization varies in different species. In some cases it is only a few hours; in the majority of our familiar flowering plants the interval is probably less than a week; in some of the Gymnosperms it is several months, and in others, like the pine, it is a year; in the oaks, the interval is even longer.

Pollen is carried from the male to the female by the wind, by various animals, such as insects, snails and birds, or by water. The most primitive method is wind pollination; plants pollinated by wind are said to be *anemophilous.* Probably all Gymnosperms are pollinated by the wind, although claims have been made that in a few species the pollen is carried by insects. Many of the lower Angiosperms like the grasses, oaks, chestnut, beech and birch are wind pollinated; but the great majority of the group are pollinated by insects, and so are said to be *entomophilous.* In a few Angiosperms, growing in the water and with flowers resting on the surface of the water, the pollen floats on the water from the anther to the stigma. *Elodea,* a very common submerged water weed, is a familiar example.

The relative position of the pollen and the ovule or stigma to which it must be carried is various in different plants. In most of our familiar flowers, like the lily, the anthers with their pollen are in the same flower with the stigma. Such flowers are "bisporangiate" or "hermaphrodite." In many plants, as in corn, the male structures (the tassel with the anthers) and the female (the ear with the stigmas — called the "silk") are borne on different parts of the same plant but not in the same flower. Such plants are "monœcious." Many Gymnosperms bear male and female cones on the same tree and so belong in this category. In a smaller number of cases the male and female flowers are on different individuals, as in the willows. Such plants are "diœcious."

In case of wind pollination, the pollen is produced in immense quantities. In *Dioon,* a Gymnosperm in the cycad family, the male cone produces about 10,000,000,000 pollen grains. The female cone produces 200 to 300 ovules, each of which exudes at its tip a small sparkling mucilaginous droplet, which catches any pollen grains that chance to fall upon it. The combined surface of the 300 droplets would be less than an inch square, and yet, if a female cone is within 100 feet of a male cone, the ovules are likely to be thoroughly pollinated. As the droplet dries, the pollen grains are drawn down to the place where they begin to germinate and form pollen tubes. The pollen may be carried for miles, but at such distance very few ovules of an ovulate cone are likely to be pollinated. In pine forests, the pollen falls in such abundance that people call it "sulphur showers."

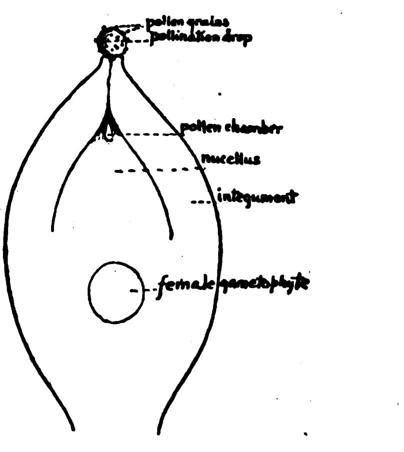

FIG. 2.—Longitudinal section of a Gymnosperm ovule showing the "pollination drop" with the very small pollen grains adhering to it. Below is the pollen chamber into which the grains will be drawn by the drying of the drop.

The comparatively few plants in which the pollen is carried by water are mostly diœcious. The pollen simply floats upon the surface of the water until it reaches the sticky, mucilaginous secretion of the stigma.

In case of wind pollination and water pollination the male and female flowers are usually upon different plants or, at least, upon different parts of the same plant. In these cases *cross-pollination* — the pollination of the stigma by pollen from another plant or from another flower on the same plant — results necessarily. Botanists agree that cross-pollination is the most efficient method and that *close pollination,* which results in close fertilization, is almost always bad for the species. However, there are some cases of efficient close pollination, chiefly in flowers which do not open, but always remain closed and, therefore, are called *cleistogamous* flowers. The common blue violet, in addition to its showy flowers, has small, nearly colorless flowers, looking like unpromising buds near the bases of the leaves. These flowers, entirely self-pollinated, produce good seed. But in most cases where the male and female structures, the anther and the pistil, are in the same flower, plants have worked out innumerable methods with innumerable variations in details to avoid close pollination. In nearly all of the cases, the pollen is carried from the anther to the stigma by insects. There are scores of books on insect pollination.

Most plants which are pollinated by insects have conspicuous flowers or a distinct odor or both. Some observers claim that the corolla does not attract insects, but none can deny the constant association of conspicuous flowers and insect pollination. All flowers pollinated by insects have nectar glands which secrete the nectar, which is the most usual cause of insect visits.

In many plants with stamens and pistils in the same flower, self-pollination is prevented by the maturing of the pollen and stigma at different times. The pollen matures and is shed before the stigma exudes the sticky substance which makes the pollen adhere to it and at the same time affords a nutritive medium in which the pollen tube begins to form; or the stigma matures and dries up before the pollen is ripe; consequently, the stigma could be pollinated only by pollen from another flower.

In many cases, however, the pollen and the stigma of a flower mature at the same time. In such flowers the devices to prevent self-pollination are innumerable. Practically all such flowers are pollinated by insects. Some of the devices afford a general protection against self-pollination, but others are so complicated and specialized that only certain insects with certain peculiarities in structure can reach the nectar, and so none but these favored guests are tempted to visit the flower.

A common contrivance for the prevention of self-pollination is seen in species in which some flowers have long anthers and short pistils, while others have short anthers of the same length as the pistil in the other flower and long pistils of the same length as the anthers of the short-styled flower. The Bluet (Houstonia) is a familiar example (Figs. 3 and 4). As the insect, usually a butterfly, thrusts its proboscis down the tube of a flower with short anthers (Fig. 3) to reach the nectar at the base of the ovary, the pollen adheres to the proboscis; then, as the butterfly visits a flower with a short style (Fig. 4) the pollen on the proboscis is at the right level to brush against the stigma and, at the same time, pollen from the long anthers adheres to the proboscis at the higher level, so that this pollen will be deposited on the stigma of any long-styled flower the butterfly may visit.

In the Snapdragon and similar flowers the two lips of the corolla are so tightly closed

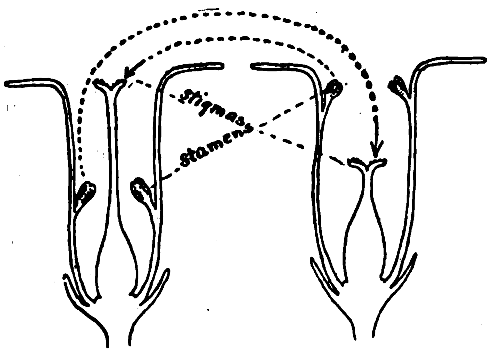

FIG. 3.—Long-styled flower with anthers near the middle of the corolla tube.
FIG. 4.—Short-styled flower with anthers near the top of the corolla tube.

that small insects cannot get to the pollen or nectar, but the lips open when some heavy insect, like the bumble bee, alights upon the flower. Thus the pollen and nectar are not wasted upon visitors which would be of little or no use to the plant in effecting cross-pollination.

The common milkweeds secrete a sticky, milky substance which hardens rapidly when exposed to air. The epidermis of those plants is very delicate in the region of the flower cluster, so that the sharp claws of ants or other creeping insects, which would be of no use to the plant in effecting cross-pollination, break through and the sticky substance holds them fast and prevents them from reaching the nectar or pollen. On the other hand, butterflies, which are very effective in accomplishing pollination in milkweeds, alight directly upon the flowers, securing the nectar and carrying the pollen to other flowers on the same plant or on different plants. In the milkweeds and in most of the orchids, the pollen grains stick together in large masses, called «pollinia» and, consequently, when pollination takes place at all it is very abundant.

The Catchfly (*Silene antirrhina*) as the flowers bloom exudes a sticky brownish substance which forms a girdle around the stem below the flowers, preventing any creeping insects from reaching the nectar or pollen. Consequently, pollination is effected only by flying insects. This hint from the Catchfly is used artificially on a large scale in the sticky girdles put around tree trunks to prevent the ascent of various pests.

Many plants, like the Evening Primrose, blossom only at night when there is not much danger from creeping insects, but when moths and other flying insects, particularly useful in effecting cross-pollination, are abroad in great numbers.

One of the Rosin-weeds, *Silphium perfoliatum,* has large sheathing leaves which form a cup around the stem. The water in the cup prevents insects from crawling up to the flowers. Only flying insects, which could carry the pollen to other plants, can reach the flowers. Many plants prevent self-pollination in this way.

In most of the cases mentioned, it is true the pollen of a flower is dusted upon its own stigma, but it is practically certain that when pollen from its own anthers and pollen from the anthers of another flower fall together upon the stigma, the foreign pollen is more likely to germinate.

A couple of instances of insect pollination, no more remarkable than scores of others, may be given as illustrations of the complicated relations between certain insects and certain plants. In the Fig, pollination is effected by small wasps. There are two kinds of urn-shaped inflorescences which we call figs, borne on different trees. One, which is called *Caprificus,* has male flowers near the neck of the urn and short-styled female flowers farther down; the other, called *Ficus,* has only female flowers with long styles. The wasp thrusts its ovipositor down through the short style of the female flower *Caprificus* and lays an egg in the ovary and a larva begins to develop, causing the flower to become distorted into a gall. As the wasps mature, the males escape first and fertilize the females which are still in the gall flowers. The males then leave the urn before the pollen is ripe, but the females stay awhile — just long enough for the pollen to ripen — and then escape, becoming dusted with pollen as they pass through the narrow opening at the top of the urn. Then they visit the younger urns, dusting the stigma with pollen and laying eggs. In case of the short-styled flowers of *Caprificus,* galls are produced; but the wasp's ovipositor is not long enough to reach the ovary of the long-styled flowers of *Ficus* and, consequently, pollen tubes develop normally, fertilization follows and normal seeds are matured.

Another remarkable instance of insect pollination is seen in the *Yucca,* an arborescent member of the lily family, with rigid, sword-like leaves, which has given it the name of «Spanish Bayonet» or «Spanish Dagger.» Pollination is effected by the moth, *Pronuba yuccasella.* The female visits the flowers for the pollen, which she does not eat, but molds into a ball and carries to another flower. Here she bores through the wall of the ovary and deposits her eggs in the young ovules and then crowds the ball of pollen into the funnel-shaped top of the stigma, thus effecting abundant pollination, which causes the young ovules to grow rapidly. The developing larvæ eat many of the young ovules, but soon bore their way out and escape, while the ovules which are left develop into good seeds.

In the case of yucca and pronuba, the moth has been considerably modified so that it is adapted to rolling up the ball of pollen. Many flowers are adapted to pollination by certain insects and many insects are adapted to certain flowers, so that a scarcity of its particular flower means hardship or death to a certain species of insect; while a scarcity of some particular insect may mean the extinction of the particular flower which it pollinates. These mutual adaptations are very numerous among the orchids.

In all the foregoing instances, pollination results between flowers of the same species. When effective pollination occurs between plants of different varieties, species or genera, and fertilization follows, the resulting individual is called a *hybrid*. It often happens that hybrids are more vigorous than either of the parents and it is often possible to combine desirable characteristics of different species by artificial pollination. An anther is plucked out from a flower and its mature pollen is dusted upon the stigma of the other species. This method has been of immense value in improving various fruits and crops. It is well known that the male and female are equally potent in transmitting hereditary characters, but cross-pollination has shown that, in some cases at least, some particular characters are regularly determined by the pollen. In corn, if self-pollination be prevented and field corn, which has a starchy kernel, be pollinated with sweet corn, which has a sugary kernel, the field corn stalks will bear an ear with sugary kernels; and, similarly, starchy kernels can be grown upon sweet corn stalks. In corn, pollination by a red-eared parent will produce ears with red kernels or with kernels showing various mixtures of red and yellow. By pollinating different stigmas of an ear with different pollen, it is possible to produce on the same ear both red and yellow and also starchy and sugary grains.

There are scores of books on pollination and a vast number of articles in magazines. Dr. Knuth, in his exhaustive treatise, lists 3,748 titles, most of them dealing with pollination in connection with other features of the life history but many of them devoted entirely to this subject.

Bibliography.— Knuth, Dr. Paul, 'Handbook of Flower Pollination' (Oxford 1906). This work in three large volumes gives citations to practically all the literature up to 1906); Darwin, Charles, 'The Effects of Cross and Self-Fertilization of Plants' (London 1888), and 'The Various Contrivances by which Orchids are Fertilized by Insects' (New York 1892).

Charles J. Chamberlain,
Professor of Morphology and Cytology, the University of Chicago.

POLLIO, pŏl'ĭ-ō, **Caius Asinius**, Roman poet, historian and orator: b. 76 B.C.; d. 4 A.D. He is known from the part he took in the political events of his time, but still more by his writings and love of literature. In the Civil War, he (49 B.C.) adhered to Julius Cæsar, whom (after defeating Gaius Curius in Africa) he accompanied to Pharsalia and then to the African and Spanish wars. He was afterward appointed prætor and held the government of Further Spain, where he fought, without success, against Sextus Pompeius. When Lepidus and Antony were reconciled, in 43 B.C., he joined them with three legions and was made administrator of Transpadane Gaul. At this time he became the friend of Virgil, whose property he saved from confiscation. After obtaining the consulship he commanded in Illyria and Dalmatia and for his victories was honored with a triumph 39 B.C. He afterward devoted his time to literary pursuits. He wrote speeches, tragedies and a history of the civil wars, comprised in 17 books, which is quoted or referred to by several of the ancient writers. He was a great patron of literary men and introduced the custom (Recitatio) of reading aloud works, before publication, to a group of expert critics. Virgil addressed two Eclogues and Horace an ode, to him. His orations are frequently spoken of by Quintilian, but his style is condemned as deficient in clearness and ease. He founded the first public library at Rome. Three of his letters to Cicero are in the Ciceronian collection and there are some extant fragments of his history of the civil wars. Wolfflin has on very inadequate grounds attributed to him the history of Cæsar's African campaign ('Bellum Africanum'). He lived on intimate terms with Virgil and Horace, the latter of whom dedicated to him the first ode of his second book. Consult Aulard, 'De Asini Pollionis Vita et Scriptis' (1877).

PÖLLNITZ, pĕl'nĭts, **Karl Ludwig**, Baron, German author: b. Issomin, Prussia, 25 Feb. 1692; d. Berlin, 23 June 1775. He belonged to a noble family but became a soldier of fortune, serving at different times in the Austrian, Papal and Spanish armies. He later gained the favor of Frederick the Great, who appointed him his reader and master of ceremonies at his court, and he subsequently became director of the theatre at Berlin. During his career he twice professed the Calvinist faith from interested motives, but before his death returned to the Roman Catholic Church. His works are witty and amusing and include 'Etat abrégé de la Cour de Saxe' (1734); 'Lettres et Mémoires' (1738–40), etc.

POLLOCK, pŏl'ŏk, Sir **Charles Edward**, English judge and writer on law: b. 31 Oct. 1823; d. Putney, 21 Nov. 1897. He was a son of Sir Frederick Pollock, had no university training and read law with his father, becoming his private secretary during his service as Attorney-General. He was called to the bar in 1847, was elected bencher of the Inner Temple in 1866, acquired large practice, took silk (that is, became queen's counsel) in 1866 and was knighted in 1873. In the last-named year he was raised to the exchequer bench and through the judicature acts received in 1875 the status of justice of the High Court. For a number of years he reported special cases and wrote several works on County Court procedure, merchant shipping, the law of evidence and other subjects. As a jurist he exhibited a remarkable erudition, especially in curious and antiquated phases of the law, and as a referee he was criticized for a too common habit of compromise. Among his works were 'The Practice of the County Courts' (1851; subseq. eds., with supplements), and 'A Treatise on the Power of the Courts of Common Law to Compel the Production of Documents for Inspection' (1851).

POLLOCK, Sir **Frederick**, English jurist: b. London, 10 Dec. 1845. He was educated at Eton and Cambridge; in 1871 was called to the bar of Lincoln's Inn, and in 1882–83 was professor of jurisprudence in University College, London. Since 1883 he has occupied the chair of jurisprudence at Oxford and during 1884–90 was professor of common law in the Inns of Court. Since 1895 he has been editor of the Law Reports. In 1888 he succeeded his father in the baronetcy. He has several times visited the United States and in the winter of 1903–04 delivered a course of lectures at the Lowell Institute, Boston. Among his published works are 'Principles of Contract' (1876; 6th ed., 1895); 'Digest of the Law of Partnership' (1877; 7th ed., 1900; 10th ed., 1915); 'Spinoza, his Life and Philosophy' (1880; 2d ed., 1899; reissue with addenda 1912); 'The Law of Torts' (1883; 5th ed., 1897); 'The Land Laws' (3d ed., 1895); 'Introduction to the History of the Science of Politics' (1890; revised ed., 1911); 'Oxford Lectures and other Discourses' (1890); 'Leading Cases done into English and other Diversions,' a series of parodies of English poets as well as of typical cases at law (1892); 'The Law of Fraud'; etc., in British India (1894); 'A First Book of Jurisprudence' (1896; 3d ed., 1911); 'The Etchingham Letters,' a novel in epistolary form (1899; with E. F. Maitland), etc. With F. W. Maitland he wrote a 'History of English Law before Edward I' (1895; 2d ed., 1899). Other works include 'The Expansion of the Common Law' (1904); 'Introduction and Notes to Main's Ancient Law' (1906; 2d ed., 1908); 'The Genius of the Common Law' (Columbia University lectures 1912).

POLLOCK, Sir **George,** English soldier: b. London, 4 June 1786; d. Walmer, 6 Oct. 1872. He was educated at Woolwich, entered the East Indian service as lieutenant of Bengal artillery, in 1835 became colonel commandant and until his death retained this post. He commanded the Bengal artillery in the Burmese War of 1824, in 1842 was made commander of the armies west of the Indus, 5 April forced the Kyber pass, 16 September entered Cabul. He was military member of the supreme council of India in 1844–45, a director of the East India Company in 1854–56 and held other offices. In 1859 he was made general, in 1870 field-marshal.

POLLOCK, Robert, Scottish poet: b. North Muirhouse, Renfrewshire, 1799; d. Southampton, England, 18 Sept. 1827. He was educated at Glasgow University, studied divinity and was licensed as a preacher by the Associate Presbytery of Edinburgh in the spring of 1827. He is the author of a series of 'Tales of the Covenanters,' published anonymously when very young and a blank verse poem, 'The Course of Time,' which in spite of many faults of execution enjoyed a wonderful popularity both in Great Britain and the United States. The former work, republished with his name in a single volume, contains three of his earliest productions in prose; originally issued anonymously, 'Helen of the Glen,' 'Ralph Semmell,' and 'The Persecuted Family.'

POLLOCK, Walter Herries, English journalist and author: b. 21 Feb. 1850. He is a brother of Sir F. Pollock (q.v.) and was educated at Eton and Cambridge. He was called to the bar at the Inner Temple in 1874 and from 1884 to 1894 was editor of the *Saturday Review.* He has published 'The Modern French Theatre' (1878); 'Lectures on French Poets' (1879); 'The Picture's Secret,' a novel (1883); 'Verse of Two Tongues' (1884); 'A Nine Men's Morrice' (1889); 'Old and New,' verse (1890); 'Jane Austen: Her Contemporaries and Herself' (1899), and 'Lectures on French Poets'; 'King Zub'; 'The Paradox of Acting'; 'The Ballad-Monger'; 'Animals that Have Owned Us.'

POLLS. See Elections.

POLLUCITE, the chief mineral in which the rare element cæsium occurs as an essential constituent, another being castorite, and, therefore, its most important ore. It occurs in cubes, but usually in small crystalline, deeply etched masses, colorless, transparent and much resembling quartz. It is a silicate of cæsium, aluminum and sodium. It is found only in Maine and in the granite of the island of Elba.

POLLUX, pŏl'ŭks, **Julius,** real name Polydeucs, Greek sophist and grammarian: b. Naucratis, Egypt. He flourished about 180–192 A.D., was well educated by his father and afterward received instruction from Adrian the Sophist, later becoming a favorite in Rome of Marcus Aurelius and his son, Commodus, by the latter of whom he was appointed teacher of rhetoric at Athens. He wrote several works, all of which have perished except his 'Onomasticon' or Greek vocabulary, dedicated to Commodus, whose preceptor he was. Each of its 10 books forms a separate treatise by itself and contains the most important words relating to certain subjects, with short explanations of their meaning. The words are not arranged alphabetically, but are given with little regard to rigorous system of any kind, according to the subjects treated of in each book. It has been found an aid of much value in the study of Greek art and literature. The first edition was published at Venice in 1502 and the best editions are those of Lederlin and Hemsterhuis (1706), Dindorf (1824) and Bekker (1846).

This scholar has been frequently confounded with another of the same name who lived in the 10th or 11th century of the Christian era and wrote a 'Chronicle' or 'Universal History' from the formation of the world to the time of Valeus. His work, which has come down to us, was edited by Biancoreé (Bonn 1779) and Hardt (Munich and Leipzig 1792).

POLLUX. See Castor and Pollux.

POLO, pō'lō, **Gaspar Gil** (sometimes written Gil Polo Gaspar), Spanish poet: b. Valencia, Spain, about 1530; d. Barcelona, Spain, 1591. Details concerning his life are few and contradictory. He studied law, and is doubtless identical with the Gaspar Gil Polo who was professor of Greek in the University of Valencia 1566–74. He occupied the office of town clerk at Valencia and in 1572 received an appointment under the government from Philip II, who apparently sent him to Barcelona in 1580. He wrote 'Canto de Turia,' in which he sung the praises of his native city, but his fame rests upon the pastoral romance 'Primera parte de Diana enamorada, cinco libros que prosiguen los siete de Jorge Montemayor' (1564), a continuation of Montemayor's 'Diana.' Its originality is questioned among critics, but his work is clear in delineation of plot and possesses beauties of diction and rhythm far surpassing that of the first 'Diana.' It is also noted for the number and variety of its episodes, raising its author far above the lyric level of his day. It ran through many editions in Spain, of which the best is Cerda's (1778) and has been translated into English, French and Latin. Cervantes excepts it from the list of books condemned to the flames, his somewhat puzzling statement that it should be guarded "as though Apollo had written it" being evidently a pun on the author's name.

POLO, Marco, Italian mediæval traveler: b. Venice, about 1250; d. there, 1324. His father, a man of noble rank, of Dalmatian origin, in 1271 took young Marco with him on a trading expedition to China and the East. The youth of 20 entered the service of the Great Khan, and traveled extensively through China and the neighboring regions. The travelers were finally desirous of return, and were allowed to accompany an embassy to Persia. Thence they made their way to Venice, which they reached in 1295. Later Marco commanded a fleet in a war with Genoa, in 1296 was taken prisoner, and did not secure his release until 1298. At this time he dictated to Rustigielo di Pisa the work of travel known as 'The Book of Marco Polo' published in French. Though his narrative made a great sensation, it was for many years regarded as a mass of fabrications and exaggerations. It had an undoubted effect, however, upon exploration; and later researches have confirmed the truth of many of the author's descriptions. It encouraged the Portuguese to find the way to Hindustan round the Cape of Good Hope, and it aroused the passion for discovery in the breast of Columbus, thus leading to the two greatest of modern geographical discoveries. It was long the sole authority possessed by Europe on the peoples of the Far East. The first Italian edition appeared in Venice in 1496, and has been often reprinted. There are now about 60 translations in various languages, including several English ones. The standard English edition is that of Yule (1875; revised 1904). An English version appeared in 1818.

POLO, an equestrian game, the object of the players being to strike the ball through the opponent's goal; all are mounted on ponies not exceeding 14½ hands and carry mallets about four feet long with which to strike the ball, made of light wood. The grounds are usually 900 feet long by 450 feet wide, level turf, at each end of which are located goal posts 24 feet apart. The proper number of players is four on a side, but a less number can play; combination and interference are important elements of success. But little is authentically known of the exact origin of the game, yet legends of the Orient give proof of its antiquity, and it is generally accepted that the game was played in Persia before the beginning of the Christian era, and had its origin in northern India. It is a matter of record that a game very similar to it was played by the Emperor Manuel Comnenus about the middle of the 12th century. Some authorities claim that the original home of the game was Tibet and that it reached India through Afghanistan. It was known and popular in most of the Himalayan countries. In 1870 polo was introduced in England by army officers who had been stationed there, and about 1885 it was introduced into the United States. The rules of the game in England and America differ materially, especially in the tendency of the English game to lessen the freedom of the player in order to increase safety; the game has always been popular with the British army officers, who have produced many of the leading experts. In America there exists a system of handicapping the players, thus giving the less experienced an equal chance. The demand for suitable ponies has developed the industry in the United States of breeding them through crossing the thoroughbred with the hardy Western ponies. In addition to horsemanship the game requires control of temper, quickness of observation, judgment, nerve and endurance; the United States army has done much to encourage the game at the various army posts, and introduced it at the West Point Military Academy. The central authority on the game in the United States is the Polo Association, composed of 34 clubs located throughout the country; it forms the rules, regulates the handicapping and arranges the tournaments, championships and other matches.

POLOCK, Moses, American publisher and bookseller: b. Philadelphia, 14 May 1817; d. there, 16 Aug. 1903. In his 14th year he began the book business, in which he continued until his death. He issued many books in fiction, the drama and general literature, and in addition dealt in old and rare books, becoming an authority in Americana. His shop for half a century was frequented by book lovers, and his collections of Washingtoniana and books printed by Benjamin Franklin were particularly notable. He had a profound knowledge of early Pennsylvanian history.

POLONAISE, pō'lō-nāz, a national dance of Poland, characterized by a slow movement in three-quarter time, and made up of a march or promenade; also the music for such a dance, in a peculiar rhythm used by many composers, but specially elaborated by Chopin in some of his finest works.

POLONIUM, an element discovered by Mme. Skiodowska Curie (1898), who, while examining some samples containing uranium obtained it from the complex mineral pitch-blende. Mme. Curie named it polonium in memory of her native land, Poland. Pitch-blende is a peculiar and very complex mineral found principally in Joachimsthal, Bohemia; Cornwall, England, and in some parts of this country, notably Colorado. It contains a large amount of the element uranium and is mined and worked over to obtain that element. It was from the refuse or waste left after the extraction of the uranium that Mme. Curie obtained polonium and afterward the far more important element radium. Polonium closely resembles bismuth in its chemical properties, and is found in company with that element when it is separated from the rest of the above refuse during the process of analysis. To separate the polonium from the bismuth is a matter of great difficulty and no sample of polonium has yet been obtained that is free or even approximately free from bismuth. The method usually used is that of fractional precipitation of the basic nitrates. A solution of the mixed nitrates of bismuth and polonium is made in concentrated nitric acid. Water is added until the liquid becomes cloudy. The white solid basic nitrates that separate at first contain a larger percentage of polonium than the original mixture dissolved in the acid. This process, repeated many times, gives a solid rich in polonium. The most important property of polonium is its radio-activity (see RADIUM). While radium gives off three kinds of rays or radiations called α, β and γ, polonium appears to give only one variety, the α rays. Polonium loses its radio-activity slowly, thereby differing from radium. It should be noted that some noted investigators in this field of radio-active substances denv the existence of polonium, claiming it to be merely a radio-active form of bismuth, its radio-activity having been induced by its association with radium in the pitch-blende.

POLTAVA, pŏl'tä-vä. See POLTOWA, RUSSIA.

POLYÆNUS, pŏl-ĭ-ē'nŭs, Greek writer: b. Macedonia, about 85; d. Rome, Italy, about 170. He wrote a historical collection of instances of military ruses employed by Greeks, Romans and barbarians. It was entitled 'Strategics,' or 'Stratagems,' and was inscribed to the emperors Marcus Antoninus and Lucius Verus. Two of its original eight books are lost, but the remainder contains much valuable information not found elsewhere. The first edition was published by Casaubon at Lyon in 1589; the best by Coreas at Paris in 1809; early English translation by Shepherd at London in 1793, and German by Seybold at Frankfort in 1793–94.

POLYANDRY (Gr. *polys*, many, *andres*, men, husbands), a marital relation subsisting between one woman and several men. Polyandry is found to exist in primitive and barbarous peoples in every age and everywhere. In antiquity we have the testimony of Herodotus for the prevalence of this custom among the Scythian peoples Agathyrsi and Massagetæ and the Nasamones, a people of northern Africa near the Greater Syrtis. A like report is made regarding the people of Libya by Aristotle, by Diodorus Siculus regarding the Troglodítæ and the Ichthyophagi on the coast of the Red Sea, by Cæsar regarding the inhabitants of Britain; Polybius finds unmistakable traces of the institution even among the Spartans. Till but a little while ago these reports of ancient authors were held to be abnormal and exceptional, for it was assumed that the primordial family had everywhere its origin in the marital relation of one man with one woman (monogamy) or of one man with several women (polygyny or polygamy). But the reports of modern travelers concerning the marriage customs of barbarous and uncultured peoples prove that among them polyandry is universal or at least usual; it is found in Malabar, the Marquesas, in New Zealand and throughout all the Pacific isles, in North and South America — in short, wherever mankind has not risen above a certain stage of social culture; nor is it confined to totally uncultivated peoples; to cite one example only, it is a legitimate custom among the Tibetans. Usually, but not always, in the Tibetan polyandric family the joint husbands of a woman are brothers, and the elder brother is credited with the paternity of the children, while the other brothers are uncles. It is the report of travelers that the female head of a polyandric family enjoys a measure of consideration and authority very unusual among barbarians; in some tribes it has grown into a real sovereignty. The universality of the custom is proof at least that over against the patriarchal family and descent through the male head of a monogamous family must be set the matriarchal family in which descent is traced to the mother; and that gynæocracy is of equal antiquity with patriarchy. Spencer, in his 'Sociology,' mentions several curious forms of the relation, each considered an advance on its predecessor, as (1) one wife has several unrelated husbands, and each of the husbands has other unrelated wives; (2) the unrelated husbands have but one wife; (3) the husbands are related; (4) the husbands are brothers.

POLYANTHUS, a name popularly applied to several unrelated plants, as a narcissus (*Narcissus tazetta*), and the tuberose (*Polianthes tuberosa*); but most commonly a certain primrose thought to be derived from *Primula elatior* as a principal parent; but perhaps a hybrid between *P. officinalis* and *P. vulgaris*, or a race developed from the last species. It is one of the most popular of its genus in American gardens. It is a hardy perennial herb with entire, simple leaves, leafless scapes terminated by an umbel of several to many early spring flowers mostly red, yellow or both these colors together. Some of the numerous varieties have two corollas one within the other and are called hose-in-hose or duplex. The plants may be grown from seeds, but individual varieties are usually propagated by division. They delight in cool, moist, shady places and rich, loamy soil.

POLYBASIC ACIDS, *in chemistry*, acids which possess more than one hydrogen atom capable of being replaced by a metal equivalent.

POLYBASITE, a black, metallic mineral, occurring in hexagonal, tabular crystals of orthorhombic symmetry. It is a sulph-antimonite of silver and copper, containing 75.6 per cent of silver, of which it is, therefore, an important ore. It occurs in many silver mines of Saxony, Mexico and the western United States.

POLYBIUS, pō-lĭb'ĭ-ŭs, Greek historian: son of Lycostas, a distinguished general and one of the heads of the Achæans: b. Megalopolis, Arcadia, about 205 B.C.; d. about 120 B.C. He was educated for arms and political life, and when about 169 B.C. the design of the Romans to make all the free states of Greece dependent became evident, Polybius took part in all the measures for the preservation of their independence. When, therefore, after the subjugation of Perseus (168), the Romans used less disguise, Polybius found himself among the 1,000 hostages whom the Achæans were obliged to deliver up to the Romans. His learning, virtues and talents soon gained him the favor of some of the most distinguished senators, especially Fabius and Scipio, the two sons of Paulus Æmilius. The hostages were not dismissed until 17 years had elapsed, when Polybius, who did not wish to see again his degraded country, remained in Rome, and entered into the service of Scipio Æmilianus. He accompanied him on his expedition to Africa, and was a witness of the destruction of Carthage in 146. He then went to Greece, where the Achæans had become involved in a war with the Romans. After the Achæan defeat he did much to obtain favorable terms of peace. His services were gratefully recognized by the erection of his statue in many towns. Polybius is the author of a historical work from the 140th Olympiad (220 B.C.) to the overthrow of Grecian independence (146 B.C.). It consisted of 38 books, besides two introductory books, containing a sketch of the Roman history from the taking of Rome by the Gauls. The first part of the work comprised a period of 53 years, from the beginning of the Second Punic War to the overthrow of the kingdom of Macedonia; the second part began with the war in Spain against the Celtiberians and Vaccæans, and ended with the destruction of Corinth. Although the affairs of Rome are the chief subject, contemporary occurrences in other countries are also related. We have of this great work only the first five books entire, and valuable fragments of the remaining books. Some of these fragments, as that containing an account of the Roman army, are of considerable length. In extent of political and military knowledge, Polybius is surpassed by no historian of antiquity. To him is also attributed the introduction of didactic politics into history — that is, of that manner of writing history which, by intermingling views of the causes, occasions and effects of events, is a useful introduction to politics. On the other hand, his style is destitute of beauty, and the narrative interrupted by lengthy digressions, which weaken the artistic effect. Livy was much indebted to Polybius after he came to the Second Punic War. Cicero mentions a particular work of his on the Numantian War. Casaubon, in 1609, published a complete edition of all that had till then been discovered of his works and made a new Latin translation of the whole. The most valuable editions of Polybius are those of Schweighauser (1789), Bekker (1844); L. Dindorf (1866–68) and Hultsch (1867–71). The history of Polybius has been well translated into English by Shuckburgh (1889).

POLYCARP, pŏl'ĭ-kärp, one of the apostolic Fathers of the Church, and styled by his disciple Irenæus a pupil of the apostle John: b. Smyrna, probably about 69 A.D.; d. there, 155. According to legend he was brought up by a noble Christian lady named Callisto, and was consecrated by Saint John as bishop of his native city. When the controversy about the time of Easter arose, he went to Rome to confer with Anacletus, who then occupied that see; and though he did not succeed in reconciling the differences between the Eastern and Western usages, the questions were discussed in the most friendly manner. During the persecution under Marcus Aurelius Antoninus he was brought before the Roman proconsul at Smyrna and urged to revile Christ, but he replied, «Eighty and six years have I served him, and he has done me naught but good, and how could I then revile my Lord and Saviour?» The people desired that he should be flung to the wild beasts, but he was sentenced to death by fire. The flames, however, according to the legend, played harmlessly around him like a swelling sail, emitting a sweet fragrance. When the judges ordered one of the executioners to run him through with a sword, the flames were extinguished by the blood that flowed from the wound. Polycarp is one of the saints in the calendar of the Church, and the 26th of January has been consecrated to his memory. He wrote several epistles, which were current in the early Church, but have all perished except one addressed to the Philippian Church, exhorting them to the practice of their Christian duties and the maintenance of the purity of the faith. There is another writing of that age of which he is the subject, a relation of the manner of his death, written by the Church at Smyrna, of which he was the bishop, addressed to the church of Philadelphia. Both of these epistles may be read in an English translation in a volume, published by Archbishop Ware, containing all the genuine remains of the Apostolic Fathers. Consult also Lightfoot, ‹Apostolic Fathers› (1891).

POLYCHÆTA, pŏl-ĭ-kē'tą, one of the two subclasses (the other being *Oligochæta*) of annelid worms composed of a large number of marine species, but only a few from fresh water, whose most striking characteristic is the presence of fleshy outgrowths (parapodia) on either side of each somite of the body, each strengthened by a number of bristles, the term, in Greek, meaning much hair. The group is separable into *Errantia* and *Sedentaria.* The *Errantia* are wandering forms which, while they burrow, can swim readily. They have a well-developed head provided with eyes, sensory tentacles and usually the mouth is armed with strong jaws. The parapodia are well developed and form the organs of swimming and usually serve also as gills. They are carnivorous, feeding upon other worms, etc. The *Sedentaria* live exclusively in burrows, and in some cases have the power to secrete tubes of horny matter, or even of lime, in which they dwell. Living in this way and not using the parapodia these structures have been reduced; while the head not infrequently bears gills and numerous long retractile tentacles which are used in obtaining food. These feed largely upon the microscopic life in the water and are without jaws. In the life-history of the Polychætes a larval form known as the trochophore is very common.

POLYCHROME BIBLE (Gr. πολύχρωμος, many-colored), an edition of the Old Testament scriptures printed in different colored type so as to show the various literary elements out of which, according to modern Orientalists, the several books were compiled. The editor is Prof. Paul Haupt of Johns Hopkins University, Baltimore, Md. The term is also applied to an American edition of the Bible, in which, in the New Testament, the words generally accepted as the utterances of Jesus Christ, and, in the Old Testament, the words quoted by him, or that have direct relation to incidents to which he referred, are printed in red.

POLYCHROMY, pŏl'ĭ-krō'mĭ, literally the use of many colors and generally used in the sense of decorative work by means of brilliant coloring or that which is brilliant in comparison with other work of the same class and character. Thus a fitting together of building-stones in patterns is polychromy, although the hues of the sandstone or limestone or marble are not positive nor strangly contrasted with one another. In French Romanesque architecture, as also in modern imitations of it, like Trinity Church, Boston, Mass., the sandstones are of two or three different shades of reddish brown, and an additional hue approaching buff; and yet this very moderate degree of contrast, when used deliberately in pattern, is called polychromy. On the other hand, polychromatic painting is always assumed to be in primary colors, or those which nearly approach them in brilliancy. Thus the painting of a Grecian Doric temple in the 5th century A.D. is known to have been in great measure carried out in the unmixed natural pigments as strong and pure as they could be procured; red and deep blue, with a free use of metallic gold in the form of gilt, bronze or the like, and the rather frequent introduction of such secondary colors as green and purple.

Color effects in architecture are as ancient as architecture itself. It never seems to have occurred to an Egyptian builder to leave his limestone walls unadorned with polychromatic effects, nor to the sculptor engaged in carving reliefs on those walls or statues to set up against them, that such human and animal forms could ever be left in the natural color of the stone. Sculpture was always completed by the paintbrush except in those cases where, chiefly for display or in the spirit of sacrifice, there was used a very costly and very hard material of some importance in its own surface and color. Thus an Egyptian statue of diorite or basalt, or a Roman statue of the imperial epoch wrought in black marble, or a portrait bust with the head and neck of white marble inserted into the draped shoulders and torso wrought in the most precious Oriental alabaster or beautiful veined marble from Greece or Numidia, would not be painted; and any polychromy that would be added by hand would be in the nature of gilding applied to the hair or the ornaments. So the bronze statue, highly esteemed for its material, which was always accepted as superior to marble or other natural stone, would receive eyes of hard natural stone or of glass, and perhaps gilding as mentioned above, but nothing more. On the other hand, some modern work in experimental polychromy has been carried further; thus the statues and busts of Charles Henri Cordier have been adorned with enamel applied freely to articles of costume, to the harp of an Egyptian harp-player, in addition to the approximation of the natural color of skin and of drapery. In the Paris Exposition of 1900 there were exquisite statuettes wrought in the precious materials, onyx, agate, alabaster and the like, with bronze of many colors or in other cases in carved and stained ivory. The most impressive piece of work of this kind was the statue by Ernest Barrias, 'Nature Unveiling Herself,' a statue somewhat larger than life, of which the whole lower part, representing the body from the bust downward with a drapery, is wrought of a single block of marble of unusual beauty — a superb piece of red and purple veining — while the breast and shoulders, arms and head, are in white marble, the hair and eyes being stained and the veil is of a natural stone of a delicate buff or perhaps greenish yellow tinge.

Polychromy in painting has not been so commonly used in modern times. For some reason painting, when applied in merely flat and unchanging masses, is looked on with some contempt by modern decorators; and the artist who controls a more complete skill, whose painted work is characterized by all the art of gradation and harmony known to the modern world, abstains from doing such purely decorative work. It was not so in antiquity, for while no fragment remains to us of the highest development of chromatic effect in sculpture, on the other hand there were no texts more intelligible than those which set forth the practice of employing painters of name and fame to adorn with color the works of the sculptors. An early but most interesting example of what this work must have been is seen in the draped statue discovered on the Acropolis in 1883 and 1886. The color is disappearing rapidly; but when it was taken from the ground it was brilliant. The outer garment (himation or peplos) has in every case a rich border of two or three contrasting hues; the larger surfaces of the stuff are shown as covered with a pattern in spots or small foliated figures; and the under garment (chiton), where visible, is often painted in a strong, deep green, which was probably in the first place more nearly blue. Hair, eyes, lips and all the jewelry shown, such as earrings, are treated separately and with what seems to have been a free use of gilding.

The great masters of polychromy are, however, the Persians and the civilized races of Asia generally. Beauty of pattern is especially the Persian gift; but this merit is shared by the people of the Indian Peninsula and by the Chinese and the Japanese, and in a lesser degree by the Malays and the inhabitants of farther India. Even the peoples of very low civilization in the north, the original inhabitants of Siberia, showed a marked gift in the arranging of decorative patterns. Both the Japanese and Chinese use polychromy in their larger works, temples and the like, with great freedom and with perfect success; the Japenese limiting brilliant effects rather to the interior and to special details of the exterior, while the Chinese had at one time the great art of polychromatic building, using their enameled potteries with perfect freedom.

Russell Sturgis.

POLYCHRONICON, the name of a work of Ramolf Higden, a Benedictine (d. 1363). It is a history of the world according to Biblical chronology down to the year 1342.

POLYCLITUS (pŏl-ĭ-klī'tŭs) **OF SICYON,** Greek sculptor and architect. He was a pupil of the sculptor Ageladas, of Argos, in whose studio he became fellow-student of Phidias. He flourished 452–412 B.C. He stood at the head of the schools of Argos and Sicyon, and is held to rival Phidias, the head of the Athenian school. The latter was considered pre-eminent for his statues of the gods, and Polyclitus in those of men. He excelled particularly in representing the graceful attitudes of youthful athletes. One of his most celebrated statues was the Doryphorus (Spear-bearer), a figure to which the name of canon, or standard of beauty, was given, as in it the artist had produced a perfect ideal of the human form. Another statue of a young man, called 'Diadumenos,' represented the subject fastening a band around his head. A group of two naked boys called 'Astragalizontes,' playing with bones the game of tali, is also celebrated, as are some statues of Canephoræ, female figures carrying baskets on their heads. His

statue of Hera, in the temple between Argos and Mycenæ, was thought by Strabo to be equal to Phidias' chryselephantine statues of Zeus and of Athena. The goddess was represented enthroned, wearing a garland on which were wrought the Graces and Hours; in one hand she held a pomegranate, and in the other a sceptre surmounted by a cuckoo. The head, breast, arms and feet were of ivory, and the robe of gold. As an architect Polyclitus won special fame from the theatre and rotunda, which he designed for Epidarus, which Pausanias pronounced to be the finest buildings of their kind ever erected. Polyclitus also wrote a treatise on the proportions of the human form. In addition to his fame as a statuary he has that of an able architect. One of his works, the theatre within the precincts of the temple of Æsculapius, at Epidaurus, was considered by Pausanias superior for its symmetry and beauty to any similar edifice extant.

POLYCRASE, a black, resinous mineral, occurring in prismatic crystals, chiefly in the granite of the island of Hitteræ, Norway, and in the Carolinas. It is of value for the rare earths which it contains, its composition being a mobate and titanate of yttrium, erbium, cerium and uranium.

POLYCRATES, pŏ-lĭk'rą-tēz, Greek tyrant of Samos; d. 522 B.C. He was one of the most daring, successful and treacherous of the Greek tyrants. Toward the end of the reign of Cyrus, about 535 B.C., with the aid of his brothers, Pantagnotus and Syloson, he conquered the island of Samos which had until then been free, and by banishing one brother and executing the other firmly established his power as sole ruler of the island. He raised a fleet of 100 vessels manned by 1,000 archers, seized several of the surrounding islands, conquered Miletus and defeated the Lesbians who came to assist the inhabitants of the latter city. Fired with the purpose of conquering the Ionian cities and the islands of the Ægean he formed an alliance with Amasis of Egypt. Herodotus informs us that Amasis, fearing the anger of the gods at the extraordinary good fortune of Polycrates in his many expeditions, persuaded him to make a sacrifice to the gods to avert misfortune. Polycrates thereupon threw into the sea a signet-ring of great value, which was found a few days later in the maw of a fish presented to him. Amasis considering his ally's doom certain, withdrew from the alliance. Grote, however, considers this story a fiction, and holds that it was Polycrates who broke off the alliance, perceiving it to be more to his interest to cultivate the friendship of Cambyses, who in 525 B.C. invaded Egypt. Polycrates sent to Cambyses 40 ships manned by the malcontents of his kingdom with the understanding that they were never to return. They escaped, however, returned to Samos and made war upon Polycrates, but were defeated, whereupon they gained the assistance of the Spartans and Corinthians and laid siege to Samos for 40 days, then abandoning the war. Polycrates continued prosperous, becoming more and more powerful until Orœtes, satrap of Sardis, nourishing a deadly hatred against him, treacherously contrived to lure him to his palace where he had him crucified. Herodotus says of Polycrates (iii, 125) that he perished in a manner unworthy of himself and of his high designs, and that none of the Greek tyrants, with the exception of those of Syracuse, were to be compared with him in greatness of character.

POLYDIPSIA, excessive thirst, such as usually accompanies diseases in which high temperatures occur. In diabetes especially it is a characteristic symptom, and the name polydipsia was formerly often given to this disorder. See DIABETES INSIPIDUS; DIABETES MELLITUS.

POLYEUCTE, pō'lē-ėkt'. Polyeucte was an Armenian Christian who suffered for his faith under the persecutions of the Emperor Decius and was afterward canonized, his day being the 9th of January. His name would no doubt to-day be no more widely known than that of the obscurest of the noble army of martyrs had not Pierre Corneille chanced to see in the story of his conversion and martyrdom the material for a tragedy and created from it a masterpiece, with the result that, as he said, «many have learned the name of Polyeucte rather in the theatre than at church.» It was a bold venture to use the language and sentiments of Christian faith on the stage, where the prestige of classical models had established the mythology of antiquity. They were held to be too sacred for such profane use. Corneille's friends of the inner circle of taste of the Hôtel de Rambouillet remonstrated with him and predicted the failure of his play. But they were wrong. His picture of the triumph of faith in the heart of the new convert and of the serene and joyful courage with which it is confessed, more still perhaps the appealing figure of Pauline, one of the noblest of Corneille's women, so steadfast in her wifely duty in the shock of the unexpected return of the lover mourned for dead, so surely after the manner of the Cornelian hero, the «captain of her soul» won the applause of the public. It proved to be one of the most successful of his plays, as it is one of the best. It is the one that is perhaps the most wholly his own creation, the most happily constructed dramatically, the most noble and at the same time most simple in thought and language. The critics continued to disapprove its use of religion, and the 18th century quite discredited it as offensive both to its taste and to its opinions. But the 19th century restored it to the rightful place of honor, which it continues to hold.

ARTHUR G. CANFIELD.

POLYGALA, a genus of annual and perennial herbs and shrubs of the family *Polygalaceæ*. The species, of which about 200 have been described, are widely distributed in temperate and tropical climates; about 100 are North American. Some of the exotic species are cultivated in gardens and greenhouses; for example, *P. paucifolia*, common from Nova Scotia to Manitoba and south to Georgia; and *P. chamæbuxus*, a European species. The former is popularly known as gaywings, fringed milkwort, flowering wintergreen, and fringed polygala; the latter as box-leaved milkwort. *P. lutea* is one of the handsomest American species. The roots of *P. senega* and of *P. crotalarioides* have been reputed remedies for snake bites, the former in America, the latter in the Himalayas. The American species is known as snake-root, seneca-root, senega-root and mountain flax. *P. polygama*, a native from Nova Scotia to Manitoba and southward to the Gulf States, has attractive flowers above ground and many flowers which are developed underground. In general the hardy species thrive best in moist soil in low situations. The seed is sown in early spring or in autumn. In greenhouses the plants succeed well in ordinary light soil which must never be allowed to dry out. The first mentioned species may be propagated by division.

POLYGAMY, the condition of a man having more than one wife at the same time. Etymologically considered, the word would signify plurality of husbands (polyandry) as well as plurality of wives (polygyny); it is employed here in the latter (the usual) sense. Polygamy among barbarous people is customary, though among them — as indeed wherever polygamy is allowed — plurality of wives is not usual except in the upper classes. The law of monogyny (one wife), we learn from Tacitus, was most strictly observed among the Germani; «almost alone among barbarians,» he says, «the Germani are content each with one wife»; yet he says that their chiefs had the right to marry several women at the same time. A custom of promiscuous marriage existed among the ancient Britons; any number of men would form a society and take an equal number of wives in common; the children born were the children of all; a like community of wives is suggested by Plato in his ‹Republic.› Polygamy was allowed among the ancient Greeks, but seems to have been rarely practised. It was never customary among the ancient Romans, though no Roman law prohibited it. Mark Antony is reputed to have been the first Roman to have at once two wives; under the empire polygamous unions were not infrequent whether in the imperial house or in the class of the very rich. Laws to prohibit polygamy in the Roman state were first enacted under Theodosius and under his two sons, Honorius and Arcadius; they were abrogated by Valentinian I. The Merovingian kings of the Franks, we learn from Gregory of Tours, were polygamous, and the same author says that Charlemagne had a numerous harem of wives. Martin Luther formally approved the taking of a second wife, the first living, by the landgrave of Hesse. The Jewish laws permitted polygamy, but probably here again the practice was confined to the wealthy class. In all Christian countries polygamy is condemned by the law of the churches and prohibited by the laws of the state under penalties. In England, till the reign of James I, matrimonial questions were matters of ecclesiastical cognizance only; but under James a statute was enacted making death the penalty for polygamy. The Mormons in Utah openly professed and practised polygamy from their first settlement there till 1890 when Congress enacted drastic laws for its suppression, and it was not till after the people of Utah had constitutionally abandoned polygamy that the Territory was admitted into the Union as a State (4 Jan. 1896). Since then it is declared that the sect still adheres to its belief in the lawfulness and the meritoriousness of polygamous unions; and though they no longer openly practise it, polygamous unions among them — crypto-polygamous unions — are not rare, as is evident from the testimony before the Senate committee in March 1904. See Mormons.

POLYGLOT (Greek, *polys*, many, and *glotta*, language), a work which contains the same matter in several languages, especially a copy of the Holy Scriptures in two, three or more languages. The most important of such works is the Complutensian polyglot, prepared under the direction of Cardinal Ximenes. It was printed (1514–17), in six folio volumes, at Alcala de Henares, called in Latin *Complutum*, whence the name of the work. It contains the Hebrew text of the Old Testament, with the Vulgate, the Septuagint, a literal Latin translation, a Chaldee paraphrase (which is also accompanied by a Latin translation). Next is the polyglot of Antwerp, called the Royal Bible, because Philip II of Spain bore part of the cost of publication. It was edited by the Spanish theologian Montanus, and appeared at Antwerp in eight folio volumes (1569–72), and, besides the Hebrew text, contains the Latin Vulgate, the Septuagint (with a literal Latin translation), several Chaldaic paraphrases (Targums), also accompanied by a Latin translation, and the New Testament in the original Greek, with the Latin Vulgate, and a Syriac translation in Hebrew and Syriac letters (also with a Latin translation). Still more celebrated is the Paris polyglot, executed principally under the direction of Gui Michel le Jay, who expended his whole fortune on the undertaking. It appeared in 1645, in 10 folio volumes, and contains, in addition to the contents of the Antwerp polyglot, a Syriac and an Arabic translation (with Latin), and also the Samaritan Pentateuch (a Samaritan text, with a translation), and likewise an Arabic translation of the New Testament, with a Latin translation of the same. The London or Walton's polyglot, in 10 languages, appeared in six volumes folio, with two supplementary volumes (London 1654–57). It was conducted under the care of Bryan Walton, afterward bishop of Chester, and contains all that is in the Paris Polyglot, but with many additions and improvements, including the original text according to several copies, with an Ethiopic and a Persian translation, and the Latin versions of each. Cromwell patronized the undertaking. Bagster's Polyglot (folio, London 1831, with later editions) gives eight versions of the Old Testament and nine of the New. The term Hexapla is applied particularly to Origen's work, an edition of the Scriptures having nominally six versions in parallel columns, though in places there were nine, viz.: (1) The Hebrew text in Hebrew characters; (2) the same text in Greek characters; (3) Aquila's version; (4) that of Symmachus; (5) the Septuagint; (6) the version of Theodotion; (7, 8, 9) Greek versions of unknown authorship. Origen had also a Tetrapla, an edition of the Greek Testament in four parallel columns.

POLYGNOTUS, pŏl-ĭg-nō'tŭs, Greek painter, flourished from 450 to 410 B.C. He was a native of the Island of Thasos, and with his brother Aristophon was instructed in their art by their father Aglaophon, a famous painter of that island. Cimon, the commander and rival of Pericles, brought him to Athens on the subjugation of Thasos, and employed him to decorate the Stoa Pœcile, or painted portico at Athens. Micon and Panænus assisted him in painting the Pœcile. His two principal pictures there represented 'The Capture of Troy' and 'The Battle of Marathon.' In the Lesche (hall) built by the Cnidians at Delphi he painted the 'Conquest of Troy' and 'Descent of Odysseus into Hades,' which are described by Pausanias. Polygnotus is represented as being the first who gave life, motion, character and expression to the countenance, and skilful disposition to the drapery. His works are without perspective or shading, and consisted only of outlines against a colored background. Yet the nobility and fineness of his drawing and the excellence of his composition, made them justly celebrated. Pliny describes him as "the first who painted women with transparent drapery, and covered their heads with variegated caps. The first to begin to open the mouth and show the teeth of his figures, and to give them an expression of countenance different from the ancient stiffness."

POLYGON, *in geometry,* a plane figure of three or more angles and sides. A polygon of three sides is termed a *triangle;* one of four sides, a *quadrilateral* or *quadrangle;* five sides, a *pentagon;* one of six sides, a *hexagon;* one of seven sides, a *heptagon;* and similarly we have *octagon* (8), *nonagon,* or more properly *enneagon* (9), *decagon* (10), and so on. *Similar polygons* are those which have their several angles equal each to each, and the sides about corresponding angles proportional. All similar polygons are to one another as the squares of their homologous sides. If the sides are all equal and the angles are likewise all equal, the polygon is said to be regular; otherwise, it is irregular. The angle of a regular polygon of n sides is $\pi\left(1-\frac{2}{n}\right)$. Every regular polygon can be circumscribed by a circle and have a circle inscribed in it. A skew polygon is a closed figure made up of consecutive linear segments not all lying in one plane. See GEOMETRY.

POLYGON OF FORCES, a diagram used in graphic statics, depending upon the following theorem: "If any number of forces acting upon a point be represented in magnitude and direction by the sides of a polygon taken in order, they will be in equilibrium," or "any side of a polygon, taken in reverse order, will represent the magnitude and direction of the resultant of any number of forces acting upon a point, when these forces are represented in magnitude and direction by the remaining sides of the polygon taken in direct order."

POLYHALITE, a brick-red or yellowish, fibrous or massive mineral, occurring mostly in closely compacted fibrous masses. It is best known as one of the salts from Stassfurt, Germany, though it is found associated with salt, gypsum and anhydrite in other salt mines in central Europe. It is a hydrous sulphate of calcium, magnesium and potassium.

POLYHEDRON, *in geometry,* a body or solid bounded by many faces or planes. When all the faces are regular polygons similar and equal to each other the solid becomes a regular body. Only five regular solids can exist, namely, the tetrahedron, the hexahedron (or cube), the octahedron, the dodecahedron and the icosahedron, having respectively 4, 6, 8, 12 and 20 faces. In the first, third and fifth the faces are equilateral triangles; in the dodecahedron they are regular pentagons; and in the cube they are squares.

POLYHYMNIA, or POLYMNIA (Latin from Gr. Πολυύμνια or Πολύμνια), according to the later Greek poets the Muse of lyric song and of eloquence, daughter of Jupiter and Mnemosyne, who presided over singing and rhetoric, and was deemed the inventress of harmony, to whom is attributed the invention of the lyre and of mimes and pantomimes. The Greek artists represented her enveloped in a mantle, crowned with a wreath of flowers, and in a meditating posture. She was sometimes represented veiled in white, holding a sceptre in her left hand, and with her face raised up as if ready to harangue, or with the forefinger of her right hand on her mouth. See MUSES.

POLYMASTODON, a fossil animal found in the Eocene beds of New Mexico. In some features it resembled the rodents and was about the size of the beaver.

POLYMIGNITE, a highly complex, black mineral found in the zircon-syenite of Frederickswarn, Norway, in slender orthorhombic prisms. It is a niobate, titanate and zirconate of the cerium metals, iron and calcium.

POLYMORPHISM, *in biology,* that condition in which different kinds of individuals appear in the same species. In the animal kingdom it has its greatest exemplification in the group of Siphonophoræ, where the whole colony is made up of members, all reducible to a common type, which are specialized for the functions of floating, swimming, reproduction, eating and touch. Among the free forms it is not so common, but still is not rare. Thus among insects we find butterflies in which not only the males and females are different in their markings, but among the females different patterns may be easily recognized; in fact, so different may they be that did we not know their life-history we should not regard them as belonging to the same species. Where but two forms are known, the phenomenon is called Dimorphism. See EVOLUTION.

POLYNESIA (Greek, *polys,* many; *nēsos,* island), a geographical name applied collectively by some writers to all the Pacific islands of strictly oceanic character, i. e., either of volcanic or coralline origin; by others restricted to the vast island-dotted region extending from southeastern Asia across the Pacific, and from Bering Strait southward to the Antarctic Ocean, also called Oceania. In an ethnological sense the term applies to the eastern groups inhabited by the brown Polynesian race. A more exact method is the common division into several sections: Australasia comprises Australia, Tasmania and New Zealand, with other islands adjacent. The numerous islands extending from the Malay Peninsula to New Guinea are known collectively as Malaysia or the Malay Archipelago. The Philippine Islands are often associated with those of Malaysia proper. The name Micronesia (Greek *mikros,* small, and *nēsos*) is commonly used as a collective name for the numerous small islands in the northwestern Pacific, between New Guinea and Japan; and Melanesia (Greek *melas,* black, and *nēsos*) includes New Guinea and a chain of islands extending southeastward to the Fiji Islands and New Caledonia, all chiefly inhabited by Papuan races. All the remaining islands, comprised for the most part within the parallels of 30° N. and 30° S. latitude, and between the meridians 180° and 120° W. longitude, constitute Polynesia in the more definite sense of the term. Yet it should be remembered that although the word «Polynesia» as a collective name for these islands has been sanctioned by general custom, the title expresses a purely arbitrary division that is founded upon no geographical, national, racial or linguistic basis. Polynesia has never formed a national unit, and the name must be taken only as a convenience to express certain islands and groups of islands in the Pacific which are inhabited by people of the same stock and linguistic family, but which do not by any means comprise the entirety of this people within their limits. The following table gives a survey of the size, approximate population and political connections of the three «nesian» groups. For the sake of reference, those islands which belonged to Germany before the World War are still marked thus in the table:

GROUP	Area square miles	Population	State
POLYNESIA:			
Hawaii	6,700	250,627	U. S.
Fanning	15	200	Gt. Brit.
Ellice	14	300	«

Fiji	8,000	140,000	Gt. Brit.

These groups of «South Sea Islands» are scattered over a hundred degrees of longitude from New Britain (149° E.) to Easter Island (109° 17′ W.) and across 70 degrees of latitude from Hawaii (23° N.) to Stewart Island at the southern extremity of New Zealand (47° 20′ S.). In this vast area of about 11,000,000 square miles of water there is hardly more than 170,000 square miles of land, of which nearly two-thirds falls to the New Zealand Archipelago, lying within the Polynesian group. The total population is perhaps under 2,000,000. Practically all the Pacific islands are now in the possession of Great Britain, France and the United States; until the World War 1914–18 some belonged to Germany. Spain at one time held extensive possessions in the Pacific; the Netherlands own the western half of New Guinea and nearly the whole of Malaysia. The islands of Polynesia proper may all be classified as volcanic or coralline, the former having an irregular surface and a higher elevation than the latter, which are low and rarely elevated above 500 feet. The atoll formation is common. Some of the smaller islands are of value only for their guano deposits. The indigenous fauna is remarkably deficient in terrestrial mammalia, the only kinds at all generally distributed being bats. The avifauna is large and interesting and several species of snakes are found in the western islands, while insects and molluscs abound in profusion. The cocoa-palm flourishes throughout all Polynesia and the sago-palm in the west. Bread-fruit, yams and the taro are staple articles of cultivation. Some of the islands, chiefly in the west, have an extensive and peculiar flora, but others, especially the more easterly, are poor in species. Though Polynesia lies almost entirely within the tropics, its climate is generally temperate and very salubrious, owing to the influence of the ocean.

The discovery of the islands began with Magellan's voyage in 1520, when he found the Ladrones, but it was not until Mendaña's expedition in 1567 that any of the large groups became known to Europeans. Mendaña also discovered the Solomon Islands. Finding gold in use among the natives, he concluded that he had found the Ophir of Scripture and named the islands after King Solomon. He made the mistake of charting them in the wrong longitude, with the result that for a long time the islands were «lost» and geographers, doubting their existence, omitted them from the maps. Mendaña himself could not find them on a second voyage in 1595, but he then discovered the Marquesas and one of the Union group. These, again, were «lost» until rediscovered in 1769 by the French navigator Surville. Quiros, formerly pilot to Mendaña, discovered Tahiti and the northern of the New Hebrides in 1606. Ten years later, Schouten and Le Maire, Dutch navigators, discovered the most northerly islands of the Tonga group and several small Polynesian atolls, but they missed the main groups of Tonga and Fiji. These were left for Tasman (q.v.) to find some 26 years later. Van Diemen, the Dutch governor at Batavia, sent out an expedition under Tasman in 1642 with momentous results, for not only were the remainder of the Tonga and Fiji groups discovered, besides numerous other islands, but also New Zealand, Tasmania and the great continent of Australia. French and English navigators led in discoveries during the 18th century. Wallis discovered the island that now bears his name in 1767 and De Bougainville discovered the Louisiades and the main islands of the Samoan group in 1768. The British geographer, Dalrymple (1737–1808), concluded that there must be a vast southern continent stretching from Australia to the South Pole. To test this theory Captain Cook's famous expedition was sent out by the admiralty in 1772. Though he naturally failed to find the continent which did not exist, Cook discovered the Raratongan group (Cook's Islands), Savage Island, the Loyalty Islands and the Sandwich group (Hawaii), though it appears from native tradition that a shipwrecked

European crew had been washed ashore at Hawaii some 50 years before. The French government despatched two frigates in 1785 under the command of the Count de la Pérouse (q.v.) to pursue scientific discovery in the South Seas. On 26 Jan. 1788 La Pérouse entered Botany Bay and handed the English governor there a package of papers to be sent to France. He set sail again on 15 March, after which the two vessels were lost to human ken. The papers duly reached their destination; the National Assembly published them and sent a naval expedition under D'Entrecasteaux to search for La Pérouse and his ships. On this voyage the D'Entrecasteaux group of islands on the eastern extremity of New Guinea were discovered. Forty years after the disappearance of La Pérouse an Irishman, Peter Dillon, landed at Vanikoro, an island of the Santa Cruz group, and found the relics of the La Pérouse expedition — but no survivors. D'Entrecasteaux might have found and saved them had he sailed further south. The last had died three years before Dillon's visit.

At the dawn of the 19th century Europeans were living on most of the large islands, mainly deserters from passing ships. The London Missionary Society sent out a number of artisan missionaries in 1799 to Tonga, Tahiti and the Marquesas. The mission to Tahiti flourished; the two others were subsequently abandoned. About that time whaling-ships began to frequent the South Seas and from this era dates the real colonization of the islands by white men. Unfortunately, however, the frequent deserters from the crews of these vessels were not a desirable type of settlers, so that the natives acquired their first knowledge of Europeans from the worst specimens of the race. A stream of real immigration began about 1850 through the influx of white traders and planters. The 16th century of Polynesian history belongs to the Spaniards; the 17th to the Dutch; the 18th to the English, and the 19th to the traders, whalers and missionaries of all nations. See MAORIS; MELANESIA; MICRONESIA; MYTHOLOGY, and the islands under their separate heads; also POLYNESIANS.

POLYNESIANS. Many studies have been devoted to the origin and migration of the Polynesian people. It has been maintained, largely upon undigested linguistic material, that they are of the Aryan race; with equal insistence certain other students on the same linguistic ground have assigned them to such intimate association with the Malay people as to predicate a Malayo-Polynesian race. Our real knowledge of the Polynesian people dates from their discovery by the great navigators in the islands of the Pacific which they now occupy. By legitimate interpretation of, and inference from, the very considerable body of Polynesian traditions, which have been collected, we may reason the past history of the Polynesian race back to its occupation of the islands now known as Indonesia, and at present occupied by Malayan peoples. Anterior to their residence at a remote epoch in Sumatra, which is abundantly confirmed by the persistence of a distinctly Polynesian strain in the Mentawei Islands, which lie off-shore along its western coast, we are lacking in data whereupon to predicate an earlier history of this race. Percy Smith, in 'Hawaiki,' proposes the identification of their ancestral home in the valley of the Ganges; dissection of certain of the linguistic material seems to suggest with equal plausibility an earlier home in conditions which most closely correspond to those of the Hadramaut of southern Arabia in the present day. With our present material the matter seems incapable of solution. Assuming, then, as susceptible of satisfactory establishment, their former residence in certain of the larger islands between Sumatra and the Philippines, we can picture to ourselves a race of people on a plane of culture which may fairly be classed as neolithic, that is to say, in possession of wooden and polished stone implements which could serve for offense or defense, according as the daily need arose. It is also clear that they were in possession of the arts of navigation to a very satisfactory extent. Upon people of this cultural plane broke in an irruption of a race of higher culture as shown by the possession of weapons of mild steel. In the datable chronology of Hindustan, this irruption may be established as the entrance of Malayan ancestors into Sumatra 400 years B.C. The possession of the superior weapon of offense meant the extermination of the club-armed Polynesian ancestors or their migration in search of a safer home, and their possession of canoes and their knowledge of how to ply the sea, led to the adoption of the latter alternative. It now becomes incumbent to examine the postulate of a Malayo-Polynesian race. This was proposed by Bopp in the second quarter of the last century, entirely upon linguistic grounds. It has been possible to collect the material which he was able to have under study and to determine that while the accessible material was sufficient to enable him to make an intelligent study of Malayan languages, the material at that time in existence pertaining to Polynesian languages was so scanty in extent and so poor in quality as to render his results entirely unworthy of credence. There remains, however, a certain speech community of Malayan and Polynesian; this amounts to little more than 250 words and the modern explanation of this community is that these words are Polynesian, which became incorporated in Malayan as loan material derived from their captives at the period of the great expulsion from Indonesia. Physically the Polynesians are one of the most attractive of the human race and are marked by a stature which, with the doubtful exception of certain Patagonian peoples, represents the highest growth of humanity. With some interesting traces of the matriarchate, Polynesian society is rather genetic than political. Each family exists as a social unit, holding all its goods in common, the chief is the family head, who is selected by common agreement from the members of that family and it is not uncommon to find the position of chief thus held by women; in general, there is no priestly class, but the functions whereby intercourse is had with the departed who have become family gods are exercised by the chief as priest. There is a wide distinction among the gods, the higher gods are self-existent, their sole activity the original creation of this world and its inhabitants, indifferent to the course of current events and not to be moved by prayer; the lesser gods are spirits which have already undergone a human existence and may, therefore, be the object of supplication, as possessing a certain sympathy with the affairs of mankind. In the highest degree the religion of the Polynesians has no connection with ethics, the moral sense and the doctrine of punishments being entirely dependent upon the tabu. The tabu is a moral prohibition; in its greater sense it may be considered as an unknown foundation of social life, in its minor sense it may be imposed for temporary and temporal uses by any person in possession of authority over the object with which the tabu is associated. The tabu is self-executive, its violation provides its own punishment and in the sensitive conscience of the Polynesian this punishment is not to be evaded. It has been found possible to establish a beginning date of the Polynesian migrations as fixed by the Malayan irruption under Aristan Shar in 400 B.C. Detailed study of Polynesian traditions makes it plain that there were two ways of migration. The earlier, that to which the name Proto-Samoan has been applied, appears to have reached the Central Pacific, that is, Samoa, Tonga and Fiji, about the Christian era. Upon this first settlement there swept a second wave of migration, that which by the Samoans is called the Tongafiti, some 600 years later. The Tongafiti were in possession of a decided advance in the arts of life and were able to rule the Proto-Samoans as a subject people for several centuries; finally, at a period very nearly contemporaneous with the Norman conquest of England, the Proto-Samoans were able to throw off the yoke of the oppressor and then began the second era of migrations in the Pacific, whereby the Tongafiti, with more or less Proto-Samoan companionship, advanced to the settlement of the more remote islands from Samoa as a distributing point. It has been possible to establish this duality of the Polynesian migration waves by a philological examination of the different Polynesian languages. This diversity is also found in the scheme of the god-head. The Proto-Samoans recognize one god, Tangaloa, the creator, held in reverence but not the object of prayer nor of sacrifice; the Tongafiti had arrived at a conception of four great gods. Tu, Rongo, Tane and Tangaloa, of whom the last was reduced to a position of small relative importance. The Tongafiti centred all their worship of the great gods in the act of human sacrifice. In certain of their branches they had arrived at the Messiah idea of a god who should return to bring blessing to his people; the vanished god was Rongo, and it was an offshoot from the belief that Captain Cook was Rongo, returning for the salvation of his people, that led to the death of that great navigator at Kealakekua, in Hawaii. The first result of the contact of European civilization with these happy islanders was deplorable, for to a people who had not acquired constitutional immunity the simplest ailments of our life, coughs and measles, led to a rapid increase of the death rate. For many years the population of Polynesia seemed to be progressing rapidly toward extinction, but in the present century, the records show an upward turn, and it is probable that the race will be able to adjust itself to the new conditions. In general the Polynesians have made but a superficial advance in the new culture, but in Hawaii, and among the Maori of New Zealand it has been abundantly established that they are capable of taking a position quite on an even plane with the British and Americans with whom they are associated. Much has been written upon the Polynesian race regarded as elements of a political problem, or as a social problem. As bearing upon their ethnic position, the principal works of reference are the *Journal of the Polynesian Society* (New Plymouth, New Zealand, current), Smith, S. Percy, 'Hawaiki' (Wellington, New Zealand 1910); Churchill 'The Polynesian Wanderings' (Carnegie Institution, Washington 1911); Dixon, Roland, 'Mythology of all Races: Oceanic' (Boston 1916). See also POLYNESIA; BIBLIOGRAPHY.

WILLIAM CHURCHILL,
Author of 'Polynesian Wanderings,' etc.

POLYNICES, pŏl-ĭ-nī'sēz, brother of Eteocles. See ETEOCLES AND POLYNICES.

POLYOLBION, pŏl'ĭ-ŏl'bĭ-an, **The**, a long descriptive poem (1613–22), by Michael Drayton. It is in effect a topographical survey of Great Britain, containing, with much other matter, descriptions of shires, rivers, mountains and forest tracts, and is not only of interest to the antiquarian, but to others as well, its accuracy as an authority being generally conceded.

POLYP, a term variously and indiscriminately applied to different animal forms, but properly designates a cœlenterate of the class Actinozoa, represented by the sea anemones, corals and the like, or any member (or zoöid) of a compound organism belonging to that class. The term *polypide* is also employed to designate each member or zoöid of the compound forms in the Polyzoa. The name *Polypidom* applies to the entire outer framework or skin-system of a compound form, such as a hydrozoan, zoophyte or an individual polyzoön. The word *polypite* refers to each separate zoöid or member of a compound zoophyte or hydrozoön, and is thus used in opposition to the term *polypide* already explained. The *polypary* of a hydrozoön specially refers to the horny or chitinous skin secreted by the hydrozoa. See CŒLENTERATA; HYDROZOA; MOLLUSCA; POLYZOA, etc.

POLYPHASE SYSTEM. See ELECTRICAL TERMS.

POLYPHEMUS, pŏl-ĭ-fē'mŭs, one of the Sicilian Cyclopes. He was a son of Poseidon and the nymph Thoösa and lived in a cave in Mount Ætna. Ulysses and his companions, driven by the storm to take refuge on the island, found shelter in the cave of Polyphemus and were found there on the return of the monster. He devoured two of the company and shut the remainder in the cave. Ulysses contrived to intoxicate Polyphemus with wine and when he fell asleep put out his single eye and then with his comrades escaped. The storms which followed Ulysses at sea were visited upon him by Poseidon in answer to the prayers of Polyphemus. Polyphemus was a suitor of the nymph Galatea and upon her accepting Acis the disdained lover killed his successful rival. In zoology the term is applied to a genus of Ostracoda, having a large head almost entirely occupied by an enormous eye.

POLYPHEMUS MOTH, a large American silk moth (*Telea olyphemus*) of a yellow-brown color, with spotted wings. The caterpillar is of a light-green color with yellow markings; the cocoon is oval and is generally enclosed in foliage.

POLYPHONY, *in musical composition*, the harmonious combination of two or more parts, each of which forms an independent theme, but progress simultaneously according to the laws of counterpoint. A fugue is the best example of polyphonic compositions. See COUNTERPOINT.

POLYPODIUM, a genus of ferns of the family *Polypodiaceæ*. The species, of which more than 350 have been described, are widely distributed throughout the world, mostly in dry situations such as banks, walls, logs and cliffs. Some tropical species are epiphytic. Many are popular as garden or greenhouse plants. Among the best known is the common wall-fern or polypody (*P. vulgare*), a widely distributed native of Europe and North America. It is one of the most satisfactory garden ferns. See FERN AND FERN ALLIES.

POLYPORUS, a genus of parasitical fungi, forming shelf-like growths on the trunks of trees and contributing to the decav of timber. It is the typical genus of *Polyporaceæ*. See FUNGI.

POLYPTERUS, a genus of ganoid fishes of a single species, *Polypterus bichir*, inhabiting the Nile, Senegal and other rivers of Africa. It attains a length of about four feet and lives in the mud at the bottom of rivers, where it crawls by means of its fins. It is capable of swimming with great rapidity. See BICHIR; ICHTHYOLOGY; MUD-FISH.

POLYPUS, *in pathology*, any tumor which forms chiefly in a mucous membrane, and which is more or less pedunculated and rounded in form. (See TUMOR). In zoology a class of radiated animals having many prehensile organs radiating from around the mouth only.

POLYTECHNIC COLLEGE, an institution of higher learning, located at Fort Worth, Tex. It was changed from a coeducational institution to Texas Woman's College (devoted exclusively to the education of women) in September 1914. The bachelor of arts is offered, the bachelor of science being discontinued, effective June 1915. In connection with the college are the school of fine arts, school of household economics and the academy. The commercial course has been discontinued. Buildings and grounds are valued at $300,000. The faculty numbers 40 and the average enrolment is in excess of 300 students.

POLYTECHNIC INSTITUTE OF BROOKLYN, founded in 1854 under the name of the Brooklyn Collegiate and Polytechnic Institute. It conferred its first collegiate degree in 1871 by special authority of the State board of regents; and in 1890 was reorganized under its present name with larger corporate powers and a full college charter. The institute now offers four undergraduate courses of four years: (1) chemistry, leading to the degree of B.S.; (2) civil engineering, leading to the degree of C.E.; (3) electrical engineering, leading to the degree of E.E.; (4) mechanical engineering, leading to the degree of M.E.; (5) chemical engineering, a five-year course leading to the degree of chemical engineer; also graduate courses of one year; science, in the department of civil, electrical and mechanical engineering, leading to the degree of M.S. The laboratories are well equipped, and there is an observatory with an equatorial telescope, and museum collections in geology, zoology and palæontology; the library, a memorial to Uriah D. Spicer, numbers 12,000 volumes. The preparatory school is closely affiliated with the institute, and is not only designed to prepare students for the institute, but also prepares them for other colleges and scientific schools. The students, including those in the preparatory school, numbered more than 1,200 in 1918. The institute is one of the oldest educational institutions of Brooklyn, and counts among its graduates many of the most influential men of the city.

POLYTECHNIC SCHOOLS. See EDUCATION, SCIENTIFIC AND TECHNICAL.

POLYTECHNIQUE, originally a French educational institution in which the technical sciences that rest in great part upon a mathematical basis, such as engineering, architecture, etc., are taught. The first school of the kind was established in Paris (1794) by the National Convention, under the name of School of Public Works. No students were admitted but those who intended to enter the public service, especially the corps of civil and military engineers and the artillery. The Polytechnic School, as it was called from 1795, has been repeatedly reorganized as the different political parties have succeeded to power. At the present time it is the institute in which France trains her artillery and engineer officers, her naval engineers, her directors of roads and bridges and of mines, her telegraph officers, in short, all her officials who require to know something of the higher branches of technical science. The Minister of War exercises supervision over the school. The degree of bachelor of arts is a prerequisite for admission to the entrance examinations. The course extends over two years and successful graduates after the final examinations elect the special branch of the public service to which they wish to attach themselves. Soldiers in service are admitted to the Polytechnique under special conditions.

POLYTHEISM, *in sophiology,* or the science of human conceptions, term employed to designate the doctrines peculiar to the ontologies of most mythological philosophy of a plurality of gods, as well as the primitive theories of knowledge out of which such doctrines proceeded. Polytheism, thus characteristic of an ontological doctrine, designates in particular all theologies which are part and parcel of an exceedingly primitive world-conception. The most obvious task in sophiology in this connection is to restate the definition of a concept, an idea; and then briefly to lay open the common character inherent in the idea of a god, the idea of a polytheon and the idea of God. And it is equally obvious that to find such common characteristics, modern prepossessions must be set on one side: we must boldly enquire: What is the minimum definition of God?

Before proceeding to these definitions let us review the situation under polytheism as a whole. For the purposes of study, sophiologists conceive of three very general phases in the development of human thinking. Distinguishing these according to the methodology peculiar to each of these phases, they have characterized human philosophies as mythological, metaphysical and critical. As every philosophy implies at least an embryo-ontology, so have we characterized the doctrine of many gods, or of a polytheon, as the theological portion of mythological ontology. For, in truth, mythology is not religion; it is primitive philosophy or science. It is religious in so far as it is theological science. And, of course, as theological it is philosophy or science of a sort that owes its origin to the existence of religious experience in the heart of man. The simplest savage who wonders at the unseen but mighty wind that streams from unknown realms of power has already felt that which abides unchangeably amid the flux of the phenomenal world; has already felt that which inspires religious feeling and its volitional consequents, cults and philosophically formulated theologies, such as polytheism. For religion is essential humanity. The wild beast to escape the storm shrinks growling into the cavern called its den. But on the same occasion the most abject human savage, awe-stricken, turns, falls and prays. The lowest man perceives a hand behind the lightning. He hears a voice abroad upon the storm, and for both these things the highest brute has neither eye nor ear. Nor is even an atheist without religious experience, unless he is inhuman. For there can be little doubt that there are at present those who are atheists only in this sense, that they merely deny every particular theism on the ground that it is an *inadequate* expression of the whole mystery of being. Now that can be no profound thinker who is without any sympathy for such a position. Again: to deny our need of religion is one thing; to deny its existence altogether in the human heart is quite another. Schleiermucher stood upon a rock when he asserted the self-authentication of the religious consciousness. For the variations among theologies, polytheistic, herotheistic or monotheistic (which are philosophies), can no more affect the experiences which constitute and succeed the spiritual new birth of anyone, than the variations among biologists can affect one's assurance that he is alive. Yet as some there be who have an atrophied intellectual consciousness, and are idiotic; so some, too, it may be granted there may be who have an atrophied spiritual sense and are inhuman. But if any possess a religious mythological philosophy, or theology, we may be quite certain that they likewise share the religious experiences. In this way even polytheism expresses the religious life of man.

Religion then, in a polytheist even, is not the intellectual formulation, in the shape of dogma, or doctrine, of mankind's conscious relation to God, a relation which all feel. Such formulation on the contrary is the work of philosophers. Principles thought to be discovered of man's relationship to the ultimate grounds of being are gathered and made into a group, a «science»; and the cultivation of this «science, or mythic system becomes, in primitive culture periods, the duty of a special class. This class is that of the priest, shamans, rab-mags, bikshus, magicians or wabeno-men. All are primitive philosophers. Thus we come to the idea of religion in the widest sense, as the perception of the supernal world together with the effects of that perception on the complex nature of man; while theology, in a way commensurate with this idea of religion, is understood as that perception and its consequences reduced to system however crude. Examples of such theologies are still extant; some systems are now building. The earliest systems are the mythical systems of polytheism which originated under influences of the experience of our most remote ancestors.

What meaning had his surroundings to primæval man when eye and ear could be directed from the prior claims of the body? (See MYTHOLOGY). In his first outlook upon the world man was altogether ignorant of the character of nature's real powers by which from the very beginnings of human life he was circum-environed. Poorly endowed with reason and blunt of sense-perception, he beholds the cold wave sweep from the north; and rivers and lakes he sees freeze over. Great forests are buried under a white mantle of snows. Piercing winds almost congeal the very life-fluids of man himself; while his source of food — the lakes and streams — lie strongly encased in a carapace of ice. Another time the sky assumes the dull appearance of a dome of brass. Midsummer heat pours down its beams upon the sands; and fiery blasts heated in a desert furnace destrov a scanty vegetation. And the fruits of the earth shrivel before the eyes of famishing men. Consider but one passage from the Bible, one originating in comparatively civilized times, under an experience, as when the voice of Jehovah sounded amidst the bursting forth of a mighty natural convulsion: «A thick cloud was upon the mount. The smoke thereof ascended as the smoke of a furnace. There were thunders and lightnings. And the voice of the trumpet exceeding loud. The Lord descended upon the mountain in fire, and the mountain quaked greatly.»

This word-pitcure comes from Exodus. It details, we think, a gigantic volcanic eruption. Mount Sinai was a volcano. How much more terrifying must have been the grandeur incident to such an experience in the soul of a poor, half-clad savage during the progress of a similar event? He stands nearby while lightning shivers a great tree and rends the skull of his companion. To a savage all nature's powers bring pain or joy, health or sickness, life or death. His well-being is involved in the answer he gives to his questions how? and why? No wonder then if at first man's attitude

of awe degenerates into slavish fear, when he presumed to confront the worlds and question them. And yet withal we find that throughout the whole mythologic period of «science,» man's sole measure of things was himself.

History in so far as it affects the inner life does not exhibit one continuous ascent. It reveals not alone rise and growth of creative effort in the philosophic field but likewise ensuing periods of exhaustion. It is in this way that it comes about that one finds recurring periods during which the human spirit manifests itself in tradition-guided behavior alone rather than in aspiration after philosophic formulation of its cosmic relations. It is only when again the human spirit retires into itself to take deeper root that new relations are perceived which need expression and explanation.

Even for the period, that of mythological philosophy, this is true. And as a consequence one may easily discriminate four phases of polytheistic thought. In one, perhaps this represents the earliest phase, everything presented to the savage mind is conceived of as alive.

An «orenda» or living magic power inheres in everything; every object is possessed of will and design. Rocks, trees, animals and men think and speak-so the earliest philosophers testify in their earliest myths. All the bright stars of heaven, the snow-clad mountains, bubbling springs, rivers, all are possessed of will and design. In this stage, every insoluble event and object is a god.

Thereupon follows a period when the savage philosopher no longer attributes life indiscriminately to all inanimate nature. But all the powers and attributes recognized in self-examination he transfers, attributing them to animals. Nowhere is the line drawn between man and beast. Men are zootheists, they worship beasts. And all the gods are animals. Zootheism persisted down to comparatively recent times. What but representatives of these gods are the gigantic zoomorphs in Yucatan and the animal-headed gods of Egypt and Assyria? And indeed there was even a scaly fellow in Paradise! Survivals of the time when all the gods were animals, and all natural processes were the doings of animal gods, are not difficult to find in mythologies.

In a third period a gulf is placed between man and all the lower animals. Animal gods are either dethroned or assume a subordinate station. Thereupon all nature's powers, all phenomena, are deified; and in the deification, anthropomorphized also. It is during this period that man worships the gods of the sun, moon, air, dawn, a deity of the darkness or one of night. Anthropomorphism is *not* absent from the Bible. In Genesis we find God walking about the Garden of Eden. With His own hands He fashions man and closes the door of the ark. He even breaths his own breath into man's nostrils, and makes *unsuccessful* experiments with animals! He scents the sacrifice of Noah. And, Othin-like, appears to Abraham and Lot in the guise of a wayfarer; or, as an angel calls directly out of heaven, God, in Genesis, verily speaks in all respects as does one man to another!

Finally a fourth, the highest, period of primitive philosophy is reached. During it, mental, moral and societal characteristics are personified, and thereupon deified. Thus was born the idea of a god of war, a god of love, a god of revelry, a god of plenty. These gods differ from all older nature gods chiefly in that they possess distinctively psychical characteristics. Many of them are among the first "moral" gods.

Religious conceptions, "theologies," thus comprehend above all that group of concepts which spring from man's relations to the supernal world; and this relation is of course always considered by philosophically inclined savages as not due to any physical activity merely, for all such activities or natural processes, they would naturally account for with purely rationalistic conceptions, as a matter of course. It is plain, therefore, that as man's knowledge of nature's laws widens, the domain of his supernal world shrinks in proportion. Theologies are always attempts to formulate just those truths considered necessary in man's struggle for existence. Of such theological opinions, ideas or conceptions, that of the gods, and the idea of God, remain even to this day the most important thoughts in human life. In all humanity, as well the lowest as the highest, there is an effort of some kind to express in doctrine man's conscious relation to the abiding in the transitory of the world. Such consciousness of a higher power is necessarily given when first the simple savage comes to such a stage of maturity that the fragmentariness of his creature life is contrasted instinctively with that in which he lives, and moves, and has his being. Thus conscious of a being more powerful, more abiding, greater than himself, man is constrained to establish some idea of that to which he must always submit. Hence arose those doctrines embodied in all polytheons, all pantheons, all aspirations to become one with God.

What is the minimum definition of God? A polytheon, a pantheon, or even the idea of God is always a world conception that dominates man's soul. In all polytheistic stages of belief, however, not all gods, even some of the higher orders, are necessarily objects of devotion. For there are in some polytheons, faineant deities, deities who are recognized as real but who do not exercise any influence in human affairs. Hence they are not worshipped. We are now prepared to understand a conception, and in particular that conception which at a minimum content conveys the idea of a polytheon, a pantheon, a god, or even of God. The definition of an idea, in particular a religious idea, and when it is familiar, even of its name, is an impulse to some activity, the usually sense-perceptive result of which is a term or member of the concept's scope. Now the word polytheism conveys the idea of many gods, monotheism signifies belief in God. What is common to both the nature of the idea of a polytheon, and the idea of God?

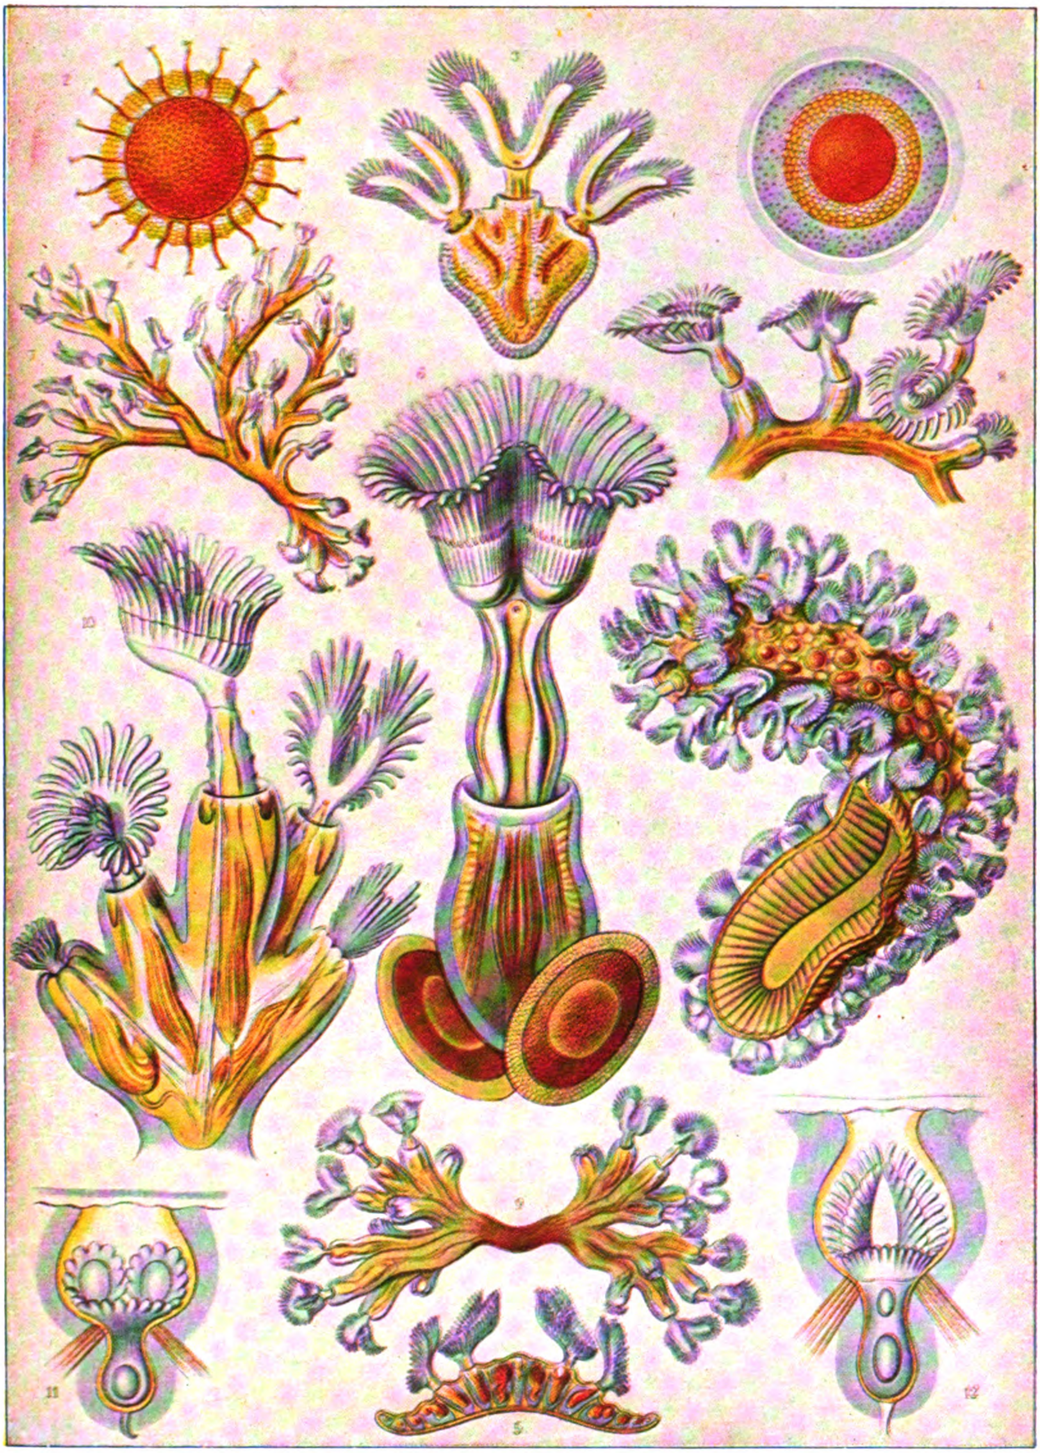
We understand by the nature of an idea its meaning. Now each and every creature properly human has to respect some higher power, a power that curtails his wishes. And each and every human being, therefore, adjusts himself to conditions; and so doing recognizes an authority of some kind to which he must submit on all occasions; and this authority of man's conduct, whatever it may be, is either his polytheon, his pantheon, his god or God. The mention of this authority even is an impulse to religious behavior. Its moral significance is without question. For even the (to us) immoral practices of savage and semi-civilized peoples prove that religion and morality, while distinct, are yet inseparable. A superstitious awe of a polytheon, yea even of God, leads to immoral practices. And in this way also a pure religion will unfailingly regenerate whoever possesses it.

But does it not make a difference whether or not the truth of the conception is mentioned in the definition of God? Maybe it does. For what do we mean by truth in this connection? In effect what one ought to mean by the truth or falsehood of the doctrine of deity is not the reality or otherwise of any events which are associated with its rise; but, on the contrary, the adequacy of the idea to inspire just such feelings and to constrain to just such religious behavior as will give expression to a believer's conscious relation to the ultimate grounds of existence, the abiding, in the measure that he *knows them*. And we are led to a second consideration in this connection. The late association of moral ideas with deity proves also to have been a fact. True ethical considerations were originally foreign to ideas of deity. In the first three stages of mythology, of the four phases mentioned above, all gods are neutral in so far as ethical qualities are concerned. Sacred awe too easily degenerates into slavish fear in the savage heart. The lowly beginnings of theology are strangely unlike its fruition. Only after having anthropomorphized the deities of his polytheon did man conceive of his gods as moral beings. For man, as a rational animal, alone is moral. Conceiving of his gods as possessing a human form, and in the days when ideas of kinship were first gaining clear recognition, early man transferred his own qualities, societal and moral, to his gods. Thus too, contrary to what Mr. Spencer says, ancestor worship was not primordial, but late, owing to the late recognition of the ties of kinships. Gods in the polytheons of the anthropomorphic age are thus usually revealed in the mythologies which have survived as organized into a tribe or other social groups. Thus arose the kinship features in all the higher mythologies, those of Vedic India and pre-Zarathustrian Iran, the polytheons of Semnites, Assyrians, Babylonians, Egyptians, Greeks, Romans, Chinese and Japanese, as well as in those of the Aztecs, Mayas, Peruvians, and in those of the natives of the Polynesian isles.

In the opinion of Jacob Grimm, polytheism almost everywhere arose in innocent unconsciousness. There is about it something soft and agreeable to one's feelings. It is never intolerant of other gods. Yet when the intelligence is roused a polytheist will revert back to the monotheism from which his faith started. Proto-historic precursors of the prophets read the signs of the weather in the skies, and their still prehistoric successors read the Will of God in their own hearts, and became priests and shamans, wabeno-men and rab-mags, untold ages before the first hieroglyph appeared carved on an Egyptian tomb or monolith. In sublime egotism the primitive philosopher of early times interpreted nature and nature's God as an extension of himself. Dream life was to him revelation. And, indeed, to say that God spoke to one in a dream, is that not to say that

1-5. Cristatella mucedo (1, a [illegible] form; 4, fully formed stock or c[illegible] individual; 7, young stock; 8, a [illegible] stock; 11, young bud not yet opened.

POLYZOA



1-5. Cristatella mucedo (1, a statoblast; 2, another, more advanced; 3, a young stock or cormidium; 4, fully formed stock or cormus; 5, cross-section of Fig. 4). 6-8. Plumatella repens (6, young individual; 7, young stock; 8, a portion of Fig. 7 enlarged). 10-12. Lophopus crystallinus (10 a young stock; 11, young bud not yet opened; 12, another bud, more advanced, but not open.).

one dreamed that God spoke to one? Soon a personal life was attributed to the sun, the moon, clouds, rivers, seas, oceans and the very trees. Some spiteful demon rooted the latter to the ground! The ever-varying phenomena of the sky, at dawn, at noon and at even-tide — many were the deities of men. All this be it remembered was not pretty invention, allegory or poetic conceit! The primitive philosophic theologian was no embryon Cabalist, no conscious fabler. On the contrary he and his disciples entertained the idea of a polytheon as their highest wisdom. He meant speaking of his gods, precisely what he said. Monotheism did not succeed polytheism. Nor did the latter succeed monotheism. They are twins, born together. For whenever the early thinker, at rare moments, though deeply and felt clearly he must have experienced, however feebly, or even grossly, the presence of an ever-abiding mystery pressing for interpretation. We have thus monotheism, in truth, throughout all ages, not in genuine conflict to polytheism in the inner life nor yet clear to thought; but potentially, in living intuition in the religious sentiment. Truly, it may be said of Him, He is not far from any of us.

POLYXENA, pŏ-lĭk'sē-nạ, in Greek legend, the daughter of Priam and Hecuba. She was beloved by Achilles, who in order to obtain her for his wife promised to bring about peace between the Greeks and Trojans. While negotiating the marriage at the temple of the Thrymbræan Apollo, Achilles was treacherously slain. Afterward his shade appeared demanding Polyxena and she was, therefore, sacrificed to his Manes. Her sacrifice is represented in the Acropolis at Athens and forms a part of the 'Hecuba' of Euripides.

POLYZOA, a group of animals, at first regarded as radiates, then as mollusks and later as members of the heterogeneous group of worms. Its precise rank and position remain to be determined. All are small and all are aquatic, the great majority being marine. At the anterior end of the body is a circle of ciliated tentacles around the mouth. By means of these food is collected and brought to the alimentary canal. The intestine is flexed on itself and the vent is on the dorsal surface, either near the tentacles (*Ectoprocta*) or inside the circle (*Entoprocta*) while the central nervous system lies between the mouth and vent. In the *Entoprocta* the body-wall is solid, but in the *Ectoprocta* there is a spacious body cavity (cœlom). Besides reproduction by eggs all multiply by budding, the result being the formation of colonies, often of considerable extent. The *Entoprocta*, the characters of which are included above, embrace only a few forms, each individual being raised on a slender stalk, the colony being connected by a running root-stalk on the support to which the animals are attached. *Urnatilla gracilis* occurs in the fresh waters of the United States. Most of the species are marine.

The *Ectoprocta* secrete a protective case, often rendered firmer by the deposition of lime around each individual, and into which the animal may quickly retreat, the opening in some cases being closed by a door or operculum. The great majority of the *Ectoprocta* belong to a group called *Gymnolæmata*, in which the tentacles are in a more or less perfect circle. All but a few of them are marine, and are among the most abundant of animals along our whole coasts, some forming encrusting sheets on shells and stones, others forming bushy growths on rock and piles. The *Phylactolæmata* are exclusively inhabitants of fresh water, and are characterized by having the tentacles folded into a horseshoe shape. In these, as in sponges, there is the formation of peculiar buds (statoblasts) enclosed in a hard shell which preserve the species through the winter or in times of drought.

The closest allies of the *Polyzoa* (which are also known as *Bryozoa*, 50 named by Ehrenberg and accepted by J. W. Thompson) are the *Brachiopoda*, the two groups having formerly been united as a class *Molluscoida*. H. Milne-Edwards united the *Polyzoa, Brachiopoda* and *Tunicata* in his group *Molluscoida*; but it has been since shown that the latter belong to the *Vertebrata*, and the relation of the first two rested on a mistaken identification of parts. The *Polyzoa* are also related to the *Phoronididæ*, which in turn show resemblances to the *Annulata*. Consequently the three groups have been united as classes in the phylum *Molluscoida* by Parker and Haswell, 'Text-book of Zoology' (1897).

POMACE FLY, a small yellowish fly of the genus *Drosophila*, frequently a nuisance in cider factories and wine houses. The eggs are laid in the pomace in which the larvæ feed and from which the adults fly to the houses. They also visit dwellings in which decaying fruit is exposed. Sometimes they breed in other organic remains. Cleanliness and the prompt removal of fermenting or decaying matter are preventive measures.

POMADE, POMMADE, or **POMATUM**, a term originally applied to a fragrant ointment prepared with lard and apples, but now wholly restricted to perfumed solid greasy substances used in dressing the hair. In the preparation of pomades the first object of consideration is to obtain their fatty basis in as pure and fresh a state as possible. Lard, beef and mutton suet, beef marrow, veal fat and bear's grease are the materials commonly employed for this purpose, either singly or in mixtures of two or more of them. The fat, which should be that of a young and healthy animal, is pounded in a marble mortar in the cold, until all the membranes are completely torn asunder; it is then submitted to the heat of a steam-bath until its fatty portion has liquified and the albuminous and aqueous matter and other foreign substances have completely subsided. The liquid fat is then carefully skimmed and passed through a flannel filter. In this state it may be perfumed at will; after which, when it is intended that the pomade should be white, it must be constantly stirred with a glass or wooden spatula until it solidifies; should it be wished transparent or crystalline it is allowed to cool very slowly without being disturbed. To prevent its becoming rancid a little benzoic acid, gum benzoin or nitric ether may be added and to increase its consistency a little wax or spermaceti. Pomade may be perfumed by enfleurage, maceration or simply by adding the fragrant essences or essential oils in the required quantity. See PERFUMES AND PERFUMERY.

POMBAL, Sebastião José de Carvalho e Mello, sä-bäs-tē-äñ'oo hō-sā' dā kär-väl'yoo ä mä'loo pōñ-bäl', or pŏm-bäl', MARQUIS OF, Portuguese statesman: b. Soura, near Coimbra, 13 May 1699; d. Pombal, 2 May 1782. He successively entered the law and the army, but soon relinquished each because of incompatibility. In 1739 he was appointed Ambassador to London, but was recalled in 1745. He was then sent to Vienna to act as mediator between the Pope and the Empress Maria Theresa. Carvalho here gained general esteem and married the youthful Countess of Daun. In 1750 Carvalho obtained from Joseph I the post of Secretary of State for Foreign Affairs and soon rendered the feeble and sensual king entirely subject to his influence. Joseph I fell in with the most daring projects of his minister; and the latter now proceeded to the accomplishment of his four favorite objects — the expulsion of the Jesuits, the humiliation of the greater nobles, the restoration of the prosperity of Portugal and the absolute command of the state in the name of the monarch. After the earthquake of 1 Nov. 1755, which destroyed Lisbon, Carvalho displayed great vigor and resolution. He was now created Count of Oeyras and in 1756 First Minister. He then removed every one who ventured to obstruct his plans. The discontented vinedressers committed excesses in Oporto, but Pombal vigorously suppressed the riots and passed most comprehensive laws against treason. He also expelled the Jesuits from their flourishing missions in Paraguay. Carvalho finally determined to remove the Jesuits entirely from the person of the king and they were ordered (16 Sept. 1757) to retire to their colleges. A conspiracy against the life of the king, who was wounded on the night of 3 Sept. 1758, by assassins, he falsely laid to the charge of the Jesuits. Pombal denounced the Jesuits to the Pope as the contrivers of the scheme and caused some of them to be executed in prison. Pombal had already banished the whole order from the kingdom by a royal decree of 3 Sept. 1759 and those who did not comply with the mandate were seized and transported to the states of the Church. A protracted dispute with the Pope followed; in 1760 Pombal transported the papal nuncio beyond the frontiers and was on the point of dissolving all connection with Rome when Clement XIII died and Clement XIV, his successor, abolished the order in 1773. Through Pombal the Portuguese army received an entirely new organization and the fortifications on the frontiers were restored. He paid particular attention to the schools; he also rendered the censorship less strict. Joseph I died 24 Feb. 1777 and was succeeded by his daughter, Maria I, who immediately deposed Pombal and deprived him of all his offices. The state-prisoners whom he had incarcerated, 9,800 in number, were released, and all his regulations abolished. All those who had been attainted with treason under Pombal's charges were rehabilitated and he himself ordered to retire to his estate, where he died. His record is one of the bloodiest in Portuguese history, yet it is said to his credit that he favored the establishment of various manufactures; encouraged the art of printing and agriculture; furnished the University of Coimbra with a chemical laboratory, a botanic garden and an observatory; and introduced into Brazil the cultivation of coffee, sugar, rice, cocoa and indigo. Consult Moore, 'Life of Pombal' (1819); Opperman, 'Pombal und die Jesuiten' (1845); Weld, 'The Suppression of the Society of Jesus in the Portuguese Dominions' (1877); Feval, 'The Jesuits' (1878).

POMEGRANATE, a shrub or tree (*Punica granatum*), native of southern Asia, widely cultivated for its fruit. It is usually of bushy growth, with glossy entire leaves and red flowers. The fruit is globular, sometimes five inches in diameter, the interior filled with numerous seeds covered with a juicy red, pink or white pulp, usually of acid flavor. The cultivation of the pomegranate in the Old World is of great antiquity. The plant is supposed to have been introduced into southern Europe by the Carthaginians, whose Latin name of "Punici" was applied to it. The fruit is cultivated in the United States along the Gulf Coast and more extensively in tropical America.

POMEGRANATE MELON. See MELONS.

POMELO, or PUMELO. See SHADDOCK.

POMERANIA, pŏm-ē-rā'ni-ą (German, *Pommern*), Prussia, a northern province and duchy, bounded north by the Baltic, west by the duchy of Mecklenburg, south by the province of Brandenburg and east by West Prussia; area, 11,629 square miles. It consists of a long and comparatively narrow tract of country, stretching longitudinally east to west. The coast is generally low and sandy and is lined by a great number of lagoons, separated from the sea by narrow belts of land or low sandhills. Along the coast are a few islands, but none of them, except Rügen, Usedom and Wollin, are of great extent. The principal rivers are the Oder, Persante and Stolpe. The soil generally is sandy and indifferent; but there are many rich alluvial tracts, particularly along the banks of the rivers and lakes, producing a surplus of grain for export. Flax, hemp and tobacco also are cultivated. The domestic animals, of which sheep and swine are the most important, are numerous, and of tolerably good breeds. The forests are of large extent and well supplied with game. Fish also are abundant. The only minerals of any consequence are a little iron, salt and alum. Manufactures early made considerable progress, in consequence of the influx of French refugees on the revocation of the Edict of Nantes, who introduced the manufacture of woolens and other fabrics. Through the Oder the province carries on a considerable trade, both general and transit. The principal exports are corn, cattle, wood, wool, wax, amber and fish; the principal imports are wine, cotton goods, coffee, sugar and other articles of colonial produce. The centre of trade is Stettin, which ranks as one of the most important commercial cities of Prussia. Pomerania was originally inhabited by Goths, Vandals and Slavs. The first mention of it in history is in 1140. It long remained an independent duchy and was of much larger extent than at present. In 1637, on the extinction of the ducal family, the electoral house of Brandenburg claimed possession, but was obliged to give way to Sweden. On the death of Charles XII the electoral house again claimed possession and the whole was formally ceded to it except a part which received the name of Swedish Pomerania. This part having been ceded to Denmark, was by it given up in exchange for the duchy of Lauenburg, to Prussia, to which the whole of Pomerania now belongs. For administrative purposes it is divided into three governments (Regierungsbezirke), Stettin, Köslin and Stralsund. Pop. 1,716,921.

POMERENE, Atlee, American legislator: b. Berlin, Holmes County, Ohio, 6 Dec. 1863. In 1884 he was graduated at Princeton University and two years later at the Cincinnati Law School. In 1886 he was admitted to the bar and has since practised at Canton. In 1887–91 Mr. Pomerene was city solicitor; in 1897–1900 prosecuting attorney of Stark County and in 1906 was appointed member of the Tax Commission of Ohio. On 8 Nov. 1910 Pomerene was elected lieutenant-governor of Ohio and on 10 Jan. 1911 was elected United States senator for the term 1911–17 and was re-elected for the term 1917–23 in 1916.

POMEROY, pŏm' or pŭm'ĕ-roĭ, **John Norton,** American lawyer: b. Rochester, N. Y., 1828; d. 1885. In 1847 he was graduated at Hamilton College and became a practising lawyer in 1851. He practised in Rochester until 1864, when for four years he held the chair of law and political science at the University of New York. He returned to his law practice at Rochester in 1869 and from 1878 to 1885 held the chair of municipal law at the University of California. Pomeroy edited Sedgwick's 'Statutory and Constitutional Law' (1874) and Archbold's 'Criminal Law' (1876). He wrote 'Introduction to Municipal Law' (1865); 'Introduction to the Constitutional Law of the United States' (1868; 9th ed., 1886); 'Remedies and Remedial Rights According to the Reformed American Procedure' (1876); 'Treatise on Riparian Rights' (1884); 'Treatise on Equity Jurisprudence' (3d ed., 4 vols., 1905).

POMEROY, Marcus Mills («Brick Pomeroy»), American journalist and humorist: b. Elmira, N. Y., 25 Dec. 1833; d. Brooklyn, N. Y., 30 May 1896. He was apprenticed to the printer's trade when very young, established the Corning (N. Y.) *Journal* and the *Athens Gazette*, and in 1857 removed to Horicon, Wis., where he successfully conducted the *Argus*. Later he went to Milwaukee where he edited the *Daily News* and subsequently secured an interest in the La Crosse (Wis.) *Union and Democrat*. After the Civil War he removed to New York and founded the *Daily Democrat*, which in 1887 was merged in *Pomeroy's Advanced Thought*. In the latter part of his life he undertook to tunnel the Rocky Mountains, and had cut nearly a mile on each side when the failure of the national government to aid him caused the abandonment of the project. His chief publications are 'Gold Dust' (1872); 'Brick Dust' (1872); 'Perpetual Money' (1878).

POMEROY, Seth, American Revolutionary soldier: b. Northampton, Mass., 20 May 1706; d. Peekskill, N. Y., 19 Feb. 1777. He was by trade a gunsmith, and early spent much time in the colonial military service, attaining the rank of colonel. In 1774–75 he was delegate in the provincial congress, in October 1774 was made a general officer, and in February 1775 became brigadier-general of militia. After having participated as a private soldier in the battle of Bunker Hill, he was appointed 22 June 1775 senior brigadier-general of the Continental army. His appointment, however, was the occasion of some difficulty in the adjustment of matters of rank, and he resigned from the service, without having acted. When New Jersey was overrun by the enemy in 1776, he headed a volunteer force and marched for the Hudson, but died on the way.

POMEROY, Theodore Medad, American jurist and statesman: b. in Cayuga, N. Y., 31 Dec. 1824; d. Auburn, N. Y., 23 March 1905. He received his early education at Monroe Academy and graduated from Hamilton College, taking his degree in 1842. He was admitted to the bar in 1846, practising until 1870. In 1851 he was elected district attorney of Cayuga County, holding that position until 1856, when he was elected to the assembly. In 1861 he was elected to Congress, remaining there until 1869 and during the 40th Congress acting as speaker of the House of Representatives. In 1875 he was elected mayor of Auburn, serving one year, and was elected to the State senate in 1878–79. After abandoning the practice of law he engaged in banking and at the time of his death was first vice-president of the American Express Company.

POMEROY, Ohio, city, county-seat of Meigs County, on the Ohio River and on the Hocking Valley and the Kanawah and Michigan railroads, 125 miles southeast of Columbus. It was first settled in 1816 and incorporated as a city in 1846. It is built on a strip of land lying between the river on one side and hills on the other. It is in a region rich in bituminous coal and salt, and is the centre of an important mining industry. It also produces calcium and bromine, and has numerous manufacturing interests. Its industrial establishments include rolling mills, salt works, machine and engine works, furniture factories, planing and lumber mills and flour mills. There is a public library. The city is governed by a mayor, who holds office for two years, and a city council. Pop. 4,023.

POMFRET, a name given in Europe to a species of *Stromateus*, allied to our butterfish (*Rhombus triacanthus*), found in the Mediterranean and Indian Ocean; and in the Bermudas to a large fish (*Brama raii*) of the family *Bramidæ*. Both of these belong to the scomberoid series of percomorphous fishes. The latter is a fish of comparatively deep oceanic waters, and is quite cosmopolitan in its range. Occasionally it has been taken in our waters on both the Atlantic and Pacific sides. As a food fish it is of excellent quality, but is nowhere sufficiently plentiful to be of importance. The family *Bramidæ* is a small one, comprising only three genera and 10 or 12 species, which are remarkable for the changes which they undergo with growth. *Brama raii* reaches a length of four feet, and has a somewhat compressed form, with the dorsal and anal fins very long. The cycloid scales are peculiar in being provided with a deep perpendicular bony plate, one side of which is embedded in the skin.

POMMADE. See Pomade.

POMO, a linguistic stock of northwest California also known as Kulanapan. It includes several tribes, once very numerous, but now almost extinct. Consult Barrett, S. A., 'Pomo Indian Basketry' (Berkeley 1908); id., 'Ethnogeography of Pomo and Neighboring Indians' (ib. 1908); Mason, O. T., 'Aboriginal Indian Basketry' (Washington 1904).

POMOLOGY, the science of fruit-culture, especially apple-culture (Lat. *pomum*, apple). It is divided into four main divisions: viticulture, or grape-growing; orcharding (itself divided into the cultivation of pomaceous fruits; drupaceous or stone fruits; citrous fruits, as oranges and lemons; nut-fruits; and palmaceous fruits); small-fruit culture; and cranberry culture. (See FRUIT-CULTURE; GRAPE INDUSTRY; HORTICULTURE; and special fruits, as apple, pear, orange, etc.). Consult Bailey, L. H., 'Cyclopedia of Horticulture' (4 vols., New York 1912).

POMONA, Cal., city in Los Angeles County, on the Atchison, Topeka and Santa Fé and the Southern Pacific railroads. It was first settled in 1875 and incorporated as a city 12 years later. It is the commercial centre and shipping point for an agricultural and fruit-growing region, particularly noted for its oranges; and also manufactures wine, and has a planing mill and a canning factory. It is a well-built, handsome city, with a fine park from which a wide view of the surrounding country may be obtained, and is a health resort. It has a high school and a public library, and Pomona College (q.v.) is located within a few miles at Claremont. The city is governed by a board of trustees; the city officials are mostly elected directly by the people. Pop. 13,150.

POMONA. See ORKNEY ISLANDS.

POMONA, the Latin goddess of fruit, orchards and gardens. Various legends are associated with her cult. The longest story as also the most famous concerning her is told by Ovid in his 'Metamorphoses' (XIV, 623 et seq.). Consult Wissowa, Georg, 'Religion und Kultus der Römer' (2d ed., Munich 1912).

POMONA COLLEGE, located at Claremont, Cal. It was established by the Congregationalists, and was first opened to students in 1888, but it is now non-sectarian in control. Women are admitted to all courses. The college offers three general courses, classical, scientific and literary, for the completion of which the degrees of A.B., B.S. and B.L. are conferred. There is also provision for graduate work, a normal course and a preparatory department. In 1917 the grounds and buildings were valued at $530,880; the amount of productive funds was $1,105,358, and the annual income $204,957. The library (1917) contained 35,510 volumes; the students number 542, and the faculty 46.

POMORYANS, a Russian sect founded in 1695 by Danilo Wiculin. Their teachings are called Danilowtchina, and inculcate the doctrine that since the deposing of the prelate Nikon (1667), Antichrist has reigned in the Orthodox Greek Church, and thus the true priesthood has been destroyed. As there are no longer true priests nor true sacraments, there is no authority to sanction marriage, and, therefore, all should live in celibacy; and those married in the Greek Church should separate. Persons desiring to join the sect are required to be rebaptized by those already members. The sect has monasteries and nunneries, and has amassed much wealth which they have expended in gathering a large and very valuable library treating principally on the fine arts — music, painting, poetry, etc.

POMPADOUR, Jeanne Antoinette Poisson, zhän äṅ-twän-ĕt pwä-sôṅ pôṅ-pä-door, MARQUISE DE, mistress of Louis XV: b. 29 Dec. 1721; d. Versailles, 15 April 1764. She was the daughter of François Poisson, equerry to the Duke of Orleans, and not butcher to the Invalides as frequently stated. The paternity of the future favorite was, however, claimed by Lenormand de Tournehem, a rich fermier-général, who spared no pains to give her a brilliant education, and at his death left her the half of his immense fortune. In 1741 she was married to her cousin Lenormand d'Etiolles. She succeeded in attracting the attention of the king, was formally presented to him and soon entirely engrossed his favor, appearing at court under the title of Marquise de Pompadour. Here she enjoyed the highest consideration, but did not at first interfere in political affairs, satisfied with appearing as the patroness of learning and the arts. She collected books, pictures and curiosities, and encouraged the institution of the military school of which Paris du Verney was the founder. But when she could only maintain her influence with the king by furnishing him other objects for favor, she turned her attention to state affairs. She filled the most important offices with her favorites, and contributed to produce those evils which afterward pressed so heavily on France. It is said to have been principally owing to her that France became involved in the war against Frederick II. The Empress Maria Theresa had propitiated her favor by writing to her with her own hand a letter in which she called her "dear cousin." The burdens and sufferings which this war brought upon France must be laid at her door, since she removed Berms, who was in favor of peace, and supplied his place by Choiseul, effected the recall of Marshal d'Estrées at the moment of triumph, and promoted incapable generals to the command. She died little regretted by the king (see LOUIS XV), and hated and reviled by the nation. To her credit, however, is awarded praise for her patronage of literary men and artists. Consult Beauporist, 'Secret Memoirs of La Marquise de Pompadour' (1885); Goncourt, 'Madame de Pompadour' (1887); Pavlovski, 'La Marquise de Pompadour' (1888); Fleury, 'Louis XV intime' (1899); De Caraman, 'La Famille de la Marquise de Pompadour' (1900).

POMPANO, an important food fish (*Trachinotus carolinus*) belonging to the teleostomous family *Carangidæ*, and found chiefly in the southern United States, especially in Florida. These fishes are related to the mackerels, but lack the median finlets which are so general in the latter. The pompano reaches a length of about 18 inches and has a somewhat elevated and compressed body with a covering of very small scales and a strongly convex steep forehead. The anal and soft

From "American Food and Game Fishes"

OLD WIFE

This is a near cousin of the famous Pompano. Photographed from life

dorsal fins are both long and of nearly equal length and similar form, being very high in front and low behind. There is a spinous dorsal fin from which the membrane disappears with age, and a deeply forked caudal without keels or bony plates on its peduncle. The jaws are at first provided with numerous small teeth which fall out with age, changes in other parts also taking place. The color is a beautiful polished silvery blue with golden reflections in parts and touches of orange on the paired fins. On the Atlantic Coast the pompano ranges from Brazil to Cape Cod; but it is only in the warm waters of the south Atlantic and eastern Gulf coasts that it is plentiful. Although occurring on the Pacific side of the continent it is there nowhere common. Except at the extreme southern end of Florida the pompano is a migratory fish, coming in from the sea and entering the shallow bays in the spring, the migratory wave gradually moving up the coast and reaching the waters of New Jersey and Massachusetts only when the summer is well advanced. In the fall they leave at a correspondingly early date. They approach the shores in large schools, swimming swiftly at the surface, but some time after entering the shallow bays break up into small parties to spawn and search for the shellfish which are their chief food. The largest runs come in April and May, and, as the dense schools approach very close to the shelving shores, seines may be operated with great effect, and large quantities are thus taken in Florida and South Carolina. Farther north, in Chesapeake Bay and on the coasts of New Jersey and Massachusetts, they are taken in pound nets. The pompano is the favorite fish of the wealthy and commands a high price in Northern markets. The name pompano is also applied to other species of the same and related genera, but the Irish pompano (*Gerres*) and California pompano (*Rhombus*) are not closely allied. Consult Goode, 'American Fishes' (New York 1888); Jordan and Everman, 'American Food and Game Fishes' (New York 1902).

POMPEII, pŏm-pā'yē (Lat. pŏm-pē'yī), ancient city of Italy, near the Gulf of Naples, and 12 miles southeast of Naples, lying at the southeast base of Vesuvius, and important as being preserved almost intact to our own time by a shower of ashes and pumice from Vesuvius 24 Aug. 79 A.D., which also covered Herculaneum. The city, according to Strabo, was founded by the Oscans; it must have come under Hellenic influence by the 6th century for a temple unearthed in the city is of the Doric of that century. Held by the Samnites from 420 B.C. to the end of the Samnite War in 290, Pompeii then became dependent on Rome; and two centuries later at the close of the Social War the city which had sided with the Italian allied forces was captured by Sulla, and was forced to cede a third of its territory for a Roman military colony. In the years that immediately followed Pompeii became a favorite resort of rich and fashionable Rome, being near the sea and having the glamor of Greek elegance. An earthquake in 63 A.D. nearly destroyed the city, and when it was rebuilt and resettled, Roman architecture somewhat took the place of Greek and the work of building seems to have been shabby and far from thorough in many instances. But the city had regained much of its old popularity when it was destroyed by the eruption of Vesuvius in the year 79. Few of the inhabitants escaped, but the better class of buildings was scarcely injured by the alternating falls of ashes and *rapilli*, or pumice. These with the additional covering of earth now amount to about 20 feet. The eruption is described by Pliny the Younger in letters written to Tacitus telling of the death of the elder Pliny, who perished in the city. The site, for a time occupied by a little village, was deserted after the eruption of Vesuvius in 472, and no attention was paid to this great storehouse of antique life until the middle of the 18th century. Indeed the precise position of the buried city was problematic, for the volcano had changed the coast line so that it is now some distance from Pompeii. In 1748 valuable finds were made by a peasant digging a well. In 1755, Charles III having become interested in the work, the amphitheatre and other public buildings were discovered. But during the next 50 years nothing systematic was done: there was still search for rare objects, but when these were found houses and streets were left to decay or were covered up again. No one realized that the prime value of the city archæologically is that it is the genuine setting of Roman life, a very different thing from remnants, no matter how curious, in a museum. Under Murat (1808–15) houses and streets were again excavated; and since the establishment of the united Italian kingdom work has been carried on systematically by the government, notably under the management of Fiorelli, who devised a method of making casts of the human remains by pouring plaster into the hollows occupied by the bones of the victims. The streets are now nearly half exposed; the completion of the work may take 50 years more. The fear has occasionally been expressed that an eruption of Vesuvius might undo all this work, and, if lava were poured down on the city, all the ancient monuments be destroyed.

The importance of the city, as has been remarked above, is that the very pose and setting of 1st century Italy is here preserved in a wonderful degree, even loaves of bread keeping their shape though turned to charcoal. It is, however, important to notice that the city is neither typical of Rome because of its being subjected to Greek influence, nor of Greece, because hastily rebuilt after the earthquake of 63 A.D. Hence generalizations as to Roman manners and customs founded merely on Pompeian remains are liable to error. The city was an irregular oval, the length being east and west, surrounded by a wall with a circuit of a little more than a mile and five-eighths (2,925 yards), which is pierced by eight gates. At each there were sentry boxes in which the Roman legionaries were found, still "on duty" when the excavations began. The most important gate is that opening toward Herculaneum, on the west end of the ovoid. From this gate leads a road paved with tombs, the Pompeian *Via Appia*. Parts of this region, the Pagus Augustus Felix, were among the earliest excavated; in 1771–74 the diggers discovered the villa of Diomedes, which got its name from the tomb of Marcus Arrius Diomedes across the street. It seems to antedate the empire. Thirty-four bodies were found in this one house, 20 of them in the wine cellar. Within the walls the streets are straight but narrow (14 to 24 feet wide), paved with lava blocks, and with high stepping stones at crossings. The streets are deeply worn with ruts. On the walls there are scribbled inscriptions, the famous graffiti, which are full of the gossip, scandal and politics of the city. The forum, a little southwest of the geographical centre of the town, was an open market place surrounded by buildings, the temple of Apollo lying to the west, the temple of Jupiter to the north and that of Mercury to the east. The last temple was flanked by the curia on the left and the house of Eumachia on the right; south of this house, across a street leading to the Sarno gate, was a school. At the intersection of this street with that connecting the Vesuvian and Stabian gates were situated the public baths; and near the latter gate were a second forum, called the "triangular," a temple of Isis north of it, a large and a small theatre to the east, the extensive gladiators' barracks to the southeast, noted for the fine arms, shields, helmets, etc., discovered here, and to the south a temple of Heracles. The gladiators' quarters include a large rectangular enclosure, which measures 183 feet long by 148 feet wide. It is surrounded on all four sides by a colonnade whose columns are painted red at the lower part, and alternately red and yellow at the upper. The wall back of the columns is covered with stucco. Other baths are on the street crossing the city from the Nolan gate. The unfinished temple of Venus Pompeiana in the southern corner of the city, near the old Sea gate and the modern hotel, seems to have been the repository of many valuables, probably left by the inhabitants who escaped from the city at the first alarm. Valuable finds of the same sort are to be looked for in villas outside the city; in 1895 in a well at Boscoreale a set of silver utensils, lamps, mirrors and candelabra was discovered. The type of art in these pieces of silver and in the mural paintings is apparently Alexandrian, with a profusion of Cupids. Among the better known private dwellings, apart from the "Villa of Diomedes" already named, are the house of Pansa, one of the largest residences of the city, a pattern of the Roman house which has often been reproduced, notably at Saratoga; the house of the Tragic Poet, so called because of the incorrect interpretation of one of its mural paintings, a small but tasteful house with remarkable scenes from the Homeric poems; the unusually elegant house of Sallustius; the double house known as Castor and Pollux; and the house of the Vettii, excavated in 1894, the home of a rich fuller, with brilliant, fresh frescoes, and the interior equipment of the house in such good condition that it has been left there instead of being carried to the Museum in Naples.

The discoveries produced by the excavation of the ruins of buried Pompeii and Herculaneum were of vast interest from the viewpoint of archæology; but a far greater effect produced was from a popular standpoint, namely, the revolution in the modern world of art, and the decorative arts especially. The early excavations created a classic influence in the architecture and decoration in France during the reign of Louis XV, which, with the more advanced disclosures, entirely dominated the style Louis XV, to become excuse for the debased copies of these antiquities in the empire style. In England the disinterment of these Greco-Roman ruins and relics brought into being the Adam Period of architecture and decorative art (1760–94).

POMPEY, pŏm'pi (CNEIUS POMPEIUS), surnamed the Great (Magnus): b. 30 Sept. 106 B.C.; d. 28 Sept. 48 B. C. In 98–87 B.C. he served in the Social War with great distinction. For some years subsequently the party of Marius was in the ascendant in Italy, and Pompey, who belonged to the aristocratic party, kept in the background. Learning, however, that Sulla was about to return from Greece to Italy, he hastened into Picenum, and raised an army of three legions, with which he successively defeated three generals of the opposite party, who attempted to prevent his junction with Sulla. That junction was accomplished in 83, and Sulla received the young soldier with the greatest marks of esteem. When the war in Italy ended, Pompey was sent to Sicily against the Marian general. He won a complete and speedy victory, and on his return was received by the people with great enthusiasm, and greeted with the surname of Magnus. He was also granted a triumph, a noteworthy distinction for one who had as yet held no public office. Subsequently he induced the Senate to send him to the aid of Metellus Pius, hard pressed by Sertorius in Spain. Pompey remained in Spain (76–71), but neither he nor Metellus could gain any advantage over Sertorius. But when the latter was treacherously murdered by Perperna, his own officer, the war was speedily brought to a close. On his return he defeated the fragments of the army of Spartacus, and claimed the glory of having finished the Servile War. He now became a candidate for the consulship, and although he was not of the legal age, and had not held any of the lower offices of the state, he was elected consul with Crassus at the end of 71. The aristocracy began to look upon Pompey with jealousy, and ceased to regard him as belonging to their

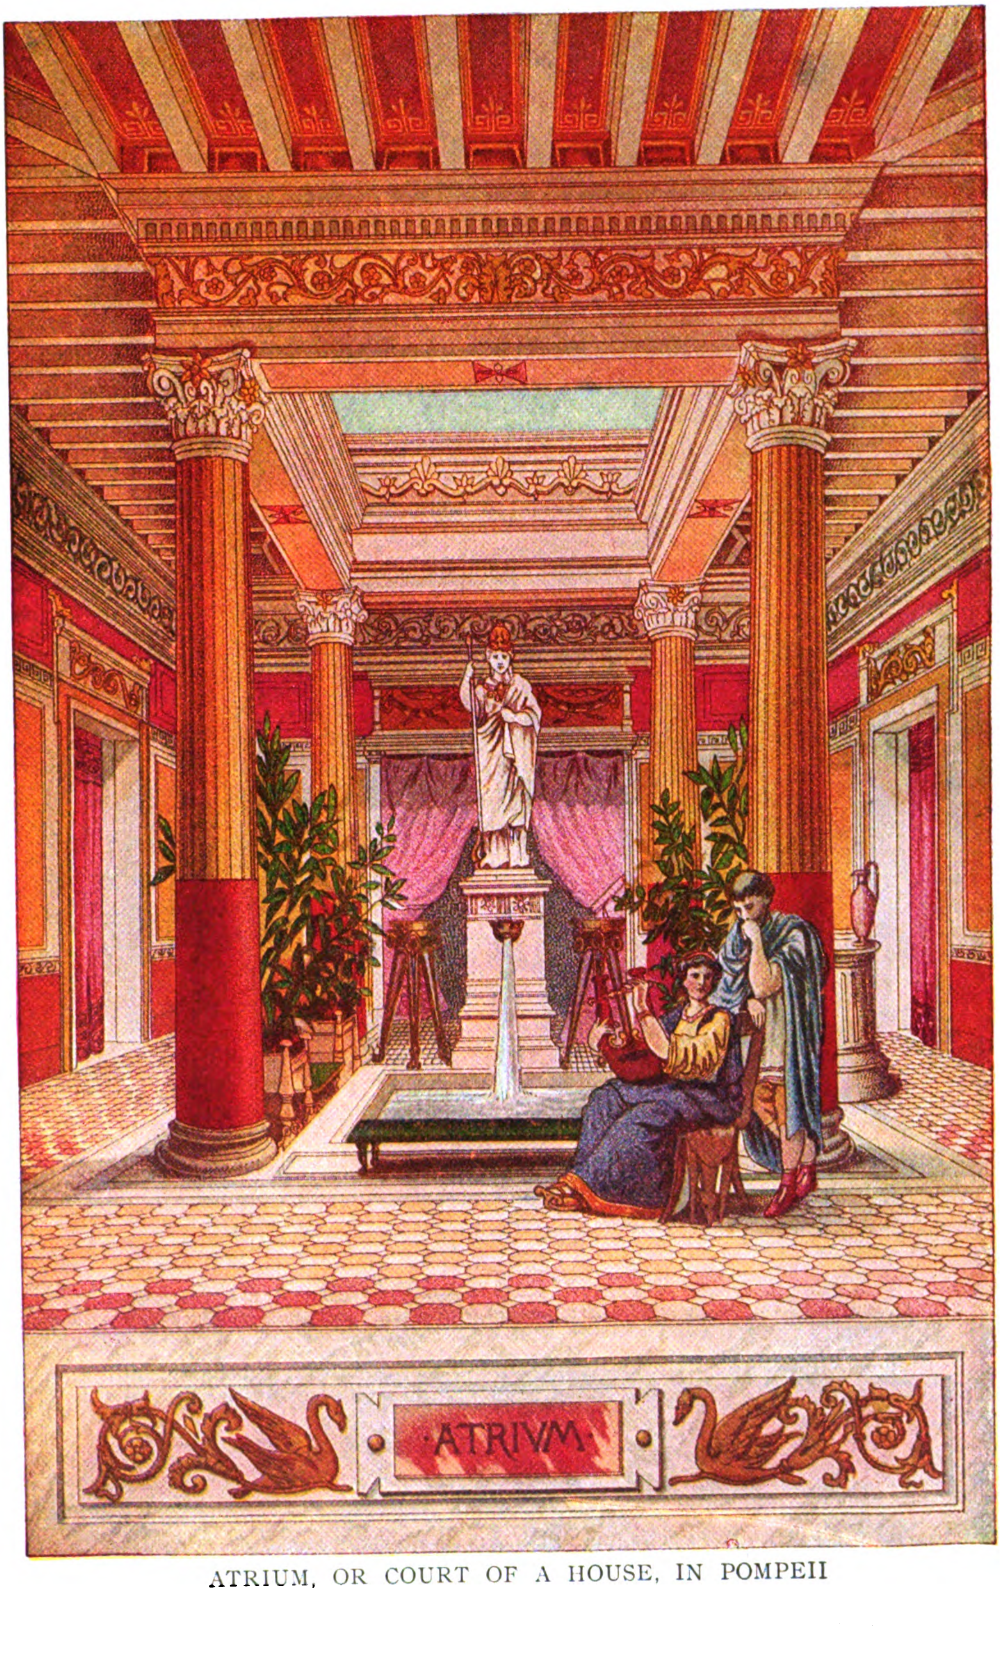
ATRIUM OF C



ATRIUM, OR COURT OF A HOUSE, IN POMPEII

party, as he and his colleague openly courted the people — Crassus, by profuse largesses, and Pompey by the restoration of the tribuneship and other popular institutions. In 67 he was invested with extraordinary powers by sea and land for three years, for the purpose of putting an end to the outrages of the pirates in the Mediterranean, in which he was successful. Meanwhile the war against Mithridates had been carried on with varying fortune, and the Romans were discontented with the slow progress of Lucullus. The tribune, Caius Manilus, proposed that Pompey should have absolute power over the army and fleet in the East, and proconsular authority over all Asia as far as Armenia, a proposal supported by Cicero in the famous oration 'Pro Lege Manilia.' It was opposed by the whole influence of the aristocracy, but carried triumphantly. In 65–62 he conquered Mithridates; Tigranes, king of Armenia; and Antiochus, king of Syria. At the same time he subdued the Jewish nation, taking Jerusalem by storm after a three months' siege. He returned to Italy in 62, and disbanded his army, but did not enter Rome till the following year, when he had the honor of a third triumph. From this date, when he was 45, his star began to wane. The aristocracy still distrusted him, yet he was unwilling to throw in his lot entirely with the popular party, which had been steadily rising in power during his absence, and over which Cæsar now possessed unlimited control. The Senate refused to sanction his measures in Asia, and to make an assignment of lands which he had promised to his veterans. Pompey, therefore, resolved to ally himself closely with Cæsar, who promised to obtain the ratification of his acts provided Pompey would assist him in the attainment of his ends. Through the mediation of Cæsar Pompey became reconciled to Crassus, who, in consequence of his enormous wealth, had a wide influence in Rome. Thus was brought about the coalition of these three powerful men, which is known in Roman history as the first triumvirate. In order to tighten the bonds of alliance Cæsar bestowed upon Pompey his daughter Julia in marriage. It was soon apparent that this alliance would not last long, as Pompey could brook no rival. The death of Julia in 54 severed one of the ties which bound the two men, soon to become open rivals. In consequence of the serious tumults which broke out in Rome on the death of Clodius in the beginning of 52, the Senate called in the assistance of Pompey, who was appointed sole consul for that year, and who succeeded in restoring order in the city. The most important state offices were now filled with Cæsar's enemies, and Pompey persuaded the Senate to pass a decree by which Cæsar was to give up the provinces of which he was governor, and the command of his army. This he refused to do unless Pompey would throw up his offices, which was a step the latter would not take. Cæsar was proclaimed an enemy to the state, and his rival was appointed general of the army of the republic. Cæsar crossed the Rubicon in 49, and in 60 days was master of Italy without striking a blow. Pompey fled to Greece, where he collected a numerous army, and was followed by Cæsar in January 48. At first the campaign was in Pompey's favor; Cæsar was repulsed before Dyrrhachium with considerable loss, and was compelled to retreat toward Thessaly. In this country, on the plains of Pharsalia, occurred the decisive battle which made Cæsar master of the Roman world. His rival fled to Egypt, where he was murdered in the presence of the king and his army by the tribune Septimius, at the instigation of Achillas and Herodotus, who feared the anger of Cæsar. His head was struck off, and was shown to Cæsar, who, however, ordered the murderer to be put to death. Consult his life in Druman's 'Geschichte Roms,' iv, 324–556; Merivale, 'The Roman Triumvirates' (1887).

POMPEY THE YOUNGER (SEXTUS POMPEIUS), Roman warrior, 2d son of Pompey the Great: b. 75 B.C.; d. 35 B.C. He accompanied his father in his flight into Egypt and after his death went to Spain, where he organized a force of fugitives and malcontents and demanded from the Roman Senate restitution of his father's property. The Senate granted him a large sum of money and made him commander of the seas. He marched to Bætica, where he crushed all opposition and assumed the powers of a sovereign. Upon the formation of a second triumvirate in 43 B.C. he was proscribed and thereupon turned pirate, waging continued war upon Rome by cutting off her supplies. He made Corsica, Sardinia and Sicily, which islands he had captured, the seat of his power, and from them sent forth his marauders. When Rome reached the point of starvation the populace compelled Antonius and Octavianus to sue for peace and a treaty most advantageous to Sextus was signed, in which he was confirmed in his occupation of Sicily, Corsica, Sardinia and Achaia, and promised the consulship. The war was, however, speedily resumed, and Sextus twice defeated the fleets of Octavianus, but his indecision permitted the Romans to rebuild their fleets and in 36 B.C. he was signally defeated. He fled to Armenia, but being overtaken by his enemies and deserted by his troops, he surrendered, and was put to death at Miletus by the Roman legate, M. Titius, who wished to remove a man who might easily be the cause of a rupture between the triumvirs. He had assumed the name of Pius, because he endeavored to avenge the death of his father and his brother, and this surname appears on many of his coins.

POMPEY'S PILLAR, the name of a celebrated column, standing on an eminence about 1,800 feet to the south of the walls of Alexandria in Egypt. It consists of a capital, shaft, base and pedestal, which last rests on substructions of smaller blocks once belonging to older monuments. One of these blocks bears the name of a monarch of the 13th Egyptian dynasty, and another that of Psammetichus I. The total height of the column is 98 feet 9 inches; the shaft, a monolith of red granite, is 73 feet long, and 29 feet 8 inches in circumference. The name it is popularly known by was applied to it by ancient travelers for no assignable reason. An inscription on the base shows that it was erected by Publius, the prefect of Egypt, in honor of Diocletian, probably to commemorate his capture of Alexandria, and the suppression of the rebellion of Achilleus. On the summit there is a circular depression of considerable size, intended to admit the base of a statue.

POMPEY'S THEATRE, a theatre of ancient Rome, erected by the great Pompey and completed in 52 B.C. It was the first stone theatre of ancient Rome; had a marble interior and is variously stated to have seated 10,000, 17,000 or 40,000 people. After surviving many conflagrations it finally collapsed in the 6th century. Some of the ruins are still discernible about the Palazzo Pio. Consult Platner, S. B., 'The Topography and Monuments of Ancient Rome' (2d ed., 1911).

POMPONATIUS, Petrus, pŏm-pō-nā'shi-ŭs pē-trŭs (Latinized name of PIETRO POMPONAZZI), Italian philosopher: b. Mantua, 1462; d. Bologna, 1525. He was one of the leading Greek revivalists of the Renaissance and taught peripatetic philosophy in Padua and Bologna, endeavoring to purify the current Aristotelianism from the ecclesiastical admixture of scholasticism. In his essay 'De Immortalitate Animæ' he taught that the application of Aristotle's method would necessarily result in a proof of the soul's mortality and confirmed the Greek criterion of «virtue for its own sake» as an ethical standard, in «Præmium essentiale virtutis est ipsamet virtus quæ hominem felicem facit.» His treatise 'De Incantationibus' was directed against the superstitions of his time. His works were published in Venice (1525) and in Basel (1567).

POMPONIUS, Lucius, Latin writer who flourished about 90 B.C. He was a native of Bonia. He was the first author to give form and finish to the Atellanæ Fabulæ, the popular plays which before his time were largely improvisations. He introduced a written text in the technical form of the Greek playwrights. The parts of his work which have come down to us show a skilful use of the rustic dialects and not a little obscenity. The fragments are contained in O. Ribbeck's 'Scenicæ romanorum poesis fragmenta' (Leipzig 1897–98). Consult Duff, J. W., 'A Literary History of Rome' (London 1909).

POMROY, Rebecca Rosignol, American nurse: b. Boston, Mass., 1817; d. 1884. She was the daughter of Samuel Holliday and in 1836 married Daniel F. Pomroy. Her experience as nurse was gained within her own family circle, and at the beginning of the Civil War she offered her services to the government. During the war she was stationed successively at Georgetown Hospital, West Hospital, Baltimore and Columbian University Hospital, Washington, D. C. On two occasions Mrs. Pomroy attended the family of Abraham Lincoln. About the end of the war she had an attack of typhoid fever which left her an invalid for many years. Upon regaining her strength she was engaged as matron in a girls' reform home at Newton Centre, Mass., and subsequently in the Newton Orphan Home, since named the Rebecca Pomroy Home.

PONAPÉ, pō'nā-pā, one of the Caroline Islands (q.v.) in Micronesia, in form nearly circular, with a diameter of 16 miles and an area of 140 square miles and ringed by a coral reef three miles distant. The interior is mountainous, the coast fertile. Mangroves flourish and durian and vegetable-ivory nut are exported. Remarkable ruins consisting of great blocks of basalt have been found. The island belongs to the group of Eastern Carolines, of which the town of Ponapé is the seat of government. Pop. (est.) 2,000. Consult Pereira, 'La isla de Ponapé' (1896).

PONCA (pŏn'kạ) **CITY**, Okla., city in Kay County, on the Arkansas River, the Atchison, Topeka and Santa Fé and the Hutchinson and Southern railroads, 63 miles north of Guthrie. It contains flour mills, oil refineries, grain elevators, glass works and a tent-making factory and has extensive wheat-growing interests. There is a public library and a considerable trade is carried on with the Indians. Pop. 2,521.

PONCA INDIANS, one of the five tribes of the so-called Dhegilia group of the Siouan family, forming with the Omaha, Osage and Kiansa, the upper Dhegilia or Omaha division. The Ponca and Omaha Indians have the same language, differing only in some dialectic forms and approximating the Quapaw rather than the Kansa and Osage languages. They are a partly civilized and peaceable race. They became separated into two bands; one, numbering about 600, remained in the former Indian Territory, while the other, numbering about 225, retained their reservation in Nebraska. In 1906 the bands numbered respectively 570 and 263, total 833.

PONCE, pōn'sā, Porto Rico, city, capital of the department of Ponce, three miles from the coast. It is the second largest city of Porto Rico and the first in commercial importance. Coffee is the most important export. Other exports are sugar, rum, molasses and tobacco. The main part of the town is connected with the port, Playa, by a good road and electric railway. The harbor is large and accommodates vessels drawing 25 feet; the custom-house is located at Playa. Ponce is connected with Yanco, 20 miles distant, by railroad and with San Juan and Arecibo by highways. The greater part of the inhabitants are engaged in commercial and mercantile pursuits; but there are a few mechanical industries, shoemaking, etc., and the mechanics of Ponce excel in the quality of their workmanship. The city is considered the most progressive on the island; it is well built and modern in appearance, with wide streets, several plazas or open squares, the largest of which is the Plaza Principal and a number of handsome residences. It has also the best market-house and best market on the island. The water supply is excellent; there are electric lights and electric railways; the chief buildings include the church of Our Lady of Guadalupe (Roman Catholic), a Protestant church, the municipal hall and two theatres. There are also several asylums and hospitals. The city has a public library and a good public school system has been established since the American occupation. In 1918 the city had two earthquake visitations; in the second (15 October) Red Cross workers estimated that 600 families were rendered homeless.

PONCE DE LEÓN, pōn'thā dā lā-ōn', **Fray Luis de**, Spanish theologian and poet: b. Belmonte, La Mancha, 1527; d. Madrigal, Spain, 23 Aug. 1591. He entered the Augustian order at 16, was educated at the University of Salamanca, where he later became professor of theology and of Thomistic philosophy. As a linguist and a theologian he became famous,

Helmets, Shields, Gauntlets, etc., found in the "Gladiators' Barracks"

but in 1572 was brought before the Inquisition on a charge of Lutheranism and of having translated into Spanish without authorization the 'Song of Solomon.' He was held in prison until 1576, when he was reinstated in his offices in the university and subsequently became vicar-general and finally provincial of his order. His lyrical poetry is chiefly of a religious character and though small in quantity is of great merit. He translated the 'Eclogues' and two of the 'Georgics' of Virgil, about 30 odes of Horace, 40 of the Psalms, besides selections from modern Greek and Italian poets. His most popular prose work was 'Perfecta casada' ('The Perfect Wife,' (1583), a treatise in the form of a commentary on portions of the book of Proverbs, a treatise on wifely duties. Another notable prose work was a treatise on the 'Names of Christ' 1583). The best edition of his works is that of Merino (6 vols., 1804–16). Consult J. Gonzales de Tejada, 'Vida de Fray Luis de León' (1863); Ford, J. D. M., 'Luis de León, the Spanish Poet, Humanist and Mystic' (in the 'Publications of the modern Language Association of America,' Vol. XIV, No. 2).

PONCE DE LEÓN, Juan, Spanish discoverer: b. Leon, about 1460; d. Cuba, 1521. He fought in the conquest of Granada and in 1493 shipped with Columbus on the admiral's second voyage. Subsequently he held under Ovando the post of governor of the eastern portion of Española, in 1508 undertook the conquest of Porto Rico and in 1510 was made governor of the island. He had already played a brave part in the struggles attending Spanish colonization in the New World, when in 1512 he obtained from King Ferdinand permission to conquer Bimini. The Indians seem to have spoken of a land called Bimini, north of Española and in the 1511 edition of the 'Decades' of Peter Martyr is a map on which appears a large island named Beimeni. To this Bimini Ponce de León was going for the «Fons Juventatis,» or fountain of youth, the belief in such a fountain being a part of the folklore of his day. A spurious letter purporting to be from John Prester (q.v.), circulated through Europe in the 12th century, tells of such a fountain. Sir John Mandeville calmy appropriated the story, described the fount as at a place called Polombe and said that he «drank thereof thrice,» and «feel me the better and the haler.» Stories of an island northward of Española, where a fountain of youth was, must have been afloat in Spain; for the same 1511 edition of the 'Decades' refers to them. In the patent granted in 1512 to De León, condition was made that the island had not been already discovered. In March 1513 the veteran set sail with three caravels from San German in Porto Rico. On the 27th he came in sight of the mainland on which he landed, 2 April, taking possession in the name of the king and calling the region Florida, since 27 March had been Easter Sunday, styled by the Spaniards Pascua Florida («flowery Easter»). The spot at which he landed was a little northward of the present site of Saint Augustine. He then coasted about the peninsula to the west side, reaching lat. 27° 30'. The bay at which he arrived was long known as Juan Ponce. He reached Porto Rico on the return voyage 21 September. He had to subdue the Caribs, a long undertaking; and not until 1521 did he attempt a new expedition. Then with a new patent for conquest and settlement, he set out with equipment for starting a colony. The hostility of the Indians, however, rendered the success of the enterprise doubtful. Ponce De León was severely wounded by an arrow and returned with the whole expedition to Cuba, where he died of his wound. He had not discovered that Florida was not an island, but he opened the path to this knowledge.

PONCELET, pôns'lā, **Albert,** Belgium clergyman: b. Liège, 30 Aug. 1861; d. Montpellier, France, 19 Jan. 1912. He was educated at Liège, Tronchiennes and Louvain; entered the Society of Jesus in 1878 and was professor of grammar at Saint Michael's College, Brussels, in 1884–85. In 1886–88 he was assistant editor of 'Acta Sanctorum' and was ordained to the priesthood in 1891. From 1892 to 1912 he was charged with the practical direction of 'Analecta Bollandiana' at Brussels. He compiled one volume of 'Acta sanctorum Belgii' (1911). His works include 'Anecdota ex codicibus hagiographicis Johannes Gielemans' (1895); 'Catalogus Codicum Hagiographicorum Latinorum Bibliothecarum Romanorum præter quam Vaticanæ' (1909); 'Catalogus Codicum Hagiographicorum Latinorum Bibliothecæ Vaticanæ' (1910); 'Bibliotheca Hagiographica Latina antiquæ et mediæ ætatis' (1911). He edited 'Annales de l'Abbage de Saint Ghislain par Dom Pierre Bandry et Dom Augustin Durot' (Vols. X, XI, XII, 1897), etc., and contributor to 'The Catholic Encyclopedia,' 'Analecta Bollandiana,' 'Précis historiques,' 'Archivio della R. Societá Romana di Storia Patria,' *Deutsche Literaturzeitung,* etc.

PONCELET, Jean Victor, French military engineer: b. Metz, 1 July 1788; d. Paris, 23 Dec. 1867. Between the years 1807 and 1810 he attended the Ecole Polytechnique, where he was a pupil of Monge. In 1812 he received the commission of lieutenant in the engineers, but on Napoleon's retreat from Moscow was taken prisoner and transported to Saratov, on the Volga. On returning to Metz in 1814 he worked out the geometrical problems he had begun to consider during his captivity, but these met with little recognition from the French Academy. In 1829 he published his 'Traité des Proprietés Projectives des Figures.' He henceforth gave himself closely to the study of applied mechanics; invented the water wheel which bears his name and published numerous works on mechanics. In 1835 he was appointed member of the National Defenses Commission and professor of applied mechanics in the University of Paris. He was promoted general in 1848 and went to the Exhibition of 1851 at London as president to the Commission of Mechanics. In 1857 he published his important account of the progress of mechanical science, 'Collection des Travaux de la Commiss' n Française.' The work which he had begun in captivity in Saratov — 'Application d'Analyse et de Géometrie' —he published in 1862. He was really the founder of modern geometry and had gained great influence among German mathematicians at a time that his countrymen had accorded him only scant recognition. Among his other works are 'Les Roues Hydrauliques Verticales' (1826); 'Experiences Hydrauliques' (1832); 'Traité de Mécanique Appliquée aux Machines'

(1845); 'Applications d'analy. se et de géométrie' (2 vols., 1862–64), etc. Consult Didion, 'Notice sur la Vie et les Ouvrages du Général Poncelet' (1869).

PONCHO, a kind of cloak worn by the Indian and Spanish inhabitants of South America. It resembles a narrow blanket with a slit in the middle, through which the head passes, so that it hangs down loosely before and behind, leaving the arms free.

POND, Frederick Eugene («WILL WILDWOOD»), American author and journalist: b. Packwaukee, Wis., 8 April 1856. He was educated at Montello, Wis., and early turned to journalism, in which he made sporting matters his specialty and was one of the first to urge the establishment of a National Sportsman's Association. In 1881–86 he was field editor of *Turf, Field and Farm*, edited *Wildwood's Magazine* in 1888–89, and when it was merged with *Turf, Field and Farm*, he became corresponding editor. Since 1897 he has edited the *Sportsman's Review*. From 1893–95 he was secretary of the National Game Protective Association. He has published 'Handbook for Young Sportsmen' (1876); 'Gun Trial and Field Records of America' (1885); 'A Strike' (1897); edited Frank Forrester's works (1879); 'Sportsman's Directory' (1892–93); Hallock's 'An Angler's Reminiscences' (1913) and has contributed to the 'Cyclopedia of American Biography.'

POND, James Burton, American lecture manager: b. Cuba, Allegany County, N. Y., 11 June 1838; d. Jersey City, N. J.. 21 June 1903. His parents settled in Wisconsin in 1847 and there he learned the printer's trade. He edited the *Weekly Journal* of Markesan, Wis., 1860–61, and becoming 2d lieutenant in the 3d Cavalry Volunteers of that State, rose to the rank of major and was among 17 survivors of the guerrilla Quantrell's massacre of a band of 118 soldiers at Baxter Springs, Kan., in October 1863. Between 1865 and 1874 he engaged in business and it was as the manager of the lecture tour of Mrs. Ann Eliza Young, the 19th wife of Brigham Young, when she renounced Mormonism, that he chanced to take up the business of manager and for the rest of his life he continued to «manage» platform speakers. He went to New York in 1879. Among famous men whom he «managed» are Wendell Phillips, William Lloyd Garrison, Robert G. Ingersoll, Henry Ward Beecher, Bill Nye, Max O'Rell and the Dean of Ely, Charles William Stubbs. He published 'Eccentricities of Genius' (1900); 'A Summer in England with Henry Ward Beecher.'

POND, John, English astronomer: b. London, 1767; d. Blackheath, Kent, 7 Sept. 1836. He was educated at Cambridge, traveled extensively and on his return to England in 1798 settled at Westbury, near Bristol, where he engaged in astronomical observations. He erected there an altazimuth instrument, two and a half feet in diameter and by a series of observations proved that the quadrant then in use at Greenwich had changed its form through age, rendering the re-equipment of the Royal Observatory a necessity. He removed to London in 1807, was elected a fellow of the Royal Society and in 1811 was appointed astronomer royal. By means of the six-foot mural circle mounted by the Royal Society in 1812 Pond compiled a catalogue of the north polar distances of 84 stars, which he presented to the society in 1813. In 1821 he substituted the mercury-horizon for the plumb-line and spirit level and in 1825 originated the system of making observations alternately by direct and reflected vision, for further experiments in which direction he was subsequently transferred to Queen's College, Belfast. Though his mathematical knowledge was slight and his work wholly technical, he nevertheless performed valuable services to science and succeeded in introducing modern methods and instruments at the national observatory. He first used two instruments for direct and reflected observations of the same star; invented the method of observing in groups; and was the first astronomer who advocated the practice of depending upon masses of observations for all fundamental data. He was pensioned and retired in 1835. He published a catalogue of 1,113 stars (1833), a work of great value and accuracy. His other publications include the volumes of 'Greenwich Observations,' during his astronomership; various 'Papers' in the 'Transactions' of the Royal and Royal Astronomical Societies; and a translation of the 'Système die Monde' of Laplace.

POND LAW, The, in American politics and legislation an act passed by the Ohio legislature in 1882, for the regulation of the liquor traffic. For eight years the liquor question had agitated Ohio politics and the Republicans finally adopted the Pond Law for the taxation of liquor selling. The law was afterward declared unconstitutional by the Supreme Court of the State.

POND-SKATERS, long, narrow bugs of the hemipterous family *Hydrometridæ* which glide swiftly over the surface of ponds and quiet pools in search of prey. The front pair of legs, comparatively short, serve to seize prey or to cling to a support; while the strong middle and hind legs carry the insect rapidly over the surface, the film bending but not breaking under the feet. The whole body is covered with a velvety fur; and when the insect dives it carries down a jacket of air, upon which it sustains breathing for a considerable time. Consult Howard, 'The Insect Book' (New York 1902). See FRESH-WATER INSECTS.

POND SMELT, a small surf smelt, numerous along the shores of Bering Sea and regarded as excellent food.

POND SNAIL, a small fresh-water pulmonate mollusk of the family *Limnæidæ*. In this family the shell is large and thin, the lip sharp, the muzzle short and broad and the eyes are placed at the base of the tentacles. The genera *Limnæa, Physa, Ancylus* and *Planorbis* are prominent. The first-named genus contains the gracefully spiral water-snails with triangular tentacles, numerous in all parts of the world and mostly less than an inch long; a widespread and familiar species (*Limnæa stagnalis*) is often twice that length and the aperture widely flaring. This form is found in streams and pools and crawls upon the leaves and stems of aquatic plants. The equally common genus *Planorbis* possesses a flattened discoidal shell, the whorls of which are coiled round a central axis and lie in one plane. The shell aperture is crescentic in shape, and the foot is round and short. The genus *Physa*, represented all over the United States by *P. heterostropha* (see SNAILS AND SLUGS), has the spiral whorls of the shell turned to the left hand; the tentacles are long and slender and the edge of the mantle is fringed.

PONDICHERRY, pŏn-dĭ-shĕr'ĭ (French, PONDICHÉRY, pôṅ-dē-shā-rē), India, the capital of the French possessions in India, on the east or Coromandel coast, 85 miles by rail southwest of Madras. Its territory, with an area of 107 square miles, is surrounded on the land side by the British district of South Arcot. It stands on a sandy beach, and consists of two divisions separated by a canal. The «White Town,» or European quarter, on the east, facing the sea, is regularly laid out, contains a spacious square, in which is the government-house, handsome planted boulevards and a number of well-built houses. The «Black Town,» or native quarter, on the west beyond the canal, consists mainly of huts of brick or earth and a few pagodas. Its streets are broad and shaded by palm-trees, but filthy. The fortifications, formerly strong, were destroyed during the war with the British, and by the Treaty of Paris they are not to be rebuilt nor is Pondicherry to be garrisoned by a native French force. The province is partly watered by the Gingee River, but is not very fertile: some rice, indigo, tobacco, betel, cotton and cocoanuts are raised; which, with cotton cloths and oil seeds, form the chief exports. The imports consist chiefly of manufactured goods. There is no harbor, but only a roadstead, where the surf beats almost as strongly as at Madras. There is, however, an iron pier. The town has been provided with a good supply of drinking water. The settlement was purchased by the French from the Bejapoor rajah in 1672. It was several times taken by the British, the last being in 1803, being restored in 1815. The population of the town in 1916 was 47,398; of the province, 168,344.

PONDOLAND, province of the Cape of Good Hope, a maritime district; area, 3,906 square miles. Its vegetation is luxuriant, and it is well adapted for the rearing of cattle and sheep. The Saint Johns River flows through its southern part, and forms at its mouth an excellent harbor. It was the last part of Kaffraria that remained independent until it became a British protectorate in 1884, and was annexed to the cape in 1894. On 31 May 1910, the colony was merged in the Union of South Africa, thereafter forming an original province of the union. Pop. 234,637.

PONIATOWSKI, pō-nyä-tŏv'skē, the name of an illustrious Polish family descended from an Italian stock. GIUSEPPE SALINGUERRA (b. 1612), of the Italian family Torelli, having settled in Poland, took the name of Eziolek, and afterward that of Poniatowski, from the estate of Poniatow belonging to his wife. Among important descendants of his may be cited (1) STANISLAS, COUNT PONIATOWSKI (b. 1678; d. 1762), known for his connection with Charles XII, whom after the battle of Poltava he followed into Turkey, and as whose Ambassador at Constantinople, he had the address to involve the Porte in a war with Russia. He wrote 'Remarques d'un Seigneur Polonais sur l'Histoire de Charles XII par Voltaire' (1741). (2) His eldest son, STANISLAS AUGUSTUS (b. 1732) was elected king of Poland in 1764. (See STANISLAS II). (3) JOSEPH ANTONY, nephew of King Stanislas (b. Warsaw, 7 May 1762; d. Leipzig, 19 Oct. 1812). When the Poles attempted in 1794 to drive the Russians out of their country, he joined the Polish camp as a volunteer. Kosciusko gave him the command of a division, at the head of which he distinguished himself at the two sieges of Warsaw. On the creation of the duchy of Warsaw, Poniatowski accepted the place of Minister of War in the new state. In 1809 he commanded the Polish army against the superior Austrian force sent to occupy the duchy, and compelled it to retire. In the war of 1812, against Russia, he was again at the head of the Polish forces, and distinguished himself throughout this campaign. After the battle of Leipzig, during which Nalopeon created him marshal of France, he was ordered (19 October) to cover the retreat of the French army; with a handful of men he protected the retreat till he was twice wounded, and then, being sorely pressed by the enemy on the banks of the Elster River, he spurred his horse into the stream and was drowned. His body was afterward removed to Warsaw, and in 1816 was deposited in the cathedral at Cracow. An equestrian statue of Poniatowski was executed for the city of Warsaw by Thorwaldsen.

PONS ASINORUM, pŏnz ăs-ĭ-nō'rŭm («the bridge of asses»), a Latin expression applied early in the 16th century to a diagram showing how to find middle terms to arguments. The original allusion seems to have been the difficulty of getting asses to cross a bridge. The name is also given to the fifth proposition of the first book of Euclid, which sets forth that, if a triangle has two of its sides equal, the angles opposite to these sides are also equal.

PONSARD, François, frāṅ-swä pôṅ-sär, French dramatist: b. Vienne, Dauphiné, 1 June 1814; d. Paris, 13 July 1867. His first venture in literature was made with a translation of Lord Byron's 'Manfred' (1837), and his first success was his 'Lucrèce,' produced in 1843, and welcomed as a return from romanticism to classicism, and when played in 1853, with Rachel in the title rôle, very popular. Among other plays by him are 'Agnes de Méraine' (1846); 'Charlotte Corday' (1850); 'Ulysses' (1852); L'Honneur et l'Argent' (1853); 'La Bourse' (1856); 'What Pleases Womankind' (1860), a trilogy; 'Le Lion amoureux' (1866); 'Galilée' (1867). He became a member of the Academy in 1855. His complete works were issued in 1876.

PONSON DU TERRAIL, pôṅ-sôṅ dü tăr-ā-ē, **Pierre Alexis**, French romancer: b. Montmaur, Isère, France, 8 July 1829; d. Bordeaux, 31 Jan. 1871. He wrote a large number of fictions which were very popular with an uncritical public. Among his works are 'Les Coulisses du Monde' (1853) which established his fame; 'Gown and Sword' (1857); 'The King of Navarre's Mistress' (1863); 'The World's Great Bohemians' (1867); 'Aurora's Amours' (1870).

PONT, Timothy, Scottish geographer, son of Robert Pont: b. about 1560; d. about 1630. He was graduated from Saint Andrew's in

1584, was Minister of Dunnet, Caithnessshire in 1601. In 1609 he subscribed for 2,000 acres of forfeited lands in Ulster and soon after conceived the idea of a Scottish atlas. In pursuance of his plan he visited all portions of Scotland to the most remote and dangerous sections, making his maps on the spot. He died some time between 1625 and 1630 and his maps, which were exceedingly neat and accurate, were ordered by King James to be purchased and published. In the troubleous times following they were forgotten until rescued by Sir John Scott of Scotstarvet, and published in Bleau's 'Atlas' (Vol. V, 1668).

PONT-À-MOUSSON, pôn'tą-moo'sôn, France, town in the Department of Meurthe-et-Moselle, 16 miles northwest of Nancy, on the Moselle, which divides the town. It contains the Gothic Church of Saint Martin, begun in the 13th century, the town hall, an old convent now used as a petit seminaire, a communal college, blast furnaces and several industrial establishments, including potteries, textile mills, sugar factories, paper and card board mills, cable works, etc. The town was founded about the late 9th century and in 1572–1763 was the seat of a university. It suffered greatly in the Great War of 1914–18, being captured by the Germans early in the war and held by them despite several attempts by the French to retake it. In the autumn of 1918 after the Americans wiped out the Saint Mihiel salient the town was again close to the battle lines. Pop. 14,000. See WAR, EUROPEAN.

PONTA DELGADA, pōn'tä dĕl-gä'dä, or **PONTE DELGADA,** Azores, town on the island of Saint Michael, the largest town in the islands. It is defended on the west side by the castle of Saint Braz, and about three miles to the east by the forts of São Pedro and Rosto de Cão. The principal buildings are churches, monasteries, convents, and an English chapel. The town has been lighted with gas since 1884. The harbor accommodations are good. The trade is considerable, and is chiefly with the British, of whom a considerable number are residents. The chief exports are wheat, maize and oranges; and the imports, cotton and silk goods and hardware. Pop. about 16,179.

PONTANO, pŏn-tą'nō, **Giovanni Gioviano,** or **PONTANUS, Jovianus,** Italian poet: b. Cerreto, 1426; d. Naples, 1503. He was educated at Perugia and at 22 settled in Naples. There he received a government appointment; became tutor to the sons of Alphonso the Magnanimous; and finally became chancellor. He founded an academy of letters at Naples and was a favorite at court and with the literary men of that capital. For having welcomed Charles VIII of France in 1495 Pontano was in disgrace after the Restoration. He is a figure of political importance in southern Italy but is best known for his poems and dissertations. His Latin is quite pure and his works are of interest in the study of the social life of the period. His chief works are 'Urania,' Latin didactic poem in hexameter; 'De hortis Hesperidum'; 'De conjugali amore'; 'Eridanus'; 'Tumuli'; 'Naeniæ'; 'Baiæ.' His works were published at Venice (5 vols., 1505–18). Consult Ardito, 'Giovanni Pontano e i suoi tempi' (Naples 1871) and Symonds, 'Renaissance in Italy.'

PONTCHARTRAIN, pŏn-chär-trăn', a lake of Louisiana, about five miles north of New Orleans, about 40 miles long from east to west, and nearly 25 wide. The water is generally from 12 to 14 feet deep. It communicates with Lake Borgne on the east and with Lake Maurepas on the west. It is connected with New Orleans on the south, by Bayou Saint John and a canal, and also by a railroad. It is surrounded by marshes, which have a dense vegetation of water plants. The residential sections, Madisonville and Mandeville, are on the north shore.

PONTEDERIACEÆ, a family of aquatic plants, the pickerel-weeds, which are perennial water of marsh herbs, with perfect, mostly irregular flowers from a one-leafed spathe; perianth corolla-like, equally six-cleft. One genus is *Pontederia,* with one American species (*P. cordata*); another genus is *Heteranthera,* with three species.

PONTEFRACT, or **POMFRET,** England market town and parliamentary borough of Yorkshire, 20 miles south-southwest of York, on the Midland, Lancashire and Yorkshire and Northeastern railroads. It has a grammar and other schools and has extensive agricultural interests. Licorice is a specialty for the manufacture of Pontefract lozenges since 1562. The remains of a Roman camp have been discovered nearby and there are ruins — an old castle in which Richard II died. The water-supply system, cemetery, markets and recreation grounds are owned by the town. Pop. 15,989.

PONTEVEDRA, pōn-tā-va'drä, Philippines, (1) pueblo, province of Negros Occidental, on the western coast on Guimaras Strait at the mouth of the Mangala River, 22 miles south of Bacolod, the provincial capital. It is a military station. Pop. 12,000. (2) Town, province of Cápiz, island of Panay, 12 miles southeast of Cápiz, the provincial capital. Pop. 9,500.

PONTIAC, pŏn'tĭ-ăk, Indian chief: b. on Ottawa River, about 1720; d. Cahokia, Ill., 1769. He became the principal chief of the allied tribes of the Ottawas, Ojibways and Pottawattomies, and it is thought that he led the Ottawas at the defeat of General Braddock (q.v.) near Fort Duquesne. After the taking of Quebec, Major Rogers was despatched to take possession of the western forts for Great Britain, under the terms of the treaty of Paris. Pontiac objected to this procedure, which he regarded as an invasion of his domain, and as a result soon began to plot the complete extermination of the English. In 1762 he sent out messengers who secured the allegiance of all tribes as far as the lower Mississippi in a confederation against the common enemy. The plan, as arranged, was that each tribe was to attack the fort nearest it, and that all were then to make a combined descent upon the undefended settlements. A great pow-wow or council was held. 27 April 1763 near Detroit; Pontiac made a stirring oration, rehearsing the wrongs inflicted upon the Indians by the English. He was himself to make an attempt to capture Detroit on 7 May, but the design was revealed, and Pontiac could lay siege only to the fort. But a long investment was a thing foreign to Indian warfare, and the lines were so loosely drawn that provisions were freely smuggled into the fort. Pontiac was supplied by the Canadians, and paid in promissory notes of birch-bark, later, it is said, scrupulously redeemed. Schooners sent through Lake Erie with supplies and reinforcements were captured by the savages, but at last one with ammunition and provisions did succeed in reaching the fort. The besieged thereupon believed themselves strong enough to venture a sally against the Indian encampment, but Pontiac, warned of the project, defeated them in the battle of Bloody Bridge (31 July). The siege was sustained until 12 October, when Pontiac withdrew his forces to the neighborhood of the Maumee. This part of the conspiracy had, it is true, been a failure; but elsewhere the success was remarkable. When the detached and unorganized character of Indian warfare is considered, recognition must be made of the notable diplomatic and military talent of the chieftain who directed the largest and most powerful coalition in Indian history, and came so near to realizing his grand object. Of 12 fortified posts attacked, eight were taken, while the garrisons of most were massacred; several English expeditions were annihilated; and the frontiers were desolated and terrified. Hostilities continued in a desultory fashion into 1764, but on 17 Aug. 1765 Pontiac formally made peace at Detroit, and in the summer of 1766 concluded a treaty with Sir William Johnson at Oswego, N. Y. In 1769 a Kaskaskia Indian, bribed by an English trader, murdered Pontiac; in vengeance the northern tribes made war on the Illinois group, which was all but exterminated. Consult Parkman, ‹The Conspiracy of Pontiac› (1851; new ed. 1898); ‹Handbook of American Indians› (Bureau of American Ethnology, Vol. II, 1910).

PONTIAC, Ill., city, county-seat of Livingston County, on the Vermilion River, and on the Illinois Central, the Wabash and the Chicago and Atlantic railroads, about 95 miles north by east of Springfield and 90 miles south by west of Chicago. It was settled about 1825, but was founded permanently in 1829, by colonists from Indiana and Ohio. In 1856 it was incorporated, and received a city charter in 1872. It is in a fertile agricultural region in which stock-raising is given considerable attention. In the vicinity are extensive coal-fields. The chief industrial establishments are candy factories, a hook and eye factory, box factory, and large shoe factories. There is considerable trade in coal, grain, livestock and manufactures. The principal public buildings are the State Reformatory for juvenile offenders, which will accommodate 1,500, the city hall, the public library, and the church and school buildings. Pop. about 6,090.

PONTIAC, Mich., city, county-seat of Oakland County, on the Clinton River, and on the Grand Trunk and the Pontiac, Oxford and Northern railroads, about 26 miles northwest of Detroit. It was settled in 1818–20, incorporated as a village in 1837, and in 1861 was chartered as a city. It was named after the Indian chief Pontiac. It is in a section of beautiful lakes in which there is considerable hunting and fishing. It is surrounded by an agricultural region, and has a number of industries connected with farm and forest products. The chief manufacturing establishments are automobiles and accessories works, farm implement works, foundry products, hardware works, carriage factories, machine shops, flour and lumber mills, knit-goods factory and gas and gasoline engine works. There is considerable trade in farm products, fruit, vegetables, wool and carriages and wagons. It has the State Hospital for the Insane, a library building (ladies' library), a public high school library, public and parish schools and churches. The government of the city is now conducted on the commission plan. The city owns and operates the waterworks. Pop. 17,524.

PONTIAC'S WAR. See COLONIAL WARS IN AMERICA; PONTIAC, and consult ‹Handbook of American Indians› (Bureau of American Ethnology, Vol. II, 1910).

PONTIANAK, pŏn-tē-ä-näk', West Borneo, town and capital of the Dutch settlements on the west coast of Borneo; on the Kapuas or Pontianak River, at the mouth of the Landak, in the administrative division of the outports. It is on the equator and 110° 20' E. longitude. It is in a region in which the chief productions are rice, sago, sugar, birds' nests, pepper and wax. Salt, opium, some clothing, wares and machinery are introduced. Pontianak is the chief port of West Borneo, which has an area of 55,825 square miles and population estimated in 1912 at 467,158. It has a Dutch resident. Pop. 10,000.

PONTIFEX, one of the highest priestly colleges at Rome, to which was entrusted the oversight of all religious observances, public or private. Their institution, like that of all important matters of religion, was ascribed to Numa. The number of pontifices was originally probably six, all patricians, exclusive of the king, whose place, after the abolition of the monarchy, was taken by the pontifex maximus, or chief priest. The Ogulnian Law (300 B.C.) raised this number to eight, or, including the pontifex maximus, to nine, five of whom were to be plebeians. Sulla increased the number to 15 and Julius Cæsar to 16, including in both these instances the pontifex maximus. The duty of this dignitary was the inauguration of the priests, and in earlier time the care of the public records (*annales maximi*). He also superintended the sacred rites of Vesta, held his office for life, and could not leave Italy. The emperors afterward assumed this title until the time of Theodosius, and it was subsequently assumed by the Christian bishop of Rome. The pontifices also had the care of the calendar, and decided lawsuits which were connected with religion (hence the *jus pontificum*). The external badge of the pontifex, at least on solemn occasions and while engaged in the duties of his office, was a dress bordered with purple (*toga prætexta*), and a tapering hat made of the skins of sacrificed animals (*galerum*). Consult Bouchè-Leclercq, ‹Les Pontifes de l'ancienne Rome› (1871); Mommsen, ‹Römisches Staatsrecht› (1887–88); Wissowa, ‹Religion und Kultus der Rômer› (1902).

PONTIFICAL ORDERS. See ORDERS, (ROYAL) and DECORATIONS.

PONTIGNY, pôn-tēn-yē, France, a village on the left bank of the Serein, in the department of Yonne, on the railway between Laroche and Isle-Angely. Its abbey, founded in 1114 by monks from Citeaux, was itself the mother abbey of 43 monasteries. Thomas à Becket, Saint Edmund of Canterbury and Stephen Langdon spent their exile here, and Saint Edmund died and was buried in the monastery, which was devastated by the Huguenots in 1567, and destroyed in the Revolution. The abbatial church (mainly 1150–70) is one of the finest examples of Cistercian architecture. The shrine of Saint Edmund (18th century) in this church was visited by a large number of English Roman Catholics in 1874. Consult Chaillon des Barres, 'L'Abbaye de Pontigny' (1844).

PONTINE (pŏn'tēn) **MARSHES,** Italy, a swampy plain, 18 to 30 miles long and 6 to 10 miles wide, lying 25 miles southeast of Rome, bounded on the south and west by the Tyrrhenian Sea and sand dunes covered with oaks, and on the east by Monti Lepini. Only a small part of this large area is actually marshy, but enough to make the whole region and much of its surroundings very unhealthy, the marsh vapors being carried to Rome itself by the south wind and being probably the cause of the Roman fever. In the early days of the Roman republic the Volscians possessed the Ager Pometinus, possibly so named from Suessa Pometia, one of its cities, and by elaborate engineering made it habitable and fertile. But the inhabitants of its 33 cities were conquered and driven out by the Romans in 358 B.C., and the land soon became dangerous; even in 312 B.C. its centre was pierced by the great Appian Way built by Appius Claudius. Cethegus attempted to drain the marsh about 160 B.C. Julius Cæsar planned to turn the Tiber into it, but died before the undertaking was commenced. Augustus built several canals, and after him Nerva, Trajan, Theodoric, and 18 popes attempted to better conditions. A law passed in 1899 by the Italian government voted 7,000,000 lire to complete the work, which is estimated to take 24 years. The region has a scanty population of farmers and shepherds, who, however, only spend a part of the year here. Consult Blanchère, 'La Malaria de Rome et le Drainage antique' (1882); Berti, 'Paludi Pontiche' (1884); Donat, 'Die Pontinischen Sümpfe' (1898).

PONTMARTIN, pôṅ'mär'tăṅ, **Armand Ferrand,** Count de, French author: b. Avignon, 1811; d. 1890. He received his education in Paris; became interested in journalism about 1830 and soon became prominent as a critic. He is the author of many novels written in a brilliant style; his best works are 'Causeries littéraires' (1845–56); 'Causeries du samedi' (1857–81); 'Semaines littéraires' (1861–63); 'Souvenirs d'un vieux critique' (1881–89). Consult his 'Mémoires' (1885–86).

PONTOON, in military engineering a flat-bottomed boat, or any light and buoyant framework or floating body, used in the construction of a temporary bridge for the passage of troops over a river or arm of the sea. As pontoons form a part of the equipment of any army they must be as light in structure as is consistent with safety. The pontoons used by armies have differed greatly at different times, the two chief types being a kind of undecked boat, and a decked boat or close cylinder. The introduction of pontoons may be considered to date from the 18th century, although long previous to this similar means were used for the passage of streams. Darius passed the Hellespont and Danube by pontoon bridges. In the World War American engineers constructed many pontoons to afford passage across streams where the Germans had wrecked bridges.

PONTORMO, Jacopo Carucci (commonly known as Jacopo da Pontormo), Italian painter: b. Pontormo, near Florence, 1494; d. Florence, 1556. He was a pupil of Andrea del Sarto and painted history and portraits. At 13 he was left an orphan and sent to live at Florence as a pupil of Leonardo da Vinci. He also studied under Pietro di Cosimo and Mariotto Albertinelli. His early work won the approval of both Raphael and Michelangelo, who foretold his future greatness. His pictures are often mistaken for those of Andrea, and the best of them are those produced soon after he had been dismissed from the school of del Sarto who, it is said, had grown jealous of him. He, however, altered his style several times, and took at last to imitating Albert Dürer. His work deteriorated in his latter years and when he admitted the public to see his 'Deluge' and 'Last Judgment,' frescoes which he had painted in the chapel of San Lorenzo, in the manner of the imitators of Michelangelo, his work met with such bitter criticism that it was whitewashed over and he is said to have died of mortification. Pontormo remained a master of design to the end of his days, but his coloring, once rich and harmonious, lost all its grace as he neared his three score years. He was a great portrait painter and some of his works in his department have been attributed to Raphael or Andrea del Sarto. His best works are at Florence, but among his finest portraits are 'A Cardinal' (in the Borghese Palace at Rome); 'Baccio Bandinelli, the Sculptor' (at Milan); 'Portrait of a Boy' (in the London National Gallery). There is a fine 'Holy Family' of his, with life size figures in the Prado Museum, Madrid.

PONTUS, in ancient geography, a country of northeastern Asia Minor, originally the part of Cappadocia lying between Armenia and Colchis and the Halys River; called first Cappadocia on the Pontus (that is, Euxinus, or Black Sea), and then simply Pontus. The country on the east and south is mountainous, but along the coast there are large and fertile plains. A son of the Persian king Darius, Artabazes, received Pontus as a separate satrapy, with the right to transmit it as an inheritance to his posterity. One of his successors, Mithridates (about 400 B.C.), assisted the younger Cyrus, and refused to pay tribute to Artaxerxes. His son, Ariobarzanes I (363–337), made himself independent during the general insurrection of the governors of Asia Minor against Artaxerxes II. Mithridates II (337–302) transferred his kingdom voluntarily to Alexander. Afterward, in the division of his empire in 322, it fell to Antigonus. His successor, Mithridates III (302–266), enlarged his paternal kingdom by conquests, and was succeeded by his son Ariobarzanes III, who reigned from 266 to about 240 B.C., and he again by his son Mithridates IV, whose reign extended to about 190 B.C. He drove back the Gauls, who at various times in the course of the 3d century B.C. invaded Asia Minor, formed settlements there, and attacked Pontus shortly after his accession. Pharnaces I, who succeeded Mithridates IV, and reigned till about 156 B.C., took possession of Sinope, and made it his residence. Mithridates the Great in 124 succeeded his father, in whose time Phrygia had become a part of Pontus. He carried on bloody wars with Rome until his death; at last he submitted to Pompey, and killed himself, 63 B.C., from despair. The western part of Pontus was then annexed to Bithynia, and the remaining parts given away to the chiefs of some of the adjoining states. Pharnaces II, the treacherous son of Mithridates, obtained only Bosporus, and when he attempted to conquer again his paternal kingdom was vanquished by Cæsar, and put to death by Asander, who had made himself king of Bosporus. Still his son Darius received through Antony a part of Pontus. Polemon, who at the same time possessed the kingdom of Bosporus, Asia Minor and Colchis, was his successor. After the death of his widow, Pythodoris, Polemon II succeeded, as king of Pontus, 39 A.D. Nero took Bosporus from him, and Pontus, under the name of Pontus Polemoniacus, became, after Polemon's death, a Roman province. When the Latins in 1204 again conquered Constantinople, Alexius Comnenus founded a new kingdom in Pontus, which remained until Mohammed II united it in 1461 with his great conquests. The most noted town on the coast of Pontus was Trapesus, the modern Trebizond. Consult Clinton, 'Fasti Hellenici' (Vol. III, Appendix); Meyer, 'Geschichte des Königreichs Pontus' (1879).

PONTUS EUXINUS, ŭk-sī'nŭs, the ancient name for the Black Sea, still called the Euxine. The name, signifying in Greek "hospitable," is supposed to have been given as a good omen to this dangerous sea.

PONTYPRIDD, pŏnt'ē-prĭd', Wales, parish market town and urban district of Glamorganshire, also known as Newbridge, 10 miles southeast of Merthyr Tydfil, on the Taff River and on the Glamorgan Canal and the Taff Vale Railway. It has numerous coal mines, iron mines, anchor, cable and chain works, brass and iron foundries, and chemical works. In the middle of the 19th century it was a gathering-place for the followers of the Neo-Druidic cult. Pop. 43,211.

PONY (Lat., *pullanus, pullus,* a young animal), a horse of small breed, usually under 13 hands high. There are several breeds scattered throughout the world. The Shetland, Connemara, Galloway, Dartmoor and Canadian types are best known in northern countries. These horses are extremely hardy and are for their size much stronger than the full-sized horse. The Shetland is the smallest of the types named. In Corsica and Sardinia there are breeds of ponies which have long existed there.

PONY EXPRESS, the mail service between Saint Joseph, Mo., and California inaugurated in 1860. Eight days were allowed for the schedule; 190 stations were established; there were 80 riders and about 400 horses and over

300 station-keepers and their assistants. The service was discontinued in October 1861. Consult article in *Century Magazine,* Vol. XXXIV, New York 1898.

PONZ, pōnth, **Antonio**, Spanish painter, archæologist and art critic: b. Bexix, Valencia, Spain, 1725; d. Madrid, 4 Dec. 1792. He was educated at the University of Valencia, but, though he made sufficient progress in theology to be able to take the degree of doctor, his tastes diverted him to foreign languages and most strongly to the fine arts; the latter led him to become a pupil of Richart at Valencia. He subsequently lived at Madrid and Rome (1751), but returned to his native land (1760) and received a commission to paint a series of portraits of Spanish authors for the Escorial. Among his published works is 'Viaje de España' (18 vols.), in which he relates his experiences as a commissioner appointed to collect paintings and statuary from suppressed monasteries. The book is full of art criticisms and sketches of Spanish social life of the period. He also wrote 'Viaje fuera de España,' an account of travels through England and France.

PONZA (pŏn'zä) **ISLANDS, or PONTINE ISLANDS,** two small groups of volcanic islands on the west coast of Italy, 20 miles from the Gulf of Gaeta and not far from the Pontine Marshes. The larger and more westerly group belongs to the department of Gaeta in the province of Caserta, and consists of: Ponza, off the coast of Naples, which attains at Monte Guarda a height of 900 feet, is four miles long and two-thirds of a mile wide, was the place where Tiberius banished Germanicus' son, where Caligula sent his sisters and Domitian banished Flavia Domitillia; Zanone (Lat. Sinone), further north with a cloister at the summit of its mountain; and Palmarola (Lat. Palmaria), whose rude and wild inhabitants brought upon the island the repute of being the home of the Devil. In the second group are Santo Stefano, the most easterly of the Ponza Islands, and Ventotene (Lat. Pandataria), the place of banishment of Julia, Augustus' daughter, of Octavia (q.v.), Nero's wife, and of Agrippina, wife of Germanicus.

POOD, or PUD, a Russian weight of 40 Russian pounds, equivalent to 36 English pounds of avoirdupois.

POODLE. See DOG.

POOK, Samuel Hartt, American naval constructor: b. Brooklyn, N. Y., 17 Jan. 1827; d. Washington, D. C., 30 March 1901. He was graduated from the Portsmouth Academy, New Hampshire, in 1843, and became a shipbuilder, afterward settling in Boston, where as a naval architect he was engaged in building several clipper ships. At the outbreak of the Civil War he entered the government service, superintended the construction of the ironclad *Galena* and assisted in building the *Monitor.* He was appointed assistant naval constructor in the United States service in 1866, promoted naval constructor in 1871, and served in different navy yards until his retirement in 1899.

POOL, Maria Louise, American novelist: b. Rockland, Mass., 20 Aug 1841; d. there, 19 May 1898. For several years she was a contributor to the New York *Evening Post* and was also connected with the New York *Tribune*. She excelled in descriptions of life in New England and among her works are 'In Buncombe County'; 'A Vacation in a Buggy' (1887); 'Tenting at Stony Beach' (1888); 'Rowena in Boston' (1892); 'Mrs. Keats Bradford' (1892); 'In a Dike Shanty' (1896); 'In the First Person' (1898); 'A Golden Sorrow' (1898); 'The Malvon Farm' (posthumous, 1899).

POOL, or POOLING, in commerce and finance, a combination of persons contributing money to be used for the purpose of increasing or depressing the market price of stocks, with a view to the settlement of differences. In pooling railroad interests the common method of dividing the traffic between competing lines, is to pool the receipts and to redistribute them on percentages based upon experience and decided by an arbitrator.

POOL, a game. See BILLIARDS.

POOLE, John, English dramatist: b. England 1786; d. London, 5 Feb. 1879. His success as a dramatist came early in life, and beside his plays he wrote several satirical and humorous books. His dramas were played by the leading actors of the day and were almost invariably successful. His fame, however, rests principally upon the widely popular comedy, 'Paul Pry' (1825), and his farce, 'Twixt Cup and Lip' (1826). Other plays of his that may be named are 'Hamlet Travestie' (1813); 'Who's Who, or the Double Imposture' (1815); 'Deaf as a Post' (1823); 'The Wife's Stratagem' (1827); 'Lodgings for Single Gentlemen' (1829). He also wrote the satirical sketches: 'Little Pedlington and the Pedlingtonians' (1839); 'Comic Miscellany' (1845), etc.

POOLE, Matthew, English compiler: b. York, 1624; d. Amsterdam, 12 October 1679. He studied at Emmanuel College, Cambridge, and took orders, but in 1662 was ejected by the Act of Uniformity from his church of Saint Michaelle-Querne in London, and turned his leisure to good account by spending 10 years on his 'Synopsis Criticorum Biblicorum,' an attempt to condense into one work the opinions of all the biblical critics of all times and countries previous to his own. The work extended to five large folio volumes, and indicates great labor and research as well as no small degree of learning; but it is now of little use, later criticism and research having done much to supersede it. Poole also wrote a defense of the non-conforming clergy (1662); 'The Nullity of the Romish Faith' (1666); 'Annotations upon the Holy Bible' (1683–85), and other works, and took an active part in the leading controversies of his time, especially those with the Socinians and Roman Catholics. The intolerant spirit of the Stuarts compelled him to seek an asylum at Amsterdam.

POOLE, Reginald Lane, English educator and author: b. London, 29 March 1857. He was educated at Oxford and at the University of Leipzig, in 1880–81 was assistant in the department of manuscripts in the British Museum and since its establishment in 1885 has been editor of the *English Historical Review*. He has lectured in modern history at Jesus College, Oxford, since 1886 and is also lecturer on diplomatics in the University of Oxford. He has published 'A History of the Huguenots of the Dispersion' (1880); 'Sebastian Bach' (1882); 'Wycliffe and the Movement for Reform' (1889); edited Wycliffe 'De Civili Dominio Liber I' (1885) and 'De Dominio Divino' (1890); 'Historical Atlas of Modern Europe' (1897–1902); 'John Bales' Index Britanniae Scriptorum' (1902), with Dr. W. Hunt, 'The Political History of England' (12 vols., 1905–10), etc.

POOLE, William Frederick, American librarian: b. Salem, Mass., 24 Dec. 1821; d. Evanston, Ill., 1 March 1894. Graduated from Yale in 1849, he became assistant librarian of the Boston Athenæum in 1851, and in 1852 librarian of the Boston Mercantile Library. From 1859 to 1869 he was librarian of the Athenæum, in 1869–73 of the Cincinnati Public Library, which he organized, and in 1874–87 of the Chicago Public Library, whose formation he also directed. From 1887 he was in charge of the Newberry Library at Chicago, founded by W. L. Newberry. In 1885–87 he was president of the American Library Association, and in 1877 vice-president of the international conference of librarians at London. He was best known for his 'Index to Periodical Literature,' originally begun in 1848, in the preparation of which he was assisted by W. I. Fletcher and many other librarians. His writings, which were very numerous, include 'The Battle of the Dictionaries' (1856); 'Websterian Orthography' (1857); 'Cotton Mather and Salem Witchcraft' (1869); 'Anti-Slavery before 1800' (1887). He also discovered and printed a manuscript of Gov. Thomas Hutchinson on 'The Witchcraft Delusion of 1692,' and reprinted, with introduction and index, the rare work 'Wonder-working Providence of Sion's Saviour in New England.'

POOLE, England, a seaport of Dorsetshire, on the eastern coast of the county, 15 miles west of Bournemouth. There are extensive municipal and harbor improvements, an esplanade, a free library, etc. Ropes, cables, sailcloth, tiles, etc., are manufactured, and there is a large coasting trade principally in clay and grain. Much of the property is owned by the town. Pop. 38,886.

POONA, or PUNA, India, (1) the capital of a district of the Deccan division, Bombay, at the confluence of the Mula and Muta, tributaries of the Bima in a plain nearly 2,000 feet above the sea, 119 miles eastward from Bombay by the Great Indian Peninsula Railway. It is well built and has a European aspect. Its main street is wide and lined with buildings ornamented with paintings and carvings; it has numerous pagodas; the Deccan College for classics, mathematics and philosophy; and a college of science, with special training in civil engineering; a training college for teachers of vernacular and Anglo-vernacular schools, a female normal school, a government first-grade high school, besides other schools: legislative council hall, public library, civil hospital, arsenal and barracks. The European cantonments are on the north, where most of the Europeans reside. In the town are the ruins of the palace (burned in 1827) of the Peishwa or head of the Mahratta confederacy, whose capital was Poona. This station is famed for salubrity, and from July to November is the seat of the Bombay government. It is an important military post, and has some manufactures of silver and gold jewelry, combs, dice and other small articles of ivory, silk and cotton fabrics and articles of brass, copper, iron and clay. Important works supply Poona with water from the Mula Valley, 10 miles above Poona. Pop. 158,856. (2) The district is bounded on the north by the district of Ahmednagar, west by the Ghats, south by Satara and east by the Nizam's dominions. Area, 5,348 square miles. It is an elevated table-land, watered by the Bima and its tributaries, and abounding in isolated heights, formerly crowned with strong fortresses. The villages are mostly open, but sometimes surrounded by hedges of cactus.

POOP-DECK, *in shipbuilding,* a deck raised over the after-part of a spar-deck, sometimes called the *round-house.* Ships formerly had several poops, the one above the other.

POOR, Charles Lane, American astronomer: b. Hackensack, N. J., 18 Jan. 1866. In 1886 he was graduated at the College of the City of New York and in 1892 received the degree of D.Ph. at Johns Hopkins. After 1891 he was successively tutor in mathematics, instructor, associate and associate professor of astronomy at Johns Hopkins. In 1903–10 he was lecturer and professor of astronomy and after 1910 professor of celestial mechanics at Columbia University. In 1901–06 he edited the *Annals* of the New York Academy of Sciences and is author of 'The Solar System' (1908); 'Nautical Science in its Relation to Practical Navigation, together with a Study of the Tides and Tidal Currents' (1910).

POOR, Enoch, American soldier: b. Andover, Mass., 21 June 1736; d. Hackensack, N. J., 8 Sept. 1780. He engaged as a shipbuilder at Exeter, N. H., until the battle of Lexington, when he raised a regiment of which he was commissioned colonel. He received rank of brigadier-general in 1777, and at Saratoga he performed brilliant service, his brigade leading the advance and bearing a heavy share of the American losses. He joined Washington in Pennsylvania after the surrender of Burgoyne, shared with him the winter at Valley Forge and in 1778 distinguished himself at the battle of Monmouth. He assisted in the campaign against the Six Nations in 1779 and by his able co-operation with General Sullivan gained advantages which resulted in the victory at Newtown. In 1780 at the request of Lafayette he was transferred to the leadership of a brigade of light infantry under his command. Shortly after he contracted the fever from which he died.

POOR, Henry William, American banker and financial expert: b. Bangor, Me., 16 June 1844; d. 13 April 1915. In 1865 he was graduated at Harvard University and three years later entered the brokerage business with his father under the firm name of H. V. and H. W. Poor. In 1890 Mr. Poor became a member of the New York Stock Exchange and was also senior member of the banking firm of H. W. Poor of New York and Boston. In 1868 Mr. Poor issued the first number of the annual which has taken such high rank as a guide to investors, 'Poor's Manual of Railroads.'

POOR HANDMAIDS OF JESUS CHRIST. See ORDERS, RELIGIOUS.

POOR AND POOR-LAWS. See PAUPERISM.

POOR BROTHERS OF SAINT FRANCIS SERAPHICUS. See ORDERS, RELIGIOUS.

POOR CLARES. See CLARE, SAINT; ORDERS, RELIGIOUS.

POOR DISTRICT. See DISTRICT.

POOR RICHARD'S ALMANAC, an American almanac published by Benjamin Franklin (q.v.) from 1732 to 1757. It was noted for the maxims it contained.

POOR ROBIN, the name of an English almanac which first appeared in 1663. It was published continuously until 1828. The title page bore the inscription "Written by Poor Robin Knight of the Burnt Island; well-wishes to the Mathematics."

POOR-SOLDIER. See FRIAR-BIRD.

POORE, Benjamin Perley, American journalist: b. Newburyport, Mass., 2 Nov. 1820; d. Washington, D. C., 30 May 1887. Placed by his father in a military school to prepare for West Point he ran away and apprenticed himself to a printer. In 1838 his father purchased for him *The Southern Whig,* which he edited until 1841 when he became an attaché at the United States legation in Belgium. In 1844–48 he was engaged in France in making a collection of historical manuscripts for the State of Massachusetts, and he also traveled extensively in Europe, Egypt and Palestine as correspondent for the Boston *Atlas* in 1843–48. On his return to the United States in 1848 he edited the Boston *Bee* and *Sentinel* until 1854, when he became Washington correspondent for the Boston *Journal* and several other newspapers, a position he occupied for 30 years, with the exception of a brief period as major in the Union army. In 1884 he became clerk of the Senate Committee on Printing Records and edited several publications concerning government affairs. Among his works are 'Campaign Life of Gen. Zachary Taylor' (1848); 'The Rise and Fall of Louis Philippe' (1848); 'Early Life of Napoleon Bonaparte' (1851); 'The Conspiracy Trial for the Murder of President Lincoln' (1865); 'Federal and State Charters' (2 vols., 1877); 'The Political Registry and Congressional Directory' (1878); 'Life of Burnside' (1882); 'A Descriptive Catalogue of the Government Publications of the United States, 1774–1881' (1885); 'Reminiscences of Sixty Years in the National Metropolis' (1886), a compilation of treaties between the United States and foreign governments, etc.

POORE, Henry Rankin, American painter and illustrator: b. Newark, N. J., 21 March 1859. He received his training under Peter Moran and the Pennsylvania Academy of Fine Arts at Philadelphia. Later he studied at the National Academy of Design in New York and under Luminais and Bouguereau in Paris. In 1916 he received a fellowship from the Pennsylvania Academy. He has also been the recipient of the following awards: the first prize of the American Art Association; the second Halgarten Prize of the National Academy of Design; the bronze medal of the Pan-American

Exposition (1901); the silver medal at the Saint Louis Exposition (1904); the gold medal at Buenos Aires (1910); and the silver medal at the Panama Exposition (1915). Poore excels in his artistic grouping of human figures with animals. He has written several valuable books of criticism including ‘Pictorial Composition and the Critical Judgment of Pictures’ (1903); ‘The Pictorial Figure’; ‘The Conception of Art’; ‘The New Tendency in Art.’ Among his best-known pictures are ‘Night of the Nativity’ (Fine Arts Academy, Buffalo); ‘The Shore’ (City Museum, Saint Louis); and ‘In the Meadow’ (Art Association, Indianapolis).

POPAYAN, pō-pä-yän′, Columbia, capital city of the department of Cauca, near the left bank of the Rio Cauca, in a plain plentifully watered by that river, 228 miles southwest of Bogota, at the foot of the volcanoes Puracé and Sotara. An episcopal city, Popayan has a college and a seminary for the training of priests. The products of its woolen mills and of the farms of the surrounding country are the main articles of commerce. The city, the first built by Europeans in this region, was founded in 1536 and was nearly destroyed by an earthquake in 1834. Pop. about 8,500.

POPE, the title of the Bishop of Rome, Supreme Pontiff of the Roman Catholic Church. (See PAPACY; TEMPORAL POWER; CATHOLIC CHURCH, ETC.) The following list of Popes has been compiled from the most careful authorities, but the dates up to the 3d century are only approximate, the chronology being very obscure previous to that time:

Peter	41–67
Linus	67–79
Cletus or Anencletus	79–91
Clement I	91–99
Evaristus	99–109
Alexander I	109–116
Sixtus I (Xystus)	116–127
Telesphorus	127–138
Hyginus	138–142
Pius I	142–154
Anicetus	154–165
Soter	165–174
Eleutherus	174–189
Victor I	189–198
Zephyrinus	198–217
Callixtus I	217–222
Urban I	222–230
Pontianus	230–235
Anterus	235–236
Fabianus	236–250
Cornelius	251–253
Lucius I	253–254
Stephen I	254–257
Sixtus II	257–259
Dionysius	259–268
Felix I	269–274
Eutychianus	275–283
Caius	283–296
Marcellinus	296–304
Marcellus	308–309
Eusebius	309 or 310
Miltiades	311–314
Sylvester	314–335
Marcus	336
Julius I	337–352
Liberius	352–366
Damascus I	366–384
Siricius	384–399
Anastasius I	399–401
Innocent I	401–417
Zosimus	417–418
Boniface I	418–422
Celestine I	422–432
Sixtus III	432–440
Leo I	440–461
Hilarius	461–468
Simplicius	468–483
Felix II	483–492
Gelasius I	492–496
Anastasius II	496–498
Symmachus	498–514
Hormisdas	514–523
John I	523–526
Felix IV	526–530
Boniface II	530–532
John II	533–535
Agapetus I	535–536
Silverius	536–537
Virgilius	537–555
Pelagius I	556–561
John III	561–574
Benedict	575–579
Pelagius II	579–590
Gregory I	590–604
Sabinianus	604–606
Boniface III	607–608
Boniface IV	608–615
Deusdedit	615–618
Boniface V	619–625
Honorius I	625–638
Severinus	640
John IV	640–642
Theodorus I	642–649
Martin I	649–653
Eugenius I	654–657
Vitilianus	657–672
Adeodatus	672–676
Donus	676–678
Agatho	678–682
Leo II	682–684
Benedict II	684–685
John V	685–686
Conon	686–687
Sergius I	687–701
John VI	701–705
John VII	705–708
Sisinnius	708
Constantine I	708–715
Gregory II	715–731
Gregory III	731–741
Zacharias	741–752
Stephen II	752
Stephen III	752–757
Paul I	757–767
Constantine II	767–768
Stephen IV	768–772
Adrian I	772–795
Leo III	795–816
Stephen V	816–817
Paschal I	817–824
Eugenius II	824–827
Valentinus	827
Gregory IV	827–844
Sergius II	844–847
Leo IV	847–855
Benedict III	855–858
Nicholas I	858–867
Adrian II	867–872
John VIII	872–882
Martin II	882–884
Adrian III	884–885
Stephen VI	885–891
Formosus	891–896
Boniface VI	896
Stephen VII	896–897
Romanus	897
Theodorus II	897
John IX	898–900
Benedict IV	900–903
Leo V	903
Christopher	903–904
Sergius III	904–911
Anastasius III	911–913
Lando	913–914
John X	914–928
Leo VI	928–929
Stephen VIII	929–931
John XI	931–935
Leo VII	936–939
Stephen IX	939–942
Martin III	942–946
Agapetus II	946–955
John XII	955–963
Leo VIII	963–964
Benedict V	964–965
John XIII	965–972
Benedict VI	973–974
Benedict VII	974–983
John XIV	983–984
Boniface	984–985
John XV	985
John XVI	986–996
Gregory V	996–999
Sylvester II	999–1003
John XVII	1003
John XVIII	1003–09
Sergius IV	1009–12
Benedict VIII	1012–24
John XIX	1024–32
Benedict IX	1033–44
Gregory VI	1045–46
Clement II	1046–48
Damascus II	1048
Leo IX	1049–54
Victor II	1055–57
Stephen X	1057–58
Benedict X	1058–59
Nicholas II	1059–61
Alexander II	1061–73
Gregory VII	1073–85
Victor III	1086–88
Urban II	1088–99
Paschal II	1099–1118
Gelasius II	1118–19
Callixtus II	1119–24
Honorius II	1124–30
Innocent II	1130–43
Celestinus II	1143–44
Lucius II	1144–45
Eugenius III	1145–53
Anastasius IV	1153–54
Adrian IV	1154–59
Alexander III	1159–81
Lucius III	1181–85
Urban III	1185–87
Gregory VIII	1187
Clement III	1188–91
Celestinus III	1191–98
Innocent III	1198–1216
Honorius III	1216–27
Gregory IX	1227–41
Celestinus IV	1241
Innocent IV	1242–54

POPE, Albert Augustus, American manufacturer: b. Brookline, Mass., 1843; d. 1909. During the Civil War Mr. Pope served with the 35th Massachusetts Infantry and attained the rank of lieutenant-colonel. After his return to civil life he merchanted shoemaking supplies. He founded the Pope Manufacturing Company in 1877, which secured control of many minor patents; in 1877 also he imported bicycles, but in the next year began to make them. During the «bicycle craze» Pope's company acquired millions. When the automobile had passed the experimental stage Mr. Pope engaged in the manufacture of cars, but was unable to duplicate his success with the bicycle. The company was placed in the hands of a receiver in 1907.

POPE, Alexander, English poet: b. in Lombard street, London, 21 May 1688; d. at Twickenham on the Thames, Middlesex, 30 May 1744. His parents were Roman Catholics. His father, to whom the poet ascribed a not-yet-established connection with the Earls of Downe, was a linen-draper «who dealt in Hollands wholesale»; his mother, Edith Turner, a second wife, was the daughter of William Turner, of Towthorpe, in Yorkshire. About 1700, Pope's father, having prospered in his business, retired to a small property he had purchased at Binfield, in Windsor Forest. Pope was not a strong child. When he was born his parents were no longer young; and from his father he inherited a frail constitution, from his mother a life-long tendency to headache. But he had in his boyhood, and retained through life, a voice like a nightingale. His education was desultory and mostly derived from Romish ecclesiastics. Writing he taught himself by copying type. From his first school at Twyford, near Winchester, he was removed because he had been severely punished for lampooning his master at the tender age of nine. At a subsequent school in London, kept by one Thomas Deane, he learned little; but he gave a taste of his future quality by tacking together an acting play from Ogilby's Homer, in which the school gardener personated Ajax. Leaving Deane, he became the director of his own studies at his home in the Forest. Here it is worth while to let him speak for himself: «When I had done with my priests, I took to reading by myself, for which I had a great eagerness and enthusiasm, especially for poetry; and in a few years I had dipped into a great number of the English, French, Italian, Latin and Greek poets. This I did without any design, but that of pleasing myself: and got the languages, by hunting after the stories in the several poets I read; rather than read the books to get the languages. I followed everywhere as my fancy led me, and was like a boy gathering flowers in the fields and woods, just as they fall in his way. These five or six years I still look upon as the happiest part of my life.» (Spence's 'Anecdotes,' by Singer, 1820, p. 193).

To this self-education his biographers have, with reason, attributed some of the peculiarities of his character and genius. His unremitting application no doubt injured his health and tended to make his life the «long disease» he afterward called it. Its enforced seclusion, coupled with the disabilities to which Papists were then exposed, fostered some of that — to give it its mildest name — disingenuousness, which came to be one of his worst faults. On the other hand, his natural parts were so keen, and his critical faculty so early matured, that it may be doubted whether any more liberal training would have better equipped him for what he afterward achieved. He is an excellent illustration of Boswell's dictum about the superior flavor of animals who «feed excursively» as contrasted with those who are «cooped up.» One result of his course of study was that he began early to versify, or, as he puts it, «lisp in numbers.» His first dramatic essay has already been referred to, and he is said to have composed another on the Legend of Saint Genevieve. A third effort was an epic on Alcander, Prince of Rhodes, being four books of 1,000 lines each on the Dryden pattern, which opened under water in the Archipelago with a description of the Court of Neptune. By his own account this must have been a medley of many notes. «There was Milton's style in one part, and Cowley's in another; here the style of Spenser imitated, and there of Statius; here Homer and Virgil, and there Ovid and Claudian» (Ib. pp. 24, 277, 279). 'Alcander' he afterward burned; but detached couplets found their way into later works. He also translated part of Ovid's 'Metamorphoses,' of Statius, and Cicero de Senectute. His chief adviser was his father, who criticised his «rhymes,» and ruthlessly «sent him down» when he did not think them good enough. The Alcander epic occupied him from 13 to 15 (Ib. p. 279), when he went to London to learn French and Italian. His education was completed by much study of Temple and Locke, of Rapin and Bossu, and of Dryden's «Prefaces.»

Already, while living at Binfield, he had made friends who served to influence his tastes. One was the old scholar and diplomatist, Sir William Trumbull of Easthampstead Park, who advised him to translate Homer; another, the wit and man of fashion, Henry Cromwell; a third, the veteran dramatist Wycherley, who was foolish enough to submit his senile poetical effusions to the criticisms of his sharp-eyed junior, a circumstance which has generally been held to have brought about a cooling of their friendship, although the manipulation of Pope's correspondence has not made it an easy matter to understand the actual attitude of affairs (Courthope's Life, pp. 73, 387–407). By Wycherley Pope was introduced to William Walsh of Abberley, in Worcestershire, the critic and minor poet, who enjoined his young friend to make correctness his «study and aim» (Spence, p. 280), in other words, «to study not only accuracy of expression,» but also «propriety of design and justice of thought and taste» (Courthope's Life, p. 25). It has been shrewdly suggested that in all probability Pope's native bias to these things suggested the judicious counsels of the critic whom Pope afterward styles «knowing Walsh.» Other literary luminaries with whom he became acquainted at this period were Garth of 'The Dispensary,' Congreve, and Lord Lansdowne.

Pope's first important publication was his 'Pastorals' (1709). After the 18th century fashion, these were much circulated in manuscript, and they were already well known to most of the contemporary literati long before they were printed. They appeared at the beginning of the sixth volume of Tonson's 'Poetical Miscellanies' (which also included a modernization by Pope of January and May, Chaucer's 'Merchant's Tale'); and exhibiting, as Johnson says, «a series of versification which had in English poetry no precedent,» met with complete success. Two years later appeared the 'Essay on Criticism,' said to have been written in the year in which the 'Pastorals' were printed. In this poem Pope aimed at occupying much the same place in English as

Horace had occupied in Latin with the 'Ars Poetica,' and Boileau in French with the 'Art Poétique'; and the performance, though of necessity a *cento,* was certainly an extraordinary one for a youth of three and twenty. Addison, who noticed it in *Spectator,* No. 253, certainly did not "damn it with faint praise" when he called it "a masterpiece in its kind," which contained things that "would have been very much admired in an Ancient Poet," though he regretted the freedom with which the writer already spoke of his brother moderns. But the commendation shows how closely Pope had followed the injunctions of Walsh; and moreover, fully justified him in offering to Steele's and Addison's paper (No. 378), his next effort, the 'Messiah,' a sacred Eclogue modeled on the 'Pollio' of Virgil. By this time his style was formed, and his metrical skill developed to an extraordinary point of excellence. Nothing was wanting but a theme suited to his peculiar gifts.

This theme he found in a little piece which, as a matter of fact, in its first form, preceded the 'Messiah,' namely the hero-comic 'Rape of the Lock,' contributed in May 1712, to another 'Poetical Miscellany,' that of Bernard Lintot. It is a flawless piece of executive jewel-work, the fragile theme of which is the theft of a lock of hair by Lord Petre, a Roman Catholic peer, from a noted beauty, Miss Arabella Fermor. Out of this trifling amatory escapade had arisen a family estrangement, which Pope was invited to reconcile by his rhymes. His poem was more successful than his purpose. Upon this he extended his plan, and improved it. Not content with the "let well alone" of Addison, who called it "*merum sal,*— a delicious little thing," Pope proceeded to weave skilfully into his first sketch a subordinate Rosicrucian machinery of sylphs and gnomes, which eventually proved the best part of what Johnson justly describes as "the most airy, the most ingenious, and the most delightful of all his compositions."

He was now launched, and his future popularity assured. His next works were 'Windsor Forest,' of which he borrowed the design from Denham's 'Cooper Hill'; and the 'Ode for Music on Saint Cecilia's Day,' a competition with Dryden suggested by Steele. Both these came out in 1713. In 1715, following the 'Lock' in its extended form (1714) and another imitation of Chaucer, 'The Wife of Bath,' came a second modernization from the same source the longer 'Temple of Fame.' But the great event of 1715 was the publication in June of the first four books of the translation of the 'Iliad.' Proposals for this had been issued in 1713, and the generous advocacy of a new friend, Swift, had largely swelled the subscription list. The task progressed until, in 1720, the Iliad was completed in six quarto volumes, dedicated to Congreve. Then came the 'Odyssey,' in which the poet was assisted by two subordinate "hands," William Broome, 1683–1745, and Elijah Fenton (1683–1730). By these two works Pope must have cleared from £8,000 to £9,000. But though he subsequently boasted, that, thanks to Homer, "he was indebted to no prince or peer alive," it is only just to recall the fact that while he was right in contending that no bounty was involved, his subscription list would have been considerably contracted if his patrician supporters were withdrawn. For this famous paraphrase itself, it must be admitted that its fame has somewhat — perhaps too much — faded at the present time. It may be that, in Gibbon's epigram, "it is a portrait with every merit but that of faithfulness to the original," — it may be that, as Bentley said "it is a pretty poem, which must not be called Homer"; but it is at least a triumph of uniform versification, and a surpassing example of sustained achievement. In that full-wigged Age of Anne, for the meridian of which it was expressly calculated, it bulks largest of the poetical output; and its influence extended far beyond its period of production. No one has written more indulgently of it than one of Pope's modern rivals, Professor Conington: "It has been — I hope it is still — the delight of every intelligent schoolboy; they read 'of kings and heroes and of mighty deeds' in language which, in its calm, majestic flow, unhasting, unresting, carries them on as irresistibly as Homer's own could do, were they born readers of Greek; and their minds are filled with a conception of the heroic age, not indeed strictly true, but almost as near the truth as that which was entertained by Virgil himself." ('Misc. Writings,' 1872, i. 43.)

A minor incident connected with the 'Iliad' was the misunderstanding between the translator and his first critic, Addison, to which it gave rise. Pope's frailty of constitution led him easily to magnify mole hills, and his literary suceptibilities were painfully morbid. His relations, moreover, with Addison had already become strained. Addison, as we have seen, had deprecated that recasting of 'The Rape of the Lock,' which subsequently proved so fortunate. Pope's suspicious nature resented this advice, especially in view of the result. When again Pope championed Addison against the rancorous old critic, John Dennis, Addison had not approved — he could hardly be expected to approve — the peculiarly Swiftian character of Pope's warfare. Finally, by an unfortunate coincidence, when Pope's 'Iliad' was announced, a rival version was put forward by Addison's bosom friend, Thomas Tickell (1686–1740), which Pope perhaps not unnaturally regarded as prompted, if not edited, by Addison himself. Modern criticism has failed to find any valid ground for this supposition. But the cumulative result of Pope's irritation was the cruelly clever portrait of Addison as "Atticus" which 18 years after Addison's death, found its final place in the Prologue to the Satires ("Epistle to Arbuthnot"). Upon the faith of Spence's 'Anecdotes,' pp. 148–149, it was long held that Pope, in his first anger, had actually sent the lines to Addison; but this is now held not to be probable (Courthope's 'Life,' 1889, p. 161); and Spence's entire account is conjectured to be a fabrication by Pope arising out of his desire to establish beyond a doubt the fact that the character was not written after the death, but during the life of Addison. In any case, the "Atticus" is a matchless piece of writing, and (as even Addisonians must allow), in some particulars, presents — to quote Thackeray on Dennis portrait of Steele — "a dreadful resemblance to the original."

After the already-mentioned 'Temple of Fame,' Pope's published works were the 'Elegy to the Memory of an Unfortunate Lady,' a poem probably idealized from the story of a Mrs. Weston of Sutton, whose relations with her husband had not been of the happiest (Courthope, 133); the 'Epistle of Eloisa to Abelard,' which is supposed to owe something of its passionate rhetorical imagery to the feelings entertained at this date by the writer for Lady Mary Wortley Montagu; and, in collaboration with Gay and Arbuthnot, the dramatic skit upon Dennis and others entitled 'Three Hours after Marriage' which ignominously failed at Drury Lane in 1717, to which year the pieces above mentioned also belong. In 1725, appeared an edition of Shakespeare in six quarto volumes which has no more authority than that of Johnson. Then, in May 1728, came the first edition of *The Dunciad*, Pope's famous onslaught upon those swarming hacks and poetasters of the day, whom his heated imagination exaggerated into an army of personal enemies. In 1729 followed a more perfect edition with a dedication to Swift. Other issues succeeded; and, in 1742, was added a fourth book directed against dunces theologic and scientific. The scheme of the poem describes the elevation, with fitting ceremonial, of Lewis Theobald (who had earned Pope's hatred by certain merited strictures on his Shakespeare) to the throne of Dulness, then vacant by the death of Dryden's 'Mac Flecknoe' Shadwell,—

"without dispute
Through all the realms of Nonsense absolute."

In 1742 Pope gratified a new antipathy by substituting Colley Cibber for Theobald, a change which can scarcely be said to have been an improvement. The Epos of the Dunces remains nevertheless a magnificent satire upon a subject which is not worthy of the powers it called forth, though it is perhaps the culminating example of the combative gifts of its author. Ruskin goes even so far as to call it "the most absolutely chiselled and monumental work 'exacted' in our country" (Lectures on Art, 1870, p. 70).

Swift has the credit of eventually prompting the 'Dunciad.' Pope's next effort, the 'Essay on Man,' is inscribed to another "guide, philosopher and friend," Bolingbroke. "One truth is clear, Whatever is, is right"— which is the last line of the first of its four epistles, might be described as the keynote of his attempt "to vindicate the ways of God to Man." The writer's metrical dexterity, his power of crystallizing precept, and his executive skill generally, were never shown to greater advantage than in this work; but the consensus of criticism has come to the conclusion that he was not in complete sympathy with, if indeed he thoroughly comprehended, the philosophical tenets of the meteoric genius whom he terms "the master of the poet and the song." Hence critics like the late Sir Leslie Stephen have come to describe the arguments as "confused, contradictory, and often childish." Yet, although the poem labors under these disadvantages, and although, moreover, it is only part of an unfinished whole, it had an extraordinary popularity with its first public, and also on the Continent, where, in its translated form, it must have made its appeal by its matter rather than its manner.

To Bolingbroke also Pope owed what must ever be regarded as his greatest and most personal performances, his 'Moral Essays' and his 'Satires and Epistles.' The 'Moral Essays' appeared from 1720 to 1735; the 'Satires and Epistles' from 1733 to 1738. These last are unrivaled in their pungent criticism and portraiture of contemporary character and manners. "It is no paradox," said the late Rector of Lincoln College, Mark Pattison, "to say that these 'Imitations' are among the most original of Pope's writings. So entirely do they breathe the spirit of the age and country in which they were written that they can be read without reference to their Latin model" (Preface to 'Satires and Epistles').

The discussion of Pope's untiring literary labors has left his life somewhat in the background. In April 1716, not long after the appearance of the first instalment of his Homer he moved from Binfield to Chiswick, where he lived in what is now known as Mawson's Row. In 1717 his works had become numerous enough to fill a handsome folio volume which was issued by Tonson and Lintot, with its author's portrait engraved by George Vertue after Charles Jervas. In October of the same year his father died; and he moved with his mother to a little villa at Twickenham in which he thenceforth resided, "twisting and twirling and rhyming and harmonizing" five acres of garden until it became "two or three sweet little lawns, opening into one another and surrounded with impenetrable woods." Here he received his friends, among others the Joseph Spence, to whom we owe the bulk of our Popiana. In 1733 his mother, to whom he had always shown an exquisite filial affection, and whom he tended lovingly to the last, died at an advanced age. Ten years later he himself was passing away. prematurely old, and worn out with asthma and dropsy, though scarcely 55. To the end he continued to "dispense his morality" (in the form of his Ethic epistles), and to revise and rearrange his other poems. Finally he died at Twickenham, 30 May 1744, and was buried in the middle isle of the parish church, where 17 years later a monument was erected to him by his literary executor, Bishop Warburton. In 1730 Gilliver had published a second volume of his poems, and in 1737–41 had appeared two corresponding volumes of his letters, etc. The story of these last,— of the artifices employed to secure their publication, of their manipulation and readjustment to suit the writer's own views would take too long to tell here. But the subject has been amply discussed in Dilke's 'Papers of a Critic,' 1875, in the "Introduction to Pope's Correspondence" (Vol. VI, 1871) of Elwin and Courthope's 'Works,' and in Courthope's 'Life' (1889).

Pope was never married. At one period of his career he had cherished a passion for the brilliant Lady Mary Wortley Montagu, by whom he was encouraged and scorned, treatment for which he took his revenge fiercely in subsequent satires. But his greatest feminine friend was Miss Martha Blount of Mapledurham, an old acquaintance of the Binfield days, with whom he renewed his relations at Chiswick and Twickenham, and whose friendship he retained at the close of his life. He had spent three or four hours a day with her for 15 years, he said in 1730; and the companionship, which was prolonged for nearly 15 years more, seems always to have had a cheering effect upon his drooping and variable spirits. Into the tangle of gossip which has gathered about this connection, memorable among literary alliances, it is profitless to enter. But that Pope was devotedly attached to his blue-eyed goddess there can be no manner of doubt.

Pope's character is so intimately connected with his personality that it is impossible to omit here some description of his habits and appearance. Though amiable and attractive in childhood, his sedentary life and close application in early youth speedily affected a constitution not radically sound at the outset. He was remarkably frail and small (four feet six), and he rapidly became deformed. As already stated he was a martyr to headaches. In his diet he required to exercise the greatest caution; and he suffered cruelly from any deviation from his régime. He was intensely susceptible to changes of temperature and climate. In his earlier days he was able to take horse exercise; but in his manhood he could not dress himself without help, nor could he come abroad without being wadded with furs and stiffened with buckram. That these things reacted upon his views of life can scarcely be contested. «He was the most irritable of the irritable race,» says one contemporary; *Mens curva in corpore curvo,* says another. «He played the politician about cabbages and turnips,» says a third. *Per contra,* it must be remembered that, however sensitive, artificial and vindictive, he was a devoted son and an attached friend. And at least he was a genuine *litterateur.*

As a poet his general position is easy to define. He was not a great lyrist; he was not a profound thinker; but he is a supreme artificer. Borrowing the heroic couplet from Dryden, he brought it, as the medium for didactic and satirical verse, to a pitch of perfection which has never been surpassed, though it has sometimes been made monotonous by imitation. He could not, as we have implied, originate; but he could decorate to any extent. Granted the theme, he could develop it; he could embroider it supremely; he could lend it every advantage in the way of condensed perspicuous and epigrammatic exposition. The major part of his work is a triumphant exemplification of Addison's dictum that «Wit and fine Writing doth not consist so much in advancing Things that are new, as in giving Things that are known an agreeable Turn.» This was Pope's chief function. With inspiration, with the unattempted or unimagined in poetry, he had small concern. But he could express, in a given metrical form, and with faultless lucidity and finish, the best floating ideas in circulation at the time of writing. His gifts of wit and irony led him inevitably in the direction of the satire; and his high-water mark is his ‹Epistle to Arbuthnot,› which exhibits his varied and exceptional powers in their fullest diversity.

Bibliography.— There are several early lives of Pope of which that by Johnson (‹Poets,› London 1781) is the most important. Of later efforts, the most notable are Carruthers (1853–57); Sir Leslie Stephen (1880); Courthope (1889). Of Pope's ‹Works› there are editions by Warburton (1751); Warton (1797); Bowles (1806), and Roscoe (1824); but all these give place to the 10 volume edition by Elwin and Courthope (1871–89). Good editions of the poems alone are ‹The Cambridge Edition,› edited by H. W. Boynton (Boston 1903); that edited with memoir by J. Dennis (London 1891) and the ‹Globe Edition› (New York 1899). Consult Spence's ‹Anecdotes,› by Singer (1820); Dilke's ‹Papers of a Critic› (above mentioned); Mark Pattison, ‹Essay on Man› (1869), and ‹Satires and Epistles› (1872); Conington (above mentioned); Abbot's ‹Concordance› (London 1875), and Montégut in *Revue des deux Mondes* (March 1888 for Pope's influence abroad. Consult also Dennis, John, ‹The Age of Pope, 1700–1744› (London 1894); Chesterton, G. K., ‹Varied Types› (New York 1903); Symonds, E. M., ‹Mr. Pope: His Life and Times› (ib. 1909).

AUSTIN DOBSON,
Author of ‹Life of Goldsmith,› ‹Life of Richardson,› etc.

POPE, Charles A., American surgeon: b. Huntsville, Ala., 1818; d. 1870. He received his education at the Cincinnati Medical College and at the University of Pennsylvania. From 1843 to 1847, Dr. Pope was professor of anatomy and physiology at Saint Louis University; from 1847 to 1853 professor of surgery and from 1848 to 1853 dean at the same institution. From 1853 to 1867 he held the chair of surgery at the Saint Louis Medical College, the medical department of Washington University. He was president of the American Medical Association in 1854 and after 1867 lived in Paris.

POPE, Franklin Leonard, American electrician: b. Great Barrington, Mass., 2 Dec. 1840; d. there, 13 Oct. 1895. He was a telegraph operator in 1857, assistant engineer of the American Telegraph Company in 1862 and in 1864 while holding a similar position in the Russo-American Company made the first survey of the territory between British Columbia and Alaska. Later with Edison he invented the stock exchange «ticker,» in 1872. He invented the rail circuit for automatically controlling electric block signals, was editor of the *Electrical Engineer,* 1884–95; and president of the American Institute of Electrical Engineers in 1885. He published ‹Modern Practice of the Electric Telegraph› (1871) and ‹Life and Work of Joseph Henry› (1879).

POPE, John, American soldier: b. Louisville, Ky., 16 March 1822; d. Sandusky, Ohio, 23 Sept. 1892. He was graduated from the United States Military Academy in 1842, was assigned to the topographical engineers, served in Florida in 1842–44, in 1846 entered the United States Army in Mexico during its advance on Monterey, was brevetted captain, and in 1849 conducted the exploring expedition which opened up Minnesota and demonstrated the navigability of the Red River of the North. In 1853 he was in New Mexico, employed in surveys for the projected Pacific Railway; and in 1854–59 explored the plains and the Rocky Mountains, being the first to experiment in the irrigation of arid western tracts by means of artesian wells. After his return from these duties, he criticized the policy of President Buchanan in a lecture delivered at Cincinnati in February 1861 and for this action was summoned to a court-martial. The trial was, however, dropped. Made brigadier of volunteers in May 1861, he was assigned to command in Missouri, quickly organized at Commerce, Mo., an army of about 12,000 and in March 1862 effected the capture of New Madrid and Island No. 10. He was promoted major-general of volunteers and made brigadier-general in the regular army. He was then placed in command of the Army of Virginia and fought the battles of Cedar Mountain and the second Bull Run. In the latter he was badly worsted by "Stonewall" Jackson (q.v.) and on his return to Washington requested to be relieved from his command. He was thereupon transferred to the Department of the Northwest, where he directed a campaign against the Sioux; and in 1865 was appointed to the command of the military division of the Missouri; subsequently made the Department of the Missouri. Later he was in command of various military districts, of the Department of the Lakes and that of the Pacific and in March 1866 was retired with rank of major-general. From his defeat in the second battle of Bull Run developed the trial, conviction and subsequent restoration of Gen. Fitz John Porter (q.v.). He published 'Explorations from the Red River to the Rio Grande' (in 'Pacific Railroad Reports' vol. III); and 'The Campaign of Virginia, of July and August 1862' (1865).

POPE, John Henry, Canadian statesman: b. Eastern Township, province of Quebec, 1824; d. 1889. He received his education at the Compton High School; took an active interest in Conservative politics after 1857 and after 1867 represented Compton County in the Canadian Assembly. In 1871–73 Pope became Minister of Agriculture in Sir John A. Macdonald's first Cabinet and held the same office in that premier's second Cabinet from 1878 to 1885. After 1885 Pope was Minister of Railways and Canals. With Tupper and Macdonald he negotiated the contract for the construction of the Canadian Pacific Railroad which was later approved by the Dominion Parliament.

POPE, John Russell, American architect: b. New York, 24 April 1874. He was educated at the College of the City New York, and in 1894 was graduated at the School of Mines of Columbia University. In 1895 he was Fellow of the American Academy in Rome, and in 1896–97 held the Schermerhorn traveling fellowship in architecture. In 1900 Mr. Pope attended the Ecole des Beaux Arts, Paris, since when he has practised in New York. His principal works are the Scottish Rite Temple, Washington; Plattsburg (N. Y.) City Hall; McDonough Memorial, Plattsburg; Lincoln Memorial, Hodgenville, Ky.; the Terminal Station, Richmond, Va.; residences of Mrs. W. K. Vanderbilt, Jr., Ogden B. Mills, Mrs. Arthur Scott Burden, Levi P. Morton, John R. McLean, Henry White and Mrs. R. S. Hitt, Washington, etc., and memorial tomb of William B. Leeds, New York. in 1916 Mr. Pope was awarded the Architectural League medal of honor in architecture and in 1919 was elected associate of the National Academy of Design.

POPE, William Burt, Methodist theologian: b. Horton, Nova Scotia, 1822; d. 1903. He received his education at Richmond College, London, and from 1841 to 1867 held pastorates in England, after which he held the chair of theology at Didsbury College, Manchester. He published 'Discourses on the Kingdom and Reign of Christ' (1869); 'The Person of Christ' (1875; 3d ed., 1899); 'Christian Theology' (2d ed., 3 vols., 1877–80); 'The Prayers of St. Paul' (1876); 'Sermons and Addresses' (1878); 'A Higher Catechism of Theology' (1883). Consult Moss, R. W., 'The Life of W. B. Pope, Theologian and Saint' (London 1912).

POPERINGHE, pōp'răng, Belgium, town in the province of West Flanders, about four miles from the French frontier and five miles west of Ypres, with which it is connected by rail. It is an ancient town and in the 14th century was a rival of Ypres. Nearby were great hop gardens, tanneries and bleaching grounds. Most of the city's ancient landmarks were obliterated during the War of 1914–18 in the exceptionally severe fighting in Ypres and its neighborhood. Laces, linens and woolens were manufactured in considerable quantities previous to the war, when the population totaled 12,205.

POPHAM, pŏp'ăm, **George,** English colonist: b. Somersetshire, about 1550; d. 1608. Becoming a partner of Gorges in projecting the colonization of Maine, he collected 120 men and sailed from Plymouth in 1607 with two vessels and arrived in August of that year at the estuary of the Kennebec. There he erected a small fort and storehouse and named the place Fort Saint George. He was chosen president of the colony, the first English settlement in New England, but his death in the following year and the severity of the winters disheartened his followers who soon after his death abandoned the colony and returned to England.

POPHAM, Sir John, English jurist: b. Wellington, Somerset, 1531; d. 10 June 1607. He was educated at Oxford, studied in the Middle Temple and became sergeant at law in 1571. After having been speaker of the House of Commons in 1581 and Attorney-General in 1585 he was made lord chief justice in 1592 and held this post 15 years. He was a brother of George Popham, and in 1607 was associated with him and Sir Fernando Gorges in establishing the Popham colony in what is now the State of Maine, the three holding a patent to an extensive tract of territory in that region.

POPINJAY, a parrot; a figure of a bird formerly put up as a mark for archers to shoot at. The green woodpecker is also so-called in provincial parts of Great Britain.

POPISH PLOT. See Oates, Titus.

POPLAR, England, a metropolitan and Parliamentary borough of London, on the Thames between Limehouse Reach and Blackwall Reach. Area, 2,328 acres. The district is poor, overcrowded and depressing, with a high deathrate and containing the largest proportion of paupers in London, the latter being 43, four per 1,000 at Christmas 1913. Blackwall and the Isle of Dogs are in the borough, and the docks — East and West India and Millwall — afford employment to the laboring population. Engineering, shipbuilding and chemicals are the chief industries. The metropolitan borough includes the Bow and Bromley and the Poplar divisions of Tower Hamlets, each returning one member. Pop. about 162,442. Consult Cowper, 'Descriptive Account of Millwall' (1853);

Forrow, 'The Thames and Its Docks' (1877); Simmonds, 'History of Poplar' (1870), and the publications of the committee for the survey of Greater London.

POPLAR, a genus (*Populus*) of trees of the family *Salicaceæ* which includes only one other genus, *Salix*, the willows. The species, which probably do not exceed 25, are widely distributed in the Northern hemisphere from sub-tropical regions to the limits of vegetation both in latitude and altitude. Half of them are American. They are mostly of small or medium size, quick growth and short duration; bear deciduous, broad, heart-shaped or lozenge-shaped leaves on long slender petioles; diœcious, naked flowers usually in pendulous catkins which appear before the leaves; and small two- to four-celled fruits (capsules) filled with cottony seeds. Their wood is generally soft, light and white. It is little used for timber or lumber; but it is an important fuel wood in regions such as the Western States, where fuel is scarce and costly. The trees are often planted for this purpose and for windbreaks, their rapid growth being in their favor. They are also favorites for copses and for pollarding (q.v.). The lumber called poplar is generally that of another tree,— the whitewood or tulip tree (q.v.). Poplars are used in enormous quantities for making wood-pulp paper, carboard, etc., especially in Ontario, Quebec and the New England States, where hundreds of acres of forest are cut for this purpose annually. As ornamental trees they are frequently planted to excess at summer resorts because they quickly make an effect. In such cases they give an air of cheapness to the place not observable where maples, oaks, etc., are prevalent. The latter should always be planted with poplars, in order to replace them.

Poplars are as easily propagated from cuttings as currants or willows; in some cases the switches need only be stuck in moist ground. The choice horticultural varieties, especially the weeping kinds, are grafted. Suckers may be used, but since their removal generally induces the growth of many more suckers, this method must be practised with caution except where the ground is not valuable. The species will succeed in a great variety of soils from sand to clay, and in almost any situation, even in crevices on rocky mountain slopes. Some of them, however, especially the cottonwood, seem to thrive best in low alluvial land upon the margins of streams.

The best-known species are probably the following: The Lombardy poplar (*P. nigra*, var. *italica*, also called *P. pyramidalis, P. italica, P. fustigiata*, etc.) is probably a native of Asia, whence it has spread to the Mediterranean region and thence to temperate countries throughout the world. It is noted for its erect instead of spreading habit, which makes it a striking specimen in ornamental plantings. It grows very rapidly, attains a height of 100 to 150 feet, but is not long-lived in the coldest States and most of Canada. It is one of the worst species to produce suckers; hence it should not be planted where the soil will be disturbed by cultivation.

The black poplar (*P. nigra*) is a native of northern Asia and Europe, and is occasionally seen as an escape in America east of the Mississippi River. It is of rather pyramidal habit, less erect, however, than its variety the Lombardy, and of darker colored foliage and slower growth than the cottonwood. It seldom exceeds 100 feet in height. The down from its seeds has been used for paper, hat and cloth-making in France, but the industry has been abandoned as unremunerative. The wood, which is not prone to shrink and swell, is used for turning, cabinet-making, toys, flooring, doors, etc.

The Carolina poplar (*P. deltoides*) is an American species well known from New Brunswick to the Rocky Mountains and southward to the Gulf States. It is the largest of the genus, specimens sometimes attaining 150 feet in height and more than six feet in diameter. It is also one of the most valuable, its timber being considered useful for nearly all the purposes mentioned. It is also more highly prized for ornamental planting than any other species, since it not only succeeds well in all soils, but possesses qualities of stability and strength lacking in other species. Its bright, glossy foliage, constantly in motion, adds cheeriness and life to plantations as few other trees can. It is one of the most popularly planted species in the Western States, not only for shelter and for fuel but for timber and lumber. In Europe it is often called the Canadian or Italian poplar. It has several horticultural varieties, among which a striking form is the golden-leaved *P. vangeertii*, which is one of the choicest of yellow-leaved trees.

The balsam-poplar or tacamahac (*P. balsamifera*) is indigenous from Newfoundland to British Columbia and extends well into Siberia, its southern limits, except in the mountains, being about Pennsylvania. Its erect growth resembles the Lombardy poplar, but it is slower in growth, more rugged and hardy. The type species and its three well-marked botanical varieties exceed the cottonwood in variability. A closely related species is the balm of Gilead (*P. candicans*), a well-known tree, frequently planted, with large buds noted for their spring fragrance. It is indigenous from Nova Scotia to New Jersey and westward to Minnesota, and is less pyramidal than the type species, usually making a rather broad top. It seems to be disappearing from the woods, though formerly it was a large tree sought for its timber. For the dark tone of its foliage it is often planted as a background tree, but not in smoky localities.

The white poplar or abele (*P. alba*), a European and Asiatic species, which grows about 75 feet tall, has been introduced into America, where it has become naturalized, from Nova Scotia to New Jersey. In Europe it is used for many of the purposes mentioned above. The European aspen (*P. tremula*), common in both Asia and Europe, is known in America mainly by its weeping variety (*P. tremula*, var. *pendula*). The American aspen (*P. tremuloides*) is one of the first trees to appear in clearings, thus acting as an important agent in reforestation, holding the soil until slower-growing trees can obtain a start. (See ASPEN).

About 100 species of insects feed upon the poplars in America. Among these are several species of plant-lice, leaf-miners and leaf-rollers (qq.v.). Among the caterpillars which feed upon the foliage, the most common are probably the larvæ of the antiopa butterfly, the io moth, tussock moth and poplar span-worm; also several general feeders of the families *Noctuidæ* and *Geometridæ*. These creatures may be controlled by spraying, when practical, with arsenites. (See FUNGICIDE). There are also a large number of borers which live in the trunks or twigs. The roots and trunk are attacked by *Prionus laticollis*, which also feed upon pine and apple trees and grape vines.

Consult Sargent, 'Silva of North America'; Packard, 'Insects Injurious to Forest Trees' (Washington 1890).

POPLAR BLUFF, Mo., city, county-seat of Butler County, on the Big Black River, and on the Saint Louis, Iron Mountain and Southern, the Saint Louis and San Francisco and the Butler County railroads, about 125 miles south of Saint Louis. It is in a section where lumbering and the manufacture of lumber products are given much attention. Stock-raising is carried on to a considerable extent. In the vicinity are valuable clay deposits. The chief manufactures are foundry and machine-shop products, cooperage products, brick and lumber products. The city owns and operates the waterworks. Pop. 6,916.

POPLAR SPRING CHURCH (PEEBLES' AND PEGRAM'S FARM, Vaughan Road), Battle of. In co-operation with the movement against Richmond from the north side of James River, 29 Sept. 1864 (see FORT HARRISON, BATTLE OF), General Grant ordered a movement from his left, south of the river, in a northwest direction toward the Boydton road and South Side Railroad, the intention being to extend his intrenched line beyond the Weldon Railroad in the direction of the South Side Railroad. General Warren, with Griffin's and Ayres' divisions of the Fifth corps, was first to secure the junction of the Squirrel Level and Poplar Spring Church roads, coming in from the southwest, at which point the Confederates had intrenchments covering the roads. General Parke, with Willcox's and Potter's divisions of the Ninth corps, was to follow Warren and form on his left, then both were to advance toward the Boydton road. Gregg's cavalry division was to move on the Vaughan road and other roads on the left and rear to the crossing of Hatcher's Run, where the Confederates had a redoubt at the termination of their intrenchments. At 7.30 A.M., 30 September, Griffin and Ayres moved out of their intrenchments at Globe Tavern, advanced cautiously three miles through a dense growth of woods and encountered a Confederate picket-line behind light works thrown up along the road in front of Poplar Spring Church. This line was driven in, and the advance continued, until it came under a sharp fire from a line of works on Peebles' farm, held by Dearing's cavalry brigade and some infantry. A short halt was made, the order to assault was given and the works were carried with small loss. On the left Parke moved through a narrow belt of timber, in a northwest direction toward the Boydton road, and encountered the Confederates on Pegram's farm. The forces holding the Petersburg intrenchments were A. P. Hill's corps and B. R. Johnson's division of infantry, with Wade Hampton's two divisions and Dearing's brigade of cavalry, all under command of A. P. Hill. The main Confederate line of intrenchments had been extended in a southwest direction nearly to Hatcher's Run, covering the Boydton road and South Side Railroad. Hill threw out two divisions, which came into collision with Potter's division, flanked it on the right and drove it back in some confusion. A new line was now formed by Parke, with Willcox's troops, which, with Griffin's line on the right, after a spirited engagement, checked the Confederate advance about dark, after a loss in Parke's command of nearly 500 killed and wounded, and many prisoners. Late in the afternoon next day (1 October) Mott's division of the Second corps came up, and on the 2d Parke advanced, under a heavy fire of artillery and musketry, and established a line of intrenchments about a mile from that of the Confederates, connecting on the right with the line held by the Fifth corps, and on the left reaching the Weldon Railroad and extending to the left and rear. On the left and rear Gregg's cavalry, 30 September, drove back Dunnovant's cavalry brigade, and next day was heavily attacked by Hampton's cavalry on the Vaughan road, but he repulsed the attack, inflicting heavy loss. The Union loss, 30 September, 1 and 2 October, was 187 killed, 900 wounded and 1,802 missing. The Confederate loss is not certainly known, but is estimated at less than 1,000. Consult 'Official Records' (Vol. XLII); Humphreys' 'The Virginian Campaign of 1864–65'; Powell, 'History of the Fifth Army Corps'; 'Battles and Leaders of the Civil War' (New York 1890).

POPLIN, in textile manufacture, a kind of finely woven fabric, made of silk and worsted. In the best poplins the warp is of silk and the weft of worsted, a combination which imparts peculiar softness and elasticity to the material; in the cheaper makes cotton and flax are substituted for silk, which produces a corresponding deterioration in the appearance of the stuff. The manufacture of poplin was introduced into Ireland from France, where it originated, in 1775 by Protestant refugees, and Ireland is still famous for its production. The Irish fabrics having a silk warp and worsted weft and in the common grades cotton or flax is mixed with the silk. The term "poplin" is a corruption of the French *papeline*.

POPOCATEPETL, pō-pō-kä-tā-pĕt'l, a volcanic mountain of the province of Pueblo, Mexico, about 40 miles southeast of the city of Mexico, whence it can be seen as if near at hand because of the clear air of the intervening country. "Smoking Mountain" is the meaning of its name, an Aztec compound, and it is constantly sending out smoke and ashes, and occasionally cinders and stones, but has had only two or three small eruptions in the last four centuries, the last recorded being in 1540. Its height is 17,784 feet, considerably more than that of Mont Blanc, and it was long reckoned the highest mountain in North America. There are oak and pine forests on its sides to a height of 12,540 feet; then a stretch of sand and sulphur before the snowline at 14,960 feet. There are small glaciers on the eastern slope of the mountain. The crater is much smaller than commonly reported, being probably not more than one-fifth of the famed three miles in circumference; its depth, reported as 1,000 feet, seems to be actually only 250. Indians gather sulphur from the rim of the crater. Some of Cortes' men explored the mountain in 1519; three years afterward Montano seems to have reached the top and let himself down into the crater; in 1827 Glennie and Taylor made the ascent.

POPOFTSCHINS. See RELIGIOUS SECTS.

POPOL VUH, pō-pool' voo, the sacred book of the Quiché (q.v.).

POPPÆA SABINA, pŏ-pē'ą są-bī'ną, Roman empress, wife of Nero: d. 65 A.D. She was the daughter of Ollius and married Rufius Crispinus, Prætorian prefect, was divorced by him and married to Otho, who in his turn was set aside for the Emperor Nero. She was famous for her beauty, but heartless and immoral. At her desire Nero murdered his mother, Agrippina in 59, divorced and put to death his wife, Octavia in 62, after which they were married. Three years later she was killed by Nero in a fit of rage. The one redeeming incident in her career seems to be the mercy she urged upon Nero in behalf of the Jews.

POPPY, a popular name for several plants of the family *Papaveraceæ;* for instance, California poppy (*Eschscholzia californica*), horned poppy (*Glaucium*), Welsh poppy (*Meconopsis cambrica*), prickly poppy (*Argemone spp.*), celandine poppy (*Stylophorum diphyllum*), tulip poppy (*Hunnemania fumariæfolia*) and various species of genus *Papaver.* Unless modified by some adjective as above the term usually refers to members of the last-named genus.

The 50 species of *Papaver* are annual and perennial herbs, mostly indigenous to the Mediterranean region. One is South African, one Australian and a few North American. They are smooth or bristly; have a milky juice; usually dissected or lobed leaves on long peduncles; showy flowers of very varied tints and forms, and capsules containing very numerous small seeds. For several centuries some of the species have been leading garden flowers, not only because of their color and form, but because of their ease of cultivation. The seed should be sown very early in the spring where the plants are to remain. Any good, well-drained garden soil will do, but it should be finely broken up and the seed covered very thinly. The seedlings should not stand closer together than six inches for the weak growing kinds and 12 inches for the strong. The removal of the pods as soon as the flowers fade will prolong the blossoming season. If allowed to ripen the seed will stock the garden as weeds. Such plants blossom about two weeks earlier than spring-sown ones. The perennial species should be replaced by new plants each second year, since in cold parts of the country they are likely to winter-kill when old.

The most cultivated species are the opium poppy (see below) and the corn poppy (*P. rhœas*), a European annual with rather small flowers and finely cut foliage.

The Oriental poppy (*P. orientale*), a native of southwestern Asia, is a perennial with large flowers. The Iceland poppy (*P. nudicaule*), an Arctic species, is a remarkably beautiful perennial, which is usually grown as an annual; it is perhaps the best species for cutting as a bouquet flower. Other species are popular with fanciers, but have not gained prominent places in general esteem.

As a garden plant the opium poppy (*P. somniferum*), an annual, is the most famous since it has probably the widest range of color and form. It is, however, noted as the source of poppy-seed oil and opium (q.v.). The seeds, which contain no opium, are rich in a bland, fixed oil (about 40 per cent), which is expressed for culinary uses, and to a small extent for painting and soap-making. The growing of the plants for this purpose has been an important industry in the Old World for centuries. In mild climates the land is made very fine by plowing and harrowing in the autumn when the seed is sown; in colder regions the seed is either scattered on the snow or sown in early spring, the land being prepared previously. Drilling and broadcasting are both popular. Shelter from wind is advisable to prevent scattering of the seed.

POPULAR VOTE. See ALIENS; ELECTORAL QUALIFICATIONS; WOMAN SUFFRAGE; ELECTIONS; NATURALIZATION; VOTE.

POPULATION, Growth of World Population from 1800 to 1919. One of the most striking facts which we encounter in searching for the causes of the wonderful growth of world commerce in the past century is the discovery that world population has doubled within that period. In all the untold centuries in which man had existed on the globe, the number of people in the world in 1830 was but 850,000,000; to-day the world total is 1,700,000,000, or double that at the time when the application of steam to transportation enabled population to expand into hitherto unpopulated areas and supplied the means by which the products of those areas could be transferred to the continents where population exceeded the food-producing power.

World Population Doubled in 100 Years.— We may fairly fix the date of the practical application of steam to transportation at the year 1830. Fulton had shown the use of the steamboat on rivers as early as 1807, and the little American steamer *Savannah* made the first steam voyage across the Atlantic in 1819, but it was not until 1838 that steam transportation across the ocean was regularly established. Steam engines had moved wagons on lines of rail as early as 1804 but it was not until 1825 that the first railway for the regular transportation of freights, the Stockton and Darlington Railway in England was put into practical operation. The world's railways in existence in the year 1830 were but 200 miles; the world's steamships but 100,000 tons and none of those crossing the ocean.

So we shall do no violence to history if we fix the year of the practical application of steam to freight movement on land and sea at about the year 1830, in which the world's population was 850,000,000 or just one-half of that to-day. The total world population in 1919 is set down by the best authorities at approximately 1,700,000,000 and most of this totalization is by actual count, for countries representing more than two-thirds of the people of the world now take periodical censuses of their respective populations. See the following table:

THE POPULATION OF THE EARTH BY CONTINENTS.

CONTINENTAL DIVISIONS	Area in sq. miles	Inhabitants (number)	Per sq. mile
Africa	11,622,619	142,751,000	12.3
America, North	8,589,257	144,084,000	16.4
America, South	7,570,015	60,854,000	8.1
Asia	17,206,000	872,522,000	50.7
Australasia	3,312,613	16,229,000	4.9
Europe	3,872,561	464,681,000	120
Polar Regions	5,081,935	....	....
Total	57,255,000	1,701,321,000	29.7

The above estimates of areas of North and South America, Europe and Australasia, and of populations are compiled from the 'Statistical Abstract of the United States' and 'The Statesman's Year-book'; the estimates of areas of Asia and Africa are based on planimetric measurements of shore lines; the estimate of polar areas is necessarily an approximation, founded on known data.

The latest estimate of the earth's fertile region in square miles is 29,000,000; steppe, 14,000,000; desert, 4,861,000; polar, 6,970,000.

The population of the earth according to race is based on an estimate by John Bartholomew, F.R.G.S., Edinburgh, revised to 1910:

RACE	Location	Number
Indo-Germanic or Aryan (White)	Europe, Persia, etc.	796,000,000
Mongolian and Turanian (yellow or brown)	Greater part of Asia	630,000,000
Semitic or Hamitic (white)	North Africa and Arabia	70,000,000
Negro and Bantu (black)	Central Africa	134,000,000
Malay and Polynesian (brown)	Australasia and Polynesia	35,000,000
American Indian (red)	North and South America	27,000,000
Total	....	1,692,000,000

Chief Causes of Growth in Last Century. —What are the causes of this wonderful growth in world population in the past century, the addition in less than 100 years of as many as had been accumulated in all the centuries preceding? While there are many causes the most important is that implied by the fact already mentioned that this growth is coincidental with the development of steam power for transportation on land and ocean. Before the advent of steam transportation, man was entirely dependent upon his immediately surrounding area for food, manufacturing materials and manufactures. When the population of a city or community became greater than the food producing power of the surrounding area, the people went hungry, diseases developed and life was shortened. When bad crop years came, there was suffering and starvation, and epidemics swept off population by millions. Life was short, infant mortality high, epidemics frequent, emigration from the congested districts difficult, immigration into the unpopulated areas equally difficult. The walled cities of Europe and Asia with their insanitary conditions and underfed population were popularly designated «man destroyers,» and yet men still thought it necessary to congregate in walled cities or towns for mutual protection, and even those engaged in agriculture lived in little villages, going out to their fields in the morning and returning to their unsanitary homes at night. Of the 850,000,000 people on the globe in 1830, approximately 700,000,000 existed on the single continent of Eurasia (which we now subdivide into «Europe» and «Asia») while the remainder of the world, Africa, North America, South America, Australia and all the islands of the seas had but about 150,000,000, though it should be added that population figures at that date are necessarily based in a considerable degree on estimates of the best experts upon this subject.

Opening New Areas to World Population. — But the application of steam power to transportation on land and sea changed all this. Great areas, especially in the interior of the Americas, which had remained unpopulated because there was no way of moving their possible products to the markets of the more densely populated continent, have developed population and production as the railways were projected into the interior and steamships built to carry their products across the oceans. The population of the United States prior to the advent of the railway was chiefly along the ocean frontage or the navigable rivers. Turnpikes were constructed to enable the areas within a dozen or 20 miles of the river or ocean to move their products to the water's edge, but the great bulk of the fertile interior was too distant from the rivers or ocean to enable its scattering population to send their crops to world markets to purchase the manufactures of other countries. As a consequence the United States only added 6,000,000 to its population in the first quarter of the 19th century, a period in which it had no railways. In the next 25 years, about 9,000 miles of railway were constructed and the additions to the population were 12,000,000, or twice as great as the preceding quarter century in which there were no railways to stimulate the development of the interior. In the third quarter century the new railway construction was 63,000 miles and the addition to the population 21,000,000, or three and one-half times as much as in the like period before the advent of the railway. In the fourth quarter of the century the railway construction was 115,000 miles and the additions to population 32,000,000, or five times as much as in the quarter century when there was no railroads on the land or steamships on the ocean. In the 19 years of the present century, railway construction has been about 75,000 miles and the additions to the population 28,000,000.

Increase of Population and Commerce Coincidental with Railway Development.— The population of the entire United States when railway building began in 1830 averaged only seven persons per square mile; to-day it is 36 per square mile. The population of the Mississippi Valley when railway building began was but 3,500,000 and to-day is 52,000,000, or 15 times as many as when that valley had no railways to connect it with the oceans and no steamships to carry the products to other parts of the world. During this period in which railway construction has developed, 30,000,000 people came from other parts of the world to the United States seeking homes, chiefly in the interior of the country, and with their aid and that of the native-born Americans, the commerce was built up from a little over $100,000,000 in 1830 to $4,250,000,000 in the year preceding the great European War which by its special demand upon our facilities coupled with increasing demand from other parts of the world brought the grand total of approximately $10,000,000,000 in the fiscal year 1919. Our international trade in the year which preceded the European War was 30 times as much as at the beginning of railway construction in the United States, and in the closing year of the war 65 times as much as in 1830 when the United States had but 23 miles of railway.

In the other parts of the American continent, the increased facilities of transportation on land and sea have been followed by a marked growth of population and commerce. The combined population of all America which was but 20,000,000, a century ago is in 1919 fully 200, 000,000, and their international commerce which was then $200,000,000 is now $15,000,000,000, or 75 times as much as a century ago when there were no railways to carry the products to the water's edge or steamships to move them across the ocean.

Growth of Population in the Various Sections of the World.— Population has shown dependency upon transportation in all the grand divisions of the world. Europe, with a shortage of food and an increasing power to produce manufactures, has, since the advent of steam transportation, drawn upon the other parts of the world for food and raw material, and to pay for them in the products ot her factories, and the other parts of the world with surplus stocks of food and a shortage of manufactures have desired to make the exchanges which Europe wanted, and with these exchanges Europe has been able to greatly increase her already dense population, by drawing food from abroad and paying for it with the products of her workshops, while the Americas, Africa and Australasia have increased their population and natural products and thus greatly enlarged their commerce. The population of Europe a century ago was but 200,000,000; it is now 465,000,000. Asia had at that date about 400,000,000; now it is 870,000,000. Africa's population at that time was possibly 100,000,000; to-day it is 140,000,000, while that of all America has, as already indicated, grown from 20,000,000 in 1830 to 205,000,000 at the present time.

Transportation Facilities, Distribution of Industries and Specializaton of Production.— Steam transportation has thus enabled the newer countries to develop population by giving them access to the vast interior areas having large producing power, while it has also increased the population of the more densely populated countries of the globe by giving to them an opportunity to bring food from other continents at such small cost of transportation that they could pay for it with products from their factories and at the same time still further increase their dense population, the improved conditions of living and better sanitary methods giving to their people greater comfort, better health and a longer span of life than when they were dependent upon the immediately surrounding areas for their daily requirements. The ability of the inhabitant of the densely populated country to obtain his food from the areas which can more readily produce it is illustrated by a recent statement by a very high authority that *a workman in England can now with one day's wages pay the cost of transporting a year's supply of bread and meat from the Mississippi Valley to his own door.* The farmers of the Mississippi Valley can produce food more cheaply than those of Europe and they willingly take in exchange the manufactures with which the dense population of that continent desires to purchase its foodstuffs and raw material.

The Span of Life Lengthened by Medical Science.—It must not be supposed however that the increase of transporting power has been the only cause of the marvelous increase in population which has characterized the past century. Medical science and hygiene have greatly decreased infant mortality and increased the span of life for those reaching maturity. No exact figures can be given by which to compare these conditions of the present time with those of a century ago, but it is an accepted fact that the «expectation of life» for the average human being is now much greater than formerly. And this has been a factor of considerable importance in the growth of world population.

Use of Machinery in Food Production.— Another factor is the ease with which food may now be produced through the use of machinery, which has thus reduced the amount of human labor and time required to produce a given quantity of the requirements of man. The United States Department of Agriculture states that the amount of human labor now required to produce one bushel of wheat is but 10 minutes against 133 minutes in 1830. This marvelous change is the result of the application of machinery to the preparation of the land, the planting of the seeds and the harvesting and threshing of crops, while the labor required to turn it into form for food has also been greatly decreased. The great slaughtering houses which now turn cattle and swine into fit form for food receive an endless procession of living animals at one entrance and with a few minutes of labor turn out the finished product at the exit, sending the fresh meats by refrigerator cars and vessels to the markets on the opposite side of the globe and at the same time so conserving the by-products that the waste which accompanied the crude methods of former years no longer exists.

New Foods Increase the Power to Sustain Population.—Another reason for the increase in power of the world to supply the requirements of man is found in the acceptance of new varieties of food which the increased facilities of transportation can now bring from other parts of the world or introduce for adaptation to the soils of countries in which they did not formerly exist. We of the United States, for example, are now bringing into this country over $100,000,000 worth per annum of food oils or the material from which they may be produced as against $15,000,000 a decade ago, and this use by us of the untold quantities of a highly valuable food formerly going to waste in all parts of the tropics is also occurring in other parts of the world, especially the densely populated countries of Europe, which are rapidly increasing the use of vegetable fats from the tropics. Sugar, an extremely valuable article of food, has developed with astonishing rapidity as a result of cheap transportation and better process of manufacturing, and the world's production of sugar in the year preceding the war was 40,000,000,000 pounds against 4,000,000,000 pounds a half century earlier. The world's corn crop of which the United States is the world's largest producer is now about five times as much as 50 years ago. Meantime we have brought from other parts of the world many grain and other food products and so adapted them to our own soils and climate as to materially increase our power of sustaining a large population.

Increased Density of Population no Longer Considered Alarming.— Even those sections of the world long looked upon as densely populated go calmly on increasing their populations at a rapid rate and producing the bulk of their own food by the exertions of their own people. Japan, for example, one of the most densely populated countries of the Orient, has doubled its population in less than 50 years, yet it imports comparatively very little foodstuffs, drawing its chief food supply from its rice fields with which the mountain sides are terraced and the surrounding seas whose fisheries supply practically all of the animal food consumed by the people of Japan. These require the time of about 2,000,000 people in accumulating and preparing the nearly $100,000,000 of sea food which that industrious people draw from the surrounding waters. Java, the most densely populated island of the world, has doubled its population in less than a half century, and its people, who now average more than 700 per square mile for the entire island, draw most of their food from the rice fields and the fishing industry, and have rendered the island extremely prosperous with such valuable products as coffee, tea, sugar, spices, cinchona, tin, petroleum and India rubber, which they exchange with other parts of the world for such requirements as they are not able to meet from their own sources of production. Germany, with an area less than our State of Texas, had doubled its population between 1840 and 1914, and with a population 10 times as dense as our own was, before it entered upon the great war, looked upon as one of the most prosperous countries of the world, drawing much of its food and manufacturing material from other sections of the globe and paying therefor with the product of the manufacturing industries. England, with a population much more dense than that of Germany and equally dependent upon other countries for food and manufacturing material, doubled her population in the past 60 years and ranks among the most prosperous of the world's nations, bringing its food and manufacturing materials from long distances and paying for them with the products of her work shops.

Relative Density of Population in Representative Countries.—We of the United States can scarcely realize how much greater is the density of population in certain other countries than that of our own. We have in continental United States, exclusive of Alaska, an average of 36 persons per square mile, while Germany has 325 per square mile, Italy 332, Japan 392, Netherlands 499 and England an average of 624 per square mile, or 17 times as much as our own. *If all the people of the entire world were set down in continental United States, exclusive of Alaska, our average density of population per square mile would be less than that of England to-day.* Yet England is looked upon as one of the most prosperous countries of the world and feeds her dense population in large part with food brought from other countries, often from the opposite side of the globe, and paying for the same with the product of her factories.

The Drift to Industrial Centres.—With this change in the habits of life among the people of the world, the exchange of food of the agricultural areas for the manufactures of other areas, the density of population in the manufacturing areas has gone on increasing without the danger of starvation or food shortage which existed a century ago when cheap transportation of food across the ocean was impossible. In England, for example, the share of the population living in cities of 10,000 or more was in 1800 but 21 per cent and 66 per cent in 1900. The British census of 1851 classed 49 per cent of the population as «rural» and in 1911 only 22 per cent was classed as «rural.» The population of the 12 great cities of England was in 1820 2,000,000 and in 1919 is 9,000,000. In Scotland in 1800 only 17 per cent of the people lived in cities of 10,000 or upward; now it is over 50 per cent. In Prussia in 1800 only 7 per cent of the people lived in cities of 10,000 or more; in 1890 it was 30 per cent and at the beginning of the war approximately 40 per cent. These changes are the result of a transfer of labor in the older countries from agriculture to manufacturing and reliance upon younger countries for food and manufacturing material.

This habit of accumulation of population in dense masses and of drawing food from other areas better able to produce material of this character is exemplified in a striking degree in the United States which has recently become a great manufacturing country. The share of our own population living in cities of more than 10,000 was in 1800 only 4 per cent; in 1890 it was 28 per cent, while the share of the population living in cities of 2,500 or more in 1910 was 46 per cent and at the present time is approximately 50 per cent. Thus it may be said that even in this comparatively new country, with its large agricultural powers, approximately one-half of our population now live in cities or towns and draw their food and manufacturing material from other areas, some of them on the other side of the globe. While the United States is still the world's greatest producer of both food and manufacturing material, it now brings from other countries, mostly across the ocean, about $2,500,000,000 worth of food and manufacturing material annually, and these two groups of material actually form 85 per cent of the merchandise imported into this country, much of it traveling half-way round the world before entering our ports. Great Britain is another example of the reliance upon other parts of the world for food, since with a population less than half our own she brings in normal years nearly $3,000,000,000 worth of merchandise, chiefly food and manufacturing material from other countries, much of it across the ocean.

Will the Recent Growth of Population Continue?— Now a word as to the future. The population of the world has doubled in the past century. Will it double again in the next 100 years? Probably not. The rate of growth has perceptibly slowed down in the past quarter century and is now at the rate which suggests a net increase of little more than 1,000,000,000 in world population during the next century, giving a grand total of about 3,000,000,000 as the world's entire population a century hence.

Can the world sustain a population of 3,000,000,000 as against 1,700,000,000 at the present time? Undoubtedly. The developments of science and industry will bring under the control of man vast areas now contributing practically nothing to his support. The great tropical and subtropical belt which stretches round the world between the 30th parallels of north and south latitude has about one-half of the land area of the globe, but now supplies but one-sixth of the products entering international commerce, despite the fact that its producing power per acre or square mile is double or treble that of the like area in the temperate zone. With the lessons of the war, man has learned to substitute the internal combustion engine for the horse which could not perform a satisfactory service in the tropics, and with this new instrument of production and transportation he will now, after long years of waiting, be able to conquer the tropics and multiply the production of the food and manufacturing materials which they can so easily turn out and for which the other sections of the world are clamoring. The producing power of the older and longer cultivated lands of the world is largely dependent upon the soil foods supplied, and with the lessons of the war, man has learned to reach out into the air and obtain unlimited quantities of that most important of soil foods, nitrate, utilizing for that work the power of the waterfalls which has been going to waste in the past. The great deserts of the world now producing nothing have shown that they only need the application of water to render them more productive per acre or square mile than those of the areas now under cultivation, and man is gradually learning methods of bringing to them the necessary moisture from beneath the surface or from distant water courses, and at the same time has learned through the application of "dry farming" to obtain enormous quantities of food from areas formerly considered of little value as food producers. The substitution of the internal combustion engine, utilizing gasoline, kerosene, heavy oils or alcohol, will take the place of the horse and thus release enormous areas of land hitherto devoted to producing food for that animal whose services will be no longer required. The scientists of the world are showing us every day the feasibility of utilizing for food purposes untold quantities of natural products which have been permitted to go to waste in the past, while the world is also gradually coming to understand the importance of so conserving the products of nature as to render them far more valuable in the future than under the wasteful methods of the past.

Division of Labor and Specialization of Industry.— All of these things, the disposition of the densely populated countries to continue their growth of population by drawing foods from abroad and increasing their output of manufactures to pay therefor, and the disposition of the agricultural countries to continue their growth by increasing their output and accepting manufactures in exchange, means the application to world industries of that great economic law "The Division of Labor and Specialization of Industry." Man long ago learned that this system would give better results in the operations of considerable groups of people under a single management. The manager of the successful factory divides the various processes required for producing the completed article among a large number of people or groups, but keeps each man or group of men steadily at the particular part of the work in which he has thus become especially expert. By this process of distributing the various parts of the proposed article to small groups of individuals and keeping each group continuously employed upon that particular part of the work, he increases the producing power of the factory and cheapens the cost of producing the articles being manufactured.

This system, of a division of labor and specialization of production, so successful in the operations of comparatively small groups of men, is now being applied, perhaps unconsciously, to the production of the world, through the co-operation of cheap and plentiful transportation. Europe, the United States and Japan have become the world's great manufacturers and the agricultural, forestal and mineral areas in other sections of the globe have become the producers of food and manufacturing materials. As a result of the distribution of labor and specialization of production in the great world industries, the quantity of the respective articles which each group of men can produce has been greatly enlarged and the cost of production, measured by man power, correspondingly reduced, while cheapened transportation developed by another group of specially trained men enables the interchange of these articles at small cost.

As these great principles of division of labor and specialization of industry are applied from day to day to the world production of the staples required by man, they are being, little by little, extended to such new articles or industries as may be developed by the ingenuity of the human mind. The producing powers of the whole world are thus steadily increased, while the amount of man power required for the production and distribution of the respective products is being decreased by the same process of specialization.

As a result of these conditions, the division of labor, the specialization of production and the cheapening of transportation, the world today is able to sustain a population double that of a century ago, with greater comfort, greater prosperity and a higher degree of intelligence than at that time. When we consider what has been done in this line in the last century, we may confidently expect that the world will be able to meet the requirements of such further additions to its population as the future may bring.

POPULATION OF THE WORLD 1800 TO 1919.

Based upon official returns and estimates by accepted authorities.

(In millions)

	Total population	Europe	America	Asia	Africa	Australasia
1800.	630	175	10	365	75	5
1820.	760	208	20	430	95	6
1840.	950	238	45	560	100	7
1860.	1,205	295	90	690	110	8
1880.	1,430	350	140	780	120	10
1900.	1,550	410	170	817	130	13
1919.	1,701	465	205	873	142	15

O. P. AUSTIN,
Statistician, National City Bank of New York.

POPULATION, Relation to Wealth to. See CAPITAL.

POPULIST PARTY, The. See PEOPLE'S PARTY, THE.

PORBANDAR, pōr-bŭn'dar, India, a seaport town, capital of a native state of the same name, in the political agency of Kathiaway, Bombay. It is built on a creek on the southwest coast of Gujerat and has an active shipping trade with Bombay and Malabar. Pop. 19,000. The state has an area of 636 square miles and a population of 85,785.

PORBEAGLE, a shark of the family *Lamnidæ*, more usually called mackerel sharks (q.v.), on the northeastern American coast. The best-known species is *Lamna cornutica*, the Beaumoris shark, which occurs in the north Atlantic, attains a length of 10 feet and feeds chiefly on fishes. The porbeagle has two dorsal fins, a wide mouth, lanceolate teeth and very wide gill openings.

PORCELAIN. An argillaceous substance characterized by its translucency and vitrification; hence the ware made from the same is often so termed. These two qualities are not found combined in other pottery, earthenware being porous and opaque and stoneware being vitreous but not translucent. The derivation of the word is not clear, but some claim it comes from the cowry shell named *porcellana* (Italian) or *porcelana* (Spanish), part of the enamel coating of which has the appearance of porcelain.

Technology.— The body or substance of which porcelain is made is termed *paste* or *pâte* (French). The Chinese hard-paste porcelain (first to become known to Western civilization) is made up of certain proportions of clays known as *kaolin* and *petuntse* or cornish stone. Kaolin is frequently called *china clay* and *cornish clay* on account of its most prolific source of high quality being Cornwall (also Devon), England. Both kaolin and cornish stone are the natural products of weathered granite (*pegmatite*). Kaolin is a silicate or alumina and infusible, while cornish stone (*petuntse*), a feldspar containing silicate of alumina combined with potash, soda and lime or barium, is fusible and acts in the furnace to produce with the kaolin a molten mass of homogeneous texture and having conchoidal fracture like glass. Porcelain is generally divided into two main classes known as *hard-paste* and *soft-paste* or *natural* and *artificial*. The French know them as *pâte dure* and *pâte tendre*, terms very frequently used by English-speaking connoisseurs. In general it may be said that the hard-paste is not scratched with a file or steel point while soft-paste is abraded under such a test. Soft-paste is slightly porous. While hard-paste porcelain is, as before stated, produced (body and glaze) from koalin and china stone, soft-paste was made (the Chinese clays being unknown at first) in imitation of the Eastern wares from substitutes after an enormous amount of research. But the old Sèvres soft-paste was an artificial body and glaze of astonishing beauty and perfection, its unctuous, soft tone contrasting much in its favor on comparison with the glaring whiteness of the Chinese natural porcelain body. Brongniard, the great ceramist and director at the Sèvres works (middle 18th century), gives the following formula as a favorite at the royal factory: molten nitre, 0.220; gray sea salt, 0.072; alum, 0.036; Alicant soda, 0.036; Montmartre gypsum, 0.036; Fontainebleau sand, 0.600; all made into a frit (fused into a vitrified mass, then pulverized). This glassy substance was mixed with the following ingredients, in the following proportions, to produce the actual *pâte:* Frit (as above) 0.75; calcareous marl from Argenteuil, washed, 0.068. A glaze formula was: calcined Fontainebleau sand, 0.27; calcined flint, 0.11; litharge, 0.38; carbonate of soda, 0.09; carbonate of potash, 0.15. The physical softness of this *pâte* and glaze allowed the colors in the decoration to sink into *pâte* and glaze so as to leave a lovely mellowness like wax. In 1769 Sèvres started hard-paste. One considerable advantage which soft-paste has over hard-paste from the manufacturing point of view is the fact that less heat is required in the baking; but, hard-paste firing at from 2,462° F. to 2,642° F. with safety, while soft-paste permits only a margin of heat of from 2,012° F. to 2,102° F. gives hard-paste a safety margin against crazing of 180° F. against a range of but 90° F. for soft-paste firing. The firing, which is done in specially constructed ovens, takes place after the wares are stacked in safety, protected by fire-clay covers, known as *saggers*. The incandescent heat of the hard-paste furnace is generally called by experts by the French term *grand feu*, sometimes *hard fire*, while the lesser heat required in baking the body of other wares is termed *demi grand feu*. The preparation of the clays for porcelain is done in blungers, sifting machines, etc.; the forming or shaping of the mass or body on the potters' mold or in the modern turning lathes, «jiggers,» «jollies,» all of which processes common to all classes of pottery, do not belong under this specialized head (see CERAMICS; CLAY; POTTERY, and related references).

Colors.—The only colors that will stand the *grand feu* heats of hard porcelain are: blue from cobalt, red from copper and *céladon* green and brown from iron. These, therefore, are used *under* the glaze. In order to extend the range of colors on hard porcelain ware a separate firing becomes necessary, either in an oven of less heat or exposed in parts of the incandescent oven which are not reached by the most intense temperature. Of such are turquoise blue from copper; purple from manganese; yellow from iron with a proportion of antimony. Colors which will stand in kilns of lesser heat are red, from iron oxide; brown, from iron chromate or manganese; green from copper; yellow from antimony; rose and purple from gold.

History.— No industry furnishes a history so full of romance as that of porcelain. The discovery of the porcelain body was made in China; the first production having the characteristics of translucence with vitrification would appear to have taken place at the end of the 6th century. The cause of its discovery is the great love and reverence of the Celestial for jadestone. Carved jade was, par excellence, the most valued of the Chinaman's possessions, and it was in the attempt to obtain a substance with the qualifications of this hard, semi-translucent, greenish-yellow mineral (*nephrite*) that kaolin was used for a body or mass, combined with other silicious material, and *céladon* was the outcome from which magnificent vases, bowls, etc., were produced. Céladon could not be called translucent. By the 7th century, at least, we know that at Changnanchin, called later Ching-tê-chên, true porcelain was in course of manufacture in large quantities having the qualities of being translucid, stone-hard, resonant and of vitreous fracture — the natives called it *Tzŭ* to distinguish it from *Wa*, earthenware. A description of the different lovely wares of the Chinese dynasties will be found elsewhere (see CHINESE CERAMICS). Already in the 16th century Chinese porcelain ware was becoming known in different parts of Europe as rare and lovely works of art of great value and Florence (under the Medici) attempted to make imitations, at the end of that century, of Chinese specimens in their possession. It was an artificial glassy porcelain made from impure china-clay (Terra-Vicenza), fine white sand and powdered glass. With the growing admiration of Europeans for the Oriental porcelains and the increasing numbers of superb collections among the royalty and nobility grew up an intense desire to produce the ware at home. The Jesuit priest, Père d'Entrecolles, during his prolonged stay in China gathered a mass of information as to the methods of manufacture of the coveted ware and sent detailed accounts home of his discoveries among the kilns of Ching-tê-chên from 1712 to 1722. They did not bring about the discovery of materials for the porcelain body, however, though they assisted greatly in giving invaluable information on the Chinese methods of porcelain decoration. To meet the popular clamor for pieces of pottery similar to the Oriental porcelains at a cost within the reach of the bourgeoisie of wealth the lovely specimens of *blue-and-white* underglaze and some polychrome pieces (see CHINESE CERAMICS) were reproduced in earthenware coated with a tin-glaze opaque white slip by the 17th-century Dutch potters at Delft. (See DELFT). In spite of diligent search, the clays which produce porcelain remain unknown. The Japanese nation claims that its knowledge of art pottery was gained from the Koreans, but Chinese influence introduced porcelain manufacture to the realm of the Mikado. With the Japanese connoisseurs porcelain took a secondary appreciation and earthenware alone received their patronage. The peculiar decorative talents of these islanders produced clever porcelain styles that quickly attracted European attention and demand and the trading companies of Holland and England were soon importing great quantities of Japanese alongside the Chinese wares. The porcelains of Japan are described fully elsewhere. See JAPANESE CERAMICS.

European Porcelains.— While both Florence and Venice had produced pieces of art ware of porcelain appearance, these were but of glass body with admixture (perhaps) of ground Chinese porcelain fragments. Of recent years the honor of making porcelain ware in industrial quantity has been awarded to Rouen, where a good quality of ware was produced in an admirable soft porcelain body. In 1673 Edme Poterat (talented faience master) secured a license to manufacture in his earthenware works porcelain as well as faience. It was carried on till 1696 by Louis Poterat, a son, who when he died had never divulged the secret working formula. Several pieces of this rare ware are in Europe and America (Morgan collection). Pierre Chicaneau's porcelain factory at Saint Cloud was active as early as 1670 and the letters of several contemporary notables testify to the fact that both in painted decoration and beauty of form and finish the ware fully equaled that of the Chinese. It continued in operation till 1766. A number of pieces are found in present-day collections proving the high quality of this ware, which, besides cups and saucers, includes tea-pots, milk jugs, candlesticks, spice-boxes, handles for knives and forks. The delicate relief work is remarkable, but the pieces are rather thick. Johann Friedrich Böttger, a German alchemist, was the first to make hard porcelain in Europe. His claims of power to turn base metal into gold caused Augustus II, Elector of Saxony, to hold him in captivity in preference to turning him over to the king of Prussia, who was anxious for him to carry out his proclaimed powers in Berlin. Böttger, under the protection of the Elector, set up his furnace and laboratory in Dresden. But his failure to bring forth the precious metal caused him to be moved from place to place as a prisoner under associates of the king. After several attempts at escape his life was in danger from anger at his deceptions till he discovered the process of making a red stoneware of extreme hardness which stood polishing on the lathe, much to the pleasure of the king, and by 1707 he was producing much of the ware for the courts. In 1709 Böttger discovered kaolin in his neighborhood (a barber is said to have been using the white powder on his wigs and told him whence the mineral was derived). His success was so quick that large quarters for the making of his true porcelain ware became necessary and he was transferred to Albrechtsburg Castle at Meissen. He died in 1719, but the factory and its ware became the most noted in Europe. The progress of the Meissen styles is one of extreme interest and is fully described elsewhere (see DRESDEN PORCELAIN). Of equal note with the beautiful productions from Meissen, Germany, are those lovely creations in *soft* porcelain made at Sèvres, France. Established first at Vincennes, in 1738, this factory, which had come into possession of the king, was transferred to Sèvres. As already described, the development of the Sèvres *pâte* was a fine art carried out with the most exhaustive research. The Sèvres body transcended in delicate beauty and softness anything produced at Meissen and we are indebted to the fact that kaolin had not been discovered in that section that we inherit an artificial porcelain body that is the admiration of the world. The wealth of royalty caused marvelous pieces in the most delicate color decoration to be made for the court and for gifts to foreign rulers, regardless of the great expense in production. A full account of the history and products of this world-renowned porcelain will be found under another title (see SÈVRES). Already in 1725 Ciquaire Cirou had established a porcelain factory at Chantilly under the patronage of Louis-Henri de Bourbon, Prince de Condé. Beautiful figures, but mainly table services, artistically decorated, were its chief products. Japanese decoration frequently is found on earliest pieces, for the factory license was granted to produce pieces in imitation of the Japanese porcelains. For Japanese porcelains were becoming vogue with their clever *kakiemon* decorative methods. Chantilly factory remained active till 1800. And from now on many members of royalty and nobility aided in the starting of porcelain factories in different parts of France, even when the laws protecting the royal Sèvres monopoly forbade the competition. Soft porcelain was made at Mennecy-Villeroy from 1734 till 1773 when the factory was transferred to Bourg-la-Reine, continuing till 1806. Others opened as follows: Lille (1711), Sceaux (1749), Orleans (1753), Crepy-en-Valois (1762), Saint Amand-les-Eaux (1771), etc. But about 1768 kaolin was discovered at Saint Yrieix (Haute-Vienne) and France turned to making *hard* porcelain at Orleans (from 1768); Brancas-Lauragais (1764), where kaolin and petuntse were also found as early as 1750; Vincennes (from 1765), Niderviller (1765), Vaux (1769), Lunéville (1769), Arras (1770). At Paris alone we find the following hard porcelain factories established: Rue de Bondy, named after the Duc d'Angoulême (1780); Faubourg Saint Antoine (about 1773); factory of the Comte d'Artois (about 1769); Clignancourt (1771); La Courtille or Basse Courtille, in the faubourg du Temple (1771); «Prince des Galles» factory, rue de Cressol; Duke of Orleans' factory in Faubourg Saint Antoine (about 1784), then transferred to Pont-aux-Choux; rue Popincourt factory (1782); rue de Reuilly (1774); rue de la Roquette (1774); rue Thiroux (1775), made «Porcelaine à la Reine.» Other notable hard porcelain factories were established as follows: Arras (1770), La Seynie (1774), Marseilles (1776), Boissette (1778), Lille (1784), Valenciennes (1785), Caen (1797). In Belgium a factory was started in 1750 at Tournay which became one of the most flourishing in Europe, lasting to the present day. In Germany very noted factories, besides that of Meissen (Dresden) and turning out the most beautiful art ware (figures, etc.), must be mentioned that of Fürstenberg, established in 1746 by Duke Karl of Brunswick with Johann Christoph Gläser of Bayreuth as expert. Its activities continue to this day. At Höchst (1746) porcelains were produced that brought the factory to be third in Germany after Meissen and Berlin, but the works were closed in 1798. In 1750 Wilhelm Caspar Wegeli established a factory at Berlin, but he closed to take up the wool industry in 1757. The sculptor, Ernest Heinrich Reichhard, got possession but turned over the place to J. E. Gotzkowski in 1761. Friedrich Elias Meyer, the modeler, was engaged with Jaques Clauce, the noted enamel painter and other skilful craftsmen. Lacking success Gotzkowski sold the factory (1763) with a rich stock, 133 figure molds and other valuable material for 225,000 thalers and the place received the title «Königliche Porzellan-Manufactur» as the property of Frederick the Great, who got craftsmen from Meissen and soon established successful operations. The early yellowish-gray paste formerly used was displaced by that made from kaolin obtained in Silesia, making a whiter paste. Rococo style was in highest vogue so Berlin pieces of the early period are steeped in the extravagances of this style. Grand pieces were constructed for the king's court, candelabra and mirror-frames for Sans-Souci Palace, a great centre table-piece for Catherine II of Russia consisting of allegorical and other figures in white biscuit (unglazed). Biscuit has been ever since the usual method of production of Berlin figures. Coffee and tea services from this factory show very delicate decoration *en camaïeu*. Berlin's iron-red and rose-crimson are two of her best successes in colors. The factory is still active but has suffered from the same degeneracy in art as other fabriques. The porcelain factories of Frankenthal (1755) and Ludwigsburg (1758) are noted for the lovely art works produced, but lack of space forbids their detail; the same must be said of the factory at Nymphenburg (1758), bare enumeration of their existence being here alone possible together with the statement that their productions when they appear in the auction-room bring extraordinary prices and are considered worthy the cost. Cassel (1766) and Kelsterbach (1758) and Fulda (1765), all had porcelain factories, and in the Thuringian forests, where kaolin was discovered and fuel was cheap, Sitzendorf-Volkstedt (1762), Gera-Unterhaus (same date), Kloster Veilsdorf (1765), have their works still active. Wallendorf (1765), Gotha (1767), Limbach (1772), Grossbreitenbach (1780), Rauenstein (1783), Tettau (1794) and Possneck (1800) are all in more or less successful operation to this day. The porcelain factory at Vienna was established in 1718 but failed to make headway, and to 1744 had been a financial failure all the time. Its sale to the state in that year permitted a more substantial condition to prevail and both demand and supply grew till the great trade depression that started in 1779 caused such an unsatisfactory financial condition at the factory that (1784) it was offered for sale without bidders. Rococo, the prevailing style of decoration of that period, predominates in the Vienna wares of this second period. In the latter-mentioned year the factory was placed under the control of Baron von Sorgenthal as director; and the fortunes of the fabrique rapidly changed for the better and with an ever-increasing demand that made the space cramped and a branch was started in 1799 at Engelhardzell, near Passau. The rococo style gave way to antique classic under Sorgenthal. In 1805 Vienna entered on her fourth period, when Sorgenthal died and Niedermayer took his position and continued the financial success in spite of the severe obstacles created by the war, such as the loss of Passau and the factory at Engelhardzell. By 1816 decline set in and in 1827 Niedermayer retired, the fifth period opening with Benjamin Scholtz directing. He used cheap clay and made poor quality of ware and the factory declined still further till 1833, when Scholtz died and Baumgartner, professor of physics at the university, succeeded. A small profit was now made by producing common porcelain for domestic use. Later more artistic work was undertaken (1856) by Alexander Lowe, but in 1864 the factory was closed to stop the continuous loss. Holland had porcelain factories at Weesp (about 1763), Oude Loosdrecht (about 1774) and The Hague (1778), but none lasted long. Switzerland, in Zürich (1763) and Noyon (end of the 18th century), had porcelain factories but they soon closed. Kaolin was discovered in Denmark (1756) and a porcelain factory was opened the same year in Copenhagen, which after changing hands was followed by a new factory in 1772, but it was no success till, in 1779, the king took up the works and it is still running and producing beautiful art work worth lengthy comment. In Italy, besides Florence and Venice before mentioned early in this article, Doccia (1737) made both soft and hard porcelain; Capo-di-Monte also made soft porcelain of lovely character and refinement from 1742 till 1759, when the king of Naples and Sicily became king of Spain and removed his factory to his palace of Buen-Retiro, near Madrid, where work continued till 1808. At Saint Petersburgh, Russia, about 1745, Empress Elizabeth started a hard-paste factory which has continued to this day. The chief work strongly imitates Meissen (Dresden) during the Seven Years' War period as the workmen were from Meissen; then followed Sèvres style.

English Porcelain.— So far as known the first English soft paste was made at Chelsea (earliest specimen dated 1745). Bow is said to have produced artificial porcelain as early as 1730, but 1740 is generally considered the date of work on a commercial scale. Derby works were started in 1756 and Worcester was established in 1751. Other factories are those of Longton Hall (1752), Davenport (1794), Minton (1798), Spode (after 1797), Lowestoft (1756?), Liverpool (Herculaneum 1800), Caughley (1772), Coalport (after 1814), Pinxton (about 1795), Church Gresley (1795), Nantgarw (about 1813), Swansea (1814). Kaolin and petuntse for making *hard-paste* porcelain were first discovered by Cookworthy (1758) in Cornwall and the first factory to make true porcelain was at Plymouth (1764); he sold out to Champion of the Bristol works (1770). Full description of the history and characteristics of the wares of prominent factories will be found under the titles Bow, BRISTOL, CHELSEA, DERBY, LOWESTOFT, WORCESTER, etc.

With the 18th century certain proportions of bone had been used in the ingredients composing the porcelain body by certain factories; with the beginning of the 19th century this *bone paste* had become standardized in all factories and, as a consequence, the English «standard» or «bone» porcelain swept aside all other kinds and the factories of the Continent found themselves faced with a condition in which the English porcelain factories filled all the common needs of the European table services with a pure white, inexpensive, hard-porcelain, impossible of competition. The «standard» ware has been universally used for commercial ware ever since.

Technical Art Expert.

PORCELAIN CLAY. See KAOLIN.

PORCELAIN TOWER, a tower which was erected in the early part of the 15th century and destroyed by the Taipings in 1853. It was octagonal in construction, had nine stories, faced with variegated porcelain (from which it received its name), and from these lamps and bells were hung. A miniature reproduction of the tower may be seen in the Green Vault in Dresden.

PORCH, a covered place of entrance to a building and differentiated from its principal mass. Its forms are various, sometimes extending above by more than one story, sometimes enclosed save for the doorway, then again open to the outside on three sides, with its outer corners supported by columns or piers. It may be simplified into an overhanging hood or baldachino. In Byzantine and Eastern churches the porch was an enclosed atrium or narthex, a feature that has developed with modifications into the mosque of the Moslems. The enclosed atrium was retained in the early basilican churches and contained a fountain where worshippers might wash their hands,— the origin of the present universal Roman Catholic practice of dipping the fingers in the holy water of the piscina. In this space, probably always called the narthex of the basilica, the penitent or unbaptized persons were compelled to stay. Such a structure may be seen in the church of San Lorenzo, in Rome, and Saint Apollinaire in Clusse at Ravenna. The narthex extended across the front of the church and its inner wall contained three doors that gave upon the nave and aisles of the main body. Of Romanesque churches, the porch of the church of

Vézelay is an important example; while the church of Saint Germain l'Auxerrois in Paris shows a Gothic edifice with a porch extending across the front, dating from 1431, its horizontal crown in sharp contrast to the climbing lines of the main edifice.

Porches are characteristic of the Gothic style in Italy, though instead of being placed in front they often occupy positions on the flanks, thus forming side entrances. A remarkable specimen in three stories, the upper and surmounting one of a pagoda-like structure, is attached to the church of Santa Maria Maggiore at Bergamo.

PORCIA. (1) The plebeian gens of Rome, flourishing from the 3d century B.C. and whose most famous family was that of Cato. (2) An ancient lady living in Rome, the daughter of Cato, of Utica. She became the wife of M. Bibulus, who was Cæsar's colleague in the consulship, in 59 B.C., by whom she had three children, and after his death married M. Brutus in 45 B.C., who later murdered Cæsar. After the death of Brutus she committed suicide.

PORCUPINE, a rodent of the family *Hystricidæ*. Porcupines are distinguished by the peculiar nature of the body-covering, which consists, especially on the back and haunches, of hairs specially modified to form the so-called *quills*, or dense, solid, spine-like structures. These quills are intermixed with bristles and stiff hairs, and in the American subfamily *Synetherinæ* are almost concealed beneath the hairy fur of the body. The incisor or front teeth number two in each jaw and spring from permanent pulps, so that they continue to grow throughout the lifetime of the animal as in the other members of the order. There are four molar teeth on each side of each jaw, exhibiting complicated foldings of the enamel on both the internal and external sides; and sometimes they, like the incisors, continue to grow throughout life from persistent roots. The skull exhibits an infraorbital foramen of very large size. The muzzle is generally short and broad. The lip is divided and the ears short and rounded. The anterior feet possess four and the hinder feet five toes, all provided with strong, thick nails. The tongue is roughened or, as in the Javan porcupine, may be provided with horny plates or scales.

The family *Hystricidæ* is divided into two groups, *Histricina* and *Synetherina*, or two subfamilies, *Hystricinæ* and *Sphingurinæ*. The *Hystricinæ* or Old World true porcupines are terrestrial, and have imperfect clavicles and open rooted molar teeth. They fall into several genera. Of these the most familiar is *Hystrix*, represented by the true porcupines. The common or crested porcupine, *Hystrix cristata*, found in southern Europe and in northern Africa, is the best-known species. The true porcupines have non-prehensile tails, which may be spiny or covered with scales or bristles. When fully grown the common porcupine measures nearly two feet in length, and some of its spines exceed one foot. The general color is a grizzled, dusky black. The upper part of its head and neck is furnished with long, light-colored hairs, capable of being raised or depressed at pleasure; and most parts of the back and sides are armed with spines, which are longest on the centre of the back. In their usual position they lie nearly flat upon the body, with their points directed backward; but when the animal is excited they are capable of being raised. The quills are loosely inserted in the skin, and may, on being violently shaken, become detached — a circumstance which may probably have given rise to the purely fabulous statement that the animal possessed the power of actually ejecting its quills like arrows or darts at an enemy. These animals generally lead a solitary life, and inhabit burrows during the day, coming forth at night in search of food, which consists of vegetable matter. The common species is quiet and peaceable, but shows no disposition to become familiar or domesticated. An Indian form (*H. leucurus*) resembles the crested porcupine, but is larger.

The genus *Atherura*, including three species, possesses a long scaly tail, which is terminated by a tuft of bristles. The species of this genus occur in the Malayan region and West Africa. The *Atherura fasciculata*, or brush-tailed porcupine, is a familiar species of this genus. The *Synetherinæ*, or American tree-porcupines, are easily distinguished by their well-developed clavicles, molars with closed non-growing roots, usually prehensile tails, the feet with tuberculated soles and the absence of the pollex. The three genera are confined to America.

The Canadian porcupine (*Erethizon dorsata*) is the best known, and is a robust animal with a short non-prehensile tail. It is about two and a half feet long; of a brownish color, mingled with white; the spines are about four to six inches long, concealed in the fur and attached in a very slight manner to the skin, and, from being barbed at the tip with numerous small reversed points or prickles, they by degrees penetrate very deeply into the flesh after having once pierced it. Small and insignificant as these defensive weapons may appear, they are capable of severely injuring dogs, wolves or indeed any animal that incautiously attempts to seize the porcupine. These spines or quills were much used among the Indians to ornament different articles of dress; they dyed them various colors, in a very permanent manner. The Canada porcupine is found in the thickly wooded parts of northeastern United States and in Canada, the northernmost limit of its distribution being the shores of the Mackenzie River and the southernmost the high mountains of Pennsylvania. They feed on the barks of various trees, apples, corn, etc. Their flesh is said to be very unpalatable, resembling flabby pork. They pair about the latter end of September and the female brings forth two young in April or May.

The genus *Synetheres* of South America to Mexico possesses a distinctive feature in the elongated prehensile tail, adapting it for an arboreal existence. They are the true tree porcupines. About 10 species of these animals are indigenous to America, the spines, as in the Canadian porcupine, being of much smaller size than in the Old World forms. In length the typical species of this genus averages one and one-half feet, the tail measuring about 10 inches.

Consult Stone and Cram, 'American Mammals' (New York 1902); Merriam, 'Adirondack Mammals' (New York 1884).

PORCUPINE ANT-EATER. See ECHIDNA.

PORCUPINE FISH. See DIODON.

PORCUPINE RIVER, a tributary stream of the Yukon. Fort Yukon is at the confluence of these rivers. The Porcupine is navigable for steam vessels a distance of about 100 miles and for about twice that distance for smaller craft. The lower Mackenzie is most easily reached via the Porcupine, and portage to the Peel River.

PORCUPINE-WOOD, the timber of certain Oriental palms. See PALMS.

PORDENONE DE SACCHIS, pôr-dā-nō'nā dā săk'kēs (or DE CORTICELLIS) really named GIOVANNI ANTONIO DA PORDENONE, Italian painter: b. Pordenone, 1483; d. Ferrara, January 1539. He painted in his native home and worked without much influence from abroad, until in his 27th year he visited Venice and was captivated by the productions of Giorgione, Palma and Titian. In 1535 he settled at Venice and before the end of the year was knighted by the king of Hungary (taking in addition to his own the name «Regillo»), and in 1538 was summoned to the court of the Duke of Ferrara, who desired his services to prepare designs for Flemish tapestry, but here he died suddenly the following year. These are the few incidents of his life with which we are acquainted. His works consist of altar-pieces and frescoes, painted in the spirit of the Renaissance. Of these the most important are the New Testament series of frescoes in the church of San Salvadore, Cotalto; the paintings on the walls and roof of the cathedral chapels at Treviso; and those in the cathedral of Cremona (1520–22). He also painted the altar-piece of the cathedral at Pordenone — ‹The Madonna Attended by Saints› (1515). Most of the frescoes he painted in houses and churches at Venice have perished. Several of his paintings are in England, notably his colossal figure of ‹An Angel› in the National Gallery, and a large picture of himself and family at Hampton Court.

PORE FUNGI. See FUNGI; POLYPORUS.

PORGY, or **PORGEE,** name applied in different localities to any one of several different fishes. In eastern United States the scup (*Stenotomus argyrops*), and occasionally the menhaden (*Brevoortia tyrannus*) are so named. The moon-fish or angel-fish (*Chætodipterus faber*) is rarely so called. The Pagrus pagrus of European waters is called the red porgy. Consult Kingsley, J. S., ‹Standard Natural History› (Vol. III, Boston 1885).

PORIFERA, the phylum of animals which includes the sponges, the term referring to the apertures or pores which characterize them. See SPONGE.

PORISM, *in geometry,* a name given by ancient geometers to a class of mathematical propositions having for their object to show what conditions will render certain problems indeterminate. Playfair defined a porism thus: «a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions.» Euclid's three books on porisms have been lost, and in consequence there has been much controversy as to what the ancients meant by the term. The porism partakes of the nature both of a problem and of a theorem, without being exactly either.

PORK, the flesh of swine, is one of the most important and widely used species of animal food. Fresh pork, though by some considered a delicacy, especially when killed young, is a much inferior article of diet to beef or mutton, and is much less used. The flesh of pork, particularly the lean, is coarser and ranker than that of the other animals chiefly used for food, but there are certain advantages which give pork a place in the supply of animal food that can be filled by no other article. The appetite of swine being much more catholic than that of their daintier neighbors, the feeding of them answers the purposes of economy, and extends very materially the supply of food. This, it is true, is attended with considerable dangers. If care is not taken that the feeding of swine should be wholesome and cleanly, their flesh becomes tainted with disease and unfit for food. Unscrupulous breeders sometimes take advantage of their exorbitant and omnivorous appetite to make them consume the most disgusting offal, and even when their feeding is not conducted with this utter recklessness of consequences it is often less careful than is consistent with sound sanitary conditions. There is in fact no animal to the perfection of whose flesh as an article of diet careful attention to feeding is more indispensable. The main recommendation of pork lies in its superiority to other kinds of animal food in undergoing the process of curing. The quality of beef and mutton is seriously deteriorated when long kept, even under the best methods of curing; that of pork is decidedly improved, and when of good quality and well cured it develops a richness and delicacy of flavor in marked contrast with the dryness and insipidity of other salted meat. Another recommendation of pork is the abundance and very digestible quality of its fat, which makes it a very suitable diet for cold climates, but which is, on the contrary, rather a disadvantage in hot ones. For long sea voyages, especially before the introduction of modern methods of keeping fresh meat, pork was by far the most common and acceptable form of animal diet, and it is still one of the most valuable items in naval stores. The swine was among the unclean animals forbidden to be eaten by the Mosaic Law. It is still regarded by the Jews as specially typical of the unclean animals. The Egyptians, Arabians and other Eastern nations had similar opinions as to the use of pork. See HOGS; NUTRITION OF FARM ANIMALS; PACKING INDUSTRY; SWINE.

PORPHYRITE, a porphyritic orthoclase rock free from quartz; so named by some petrologists, by whom the name has been applied to various rocks generally of this character. Some of these rocks, however, include varieties in which the orthoclase constituent is more or less replaced by oligoclase. Many porphyritic dolerites have been also included under this name. By the presence of hornblende it often approaches the composition of a syenite, with which it is frequently associated.

PORPHYRY (PORPHYRIOS), Greek philosopher of the Neo-Platonic school, celebrated as an antagonist of Christianity: b. either at Tyre, whence he is called Tyrius, or at Batanea, the Bashan of Scripture, a town of Syria, whence he is also called Bataneotes, about 233 A.D.; d. Rome, about 304. His original name was Malchus, from the Syrophœnician *melech*, king. Longinus, whose pupil he became, gave him the title of Porphyrios, that is, purple-clad. He early became the pupil of Origen, and afterward studied under Apollonius and Longinus in Athens. At 30 he came for the second time to Rome to place himself under the teaching of Plotinus. Porphyry at first disputed the doctrine taught him, in a treatise in support of the position «that the things perceived by the mind exist out of the mind,» which he submitted to Plotinus. Amelius, his associate and assistant, wrote a treatise in reply; and after some further controversy Porphyry read a recantation in the school. This incident is important, as indicating the teaching of Longinus, and possibly by implication of Ammonius, the instructor of Plotinus. Porphyry finished by entirely adopting the opinions and obtaining the confidence of Plotinus, whose literary assistant and executor he became, and whom he induced to commit his views to writing. Porphyry was naturally of a hypochrondriacal disposition, and the abtruse mysticism of Plotinus incited in him a tendency to cherish thoughts of suicide, which Plotinus perceiving recommended to him a change of situation, and about 268 he went to Sicily. Here he is said to have written his treatise against the Christians in 15 books. It was publicly burned by the Emperor Theodosius, and is known only from fragments in the authors who have refuted him. Porphyry, as well as Plotinus, recognized Christ as an eminent philosopher; but charged the Christians with corrupting his doctrines. The philosophy of Porphyry is completely identified with that of Plotinus (q.v.). Porphyry represented chiefly the religious phase of this philosophy, and we need here only refer to its relation to the popular mythology and theurgy, which has been merely adverted to in the life of Plotinus. The best ancient philosophers found no difficulty in reconciling polytheism with the belief in one supreme and omnipotent God. Plotinus and Porphyry joined a belief in good and evil demons and a respect at least for the Greek mythology with their philosophical tenets. These beliefs have been the ground of accusations of inconsistency against Porphyry, who dwells on them occasionally in his writings. He believed, as did Plotinus, in enchantment as a means of acquiring power over demons and the souls of the dead; but always ranked philosophy higher than mythology, and from his letter to the Egyptian prophet Anebo it appears that at a later period of his life doubts of the popular theology, and of the theurgical notions associated with it, had begun to prevail with him. The practical tendencies of his philosophy were ascetic. He held that all matter was polluted, and that no material sacrifice ought to be offered to the supreme God. He abstained from animal food, and would also, had it been possible, have abstained from vegetable diet. He distinguished four degrees of virtue — political virtue, or that of moderation is the first grade; purifying virtue, which sets the soul free from passion, and by means of which men are made to resemble demons, is the second grade; in the third grade, which corresponds with the absorbing devotion of philosophy, man becomes a god; and in the fourth, answering to the ecstatic state of Plotinus, he becomes the father of the gods. He recognizes a soul in animals, and accords to them a certain amount of intelligence and reason. Porphyry was a voluminous writer, but comparatively few of his works are extant. Besides his editorial work for Plotinus, the most important are his Lives of Plotinus and Pythagoras, the latter supposed to be a fragment of a larger history of philosophers. Among his other works are ‘Principles Concerning Intelligibles,’ a resumé of the Philosophy of Plotinus; the ‘Cave of the Nymphs in the Odyssey’; four books, ‘On Abstinence from Animal Food’; an ‘Introduction to the Categories of Aristotle’; a ‘Commentary on the Harmanica of Ptolemy,’ a 10-volume work in verse, ‘De Philosophia ex Oraculis Libri,’ and a contribution to a symbolical interpretation of Homer. Consult Bouillet, ‘Porphyre, son Role dans l'Ecole Neoplatonicienne’ (1864).

PORPHYRY, any one of various kinds of compound rock having a basis in which the other contemporaneous constituent parts are imbedded. The base is sometimes claystone, sometimes hornstone, sometimes compact feldspar, jade, pitchstone, pearlstone and obsidian. The imbedded parts are commonly orthoclase feldspar and quartz; the former in more or less distinct crystals. There are porphyries of different ages. One variety is found graduating into granite and gneiss, but this does not possess the characteristics of the rock in the highest perfection; another is found in overlying strata, and unconformable to other rocks, which is the true porphyry. Its color is often red or green, and when polished it is valuable for ornamental work, being superior to marble on account of its great hardness.

PORPOISE. Any small or moderate-sized cetacean is usually called a porpoise, but the name is applied chiefly to members of the family *Delphinidæ*, belonging to the suborder *Odontoceti*, or the toothed whales. Its principal characters are as follows: The anterior pairs of ribs are joined to the vertebræ by both a tubercle and a head. The sternal ribs are completely ossified. The cervical vertebræ are more or less united. In the skull the pterygoid bones are inflated. The symphysis of the mandible is short. The teeth are always present, but vary greatly in number in different genera; they usually occur in both jaws and are simple and conical. The genus *Grampus* is without teeth in the upper jaw, and the genus *Monodon* without teeth in the lower jaw. The blowhole is single and crescentic in form.

Between 60 and 70 species of porpoises are known, representing 19 genera. They are greatly diversified in form and color. Some have a large, falcate dorsal fin, while in others the fin is reduced in size, or is represented only by a low ridge, or is entirely absent. The pectoral fins are equally varied in size and proportions, being short and broad in some forms and very long and narrow in others. The beak may be long or short, compressed or depressed, and is sometimes replaced by a narrow rim, or is absent altogether. The representatives of several genera of porpoises have received special names, such as killers (genus *Orcinus*), grampuses (genus *Grampus*), blackfish (genus *Globicephalus*), beluga or white whale (genus *Delphinapterus*), narwhal (genus *Monodon*), etc.

The *Delphinidæ* are chiefly marine, but some species of the genus *Sotalia* live in the Amazon River, and in the rivers of China, and one species af the genus *Orcäella* in the Irawadi River, Burma. The harbor porpoise (*Phocæna phocæna*) and the bottle-nosed porpoise (*Tursiops truncatus*) frequently ascend the Potomac, Hudson and other rivers of the eastern coast of the United States, and the beluga ascends the Saint Lawrence regularly every spring in large numbers.

The geographical range of the porpoises as a group extends over all seas from the Arctic to the Antarctic, but while some species, such as the common dolphin (*Delphinus delphis*) have a very wide distribution, that of others is more circumscribed. Thus, the narwhal is confined to the Arctic Ocean, and rarely leaves the ice. The beluga is also an Arctic species, though it ranges southward regularly in spring to the Saint Lawrence, as already stated, and occasionally individuals stray as far south as Cape Cod and the New Jersey Coast. The white-lipped porpoise (*Lagenorhynchus albirostris*) is common about the British Isles, but is not found on the coast of the United States. The species of blackfish (*Globicephalus melas*) found on our east coast north of New Jersey is different from that occurring further south. Our commonest east coast porpoise (*Tursiops truncatus*) is not found in Greenland waters, while the harbor porpoise (*Phocæna phocæna*), which is abundant in the gulf of Maine and northward, does not range south of New Jersey. Many species occurring in the tropics and the south seas are never seen in North American waters.

The majority of porpoises feed upon fish, but the various species of blackfish, the narwhal and the white whale subsist chiefly or exclusively upon cuttlefish, while the killers devour the young or other cetaceans and of various amphibious mammals, such as seals, sealions, etc. The stomach of a porpoise (*Sotalia teüszii*) recently discovered on the west coast of Africa was found to contain leaves of the mangrove tree and other vegetable matter. Porpoises are gregarious animals, congregating in large herds or «schools,» which sometimes comprise an enormous number of individuals. Schools of blackfish numbering hundreds of individuals occasionally approach the land at the Faroe Islands, the Orkney Islands, Cape Cod, and other points, where they strand, or are driven ashore by the fishermen. They are the source of a considerable profit, on account of their oil, which is of a superior quality. The skins of the blackfish and of the white whale are valuable for leather, but the dermis of the majority of porpoises is too thin, or too irregular in texture, to form good leather.

Besides the porpoises of the family *Delphinidæ*, there are a few species generally called river dolphins representing three genera, which belong to a separate family, the *Platanistidæ*. The best known are the susu of the Ganges River, genus *Platanista*, a blind form which subsists chiefly upon fresh-water crustaceans; the inia, genus *Inia*, of the Amazon River; and the *Pontoporia*, found about the mouth of the La Plata River. These porpoises are remarkable for their long beaks, their broad pectoral fins, their free cervical vertebræ, and their rugose or otherwise peculiar teeth. They are regarded as highly specialized forms of ancient origin. Numerous fossil species of *Delphinidæ* and *Platanistidæ* occurs in the Tertiary and latter geological formations, beginning with the Miocene. Consult Beddard, F. E., ‹A Book of Whales› (London 1900); Goode, G. B., ‹Fishery Industries› (Washington 1884); True, F. W., ‹Bulletin of the United States National Museum, No. 36› (Washington 1889).

PORPORA, pŏr'pō-rä, **Nicolo**, Italian composer: b. Naples, 19 Aug. 1685; d. there, February 1766. He studied under Scarlatti and his first opera, ‹Ariana e Teseo,› was brought out at Vienna, 1717. In 1725 Porpora went to Vienna with his celebrated pupil, Farinelli, and in 1728 accepted a pressing invitation from the court at Dresden. He had already composed 50 operas, and was regarded as without a rival. In 1729 a faction in London, discontented with Handel, opened another opera house, and called Porpora to take the direction of it. Porpora, supported by Farinelli and other distinguished singers whom he had trained, triumphed, and Handel accordingly gave up the theatre, and devoted himself to oratorio. Porpora now gave up his engagements in Dresden, and established himself in London. Here his reputation, especially as a singing-master, continued to be great; but after a few years he went to Venice and later was established in Vienna where in 1754, Haydn, for the sake of obtaining his instructions, became his valet. In 1760 he presided at the production in Naples of his last and feeblest opera, ‹Il Trionfo di Camillo.› Only a few of his operas are now known, and none of them have retained popularity; but he is regarded as the most accomplished singing-master who has ever existed. His religious compositions, and especially his cantatas, are the works in which he appears to most advantage. Besides the 50 operas, he composed six oratorios, many masses and other church music, and numerous cantatas, and published six ‹Sinfonie da camara.› Consult Marchese Villarosa (in ‹Memorie dei compositore,› 1840, and Clément (in ‹Musiciens célèbres›).

PORRAS, pôr'räs, **Belisario**, Panaman statesman: b. Panama, 1860. He received his education at Bogotá and Brussels; was counsel for the French Canal Commission, and professor of international law at the Universities of San Salvador and Managua. He subsequently became judge of the Supreme Court of Colombia and served his country as consul-general in Belgium. He was Panaman delegate to the Hague Peace Conference in 1907 and in 1910–11 was the Panaman Minister at Washington, D. C. In 1912 Mr. Porras was chosen president of Panama.

PORRO, pôr'rō, **Count**, Italian general: b. Bologna, 1854. He passed through the Turin Military Academy and received his commission as sub-lieutenant of artillery at the age of 22. On reaching the rank of colonel, he was nominated to the General Staff and later acted as director of the War School and under-secretary of war in the Second Fortis cabinet (1905–06). Promoted lieutenant-general in 1911, he commanded divisions at Verona and Milan, and was offered the portfolio of War in the Salandra cabinet. In 1915 he became under-chief of Staff. Together with General Cadorna (q.v.) he was relieved of his command after the Italian defeat on the Isonzo in October 1917, and in July 1918 both officers were placed on the retired list with loss of rank and pay. General Capello suffered the same fate.

PORSENA, pôr'sĕ-nạ, or **PORSENNA, a Lars** (or «mighty lord»), king of the Etrurian city of Clusium. According to the legend narrated by Livy, he received the Tarquins on their expulsion from Rome (B.C.) 508, and after endeavoring in vain to effect their restoration by negotiation, advanced with an army to Rome. He would have entered the city with the flying Romans had not Horatius Cocles disputed the passage until the bridge was broken down. Porsena then besieged Rome, and a famine was produced in the city, when another Roman youth, Mucius Scævola, gave striking proof of his patriotism. (See SCÆVOLA). A truce was now agreed upon, and the Romans sent 10 young men, and as many girls, as hostages to the Etrurian camp. The latter escaped to Rome by swimming across the Tiber, but the consul Publicola conveyed them back again to Porsena, and was on this occasion treated with the greatest indignity by the Tarquins. Indignant at the perfidy of the Tarquins, and respecting the magnanimity of the Romans, Porsena separated himself from the former, and concluded peace with the latter without taking away their hostages. To relieve the wants of the Romans without offending their pride by a formal present, he left behind at his departure his camp with all its stores, and in remembrance of his magnanimity the senate erected to him a monument, and presented him with an ivory chair and sceptre, a golden crown and a royal robe. Thenceforward Porsena lived in undisturbed friendship with the Romans. The accounts in Dionysius (v, 33), Plutarch ('Publ.' 19) and Livy ('Hist. Natl.,' xxxiv, 13) will be found to be inconsistent with one another. Modern critics have held that Rome was completely conquered by Porsena, and that the gifts they are represented as offering from gratitude were really a tribute indicating subjection. Aruns, the son of Porsena, was defeated by a league of the Latin cities, after which the Romans are believed to have recovered their independence. According to Pliny, Porsena forbade the Romans the use of iron, except for agricultural purposes.

PORSON, Richard, English Greek scholar: b. East Ruston, Norfolk, 25 Dec. 1759; d. London, 25 Sept. 1808. He was educated at Eton and Cambridge, took the degree of M.A. in 1785, and not choosing to take holy orders, on account of conscientious scruples in regard to signing the 39 articles was obliged to relinquish the fellowship he had held from 1781. In 1792 he was appointed Greek professor, and in 1794 began the publication of the Tragedies of Euripides, with annotations, but continued his labors only through four—'Hecuba,' 'Orestes,' 'Phœnissæ' and 'Medea.' He assisted in editing the Grenville Homer (1800), and corrected the texts of the tragedies of Æschylus for an edition which issued from the Foulis Press at Glasgow. He had the reputation of being one of the best Greek scholars and critics of the age, notwithstanding which he experienced little patronage, a circumstance partly attributable to his intemperate habits. He was the author of 'Letters to Archdeacon Travis, in Answer to his Defense of the Three Heavenly Witnesses' (1790, 8vo.), in which he is allowed to have proved that the received text of 1 John v, 7, 8 is spurious. After his death were published his 'Adversaria, or Notes and Emendations of the Greek Poets'; and his 'Tracts and Miscellanies' (1815). In Porson acute discernment and solid judgment were united to intense application and a stupendous memory. Consult Watson, 'Life of Richard Porson' (1861).

PORT. See HARBORS, DOCKS AND BREAKWATERS; SHIPBUILDING; ETC.

PORT ADELAIDE, Australia. See ADELAIDE.

PORT ARTHUR, Canada, city and port of entry in Thunder Bay District, province of Ontario; on Lake Superior; the lake terminus of the Canadian Northern, also on the Canadian Pacific, and the Grand Trunk Pacific railways, about 200 miles northeast of Duluth, Minn., and about 500 miles from Manitoba. It is the principal commercial point on the northwest shore of Lake Superior. It is in a lumbering region and valuable mines of gold, silver and iron are adjacent. Large shipments of merchandise, coal, wheat, etc., are made to eastern ports. Iron is smelted here. The city is the iron centre of the north shore and district, and there are also foundries, blast furnaces, brick yards and other manufactories, railway coal and ore docks, lumber yards, refrigeration plants, etc. Port Arthur has several churches, a high school, public schools and a Separate school, public library, armory, sailors' institute, Y. M. C. A. buildings, and district courthouse. The city was first settled in 1870, became a borough in 1884, and a city in 1907. The government is vested in a mayor and council of 10 members. The city is the county-seat for judicial purposes. Pop. 18,500.

PORT ARTHUR, or **LU-SHUN-KOU,** Manchuria, a strongly fortified seaport town at the southern extremity of the Liao-tung peninsula, dominating the Lao-tie-shan channel entrance to the Gulf of Pe-chi-li from the Yellow Sea and Korea Bay. Prior to its capture by the Japanese in the War of 1894 it was a Chinese fortress and naval arsenal. Its occupation by the Japanese was prevented by the Russian, German and French coalition, but on 27 March 1898, the Chinese government leased it to Russia with adjacent territory for 25 years. Under the Russians it became the terminus of a railway line connecting with the Trans-Siberian Railway, the Chinese railway systems, and with modern Dalny, the important commercial seaport city, 14 miles to the northeast. It was fortified, its harbor and dock accommodations extended, and it was considered one of the strongest fortresses and navel stations in Chinese waters. At the outbreak of the Russo-Japanese War in 1904, it was the scene of a series of disasters inflicted on the Russian navy, not only by the torpedo boats of the enemy, but also by their own submarine mines and forts. It was surrendered to the Japanese, 3 Jan. 1905, after a remarkable siege, for the term of the Russian lease (25 years from 1898). The lease was extended in 1915, undue pressure being put on China by the Japanese. Pop. 17,000. See CHINA; DALNY; JAPAN; MANCHURIA.

PORT ARTHUR SHIP CANAL, Texas, an artificial waterway, named after the town of Port Arthur, Tex., which is situated on Sabine Lake, a body of water three miles long and 10 miles wide, which marks the boundary of Texas and Louisiana. Seven and one-half miles from Port Arthur Sabine Lake narrows into a long channel called Sabine Pass. This channel is from 26 to 40 feet deep and extends for seven miles to the south, terminating in the Gulf of Mexico. At the outer end of the pass is a bar which has been pierced by a channel formed by extending for a mile or more from shore two jetties of piled stone built by the United States government. The jetties narrow the entrance to the pass from the Gulf, and the wash of the imprisoned waters to and fro, with the ebb and flow of the tide, scoured a channel over the bar of 16 to 25 feet deep. The opening of this canal signalized the creation of a new seaport on the Gulf for the largest ocean vessels, the connection of a land-locked fresh-water harbor with the terminus of a great railway system, and the reduction by 500 miles of the distance over which the export food products of the southwest States have been hauled by east and west lines. The canal was formally opened 25 March 1899. In 1912 further operations were begun to obtain a channel of 26 feet navigable depth, and 150 feet wide, a turning basin 25 feet deep, 600 feet wide and 1,700 feet long, to cost $2,000,000, and with $190,000 annually for maintenance. The work was completed in 1915.

PORT BLAIR, the principal port of the Andaman Islands (q.v.) on South Andaman. It is connected with Calcutta, Rangoon and Madras by a mail steamer line; has a fine harbor with safe anchorage, and is an important penal settlement.

PORT BRETON, a name given to the southeast part of New Mecklenburg (formerly and again called New Ireland), in the Bismarck Archipelago off Kaiser Wilhelm Land, New Guinea, the scene in 1879 of a disastrous colonizing experiment by a company of French Legitimists. In 1883, the Marquis Du Rays, who floated the company, and his associates were condemned to various terms of imprisonment for fraud and raising money by false pretenses. German New Guinea was occupied by an Australian force 12 Sept. 1914, and came under British military occupation.

PORT CARBON, Pa., borough in Schuylkill County, on the Schuylkill River, and on the Philadelphia and Reading Railroad, about two miles northeast of Pottsville. There are iron-works within the boroughs, but the mining of coal is the chief industry. Pop. 2,678.

PORT CHESTER, N. Y., village, Westchester County, on Long Island Sound, and on the New York, New Haven and Hartford Railroad, 26 miles northeast of New York City. It was settled in the middle of the 18th century, and was at first called Saw Pit; the name was changed in 1837, and the village incorporated in 1868. It contains foundries, screw and bolt factories, carriage works, shirt factories and a woolen mill. It is also a summer resort. It contains a public hospital, also a public library and high school which has its own school library. The village is governed by a president and a board of trustees, all holding office for two years. Pop. 15,000.

PORT CLARENCE, Alaska. See CLARENCE HARBOR.

PORT CLINTON, Ohio, village, county-seat of Ottawa County, on Lake Erie at the mouth of the Portage River, and on the Lake Shore and Michigan Southern Railroads, 64 miles west of Cleveland. It has a good harbor and carries on a considerable lake trade, being the commercial centre of a region where the chief industry is grape and peach culture; lime and building stone are also obtained in the vicinity, and gypsum is mined. Fruit baskets are manufactured, and the fisheries are also of commercial importance. The village contains a public high school. Pop. 3,007.

PORT DARWIN, Australia, one of the finest harbors of the Commonwealth, on the north coast of the state of South Australia. Its entrance is two miles wide, and vessels of any tonnage can float in it with safety. Palmerston, the chief town on its shores, is the land terminus of the overland telegraph, 1,973 miles from Adelaide, and of the cable to Java. Since 1891 it is also the starting point of a railway to the gold fields of the interior, 150 miles distant.

PORT ELIZABETH, South Africa, a seaport city of Cape Colony, on the west side of Algoa Bay, about 420 miles east of Cape Town. It has many fine buildings, including a handsome town hall, custom-house, hospital, college, public library, museum, Grey Institute, and several churches, etc. It is the great centre of trade for the eastern portion of the colony as well as for a large part of the interior, being the terminus of railways that connect it with Kimberley and other important inland towns. The exports and imports together amount to over $50,000,000. There are a seawall and two iron jetties, but the shipping is much exposed to easterly winds and extensive harbor works are being built. Pop. 18,190.

PORT ESSINGTON, Australia, an inlet in the Coburg Peninsula of the northern territory of South Australia, on the Arafura Sea, forming a fine harbor. The British Government had a penal settlement on its shores from 1831 to 1850.

PORT FAMINE, Chile, a deep bay on the east coast of the Straits of Magellan, so named in 1587 by Cavendish. It was a Chilean penal colony in 1843–53.

PORT GIBSON, Battle of. After much unsuccessful effort to reach Vicksburg from the north, General Grant, late in January 1863, directed his attention to opening a canal which had been begun the year before across the peninsula on the west bank of the Mississippi. The canal proving impracticable and other plans failing, among them an expedition up the Yazoo River, Grant determined to move his army by land down the west bank of the river some 70 miles and across the Mississippi below Vicksburg, while transports for crossing should run past the Vicksburg batteries. Admiral Farragut had already run two of his vessels past the

Confederate batteries at Port Hudson and Grand Gulf, and cleared the river of the enemy's boats below Vicksburg. On the night of 16 April, Admiral D. D. Porter ran the Vicksburg batteries with a fleet of six vessels and three transports carrying stores, one of the transports being lost. Six days later, five more transports, towing 12 barges, ran the batteries safely, a sixth being sunk and half the barges disabled. Meanwhile, Grant had marched McClernand's and McPherson's corps from Milliken's Bend for New Carthage, and upon arriving at that place and finding a limited number of transports the troops were marched to Hard Times, where a number of boats were collected from the different bayous in the vicinity, and 29 April, having 10,000 troops on barges and transports, Grant was opposite Grand Gulf, prepared to land and carry the place by storm the moment the batteries beating on the river had been silenced by the navy. Admiral Porter, with seven ironclads, opened the attack at 8 A.M., and engaged at close quarters until 1.30 P.M.; but from the great elevation of the Confederate batteries, he found it impracticable to silence them with his guns, and therefore withdrew, when Grant immediately decided to land his men on the Louisiana shore and march them across the point to below Grand Gulf, the gunboats and transports to run the batteries. At dusk the gunboats engaged the batteries, and all the transports ran by, the gunboats following. Grant had heard of a good landing on the east bank of the river, and at daybreak of the 30th transports and gunboats began the ferrying of the troops across to Bruinsburg, 10 miles below Grand Gulf and 32 in a straight line below Vicksburg. At noon McClernand's corps, four divisions, 18,000 men, had been landed, and at 4 P.M. McClernand pushed out into the country, and at 1 A.M. of 1 May met the Confederates 12 miles from Bruinsburg and four from Port Gibson, and after slight skirmish the advance division, under General Carr, lay on its arms until daybreak. The Confederate force met was General Green's brigade, which had marched from Grand Gulf on the afternoon of the 30th. During the night it was joined by General Tracy's brigade from Vicksburg, and line was formed about three miles west of Port Gibson, across two roads converging on the town and uniting just outside of it. Green was across the southern road, and Tracy across the northern one, the roads running on two ridges, separated by a deep ravine, filled by a dense growth of cane and underbrush. At 5 A.M. 1 May the battle was opened by the advance of Osterhaus' division on the left, which was checked and repulsed by Tracy's brigade with much loss, and made no further progress until late in the afternoon. Carr's division, supported by Hovey's, advanced on the right and assaulted the ridge held by Green's brigade, and after a hard fight carried it, capturing two guns and over 300 prisoners, Green falling back toward Port Gibson. Gen. J. S. Bowen, commanding the Confederate forces at Grand Gulf, arrived on the field with General Baldwin's brigade, about 9 A.M., and formed line in Green's rear, Carr and Hovey continued to press Green, who was soon withdrawn and sent to assist Tracy, leaving Baldwin to oppose them. Early in the afternoon Baldwin was attacked, and a severe contest ensued, lasting nearly two hours, during which Bowen, with two regiments of Col. F. M. Cockrell's brigade, which had arrived about noon, made a very determined effort to turn McClernand's right, but the attempt was defeated, and Cockrell's men joined Baldwin. Meanwhile, Logan's division of McPherson's corps had come up and, part of it joining Osterhaus, both advanced on Tracy's and Green's brigades and slowly forced them back. McClernand's troops on the right again attacked Baldwin, and just at sunset the entire Confederate force, Baldwin covering the rear, fell back through Port Gibson and destroyed the bridge over the south fork of Bayou Pierre, two miles beyond Port Gibson. Grant entered the place next morning. The Union forces engaged were four divisions of McClernand's corps and part of Logan's division of McPherson's, in all about 23,000 men, and their losses were 131 killed, 719 wounded and 25 missing. The Confederate forces, under Bowen, were four brigades of 6,000 men and 13 guns. They lost five guns and reported 68 killed, 380 wounded and 384 missing. Consult 'Official Records' (Vol. XXIV); Greene, 'The Mississippi'; Grant, Ulysses S., 'Personal Memoirs' (Vol. II); 'Battles and Leaders of the Civil War' (New York).

E. A. CARMAN.

PORT-GLASGOW, Scotland, a seaport town of Renfrewshire, on the estuary of the Clyde, 20 miles west-northwest of Glasgow and about two and a half miles above Greenock. In 1662 the magistrates of Glasgow purchased here 13 acres of land on which they built harbors and the first drydock in Scotland. The town was intended to be the seaport of Glasgow and long did a large shipping trade; but when the Clyde was deepened so as to enable large vessels to sail up to Glasgow the trade rapidly diminished. The staple industries are shipbuilding and marine engineering, and there are manufactures of sail-cloth, ropes, etc., iron and brass foundries, bolt and rivet works. Pop. about 18,000.

PORT HAMILTON, Chosen, formerly Korea, a spacious, well-sheltered harbor, formed by three islands of the Nanhow group in the Chosen or Korean archipelago, 30 miles south of Chosen or Korea and 45 miles northeast of Quelpart Island. It was explored and named by Belcher in 1845. In 1885 it was annexed by Great Britain as a prospective coaling station, but was abandoned the following year.

PORT HOPE, Canada, town, port of entry in Durham County, in the province of Ontario, on Lake Ontario, and on the Grand Trunk Railroad, about 60 miles east by north of Toronto. There are steamer connections with the principal lake ports and there is here a good harbor. The chief industries of the place are fishing (it has a large fishing fleet), and manufacturing of leather, machinery, steam engines, iron castings, buttons, woolen goods and woodenware. There is a large trade in its own manufactures, grain and lumber. Pop. 5,092.

PORT HUDSON, Siege of. Port Hudson, a small village of East Baton Rouge Parish, La., on the east bank of the Mississippi, 135 miles above New Orleans, was occupied by the Confederates, under General Breckinridge, after their defeat at Baton Rouge, 5 Aug. 1862. The place was in a sharp bend of the river, on bold bluffs rising 75 to 90 feet above it, which for three miles along the river were strongly fortified and armed with heavy guns. In November 1862 General Banks was ordered to relieve Butler, in command at New Orleans, under instructions from Halleck requiring Banks to clear the Mississippi River, also to occupy the Red River country as a protection for Louisiana and Arkansas and as a basis for future operations against Texas. He was authorized to assume control of any military forces from the upper Mississippi which might come within his command, and to exercise superior authority as far as he might ascend the river. When these instructions were issued General McClernand had been given authority to organize an expedition on the upper Mississippi to reduce Vicksburg, and the intention was that Banks should ascend the river from New Orleans, join forces with McClernand at Vicksburg, and assume command for operations against that place. When Halleck gave the instructions he did not suppose that there were any barriers on the river that would seriously interfere with Banks' movement to Vicksburg. Banks arrived at New Orleans with about 20,000 men 14 December, relieved Butler, and was surprised to learn that the Confederates held Port Hudson, with 21 heavy guns on the bluffs and a garrison reported as numbering from 12,000 to 16,000 men. Nothing was heard from McClernand or Grant. On the 18th General Grover, with a division of 18,000 men and some artillery, was sent to occupy Baton Rouge, 25 miles south of Port Hudson, which was accomplished without opposition and was the first step in the reduction of Port Hudson.

After providing for the security of New Orleans, Banks organized his available forces into a corps of four divisions, under command of Generals Augur, Thomas W. Sherman, Emory and Grover. Exaggerated reports of the strength of the Confederates at Port Hudson forbade a direct attack upon it, and Banks endeavored to turn it on the west and reach Vicksburg by means of the Atchafalaya, the mouth of Red River and the various bayous connecting the Atchafalaya with the Mississippi, but was unsuccessful, and was turning his attention to a movement from Berwick Bay by the Atchafalaya, when news came that two of Colonel Ellet's rams, after running the batteries of Vicksburg, had been captured. Admiral Farragut, who was co-operating with Banks, now proposed to run his fleet past the batteries of Port Hudson, recapture or destroy the rams and thus control the river as far up as Vicksburg, and cut off supplies from the Red River country. Banks promptly assented and moved from Baton Rouge, with 17,000 men, to the rear of Port Hudson, on 14 March 1863, to co-operate with the fleet. That night Farragut started to run the batteries with nine vessels, carrying 116 guns. Most of the fleet, under the heavy fire brought to bear upon them, failed to get through, and put back; the *Mississippi* passed the lower batteries, then ran aground and, being under fire of three heavy batteries, was burned by her commander, the crew taking to boats and going back; the *Hartford* and *Albatross* made the passage and communicated with Porter's fleet above Vicksburg. Farragut's loss was 113 killed and wounded; one vessel had been destroyed and four disabled. The navy now had control of the mouth of Red River, and Banks, reverting to the execution of his turning movement by the Atchafalaya, recrossed the Mississippi, drove back the Confederate forces of Gen. R. Taylor, after two severe engagements at Fort Bisland and Irish Bend, in which he lost 353 men, and occupied Opelousas 20 April, from which place he marched to Alexandria, on Red River, reaching there 7 May, Taylor retiring before him to Shreveport and into Texas. He had captured a large number of prisoners and 22 guns, and Farragut had destroyed three gunboats, including those that had been taken from Ellet. Meanwhile he had received word from Farragut that Grant, 23 March, had written him that should river transportation be secured he would send 20,000 men through the Tensas, Black and Red Rivers to join in reducing Port Hudson, and at the same time a letter from Grant that he could spare him an army corps to enable him to get up the Mississippi. Upon arriving at Alexandria, Banks received a dispatch from Grant, dated at Milliken's Bend 14 April, proposing to send an army corps to Bayou Sara by the 25th, and requesting that Banks should, after the reduction of Port Hudson, send all the troops he could spare to Vicksburg. Banks assented to the proposition, saying that the troops could be shipped from New Orleans, but he was afterward informed by Grant, in a dispatch dated Rocky Springs 10 May, and received on the 12th that he had crossed the Mississippi to Grand Gulf and was then in close pursuit of the enemy and, under the circumstances, could not retrace his steps, nor send the promised troops; and as he had heard and believed that Port Hudson was almost entirely evacuated, he requested Banks to join his command at Vicksburg. Regarding the proposed co-operation Grant says: «While at Grand Gulf (3 May) I heard from Banks, who was on the Red River, and he said that he could not be at Port Hudson before the 10th of May, and then with only 15,000 men. Up to this time my intention had been to secure Grand Gulf as a base of supplies, dispatch McClernand's corps to Banks and co-operate with him in the reduction of Port Hudson. The news from Banks forced upon me a different plan of campaign from the one intended; to wait for his co-operation would have detained me at least a month. . . . I therefore determined to move independently of Banks.» Halleck was intensely provoked at the action of Grant and Banks, and wrote sharply to both of them. That it was his intention that their two armies should unite or co-operate under the chief command of Banks, and first take Port Hudson, is evident from his letters. To Grant he wrote 11 May, after he knew that he was operating in rear of Vicksburg, that his forces and those of Banks should be concentrated between Port Hudson and Vicksburg, so as to attack these places separately with the combined armies. Grant says that he received this letter on the Big Black on the 17th, and that in it he was ordered «to return to Grand Gulf and to co-operate from there with Banks against Port Hudson, and then to return with the combined forces to besiege Vicksburg.» To Banks, Halleck wrote a few days later: «I assure you that the government is exceedingly disappointed that you and Gen. Grant are not acting in co-operation. I thought to secure that object by authorizing you to assume the entire command as soon as you and Gen. Grant could unite." When these letters were received both Grant and Banks had fully committed themselves to the independent sieges of Vicksburg and Port Hudson.

The failure of Grant to co-operate with him was a keen disappointment to Banks. He could not join Grant for want of water transportation; he could not leave Port Hudson, with its large garrison in his rear, without endangering New Orleans and all the Red River region; and, therefore, he concluded to concentrate his command and move immediately against Port Hudson. On 14 May he marched from Alexandria for Bayou Sara, crossed the Mississippi on the night of the 23d, and on the night of the 24th was in rear of Port Hudson, where he was joined next day by General Augur, who had come up from Baton Rouge, defeating the Confederates at Plains' Store, on the 21st, with a loss of 86 killed and wounded, the Confederate loss being about the same. The investment was completed on the 26th with about 14,000 men, Gen. Frank Gardner, commanding at Port Hudson, having about 7,000 men. Gardner had been ordered by Gen. J. E. Johnston, 19 May, to evacuate the place forthwith and move toward Jackson, but the order came too late. Under the impression that Gardner's force was much less than it was in reality, as it was reported much reduced by troops sent to oppose Grant in rear of Vicksburg, Banks ordered a general assault to be made on the morning of the 27th. The Confederate fortifications on the land side of Port Hudson consisted of a series of strong works connected by rifle-pits, with their flanks resting on the river above and below the place. Their length was nearly four miles, and upon them were about 30 field-guns. The approach to them was difficult, being cut by ravines and for the most part covered by dense groves of magnolia and other trees. The investing line was seven miles in length. The brigade of General Weitzel and the divisions of Generals Dwight and Grover were on the right, Augur's division in the centre, and a part of Thomas W. Sherman's on the left. The assault, which was ordered simultaneously along the entire line, was preceded by a heavy fire of artillery, and at 10 A.M. Weitzel, on the right, commanding his own troops and Dwight's, moved forward fighting severely until late in the afternoon, and gaining some ground; Grover, on his left, gained and held commanding positions within 200 yards of the Confederate works. In the centre and on the left Augur and Sherman did not advance until 2 P.M., when they made a most determined effort, under a severe fire of canister and musketry, and reached the ditch of the works, but could not cross the parapet, and were withdrawn at night. The only advantages gained were the advanced positions held by Weitzel and Grover. The Union loss in the assault, in which 13,000 men participated, was 293 killed, 1,545 wounded, and 157 missing. The Confederate loss was about 235 killed and wounded. Regular siege operations began next day, siege-guns were planted, and constant skirmishing was kept up, during which, with some checks, the Union lines gained some ground, which was immediately intrenched. On 10 June a heavy artillery-fire was kept up and at 3 o'clock on the morning of the 11th an attempt was made to get within assaulting distance of the works. A portion of the troops worked their way through the abatis, but were repulsed with loss and some captured. Meanwhile Banks had reorganized his command. Sherman, who had been severely wounded on the 27th of May, was succeeded by General Dwight, and General Grover was assigned to the command of the right wing, consisting of his own and Paine's division and Weitzel's brigade. The line was formed in this order from right to left: Weitzel, Grover, Paine, Augur and Dwight. On 14 June, the line of investment being well advanced, Banks made a second general assault at daylight from his left and right. Dwight, on the left, endeavored to gain entrance to the works by passing a ravine, while the main attack was made on the right by Grover and Weitzel. The assault ended in a bloody repulse, the Union loss being 203 killed, 1,401 wounded, and 188 missing. The Confederates had 22 killed and 25 wounded. The only advantage gained was a few yards nearer approach to the works on the right, and on the left an eminence commanding a strong part of them, and which later enabled Banks to get possession of the bluff within 10 yards of the enemy's lines. Siege-operations were continued and on the right saps were run to the very line of the Confederate works. On the left a mine had been prepared for a charge of 30 barrels of powder, and a storming column of 1,000 volunteers organized, when, during the night of 6 July, news was received that Vicksburg had surrendered. Gardner soon heard the news, and asked Banks to give him an official assurance of its truth, adding that if true, he requested a cessation of hostilities with a view to consider terms for a surrender. Banks furnished him a copy of Grant's despatch, terms were agreed upon, and on the 8th Gardner surrendered 6,340 officers and men, 51 guns, about 7,500 muskets, large quantities of ammunition, and two river steamers. In an address commending the gallantry of his men, Gardner stated that his surrender was not on account of the fall of Vicksburg, nor for want of ammunition or provisions, but was due to the exhaustion of his men, who had been without rest for more than six weeks, and who could not resist another attack. In all the operations against Port Hudson the fleet under Farragut had co-operated and assisted. The Union loss during the siege was 708 killed, 3,336 wounded and 319 missing, an aggregate of 4,363. Incomplete Confederate returns show a loss of 176 killed and 447 wounded. Consult 'Official Records' (Vol. XXIV, XXVI); Greene, 'The Mississippi'; Grant, 'Personal Memoirs,' (Vol. I); The Century, 'Battles and Leaders of the Civil War' (Vol. III).

E. A. CARMAN.

PORT HURON, Mich., city, port of entry, county-seat of Saint Clair County, at the mouth of Black River, the head of Saint Clair River, and at the foot of Lake Huron, on the Grand Trunk Western, and Grand Trunk, The Detroit, Bay City and Western, and the Pere Marquette railroads, about 58 miles northeast of Detroit. Port Huron is the most easterly point in the State. It has steamer and electric railway connection with Detroit, and steamer connection with all the principal ports of the Great Lakes. A railroad tunnel under the Saint

Clair River extends from Port Huron to Sarnia, Ontario. This tunnel is over a mile long directly across, but including the approaches it is nearly two miles long. It cost about $2,700,000, and was opened in 1891. The climate, scenery, mineral springs and opportunities for fishing have combined to make Port Huron a favorite summer resort. It has considerable manufacturing interests; the chief industrial establishments are shipbuilding works, knitting mills, overall factory, paper mill, wire fence factory, two large foundries, engine and thresher works, Grand Trunk car and locomotive shops, fibre works. Port Huron has an extensive commerce, especially with Canada. The exports in a recent year were valued at $37,000,000 and the imports at $8,100,000. The principal public buildings are the custom-house and post office, courthouse, auditorium, hospital and home, the Carnegie Library, and two Maccabee Temples. The educational institutions are several public schools, including two high schools. The city has just voted to build another $100,000 high school. The commission form of government is in operation. In 1686 the French under Duluth built a fort here but it was maintained for two years only. The United States built Fort Gratiot on the site in 1814 and maintained it until 1879. The village of Port Huron was organized in 1849 and became a city under a charter of 1857. Pop. 18,863.

PORT ISABELA, ē-sä-bä'lä, Philippines, harbor in channel between Malamaui Island and the northwest coast of the island of Basilan. It has a naval hospital, a small arsenal and equipment for the repair of small vessels. The town Isabela de Basilan is the capital of the island. Pop. about 1,331.

PORT JACKSON, Australia, the beautiful and extensive inlet on the east coast in New South Wales, forming the well-sheltered harbor on the south shore of which Sydney stands. See SYDNEY.

PORT JACKSON SHARK. See CESTRACION.

PORT JERVIS, N. Y., city in Orange County, on the Delaware and Neversink rivers, where the States of New York, New Jersey and Pennsylvania meet, and on the New York, Ontario and Western railroads, 88 miles northwest of New York City. It was settled in the last of the 18th century, and laid out as a village in 1826. The first permanent settlers were descendants of the French Huguenots and the Dutch, who settled the town of Deerpark. It is a popular summer resort on account of the many waterfalls nearby and the beauty of the scenery in general. Its water-power and transportation facilities have contributed toward making the village of commercial and industrial importance. The chief manufacturing establishments are railroad shops, glove factories, silk mills, silver plating works, necktie factory, overall factory, saw factory, shirt factory, and other industrial works are a flour and planing mills, sash factory, printing works and a number of smaller establishments which supply local needs. The principal public buildings are the Carnegie Free Library, cost $30,000; Port Jervis chamber of commerce, two hospitals, the Y. M. C. A. building, Saint Mary's Orphan Asylum, and churches of several denominations, Elks Home, Federal building, and a new $35,000 parochial school. The educational institutions are public and parish schools, a new high school, two private schools, a conservatory of music and the public library. In recent years the city has paved several streets with brick, erected an electric-light plant, and installed a new electric-lighting system. The Erie Railroad whose interests are closely identified with those of the city has erected a monument to the founders of the city. The demand for extra housing facilities has resulted in increasing activity in building operations. Pop. 9,564.

PORT LOUIS, loo'ĭs or loo'ē, Mauritius, capital of the British colony of Mauritius; on the northwest coast, on a cove formed by a series of basaltic hills, portions of which are covered with forest. The streets are narrow, laid out at right angles with basaltic curbstones, and shaded by large acacias. A mountain stream traverses the town. The town and harbor are protected by Forts Adelaide and George. The principal buildings and institutions are the Roman Catholic and Protestant cathedrals, the barracks, theatre, hospital, botanical gardens, an observatory and library. It is the chief commerical port of the island and a coaling station for the British navy. Great damage and loss of life were caused by a hurricane in April 1892. Pop. (with suburbs) 50,060. Consult Flemyng, 'Mauritius, or the Isle of France'; Decotter, 'Géographie de Maurice et de ses Dépendances.'

PORT MAHON. See MAHON.

PORT-MOODY, Canada, a harbor at the head of Burrard Inlet, British Columbia, a little to the north of New Westminster. It was at one time intended for the terminus of the Canadian Pacific Railroad, but was abandoned for Vancouver, at the entrance to Burrard Inlet.

PORT NATAL, ną-täl', South Africa. See DURBAN.

PORT ORCHARD (formerly Sidney), Wash., a United States naval station in Kitsap County, on Port Orchard Bay, an inlet of Puget Sound, about 20 miles west of Seattle. The station was established in 1891, when the government purchased here 200 acres of land, built a dry dock 600 feet long and 75 feet wide, and capable of holding vessels with a 30-foot draft. The original cost of the improvements, not including purchase price of land, was $700,000.

PORT DE PAIX, pōr dė-pä, Haiti, town on the Tortuga Channel, and on the right bank of Trois Rivières, about 95 miles north of Port-au-Prince. The place was visited by Columbus in 1492, and by him was named Valparaiso. It is in an agricultural region, in which coffee is the principal production. There is a large trade in coffee and fruit. Pop. estimated at about 10,000.

PORT PHILLIP, Australia. See MELBOURNE.

PORT-AU-PRINCE, pōrt'ō-prins' (Fr. pōr-tō-präṅs), or **PORT RÉPUBLICAIN,** pōr-rā-püb-lē-käṅ, Haiti, city, capital of the Republic of Haiti; on the Bay of Haiti. It is the principal seaport, and although it has an excellent harbor, the low marsh land surrounding it renders it undesirable as a place of residence.

The buildings are mostly of wood. There is considerable trade in fruits, the cocoanuts, and cabinet woods. It has municipal buildings, a mint, college and lyceum. The city was founded in 1745, and was completely destroyed by an earthquake in 1770. It has also been ravaged by fires in 1791, 1843 and 1867. In recent local disturbances it was occupied by American marines. Pop. about 100,000.

PORT REPUBLIC, Battle of. Gen. «Stonewall» Jackson defeated General Banks at Winchester, 25 May 1862, drove him across the Potomac, and then retreated up the Shenandoah Valley, slipping between the converging forces of General Frémont and McDowell near Strasburg on the 31st. Frémont pursued by the Valley road, and General Shields, commanding a division of McDowell's corps, endeavored to fall upon his flank and intercept him by moving up the Luray Valley. On the evening of 1 June Shields moved out of Front Royal, Col. S. S. Carroll leading, with some cavalry, infantry and four guns, to destroy the bridges over which Jackson might retreat to Stanardsville. But Jackson himself had destroyed the bridges by which his flank could be reached, and Shields halted his advance brigades at Conrad's Store and Columbia Bridge. On hearing that Jackson had passed through Harrisonburg in the direction of Port Republic, and that Frémont had reached Harrisonburg in close pursuit, Shields ordered Carroll's and Tyler's brigades forward to head off Jackson while Frémont pressed his rear. The orders to the two brigade commanders were to guard the river at Port Republic and cut the railroad at Waynesboro. Shields, with two brigades, remained at Luray to watch Longstreet, who was incorrectly reported moving into Luray Valley, by the gaps of the Blue Ridge, with 10,000 men. Carroll, with less than 1,000 infantry, 150 cavalry and Clark's regular battery of six guns, marched from Conrad's Store on the afternoon of 7 June, and halted in the night six miles from Port Republic, where his scouts brought information that Jackson's train was packed near the place, guarded by about 300 cavalry. Carroll, with his 150 cavalry and four guns, leaving his infantry to follow, started very early in the morning of the 8th, drove in the Confederate outposts and put two guns in position commanding both ends of the bridge over the South Fork of the Shenandoah River, and ordered the cavalry to charge and seize the bridge. The charge was made and the bridge seized, Jackson, whose headquarters were in the village, narrowly escaping across it, while some of his staff were captured. Carroll, with two guns, followed his cavalry to the bridge; some of the cavalry entered the village and attacked the wagon-train. By some misunderstanding the bridge was not burned as Shields says it was intended to be, and Jackson, the moment he crossed it, ordered batteries in position which opened on Carroll, and a regiment of infantry rushed down and over the bridge, driving him away and capturing one of his guns. Carroll retreated two miles down the river, with a loss of 39 men killed and wounded, the greater part of which was in the 7th Indiana, which came under artillery fire as it was moving to the support of the cavalry. Jackson moved Taliaferro's brigade into the village to hold the fords of South River, a branch of the South Fork of the Shenandoah, and placed Winder's brigade on the north side of the latter to observe Carroll and by artillery check any renewed advance. While all this was transpiring the battle of Cross Keys (q.v.) was going on, and Jackson, hearing the sounds of the engagement, rode to the field. At 2 P.M. Tyler came up with his brigade and joined Carroll, and as senior officer assumed command. He had about 3,000 men and 16 guns, and took position with his right on the South Fork of the Shenandoah and his left on commanding ground, on which was disposed the greater part of the artillery. Jackson, who had repulsed Frémont at Cross Keys, on the 8th, returned to Port Republic during the night, leaving Ewell, with a small force, to confront Frémont, and early in the morning of the 9th led Winder's brigade across the bridge and attacked Tyler's right, with the intention of turning it, but was repulsed. Winder, rallying a part of his brigade and reinforced by a regiment of Taylor's Louisiana brigade, made another effort and was again repulsed, with the loss of one of his guns and many men. Meanwhile some of Ewell's troops from Cross Keys came on the field and Taylor's Louisiana brigade was ordered to turn Tyler's left and take his guns. Taylor moved under cover of dense woods to a position on the flank of Clark's battery of six guns, from which support had been withdrawn, and charged it; but Clark, turning his guns upon him, repulsed him with shell and canister. The attempt was renewed on that flank, but Tyler's infantry was now supporting the guns, and the contest around and among them, at close quarters, was severe, but the Confederates were held in check. The fight had now raged more than four hours, Jackson had withdrawn all his forces from Frémont's front, crossed the bridge and destroyed it, and concentrated against Tyler, who saw that the time had come to retreat, and gave the order, Carroll having charge of the movement. The artillery and infantry on the right were withdrawn in good order, but on the left so many horses had been killed or disabled that but one gun was saved, the Confederates advancing and seizing five, as Tyler's men began the retreat, and turning them upon the retiring troops, throwing the rear of the column into some disorder. The Confederate infantry followed four miles, the cavalry until Shields came up with the rest of his division, when pursuit was checked and Shields continued the retreat to Conrad's Store. After the retreat Frémont appeared on the opposite side of the river, which he could not cross, and opened upon Jackson with his artillery. During the morning Jackson had put his trains in motion for Brown's Gap of the Blue Ridge, and after the battle he followed them. The Union loss was 67 killed, 393 wounded, and 558 missing; the Confederate loss, 816 killed, wounded and missing. Consult 'Official Records' (Vol. XII); Allan, 'Jackson's Valley Campaign'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. II).

E. A. CARMAN.

PORT-ROYAL, pōrt-roi'al, a Cistercian convent in France, which played an important part in the Jansenist controversy (see JANSENISM). It was founded in 1204 by Mahaut de

Garlande, wife of Matthieu de Montmorency, was situated near Chevreuse in the Yvette Valley, at what is now called Les Hameaux, about 15 miles southwest of Paris, and was under the rule of Saint Bernard. The original name of the site was Porrais or Porrois; this was transformed first into Port-du-roi, then into Port-Royal. Port-Royal had declined from its original severity, when in 1609 the abbess Jacqueline-Marie-Angelique-Arnauld undertook its reform. The number of the nuns increased under her rule, and in 1625 amounted to 80. The building had become insufficient, and the situation was unhealthy. The mother of the abbess therefore presented to the nuns the house of Cluny, situated at the end of the Faubourg Saint Jacques in Paris. The old site was subsequently improved by drainage, and a new house built on higher ground. The two sections of the convent were now distinguished as Port-Royal des Champs and Port-Royal de Paris. About 1636 a group of eminent literary men of religious tendencies, mostly the relatives of the abbess, took up their residence at a house called Les Granges, near Port-Royal des Champs, where they devoted themselves to devotional exercises, manual and literary work, the education of youth, and the compilation of educational works. These were regarded as forming a joint community with the nuns of Port-Royal, among whom most of them had relatives, and who in most matters followed their counsels. Among them were Antoine Arnauld, Arnauld D'Andilly, le Maistre de Sacy and his two brothers, the first two being brothers, the last three nephews of the abbess; Nicole, and subsequently Pascal, whose sister Jacqueline was a nun of Port-Royal. These men founded here an educational institution, which flourished till 1660, and became a rival to the institutions of the Jesuits, and as they adopted the views of Jansenius, subsequently condemned by the pope, a quarrel ensued, in which the Port-Royalist nuns, siding with their male friends, became subject to the opposition of the Jesuits, which culminated in the ruin of their institution. Port-Royal de Paris had, in the meantime, been growing rapidly in wealth and influence. It was protected by many persons of high rank at the court, some of whom made it their last retreat and bequeathed their fortunes to it. It was under the direction of the Abbé de Saint Cyran (Duvergier de Hauranne), whose virulent Jansenism led, during the last days of Richelieu, to his imprisonment in Fort Saint Vincennes. During the wars of the Fronde the house in the country exercised a liberal hospitality. The history of the struggle in which the two convents of Port-Royal successively succumbed to their foes is too long to be dealt with here. It has been related in detail by Racine, the most distinguished pupil of the Port-Royalist seminary, in his ‹Histoire de Port-Royal.› The most remarkable incident in it was the miracle alleged to have been wrought upon the person of the niece of Pascal, and firmly believed in by two such men as Pascal and Racine. The object of this miracle, wrought by means of a thorn from the crown of our Saviour, was to demonstrate the innocence of the nuns of Port-Royal, accused by their opponents of contempt of the holy sacrament. But this vindication was unavailing. In 1664 Port-Royal de Paris was occupied by the police. The nuns, save few who acceded to the terms of the court, and henceforth became declared enemies of their former associates, were imprisoned for some months and then sent to Port-Royal des Champs, which was put under military surveillance till 1669. In 1669 the two houses were permanently separated by royal authority. Port-Royal des Champs retained 80 nuns and two-thirds of the joint property, Port-Royal de Paris 10 nuns and one-third of the joint property, and was placed perpetually under the nomination of the king. The nuns of Port-Royal des Champs still persisted in refusing to sign the papal edict condemning the doctrines of Jansenius, and on 29 Oct. 1709 the convent was finally suppressed by order of Cardinal Noailles, in execution of a bull of Pope Clement XI. The nuns were dispersed in different convents, and their property given to Port-Royal de Paris. This convent continued in existence till the Revolution, when its house was converted into a prison, and subsequently (1814) became the Maternity Hospital. In 1825 some Jansenist descendants bought the site at Les Hameaux, on which they have erected a museum rich in Jansenist relics. The grounds have been restored as far as possible to their original appearances. (See ARNAULD; JANSENISM; PASCAL, BLAISE). PORT ROYAL, Jamaica, the principal naval station owned by the British in the Caribbean Sea. Port Royal, the city, which was destroyed by an earthquake in 1693, was near the site of the present naval station. The present Port Royal is at the entrance to Kingston Harbor. It is strongly fortified and has a barracks, arsenal and a hospital.

PORT ROYAL, S. C., village in Beaufort County, at the southern end of Port Royal Island, on the Port Royal and Augusta Railroad, 53 miles southwest of Charleston. Near here, a French Huguenot colony was established in 1664 by Ribault, which was taken by the Spaniards in 1665 and all the garrison killed. On 3 Feb. 1779, during the southern campaign of the Revolution, Major Gardiner, with 200 British soldiers, attempted to seize Port Royal Island, but was attacked and defeated by General Moultrie with about the same number of men, the British loss being serious, that of the Americans slight. In the Civil War the harbor of Port Royal was defended by two forts, Fort Walker and Fort Beauregard, built by the Confederates and garrisoned by a Confederate force under Drayton and Ripley. On 7 Nov. 1861 an attack was made on these fortifications by the Federals with a force of two frigates, three sloops and seven gunboats, commanded by S. F. Dupont (q.v.). This fleet opened fire on both forts at once, on entering the harbor, but later concentrated the attack on Fort Walker till that fort surrendered; Fort Beauregard was surrendered shortly afterward. Port Royal has an excellent harbor, and a large drydock, and has been the rendezvous of the North Atlantic Squadron. Pop. about 700. Consult Parkman, 'Pioneers of France in the New World' for an account of the Huguenot colony.

PORT ROYAL BAY, Battle of. As early as June 1861 the United States authorities, in order more effectually to maintain the blockade and to secure a military and naval base of operations on the southern Atlantic Coast, determined to seize a good port south of Cape Hatteras; and in August a naval and land expedition was ordered for the purpose. Capt. S. F. Dupont was ordered to organize the naval expedition, and Gen. Thomas W. Sherman to organize a force of 12,000 men to accompany it. It was agreed between Dupont and Sherman to seize Port Royal Bay, one of the finest harbors on the coast, 56 miles south of Charleston and 25 north of Savannah. The destination was kept a profound secret. The fleet of 16 war vessels and nearly 40 transports, carrying Sherman's 12,000 men with supplies, sailed from Hampton Roads on the morning of 29 October, and on the night of 1 November was struck by a furious storm off Hatteras and scattered. Four vessels and a few lives were lost, one war vessel was disabled and, with two transports, returned to Hampton Roads; but by the 6th the fleet had assembled off the entrance to Port Royal Bay, the gunboats, preceding, having driven into the harbor three Confederate vessels that had run out and opened fire upon them, and coming under a long cross-fire from two works commanding the entrance to the bay. It had been the intention to silence and take these works on the afternoon of the 6th but necessary arrangements were not perfected until too late in the day. The bay was defended by two earthworks and some shore batteries, one earthwork on each side of the entrance, Fort Walker, on Hilton Head, the south side, and Fort Beauregard, on Bay Point, Saint Phillips Island, on the north. These were strong and well-constructed works, mounting 42 heavy guns, 22 of which were in Fort Walker, and garrisoned by nearly 3,000 men, under Gen. T. F. Drayton. The distance between the two works was two and one-half miles. In addition to the landworks, there were three small Confederate gunboats of two guns each in the bay, under command of Com. Josiah Tatnall. The *Wabash*, the flagship of the fleet, carrying 46 guns, was to lead in the attack, followed by nine other vessels, a ship's length apart, and a flanking column of five gunboats was to move on the right. The fleet was to pass up the roads on the Bay Point side, delivering broadsides on Fort Walker until each vessel had reached a point two miles above the fort, when they were to turn and come down and again deliver their broadsides at Fort Walker and enfilade its two water-faces. Having completed the circuit, the line was to repeat the movement until the forts surrendered. At the same time the five flanking gunboats were to pass and attack Fort Beauregard and, on reaching the turning-point two miles above it, remain there and hold Tatnall's fleet in check, with special orders to see that it did not make a dash upon the transports. At 9 A.M. 7 November the fleet crossed the bar and advanced in a long well-ordered column to the attack, while the transports lay at anchor outside ready to land troops. Captain Dupont led the *Wabash* up the middle of the bay, receiving the first fire from both forts at 9.26 A.M., and replying to both, until two miles beyond them; then he turned to the left in a wide circle and led back past Fort Walker at 800 yards distance, opening upon it broadside after broadside. The rest of the column followed, each vessel in succession opening its guns, as it came within range and maintaining a rapid fire as it slowly drew past. The gun-fire from the fleet was a terrific continuous roar and was replied to by a well-maintained fire, notwithstanding the fact that hundreds of shells were dropping into the fort and almost burying its defenders, under the dirt thrown up. At the same time the flanking column of five gunboats steamed up the bay, nearer to Bay Point, and poured broadsides into Fort Beauregard and then, steering to the other side, advanced against Tatnall's fleet, driving it into Scull Creek and, taking position near the shore and flanking Fort Walker, opened upon it a destructive fire, to which it could not respond, as the one gun on that flank of the fort had been shattered by a round shot. After the main column had passed down the bay about two miles, it turned, at 11 A.M., and again passed in front of Fort Walker, at 300 yards closer range than before, and with a more terrific fire, part of which was against Fort Beauregard. As the manœuvre was repeated for the third time it was discovered that the Confederates were abandoning Fort Walker; its guns were silenced; a few shots were fired, to which there was no response; a small party was sent ashore, the Confederate flag hauled down, and the Union flag run up at 2.20 P.M. Before the close of the action the *Pocahontas*, Commander Percival Drayton, which had been delayed by injuries received in the storm, entered the bay and opened fire on the fort. Commander Drayton was a brother of the commanding officer of the Confederate forces. The Confederates had left in haste, leaving tents standing, and escaped across Scull Creek, being assisted by the boats of Tatnall's fleet. By nightfall the transports had come into the bay and landed Gen. H. G. Wright's brigade at Hilton Head. Fort Beauregard was abandoned about 5 P.M., after its commanding officer had spiked the guns and destroyed the greater part of the powder. It was occupied next morning by General Stevens' brigade. The battle was of great value to the Federal government in its moral and political effect, in addition to the fact that it gave the Union army one of the finest harbors on the Atlantic Coast, as a base for future operations for both the army and navy. The Union loss was 8 killed and 23 wounded; the Confederate loss, 11 killed, 48 wounded and 7 missing. Consult 'War Records' (Vol. VI); 'Naval War Records' (Vol. XII); Ammen, 'The Atlantic Coast'; Maclay, 'History of the United States Navy' (Vol. II); 'Battles and Leaders of the Civil War' (Vol. I).

PORT ROYAL-DES-CHAMPS, pōr rwä-yäl dā shäṅ. See PORT ROYAL.

PORT ROYAL FERRY, Engagement at. After the naval battle of Port Royal Bay (q.v.), 7 Nov. 1861, the navy explored the various sounds and creeks in the vicinity, capturing some abandoned guns. While the navy was thus employed the army had completed a very large and strongly intrenched camp on Hilton Head, surrounding Fort Walker, and on 11 December occupied Beaufort, some Confederate cavalry falling back across Coosaw River, taking to the farther side the ferry-boat and ropes and all other boats and covering the crossing by a blockhouse, which was soon destroyed by two adventurous soldiers who swam the river. By the end of December the Confederates had erected a strong field-work on the mainland opposite and commanding Port Royal Ferry, on the Coosaw, and they repulsed the efforts of the gunboats to dislodge them. The position was held by the 14th South Carolina regiment, four companies of the 12th South Carolina, about 45 cavalry and a section of Leake's battery, all under command of Col. James Jones. Obstructions had been placed in the Coosaw above and below the ferry to prevent the ascent of the gunboats, and a battery put in position opposite Seabrook's Point. A combined land and naval expedition was set on foot to take the position and clear the river. Gen. I. I. Stevens' brigade, reinforced by two regiments, in all 3,000 men, was to cross the Coosaw several miles below Port Royal Ferry, advance up the left bank of the river and take the work in rear, while two gunboats, an armed tug and four boats armed with howitzers, all under Commander C. R. P. Rodgers, were to enter the Coosaw by Beaufort River. A naval co-operating force was to move up Broad River and thence to the Coosaw to attack the battery opposite Seabrook's Point. On the night of 30 December a large number of flatboats were collected and sent up Beaufort River, and at 1 A.M. 1 Jan. 1862 the embarkation began and, passing up the Coosaw, the troops were landed during the morning. At 1.30 P.M. they moved for Port Royal Ferry, marching parallel with and close to the river, the gunboats and launches shelling the woods in advance of the skirmish-line. A mile had been marched when a concealed battery opened its fire on Stevens' column, but Stevens soon drove it and its infantry support from the field and, closely following, reached the fort which had been abandoned, upon the appearance of the gunboats, the enemy leaving one gun. Meanwhile the gunboats moving by way of Broad River had cleared the Coosaw, beyond the ferry. During the night the ferry was completely restored, the captured fort leveled to the ground, and next morning the troops crossed the ferry and marched back to Beaufort with the captured gun and a few prisoners. The result of the action was an abandonment of any future attempt to plant batteries on the Coosaw or the adjacent network of waters; and, being almost the first Union success since the defeat at Bull Run, it was considered of so much importance that the thanks of the government were given in general orders to General Stevens and his command for their victory at the battle of Port Royal Ferry. The Union loss was 3 killed and 14 wounded; the Confederate loss, 8 killed and 23 wounded. Consult 'Official Records' (Vol. VI); Ammen, 'The Atlantic Coast'; Stevens, 'Life of Gen. I. I. Stevens' (Vol. II); 'Battles and Leaders of the Civil War.'

PORT SAÏD, sä-ēd', Egypt, seaport at the Mediterranean end of the Suez Canal and capital city of the Egyptian department of the Isthmus. It lies in the easternmost part of an island between the Mediterranean and Lake Menzaleh, about 110 miles north-northeast of Cairo, in lat. 31° 16' N. and long. 32° 19' E. Its whole being is dependent on the canal and it was not founded until the canal was partly built. Hence its architecture is European, and many of the houses are wooden with sloped roofs. North of the city on the coast of the canal and of the Mediterranean is an electric light about 173 feet high and visible 20 miles out. Two great concrete moles 5,300 and 7,400 feet long reach out into the sea. The trade of the city is almost entirely transit. The city was named for Said Pasha, viceroy of Egypt 1854–63. A fountain and statue of Queen Victoria was built in 1898, and a colossal statue of De Lesseps, by Frémiet, has stood since 1900 at the entrance of the canal. Attempts by the Turks in the World War to capture the city and wreck the Suez Canal proved signal failures. The population of Port Saïd and Ismailia, including more than 10,000 Europeans, mostly French and Greek, numbered about 90,000 in 1917.

PORT OF SPAIN, Trinidad, city, capital of Trinidad (q.v.), one of the West Indies group, belonging to Great Britain. The city has a large safe harbor, steamer connections with all the principal ports of the Caribbean Sea and Gulf of Mexico, and with many South American ports; and railroad connection with San Fernandino, to the south, and with several other places on the island. The most of the products of the Orinoco region are shipped from Port of Spain. The city is well built and has many fine residences. It has the government buildings, botanical gardens and the Immaculate Conception College. It is a Roman Catholic archiepiscopal see. Pop. 60,000.

PORT TAMPA CITY, Fla., town, Hillsboro County, on Tampa Bay, and on the Atlantic Coast Line Railroad, eight miles south of Tampa. It was founded in 1889 and incorporated as a town in 1891. In the Spanish-American War, the United States troops were mobilized here for embarkation to Cuba. It is the port of Tampa (q.v.), has a large and excellent harbor and is connected with the West Indies, Mobile and other ports by steamer. It is in a fruit-growing and agricultural region for the products of which it is the shipping point. Pop. 1,343.

PORT TONNAGE. Some interesting facts are shown as to the relative rank in tonnage movement of the principal ports of the world, in a table prepared by the Bureau of Statistics of the Department of Commerce and Labor at Washington. The table is as follows:

PORT	Year	Entered tons	Cleared tons
New York	1910	13,042,818	12,541,903
Antwerp	1909	11,907,689	11,894,492
London	1909	11,605,698	8,622,316
Hongkong	1909	11,150,560	11,194,098
Hamburg	1909	11,061,041	11,247,191
Rotterdam	1909	9,217,493	8,902,570
Shanghai	1909	9,092,427	9,400,382
Liverpool	1909	7,747,904	6,593,094
Singapore	1908	6,994,980	6,948,225
Colombo	1909	6,593,591	6,587,028
Aden	1909	5,973,065	3,055,376
Cardiff	1909	5,771,476	8,888,756

Hongkong would show a much higher figure, but for the fact that Chinese junks engaged in the foreign trade are excluded from the estimate, the tonnage of these vessels entered in 1901 having been 1,126,931, and of those which cleared, 1,130,279. Singapore excludes native craft and vessels under 50 tons, excepting vessels engaged in trade between the Straits Settlements.

In this connection it is interesting to note that during the fiscal year 1 July 1917–30 June 1918, the net tonnage of vessels that entered the various ports of continental United States aggregated 45,455,937 tons, of which 19,283,530 tons represented American vessels; and the net tonnage of vessels that cleared the ports aggregated 46,069,482, of which 19,261,733 were American. It should also be noted that during this period the imports of merchandize into the United States aggregated in value $2,946,-059,403, and the similar exports from the United States, $5,928,285,641 — the largest totals on record. And this when the world was aflame from the Teutonic torch.

In the previous fiscal year the tonnage entrances and clearances at United States customs districts aggregated 50,472,176 and 52,077,070 tons, respectively, as follows: Atlantic Coast, 24,010,685 and 25,047,868; Gulf Coast, 6,991,-335 and 7,570,242; Mexican border, 65,670 and 64,396; Pacific Coast, 5,453,278 and 5,411,299; and Northern border, 13,951,208 and 13,983,265.

PORT TOWNSEND, Wash., city, county-seat of Jefferson County, on Port Townsend Bay, at the entrance to Puget Sound (q.v.), and on the Northern Pacific and the Port Townsend Southern railroads, about 70 miles north of Olympia. It has steamer connection with San Francisco, Alaska and many of the principal ports on the eastern coast of Asia. The harbor ranks with the largest in the world. The place was settled in 1851 and in 1860 was incorporated as a city. Port Townsend is on the west side of the bay, five miles by land and two and one-half miles by water from the city, and other government fortifications are located on Admiralty Head, Point Hudson, Point Partridge and Marrowstone Point. The government has established a marine hospital and a quarantine station. The city is included in the Puget Sound customs district, through which about $140,000,000 in trade passes annually.

The city is in an agricultural and lumbering region. In the vicinity are deposits of oil and valuable minerals. The chief industrial establishments are lumber and planing mills, a shipyard, machine shops, steam-boiler works, bottling works, herring pickling and curing works, salmon and sardine canneries, grain elevators and flour mills. The chief exports are grain, lumber, fish, oil, livestock, farm and dairy products and pig iron. The pig iron is from the Irondale furnaces. The principal public buildings are the government custom house, city hall, county courthouse, United States Marine Hospital, the quarantine station, a sanatorium and Saint John's Hospital. The educational institutions are a high school, public elementary schools, private business schools and a public library. The scenery around Port Townsend is beautiful, surrounded as it is by water and mountains. The government is administered under a charter of 1890, which provides for a mayor, who holds office one year, and a council. The administrative officials are appointed by the mayor or elected by the council. Pop. 4,181.

PORT WASHINGTON, Wis., city and county-seat of Ozaukee County, on Lake Michigan and on the Chicago and Northwestern Railroad, 25 miles north of Milwaukee. Its industries include the manufacture of woodenware, foundry products, internal-combustion engines, etc. Pop. 3,792.

PORT WINES. The name of port wines, or Oporto wines, is given, in commerce, to the produce of the vineyards of Portugal, the district in which they are produced being a rugged and mountainous tract that begins about 60 miles above Oporto, and extends for 30 or 40 miles with an extreme breadth of about 12 miles. Port is naturally a very rich and delicate wine, varying in color from a pale rose to a deep red. It owes its special character partly to the soil of the district where it is grown, partly to the climate, which is cold in winter and very hot in summer. The harvest lasts from the beginning of September to the middle of October. The wines for export are very much mixed and are strongly fortified with brandy, partly to make them sooner ready for export and partly to suit the taste of the foreign markets. The mixing of the various wines considerably reduces the variety of qualities of port exported, compared with those which are naturally produced. The English market has always been the principal market for port wine. English connoisseurs have tended more than anything else to spread its fame in other countries. The taste for this wine was introduced into England in the 17th century and English establishments were formed in Oporto to direct the purchase and shipping of the wines. These companies eventually united into a sort of corporation called the English Factory, which became completely master of the market. In the following century (1756) the Marquis of Pombal organized an association of producers to oppose this monopoly of buyers and the company then established imposed restrictions on the trade which were not finally abolished till 1853, a new company having latterly taken the place of the old. In recent times the vines have suffered rather severely both from the oidium and from the more serious plague of the phylloxera. See WINE and WINE MAKING.

PORTAELS, Jean François, zhŏṅ fräṅ-swä pōr-täls, Belgian painter: b. Vilvorde, near Brussels, 1 May 1818; d. Brussels, 8 Feb. 1895. He owed his early art training to Navez of Brussels and afterward proceeding to Paris became the pupil of Paul Delaroche, gaining the «Grand Prix» in 1842. After traveling in Syria, Egypt, Palestine, Greece and Turkey, he was appointed director of the academy in Ghent, an office he retained for three years. He then resumed his travels which included the whole of Europe in their range. He ended his days as director of the Brussels Academy. His works are faulty in composition and deficient in living characterization, but in spite of occasional insipidity they are pleasing and full of expression. Among them the most important are ‹The Journey of the Magi›; ‹Funeral Procession in the Desert of Suez›; ‹Jeptha's Daughter›; ‹The Daughter of Zion›; ‹The Flight into Egypt›; ‹Leah and Rachel›; ‹The Young Witch›; ‹The Simoon.›

PORTAGE, N. Y., town in Livingston County, on the Erie and Pennsylvania Railroads, 60 miles southeast of Buffalo. It is the distribution and marketing centre for a prosperous agricultural district and here also is Letchworth Park of 1,000 acres crossed by the Genesee River, which is crossed by a fine bridge. The falls of the river and the cañon at this point are very picturesque. The town contains a museum. The park is the gift to the State of William Pryor Letchworth. Pop. 1,273.

PORTAGE, Pa., borough of Cambria County, on the Pennsylvania Railroad, six miles southeast of Ebensburg. There are several coal mines nearby and coal-mining is the principal industry. Pop. 2,954.

PORTAGE, Wis., city, county-seat of Columbia County, on the government ship-canal between the Fox and Wisconsin rivers, and on the Chicago, Milwaukee and Saint Paul and the Minneapolis, Saint Paul and Sault Sainte Marie railroads, about 92 miles west by north of Milwaukee and 35 miles north of Madison, the State capital. It was settled in 1835, incorporated in 1837 and in 1854 was chartered as a city. It is in a productive agricultural and lumbering region and is the commercial and industrial centre for quite a large portion of Columbia County. The chief manufactures are flour, brick, hosiery, knitgoods and farm implements. The educational institutions are a high school, public and parish elementary schools and a public library. In the vicinity are the ruins of Fort Winnebago (1828). The government is according to the commission plan since 1912. The city owns the waterworks. Pop. 5,440.

PORTAGE GROUP, *in geology,* a portion of the Devonian series, so-called by the geologists of the New York State Survey because largely developed near the town of Portage, N. Y. The rocks of this period are chiefly sandstone and shale.

PORTAGE LA PRAIRIE, pôr'tāj lä prā'rĭ, Canada, a town in Manitoba, on the Canadian Pacific, Grand Trunk Pacific, Canadian Northern and Great Northern railway, 56 miles west of Winnipeg and 15 miles south of Lake Manitoba. It is an important railway centre and the receiving and distributing point for the fertile «Portage Plains,» one of the finest wheat-growing sections in the world. It has railway machine shops, a large flouring mill, grain elevators, a paper mill, brickworks, and is the seat of an Indian industrial school and the provincial home for incurables. Pop. 5,892.

PORTE, The, or **OTTOMAN PORTE.** See SUBLIME PORTE.

PORTE CRAYON. See STROTHER, DAVID HUNTER.

PORTEOUS RIOT, so called from the lynching of Capt. John Porteous, commander of the city guard of Edinburgh, 7 Sept. 1736, was occasioned by various incidents connected with the trial and execution of Andrew Wilson, a smuggler, who with two companions had robbed the Kirkcaldy excise officer. The mob after the execution became disorderly and commenced throwing stones, whereupon Porteous ordered his command to fire into the crowd, with the result that seven people were killed and 20 wounded. Porteous, after trial, was condemned to death, but being reprieved, a mob broke into the jail and hanged him. The city was fined $4,500 for the benefit of the widow and the provost was imprisoned for a year and disqualified from holding any further official position. The Porteous Riot is one of the main features of Sir Walter Scott's ‹Heart of Midlothian.›

PORTER, Alexander, American jurist: b. Armagh, County Tyrone, Ireland, 1786; d. Attakapas, La., 3 Jan. 1844. He came to the United States in 1801, settled in Nashville, Tenn., studied law and was admitted to the bar in 1807. He established a law practice in Saint Martinsville, La., in 1810; was a member of the convention which framed the State constitution in 1811; in 1821 was appointed a judge of the Supreme Court of Louisiana. During his 12 years' occupation of that office he established a fixed system of jurisprudence to supersede the chaotic mixture of Spanish, French and civil law in use. Elected United States senator in 1833 he voted to censure President Jackson for removing the deposits from the United States Bank, opposed the abolition of slavery in the District of Columbia and the bill to compel specie payment for public lands, advocated the division of surplus revenue among the States and also the recognition of Texas' independence. He was re-elected to the Senate in 1843.

PORTER, Anna Maria, English novelist, sister of Jane Porter (q.v.): b. 1780; d. near Bristol, Gloucestershire, 21 Sept. 1832. Before she was 15 she published two volumes entitled ‹Artless Tales.› The greater part of her life was spent with her mother and sister Jane in the neighborhood of London. She produced numerous novels, which enjoyed considerable popularity in their day. Among them are ‹Walsh Colville› (1797); ‹The Lake of Killarney› (1804); ‹The Hungarian Brothers› (1807); ‹The Recluse of Norway› (1814); ‹The Knight of Saint John› (1817); ‹Rocke Blanche› (1822); ‹Honor O'Hara› (1826); ‹The Barony› (1830). She also published ‹Tales of Pity› and ‹Ballads, Romances and Other Poems.› Nearly all her books were translated into French and several were republished in this country.

PORTER, Benjamin Curtis, American portrait painter: b. Melrose, Mass., 27 Aug. 1843; d. New York City, 2 April 1908. He early became a pupil of Dr. Rimmer and A. H. Bicknell in Boston, studied art in Paris and Vienna in 1872–78 and first devoted himself to figure painting, but later made portraits his specialty. In 1880 he became a member of the National Academy. His work showed harmonious coloring, and his portraiture was accurate and striking. Among his works are 'Henry V and the Princess Kate' (1868); 'Cupid with the Butterflies' (1874); 'Portrait of Boy with Dog' (1884), etc.

PORTER, Charles Talbot, American mechanical engineer: b. Auburn, N. Y., 1826; d. 1910. In 1845 he was graduated at Hamilton College; was admitted to the bar and practised law for many years before he adopted the career of engineer. He became a partner of John F. Allen and with him controlled the manufacture of the Porter-Allen engine. He was the first engineer to complete the resistances of the reciprocating type of engine and to evolve the high-speed stationary engine. He invented two successful steam-engine governors. His published works include 'Mechanics and Faith, Spiritual Truths in Nature' (1885) and 'Engineering Reminiscences' (1908).

PORTER, Charlotte, American author: b. Towanda, Pa., about 1853. In 1875 she was graduated at Wells College. In 1886–88 she edited 'Shakespeareana' and the *Ethical Record* from April to December 1888. With Helen A. Clarke she founded *Poet-Lore,* of which she is still editor; and with her also edited 'Poems of Robert Browning' (2 vols., 1896); 'The Ring and the Book' (1897); 'Clever Tales' (1897); 'Robert Browning's Complete Poetical Works' (12 vols., 1898); 'Mrs. Browning's Complete Works' (6 vols., 1900); 'Pembroke Edition of Shakespeare' (12 vols., 1903); 'Poets' Parleys' (1903). She is sole author of 'Dramatic Motive in Browning's «Strafford»' (1897); 'Browning Study Programmes' (1900); 'Stage Version Browning's Return of the Druses' (1903); 'Maeterlinck's Monna Vanna' (1904); 'Shakespeare Studies — Macbeth' (1902); 'The Tragedies' (1911); 'The Comedies' (1912); 'The Histories' (1913); 'Poetic Translation of D'Annunzio's Daughter of Jorio' (1907); 'Lips of Music,' poems (1910); 'Revels of Father Christmas and the Bishop' (1917), etc., and contributions to periodicals.

PORTER, David, American naval officer: b. Boston, 1 Feb. 1780; d. Pera, near Constantinople, Turkey, 3 March 1843. He made voyages in the West Indian merchant service, was twice impressed by the British, but escaped, and in 1798 entered the United States navy as a midshipman. He was on board the *Constitution* in the fight with *L'Insurgente* in 1799, and served as a lieutenant in the war with Tripoli. Captured with the *Philadelphia,* he remained in imprisonment until the peace. In the War of 1812, he fought with distinction, capturing many English merchantmen, and seriously crippling Great Britain's whale-shipping in the Pacific. His vessel, the *Essex,* was blockaded in 1813 in Valparaiso Harbor by two English vessels, which he offered to fight either singly or together. This offer having been refused, he attempted to make a dash for the open sea, but his ship was severely damaged by a squall, and he put back, anchoring a half mile off the shore, and three miles from the town. There the English, regardless of neutrality laws, attacked him, and after a struggle of two and a half hours, one of the fiercest in naval history, compelled him to surrender. He described the situation in a communication to the Secretary of the Navy by saying, «We have been unfortunate, but not disgraced,» and upon his return he was voted the thanks of Congress and several State legislatures, and received with much distinction. He was sent in 1824, being then a commodore, to operate against pirates in the West Indies. An officer sent by him to make an investigation at Fajardo, Porto Rico, was seized and imprisoned. Porter compelled the Spanish authorities to apologize for the act; was deemed to have exceeded his authority; and was suspended for six months by court-martial. On 18 Aug. 1826 he resigned his commission, and became rear-admiral in the Mexican service. From this, too, he resigned in 1829; and later was consul-general to the Barbary states and chargé d'affaires at Constantinople. Among his writings are 'Journal of a Cruise Made to the Pacifick Ocean' (1815), and 'Constantinople and its Environs' (1835). Consult 'Trial of Commodore David Porter before a Court-Martial' (1825); Porter, D. D., 'Life of Commodore David Porter' (1875).

PORTER, David Dixon, American naval officer: b. Chester, Pa., 8 June 1813; d. Washington, D. C., 13 Feb. 1891. He was son of David Porter (q.v.). In 1826 he entered the service of the Mexican navy as midshipman, and while serving on board a vessel employed in damaging Spanish commerce was captured and for a time held prisoner in the Spanish guardship at Havana. Not long after his release, he was made midshipman in the United States navy, and until 1835 was on duty on the European station. In the Mexican War he distinguished himself as a lieutenant, and later as commander of the *Spitfire.* After the war he commanded passenger steamers during an extended furlough. At the beginning of the Civil War he was made commander of the *Powhatan* for the relief of Fort Pickens. On 22 April 1861 he was made commander, soon afterward was placed in charge of the mortar fleet, in March 1862 joined Farragut, and on 18–24 April exploded 20,000 bombs in the Confederate forts Jackson and Saint Philip, below New Orleans. Farragut's fleet was thereby enabled to pass them and capture New Orleans; and the forts finally surrendered on 28 April. At Vicksburg, also, Porter by his remarkably effective bombardment of the forts enabled the fleet to pass safely. He was ordered in September 1862 to command the Mississippi squadron as acting rear-admiral. With an improvised navy-yard at Mound City, he quickly increased his squadron to 125 vessels, and in January 1863 aided Sherman in the capture of Arkansas Post. Not long afterward he ran the Vicksburg batteries, captured the enemy's fortifications at Grand Gulf, communicated with Grant, and then cooperated with that general in the well-known siege of Vicksburg. On 4 July 1863 the city fell. Porter's commission as rear-admiral bore that date; he also received the thanks of Congress. He then aided Banks (1864) in the Red River expedition, and only with difficulty rescued his vessels. He was placed in command of the North Atlantic blockading squadron in 1864; and with Gen. A. H. Terry co-operated in the capture of Fort Fisher 15 Jan. 1865. After the war he was superintendent of the United States Naval Academy in 1865–69, and did much to improve it. He was promoted vice-general in 1866 and admiral in 1870. He wrote a 'Life of Commodore David Porter' (1875); a romance 'Allan Dare and Robert le Diable' (1885); 'Incidents and Anecdotes of the Civil War' (1885); 'Harry Marline' (1886); 'History of the Navy in the War of the Rebellion' (1887), and other works. Consult Chesney, 'Essays in Military Biography' (1874); Soley, 'Admiral Porter' (1903).

PORTER, Fitz-John, American soldier, cousin of David Dixon Porter: b. Portsmouth, N. H., 13 June 1822; d. Morristown, N. J., 21 May 1901. He was graduated from the United States Military Academy in 1845, was assigned to the 4th artillery, served in the war with Mexico, and was brevetted successively captain for services at Molino del Rey and major for similar services at Chapultepec. After the war he was on garrison duty until 1849, and then was made assistant instructor of artillery at West Point, where in 1854–55 he was instructor of artillery and cavalry. Appointed assistant adjutant-general in 1856, he served under Gen. A. S. Johnston (q.v.) in the Utah expedition of 1857–60. In 1860 he was made assistant inspector-general, with headquarters at New York; and in this post, during the Baltimore riots, he superintended the defense of the railway between Harrisburg and Baltimore. He became colonel of the 15th infantry, a newly-organized regiment, on 14 May 1861, and on 17 May brigadier-general of volunteers. After having been for a time on duty in Washington, he participated in the Peninsular Campaign (1862) in Virginia, and after the capture of Yorktown, in the siege of which he had fought (5 April–4 May), was for a brief while its governor. He was then made commander of the Fifth corps, which he led at Mechanicsville (26 June 1862) and Gaines' Mills (27 June). He was in command of the left flank, the centre of the conflict, at Malvern Hill (1 July 1862); and for his conduct at the battle of Chickahominy was brevetted brigadier-general, United States army. On 4 July 1862 he was made major-general of volunteers. While he was temporarily attached to Pope's Army of Virginia, the battle of Manassas or the second Bull Run occurred (29–30 Aug. 1862). On the first day his corps was ordered to advance, but found itself unable to do so; on the afternoon of the second day, however, it was in action, and by its stubborn bravery saved the defeat from being a complete rout. Pope was greatly dejected by the reverse, which he attributed largely to Porter's failure to execute orders. He made a complaint in his report but preferred no charges. Porter was in the defenses of Washington 2–13 September, then commanded the Fifth corps, Army of the Potomac, September–November, fought at Antietam (17 September), and afterward in the skirmish at Shepardstown (19 September). On 27 Nov. 1862 he was arraigned before a court-martial at Washington, charged with disobeying orders at the second Bull Run. On 21 Jan. 1863 he was cashiered, and, for violation of the 9th and 25th articles of war, was «forever disqualified from holding any office of trust or profit under the government of the United States.» This sentence for years remained unaltered. Its justice was much debated. Numerous appeals were made for a reopening of the case, and Porter himself several times petitioned for a reversal of the judgment. Grant, while President, declined to reopen the case; but after his second term, upon an examination of all the testimony, published in an article entitled 'An Undeserved Stigma' (December 1882) his conclusions to the effect that Porter was by the evidence vindicated of the charges against him. Under President Hayes a military board acquitted Porter of all fault save unwise criticism of his superior. On 4 May 1882 President Arthur remitted the sentence so far as disability to hold office under government was concerned but a bill for Porter's relief failed to pass. A subsequent bill passed the 48th Congress, but was vetoed by Arthur on a technicality. A third bill, however, passed, and was signed by President Cleveland; and by the act of Congress of 1 July 1886 Porter was made colonel of infantry 5 Aug. 1886 to rank from 14 May 1861. On 7 Aug. 1886 he was placed on the retired list. Subsequent to 1863, Porter was superintendent of certain mining operations in Colorado in 1864–65; a merchant in New York 1865–71; superintendent of the erection of the New Jersey State asylum for the insane at Morristown; commissioner of public works, New York, 1875–76; assistant receiver of the Central Railroad of New Jersey, 1877-82; police commissioner, New York, 1884–88; fire commissioner, 1888–89; and cashier of the post-office, 1893–97. An offer, received in 1869, from the Khedive, to command the Egyptian forces with major-general's rank, was declined by Porter. Among the best statements of the case for and against Porter may be respectively mentioned, besides the article by Grant above cited (Vol. 135, *North American Review*), Lord, 'A Summary of the Case' (1883), and Cox, 'The 2d Battle of Bull Run as Connected with the Fitz-John Porter Case' (1882). See also POPE, JOHN.

PORTER, Gene Stratton, American author, ornithologist and illustrator: b. Wabash County, Ind., 1868. She received a private education and in 1886 was married to Charles Darwin Porter. For two years she was editor of the camera department of *Recreation* and two years on the natural history staff of *Outing*. Subsequently she was for four years specialist in natural history photography on the *Photographic Times Annual Almanac*. Mrs. Porter is the author of many entertaining and deservedly popular works including 'The Song of the Cardinal' (1902); 'Freckles' (1904); 'What I Have Done with Birds' (1907); 'At the foot of the Rainbow' (1908); 'A Girl of the Limberlost' (1909); 'Birds of the Bible' (1909); 'Music of the Wild' (1910); 'The Harvester' (1911); 'Moths of the Limberlost' (1912); 'Laddie' (1913); 'Michael O'Halloran' (1915); 'Morning Face' (1916); 'Friends in Feathers' (1917).

PORTER, Horace, American diplomat: b. Huntington, Pa., 15 April 1837. He studied at Harvard and was graduated from West Point in 1860; served for a short time as instructor there and at the outbreak of the Civil War was assigned to duty in the Department of the East. He commanded the siege batteries at Fort Pulaski and was brevetted captain for his gallantry. After the battle of Antietam he was transferred to the Army of the Ohio and later to that of the Cumberland. He was engaged at Chattanooga, Chickamauga, the battle of the Wilderness and New Market Heights, and as aide-de-camp on the staff of General Grant witnessed the surrender at Appomattox. In 1865 he was brevetted brigadier-general for his services throughout the war. He was assistant to Grant when that general was Secretary of War for a few months in 1867 and upon Grant's election to the Presidency Porter became his private secretary. In 1873 he resigned from the army. After the close of Grant's second term as President, Porter entered upon a business career in which he was eminently successful, became noted as an author and lecturer, and through his efforts the Grant Monument was completed. In 1897 he was appointed by President McKinley, United States Ambassador to France, which position he filled with tact and ability till 1905. He succeeded in finding the burial place of John Paul Jones, the American naval hero, and recovered the body, later sending it to the United States for burial in Annapolis. He was awarded the thanks of Congress and the privilege of the floor of each House for life, and was a delegate to The Hague Peace Conference of 1907. He wrote 'West Point Life' (1866); 'Campaigning with Grant' (1897).

PORTER, James, American Methodist Episcopal clergyman: b. Middleboro, Mass., 1808; d. 1888. In 1830 he became a member of the New England Conference and in 1856 became an agent of the Methodist Book Concern, and was reappointed in 1860 and 1864. From 1868 to 1882 Mr. Porter was secretary of the National Temperance Society; in 1852–55 was an overseer of Harvard University and in 1855–71 was trustee of Wesleyan University. He was the author of several works on religious topics.

PORTER, James Davis, American politician: b. Paris, Tenn., 7 Dec. 1828; d. Paris, Tenn., 18 May 1912. He was graduated from the University of Nashville in 1846; admitted to the bar in 1850; and sat in the Tennessee legislature, 1859–61. He served in the Confederate army during the Civil War, and was adjutant-general on the staff of Major-General Cheatham. In 1870–74 he served as judge of the 12th judicial circuit and in 1874–78 was governor of Tennessee. He was United States Assistant Secretary of State in 1885–89 and Minister to Chile in 1893–97. He wrote 'The Confederate Military History of Tennessee.'

PORTER, Jane, English novelist: b. Durham, England, 1776; d. Bristol, Gloucestershire, 24 May 1850. She was a sister of Anna M. and Sir Robert Ker Porter (qq.v.) and was brought up at Edinburgh and in London. She became immediately famous in 1803 by her historical romance, 'Thaddeus of Warsaw,' and 'The Scottish Chiefs' (1810) was even more successful despite its high-flown sentiment and stilted characterization. Other works of hers were 'The Pastor's Fireside' (1815); 'Duke Christian of Luneburg' (1824); 'Tales Round a Winter's Hearth' with Anna M. Porter (q.v.) (1824); 'The Field of Forty Footsteps' (1828), and 'Sir Edward Seaward's Narrative of his Shipwreck and Consequent Discovery of Certain Islands in the Caribbean Sea' (1831), a praiseworthy fiction, edited.

PORTER, Jermain Gildersleeve, astronomer: b. Buffalo, N. Y., 8 Jan. 1852. He was graduated from Hamilton College, Clinton, N. Y., in 1873 and studied at the University of Berlin. He was appointed to the United States Coast and Geodetic Survey in 1878 and since 1884 has been director of the Cincinnati Observatory and professor of astronomy at the University of Cincinnati. In 1894 he received the *Astronomical Journal* Comet Prize. His principal investigations have been on the motions of the stars and the variation of latitude. He published 'Our Celestial Home' (1888); 'The Stars in Song and Legend' (1901); also many catalogues of stars and nebulæ, and memoirs on various astronomical subjects.

PORTER, Noah, American educator: b. Farmington, Conn., 14 Dec. 1811; d. New Haven, Conn., 4 March 1892. Graduated from Yale in 1831, he was a tutor and student of theology there in 1833–35, was pastor of Congregational churches at New Milford, Conn., 1836–43, and Springfield, Mass., 1843–46. In 1846 he was made professor of moral philosophy and metaphysics at Yale, and from 1871 until his resignation in 1886 was president of that institution. His administration was a distinguished one. During it the curriculum was broadened by the introduction of new elective subjects, although Porter never favored the development of the elective system attempted at Harvard and supported the classic for the leading place in a scheme of liberal training. The material progress was also of note, large additions being made to the buildings and funds. Porter was also known as the editor of revised editions of Webster's 'Unabridged Dictionary.' He ranked among the foremost American metaphysicians of his time. Among his writings are 'Historical Discourse on Farmington' (1841); 'The Educational Systems of the Puritans and Jesuits Compared' (1851); 'The Human Intellect' (1868; and many subsequent eds.); 'Books and Reading' (1870); 'American Colleges and the American Public' (1871); 'Science of Nature *vs.* the Science of Man' (1871), a review of the philosophy of Spencer; 'Elements of Intellectual Science' (1871); 'Evangeline; the Place, the Story and the Poem' (1882); 'Science and Sentiment' (1882) 'The Elements of Moral Science' (1885); a 'Life of Bishop Berkeley' (1885) and 'Kant's Ethics: A Critical Exposition' (1886).

PORTER, Peter Buel, American soldier: b. Salisbury, Conn., 14 Aug. 1773; d. Niagara Falls, N. Y., 20 March 1844. He was graduated at Yale College in 1791, studied at the Litchfield Law School, and in 1795 began practice at Canandaigua, N. Y. In 1808 he was chosen a representative in Congress, where as chairman of the Committee on Foreign Relations he prepared and introduced the celebrated report of December 1811, recommending war against Great Britain. As soon as hostilities had been declared he resigned his seat in Congress, was appointed quartermaster-general of New York and took command of a body of Pennsylvania and New York volunteers and Indians of the Six Nations. Black Rock, where General Porter resided, having fallen into the hands of the British in June 1813, and his own house, from which he had barely time to escape, being their headquarters, he rallied a force by which they were expelled and their commander mortally wounded. In July 1814 he joined Brown's invading army with a brigade of 3,500 volunteers and Indians and distinguished himself at Chippewa and Lundy's Lane, and the siege of Fort Erie. He declined President Madison's appointment as commander-in-chief of the army in 1815, and served again in Congress for a few months. Porter was one of the earliest projectors of the Erie Canal, and was named, with Morris and Clinton, on the first board of commissioners to explore a route for it. In 1816 he was appointed commissioner under the Treaty of Ghent for determining the northwestern boundary. In May 1828 he was appointed Secretary of War by President Adams.

PORTER, Pleasant, Creek Indian leader: b. near Clarksville, in the Creek Nation, 26 Sept. 1840; d. Vinita, 3 Sept. 1907. His paternal grandfather, a native of Pennsylvania, was a captain in the United States army at the time of the Creek War and showed such consideration for the defeated Muskogees that they formally adopted him as a member of the tribe. Years later, Pleasant Porter's father, Benjamin E. Porter, settled in the Indian Territory, where he married the daughter of a prominent chief, Tah-to-pee Tust-e-nuk-kee, and became a planter. Pleasant Porter's early life was simple and uneventful. He was educated at the Presbyterian mission school at Tallahassee. At the outbreak of the Civil War he entered the Confederate service as a private soldier in one of the Creek Indian regiments. He saw much active service and was promoted through the non-commissioned grades to the rank of a first lieutenant. The end of the war found him, like most of his fellow-tribesmen, penniless. He then began the life of a farmer. His first official position in civil life was that of superintendent of schools in the Creek Nation, in which capacity he reorganized the tribal public school system, which had ceased to exist during the war. His ability becoming recognized, his services were soon in demand as a representative of his people in Washington. As the commander of the Creek National forces during the intratribal insurrection known as the Spiechee War, in 1882, he displayed not only courage but also good judgment and tact as well. During his later years he occupied the position of principal chief of the Creek Nation. In 1905 he was chosen as president of the Sequoyah Constitutional Convention, which gathered at Muskogee to frame the organic law for a commonwealth to be composed of the tribal domains of the five civilized tribes.

PORTER, Sir Robert Ker, English artist, brother of Jane and Anna Maria Porter (qq.v.): b. Durham, 1775; d. Saint Petersburg, Russia, 4 May 1842. He studied at the Royal Academy in London, and became famous for his battle pieces. In 1804 he was appointed historical painter to the czar of Russia. In 1808 he served under Sir John Moore in Spain, and in 1811 returned to Russia, where he married the Princess Sherbatoff. He was knighted in 1817, and from then until 1820 was engaged in antiquarian studies in Asia. In 1826–41 he was British consul at Venezuela. Of his paintings the most notable were 'The Storming of Seringapatam' (1800, destroyed by fire); 'The Siege of Acre'; 'Agincourt'; 'Peter the Great Planning the Port of Cronstadt and Saint Petersburg'; 'Christ at the Last Supper Blessing the Cup,' etc. He wrote 'Travelling Sketches in Russia and Sweden' (1808); 'Letters from Portugal and Spain' (1809); 'Narrative of the Late Campaign in Russia' (1813); 'Travels in Georgia, Persia, Armenia and Ancient Babylonia' (1821–22), etc.

PORTER, Robert Percival, American journalist: b. Norwich, England, 30 June 1852; d. 28 Feb. 1917. In his youth he emigrated to the United States and in 1872 was engaged on the staff of the Chicago *Inter-Ocean*. He specialized in economics and statistics; prepared census reports of the 10th census, and was appointed member of the Tariff Commission in 1882. On behalf of the *Tribune* of New York and the *Press* of Philadelphia he studied industrial and housing conditions in Europe. With Frank Hatton he founded the New York *Press* in 1887 and in 1890–94 was superintendent of the 11th census. He became a member of the staff of the London *Times* in 1904, and subsequently investigated social and industrial conditions in Cuba, Porto Rico and Japan. His published works are 'The West in 1880' (1882); 'Breadwinners Abroad' (1885); 'Free Trade Folly' (1886); 'Commerce and Industry of Japan' (1896); 'Life of William McKinley' (1896); 'Industrial Cuba' (1899); 'Lectures and Addresses on Municipal Ownership' (1903); 'Dangers of Municipal Ownership' (1907); 'The Full Recognition of Japan' (1911).

PORTER, Thomas Conrad, American botanist: b. Alexandria, Pa., 1822; d. 1901. In 1840 he was graduated at Lafayette College and three years later at the Princeton Theological Seminary. After five years of preaching he became professor of natural science in Marshall College (later Franklin and Marshall). He removed to Lafayette College in 1866 as professor of botany. In 1897 he resigned his professorial duties and became curator of the botanical collection of the college and dean of the Pardee school. His published works are 'Sketch of the Flora of Pennsylvania' (1872); 'Sketch of the Botany of the United States' (1873); 'Synoptical Flora of Colorado,' with J. M. Coulter (1874); 'The Carices of Pennsylvania' (1887); 'The Grasses of Pennsylvania' (1893).

PORTER, William David, American naval officer: b. New Orleans, La., 1809; d. 1864. In 1823 he entered the United States navy as midshipman; was gazetted lieutenant in 1833; retired in 1855, but restored to active service in 1859 with rank of commander. He was actively engaged during the war with Mexico in the '40's and organized the Lighthouse Service. When the Civil War broke out Porter was in command of the ironclad *Essex*, in the Mississippi, took part in the taking of forts Donelson and Henry and effected the passage of the river from Cairo to New Orleans through the fire of several Confederate batteries. On his second engagement with the ram *Arkansas* of the Confederate navy on 6 Aug. 1862, he sank her and sometime afterward bombarded the batteries at Natchez, Port Hudson and Vicksburg. On 16 July 1862 he was made commodore.

PORTER, William Sydney, American short-story writer, well known under the nom-de-plume of "O. Henry": b. Greensboro, N. C., 1862; d. 5 June 1910. He received an academic education in Texas, in which State he spent some time on a cattle ranch before beginning his journalistic career as reporter on the Houston *Post.* Shortly afterward he purchased *Brann's Iconoclast,* which he converted into a 10-page fiction weekly, and for which he furnished himself most of the copy. He renamed it the *Rolling Stone,* but soon abandoned the venture and undertook a journey to Central America. This trip was in after years of great use to him as a mine from which to draw some of his best tales. He set about raising bananas on a large scale and the venture proving unsuccessful he returned to Texas and sought employment as a druggist's clerk. Soon afterward he removed to New Orleans and there his literary work began in earnest. His stories were sent all over the country, but he remained in comparative obscurity until his removal to New York in 1901. Within a few years he became one of the most popular short-story writers in America. His 'Heart of the West' (1907) and 'Roads of Destiny' deal with Western life as he knew it, and his 'Cabbages and Kings' deals with life and incidents in Central America. His fame, however, rests on his stories of New York life in its many phases, from the palatial mansion of the millionaire to the homeless wayfarer and tramp of the slums. His stories are marked by a freshness of style and by keen penetration and characterization, albeit deficient in psychological insight and abounding in slang. The short stories have appeared in the following collections: 'Cabbages and Kings' (1905); 'The Four Million' (1906); 'The Trimmed Lamp' (1907); 'The Gentle Grafter' (1908); 'The Voice of the City' (1908); 'Options' (1909); 'Whirligigs' (1910); 'The Two Women' (1910); 'Strictly Business' (1910); 'Sixes and Sevens' (1911); 'Rolling Stones' (1912). A complete edition of his works was published at Garden City (1912).

PORTERANTHUS, an erect, perennial, medicinal plant of the rose family, growing in woodlands from two to four feet in height and bearing five-petaled white or pinkish flowers in May to July. Two varieties are known: *P. trifoliatus,* found in the area from New York and Lower Canada southward as far as Georgia and westward as far as Missouri; and *P. stipulatus,* found from western New York southward to Louisiana and westward as far as Oklahoma. The latter variety is smaller than the former and has five-parted leaves instead of three-parted leaves as in the former. The plant is popularly known by several names: False Ipecac, American Ipecac, Bowman's Root and Indian Physic.

PORTERSVILLE, Cal., city in Tulare County, on the Southern Pacific Railroad, 30 miles south of Visalia. The city is situated in the citrus-fruit region, which produces also great quantities of olives, deciduous fruits, berries, etc. Cattle-raising is also an important industry. The warehousing and shipping of these gives employment to a great number of Portersville citizens. In addition, there are marble and granite works, canneries, creameries, cement works and lumber yards, a public library, high school, recreation parks, etc. The water-supply system is the property of the municipality. Pop. 2,696.

PORTLAND, Conn., town of Middlesex County, situated on the Connecticut River, directly opposite Middletown, on the New York, New Haven and Hartford Railroad. It has manufactories of engine parts and there are brownstone quarries. Pop. 3,425.

PORTLAND, Ind., city, county-seat of Jay County, on the Salamonie River, Grand Rapids and Indiana, Lake Erie and Western and Chicago, Bluffton and Cincinnati railroads, and the Muncie and Portland Traction line, about 45 miles southeast of Fort Wayne. It is in the midst of a productive agricultural region. The chief manufacturing establishments are woodworking plants, automobile parts, flour mills, clay and tile works, machine shops, cooperage and creameries. The manufacturing investment aggregates $850,000 and value of products $1,400,000. The educational institutions are five public schools and a free public library. There is a public hospital. The city owns and operates an electric-light plant and waterworks. There is a supply of natural gas. The five banks have annual clearings over $16,000,000. The city is especially noted for large mercantile trade. There are six miles of brick streets. Pop. 6,300.

PORTLAND, Me., the largest city in the State, an important seaport and county-seat of Cumberland County, is situated on Casco Bay, 106 miles northeast of Boston, with which it is connected by the Boston and Maine Railroad. The Maine Central and Grand Trunk railways connect it with the eastern part of the State and the British provinces. It has direct steamship connections with Boston, New York and other Atlantic Coast ports, and steamship lines to Europe. The government defense works here, recently enlarged, include Fort Preble, Fort Williams on Portland Head, Fort Levett on Cushing's Island and Fort McKinley on Great Diamond Island. Forts Scammel and Gorges, formerly strongly equipped, command the entrance to the harbor.

Topography.— The city proper has an area of 17½ square miles and is well laid out, with beautiful shade trees lining its streets and avenues. The site is one of great natural beauty, rising on a peninsula extending into Casco Bay, in view of many small islands, which have become popular summer resorts for Portland residents. In the vicinity are many other resorts and watering places, popular with people from all parts of the Union and an increasing number of tourists from foreign countries. The drives around the two hills at the extremities of the peninsula are not surpassed in beauty by any in the United States. The city slopes from the water front to two heights, forming a natural amphitheatre, giving the city a picturesque appearance from the sea. The harbor is protected by a massive breakwater.

Park System.— The extensive public park system of Portland includes over 115 acres and embraces the Eastern and Western Promenades, on the latter of which is a fine statue of Thomas B. Reed, Lincoln Park, Fort Sumner and Fort Allen parks, Deering's Oaks and Monument square, in the latter of which stands an elaborate memorial, the work of Franklin Simmons, a son of Maine, to the Maine soldiers who were killed in the Civil War. These parks will soon be connected by a boulevard extending around Back Bay, forming a driveway of about three miles and affording extensive views of sea and mountains.

Public Buildings.—Among the prominent buildings are the United States Courthouse, the City Hall, the Custom House, Post Office, Mechanics' Hall, United States Marine Hospital, the Public Library, containing over 80,000 volumes, and the library of the Maine Historical Society of 14,000 volumes; the Portland Society of Natural History; the Maine Eye and Ear Infirmary, the New City Building, the Portland Society of Art, the Cumberland Club, the Trelawny building, the Fidelity building, Portland School for the Deaf, Old Men's Home, Home for Aged Women, Saint Elizabeth's Academy, Female Orphan Asylum, Episcopal and Roman Catholic cathedrals and several noted colonial mansions, including the Longfellow House and Deering Mansion.

Government.— The city is governed under a charter granted in 1863, subsequently amended, and later acts, by a mayor elected annually, a bicameral council, consisting of 36 members, three councilmen and one alderman from each ward, and city officials, most of them elected by the people. The city marshal, commissioner of public works and members of the board of health are appointed by the mayor. The members of the board of education are elected by popular vote. The city has waterworks, electric lighting system and electric street railways.

Schools.— The graded school system of Portland is excellent and managed by a school board of 12 members, including three women, who are elected as members at large. The mayor is chairman ex-officio of the board. There are two high schools, 19 grammar, 31 primary, nine kindergarten, besides a manual training school. The cost for maintaining the schools was for 1915 $303,822.35. The Roman Catholics maintain four parochial schools.

Fire Department.— There is an efficient fire department, under the charge of a chief and four assistants. The department is managed by a committee of the city government; the cost for the year 1915 was $157,037.93.

Churches.— Portland has 52 churches, among which are three Baptist, three Roman Catholic, 14 Congregational, four Episcopal, three Lutheran, 15 Methodist, one Presbyterian, two Second Advent, two Unitarian and five Universalist churches. No city of its size has more benevolent societies.

Courts and Police Department.— There are United States courts, circuit and district; supreme-judicial; superior; probate and municipal courts. The police department is under the charge of a chief and two deputies. The mayor is at the head of the deparment. The cost of maintenance for 1915, including pensions ($5,007.93), was $129,760.14.

Manufactures.— Portland has 271 manufacturing establishments, of which by last public report the output was valued at $11,950,000. The industries include boot and shoe factories, rolling-mills, foundries, machine shops, locomotive works, engine and boiler works, petroleum refineries, match factory, chemical works, carriage and sleigh factories, manufactories of stoneware, jewelry, edge tools, varnishes, soap, meat-packing establishments, cooperage shops, lumber mills, etc. The capital invested in these industries, according to last census, was $9,597,000. Shipbuilding is still carried on, though of less importance, relatively, than in former years. Fishing and the shellfish industry are extensively pursued. The assessed property valuation (1915) was $71,843,235. Net public debt, $408,937.71. Tax rate (per $100), $2.28.

Trade and Commerce.— In the earlier days Portland had an extensive and valuable trade with the West Indies, a portion of which it still enjoys. It has large commercial interests and is noted for its exports of grain, fruit and livestock. Exports in 1916 from Grand Trunk piers and elevators: Grain, 1,092,622 tons; package freight, 122,593 tons; horses, 22,593; mules, 6,194; also 39,083 pieces of cooperage stock. Imports (trans-Atlantic), 16,260 tons; sulphur, 102,344 tons; pulp wood, 20,205 tons; china clay, 38,861 tons; fire clay, 13,315 tons; lumber, 1,575 tons; ore, 6,644 tons. The fish receipts were approximately 13,960 tons. Miscellaneous: Mexican crude petroleum oil, 21,769,104 gallons; coal, 1,511,168 net tons; salt, 3,184 tons; through this port by water, 75,614 tons. The harbor is of easy access, capacious, safe, deep enough for the largest vessels and rarely obstructed by ice; hence it is an important seat of winter traffic between Great Britain and Canada. There are docks and other facilities for the repair of vessels. The greater part of the steamship-carrying trade to and from foreign parts is in British ships. The coasting trade is extensive. England, France, Portugal, Uruguay, Haiti, Argentine Republic, Norway and Sweden maintain consular service here.

Newspapers.— Portland has 14 newspapers; six political, two religious, one agricultural, one Masonic, four miscellaneous.

Banks.— There are five national banks, with a capital of $2,000,000; five trust companies, with a capital of $1,000,000; two savings banks (resources), $34,186,217.25.

Insurance Companies.—Two, with assets of $18,537,161.04.

History.— In 1623 Christopher Levett of York, England, visited the Maine coast and under a patent embracing the present site of Portland built on one of the islands in the harbor a fort, in which he placed 10 men and sailed for England, intending to return and plant a colony. To the site of his proposed plantation he gave the name York, from his native city. The project failed, owing to war between England and France, and the place remained uninhabited by Europeans until 1632, when George Cleeve and Richard Tucker of England made a settlement on the eastern ex-

tremity of the peninsula within the limits of the present city of Portland. The Indian name of the place was Machegonne and was entitled in the patent to Cleeve and Tucker Stogomor, from Stogumber, the birthplace of Tucker. This was shortly changed to Casco Neck. In 1658 the name was changed to Falmouth. The Indians made an attack on the town in 1676, burning houses, killing some of the inhabitants and making many captives. It was completely destroyed by the French and Indians in 1690. The General Court authorized its resettlement in 1714, and in 1716 it was resettled by Col. Samuel Moody, who soon gathered about him about 50 families. On 10 March 1719 the first town meeting was held. The town suffered severely during the Revolutionary War from a bombardment by a British fleet in 1775. It was again rebuilt, and in 1836 received its first city charter. On 4 July 1866 a fire destroyed 1,500 buildings, involving a loss of $10,000,000. Longfellow, N. P. Willis, William Pitt Fessenden, Neal Dow and Thomas B. Reed were natives of Portland. Pop. at present time estimated at 65,000.

Bibliography.— Neal, 'Portland' (1874); Willis, 'History of Portland' (1865); Elwell, 'Portland and Vicinity' (1876); 'George Cleeve and His Times' (1885); 'Portland in the Past' (1886); 'Christopher Levett' (1893); Powell, 'Historic Towns of New England' (1898).

James Phinney Baxter.

PORTLAND, Ore., chief city of the State and county-seat of Multnomah County, situated just above the confluence of the Willamette and Columbia rivers, a position made doubly important through the continuous improvement of these great commercial waterways by the United States government and the port of Portland. The city is 771 miles north of San Francisco, 115 miles from the ocean and covers an area of 66.36 square miles. The population of the city is steadily increasing at a rate approximating 10 per cent annually. It is called «The Rose City» in appreciation of the fact that its people pay special attention to the beautification of their homes and especially to the planting of rose gardens and hedges. Portland is unique in its efforts to develop the country throughout the State and this policy has reacted very advantageously indeed on the trade of the city. Geographical contours give a water-level route from far in the interior. Railway lines operating on this grade pour their traffic into the city most economically as a consequence. The splendid fresh-water harbor is the best one on our Pacific Coast and there is better than a 30-foot channel to the sea at low tide with 35 feet assured in the near future.

Columbia River Entrance.— The entrance to the Columbia River is deeper than any other Pacific Coast port, the most recent government figures showing a depth of water in excess of 42 feet for a width of over half-a-mile and a depth of 35 feet for an additional half-mile of width. The United States government has spent $16,000,000 to remove what was once considered a hazardous bar at the mouth of the Columbia. This obstruction has been entirely removed by the construction of two long jetties, one on either side of the river entrance. The waters of the Columbia constantly are scouring the channel and the depth of water is increasing year by year. Portland is the chief lumber manufacturing city in the world. The by-product of lumber is the manufacturing of furniture, the city having some of the largest furniture manufacturing plants in the United States. Portland is also the chief wheat exporting port of the Pacific Coast and in normal times the second largest wheat shipping port in the United States, handling the bulk of the great crop produced in the Inland Empire (eastern Oregon, eastern Washington and Idaho), and in 1915 the wheat receipts of the city mounted to 18,718,755 bushels. Portland has 772.39 miles of improved streets; of this, 384 miles are hard surfaced, 116.30 miles macadam and gravel, and 269.66 miles graded. Completed sewers show a total of 574 miles. The assessed valuation of taxable property in Portland at the end of 1918 was $305,200,640. The tax rate is $1.20 per hundred dollars and the net bonded indebtedness of the city is $11,859,011.38.

Streets and Parks.— Portland is continuously improving its streets and in this respect stands among the most modern cities of the country. Blocks are 200 × 200 feet, with no alleys, giving the city a fine appearance. The city is a huge park, in that great Douglas fir trees, oaks and cedars and other large growths grow on the hills and close down to the border of the city limits. The streets are lined with shade trees and practically every home has its lawn and rose hedges. Boulevards run along each side of the river, both above and below the business district. Council Crest drive is one of the city's show places, because of the vast panorama of mountain, hill, valley and city that unfolds to the view of the spectator. Terwilliger boulevard, following the contour of the hills on the west side of the river, is a connecting link of an extensive chain of scenic roads that lead from the city into beautiful verdure-garbed valleys dotted with orchards and farm homes.

Columbia River Highway.— The Columbia River highway, along the east bank of the Columbia River, is said to be the most beautiful highway in the world. It traverses the gorge of the Columbia River for 50 miles east of Portland. This portion of the highway is hard surfaced. By the fall of 1920 the Columbia River highway will be completely hard surfaced from Pendleton in eastern Oregon to Astoria, at the mouth of the Columbia River, a distance of 370 miles. The Pacific highway, from Portland south to the California line, is also a wonderful roadway. Hard surfacing will also be completed by the fall of 1920, the distance being about 360 miles. Oregon is spending $33,000,000 on her highways in the next three years. Portland's park area compares favorably with other cities of its size. Washington Park is situated on the edge of the western hills, a most sightly location, where some of the most magnificent views of the city and mountain peaks are to be obtained from an eminence in this park. Another one of the interesting parks of the city is Peninsula Park, where are to be found beautiful sunken gardens, said to be the largest rose park in the United States and accessible by street car from the centre of the city. Macleay Park is situated in the Willamette Heights district and was donated by an early pioneer with the request that its natural ruggedness be maintained in its present state.

There are 21 parks and playgrounds in and about the city, many of which are highly improved. In addition to public parks, Portland has four splendid golf courses, one of which is controlled by the municipality, also a number of fine privately controlled amusement parks.

Libraries.— Portland is the seat of the magnificent new Multnomah County Library. This, with five tastefully designed and substantial branch buildings and 12 sub-branches and 22 deposit stations, gives easy access to its privileges from every portion of the city; its circulating rural libraries throughout the entire county and affiliations with suburban communities make this institution unique among American libraries. A feature of the new building is a series of commodious halls, available without charge for meetings of a civic or development nature. More than 50 organizations regularly avail themselves of this opportunity. The circulation is about 1,385,964 volumes annually. Portland, according to the latest available government statistics, is the most highly cultured city in the United States; the percentage of illiteracy is but 1.2 per cent.

Schools and Education.— Portland has an excellent public school system. There are 71 school buildings in the city under the control of the school board. There are 1,202 teachers and supervisors employed, and 44,996 pupils enrolled, segregated as follows: Elementary schools, 35,636 pupils; high schools, 4,672 pupils; trade schools, 1,623 pupils; night schools, 3,065 pupils. There are four special schools and many private schools of high class and efficiency, as well as numerous trade and technical institutions. The University of Oregon maintains its medical department in this city. The largest dental college on the Pacific Coast, teaching dentistry and pharmacy, is located in Portland, besides private medical institutions and law schools. A public art institution fosters the fine arts. The Reed College is an institution offering courses of the highest order in the arts and sciences. It has a large endowment fund and is fast forging to the front as a school of national prestige. Music conservatories and voice culture schools rank among the highest in the country.

Newspapers.— Five daily newspapers are published in Portland, the *Oregonian, Oregon Journal, Evening Telegram, Portland News* and the *Nachtrichten* (German), with an additional 80 semi-weekly, weekly and monthly publications.

Climate.— Portland has an equable climate. The summers are cool and comfortable, the winters mild and rainy. For a period covering the last 30 years the United States Weather Bureau gives the average annual rainfall as 45 inches; the average yearly temperature was 52.4°. There are no destructive storms, wind or electric disturbances.

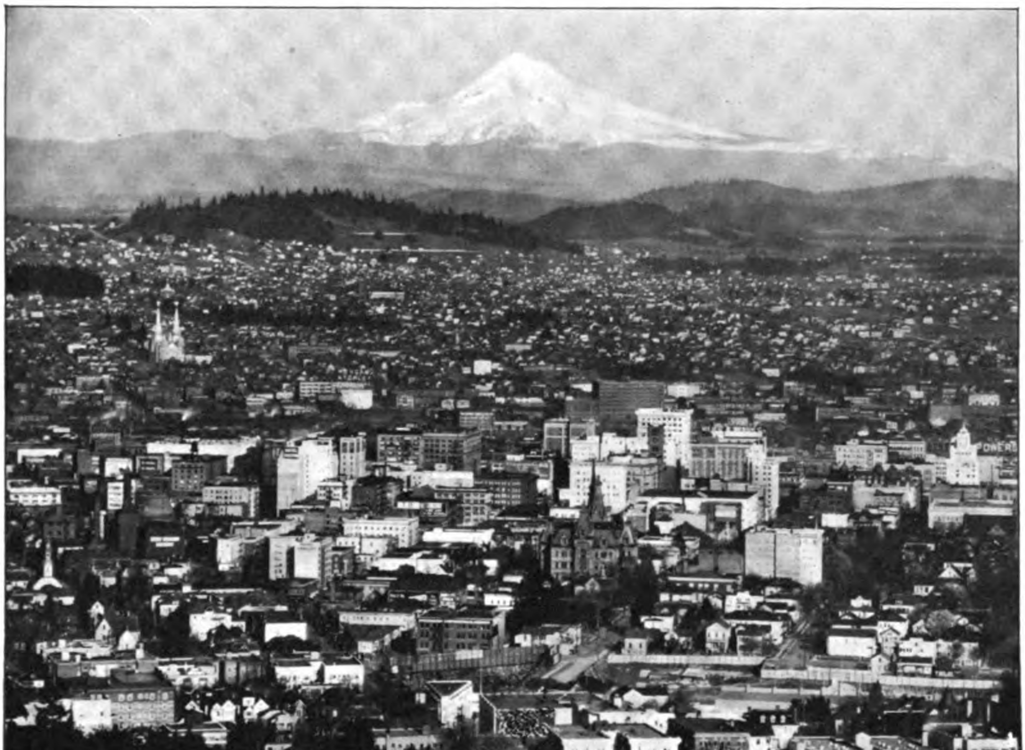
Churches.— Portland has 213 churches, with church buildings valued at approximately $3,150,000. The Y.M.C.A. and Y.W.C.A have large memberships and splendid buildings of their own. The B'rai B'rith have also a building of their own.

State Exhibit.— The State of Orgeon maintains an exhibit of Oregon products, agricultural, mineral and manufactured, on the ground floor of the Oregon building, in which building also is located the Chamber of Commerce with an information bureau for home-seekers. The Portland Chamber of Commerce maintains several bureaus where the home-seeker, investor or tourist may secure information pertaining to any particular subject in which he may be interested. The Oregon development bureau of the Chamber of Commerce is of special interest to the home-seeker. Information as to lands and agriculture and advice is furnished free of charge.

Clubs and Commercial Organizations.— Club life is well developed here. In addition to various social organizations there are strong commercial bodies. The Portland Chamber of Commerce is one of the largest in the world. The East Side Business Men's Club, Press Club, the Portland Ad Club, Civic League, Progressive Business Men, Realty Board, Rose Festival Association, Rose Society, Royal Rosarians, the Kiwanis and Rotary Club deal with public questions and do valuable publicity work. All have large memberships, made up of the most substantial business interests in the city. There are many social, educational, literary and musical clubs. The city is widely known for its symphony orchestra. Notable among the clubs owning their own homes are the Arlington Club, University Club, Elks Club, Multnomah Club, Oregon Yacht Club, the Hunt Club, Irvington Tennis Club, Rose City Park Club, the Laurelhurst Club, Portland Heights Club, Concordia Club, Waverly Golf Club, Tualatin Country Club, Portland Rowing Club. The holdings of these clubs would aggregate more than $3,000,000.

Lumber.— There is tributary to Portland 564,000,000,000 feet of merchantable timber, consisting of yellow and red Douglas fir, yellow, white and sugar pine, spruce, cedar, hemlock, larch and other commercial woods. During the great European War, Portland, which is the largest lumber manufacturing city in the world, was governmental headquarters for spruce production for aeroplanes.

Manufactures, Commerce, etc.—The city is rapidly forging to the front as a manufacturing centre and is one of the chief manufacturing cities in the Pacific Northwest and is the centre of the jobbing trade. There are 950 manufacturing establishments here, representing an investment of $75,000,000. There are 40,000 factory employees, officials and office men, whose wages amount to $65,000,000 per annum. The value of the product in 1918, not considering shipbuilding, was $200,000,000. The principal lines of manufacturing are lumber and its by-products, flour, furniture, woolens, harness and saddlery, machinery, fruit-canning and meat-packing and railroad cars and equipment. Portland's shipbuilding contracts for the period of the war approximated $230,000,000. Oregon and the Portland district were the largest producers of commercial ships, steel and wood, in the United States during the war. Portland has been the business centre of the Oregon country since the earliest days, when the State name included the whole Pacific Northwest. This city has been the banking centre for this corner of the United States and her banks are the largest and most substantial in the territory. They have a wide reputation for strength and conservative methods. Portland



1 View of Portland, showing Mount Hood **2 View of Portland Harbor**

Scene in Portland harbor

has 23 banks, eight of which are national institutions. In 1918 the bank clearings amounted to $1,323,082,798.21 and the deposits for the year ending 31 Dec. 1918 aggregated $140,-299,968.19. Postal receipts for 1918 were $1,630,000; postal savings for 1918 were $1,800,000.

Livestock Markets.— The rapid and substantial growth of the Portland Union stockyards since their opening in 1909 has conclusively demonstrated that Portland is the one great livestock centre on the Pacific Coast. In fact, it is the only competitive market west of Denver, and is growing in importance each year. Portland's livestock industry in 1918, including packing-house products, involved $75,000,000.

Railroads.— Portland's growth as a railroad centre within the past few years has been almost phenomenal. The fall of 1906, when the Spokane, Portland and Seattle (the North Bank Road, affiliated with the Hill system) was built down the north bank of the picturesque Columbia River at a cost of $53,000-000, marked the opening of a new era in railroad development for Portland, since which time millions of dollars have been expended annually within the State in railway improvement and extension. The completion of this line opened up a vast new territory to Portland. Then came the extension of the Oregon-Washington Railroad and Navigation Company (Harrison system) and the building of the Oregon Trunk (Hill system). The city is also reached from the south by the Southern Pacific. Building of feeder lines, double-tracking and electrifying of present systems, is going on continuously in the territory contiguous to Portland and numerous electric interurban lines stretch out in all directions from the city throughout the Willamette Valley. Most notable among these latter are the Oregon Electric (Hill system) with a total mileage of 154 miles; the United Railways operate in connection with the Oregon Electric, which operates from Portland to Linnton and Wilkesboro, in Washington County, a distance of 28 miles, and the Portland, Eugene and Eastern branch of the Southern Pacific, which has a network of electric lines throughout the Willamette Valley. Two main depots give excellent passenger accommodations and freight terminals and warehouse facilities here are constantly being enlarged to meet requirements of ever-increasing traffic. The great transcontinental railway systems operating into Portland at present include the Northern Pacific, Great Northern, Burlington, Union Pacific, Southern Pacific and Canadian Pacific.

Water Transportation.— Portland's commerce reaches every prominent port. Steamship lines ply to the Orient, to Pacific Coast ports and to the Atlantic Coast via the Panama Canal. The Panama Canal affords much closer connection with Atlantic ports and is having important bearing on Portland's progress. Tramp steamers and sailing vessels carry lumber and wheat from Portland to world markets and the great foreign shipping-houses have branches here. The harbor is in the heart of the city and vessels dock close to wholesale and warehouses.

City and Interurban Transportation.— Excellent street car service is afforded by the Portland Railway, Light and Power Company. The street car mileage of this company totals 215.49 miles within the single-fare zone. Only cars of the most modern type are used, embodying the latest improvements for safety and comfort of the passengers. Frequent interurban electric trains connect Portland and the surrounding district for a radius of from 25 to 125 miles.

Water, Electricity and Gas.— Portland's pioneers were far-sighted and made reservations of Bull Run River, a splendid mountain stream, for the perpetual domestic water supply of the city. A municipal gravity system has been built that brings the water from its source, the Bull Run River, which is fed by melting mountain snows, through conduits for a distance of 24 miles. There is ample supply for all purposes and the water is remarkably soft and pure. Over 67,000,000 gallons of water are carried through two huge pipe lines to the city every 24 hours. The city in 1918 possessed 738 miles of water mains. The chief supply and distribution of electricity for light and power purposes is made by the Portland Railway, Light and Power Company, which operates five water-power plants and four steam plants with a total capacity of 109,340 horse power. The power furnished by this company is all generated within 40 miles of Portland, the hydraulic plants being located on the Willamette River, Clackamas River and Bull Run River. This arrangement, in connection with the five steam plants, ensured reliable service to all parts of the company's system. Some parts of the city are also supplied by the Northwestern Electric Company, with a hydraulic generating plant at White Salmon, Wash., and two steam plants in the city with a present capacity of 34,500 horse power. These two systems combined have a generating capacity in excess of the present demand of approximately 65,000 horse power, ensuring an ample power supply for Portland to meet future demands. There are 50,000 consumers of electricity within the territory served by these light and power companies. Gas for lighting, heating and power purposes is adequately supplied to all parts of the city by the Portland Gas and Coke Company.

History.— When William Overton in November 1843 landed his Indian canoe on the river's western bank and examined the townsite of Portland, now spreading for miles along both shores, his imagination probably did not suggest to him its present magnitude. A solid mass of forest and underbrush, skirted on the one side by the Willamette River and on the other by massive hills, was all that met his view. With William Overton was A. L. Lovejoy, having come from the Hudson Bay Company's resort at Vancouver, Wash., and decided this was the best location for a town site. Mr. Overton disposed of his property to F. W. Pettygrove and the latter and Mr. Lovejoy had the site surveyed and the boundaries established during the summer of 1844. They recognized the advantages of the location and reasoned that some day it must not only become a metropolis of a vast region but also one of the chief seaports of the Pacific Coast. The first house, made of logs, was built in the winter of 1844. F. W. Pettygrove was a native of Maine and A. L. Lovejoy of Massachusetts. The former wanted to name the new town Portland and the latter favored Boston. It was decided by the toss of a coin — «Heads it is Portland,» «Tails it is Boston» — Pettygrove winning twice out of three. Portland was incorporated in 1851. The first city election held 7 April 1851 showed a total vote cast of 140. In 1860 the population was 2,874. The population has more than doubled each decade. If these founders of Portland could now return for one brief moment, the scene which would meet their eyes would without doubt surpass their most sanguine anticipations. They might easily recognize the beautiful snow-capped mountains and nature's many artistic environments of their pioneer home, but this is all that would appear familiar to them. They would find a cosmopolitan city, large blocks of commercial buildings, massive and at the same time models of architectural beauty, while the residences, churches and schoolhouses are not surpassed by those of equally large cities of the East. Pop. 330,000. Consult Gaston, Joseph, 'Portland, Ore.: Its History and Builders' (3 vols., Chicago 1911).

SYDNEY B. VINCENT,
Portland Chamber of Commerce.

PORTLAND, Isle of, a peninsula of the coast of Dorsetshire, England, about four miles long and of an extreme width of one and three-fourths miles. Only on the south is it accessible from the sea, its shores being wild and precipitous. Once an island the waves have built up a narrow ridge of shingle, Chesil Bank, which connects it with the main land. Great quantities of building stone have been taken from its beds of Oölitic limestone, including material for Saint Paul's, London. Portland Castle was built by Henry VIII in 1520. Pop. 17,011.

PORTLAND CANAL, a narrow body of water separating Alaska from British Columbia, and extending for over 80 miles in a northeastern direction. Its shores are precipitous cliffs of from 3,000 to 6,000 feet in elevation.

PORTLAND CEMENT. Portland cement is the product obtained by finely pulverizing clinker produced by calcining to incipient fusion an intimate and properly proportioned mixture of argillaceous and calcareous materials with no additions subsequent to calcination excepting water and calcined or uncalcined gypsum.

The old Roman cements were natural cements or were a mixture of slaked lime and volcanic dust which was found in large quantities in Italy. Indications are that concrete was prepared much as it is to-day and even this combination which is crude in comparison with the modern portland cement concrete produced an artificial stone which has stood the test of time. There is a gap of about five centuries between the Roman times until the next record of the use of cement. In 1756 John Smeaton, an engineer who constructed the Eddystone lighthouse in the English Channel, while searching for a suitable mortar discovered that an impure limestone containing a certain amount of clayey matter possessed decided hydraulic properties when calcined or roasted.

These early natural cements were very different from modern cements, however. It was necessary to use rocks with the proper proportion of material in their makeup and any variation in the composition could not be regulated since the nature of the material was not understood.

Portland cement originated with Joseph Aspdin, a bricklayer of Leeds, England, who in 1824 took out a patent for a cement to which he gave the name of «Portland» on account of its resemblance when hardened to the famous stone used extensively for fine building and found on the Isle of Portland on the northern coast of England. It is interesting to note that about a quarter of a century later came one of the earliest recorded uses of the modern reinforced concrete construction in the building of a reinforced concrete rowboat by M. Lambot, near Carces, France, which is the forerunner of the modern concrete ship.

In his patent, Aspdin signified that definite amounts of clay and limestone be used and described a process of putting these two materials together, then calcining them in the manufacture of his «Portland» cement. This is the distinction between natural and portland cements. As one writer has said, «A natural cement is a gift of Nature depending as it does upon Nature for the proper materials correctly proportioned for the manufacture of cement. A portland cement is a manufactured product, its composition being governed at all times by the proper selection of raw materials of which it is made, and any variation in the composition of these raw materials is easily detected and it is, therefore, a highly dependable product.»

The history of the commercializing of portland cement is a history of inventions and improvements in its manufacture. In this, American engineers and inventors have had remarkable success, for although this country was one of the last to begin the production of portland cement the output to-day has far outstripped that of Europe.

Aspdin's portland cement was found greatly superior to the Roman cement, Puzzoulana cement and hydraulic lime previously used and its manufacture extended rapidly, especially in England and Germany. In this country it was first successfully made at Coplay, Pa., in 1878 but until 1890 practically all the portland cement used in this country was imported from Europe. After that date the industry increased with great rapidity until the United States ranks as the chief cement producing country of the world. From a production of 42,000 barrels of portland cement in 1880, the annual output in the United States rose to nearly 93,000,000 barrels in 1917.

Modern portland cement is manufactured from a mixture of two materials, limestone rock or similar material like chalk or marl which is nearly pure lime and another material supplying the other ingredients needed which is usually shale or clay although blast furnace slag is also used in conjunction with limestone. The one supplies the calcareous materials and the other the argillaceous or clayey materials. It is essential that the mixed raw materials contain certain exact percentages of these ingredients; this proportion differs slightly with different materials but ranges generally 75–80 per cent of carbonate of lime to 25–20 per cent of anhydrous clay.

Material for portland cement must be comparatively free from magnesia since the specifications limit the magnesia content to 5 per cent. The clay or shale must be siliceous, preferably containing two and one-half to three times as much silica as alumina plus iron oxide. In preparing the mixture the proportions must be correct and uniform. It is found that the best results are obtained with mixtures in which the percentage of lime is = 2.8 silica + 1.1 alumina.

In the manufacture of portland cement, the first essential is to mix the raw materials in the correct proportions and grind the mixture to a high degree of fineness. Failure to produce cement of good quality results more often from neglect of the latter precaution than from all other causes combined. In England, the mixture of chalk and clay was generally made by the wet process, in which the materials were stirred with water in wash-mills and the "slurry" allowed to settle in large reservoirs until firm enough to be cut into blocks and dried by the waste heat of the burning kilns. The dry process is generally used in the case of limestone and cement rock, both in Europe and America, although a number of plants using limestone and clay are operating on a semi-wet process. In the dry process, the materials are crushed, dried and finally ground together in tube mills which consist of revolving cylinders partly filled with rounded pebbles. Marl and clay are usually treated by a wet process, in which the materials are mixed as taken from the beds and ground in tube mills with sufficient water to make a thick slurry.

The burning of portland cement was formerly done in simple, intermittent vertical kilns similar to lime kilns or in ring kilns consisting of a number of chambers connected to a central stack into which the fuel was introduced through openings in the roof. Later, continuous kilns were adopted in which the bricks of dry slurry and the fuel were fed in at the top and the clinker periodically withdrawn at the bottom. These three classes of kilns required the materials to be molded into bricks and dried, an operation involving much labor.

In 1885 Ransome patented in England a process of burning cement material in the form of powder in revolving kilns heated by a flame of gas. The invention was a failure in Europe but was taken up and developed by American engineers and found to be especially adapted to conditions in this country. Petroleum was first used as fuel and later this gave place to powdered coal blown in by a blast of air. The rotary process was found to yield cement superior in several respects to the product of the older types of kiln and to be adapted to the burning of cement mixture in the form of dry powder or wet slurry without previous molding into bricks. With the advantage of the rotary kiln, the American portland cement industry began, about 1890, a career of wonderful expansion and development which is still in active progress. At the present time there are more than 600 kilns of this type in operation in the United States and many have been built after American designs in the leading factories of Europe.

There are three distinct and separate operations from the preparation of the raw material to the finished product. The first is mechanical and includes the assembling, preparing, grinding and amalgamating of the raw materials; the second is chemical, during which the material prepared by the first process is calcined or roasted at a high temperature, bringing about chemical composition of the various ingredients. The third and final process is partly mechanical and partly chemical, in which the clinker resulting from the calcination together with a small percentage of retarder is reduced to a fine powder.

In the dry process the raw materials are quarried, crushed, dried, pulverized, and mixed in the proper proportions. The powdering or pulverizing of the raw materials is one of the most important steps in cement manufacture and decided advances have been made in the last few years in grinding and pulverizing machines. Grinding machines nearly all work on the principle of striking or pounding the material between a hammer in some form and a solid metal mass.

After the raw material has been prepared for mixing this operation is accomplished by means of automatic weighing machines which weigh out just the right quantity of each of the two materials. These machines are always under the direct control of the chemist in charge of the operation day and night. There is then a perfect grinding of the raw materials to fine powder called the "raw mix." In the wet process used by some plants, a slurry is made containing the proper amount of each raw material which is then put in storage tanks and from there pumped into the rotary kilns.

The modern rotary kiln consists of a steel cylinder lined with fire brick, generally 60 to 220 feet in length and from 6 to 12 feet in diameter, set in a slightly inclined position upon rollers so that the raw material when fed into the upper end gradually moves toward the lower or discharge end as the kiln slowly rotates about its own axis. The output of the rotary kiln is from 150 to 2,000 barrels each per day. In these kilns the raw mix is burned or "calcined to incipient fusion" by powdered coal blown in at the lower end through a hood with 50 to 100 per cent excess air over the amount theoretically required for combustion of the coal.

The cement mixture in powder or as wet slurry is continually fed in at the upper end and as it travels downward becomes dried (if wet) and is gradually brought to the white heat of the hottest zone, issuing finally in the form of black, rounded nodules of clinker varying in size from birdshot to perhaps two inches. The clinker is cooled and then ground and pulverized to fine powder usually in mills of the pendulum type or in tube mills. About 2½ per cent of gypsum is ground with the clinker to regulate the time of set of the cement. The fineness of grinding is such that at least 78 per cent of the product will pass a sieve of 200 meshes to the linear inch. After the cement has been ground it is usually deposited in bulk bins holding several thousand barrels each. Samples are then taken and complete tests made for fineness, setting, soundness, strength, chemical analysis, etc.

Portland cement is a gray powder weighing from 80 to 110 pounds per cubic foot, depending upon its fineness and how much it has been compacted; in actual practice a sack of cement is ordinarily considered as containing one cubic foot and weighing 94 pounds net. Mixed with water to a paste it sets or hardens slowly, resisting pressure of the finger nail after several hours. After setting it gains rapidly in hardness during the first 30 days, the increase continuing, though more slowly, through a long period of years.

In testing portland cement, the most important qualities to be observed are fineness, time of setting, tensile and compressive strength and soundness. Fineness is determined by sifting through standard sieves of the correct number of meshes and gauge of wire. The time of setting is determined by preparing a test piece of suitable form from neat cement and noting the time at which needles of certain definite size and having certain definite weights cease to make appreciable indentations on the test piece. A needle exerting a different unit pressure on the test piece is used for determining the initial set from that used for determining the final test. For tensile strength briquettes one square inch in smallest section are made by filling standard molds with a plastic paste of cement and sand. These are kept 24 hours in moist air, then immersed in water and broken in a testing machine at the age of 7 and 28 days and if desired at longer periods. Soundness or constancy of volume is tested by making pats of cement with thin edges on plates of glass, keeping them in moist air 24 hours and then exposing in a loosely covered vessel to an atmosphere of steam above boiling water for five hours. These pats should remain firm and hard and show no signs of distortion, cracking, checking or disintegration.

The use of concrete is continually extending and being applied to many new enterprises in the structural and commercial fields. The construction of concrete roads and streets is perhaps the most prominent development of the past decade and has reached such proportions that there are at the present time practically 150,000,000 square yards of such pavement in the United States, an amount sufficient to make nearly 15,000 miles of 18-foot highway. The recent war brought the practical development of the ocean-going concrete ship of large tonnage and the concrete barge for harbor and inland waterway transportation, also the underground concrete tank of large capacity for the storage of crude oil, fuel oil, etc. New uses for the material are discovered almost daily so that the present century may well be called the Cement Age.

PORTLAND STONE, (1) in England, a limestone of the Upper Oölite, located between the Purbeck Beds, the highest of the Jurassic Epoch, and the Kimmeridge Clay. It is so named from the Isle of Portland. It was used in the construction of Saint Paul's Cathedral, Somerset House and other notable buildings. (2) In the United States, the name is applied to the brownstone, much used as a building stone in New York, quarried at Portland, Conn. This belongs to the New Red Sandstone of the Triassic Epoch.

PORTLAND VASE, a cinerary urn or vase and a beautiful specimen of Greek art found in the marble sarcophagus of the Emperor Alexander Severus at Monte del Grano, near Rome, during the pontificate of Urban VIII (1622–44). It is formed of glass of a dark-blue color, and is ornamented with relieved figures in white enamel, representing the marriage of Peleus and Thetis. It is 10 inches high, seven in diameter at the broadest part, and is furnished with a handle on each side. It was placed in the Barberini Palace, where it remained till 1770, when it was purchased by Sir William Hamilton, from whose possession it passed into that of the Duchess of Portland. In 1810 the Duke of Portland gave it on loan to the British Museum, of which he was a trustee. In 1845 a stupidly malicious fellow, or more probably a lunatic, who had been admitted to the museum as a visitor, deliberately smashed it with a stone. It was skilfully repaired, however, and is exhibited to visitors.

PORTO ALEGRE, pōr'too ä-lā'grā, Brazil, capital city of the state of Rio Grande do Sul, about 710 miles from Rio Janeiro, on the left bank and near the mouth of the Jacuhy River, and northwest of the Lagoa dos Patos, on railroads connecting it with the interior. The streets are broad and clean with handsome squares. The charm of the city and its surroundings gave it the Portuguese name of «Smiling Harbor» (Porto Alegre). A hospital, theatre and cathedral are the main public buildings. There are good schools and a large colony of Germans, who, prior to the World War, handled most of the city's commerce. This consists chiefly of the produce of the rich agricultural and grazing lands. It has several steamboat lines to Rio Janeiro, to the former German colony of São Leopoldo, etc. The imports are mostly English and German wares. Porto Alegre was founded in 1742 by colonists from the Azores. Pop. 100,000.

PORTO CABELLO. See PUERTO CABELLO.

PORTO MAURIZIO, Italy, the capital and chief town of the province of Porto Maurizio. It is situated on a promontory projecting into the Ligurian Sea, 14 miles from San Remo, 58 miles by rail southwest of Genoa and 41 miles by rail east by north of Nice. The harbor is formed by two moles and is entered from the south-southwest. Olives are produced in considerable quantities, and there is an extensive shipping trade in fish, agricultural produce and olive oil. The town consists of an old section on a hill and a new section near the sea, the latter containing a fine church, a theatre, a technical school, a school of navigation and a library. Pop. 11,603. Pop. of province, 141,778.

PORTO RICO, pōr'tō rē'kō, or **PUERTO-RICO**, an island of the West Indies and a possession of the United States; the easternmost and smallest of the group of Greater Antilles, about 1,400 miles from New York, 1,000 miles from Havana and less than 1,000 miles from Colón, Republic of Panama; lying between lat. 17° 50' and 18° 30' N. and long. 65° 30' and 67° 15' W. The estimate of its area commonly accepted is 3,608 square miles, or, without Vieques, 3,550. Adjacent and subject to the same jurisdiction are the small islands Vieques and Culebra, in the passage between Porto Rico and the Virgin group; Mona, between Porto Rico and Santo Domingo, and a few other islets.

CARIBBEAN SEA

are ranged in two nearly parallel lines with intervening tablelands and high valleys, crosses the island from west to east, culminating in the peak called El Yunque (3,700 feet) in the northeast. Lower transverse ridges, running northward and southward from the principal chain, sink into the wide plains which border the coasts, forming a large number of pretty scenes and valleys. The eastern and northern slopes, valleys and plains receive an abundant rainfall through all the year, while the regions on the other side of the mountains are often parched by drought. The mean temperature at San Juan ranges in different years from 78° to 82° F., the maximum on record being 99° and the minimum 57° F. The climate of the highlands, where the mean annual temperature is 72° F. or less, is very agreeable all the year, although it contains an excess of moisture at some points. (See also paragraph *History* for statement in regard to hurricanes). The island is well watered. Streams are uncommonly numerous, and some of them are navigable for small craft near their mouths. On the north coast 17 rivers flow into the sea; on the east coast, 9; west of Cape Mala Pascua on the south coast, 16; on the west coast three, beside the outlets of several freshwater lakes. There are several falls of considerable size, the largest being Comerio and Rio Blanco falls. Harbors are those of San Juan, Culebra, in the island of Culebra (at both of which United States naval stations are established), Guánica, Hobos or Jovos, Guayanilla and Ensenada Honda.

Mineral Resources.— It is certain that large quantities of gold were found in the alluvium deposits during the early years of Spanish occupation; it seems probable, therefore, that lodes of gold-bearing quartz or conglomerate will be discovered in the central range from which the streams issue. A systematic geological and mineralogical survey is required. Casual explorations have shown the presence, in several places, of magnetic and specular iron in large quantity, especially in the eastern part of the island; copper, agate of good quality, garnet, malachite, manganite, etc. Here, as throughout the Antillean regions (see CUBA and CENTRAL AMERICA), the older metamorphic rock and conglomerates, even on the summits of the mountains, are covered with limestone formations.

Flora and Fauna.— The island was once covered with a beautiful virgin forest, but unfortunately "Forestry regulations," according to Robert T. Hill, "have not been more wisely observed in Porto Rico than elsewhere in the West Indies"; however, in the highlands the conditions, both in soils and climate, are favorable to vegetation. The trees, which are noteworthy on account of their size or beauty, are the several species of palms and tree-ferns, tillandsia, *Cocobola macrophylla*, lobelia, etc. Useful woods are the ausubo, cedar, aceitillo, mahogany, laurel, West Indian sandalwood, ebony and willow and a large variety of dyeing wood. Trees producing edible fruits and plants valuable medicinally are especially numerous. The fauna includes no indigenous quadrupeds; there are no beasts of prey or wild animals of any kind, and unlike the Caribbees, or the tropical continent, Porto Rico is not infested by poisonous snakes and other noxious reptiles, though centipedes and the tarántula are not unknown. There is a large variety of bees. Birds are multitudinous and are noted both for their fine singing and beauty of their plumage; they include the canary-bird, humming-bird, nightingale, parrot, and doves. The tortoises of the island are said to be closely allied to those of the Galapágos Islands (q.v.). Some of the rivers are well stocked with fish, and the fisheries, on the north coast especially, are valuable.

Agriculture, the Fruit Industry, etc.— — Compared with that of the other West Indian islands, Porto Rico's agriculture is remarkably diversified, the chief products being sugar, tobacco, coffee, pineapples, grape fruit, oranges and other tropical fruits, sea island cotton, textile fibres, bat guano, phosphate and vegetables. The sugar crop for three years was as follows: 1915, 488,943 tons; 1916, 483,-589 tons; 1917, 502,390 tons. Sugar exported in 1917 amounted to 488,943 tons, valued at $54,-015,903, being over 66 per cent of all exports of the island. When the Americans occupied the island there were 250 sugar mills and about 20 centrals. The latter have been increased in number as well as in capacity, due to the protection enjoyed by Porto Rican sugar in the United States markets, while the old-fashioned mills are gradually disappearing by their constant conversion into modern centrals. Next to sugar the tobacco industry takes the lead. But although the number of acres of land dedicated to tobacco has increased by tenfold during the last 20 years, and the quality has been much improved, it may be safely stated that the industry has not yet attained its full development. The cocoanut industry is also very promising; the farmers dedicate more land to it steadily, and better attention is paid to the selection of seed. At present hundreds of acres are dedicated to cotton, and much effort is being made by merchants of San Juan to encourage farmers to increase the acreage as well as improve the quality. There is a ginnery in San Juan. Before the American occupation the oranges and pineapples of Porto Rico were famous for their flavor and sweetness, but they grew wild and in such small quantity that seldom were they exported. Since then, however, the fruit industry has undergone such a favorable change, that while the number of acres dedicated to oranges or pineapples has not been exactly estimated, yet the former are now shipped to the United States in large quantity and in 1917 more than $900,000 worth of pineapples were exported. It may be safely asserted that the fruit industry will be the future industry of this island, as roads are built and better transportation facilities are offered to shippers. Rice, corn, bananas and beans are also raised, but not in sufficient quantity for export trade. Cattle-raising is an important industry, the best pastures lying on the northern and eastern slopes.

Commerce.—The exports of sugar are given above under AGRICULTURE. In 1917 210,399,-365 cigars and 9,571,250 cigarettes were exported. Over 9,000,000 pounds of leaf and scrap tobacco, valued at $3,850,670, were exported in 1917. The coffee crop, which in 1916 amounted to 32,144,283 pounds valued at $5,049,-283, reached 39,615,146 pounds in 1917 with a value of $5,892,081. In the same year oranges to the value of $1,009,737 were exported; fresh pineapples to the value of $916,415; canned pineapples to the value of $139,765; grapefruit to the value of $939,677; and cocoanuts to the value of $438,564. The total imports of 1917 aggregated $53,545,224; domestic exports to foreign countries amounted to $7,855,693. United States goods to the value of $49,539,249 were shipped to Porto Rico in the same year and foreign merchandise to the value of $4,005,975. Porto Rican shipments to the United States in the same year were valued at $73,115,224.

Manufactures.— The chief industries of the island are manufactures of cigars, cigarettes, hats, embroiders, drawn-work, rum, etc. According to the last census there were on the island 939 industrial establishments, employing 18,122 persons, of whom 15,582 were wage-earners, having a total capital of $25,544,385, with an output valued at $36,749,742; of these there were 108 establishments connected with the sugar and molasses industry, employing 5,062 wage-earners and having an annual product valued at $20,569,000; there were 282 tobacco establishments employing 7,025 wage-earners, with annual products valued at $6,060,000. Other classes in order of their importance were bakeries and bakery products, boots and shoe factories, printing and publishing, lumber and timber products, etc.

Railways and Roads.— The undertaking to encircle the island with a railway dates from 1888. By 1892 there had actually been built 119 miles. There are now over 1,100 miles of road in the island and about 300 miles of railway. The railway system connects towns on the west coast and now almost encircles the island and penetrates the interior. A line is operated from Rio Piedras to Caguas inland. Extensions of existing lines are being undertaken and a new line across the island, with many branches, is projected. There are 80 post offices and 73 telegraph stations, 1,544 miles of postal telephone and telegraph wire. Passenger and freight lines connect Porto Rico with the United States, Cuba, Panama, France, Spain and other countries.

Finance.— The annual budget of the island has varied from three to four millions of pesos, aside from city budgets. This budget included from 1,250,000 pesos to 1,500,000 pesos which the Island contributed to the national expense, under the subheads of Ministries of Colonies, War and Navy. In 1909 no appropriation bill was passed and Congress continued the appropriation of 1908.

The budget for 1898–99 (the first year under the home rule system) showed expenditures of 4,446,952 pesos and income of 4,782,500 pesos. The first budget under the civil government established by the Foraker Act was about $2,000,000 (expenditure); that of the year 1906 about $2,500,000 (expenditure). The main source of income under the Spanish rule was from custom duties on imports and exports, especially on sugar, as up to 1901 there was no regular system of taxation in the island. Porto Rico, however, was always able to meet its budget and besides have a surplus in its treasury. It is from this surplus that Spain drew $2,000,000 to fight the Cubans in 1895–96. This money was lost to the island. The taxable property of the island at present is valued at $182,622,164. The present sources of revenue are customs and excise, general property tax, collateral inheritance tax, taxes on insurance companies and from various licenses and fees. The treasury statement of 1 July 1917 is as follows:

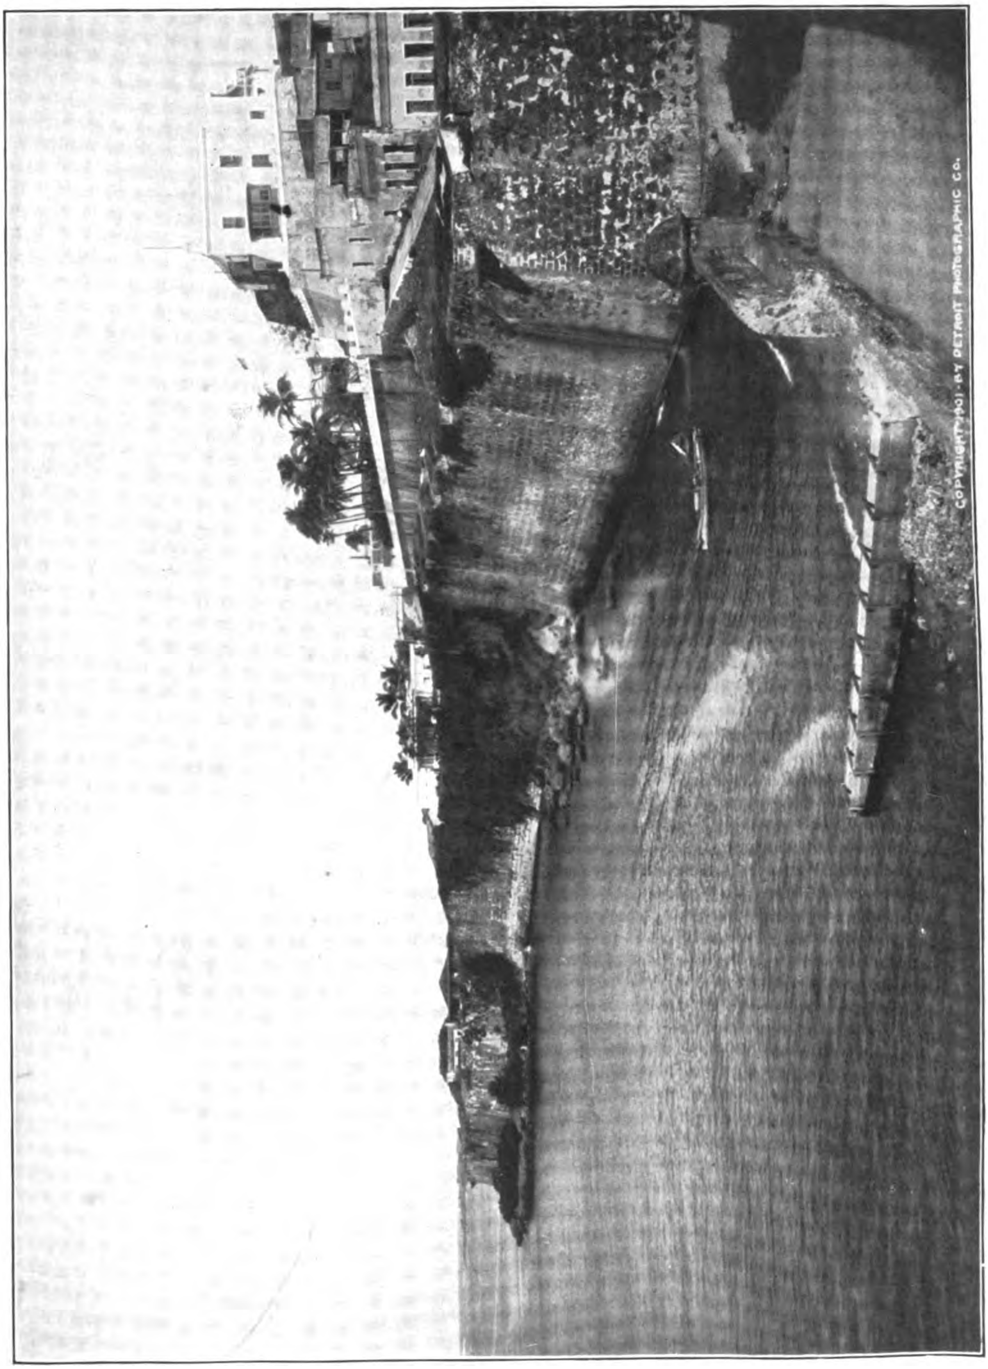
Balance, 1 July 1916	$2,910,648
Receipts, 1916–17	10,937,947
	$13,839,595
Disbursements, 1916–17	9,733,750
Balance, 1 July 1917	$4,105,845

The bonded indebtedness amounts to $9,280,000.

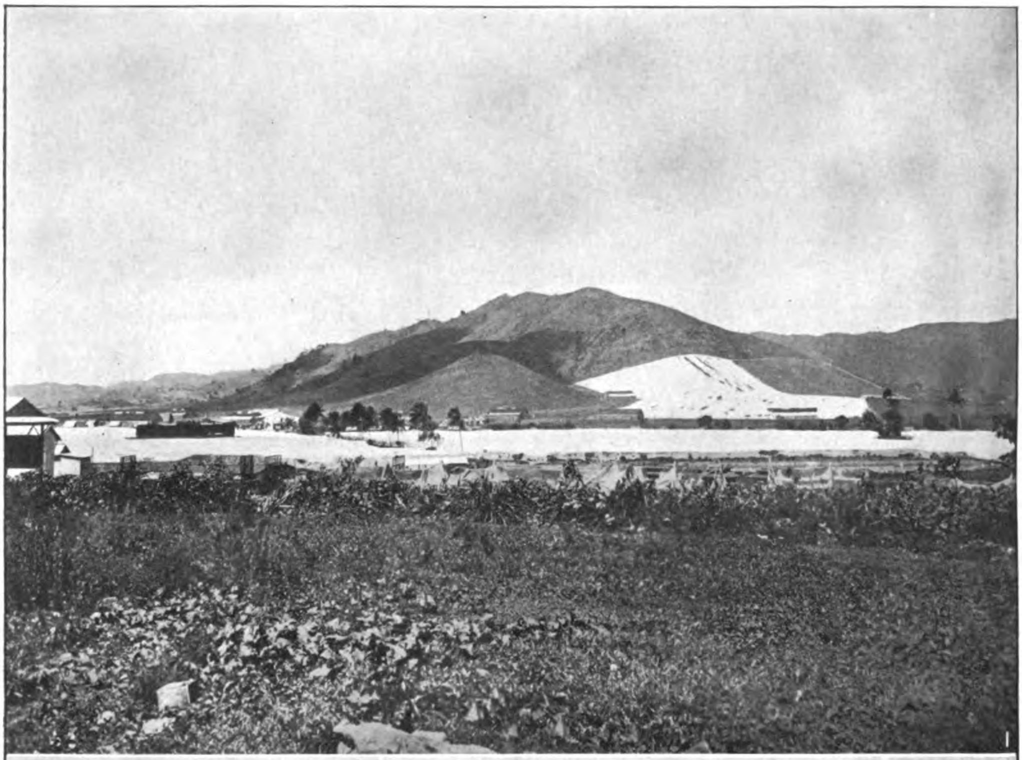
Porto Rico has had several currencies. The macuquina, which was introduced in the island as early as 1800 from Venezuela, was the legal tender up to 1857. This currency was very imperfect; it consisted of pieces of solid silver and copper, irregularly cut, bearing a poor imitation of the Spanish coat of arms and had a discount of 12½ per cent on the Spanish national currency. To withdraw the macuquina money the Spanish government sent to the island 1,350,000 Spanish pesos, the island losing 215,466 pesos, which was necessary to cover the difference in value. In 1867 the island of Santo Domingo having gained its independence, its money, known as calderilla, was brought to Porto Rico. The same year a royal decree allowed the free circulation of foreign money in the island, fixing a relative value on the basis of the Spanish legal tender. This measure brought abundance of money into the island. In 1879 a royal order made the Mexican peso the official currency, given it a value of 95 cents American money; and another royal order in 1881 authorized its free circulation. In 1895 the government ordered the exchange of the Mexican money for what was called the "special currency"; 6,426,393 pesos were thus exchanged, at a cost to the island of $1,210,000 for recoining, transportation expense, etc. This special provincial money was finally exchanged for the American legal standard at a discount of 66⅔ per cent.

Banks.— These institutions were unknown in Porto Rico up to 1888, in which year the Spanish Bank (known now as the Porto Rico Bank) was organized, but not opening its doors until February 1890; capital 1,500,000 pesos, 750,000 paid up; in 1898 it had issued notes to the extent of $2,587,445; head office in San Juan. The Banco Territorial-Agricola (Agricultural Bank) was established in July 1894; capital 2,400,000 pesos; head office in San Juan. The Banco Popular was also organized in 1894 with a capital stock of $18,000; head office in San Juan. The Crédito y Ahoro Ponceño (a savings bank) was organized in November 1894, with a capital stock of $200,000; head office in Ponce. American Colonial Bank was established in 1899 with a capital stock of $400,000; head office in San Juan. National Bank, branch in San Juan, Porto Rico, opened in 1902 with a capital stock of $100,000. Union Bank of Halifax, in San Juan, with a capital stock of $1,500,000, was established in August 1906. There are now 15 banks with combined capital aggregating $2,250,000, deposits over $12,000,000.

Population.— On 14 Dec. 1910 the number



San Juan



1 Porto Rican Tobacco Fields

2 Harbor of San Juan

of inhabitants was 1,118,012 (consisting principally of whites, mulattoes, negroes and Chinese). It is to be observed that while the census taken in 1887 shows a black population of 76,985, and that taken in 1897 reduces the figure to 75,824, the census of 1899 further reduces the figure to 59,390. If this decrease should continue for a number of years, the black race would eventually disappear from Porto Rico, unless there is an immigration of that race from the other West Indian islands in the future. This is the only island in all the West Indies where the white population is so overwhelmingly in the majority. At the last census there were 50,245 negroes and 335,192 mulattoes, 732,555 whites and 20 Chinese. In 1910 the colored population was 35 per cent of the whole. The estimated population in 1914 was 1,184,489. Of the working population 63 per cent are engaged in agriculture, fisheries and mining; 21 per cent in domestic and personal service; 8 per cent in manufacturing industries and 8 per cent in trade and transportation. The percentage of illiteracy which was over 83 per cent in 1899 has been reduced to 66.5 per cent. The white population was divided into three classes: (1) the aristocracy of the country, not seldom colonial branches of excellent families of Spain; (2) trades-people in the towns; (3) a peasantry plagued with anæmia, the so-called *jibaros,* of whom Mr. van Middeldyk says: «Intellectually the *jibaro* is as poor as he is physically. His illiteracy is complete.» But the *jibaro,* it must be admitted, has had hard luck. The descendants of the early Spanish colonists and in the majority of cases of the Indians, they retained the superstition of the former and a little of the natural timidity and reserve of the latter. These atavic traits, added to the fact that they have been robbed and deceived by the Spanish merchants, who took advantage of their ignorance, reducing them to a sort of serfdom worse than slavery, have made them what they are to-day, a physically degenerated class with no ambition whatever. They are, however, naturally bright and generous, and once you have gained their confidence, dispelled their mistrust, they are most hospitable and loyal. Above all they love peace and fear the law. Education, which they never had a chance of getting, and the development of the interior, will improve their way of living, awake their dormant intellect and redeem them from their present debased condition.

The members of the first class who were rich and could receive a liberal education went to Europe or the United States, where they would become lawyers, physicians, engineers, etc., and return to their country to practise their profession. Those who were poor were compelled to remain home, contented with what knowledge could be acquired in a very reduced number of public schools, a normal school and a high school in San Juan (where the degree of bachelor of arts could be obtained); the second and third classes did not receive any education at all, except in rare cases, no efforts being made by the government to raise the standard of education either by making it compulsory or by furnishing sufficient public schools, the number never exceeding 124 and the system being extremely antiquated.

Education.— In 1899 only 16 or 17 out of 100 Porto Ricans could read and write. Under the new government the number of schools was increased to 1,104; local authorities were required to provide suitable school buildings; primary instruction was made compulsory; and existing institutions of higher education were supplemented by normal, trades and high schools. In 1917 there were 1,666 school buildings, with 115,000 pupils enrolled; and a well-distributed system of night schools and kindergartens. There are also a number of private schools. The University of Porto Rico, established in Rio Piedras, near San Juan, is coeducational. There are 41 school districts on the island, each under a supervising principal, who is appointed by and represents the Commissioner of Education. There are local school boards of three elected for terms of four years by popular vote.

History and Government.— On 19 Nov. 1493 Columbus landed on the western coast, and named the island San Juan Bautista. On 14 Aug. 1509, Juan Ponce de Leon, who had discovered gold on the island, was appointed governor by King Ferdinand. The natives, who called their island Borinquén, and had chiefs of their own, were enslaved and forced to work the placer deposits. In June 1511 the Indians slaughtered about one-half of the Spanish force, but were reduced to submission. The aboriginal population at that time probably numbered from 80,000 to 100,000 (not 600,000 — an estimate often repeated, but resting upon a wholly unwarranted statement in Friar Abbad's 'Historia'); on 27 April 1515 Counselor Sancho Velasquez wrote to the king that, excepting the Indians assigned to the royal estate and those of the Crown officers, «there are not 4,000 left.» The greater number of the natives perished; some poisoned themselves; others emigrated to the neighboring islands — so cruelly were they treated — and the rest gradually blended with the invaders. About this time it became customary to refer to the capital as «Puerto Rico,» instead of Capárra. Thus modern usage precisely reverses the original intent; for the name Columbus gave to the island is applied only to its chief town, while the name by which Ferdinand designated the settlement on the northern «port» has supplanted both «Borinquén» and «San Juan Bautista.» On 26 Feb. 1521 Ponce de Leon sailed on his second expedition to Florida. Again disappointed and repulsed, he did not return to Porto Rico, but sought refuge in Cuba, where he died. On 18 April 1533 the authorities of the capital petitioned the empress against the further introduction of African slaves. It appears from a letter written by Governor Lando to the emperor in 1534, that very few negroes had been sent to the island up to that time; but a few years later they arrived in large numbers, taking the place of the Indian laborers. Palm Sunday 1554, the principal settlement on the south coast was destroyed by a landing party from three French ships. On 22-25 Nov. 1595 Sir Francis Drake, commanding a strong fleet, attacked San Juan. That port was well defended and the English withdrew. Two years later a large body of English troops, under the Duke of Cumberland, occupied San Juan, then garrisoned by a small body of troops, for a few months. From 25

Sept. to 2 Nov. 1625 San Juan was besieged by a Dutch fleet; landing was effected, but the besiegers were compelled to withdraw with heavy losses. The city was under the command of Don Juan de Haro. From 1640 to 1780 expeditions were equipped in Porto Rico for the long struggle with the buccaneers. In 1702 some English troops landed at Arecibo, but were defeated by a body of militia under Captain Correa. On 17 April 1797 an English fleet, 15 ships and several transports, under Admiral Harvey, with troops commanded by Sir Ralph Abercromby, numbering over 6,000 strong, appeared before San Juan; the city was under the command of Don Ramón de Castro, who gathered with him among regulars, militia and volunteers, about 4,000 men. The forts were manned by Frenchmen, then the allies of the Spaniards. The invading force landed back of the city by the place known as Cangrejo, and marched on to the city, but before they came to the San Antonio bridge, they met such strong resistance, both from the infantry and artillery on the forts, that they were compelled to re-embark, apprehending an attack from the rear, with great losses both in war materials and men. The ineffectual siege was maintained only 15 days. This attack and that made by the Dutch in 1625 are perhaps the most important events in the history of the island since the conquest from a military standpoint. To the city, as a reward for gallant resistance at this time, was granted the privilege of adding the words "very noble and very loyal" to its coat-of-arms. Loyalty was strikingly evinced early in the following century. On 20 Dec. 1819, in February 1825 and November 1829 expeditions from Colombia landed in Porto Rico, to encourage the inhabitants to rebel against Spain; they were not welcomed. Nevertheless, in 1837, Porto Rico was deprived of the right of representation in the Spanish Cortes, which she had since 1808, as a result of the advent of Ferdinand VII to the throne. During half a century the captains-general as a rule favored a systematic demoralization of the common people. "While they dance and gamble, they will not conspire," said one of these pernicious governors. Another means by which the government encouraged the demoralization was by promoting and giving good offices to those of the natives who would be traitors to their country by denouncing imaginary conspiracies and revolutions. But one fact about this little people is that, while they feel proud of their Spanish ancestry, yet neither money nor threats could ever win an intellectual Porto Rican to serve the cause of tyranny. On 20 Sept. 1868 the "insurrection of Lares" broke out — an insignificant rising, quickly suppressed. The plan was to follow Cuba, which island was then struggling to throw off the Spanish yoke. Dr. Betances, the leader of this movement, escaped to the neighboring island, and then went to live in exile in Paris, where he died some 30 years later, never forgetting his little island, and never forgotten by those whom he once dreamed he could free. As one result of the revolution of that year in Spain and the subsequent establishment of the republic, Porto Rico was again permitted to send representatives to the Cortes. On 22 March 1873 the slaves in Porto Rico were manumitted, 31,000 receiving freedom in a single day. The slaveholders were paid in government bonds, which a foreign syndicate bought up at 15 per cent. Then followed a period of political unrest with the restoration of the monarchy, marked by abuses of all kinds committed by the officials sent by Spain. By this time, 1873–74, political parties were organized following the line of the Cuban reform party and later (1886) the Home Rule party. This movement on the part of the Porto Rican patriots brought about in 1887, under General Palacios, what is called the "Componte" era, when the people were tortured by the mounted police (*Guardia Civil*), and the most honorable citizens were thrown into the dungeons of "El Morro" and barely escaped being shot. This is perhaps one of the darkest periods of the colonial history of the island. By the end of 1896 the Porto Ricans again began to feel the influence of the Cuban ideas, and the western part of the island showed a disposition to revolt, and might have done so if some one of the Porto Ricans who had gained honor and renown in the Cuban War had landed to lead them. But as a rule the Porto Ricans are a peace-loving people; they at all times preferred to gain what liberties they could bargain from Spain by means of the press and other means of propaganda, rather than resort to arms. It was about this time that some prominent citizens from Camuy were imprisoned and tortured and everything indicated that the horrible scenes under General Palacios were to be once more repeated under General Sabás Martín. It was now, however, too late for this, for although the Spaniards never doubted that they would ultimately come out victoriously from a conflict with the United States, nevertheless a little apprehension as to the future made them more humane and cautious in their treatment of defenseless Porto Ricans. On 25 Nov. 1897 the royal decree conceding autonomy to Porto Rico was signed.

After 400 years of a military government of a most absolute character, Porto Rico finally secured what is called an Autonomic Constitution, which gave the island a Parliament consisting of a senate of 15 members, eight of whom were elected by the people and seven appointed by the Crown; and a lower house, consisting of one representative for every 25,000 inhabitants. The system also provided for a body of five ministers,— Minister of Justice and State (Gracia, Justicia, y Gobernacion), of Finance, of Education, Public Works and Roads, and of Agriculture, Industry and Commerce,— appointed by the governor, thus practically providing for the separation of the three powers. The power of veto was retained by the government at Madrid. It has been asserted by the natives that this measure of home rule fully satisfied their ambition. Notwithstanding it has often been set up against this law that it was not in good faith, and was not to stay, being only a measure of war and a trick of Spain to induce the Cubans to lay down their arms. It is probable that the law was so intended; those, however, who so speculate seem to forget that colonizing nations never granted any degree of liberty to their colonies, except they were compelled to by the force of circumstances; but no one will question the fact that once Spain had granted to her colonies in America a liberal form of government, she could never have been able to restore on this side of the ocean her 16th century régime. This self-government, however, was of short duration, for a few months after the elections, 21 April 1898, Governor-General Macias suspended the constitutional guarantees and declared the island in a state of war. On that day war began between the United States and Spain, though not formally declared until the 25th. On 12 May 1898, the capital was bombarded by Admiral Sampson, only a few buildings being damaged and probably a dozen casualties. On 25 July 1898 American forces occupied Guanica; three days later Ponce; on 10 August skirmishes took place at Hormigueros and Guamani, on the west and southeast parts of the island, and on 12 August at Las Marias, on the west, and near the Asomante, on the Ponce road. On 12 Aug. 1898 the protocol was signed providing for the cession of Porto Rico, etc., to the United States; 18 Oct. 1898 the last of the Spanish troops to sail embarked for the peninsula; the forces of the United States occupied San Juan, Maj.-Gen. John R. Brooke taking up the duties of military governor. His successors in that office were: on 6 Dec. 1898, Maj.-Gen. Guy V. Henry, and 18 May 1899, Brig.-Gen. George W. Davis. This government is noted in the history of Porto Rico for its mildness and wisdom. On 8 Aug. 1899 a hurricane, accompanied by excessive rainfall, devastated the island, 3,369 persons being killed outright, while thousands died from starvation. The army distributed 32,000,000 rations to the sufferers. Disasters of this nature have befallen Porto Rico, although probably never so severe, more than 20 times since the year 1515, occurring most commonly in July, August and September. On 12 April 1900 an act of Congress required that there should be established for Porto Rico a modified territorial form of government, consisting of executive, legislative and judicial branches. For the benefit of such government a tariff of 15 per cent was imposed on imports from the United States into Porto Rico, and vice-versa. On 1 May 1900 civil government was inaugurated, having the following general features: Governor, appointed by the President of the United States; legislative assembly, consisting of an executive council or senate appointed by the President (six Americans and five Porto Ricans), and a house of delegates (35 members elected by the people); judiciary, including Supreme and United States District Courts. The first governor was Hon. Charles H. Allen. His successor, 15 Sept. 1901, Hon. William H. Hunt; 25 July 1901 the President proclaimed cessation of tariff duties between Porto Rico and the United States. On 2 Dec. 1901 the Supreme Court of the United States decided that Porto Ricans were not *ipso-facto* citizens of the United States. In December 1902 the insular treasury had on hand a considerable balance from revenues produced by the system of local taxation enacted by the legislative assembly. On 4 July 1904 Beekman Winthrop took the oath of office as governor; followed by George R. Colton. Mr. Colton was succeeded by Arthur Yager in 1913. The present constitution is determined by the "Organic Act" of 1916, the main features of which are the granting of American citizenship to the people of Porto Rico, the separation of the legislative and executive departments, extension of the appointive judiciary system and an elective senate. The franchise is restricted to citizens of the United States 21 years of age or over, residence of one year and such additional qualifications as may be prescribed by the legislature, but no property qualification may be imposed. The governor is appointed by the President of the United States. The senate is composed of 19 members and the house of representatives of 39 members. The island is represented in the United States Congress by a resident commissioner elected for four years. Six heads of departments form a council to the governor.

There are two political parties in Porto Rico, both working to change the status of the island; one, which is called the Republican party, with a marked tendency for Americanization, wants the island to become a State of the Union, and the other, the Unionist party, with a platform advocating either home rule under a colonial government, statehood or independence. In one point both parties agree, and that is that the upper house, which is now appointive, should be elective, at least a majority of it.

Literature, History, Arts.— Porto Rico has a considerable literature. It is not very intense or varied, but it has originality. *Poets:* The natural beauty of the country, its exuberance, and the despotism to which it has been subjected, have fostered poetic production, the genre of literature more successfully cultivated. Among the poets who flourished between the years 1860 and 1880 are José Gauthier Benitez, of exquisite sensibility, a Lamartinean melancholy and a rare sense of beauty; and José G. Padilla, better known as the "Caribe," a brave heart, who gave vent to his patriotic indignation in vigorous and well-rhymed stanzas. Decadence set in after the death of these two poets. There are, however, some younger poets of considerable talents, among who may be mentioned J. de Diego, Lola Tio, R. del Valle, J. Gordil, Negron Sanjurjo, F. Cestero, E. del Toro, Negron Flores, and F. G. Marin who was killed in Cuba fighting for the cause of liberty. *Historians* (local): By the middle of the 19th century Alejandro Tapia published his 'Biblioteca Historica de Puerto Rico'; later J. Julian Acosta published a revised and commented edition of the 'History of Porto Rico' by Fray Iñigo Abbad; and among the contemporary authors we have Salvador Brau and Drs. Stahl and Coll. *Orators:* Manuel Corchado, who died while still young (1840–84), has been perhaps the most eloquent orator produced by Porto Rico. His brilliant speeches in behalf of the liberties of his country are still remembered. He was also a poet and writer. Among the orators of the day are J. Hernandez Lopez and R. Matienzo Cintron, both powerful and brilliant, good specimens of the best parliamentary speakers, and Alvarez Neva, a powerful forensic orator. *Journalism:* This was the means chosen by the Porto Ricans to contest the Spanish oppression from the middle of the 19th century. This journalism, however, is not as it is understood in the United States; it is more of doctrinal and polemic character; but reporting is gradually creeping in, and we may say that the influence of modern ideas in Porto Rico is nowhere better manifested than in the field of journalism. Among the ablest newspaper men of the day are L. Muñoz Rivera, Dr.

Zeno Gandoa, Manual Rossy and Matos Bernier. *Music:* The higher order of music is not cultivated in the island, so far as production is concerned; there are, however, some clever composers of «danza,» a dancing piece, a sort of a rondo andante which, being exceedingly graceful and melodious, evinces better than anything Porto Rican the nature and sensibility of this people. *Painters:* Campeche and F. Oller.

PORTO RICO, University of, an institution for the promotion of higher education, created by an act of the insular legislature which was approved 12 March 1903. The president of its board of trustees writes that one of the first acts of the «army officers» during the occupation of the island by military forces of the United States at the close of the Spanish-American War was the establishment of a normal school. (For the need of instruction, and of teachers to give it, see PORTO RICO: *Population and Education*). That school was located at Fajardo on a site of 80 acres given for the purpose by the citizens of that town. It soon became evident, however, that a more central location was required, and, therefore, in 1901 the school was transferred to Rio Piedras. When the university was founded (1903) the normal school with its land, etc., passed under the control of the university board of trustees and became the first department of that institution to be put into full operation. In its building and equipment the normal department has enjoyed the liberality and interest of the people of Porto Rico. Its growth has been steady. At the April 1913 meeting of the board of trustees of the university resolutions were passed creating a college of law, college of pharmacy, university high school and extending the course of the college of liberal arts to four years, giving authority for the granting of the degree of bachelor of science or bachelor of arts upon the satisfactory completion of this course. The college of liberal arts had, indeed, been legally constituted since 1911, but no particular effort had been made to attract students. The president of the University of Porto Rico states that the act of 12 March 1903 vested authority in a board of trustees composed of 11 members; that the bond of connection between this new university and the Department of Education was preserved through the appointment of the commissioner of education as president of the board of trustees and chancellor of the university, ex officio; and that «except for this connection, the university is an independent and separate department of the insular government.» The same act gave the board of trustees power to establish new departments and the right to confer degrees. Subsequently the number of members of the board of trustees was reduced from 11 to 7, the governor appointing four while the remaining three, namely, the commissioner of education, the treasurer of Porto Rico and the speaker of the house of delegates, are ex officio members. The work of that department known as the college of agriculture and mechanic acts, at Mayaguez, was begun in 1912. Consult Annual Reports of the Governor of Porto Rico (in Annual Reports, War Department, Washington).

PORTO RICO EXPEDITION, Military and Naval Society of the, an association projected at Caguas, Porto Rico, 11 Oct. 1898, and formed at Columbus, Ohio, 5 June 1900, to bring into permanent relationship the men connected with the military and naval operations during the Spanish-American War which led to the acquisition of Porto Rico by the United States. There are three classes of members, active, associate and honorary. The active members comprise those officers and enlisted men in any branch of the United States service who accompanied the Porto Rico expedition and were on the island on or before 18 Oct. 1900, the day when the American flag was raised over the Capitol at San Juan. The associate members are those soldiers or sailors of good reputation who were attached to organizations or vessels which composed the expedition but who, through sickness, disability or by assignment to other duties, were detained in the United States and failed to actively participate in the expedition. Members of the Red Cross Society, volunteer nurses and others who served with the army in Porto Rico may also become associate members.

PORTO SANTO, pōr'too sän'too, one of the Madeira Islands, 26 miles northeast of Madeira (q.v.). Its area is about 20 square miles. It is six to eight miles in length, two to three in breadth and not more than 500 feet above sea-level, though the surface is rugged and hilly. It is of volcanic origin, and almost destitute of trees. The soil is poor; the only productions are limestone, maize, barley, vegetables, a few fruits and a poor kind of wine. Its capital, La Vilha do Porto Santo, on a handsome bay with a good harbor, protected by a battery, is frequented by vessels going to and from the Cape of Good Hope. Pop. of island about 1,600.

PORTOBELLO, pōr-tō-bĕl'ō, Scotland, a suburban watering-place of Edinburgh, three miles to the east, on the Firth of Forth. Its first house was built in 1742 by one of Admiral Vernon's officers, in the expedition against Puerto Bello, whence its name, but its progress dates like that of its east extension, Joppa, from 1804. It has some manufactures of glass, pottery, bricks, etc., and is fully equipped with the usual accompaniments of a popular summer sea-bathing resort.

PORTOVIEJO, pōr"tō-vē-ā-hō, Ecuador, the administrative seat of Manabi Province, 100 miles north of Guayaquil. It was founded in 1534, and was frequently captured and destroyed by buccaneers. It has manufactures of straw hats.

PORTRAITURE. See PAINTING; PHOTOGRAPHY.

PORTSEA, pōrt'sē, England. See PORTSMOUTH.

PORTSMOUTH, pōrts'mŭth, England, the principal naval station of Great Britain, a seaport and municipal and parliamentary borough, in Hampshire, on the southwest extremity of Portsea, 68 miles southwest of London by rail.

The island of Portsea is bounded on the east by Langston Harbor, on the west by Portsmouth Harbor, and on the south by the roadstead or channel of Spithead, across which is the Isle of Wight; it is separated from the mainland by a narrow creek called Portbridge Canal. It consists of the four districts, Portsmouth proper, Portsea, Landport and Southsea, these being now more extensive than the towns to which they belong. The towns, united so as to form a fortress, are protected by one of the most extensive modern systems of fortifications, which have replaced the former moats, walls, and ramparts, entered by four gates, one of them designed by Inigo Jones. Landport and Kingston are adjacent to Portsea on the north, and Southsea, on the east side of the town of Portsmouth. The two first-named districts are for the most part occupied by artisans connected with the royal naval dockyard in Portsea. A fine park, the Victoria, is in a conveniently central situation. Southsea is one of the favorite English seaside resorts. Its situation commands fine views of the anchorage at Spithead, and of the Isle of Wight. Southsea common, which extends down to the beach, forms a fine public recreation ground, and on it troops from the neighboring garrisons are often assembled for field days and reviews. Southsea Castle with its adjacent earthworks, the batteries of the Gosport side, and the circular forts in the roadstead, command the entrance to Portsmouth Harbor. The town of Gosport on the opposite side of the harbor entrance is connected with Portsmouth by a floating bridge ferry.

The best street in Portsmouth is the High street, which divides the town into two nearly equal parts and contains the principal shops, hotels and places of business. The prominent public buildings include Government House, the splendid new town hall opened in 1890, the post office, the grammar school, Athenæum, Theatre, hospital, Sailors' Home, Central Railway station, the parish church (Saint Thomas à Becket's), built about 1170, the Roman Catholic cathedral with schools adjacent, the Presbyterian Church, the Independent Chapel in King street, and numerous other places of worship.

The royal dockyard, which has been extended by the addition of new docks and basins, covers an area of about 500 acres. It is enclosed by a wall 14 feet high, and entered by a lofty gateway. It includes vast storehouses, machine-shops, extensive slips and docks, ranges of handsome residences for the port-admiral and other officials, etc. Outside the dockyard an area of 14 acres contains the gunwharf, where vast numbers of guns and other ordnance stores are kept; and there is an armory with 25,000 stand of small arms.

Portsmouth has no important manufactures except those connected with its naval establishments, and a few large breweries. Its trade, both coasting and foreign, is of considerable extent; the former consisting chiefly of coals from the Welsh and Newcastle coal fields, cattle and sheep from the Isle of Wight and the west of England, and large quantities of corn and provisions from Ireland; and the latter of wine from different parts of the Continent, eggs from France, and timber from the Baltic.

Portsmouth is mentioned in the *Saxon Chronicle* as existing in 501. It appears to have taken the place of Porchester, which as *Portus Magnus* had been selected by the Romans for a naval station, but became unfit for that purpose in consequence of the silting of the harbor. During the reign of Alfred a fleet of nine ships fitted at the port defeated the Danes, who had long infested the coast; and immediately before the Conquest a large fleet was fitted out here to intercept the Norman armament. About 1256 Henry III assembled an army here for the invasion of France. In 1377 Portsmouth was attacked by the French, who succeeded in burning a part of the town. This disaster appears to have shown the necessity of fortifying the place, and the works, commenced by Edward IV, were much improved and extended during succeeding reigns. The town was taken by the Parliamentarians in 1642. The *Royal George* battleship in 1792 heeled over and sank in Portsmouth Harbor, drowning nearly 1,000 persons. Pop. about 231,141.

PORTSMOUTH, N. H., city, one of the county-seats of Rockingham County, on the Piscataqua River near its mouth, and on the Boston and Maine Railroad, 57 miles north of Boston. It was first settled in 1623 by a company under the direction of Fernando Gorges, and was under the jurisdiction of Massachusetts until 1679, when New Hampshire became a separate colony. It was incorporated as a town in 1653, when it received the name of Portsmouth, and became a city in 1849. It was the capital of the State for some time, and is now alternately with Concord the seat of the sessions of the United States District Court of New Hampshire. It is built on a peninsula, and has an excellent harbor, deep, well sheltered and always free from ice; it is the only seaport in the State, yet has practically no foreign commerce, but a considerable coasting trade, particularly in coal. Over 1,000,000 tons of coal are shipped annually to Dover, Concord, Manchester and other inland cities. The harbor is protected by earthworks at Jaffrey's Point and Gerrish's Island. The manufacturing establishments are important; they include boot and shoe factories, cotton mills and marble works, button works, tanneries, foundries, oil refineries, lumber yards. Shipbuilding was formerly an important industry, and small vessels are still built. The industrial output of the city is valued at $3,000,000 yearly. It has railroad and trolley connection with York Beach, Hampton Beach, and other popular summer resorts; and, in the summer, daily steamboat connection with the Isles of Shoals. It is a quiet city and old-fashioned in appearance, containing many colonial houses of historic interest; chief among these are the Wentworth house, the Warner house, the Moffatt house, the Pierce mansion and the Langdon house. Other buildings of note are the Saint John's Church, the North Congregational Church, the Federal custom house, the Athenæum, the Rockingham County courthouse, the Portsmouth Hospital, the three national banks, two savings banks and the trust company. The latter has a library of over 25,000 volumes, and there is also a public library of 20,000 volumes. The city contains a Home for Indigent Women, a Home for Children and other charitable institutions. The navy yard, which is officially known as the Portsmouth navy yard, is situated on an island of the Piscataqua (formerly known as Fernald's Island), within the limits of the township of Kittery, Me. It has large drydocks and in the days of wooden ships many were built here including the *Ranger* and the *Kearsarge*. For many years the historic frigate *Constitution* was kept at this navy yard, until taken to Charleston. In 1898 the Spanish prisoners from Cervera's fleet were brought here and given comfortable quarters on a small island connected with the navy yard island. The treaty ending the Russo-Japanese War was negotiated at Portsmouth in the «Peace Building,» on Leavey's Island. There are three public parks, Langdon, Haven and Goodwin. There is a statue of General Porter in Haven Park and a Soldiers and Sailors' Monument in Goodwin Park. There is also a large public playground. The city government is vested in a mayor, who holds office for a year, and a legislative council. The police commissioners are appointed by the State. The waterworks are under municipal management. Pop. 11,602. The city claims among her illustrious sons Gov. Benning Wentworth, his nephew, Gov. John Wentworth, Gov. John Langdon, Tobias Lear, the private secretary of George Washington, Benjamin P. Shillaber, James T. Fields, Thomas Bailey Aldrich and Gen. Fitz John Porter.

PORTSMOUTH, Ohio, city and county-seat of Scioto County, at the confluence of the Scioto and Ohio rivers, at the southern terminus of the Ohio Canal, and on the Chesapeake and Ohio, the Baltimore and Ohio, the Norfolk and Western, the Chesapeake and Ohio Northern and the Ohio Valley Traction Line railroads, about 80 miles in a direct line south of Columbus and 107 miles east by south of Cincinnati. It has steamboat connection with all the Ohio River ports. It was settled in 1803 and in 1814 was incorporated. It is in an agricultural region, and in the vicinity are valuable deposits of fire-clay. It is the commercial centre of an extensive mining and manufacturing section. The chief manufactures of the city are steel mill products, foundry and machine-shop products, paving and building brick, fire-brick, cars, lumber products, stoves, ranges, beer, rectified spirits, paper boxes, wagons, carriages, furniture, veneer factory products and boots and shoes. The invested capital in manufacturing plants is $7,500,000; and the value of the products aggregates $10,000,000 yearly. The principal public buildings are the government building, county courthouse, municipal buildings, some of the business blocks, the church and educational buildings. It has a city hospital, homes for old ladies and orphanages. The educational institutions are the public and parish schools, several private schools, a public library and the Hamilton Peebles reading room. The principal parks are Athletic, Grandview, York, Millbrook and Tracy. In the vicinity are interesting remains of the Mound Builders.

The government is vested in a mayor, who holds office two years, and a council. The administrative officials who are chosen by popular vote are the members of the school board, the justices of the peace, the board of public service, the assessors, city treasurer, city solicitor and city auditor. The business management of the city is in charge of the board of public service. Other subordinate officials are appointed by the mayor, subject to approval by the council, or are elected by the council. The city owns and operates the electric-light plant and the waterworks. Pop. 30,000.

PORTSMOUTH, R. I., town and county-seat of Newport County, 10 miles north by east of Newport, on the New York, New Haven and Hartford Railroad. It has a public library, courthouse, good schools, churches, etc. Agriculture and fruit-growing are the chief industries. Pop. 2,861.

PORTSMOUTH, Va., city and county-seat of Norfolk County, occupies the western or mainland side of the harbor of Norfolk-Portsmouth, where the larger rail systems of the South — the Southern Railway, Atlantic Coast Line Railroad and Seaboard Air Line Railway — have their deep water terminals; other lines serving Portsmouth are the New York, Philadelphia and Norfolk (Pennsylvania System), Chesapeake and Ohio, Virginia, Norfolk and Western and Norfolk Southern. Norfolk which lies just across the harbor is connected by a commodious steam ferry which runs at 10 minute intervals, also by railroad ferries. The city is governed by a council of seven, one of whom is the chairman and in all respects is mayor, excepting he is without the power of veto. The council selects a manager and the people expect results. This new form of government took effect 1 Sept. 1916. Real estate and personal valuations total $15,297,507, which together with railroad property assessments and the government holdings bring the total to $32,297,507. Portsmouth was named for the city of that name in England. Its most notable feature is the navy yard; although situated within seven blocks of the heart of Portsmouth, it is officially known as the Norfolk navy yard. Built by the British in the 18th century, it was purchased by the United States in 1801. Burned by the Federals in 1861, it was rebuilt by the Confederates and held by them until Portsmouth was reoccupied by the Federals near the close of the war. It is now the most important and largest in the country, occupies 350 acres, has three large drydocks and another has been authorized by Congress. General travel is facilitated by the centring in this harbor of five other roads and numerous steamship and steamboat lines, while foreign transportation is represented by many of the great trans-Atlantic lines. It is estimated by the United States government that the value of the traffic passing through the harbor during the fiscal year 1915 approximated in value $1,373,142,923 and represented a tonnage of 36,433,935. Exports during the same period totaled $20,000,000 and imports nearly $4,000,000. Seventy-five manufacturing concerns representing 42 industries have sprung up within a comparatively short period, due to a manufacturing zone that followed the building of a belt line railroad to facilitate the interchange of freight between the eight rail lines. Cotton seed oil products, soap for textile purposes, talcum powder, creosoted conduits, underwear, hosiery, excelsior, butter dishes, copper smelting, cotton seed hull products, blotting paper, paper boxes, dyeing, box shooks, etc., are among the many items that are manufactured here. Portsmouth contains a naval training station, a naval magazine and a United States Naval Hospital and park; also the King's Daughters Hospital, armory, public library, orphanages, homes for the aged, a Y. M. C. A. building, Trinity Church, built in 1762 and several large commercial structures. Pop. 39,658.

PORTSMOUTH, Treaty of. The treaty of peace signed 5 Sept. 1905 at the navy yard, Portsmouth, N. H., which ended the Russo-Japanese War, 1904–05. After nearly 16 months of war between Russia and Japan over the former nation's occupation policy in Manchuria (q.v.), President Roosevelt in the early part of May 1905 made known his sincere belief that the time had come for the two belligerents to end the war and conclude peace. In accordance with these proposals Russia and Japan named their plenipotentiaries, who were sent to the Portsmouth, N. H., navy yard, which had been selected as the place of conference, and on 10 August the negotiations were begun. On 29 August an accord was brought about, the treaty signed by the plenipotentiaries on 5 September, and approved by the emperor of Japan and the tsar of Russia on 14 October to take effect on the 16th. Japan consented to yield some of the Manchurian territory won and Russia consented to Japanese supremacy in Korea. Incidentally, owing to racial sympathies and because of the prestige gained, Japan attained supremacy in Chinese affairs. See CHINA; JAPAN — *Russo-Japanese War;* RUSSIA — *History.*

PORTUGAL, pŏr'tū-gal (Port. pōr-too-gäl'), the southwesternmost republic of Europe, on the Iberian or Pyrenean Peninsula, between Spain and the Atlantic Ocean. The Portuguese title is *Republica Portuguesa.* No natural boundaries separate Portugal from Spain, except on a small part of the frontier, the Minho River forming part of the northern boundary, and the Guadiana River part of the southeastern. The shape of Portugal is nearly that of a parallelogram. Its greatest length, north to south, is 353 miles, greatest breadth 138 miles, extending respectively between latitudes 36° 55′ to 42° 7′ N., longitudes 6° 15′ to 9° 30′ W. The territory is divided into the three provinces of Minho, 2,790 square miles; Tras-os-Montes, 4,163 square miles; Beira, 9,208 square miles; Estremadura, 6,937 square miles; Alemtejo, 9,219 square miles; Algarve (Faro), 1,937 square miles; and, with the insular provinces, comprising the Azores, 922 square miles, and Madeira, 314 square miles, gives a total area of 35,490 square miles for the republic; but this does not include the colonies noted below. The only large cities are Lisbon (q.v.), the capital, and Oporto (q.v.), the chief port. Setubal, Funchal (Madeira), Braza and Coimbra have each over 20,000 population.

Colonies.— Besides the Azores and Madeira islands, mentioned above, the Portuguese African colonies are 823,334 square miles in area, with an estimated population of over 8,000,000. The largest of these is Portuguese West Africa, formerly called Angola; nearly as large is Portuguese East Africa (q.v.), formerly called Mozambique. There are also the Cape Verde Islands (q.v.), Portuguese Guinea (q.v.), Principe (or Prince's) and Saint Thomas islands. Their Asiatic colonies of 8,933 square miles have an estimated population of 950,000. Goa, Damio and Timor in India, and Maceo Island and some small islands in the Indian Archipelago complete the other dependencies.

Topography and Physical Features.— The coast-line, of great length in proportion to the extent of the whole surface, lies mainly north and south on the Atlantic, but extends some 50 miles westward to Cabo da Roca, the most westerly point of the peninsula and of continental Europe. Here it becomes somewhat irregular, forms two bays — that of Lisbon and that of Setubal — by the interjection of the remarkable promontory which terminates in Cape Espichel, and again curves round in a south-southwesterly direction till it reaches Cape Saint Vincent, where it suddenly turns east. This direction it retains to its termination at the mouth of the Guadiana. It is occasionally bold and rises to a great height, particularly at Cabo da Roca, where it presents a range of precipitous cliffs; but for the greater part is low and marshy, and not unfrequently lined by sands and reefs, which make navigation dangerous. It is indented by some 21 harbors; the only ones of importance, either from their excellence or the trade carried on at them, are those of Lisbon, Oporto, Setubal, Faro, Figueira, Aveiro and Vianna. The interior is generally mountainous, a number of ranges stretching across the country, either in west, southwest or south-southwest directions, forming a succession of independent river basins, while their ramifications, penetrating in all directions, form the watersheds of numerous subsidiary streams and enclose many wild and beautiful valleys. The loftiest range is the Serra da Estrella, which may be considered as a continuation of the central chain which stretches across Spain between Old and New Castile, and between Leon and Estremadura. Near the town of Guarda it forms a sort of fork, one limb of which proceeds north and another southeast, while the main chain, running southwest, attains its culminating point of 6,537 feet about five miles west of the town of Covilhão, and ultimately terminates in the lofty cliffs of Cabo da Roca. Nearly parallel to this chain, and at no great distance from it, are on the north the Serra de Alcoba, and on the south the Serra Moradal. In the north branches or continuations of the Spanish mountains enter Portugal, and attain heights of 4,740 feet in Peneda, and of 5,180 in Larouco. At the opposite extremity the Serra Monhique, stretching across the country at a short distance behind the south shore, attains, at its western extremity in Mount Foia, the height of nearly 3,000 feet. The rugged nature of the surface makes the plains both few in number and of limited extent, but many valleys equally remarkable for beauty and fertility occur. The chief plains are those of Almedia and the Terra de Braganza, the former in the province of Beira and the latter in that of Tras-os-Montes; the chief valleys, those of Chaves, Villarica and Besteiros.

Hydrography.— No rivers of importance take their rise in Portugal, and yet few countries in proportion to their extent are better supplied with large and navigable streams. The Minho in the north, forming the boundary between Spain and Portugal in the lower part of its course; the Douro, first skirting the east frontier and then pursuing its course west to its mouth at Oporto; and the Tagus, all flow east to west; the Guadiana is the only large river of Portugal which deviates from the general westerly direction, and flows mainly south, forming part of the boundary line with Spain. In addition to these rivers, for which Portugal is indebted to Spain, the purely local rivers are the Vouga, Mondego and Sado. Numerous small lakes are scattered over the plains and among the mountains and valleys. The fisheries, especially those of sardine and tunny, are of considerable commercial importance, giving employment to about 45,000 people. The yearly catch is worth $5,000,000.

Geology and Mineral Resources.— The nucleus of the mountains is usually granite, overlain in the north by micaceous schist and other metamorphic rocks. Crystalline rocks and Palæozoic formations (especially Silurian) occupy about two-thirds of the surface, but the Jurassic, the Cretaceous and various Tertiary formations are also represented in the more southerly parts of the country. Volcanic formations are very apparent in the Serra de Caldeirão, forming a continuation of that of Monchique. The mineralogical treasures seem more remarkable for their variety than for their value, though some are, and many more it is supposed might be, worked to advantage. They include argentiferous lead, copper, iron, cobalt, bismuth, antimony, fine marble, slate, saltpeter, lithographic stones, mill-stones and porcelain earth. Some gold also is washed from the sands of the Douro, Mondego and other streams, and in several serras, particularly those of Estrella and Gerez-Larouco; and many valuable pebbles and rock-crystals are found in a great number of places. Large quantities of salt are formed in bays along the coast by natural evaporation; there are numerous salt marshes; and over 200 mineral springs, mostly impregnated with sulphur.

Climate.— The climate is greatly modified by the proximity of the sea and the height of the mountains, the former tempering the excessive heat of summer by refreshing breezes and the latter making the winter more rigorous than usual in countries under the same latitude. In general, however, winter is both short and mild, and in some places never completely interrupts the course of vegetation. In consequence of this many parts of Portugal enjoy the benefit of a double spring. Early in February vegetation is in full vigor; the plants shoot forth rapidly, attain maturity and either wither away or if of economical value are gathered and harvested. During the month of July the heat is often extreme, and, rain seldom falling, the whole country, particularly at its lower levels and along the coast, assumes a very parched appearance. The drought generally continues throughout August and far into September; but at last the sky, which had previously been serene, becomes overcast and copious showers descend. The second spring now begins, and the fields again become covered with flowers and verdure. Winter begins at the end of November. In the mountainous districts the loftier summits obtain a covering of snow and retain it for a greater or less period according to their altitude; but in all the country south of the Douro, and at a moderate elevation, snow generally soon melts away. The mean annual temperature in the north of Portugal is about 50° F., and of the south 65°. Deluges of rain, however, continue to fall, with occasional violent hurricanes and thunderstorms. Shocks of earthquake are sometimes felt, particularly in the vicinity of the metropolis, where those of 1755 were overwhelmingly disastrous.

Forestry, Flora and Fauna.— Many of the mountains are clothed with fine forests, chiefly pine and oak, both the ordinary species, or *Quercus robur*, and the cork-tree, or *Q. suber*, are conspicuous. In the central provinces, at a moderate elevation, magnificent chestnuts are very prevalent. Nearly one-sixth of the country's area is in timber, there being 2,000,000 acres of pines, over 1,000,000 acres of oaks, 800,000 acres of cork-trees and 210,000 of chestnut. In the south, in the province of Algarve, both the date and the American aloe are not uncommon. There are few countries with a more varied flora than Portugal. The number of species has been estimated to exceed 4,000, and of these more than 3,000 are phanerogamous. Both the flora and fauna of the kingdom are similar to those of Spain (q.v.).

Land Tenure, Agriculture and Stock-Raising.— The common forms of land tenure are peasant proprietorship, tenant farming, métayage and emphyteusis (ground rent). Large estates and tenant farming are common in the south; peasant proprietorship and emphyteusis prevail in the north. Agriculture is just about equal to the country's needs, one-fourth of the area being in cereals or grass and 7 per cent in vineyards and fruit orchards, 17 per cent under forest and 43 per cent is waste land. Barley and rye are important crops in the north, elsewhere wheat and maize are of more importance. In swampy localities some rice is grown. The production in 1916 was: wheat, 7,115,790 bushels; rye, 2,676,107 bushels; oats, 3,189,078 bushels; barley, 1,158,461 bushels; beans, 1,102,401 bushels; potates, 1,709,527 hundredweight. In the north the chief products are maize and oxen, in the central region, wheat and maize and in the south, wheat and swine. Wine is produced in large quantities. In 1917 the vintage amounted to 109,808,265 gallons. Olive oil was produced the same year to the extent of 362,094,084 gallons. Figs and tomatoes are also important crops.

Fruits of excellent quality are common in every quarter, though it is only in the warmer and better-sheltered districts that the orange, lemon and olive are cultivated with success on an extensive scale. The mulberry is admirably adapted to the climate, and by means of it a good deal of excellent silk is obtained; and a large extent of country is devoted to vine culture, caused partly by the demand for Portuguese wines in Britain. Among domestic animals the first place is due to the mule, of which very superior breeds have long been possessed and are carefully preserved. Sheep, goats and hogs are numerous, but little attention is paid to their improvement. Cattle are of comparatively less importance.

Manufactures and Commerce.— Manufactures are still limited, although they have been rapidly increasing of late years, and cotton goods are now exported. Among the articles made to some extent on a wholesale or commercial footing are textiles at Lisbon; woolen cloth and other woolen stuffs at Portalegre, Covilhão, etc.; porcelain at Vista Alegre; delft and ordinary earthenware at Lisbon, Oporto, Coimbra, Beja, Estremoz, etc.; cottons at Oporto; prints and lace at Lisbon and Oporto; cotton-twist at Thomar; silks at Braganza, Chacim, Oporto, etc.; copper and tinware at Lisbon and other places; corks, ribbons, embroidery, hats, confectionery, fine soap, jewelry and cut gems, glass, paper, wickerwork and tobacco. Shipbuilding is carried on to some extent, vessels being constructed at Lisbon, Figueira, Oporto and elsewhere. The principal exports besides wine are cork, cattle, cottons, olive-oil, sardines and tunny fish, fruits, iron and copper pyrites, tin and horses; the principal imports are cereals, colonial produce, woolen, cotton, linen and silk tissues, iron, steel and various other metals, machinery, cured fish, coal, petroleum, timber, dyes and drugs, etc. In 1913 (the last normal year before the war) the value of the exports was over $40,000,000 (more than half foods), imports $78,000,000. The bulk of the trade is with Great Britain and France, and the chief export to the former is wine. The value of the wine sent to Great Britain annually is nearly $5,000,000. Coal and cotton goods have the highest value among the exports from Great Britain to Portugal, with considerable amount in iron (wrought and unwrought) and machinery.

Shipping and Navigation.— The mercantile shipping of the republic in 1911 comprised 66 steamers and 259 sailing vessels, with an aggregate of 114,000 tons. In 1914, 9,017 vessels of 20,505,334 tons entered, and about the same total cleared the ports of Portugal.

Communications.— The length of sea-coast, with the harbors found upon it, and the number of rivers, furnish great facilities for trade, but all the other means of internal communication are defective. There are over 9,000 miles of public roads; in 1914, 1,849 miles of railway were open for traffic, of which 711 miles were owned by the state; in the same year there were over 5,945 miles of telegraphic line in operation. There are 4,300 post offices, handling annually 55,000,000 letters, 24,000,000 cards, and 50,000,000 pieces of printed matter.

Money, Weights and Measures.— The republic of Portugal established a new monetary system, the main unit being the escudo, worth a little more than one dollar, or 100 centavos; four and one-half escudos are legal tender for an English sovereign. Paper and silver are the chief media of circulation. The French metric system of weights and measures was introduced into Portugal between 1860 and 1863. The Portuguese *libra* was 1.012 pound avoirdupois, the *arroba* was 32 libras, the *quintal* four arrobas. The chief linear measures were the *legoa*, or league of 18 to the degree; the *milha*, or common geographical mile; the *braça*, or fathom=7.4 feet; the *vara*, or yard, one-half of the former; and *pe*, or foot=about 13 inches. For dry measure the *moyo*=22 bushels; and for liquids the *almudo*=from 3.7 to 5.6 gallons, were used.

Government.— The last king of Portugal was Manoel II, who came to the throne 1 Feb. 1908, on the assassination of his father and elder brother, Luiz Philip. In 1910 there was a short revolution, that culminated 5 October in the proclaiming of La Republica Portuguesa. A provisional government held authority until a constitution had been formed and a regular election took place, in August 1911, when Manoel de Arriaga was chosen the first constitutional President (24 Aug. 1911–27 May 1915). He did not serve out his term, but was succeeded by Theophilo Braga as provisional President from 29 May to 5 Oct. 1915. The new constitution was patterned in some respects after that of the United States, though with several marked differences. There are two Chambers, the National Council, having 164 members, directly elected every three years, and the Second or Upper Chamber, of 71 members, elected by all the municipal councils, half of them elected every three years. The Chambers elect the President for a single term of four years. The President appoints the Cabinet or Ministry, but they are responsible to the Parliament, consisting of the two Chambers. The constitution may be revised once in 10 years. Bernardino Machado was elected the second constitutional President of the republic, and took office 5 Oct. 1915. On 25 April 1917, he formed a new Cabinet, Affonso Costa being Premier and Minister of Finance, Lieut.-Col. Norton de Mattos, Minister of War, and Augusto Soares, Minister of Foreign Affairs. Machado held office until 8 Dec. 1917, when he was swept out of office by a revolution. A revolutionary Junta succeeded; it was led by Sidonio Paes, who, on 12 Dec. 1917, became Premier and on the 28th of the same month was made acting President, pending the regular election of a President by Congress. On 28 April 1918 Paes was elected President. The new government assumed the old public debt, which was about $800,000,000, and which has grown steadily, being at the billion mark in 1918. The revenue for the three years previous to the war was about $84,000,000 annually, with slightly greater expenditures. In 1917 the revenue fell off and the expenses were scaled to meet the funds. The war expenses were separate. (See ARMY AND NAVY). In addition the colonies of Portugal have an annual revenue of about $18,000,000, balanced by equal expenditures.

Banking.—The Government financial institution is the Bank of Portugal, which has branches in 22 cities. Taking the last normal year (1914) as the fairest statement the annual transactions are about 1,205,000,000 escudos ($1,301,000,000), and the cash on hand — gold 8,505,000; silver, 3,563,000; nickel, 104,000; copper, 13,517 escudos. Bills discounted, 66,000,000; loans, 2,327,000 escudos. There are 18 other banks, with 47,000,000 escudos capital, and deposits of 30,000,000 escudos.

Army and Navy.— The army consists of about 30,000 men on the peace footing and 175,000 on a war footing. Compulsory service was introduced in 1895, and all above 21, with certain exceptions, are liable to serve three years with the flag, five in the first reserve, and seven in the second. The reserve army, which was mustered during the World War, consisted of 35 regiments of infantry, eight squadrons of cavalry and 24 field batteries. The military bugdet for 1915–16 was over $100,000,000, to which was added $42,000,000 for extraordinary expenses. The navy consists of five protected cruisers, some old gunboats, five destroyers, four torpedo boats, three submarines, etc., with a program for constructing three more cruisers, three dreadnoughts, 12 destroyers and six submarines.

Ethnology.— The Portuguese are a mixed race—originally Iberian or Basque, with later Celtic admixture. Galician blood (derived from the ancient Gallaici, presumably Gallic invaders) predominates in the north; Jewish and Arabic blood are strongly present in the centre, and African in the south. The Portuguese differ essentially from their Spanish brethren, whom they regard with inveterate hatred and jealousy, mainly on account of their past attempts to subvert the independence of Portugal. They are short of stature, have a long cranial index, dark hair and olive skin. The opinions of observers differ as to the national traits of the people. They are, however, generally sober, good-natured, obliging and patriotic, but shiftless and not over-clean.

Population.— At the last census there were 2,828,691 males and 3,131,365 females. The urban population was 32.4 per cent and the rural 67.6 per cent of the total. The foreign population in 1911 numbered 41,197, comprising 20,517 Spaniards, 12,143 Brazilians, 2,576 English, 1,832 French and 1,645 Armenians. The rate of illegitimate births is 12.5 per cent of the total births. In 1914 there were 193,942 births, 117,967 deaths and 41,724 marriages. In the same year 25,722 persons emigrated chiefly to Brazil and the United States.

The following table gives the population at the census of 1900 and 1911. The Azores and Madeira are regarded as an integral part of the republic:

PROVINCES AND DISTRICTS	Area, sq. miles	Population 1900	Population 1911
Entre Minho-e-Douro			
Vianna do Castello	857	215,267	227,420
Braga	1,040	357,159	382,461
Porto	893	597,935	679,978

Grand total	35,490	5,423,132	5,957,985

Religion, Education.— The state religion was that of the Catholic Church, which largely prevails, though toleration is extended to all other creeds. There are three ecclesiastical provinces presided over by the cardinal patriarch of Lisbon, the archbishop of Braga, who is primate of the kingdom, and the archbishop of Evora; these dignitaries rule over 14 bishops. The monasteries were dissolved in 1834, their properties, yielding about 1,000,000 sterling annually, being appropriated by the state. Their books were collected, and form a library of 30,000 volumes at Lisbon. There are only about 5,000 Protestants, mostly foreigners, and 500 Jews. Education is superintended by a council, at the head of which is the Minister of the Interior, and is entirely free from the supervision and control of the Church. Compulsory education was enacted in 1844, but was far from being fully enforced, until the republic took it up actively in 1911. In 1913 there were 5,563 public elementary schools and 31 secondary schools, the teachers being trained in the universities (three in number), of Lisbon, Coimbra

and Oporto. The secondary schools had 11,000 students in 1916 and the universities over 3,000. There are also numerous private schools; polytechnic academies at Lisbon and Oporto; and clerical, medical, agricultural, naval and military training-schools. The university at Coimbra (established 1290), one of the oldest in Europe, has five faculties, 75 professors and about 900 students.

Judiciary and Local Government.— For judicial purposes Portugal is divided into 193 comarcas, each having a court of first instance. There are appeal courts at Lisbon, Oporto and Punta Delgada (in the Azores); and a Supreme Court at Lisbon. For the purposes of local government the six provinces of continental Portugal are subdivided into 17 districts, and the insular province into four, the Azores three, and Madeira one.

History.— Portugal forms the greater part of ancient Lusitania. It was subjugated by the Romans, in the time of Augustus, and was constituted into a province. In the 5th century, on the overthrow of the Roman supremacy, Portugal was invaded by the Alans and Visigoths, and suffered with Spain, of which it was then a part, all the troubles and vicissitudes endured by the inhabitants of the peninsula till the 8th century, at which time the Arabs, called indifferently Saracens or Moors, possessed themselves of the whole of Portugal, and kept absolute dominion for nearly 400 years. When the gallant Spaniards of the Christian kingdoms of Castile and Leon finally wrested the country between the Minho and the Douro from Moorish hands, they placed counts or governors over this region. Henry the Younger of Burgundy, whose grandfather Robert I, Duke of Burgundy, was grandson of the French king Hugh Capet, came into Spain about 1090, to seek his fortune in the wars against the Moors. Alfonso VI, king of Castile and Leon, gave him the hand of his daughter, and appointed him (1095) count and governor of the conquered districts, which comprised the provinces Entre Minho e Douro, Tras os Montes, and a part of Beira, and the harbors of Oporto (Portus Calle), from which Portugal is said to have derived its name. The count resided at Guimaraens, owed feudal service to the Castilian kings, but was permitted to hold in his own right whatever conquests he should make from the Moors beyond the Tagus (1112). Under his widow, Theresa (1114–28) the country acquired a sense of national unity and a certain measure of independence. Their son, Alfonso I, made Portugal an independent kingdom (1143) — through the victory of a picked body of Portuguese knights over a picked body of Castilian knights in a tournament — and gained signal advantages over the Arabs, whom he fought for 25 years, his greatest exploits being the victory in the plain of Ourique, in Alemtejo, in 1139, when he was saluted king of Portugal on the battle-field, the capture (with the help of English crusaders) of Lisbon in 1147, and of Alcacer do Sal in 1158. The Burgundian House, which continued in possession of the throne for 440 years, gave to Portugal some of its best kings. The immediate successors of Alfonso I were engaged in incessant wars against the Moslems and in severe struggles with the clergy and nobles, who were always ready to combine against the sovereign; but, although often baffled in their attempts to uphold the independence of the crown, the dignity of the kingdom was, on the whole, well maintained by the representatives of this family, who were, moreover, distinguished as the promoters and champions of the maritime glory of Portugal. Prominent among these was Diniz or Denis (1279–1325), son of Alfonso III. He encouraged agriculture, manufactures, navigation and commerce. He admitted the representatives of towns to the Cortes. He liberally patronized learning, and founded a university at Lisbon, which in 1308 he transferred to Coimbra. By these and other acts of a wise and beneficent administration he earned the title of «Father of his Country.» Among his other cognomens the most frequently applied is the «Farmer.» He was succeeded by Alfonso IV. In conjunction with Alfonso II of Castile he defeated the Moors at Salado in 1340. He murdered Inez de Castro, the wife of his son Pedro, in 1355. (See CASTRO, INEZ DE). He was succeeded by his son Pedro I, who exhumed the body of Inez, and caused her to be crowned along with him (1361). He died in 1367, and was succeeded by Ferdinand, on whose death in 1383 the male line of the Burgundian princes became extinct. In 1385 the king of Castile laid claim to the crown, but was opposed by Don John, the illegitimate brother of Ferdinand, who ascended the vacant throne and ruled his subjects with justice and prudence. Under this wise and enlightened sovereign the Portuguese first directed their attention to those maritime adventures which subsequently placed Portugal at the head of all European nations. Under John I the Portuguese first projected those Atlantic discoveries on the African Coast, fraught with such territorial and commercial advantages to the nation; and, under John II and Emanuel, between 1481 and 1521, Vasco da Gama explored the Indian Ocean; the riches of the East began to pour into Europe; Goa became a prosperous possession, and Brazil was added to the possessions of the crown of Portugal. The latter monarch, Emanuel, has been regarded as the greatest and best man who e,er sat on a throne. Under his wise, just and benevolent reign distress was banished from the kingdom, and his subjects rendered rich and happy. Sebastian III, fired with a holy zeal to exterminate the infields from his country, commenced a sanguinary crusade against the Moors, which he carried on through such repeated defeats that he eventually lost both his crown and life in the struggle. With Henry the Cardinal, his uncle, an old man of 70 who died after a reign of two years, the male line terminated, after enduring for 460 years. Spain once more laid claim to the vacant throne, and Portugal again became a dependency of the Spanish crown, the nation suffering all the injustice, exactions and tyranny usually inflicted on a conquered country by its haughty masters. After enduring 60 years of intolerable hardships and exactions, a Portuguese nobleman named John, Duke of Braganza, pitying his unfortunate countrymen, excited a revolution, which again broke the Spanish fetters, while the people hailed their deliverer as their king, who, being crowned as John IV, commenced the dynasty of the House of Braganza, a family whose descendants still sway the destinies of Portugal. During the 18th century, as an ally of Great Britain, Portugal became rather a commercial dependent, especially after the Methuen Treaty (q.v.) of 1703.

When Napoleon, in 1807, entered the country, and declared the family of Braganza had ceased to reign, the royal family of Portugal, consisting of Pedro, the old king and his imbecile wife, Maria Frances Isabella, queen-regent, the prince-regent and all the court set sail from the Tagus to Brazil, transferring the capital to Rio de Janeiro. On the death of the queen-regent, John VI ascended the throne of Portugal and Brazil. After the downfall of Napoleon, the history of Portugal is composed of a long succession of political disturbances. The Inquisition introduced in 1536 was abolished in the Portuguese dominions in 1815, and the Jesuits, established in 1540 and banished in 1759, were refused admission. The Jews, at the request of the pope in 1817, were allowed the same privileges which they enjoyed in the Roman states. The absence of the court was viewed with dislike by the nation; the military were dissatisfied with the British influence of Marshal Beresford and the general feeling required some fundamental changes in the administration and constitution of government. A revolution in favor of constitutional government was effected without bloodshed (1820), and the king invited to return home. Before landing in Portugal he swore to observe the constitution which had been adopted. A counter-revolution of the nobles and clergy was vigorously repressed by the Cortes (February 1823); but the queen, a Spanish infanta, who exercised great influence over her son, Dom Miguel, gained the colonels of several regiments; a new reactionary movement was organized; and the Cortes, being overpowered, dissolved itself after a solemn protest on 2 June 1823. In 1822 Brazil threw off the yoke of Portugal, and proclaimed Dom Pedro, son of John VI, emperor. Her independence was recognized in 1825. John VI died 10 March 1826, having named the Infanta Isabella Maria regent. She governed in the name of the Emperor of Brazil, Dom Pedro IV of Portugal, who granted a constitution with two chambers, modeled on the French, 23 April 1826. In May he abdicated in favor of his daughter Maria da Gloria. He imposed on her the condition of marrying her uncle Dom Miguel, who was entrusted with the government as regent; but the Absolutist party in Portugal set up the claim of Dom Miguel to an unlimited sovereignty and a revolution in his favor, notwithstanding the intervention of England placed him on the throne in 1828. In 1831 Dom Pedro resigned the Brazilian crown and returning to Europe, with the aid of English partisans succeeded in overthrowing Dom Miguel and restoring the crown to Maria in 1833. In 1836 a successful revolution took place in favor of the restoration of the constitution of 1820 and in 1842 another in favor of that of 1842. Maria died in 1853. Her husband, Ferdinand of Saxe-Coburg, brother of Prince Albert of Britain, became regent for her son Pedro V. He placed the government on a purely constitutional basis, which was maintained by his son Pedro, who died in 1861 and by Louis I, who succeeded him and who died in 1889. The abolition of monopolies, the improvement of finances, the formation of railways and the cadastral survey of the country, are among the measures which distinguished his reign. Slavery was abolished in 1868 in the Portuguese dependencies. Carlos I ascended the throne in 1889. His reign was marked by serious colonial, financial, social and political troubles. Carlos and his oldest son were assassinated and his second son driven from the throne. A national assembly was formed and on 19 Aug. 1911 it completed and signed the constitution of the Republic of Portugal and elected a President as stated under *Government*. Portugal came into the World War on the side of the Entente Allies in 1916.

PORTUGUESE (pōr'tū-gēs, or -gēz) **EAST AFRICA, or MOZAMBIQUE.** See EAST AFRICA; PORTUGUESE; and MOZAMBIQUE.

PORTUGUESE EAST INDIA COMPANY. See EAST INDIA COMPANIES.

PORTUGUESE GUINEA, a northwest African colony on the Atlantic Coast, extending from the Cacheco River southward to Katafine, and eastward to long. 13° W., its boundaries on all its land sides, fixed by the convention of 12 May 1886, being the French Senegambian possessions. The climate is very hot and unhealthful for Europeans. The Bissagos archipelago with other islands off the coast belong to the colony, which has a total area of 14,440 square miles. The capital and chief port is Bulama on Bulama Island; other trading ports are Bissao, Bubah, Geba and Cacheo. The coast is indented by the estuary of the Rio Grande River with its numerous deltaic islands; the colony from the eastern mountains westward lies on both sides of the river and is mainly an alluvial plain covered with tropical forests and vegetation. Rice and millet are cultivated. The chief commercial products, largely controlled by the French, are rubber, ivory, hides, oil-seed and wax; the annual exports amount to over $6,000,000; the imports to $1,500,000. There is a small coasting trade, 150 vessels with an aggregate of 57,007 tons, entering the ports in one year. There is fine hunting, elephants and hippopotami being still common. The colony is administered by a Portuguese governor and council. The military force numbers about 250. The colony is non-supporting, the revenue being less than the expenditure. The United States in 1870 as umpire settled the long-standing disputes between Great Britain and Portugal over this territory in favor of the latter. The population, almost wholly native blacks, is estimated at about 1,000,000. Consult Machat, J., 'Rivieres du Sud' (Paris 1906).

PORTUGUESE LANGUAGE, LITERATURE AND ART.— The Portuguese is one of the Romance family of languages, formed by the junction of the Latin-speaking Celts with the Teutonic races. Words of Greek, Phœnician, Iberian, Celtic and Carthaginian origin are found in Portuguese as in Spanish, indicating the relations into which commerce or conquest had brought the early inhabitants of the country. The Moorish occupation has further infused into it a Semitic element. Under the early kings of Portugal all documents were written in Latin; judicial sentences were written in Latin till a comparatively recent time; it is still used in seals, coins and monumental inscriptions. It was only under Alfonso III and Diniz that Portuguese began to be generally used in documents. The differences between Portuguese and Spanish are comparatively of modern origin, the two languages being very nearly alike in the time of Alfonso I (1143). These differences are due partly to the different spheres of activity of the two peoples. The relations of Spain were with France, Italy, Austria, and the Low Countries; those of the Portuguese were almost exclusively with the Spaniards themselves, or with peoples removed from European civilization. The dialect of Spanish spoken in Portugal at the beginning of the monarchy, moreover, was the Galician, which was also that of the court of Leon; but that court subsequently adopted the Castilian, which became the dominant language of Spain. The decline of the Galician dialect in Spain and the formation of the Portuguese language through the influences peculiar to the people finally determined the separation of Spanish and Portuguese, and from cognate dialects made them distinct languages. Early French introduced by Henry of Burgundy and his suite also constituted an element in the formation of the Portuguese language, and old French words which have fallen into desuetude are still to be found in Portuguese. The heraldic devices of the oldest Portuguese families are in French, while in modern times the Portuguese have shown a strong tendency to imitate the French in everything, and the language has been considerably modified by the introduction of French expressions and grammatical forms.

The 16th century is the classical age of Portuguese literature, and the Royal Academy of Sciences began a dictionary in which all doubtful points in regard to the language are referred to quotations from the writers of that age. There is no determined orthography except that which the rules of printers have made prevalent in printed books. Royal edicts and other public documents were formerly cited as models of language, but in later times they were far from being distinguished by accuracy.

The Portuguese language, by means of colonization and emigration, has been pretty widely spread. It is spoken in Portugal, the Azores, Brazil, the Portuguese colonies in Asia, Africa, and in the United States, and among the Portuguese Jews scattered over Europe, particularly in Hamburg and Amsterdam. The Portuguese possesses the richness and conciseness of the dialects founded on the Latin tongue. It appears to have derived from French the *j* sound and the nasal syllables, and it lacks the strong aspirations and guttural sounds of the Spanish. It has less dignity than the Spanish, but is superior in flexibility. In popular songs it displays a delicacy and variety of expression which have made the Spaniards call it the language of flowers. It makes free use of augmentives and diminutives. It is soft and sonorous in sound, but the too frequent occurrence of the nasal *ão* somewhat mars its harmony. The words are systematically grouped, every noun having in general an adjective, a verb and an adverb corresponding to it. Latin terms are preserved in Portuguese which are found in no other language in Europe; but these, as well as its other Latin elements, are more radically changed than elsewhere, so that it is often extremely difficult to trace the derivation of Portuguese words. Medial consonants, such as *l* and *n*, are frequently suppressed, *doler* becomes *dor; populus, povo; ponere, pôr* (Italian *porre*). The dialects of Portuguese differ only slightly from each other. Those of Minho, Algarve, the Azores in Europe, and of Goa, Macao, East Africa and Brazil are farthest from the written. The *lingoa geral* spoken on the eastern and western coasts of Africa, as well as in some parts of India and Ceylon, which bears an analogy to the *lingua franca* of the Mediterranean, may be regarded as a dialect founded on Portuguese, and as containing reminiscences of the ancient maritime power of the people.

Literature.— The earliest productions of Portuguese literature do not go back farther than 1125, from which date the poetical compositions of Egaz Moniz Coelho and of Gonzales Hermiguez. These are written in the Galician dialect. This closely resembled the Provençal and the Provençal bards who were received at the court of the kings of Portugal just missed assimilating the Portuguese as well as other languages of southern Europe to their own. The Provençal literature for some time absorbed all the efforts directed toward the cultivation of the higher arts of writing, and in Portugal, as elsewhere, it retarded the development of the native literature. During the 12th and 13th centuries the Portuguese native literature could boast of nothing more than a collection of popular songs (*chacras*), remarkable for freshness and vigor. The first Portuguese collection of poetry (*cancioneiro*) was made by King Diniz. It consisted of a selection of the court lays composed about this time by the Portuguese, Provençal and Galician bards. The manuscript of this collection, discovered in the Vatican by Ferdinand Wolf, has been published in Paris and Lisbon (1847) under the title of 'Cancioneiro del Rey Dom Diniz.' To Dom Pedro, Count of Barcellos, son of Diniz, is attributed a 'Cancioneiro do Real Collegio dos Nobres.' His half-brothers, Alfonso IV and Affonso Sanchez, were likewise poets. Some of the Portuguese poets of this time wrote in Castilian, and are reckoned among Spanish writers. Some poems on the death of his wife, one of which is in Castilian, are attributed to Pedro I, husband of Inez de Castro. There is also a prose chronicle of Pedro's reign by Fernão Lopez, from which are derived the chief particulars of his vengeance on the abettors of the murder. In the 15th century the court was still the centre and source of the national literature. The sons and grandsons of John I were poets and patrons of the troubadours. Galician, Castilian and Provençal were still cultivated as well as the native language. Garcia de Resende, a poet of some merit, who lived under Emanuel, has collected in a Cancioneiro (Lisbon 1516) the principal poetical works of this age. Bernardim Ribeiro wrote pastoral poems and romances in imitation of the Italians and Spanish. Sà da Miranda, who succeeded him in the same line, marks the transition from the 15th to the 16th century and the separation of the Portuguese from the other Spanish dialects and from the language of the troubadours. This progress is also observable in the prose chronicles which record the current history of the day. The reign of King John, the discovery and conquest of Guinea, the career of Prince Henry and the first voyage of Columbus are among the subjects dealt with by the chroniclers. Literature still continued to be patronized by the royal family. King Edward (Duarte) wrote a book of morals for the use of his sons, and two works, 'The Art of the Cavalier' and 'The Loyal Councillor,' which have been republished in France. There is also a treatise on military art by Alfonso V. The 16th century is the classic era of Portuguese literature. Pastoral poetry, the epic and the chivalric romance flourished in an especial manner. The chief names are Sà da Miranda, Antonio Fereira, Camoens, Diego, Bernardes, Andrade, Caminha and Alvares do Oriente. Their compositions are distinguished by elegance and variety, but like other modern pastorals, exhibit rather a tedious affectation of rusticity than a life-like representation of rural life. Sà da Miranda has also written epistles, sonnets, hymns and other compositions. In his hymns he has employed for the first time the hendecasyllabic verse, which has become the chief instrument of Portuguese poetry. The numerous hymns, odes, elegies and sonnets of Camoens are equally distinguished for elegance, but are marred by numerous conceits according to the taste of the period. The principal epic and the greatest poem in the Portuguese literature, almost the only one which has acquired a European reputation, is 'Os Lusiadas' ('The Portuguese') of Camoens, which has placed its writer in the rank of the few great poets of the highest class whose genius is universally recognized by the whole world. (See CAMOENS). After Camoens as an epic writer comes Cortereal, who has celebrated the siege of Diú and the shipwreck of Sepulveda.

The Portuguese romance writers claim to be the originators of the character of Amadis, but the question remains undecided between them and the Spaniards. Vasco de Lobeiro, Francisco Moraes and Bernardim Ribeiro are among the leading romance writers. Lopez de Castanheda has written a Libro de Caballeria. The drama also began to be cultivated in the 16th century. The first *autos* and rustic dialogues were probably composed for the festivities of Christmas; a few rude comedies also preceded the classic period. Sà da Miranda studied and imitated Plautus. Ferreira, who followed his example, composed the first regular tragedy, Ines de Castro, only a few years after Sofonisba was produced at Rome by Trissino. Camoens wrote several theatrical pieces, among which are 'Amphitryon' and 'Seleucus.' *Autos, farsas* and *comedias magicas* were far more numerous than simple dramas.

The chronicles in the same age expanded into history. The events of their own day, in which their country played so large a part, afforded ample matter of inspiration for historians as well as poets. Barros is esteemed the Livy of Portugal though he is also a writer of fiction. He wrote the 'History of the Conquest of India' in an elegant, pure and energetic style. The 'Commentaries of Alphonso d'Albuquerque,' by a nephew of the conqueror; the 'Chronicle of King Manual and of Prince John,' by Damian de Goes, a Portuguese ambassador; the 'History of the Discovery and Conquest of the Indies,' by Lopès de Castanheda; the 'Chronicle of King Sebastian,' by Diego Bernardo Cruz, are all works of great merit. Narrations of voyages are fewer than might have been expected, but there are a few of great interest — 'A Letter to the King of Portugal on the Discovery of Brazil,' by Vas de Caminha, companion of Cabral; the 'Voyages of Magellan,' narrated by some of his comrades; and the 'Voyages of Pinto,' who visited China, Tartary, Arabia and other countries. This work is one of the classics of the 16th century.

The opening of the 17th century is distinguished by the crowd of imitative epics which naturally followed the success of the Lusiad. Quevedo de Castro, Mascurenhas and Brandam are among the principal authors of these works, the most noticeable feature of which is the national patriotism they continue to display after the loss of the political independence of Portugal. This century is also distinguished by great historical compilations. It was the period of repose after an epoch of great activity and the absorption of the Portuguese nationality in the more powerful monarchy of Spain naturally turned all eyes to the recent period of its glory. The 'Monarchia Lusitana' (1597–1690); Bernardo Brito's 'Eulogy of the Kings of Portugal'; Faria de Souza's 'Europa Portugueza' (1667); 'Asia Portugueza' (1666–75), 'Africa Portugueza' (1680); 'America Portugueza' (left in manuscript), the historical works of Nunez de Laïo, Manoel de Mello and others belong to this epoch. Antonio Vieira, a Jesuit preacher, is one of the most vigorous prose writers of this century. The letters of Alcofarrara are also among its notable productions. But the most prolific writer of all was the padre Macedo, who composed a number of epic poems, besides 110 odes and numerous dissertations. He wrote chiefly in Latin, Spanish and Italian.

The Portuguese drama was nearly extinguished during this century by the predominance of the Spanish, to which even Portuguese writers contributed. Cocho Rebello has collected a number of the minor indigenous productions of the art, 'A Musa Entretenida de Varios Entremeses' (Coimbra 1658).

In the 18th century the influence of the French writers of the age of Louis XIV so completely dominated Portuguese literature that it became almost entirely imitative. Translations from and imitations of the French formed the staple of its products in every department, and the nation that gave birth to the Lusiad condescended to copy the Henriade and the Lutrin. Scholarship in this age made greater progress than literature. The academy called the Arcadia was founded in 1757 by Antonio Diniz da Cruze Silva, the Portuguese Boileau, and other promoters of the revival of learning. It became extinct in 1776 and was replaced in 1779 by the Royal Academy of Sciences of Lisbon. Toward the close of this century two writers appeared who have formed schools, Francisco Manoel do Nascimento (1734–1829), an elegant lyrist, and Barbosa du Bocage, who introduced an affected and hyperbolical style of writing, which has been called, from the pen-name Elmano, which he adopted, *Elmanism*.

In the 19th century the classic school was represented by the followers of Manoel do Nascomento, Domingo Maximiano Tores and Ribeiro do Santos. Among poets of the century possessing some claim to originality are Roque, Carvalho Moreira, Mouzinho de Albuquerque, Feliciano de Castilho, Herculano de Carvalho, Almeida Garret, João de Lemos, Antonio de Serpa and Palmeirim. Through the efforts of these and other Portuguese literature has again begun to assume an aspect of native vigor. The drama has also been revived by J. B. Gomez, Pomenta de Aguiar, Mendes Leal and A. Herculano. Alexandre Herculano and Rebello da Silva are also writers of history and historic romance. Castello Branco is a novelist. To the Coimbra School, which found inspiration in the leading writers of modern France and Germany, belong the lyric poet João de Deus, the historian Theophilo Braga, the philologist Coelho and other less-known writers. Science, law and political economy are likewise well represented.

Portuguese literature is also cultivated with considerable independence and success in Brazil. For an extended discussion of Portuguese-Brazilian literature see section *Brazil* in the article West Indian, Central America and Brazilian Literature.

Art.— The principal architectural monuments which Portugal possesses are due to the Goths and Moors. There are also numerous architectural relics of the Roman dominion, such as the ruins of an amphitheatre at Lisbon, those of a Corinthian temple dedicated to Diana at Evora and a round tower named after Sertorius. The cathedrals of Coimbra and Braga and the church of Cedofeita at Oporto are due to the Goths. The châteaux of Pombal, Feira, Alcobaça, etc., were palaces inhabited by the Saracen princes. There are no native works of any importance. Although the art has been well patronized Portuguese painters are few and have never formed a recognized school; the same may be said of native sculpture.

PORTUGUESE MAN-OF-WAR, a pneumatophone or air-sac, often seen floating on the ocean, supporting or carrying suspended below a colony of *Physalia*. They are usually found floating in tropical seas, but in the latter part of summer often seen off the southern coast of New England. The float is an oblong, crested bladder, flattened on the lower side, from which are pendent the various individuals of the colony. The gaseous contents of the air-sac or bladder appear to be under the control of the individual, so that it can sail awash or submerged like a submarine. The long filaments, sometimes trailing out to a distance of fully 20 feet, have batteries of nettle-cells numerous and powerful enough to paralyze fishes, and cause much discomfort to human beings, even when the organisms in question are dead on the beach. See SIPHONOPHORA.

PORTUGUESE WEST AFRICA. See AFRICA.

PORTULACA, a genus of annual and perennial herbs of the family *Portulacaceæ*. The species, of which about 20 have been described, are natives of warm and temperate climates and are mostly American. They are often trailing, have fleshy stems, usually thick leaves and generally terminal flowers followed by small conical capsules containing numerous tiny seeds. The flowers open in sunshine but close in shade. The two best known species are *P. grandiflora* and *P. oleracea*. The former is widely cultivated in gardens for its very showy but ephemeral flowers which have a wide range of color. The hottest, dryest, sunniest places and light soils suit the plant well. It is a native of Brazil. The other species is said to be a native of Persia, where it was used as a potherb more than 2,000 years ago. It is also said to be indigenous in the southwestern United States. Popularly known as pusley and purslane, it is one of the commonest weeds in warm and temperate climates upon light loamy and sandy soils, but rarely upon heavy. It has several improved varieties which are cultivated, especially by the French, for greens.

PORTUNUS, pôr-tū'nŭs, or **PORTUMNUS,** Roman god of harbors. He corresponds to the Melicerta or Palæmon of the Greeks and was originally the god of doors, symbolized and represented with a key in his hand. He had a temple on the Tiber where his festival, the Portunalia, was annually celebrated on 17 August.

PORUS, king of India: d. 317 B.C. He was of ancient and noble lineage, and his kingdom occupied the north of India between the Hydaspes and Acesines. When Alexander invaded India in 326 B.C. he found the army of Porus barring his further passage at the Hydaspes. After considerable delay Alexander succeeded in fording the river higher up in its course, but was met by Porus and a terrific battle ensued, in which the Indian king was wounded and taken prisoner. Brought before Alexander his noble bearing aroused the admiration of the conqueror and they became friends and allies. Alexander extended the kingdom of Porus to the Hyphasis and when he retired from India left him as ruler of the enlarged kingdom. Porus seems to have extended his domain still further after the death of Alexander, but in 317 B.C. was assassinated by the satrap Eudemus.

There appear to have been two other Indian rulers of the same name. One of these was a nephew and an enemy of the great king, and the other a king of Madura, on friendly terms with the Emperor Augustus. Consult McCrindle, 'Invasion of India by Alexander the Great' (1896); Macdonell, 'History of Sanscrit Literature' (London 1913).

PORY, pŏr'ĭ, **John,** English colonist: b. England about 1570; d. there, before October 1635. He was graduated from Gonville and Caius College, Oxford, in 1592, studied under Hakluyt and in 1619–21 was secretary to Sir George Yeardley in Virginia. His accounts of his excursions among the Indians are published in Smith's 'Generall Historie.' He returned to England in 1621, but in 1623 was appointed commissioner of the privy council, resided in Virginia for another year, and the remainder of his life appears to have been spent in England. His letters are in the British Museum. He translated 'Geographical Historie of Africa, written in Arabicke and Italian by John Leo, a More.'

POSADAS, a name given in Mexico to the nine consecutive days' celebration immediately preceding Christmas day. From their nature the posadas would seem to have originated in a miracle play employed to teach the Indians the story of the birth of Christ. The Aztecs were accustomed to hold a year-end celebration of five days (an aboriginal week), beginning on or about 16 December. The Spaniards held another from 22 to 24 December. As it was impossible to suppress the Indian heathen celebration, the Catholic Church extended the Christian festival to cover the nine days of the posadas.

POSEIDON, pō-sī'dŏn, in Greek mythology the lord of the sea, identified by the Romans with the Italian deity Neptune. He was a son of Cronus and Rhea, and hence a brother of Zeus, Hades, Hera, Hestia and Demeter. His usual residence was in the depths of the sea near Ægæ, in Eubœa, where he had a palace, and kept his horses, with brazen hoofs and golden manes. He is called the earth-holder or earth encompasser, as the sea surrounds the earth, and the earth-shaker, as the earth is shaken by the waves of the sea beating on the shore. He is the ruler of all other marine deities and of all animals that live in the sea. He gathers clouds and raises storms and allays them. In several myths he is represented as contending with some land divinity for the possession of particular spots of earth. The horse, and more particularly the war-horse, was sacred to Poseidon, and one of the symbols of his power. The other well-known symbol of his power is the trident, or three-pronged sceptre. During the Trojan War Poseidon was the constant enemy of Troy. The cause of this enmity was the ingratitude shown him by Laomedon, the second king of Troy, and the builder of the walls of the city. Poseidon had numerous offspring by mothers divine and human. The worship of Poseidon was common throughout Greece and the Greek colonies, but especially prevailed, as is natural, in the maritime towns. The animals sacrificed to him were horses and bulls, sometimes also wild boars and rams. The Isthmian games, and the Panionia or festival of all the Ionians, celebrated near Mycale, were held in his honor. In works of art Poseidon is represented with features resembling those of Zeus, but he has not the calm majesty of the supreme god, although he is more powerfully built. When represented standing, he always bears the trident in his right hand and a dolphin in his left. (See NEPTUNE). Consult Farnell, L. R., 'Cults of the Greek States' (Vol. IV, 1907).

POSEN, pō'zĕn, Germany, (1) a fortified town in Prussia, capital of the province and government of the same name, on the river Warthe, 149 miles east of Berlin and 103 north of Breslau. Fort Winiary, adjoining the town, serves as the citadel. It is a railway centre, enjoying an active trade also by water. Of its public edifices the chief are the Roman Catholic cathedral and the parish church, the former having the splendid «golden chapel» attached; the archiepiscopal palace; the town-hall, a Renaissance building mostly of the 16th century; the Raczynski Library; the Mielzynski Museum, the archæological museum and library, the realgymnasium and two other gymnasia (one Protestant and one Roman Catholic), an academy, normal and other schools, hospital, a theatre and some elegant private mansions. The manufactures consist chiefly of agriculture and other machines, carriages, artificial manures, etc. There are also large breweries and distilleries. Posen is the see of an archbishop, the residence of a provincial governor and the seat of important courts and numerous public offices. It was one of the oldest and most important towns of Poland, and its inhabitants still largely consist of Poles. It was at one time allied with the Hanseatic League. It is one of 10 fortified cities of the first class in Germany and has underground and wire connections with the nearby fort of Geogau. It was a Russian objective in their advance in 1914–15. Pop. about 156,691. (2) An eastern grand duchy and province of Prussia, bounded north by West Prussia, east by Russian Poland, south by Silesia and west by Brandenburg; area, 11,186 square miles. The surface is generally flat and extensively occupied by lakes and marshes. A small portion belongs to the basin of the Vistula, which touches it on the northeast; the rest belongs to the basin of the Oder, which receives its drainage through the Warthe in the south and centre and the Netze in the north. The soil is for the most part light and sandy, and considerable tracts are covered with heath; many parts are covered with a rich alluvium or vegetable mold, yielding all the ordinary species of grain, millet, flax, hemp, tobacco and hops. The pastures are extensive and feed numerous herds of cattle, horses and swine; considerable attention is paid to the rearing of poultry, particularly geese, and also to the rearing of bees. The minerals, comparatively unimportant, include bog iron-ore, saltpetre, limestone and building-stone. The manufactures consist chiefly of spirituous liquors, woolen stuffs, linen and leather. The trade in these articles and in horses and swine is considerable; other exports are corn, cattle, tallow, leather, honey, wax, goose-feathers and hogs'-lard. There are 1,200 miles of railway in the province. The inhabitants include a considerable mixture of Germans and Jews, but the great majority are Poles, Posen being one of the acquisitions which Prussia made by the dismemberment of Poland. It is divided into the two governments of Posen and Bromberg and has been subjected to a representative rule to overcome disaffection. It is represented in the Imperial Reichstag by 15 members and in the Prussian Landtag by 29 delegates in the lower and 19 in the upper chamber. As part of Poland, Posen was divided into the palatinates of Poznania, Gnesen and Inowraclaw. At the first partition of Poland in 1772 the district of the Netze fell to Prussia, and the remainder in the second partition of 1793. Between 1807 and 1815 Posen formed part of the grand duchy of Warsaw, but in the latter year reverted to Prussia. Pop. 2,099,831.

POSEY, pō'zĭ, **Alexander Lawrence**, Creek Indian educator, journalist and poet: b. near Eufaula, Okla., 3 Aug. 1873; d. 27 May 1908. His father was a white man of Scotch-Irish descent, born about 1842 in the Indian Territory, being the child of white intruders in the Cherokee Nation. His mother was a Muskogee Indian of unmixed blood. Until he was 12 years old, Alexander Posey spoke only the language of his mother's people. Then his father, who was in independent circumstances, employed a private teacher and compelled the son to learn to speak and write English. A year or two later he was sent to the public (tribal) school at Eufaula. When he was 17 he entered Bacone Indian University at Muskogee, where he acted as librarian, learning to set type on *The Instructor*, a small paper published by the faculty, and discovered his own bent for literary work. In October 1892 he published 'The Comet's Tale,' a lengthy poem relating to the Indian tradition of the coming of the first ships of the white men to discover America. Immediately after his graduation, in 1895, he entered public life, being elected a member of the Creek House of Warriors, the popular branch of the tribal legislative council. In 1896 he was appointed superintendent of the Creek Orphan Asylum at Okmulgee. A year later he became tribal superintendent of schools, but held it only a short time, resigning to settle on his farm near Stidham. There he continued to write as inspiration prompted. He was pre-eminently a poet of nature and loved the solitudes of which he wrote. Then he was called back to educational work as superintendent of the Creek National High School at Eufaula, with a brief term of service at a similar institution at Wetumka, but soon relinquished that work to take charge of the publication of the *Indian Journal* at Eufaula. There he found his literary opportunity, developing marked ability as a satirist. His inimitable «Fus Fixico» letters, in which he humorously discussed the white man's politics through the medium of dialogues between fictitious characters who were typical of the older and more conservative Creek full-blood element — Wolf Warrior, Hot Gun and others — who talked in the broken Creek-English dialect, were widely copied in States far from Oklahoma, where the force of their satire could not be appreciated because its object was unknown. Because of his sympathetic understanding of the uneducated people of his tribe, whose interests were jeopardized in the readjustment incident to the allotment of lands in severalty, he gave up newspaper work to become a field agent of the allotting commission, in which position he rendered valuable service. In 1905 he was chosen a delegate to the Sequoyah Constitutional Convention, which met at Muskogee, and of which he was elected secretary. The simple, terse, clear English of the instrument framed by that convention was said to have been largely due to his writing and revising. He met death by drowning in the

North Canadian River. A volume of his poems was published after his death.

POSEY, Thomas, American soldier: b. eastern Virginia, 9 July 1750; d. Shawneetown, Ill., 19 March 1818. He was quartermaster in Lord Dunmore's expedition against the Ohio Indians and was engaged in the battle at Mount Pleasant in 1774. In 1775 he was a member of the Virginia committee of correspondence and raised a company of which he became captain for the 7th Virginia Continental Regiment. He assisted in defeating Lord Dunmore at Gwynn's Island in 1776; in 1777 joined the Continental army at Middlebrook, N. J., and with his company was transferred to Morgan's renowned rifle-corps, where he played a conspicuous part in the engagement at Piscataway, N. J. He served with great gallantry under Gates at the battles of Bemis Heights and Stillwater, and in 1778 was promoted major and had charge of the expedition against the Indians of Wyoming Valley in that year. In 1779 he commanded a battery under General Wayne at Stony Point and was one of the leaders in the assault which carried the enemy's works. He was present at the surrender of Yorktown, organized a regiment of which he was given command with the rank of lieutenant-colonel, and served under General Wayne in Georgia until the surrender of Savannah, where he routed the Indians under Gueristersigo. After the war he lived in Spottsylvania County, Va., until 1793, when he was appointed brigadier-general and served under General Wayne in his campaign against the Indians in the Northwest. He resigned in 1794, settled in Kentucky, entered the State senate and was ex officio lieutenant-governor. He raised a company of which he was for a time captain in the War of 1812, and in 1812–13 he served as United States senator from Louisiana. He was governor of Indian Territory from 1813 until her admission into the Union as a State and from 1816 until his death was Indian agent.

POSIDONIUS, pō-sī-dō'nĭ-ŭs, Greek Stoic philosopher: b. Apamea, Syria, about 135 B.C.; d. after 51 B.C. He studied at Athens under Panætius of Rhodes, after whose death in 112 he presently established himself as a teacher at Rhodes, whence he is called the Rhodian. He taught the Stoic philosophy with great applause, was at the same time a statesman and one of the Prytanes, and went at 50 as an ambassador to Rome. The most distinguished Romans were his scholars, and Cicero was initiated by him into the Stoic philosophy. He wrote many works on history, astronomy and geography, now lost. In his physical investigations he was more nearly a follower of Aristotle than of the Stoic school, the members of which he greatly excelled in this department of knowledge. Fragments of his writings were edited by Bake (1814), and by C. Müller in 'Fragmenta Historica Græcorum' (1849). Consult Ritter-Preller, 'Historia Philosophiæ Græcæ' (1913).

POSILIPO, pō-sē-lē'pō, or **PAUSILIPPO**, pow-sē-lē'pō (Latin, *Pausilipona*), Italy, a hill and grotto to the southwest of Naples, the grotto furnishing a passage from that city to Pozzuoli. This grotto, or tunnel, leads directly to the village of Fuorigrotta; its height is about 70 feet, and the breadth 21 feet. It was long supposed that it was earlier than the time of the Romans, but it is now supposed to date from the time of Augustus or Tiberius. It was widened in 1442 by Alphonso I, plastered by Pietro of Toledo, and again repaired in 1754 by Charles III. Since 1885 there has been a second «grotto,» about 150 feet longer, which is more commonly used, as is also a road over the mountain built in 1822. On the hill above the grotto is the famous Tomb of Virgil. To the south is Cape Posilipo. The town of Posilipo on the hill has about 4,500 inhabitants.

POSITIVE, that which is active, affirmative, known, virile, definite, strenuous; opposed to negative, which is quiescent, receptive, unresponsive, indefinite. The word has many specific senses: (1) In electricity, the active pole, from which a current is regarded as flowing. (2) In photography, a picture so taken that the lights and shades appear naturally, which is opposite to a negative, in which they are reversed. (3) In optics, a lens that shows a view naturally instead of upside-down. (4) In general, that one of two opposite things which is regarded as primary or active. (5) The thing that is known, can be seen clearly or sensed readily. (6) An adjective, characterizing a dogmatic person, who «always knows he is right.» It is also applicable to the manly nature, as opposed to the womanly, feminine or negative, nature.

POSITIVISM, pŏz'tĭ-tĭv-ĭzm, originally denotes any theory that takes the affirmative side and states its tenets in positive terms. In this sense one speaks of positive Christianity or positive theology, as synonymous with dogmatism, indicating thereby that liberal religion which rejects belief in miracles, or a special revelation, or the traditional Church doctrines, is negative.

The term was appropriated by August Comte to denote a philosophy that would limit itself to the positive sciences and exclude all metaphysical speculation. Comte propounded positivism as the ultimate aim of the evolution of knowledge, which (as Turgot had indicated) necessarily passed through three stages, the theological, the metaphysical and the positive. In the theological stage, the classified phenomena of nature are personified as gods — a view based upon a mythological interpretation of nature which reaches its climax in minotheism and leads to the metaphysical stage in which the laws of nature are conceived as impersonal essences or powers. The highest and last stage is attained when the scientist is satisfied simply to describe the facts and leave out all metaphysical speculation.

Comte felt that there was something wrong with metaphysics, and he eliminated it from the domain of his philosophy, but instead of solving the problem, he ignored it on the plea that it was unsolvable. His great work 'Philosophie Positive' (consisting of six volumes) contains simply a recapitulation of the whole range of human knowledge, the systematic arrangement of which he called the hierarchy of the sciences. Comte does not deny the existence of something metaphysical, but only maintains that research in this domain is fruitless.

Eugen Dühring, a German philosopher of great acumen, rightly criticizes Comte's positivism in saying that «its main contents, strangely enough, consist in negativism," and "a hierarchy of the sciences offering a digest of knowledge cannot pretend to be philosophy." (Krit. Gesch. d. Phil. p. 486).

In a more advanced stage of his life, Comte felt the need of going beyond the standpoint of the positive sciences. In response to this need of his nature he invented a religion of mankind which should be based on science, replacing the idea of God by the conception of ideal mankind. Comte's conception of a scientific religion is worthy of a great genius, but the rituals which he prescribes are too artificial, and proved acceptable only to a very limited circle of his admirers.

Littré, the well-known author of a French dictionary, disavowed Comte's religion as fantastic, but he accepted his philosophy which he formulated as follows: "The domain that lies beyond refers to the things that cannot be known. Positive science proposes neither to deny nor to affirm them. In a word, it does not know the Unknowable, but it recognizes its existence. This is the highest philosophy. To go beyond is chimerical, to go not so far is to miss the mark."

The most prominent English representative of Comtean positivism, George Henry Lewes, sums up the tenets of positivism in this sentence: "Our province is to study her (nature's) laws, to trace her processes, and, thankful that we can so far penetrate the divine significance of the universe, be content — as Locke wisely and modestly says — to sit down in quiet ignorance of all *transcendent* subjects."

The modern representative of Comte's positivism in England, averring both his philosophy and his religion, is Frederick Harrison, president of the English Positivist Committee, and author of 'Positive Evolution of Religion' (New York 1913).

In spite of the shortcomings of Comte's philosophy, the conception of positivism is a great and recommendable ideal; but positivism in order to fulfil its purpose should be truly positive. Genuine positivism would be a philosophy based upon the facts of experience. Whether or not metaphysics is wrong depends entirely upon the definition of the word. If "the metaphysical" is a mysterious essence or power behind nature, the scientist should not merely ignore it but deny its existence; but if, after the precedence of Aristotle, we understand by metaphysics "the science of first principles," we must grant that its study, far from being fruitless, is indispensable for every scientist.

The aim of a positive philosophy should be to understand the methods and general spirit of science, to systematize the results of the totality of human knowledge and to apply them to practical life. Accordingly, philosophy will serve three purposes: it will be (1) the propædeutics (preliminaries) of science, (2) a synopsis of all knowledge and (3) ethics or the science of moral conduct. The first branch of philosophy includes logic, epistemology and methodology, that is, the sciences which are equally needed as intellectual tools in all the several branches of inquiry. The second part, a synopsis of all knowledge, cannot be a mere compendium or a hierarchy of the sciences, but must be worked out into a systematic world-conception, not a mere sum of the sciences but their product, which might be called "ontology," that is, the science of existence or "cosmonomy," the science of the world constitution. Ontology in the old sense is an a priori construction of a system of abstract thought; in the new sense it would be a methodical arrangement of the facts of experience, a monistic or consistent system of knowledge. Cosmonomy explains the prevalence of uniformities and their formulation as general rules, called laws of nature, etc. It points out the permanent background of existence, the eternal conditions of becoming from which world-systems originate and, above all, defines man's position toward the whole of existence, toward his fellows and especially toward those factors that determine his destiny — in religious nomenclature called "God." The third part of philosophy would be a practical application of the second, resulting in what has been called philosophy proper, world-wisdom or, broadly speaking, ethics. Consult Huxley, Thomas, 'Scientific Aspects of Positivism' (in 'Lectures and Lay Sermons,' Everyman's Library, 1910).

PAUL CARUS,
Editor of 'The Monist.'

POSSE COMITATUS, pŏs'ē kŏm-ĭ-tā'tŭs, in law, the force of able-bodied male citizens whom the sheriff by the common law is authorized to call to his assistance in case of invasion, rebellion, riot, breach of the peace, forcible resistance to process, etc., in the county or district in which he holds office. All persons included in the posse comitatus are bound, under penalty of indictment, to assist the sheriff when lawfully called upon and are justified in killing a person in case of resistance. Unnecessary violence on their part, however, is punishable.

POSSESSION, a legal term, which has come to have a larger meaning than in common usage of the word or the primary sense, from Latin *possideo* — to sit upon. It has grown to mean something distinct from mere custody. It is defined as the detention and enjoyment of a thing which one holds and exercises by oneself or through another in his name. It is the condition by which a person may exercise power over a thing at his pleasure and to the exclusion of all others. There are two requisites to complete possession: first, occupancy, and second, the taking with intent to possess — hence persons who are without legal wills — as children, idiots, etc., cannot acquire possession; however, a child of sufficient understanding may legally acquire possession of a thing.

One is said to be in actual possession when the thing is in immediate occupancy and constructive possession when one claims to hold by virtue of a title without actual occupancy; possession may be enjoyed by the proprietor of a thing — thus the proprietor of a house possessing it by his tenant. A thief may have a thing he has stolen, but he does not rightfuly possess it. One who borrows his friend's horse has it in his custody, but is not a legitimate possessor.

To acquire possession of a property it is requisite that there be intention of possessing as owner and also the possession of the thing.

Possession is lost when one transfers a property to another with the intention of divesting himself of the title or when he does some act which manifests his intention of abandoning possession. Though, of course, no proof of ownership or title to property or a thing, the possession is a fact in evidence of it and it is sufficient evidence against anyone who cannot show a better claim. Continuous possession of land for a time, which varies in the statutes of various jurisdictions, usually 20 years, will give the occupant title by adverse possession. With chattels a replevin suit is often instituted to regain custody, when the goods are illegally withheld from the rightful owner. See BAILMENT; TITLE; REPLEVIN.

POST, Alfred Charles, American surgeon: b. New York, 13 Jan. 1806; d. there, 7 Feb. 1886. He was graduated from Columbia in 1822 and from the College of Physicians and Surgeons in 1827. After two years' further study in Paris, Vienna, Berlin and London he established a practice in New York, in 1831–35 was demonstrator of anatomy in the College of Physicians and Surgeons, in 1836 became an attending surgeon at the New York Hospital and throughout his life continued his connection there, occupying at his death the office of consulting surgeon. He was appointed professor of ophthalmic surgery at Castleton Medical College, Vt., in 1843, and of surgery in the following year. In 1851–75 he was professor of surgery in the University of the City of New York, vice-president of the New York Academy of Medicine in 1861–66 and its president in 1867–68, president of the Pathological Society and for many years was connected with Saint Luke's, the Presbyterian and the Women's hospitals. He conducted a weekly clinic at the University Medical College in New York, for many years, was the first surgeon in the United States to perform an operation for the cure of stammering and was the inventor of several valuable surgical instruments and appliances. Besides numerous medical papers contributed to scientific journals, he published 'Strabismus and Stammering' (1840) and 'Observations on the Cure of Stammering' (1841).

POST, George Browne, American architect: b. New York, 15 Dec. 1837; d. 28 Nov. 1913. In 1858 he was graduated at New York University and in 1859–60 studied architecture under the direction of Richard M. Hunt. In the Civil War he was commissioned captain of the 23d New York Volunteers and at the end of the war had risen to the rank of colonel. In 1865–67 he practised as an architect in New York with Gambrill and thereafter independently. He became one of the most successful of American architects of the late 19th century. Among his works are the old Equitable building, Produce and Stock exchanges, the World building and City College buildings in New York; also the residence of Cornelius Vanderbilt in the same city, the Prudential building, Newark, N. J., Liberal Arts building, Chicago, the Wisconsin State Capitol, etc. He was a member of several societies, a chevalier of the Legion of Honor (1901), member of the National Academy of Design and of the National Commission of Fine Arts.

POST, George Edward, American missionary: b. New York, 1838; d. 1909. In 1860 he was graduated in medicine at the University of the City of New York and in the following year at Union Theological Seminary. He was appointed to the chair of surgery at the Syrian Protestant College of Beirut, where he remained until his death. He was an accomplished linguist and wrote several Arabic works, including 'Flora of Syria, Palestine and Egypt'; 'Textbook of Botany'; 'Textbook of Mammalia'; 'Textbook of Birds'; translation of Butler's 'Physiology'; 'Concordance to the Bible'; 'Textbook of Surgery'; 'Textbook of Materia Medica'; 'Dictionary of the Bible.'

POST, Melville Davisson, American lawyer and novelist: b. Harrison County, W. Va., 19 April 1871. He was graduated from the University of West Virginia and has since practised law in Grafton, W. Va. In 1898 he was chairman of the Democratic Congressional Committee of West Virginia. He has published 'The Strange Schemes of Randolph Mason' (1896); 'The Man of Last Resort' (1897); 'Dwellers in the Hills' (1901); 'The Gilded Chair' (1910); 'The Nameless Thing' (1912).

POST, Wright, American surgeon: b. North Hempstead, N. Y., 19 Feb. 1766; d. Throgg's Neck, N. Y., 14 June 1828. He received his medical education in New York and London and in 1786 established a practice in New York. In 1792 he was appointed professor of surgery at Columbia, where he later occupied the chair of anatomy and physiology, afterward holding the same chair in the Medical School of New York. For 35 years he was consulting surgeon in the New York Hospital, president of the College of Physicians and Surgeons in 1821–26, and was prominently connected with numerous medical societies. He made himself famous by his surgical achievements, many of which were departures from the old school.

POST-NUPTIAL CONTRACT. See LAW OF HUSBAND AND WIFE.

POST-OBIT BOND, a mode of contracting loans sometimes resorted to by heirs and others who expect a legacy on the death of some third party. The condition in the bond is, that the sum borrowed shall not be exigible till that party's death; and hence, not only in consequence of the uncertainty of the event, but also sometimes in consequence of the uncertainty of the succession itself, which may be contingent, and perhaps never be realized, the creditor usually makes very exorbitant terms.

POST-OFFICE. See POST-OFFICE DEPARTMENT.

POST-OFFICE CLERKS, United National Association of, an association formed in 1890, for the purpose of securing, through legislation and other means, the classification of post-office clerks with a view toward securing more equitable salary rates, regulation of hours of labor and other similar objects. The organization also issues death benefit insurance policies.

POST-OFFICE DEPARTMENT. The official title of one of the executive departments of the government; established in 1794. It is under the management of the Postmaster-General, who since the time of Andrew Jackson has been a member of the President's Cabinet.

He is appointed by the President and confirmed by the Senate. The department is divided into four great bureaus each under the immediate charge of an assistant postmaster-general. The first assistant's bureau has charge of the large clerical and carrier forces and all the matters of actual management. It supervises an annual expenditure close to $100,000,000. The bureau of the second assistant has the immense task of providing for the transportation of the mails at a yearly cost of about $80,000,000. That of the third assistant looks after the financial side, furnishes the stamps and keeps the accounts. The fourth assistant has charge of the appointment of 55,000 postmasters and directs the force of inspectors.

The Railway Post Office.— The idea of a railway post office was first brought officially to the notice of the department of First Assistant Postmaster-General Hobbie, who, in 1847, had been in Europe, and in his report gave his impressions of the traveling post office in England. Under Postmaster-General Holt, in July 1862, the first railway post office was introduced in this country. In 1864 the leading railroads were induced to alter the cars for the purpose of the railway post office, and from that time this service has grown, until now it is a model institution of its kind. In 1916 there were 3,479 railway routes, 8,027 mail messenger routes, 571 electric car routes, 264 wagon routes, 260 steamboat routes, 21 star routes (in Alaska), and six pneumatic tube routes. The cost of the railway mail service was $28,516,000, and railway mail pay $61,692,000.

Money-Order System.— The money-order system was established in 1864, under the administration of Postmaster-General Blair. In order to accommodate soldiers and others wishing to transmit small sums of money, he advised the incorporation of this idea in our postal system. At its beginning only 138 offices were allowed to issue orders. The number increased to 34,547, which during 1903 issued 45,941,681 domestic money-orders, and in 1917, 133,292,000 domestic orders, and 1,973,714 foreign orders, this latter a decrease due to the war. See POSTAL MONEY ORDER SERVICE.

Rural Free Delivery.—The rural free delivery service was established under President McKinley, in 1897. That year 44 routes were put in operation. The service has grown steadily. By 1901 the mileage had grown to over 100,000, the cost was $1,750,321, and over 15,000 carriers were employed. In 1905 the mileage was 721,237, cost $20,864,000, with 32,055 carriers. In 1910 the mileage was 993,068, cost $36,915,000. with 40,997 carriers. In 1917 the mileage was 1,112,556, cost $52,420,000, with 43,338 carriers. The net advantage of the Rural Free Delivery system include (1) postal receipts increased; (2) value of farm lands enhanced; (3) farmers brought into touch with markets; (4) social and educational benefits derived in country and town by being kept in touch through the daily receipt of papers and correspondence; (5) benefits to small towns. In three, at least, of these advantages the benefit of the postal service to commerce is distinctly notable. See PARCEL POST.

Dead Letter Office.— The dead letter office dates back to 1825. An act of Congress made it the duty of postmasters to publish quarterly, or oftener, whenever the Postmaster-General might direct, a list of letters remaining in their offices, and once every quarter to forward those that could not be delivered to the department at Washington. Here are received annually about 15,000,000 pieces of mail matter.

The Postal Union.— Under the terms of a treaty concluded at Berne, 9 Oct. 1874, the object of which was to secure uniformity in the treatment of correspondence, and the simplification of accounts, as well as the reduction of rates within certain limits, and whose provisions were carried into operation generally 1 July 1875, the whole of Europe, the United States, Egypt, British India and all the colonies of France were at the outset, or shortly thereafter, included in the union, and many other countries and colonies have since joined it. The international accounts in respect of postages are based on a month's return of correspondence taken every third year.

Postal Savings Banks were established by the Postal Savings Act of 25 June 1910. See BANKS AND BANKING; POSTAL SAVINGS BANKS and POSTAL SAVINGS SYSTEM.

Increase of Rates.— In November 1917 the law for increased postage for war revenue went into effect, and first class mail, drop letters and post cards were raised one cent each. The rate on magazines containing over 5 per cent advertising was also increased, according to zones of delivery. Former rates restored 1919.

Post-Office Statistics.— In the United States in 1789 there were only 75 post offices established, the length of the post routes being 2,275 miles and the gross revenue of the department being only $7,510. The expenditures for the same year were $7,560 and of this only $1,657 were paid in salaries to postmasters. In 1875 there were 278,000 miles of postage routes, a revenue of $27,000,000, with expenses of nearly $34,000,000. In 1900 there were 428,000 miles of post routes, a revenue of $110,000,000, and expenses of $120,000,000. The total number of post-offices was reduced from 74,169 in 1903 to 55,413 in 1917, rural free delivery causing the dropping of small offices. There were in 1910, 59,580 post offices in operation, 447,998 miles of post routes, 553,312,998 miles of mail service performed. The gross revenues of the department were $224,128,657.63, the expenditures $229,977,224.50, and $27,521,013.29 were paid as compensation to postmasters. In 1917 these figures had grown to 55,413 offices, 479,487 miles of post routes, $329,726,116 revenue, and $319,838,718 expenditure. In 1911, 1913, 1914, 1916 and 1917 the post office showed a profit, and it is the policy of the department to continue making a slight profit. From June 1847 to June 1851, 4,603,200 postage stamps were issued, while in the single year 1910, 11,360,353,679 stamps were used by the people of the United States. In 1853, the year in which stamped envelopes were first issued, 5,000,000 were used, while in 1910 the total was 1,506,861,593. The first year's issue of postal cards — 1873 — numbered 31,094,000, while in 1910 726,441,000 were issued. The registry system was started in 1854, and in that year the registered pieces numbered 629,322. In 1910 they numbered 42,053,574. In 1865 money-orders to the amount of $1,360,122 were issued, while in 1910 the total amounted to $647,736,327, and in 1917 it was

$855,000,000. The number of pieces of matter of all kinds mailed increased from 500,000 in 1790 to about 20,000,000,000 in 1919. For further information see PHILATELY; POST AND POSTAL SERVICE; STAMPS, POSTAGE; and related references.

POST-PLIOCENE, that division of geologic time and the strata laid down in it which follows immediately after the Pliocene. The term has been used as designating all that period from the end of the Pliocene till now, in which sense it is equivalent to Quaternary (q.v.) or, by some geologists, as applied only to the earlier portion of this period, in this sense being equivalent to Pleistocene (q.v.).

POST AND POSTAL SERVICE. The word post is derived from the Latin *positus*, meaning «placed,» because horses were put or placed at certain distances to transport letters or travelers. From this ancient beginning, the post has developed into one of the most effective instruments of civilization. In the Old Testament are frequent references to the posts. In 2 Chron. one will find: «So the posts went with the letters,» and «So the posts passed from city to city.» In Esther, also, and in Job and Jeremiah one will find other allusions to the posts. But they were never for the use of the common people. The first recorded postal system was in the Persian Empire. According to Xenophon, Cyrus the Elder caused couriers, with saddled horses, to stand ready at different stations throughout the empire, situated one day's journey from each other, in order to receive reports from the provinces without delay. In the time of Julius Cæsar the service of couriers in the parts of the Roman dominions under his government was so well organized that of two letters which he wrote from Britain to Cicero at Rome, the one reached its destination in 26 and the other in 28 days. Such services, however, were only established by governments or persons in authority for their own use. Private persons, in their intercourse with one another, had to employ slaves to convey their letters to destination, or to trust to the chance of finding some person who was going to the place to which the letter was addressed, and was willing to undertake the delivery of it. The Emperor Diocletian, at the end of the 3d century, appears to have been the first to establish a postal system for the benefit of private persons. At later dates Theodoric the Great, Charlemagne and others had well-organized services for communication with all parts of their empire.

Earliest British Postal Envelope (1840).

Early History of the Public Post.— The earliest postal system was established in France by the University of Paris. From the end of the 13th century this institution maintained couriers, who at certain times took charge of letters and money for the students collected in that city from almost all parts of Europe. Louis XI established for his own use mounted messengers, and by an edict of 19 June 1464 instituted post stations on the chief roads of France. This system was continued under the following reign, and ultimately private persons began to make use of the royal couriers for the transmission of their own correspondence. During the reign of Louis XIII the French system of posts received a more regular form from the establishment of a comptroller-general of posts.

In Germany the first post was established in Tyrol in the latter half of the 15th century, by Roger I, count of Thurn, Taxis, and Valsassina. His son established another from Brussels to Vienna in 1516, by the wish of the Emperor Maximilian I. In 1522 a post was established between Vienna and Nuremberg, and Charles V, anxious to have news as quickly as possible, on account of the vastness of his states, caused Leonard of Thurn and Taxis to establish a permanent riding-post from the Netherlands through Liège, Trèves, Spire and Rheinhausen, through Württemberg, Augsburg and Tyrol to Italy.

The postal system of Italy began in Piedmont. Until 1561 the transmission of letters was in the hands of the communes or private persons, who were authorized by the state to charge for the service a sum which varied according to circumstances. In the year mentioned the posts were farmed out by Emmanuel

Philibert, Duke of Savoy, to a postmaster-general. This arrangement continued until 1697, when Duke Victor Amadeus II added the proceeds of the post office to the revenue of the state, an indemnity being paid to the postmaster, who had the contract for them. From 1710 downward the post office was administered directly by the state.

The British Post.— There were private posts in England from the time of Edward III. In 1635 a public post was established between London and Edinburgh. In 1644 Edmund Prideaux, then a member of the House of Commons, was appointed master of the posts, and first established a weekly conveyance of letters into all parts of the nation. In 1683 a penny post was set up in the metropolis. During the government of William III acts of Parliament were passed which regulated the internal postal system of Scotland; and, by the ninth act of Queen Anne, the postal system of England was arranged on an improved footing. A general post office was instituted at London for the British dominions with chief offices at Edinburgh, Dublin and other places, while the whole system was placed under the control of a postmaster-general with power to appoint deputies for the chief offices. At this time the letter rate of postage was eight cents for 15 miles or under, with a rising scale to 25 cents for 300 miles. In 1837 Sir Rowland Hill inaugurated a movement for reform in the postal service. Penny postage resulted in 1839, and on 6 May 1840 the first postage stamp, designed by W. Mulready, was first brought into use. In the same year the money-order system was adopted and in 1848 the book post was established. In 1855 pillar letter-boxes were introduced, and London was divided into 10 districts, for greater facility in the distribution of city letters. The British post-office system developed rapidly after 1860, and has long included a parcels post and banking and telegraph systems. The service is under the immediate control of the Postmaster-General, assisted by the chief secretary of the post office in London. There are also chief officers in Edinburgh and Dublin. The Postmaster-General is a member of the Privy Council, and sometimes a Cabinet minister. In 1915 there were 24,509 post offices in the United Kingdom and 50,285 road and pillar letter-boxes. The total number of letters delivered during the year was 3,409,000,000.

The Colonial Post in America.— In the American colonies the post office made its first appearance in Massachusetts in 1639, when the General Court of that colony issued the following: «It is ordered that notice be given that Richard Fairbanks, his house in Boston, is the place appointed for all letters, which are brought from beyond the seas, or are sent thither, to be left with him, and he is to take care that they are to be delivered or sent according to direction: and he is allowed for every letter a penny, and he must answer all messages through his neglect of this kind.» In 1657 a postal service was established in Virginia. The colonial law required every planter to provide a messenger to convey the dispatches, as they arrived, to the next plantation, and so on, on pain of forfeiting a hogshead of tobacco for default. In 1672 the government of New York established a mail to go monthly between New York and Boston. In 1674 the General Court at Hartford enacted laws to regulate the postal services in the colony. In July 1683 William Penn established a post office in Philadelphia, with weekly mails to various places near the city, and about the same time opened mail routes between Philadelphia and the larger towns of Pennsylvania and Maryland. These represent the several colonial enactments in relation to postal communication.

Neale's American Post.— The beginning of the American post proper dates with the signing of a patent 17 Feb. 1691 vesting in Thomas Neale the American post. On 4 April following, Neale and the Royal Postmaster-General appointed Andrew Hamilton postmaster-general of America. Hamilton undertook the arduous duty of establishing an intercolonial post. He visited all the colonies, was trusted implicitly and satisfied each colony of his ability and resources in the new venture. The co-operation of all the colonies except Virginia having been secured, services began on 1 May 1693, and consisted of a weekly post from Portsmouth, N. H., to Boston, Saybrook, New York, Philadelphia, Maryland and Virginia. Five riders were engaged to cover each of the five stages twice a week. In winter, service was performed fortnightly. Hamilton died in 1703, and his son, John Hamilton, succeeded him. In 1707 the Crown purchased the good will of the American post office and continued John Hamilton as postmaster-general. From 1707 to the year before the Revolution the General Post Office in London controlled the service in America. In 1711 there was a weekly mail operation between Boston and Main, and fortnightly exchange between Boston and New York. In 1717 the mail ran weekly between New York and Williamsburg, Va., and 10 years later there was a fortnightly mail between Philadelphia and Annapolis, Md. The period of activity in the establishment of postal facilities began when Benjamin Franklin was appointed postmaster at Philadelphia in 1737. At the request of the deputy postmaster-general for the colonies, he assisted him in the regulation and management of the various post offices then established, and when that official died, in 1753, Franklin, in company with William Hunter, was appointed to succeed him. In consequence of some difficulty with Governor Hutchinson of Massachusetts, Franklin was removed in 1774.

The United States Post.— The Continental Congress met at its second session, in Philadelphia on 26 July 1775, and its members resolved to have a post-office system of their own, and Franklin was elected to carry on the work. A salary of $1,000 a year was voted him. However, Franklin's great diplomatic talents secured him soon afterward a transfer to a wider field, and in 1776 his son-in-law, Richard Bache, was appointed to succeed him. Mr. Bache was succeeded in 1782 by Ebenezer Hazard, who had, in 1775, been the «constitutional postmaster» of New York, so termed to distinguish him from the British deputy at that place. The Colonial Congress in 1782 passed an act authorizing the postmaster-general to establish a line of posts between New Hampshire and Georgia, and to such other places as Congress might direct and to appoint the necessary deputies, for whose faithfulness and honesty he was to be held accountable. On 8 May 1794 the Congress passed the first law for the proper management of the postal service. In 1799 the postal laws were revised, and flogging substituted for the death penalty for robbing the mails. This law, however, was repealed by a subsequent enactment, and imprisonment for a term of years made the penalty. The office of Second Assistant Postmaster-General was created in Madison's administration, and the scale of postage changed. Single letters — that is, containing one piece — were charged from eight to 25 cents, according to distance. The Sunday delivery at post offices began in 1810, bringing forth vigorous remonstrances from various religious bodies, and the strife was kept up in Congress and occupied the attention of the Department for 20 years. In 1813 the mails were first conveyed in steamboats from one post town to another. The postal laws of 1816 made a change in the postage, which lasted until 1845. The new scale charged for letters, consisting of one piece of paper, not going over 30 miles, six cents; not over 80 miles, 10 cents; not over 150 miles, 12½ cents; and not over 400 miles, 18¾ cents; and for greater distances, 25 cents. The success of the postage stamp in Great Britain led local postmasters in a number of United States cities — notably New York, Baltimore, Saint Louis, Providence and New Haven — to issue stamps. They proved popular, and in 1847 the United States introduced stamps and the 5 and 10-cent denominations, with the faces of Franklin and Washington respectively. Previously the postage was collected entirely in money, its prepayment being in all cases optional. On 1 July 1851 a new series of stamps was adopted, consisting at first of denominations of one and three cents, but afterward of larger amounts. Stamped envelopes were first used in 1853. The registration system was instituted in 1854, during the administration of President Pierce. The first fee was five cents; the price was raised in 1863 to 20 cents. It is now ten cents. In the administration of President Lincoln the free delivery service was established. As early as 1825 provision was made by Congress for the delivery of letters by carriers at a cost of two cents each to the persons receiving them. In 1836 this was further amended by allowing newspapers and pamphlets to be delivered at half a cent each. In 1863 Postmaster-General Blair introduced the free delivery system, beginning the practice in cities of 50,000 population. Receiving boxes were also put up and deliveries provided for as often as the public convenience demanded. The postal card was introduced in 1873. For the further development of postal service see POST-OFFICE DEPARTMENT and related references.

POST-RENAISSANCE PAINTING, painting as practised in Europe after the middle of the 15th century.

Seventeenth Century.— The great color school of monumental and decorative painting which was the glory of Venice was one of the last to disappear (see RENAISSANCE PAINTING). Paris Bordone (q.v.), a pupil of Titian, did little to maintain it, but a much more vigorous and original talent was that of Jacopo Robusti (1518–94), called Il Tintoretto from his father's occupation as a dyer, and also surnamed Il Furioso from his manner of working. The number of his paintings was very great, and their merit very unequal. From the school of Verona, which had been for some time rising in importance, and even in the 15th century had produced some painters of note, came another illustrious artist to add to the fame of Venice, Paolo Cagliari (q.v.), called Paolo Veronese (1532–88), one of the most brilliant of all decorative painters. The school of Bologna was founded by Lodovico Carracci, aided by his two cousins, Agostino and Annibale, in 1589, at the period of the rise of the Electric school, protesting against the Mannerists, and of the *naturalisti*, rejecting all tradition and professing to study nature directly. In Naples appeared an Hispano-Neapolitan school of which the chief was Jusepe Ribera, called Lo Spagnoletto. Spain produced a number of native painters in the 15th and at the beginning of the 16th century; and the influence of Italian art became more predominant toward the middle and at the close of the latter. But the authority of the Inquisition was strongly restrictive. Francisco de Zurbaran (q.v.) (1598–1662?) was preeminently a painter of monks. The three great names in Spanish art are Alonzo Cano (q.v.) (1601–67), a pupil of Francisco Pacheco, the master and also the father-in-law of Velasquez; Diego Rodriguez de Silva y Velasquez (q.v.) (1599–1660); and Bartolome Estéban Murillo (q.v.) (1618–82). The name of Velasquez has been raised by modern criticism to the summit of the art of painting. In Germany, no painter attained the eminence of Dürer and Holbein for more than two centuries; after them, a baleful imitation of the mannerisms of the Italians suppressed any assertion of national individuality, and the so-called inspiration from Michelangelo affected even foreign painters visiting in Germany,— as the Hollanders Goltzius, Hubert and Hendrick. The works of Adam Elzheimer (1578–1620), though he visited Italy and died in Rome, displayed a curious and original talent, both in figures and landscape, unusual at this period.

But it was to the Netherlands that the chief seat of the art of painting was transferred in the 17th century, made illustrious by the great development of all resources of the art; the influence of Peter Paul Rubens (q.v.) (1577–1640) not only revolutionized the schools of painting of his era but is still felt in those of our day. One of the most celebrated of his pupils was Anton Vandyck (q.v.) (1599–1641), whose portraits constitute his chief title to eminence; another was David Teniers the elder (q.v.) (1582–1649), instructor of his still more famous son of the same name. In the works of the latter, and of a number of the painters of Holland, Adrian Brauwer (q.v.), Adrian Van Ostade (q.v.), Jan Steen (q.v.), Gérard Terburg (q.v.), Gabriel Metzu (q.v.), Gérard Dow (q.v.), is carried to the highest point the genre painting of contemporary life, the *extériorité*, which so strongly differentiates this Northern art from that of Italy. In the painting of landscapes, animals, marines and even still-life, this excellence of technique was also maintained, reaching its supreme development in the genius of Rembrandt (q.v.) (1607–69), the greatest master of light and darkness of any school of painters. Under François I, a number of Italian painters were induced to visit France, many of them being employed in the decorating of the palace of Fontainebleau, and their influence prevailed strongly for nearly two centuries. The art of the 17th century was largely the official art of Louis XIV and of his court painter, Charles Lebrun (q.v.); one of the most important events was the establishment of the Academy of Painting and Sculpture at Paris in 1648. A much more graceful and idyllic art was introduced by Nicholas Poussin (q.v.); and the classic landscape by Claude Gelée, called Claude Lorrain (q.v.). In England, also, foreign artists, in this case French, Flemish and even Greek, were largely employed before the reign of Henry VII (1485–1509), in painting miniatures on glass, enamels, etc. The example of Henry VIII in encouraging the great Holbein was followed by his successors,— Mary Tudor employed Antonio de More (Antonio Moro); Elizabeth, Lucas de Heere and Frederico Zuccari; Charles I, Rubens and Van Dyck; Charles II, Peter Lely, of Soest in Westphalia, and Godfrey Kneller of Lübeck. The only English names that assume any importance in these annals are those of Isaac Oliver, his son Peter, Samuel Cooper, a pupil of Van Dyck, Robert Streator, Henry Anderton and Peter Monamy.

Eighteenth Century.— During the 18th century the art of the Netherlands passed into an eclipse, recognized, and deplored, by the national historians, and that of Germany into another, which was long hailed as a «revival.» Belgium, the battle-ground of Europe for so many years, exhausted and ravaged under its constantly changing rulers, could furnish no encouragement to the arts, and the painters, like those of Holland, with a very few exceptions, abandoned their own initiative and the study of native art for the servile imitation of the works of their predecessors,— the portraitists and the figure painters, such as Rubens and Lebrun; the landscapists, like Poussin; the battle painters, like Philips Wouwerman (q.v.), etc. In Germany, the revolt against the general decline was called the Classic Movement, the first of the three great epochs into which this revival is divided, and which is dated from the arrival of Raphael Mengs (q.v.) in Rome, in 1741. The future leaders in the second phase of this movement, Cornelius, Overbeck, Veit, Schadow, etc., were all born in the very last years of the century. Great Britain and France, on the contrary, developed, in a number of distinct schools each, fresh evidences of a national and original art, in practically all the branches of painting. In portraiture, the British record the names of Reynolds, Gainsborough, Romney and Raeburn; in genre, not always satiric, Hogarth — one of the most preeminently national of all artists, and Wilkie; in landscape, Gainsborough, Old Crome, Constable and Turner. In academical and historic art, the Americans, Copley and West, rose to international eminence. In France, the last days of the monarchy were made illustrious by the delicate and graceful courtly art of Watteau (q.v.), Pater, Lancret and Fragonard, the frail idylism of Greuze (q.v.) and the admirable naturalism of Chardin (q.v.) — to be succeeded in their turn by the pedantic «classicism» of David and the Empire. This century is distinguished also by the growing recognition of the popular interest in art, encouraged by the opening of royal galleries and the dissemination of engraving. Three female painters appear, whose graceful talents entitle them to recognition,— in Venice, Rosalba, Carriera (q.v.) 1675–1757); in Germany, Angelica Kauffmann (q.v.) (1741–1807); and in France, Mme. Vigée-Lebrun (q.v) (1755–1842). In Italy, the last glories of the Venetian school flamed up in the daring and truly decorative work of Giambattista Tiepolo (q.v.) (1696–1770).

Nineteenth Century.— During the 19th century the supremacy in painting and sculpture was transferred to France; Paris, with its annual official Salons, became the recognized capital of the fine arts for Europe and America. French art in this century has been considered to have passed through three great periods, corresponding closely with changes in the national government,—Classicism, Romanticism and the third period, dating from 1848, the schools of the Second Empire and the Third Republic. All these have naturally had many subdivisions. The classicism of Louis David (q.v.), with its sacrifice of everything in painting to the outline and to what was considered to be an imitation of the antique, was obliged to yield gradually to the Napoleonic art, representations of battles and of state ceremonies, and to genre painting,— the last not being officially recognized till 1816. Classical painting, which dominated in Europe for 50 years, was almost exclusively figure painting; its rigid formalism gave way to a greater sympathy with nature even in the works of David's immediate pupils and followers, Regnault (q.v.), Picot (q.v), Baron Gérard (q.v.), Gros (q.v.) and Ingres (q.v.). And much more living and sympathetic classic taste than David's was that of Prud'hon (q.v.). Romanticism found its first expression in painting in the works of Géricault (q.v.), though Delacroix (q.v.), more emotional and more of a colorist, is considered to have been the leader. The essential narrowness of this form of art was also gradually tempered by naturalism, so that its range became wider,— as in the very different art of Decamps (q.v.), first of the Orientalists, and of Ary Scheffer (q.v.) and Paul Delaroche (q.v.). Landscape painting began to assume that great importance which it has ever since maintained in modern art, and the way was opened for the famous Fontainebleau school of Corot (q.v.), Rousseau (q.v.), Troyon (q.v.), Diaz (q.v.), Daubigny (q.v.) and Jules Dupré (q.v.), in which the painting of cattle is also raised to its highest eminence. The school of the peasant — as it might be called — which has played so large a part in contemporary painting, both of France and of all the nations whose students have imbibed French methods and conceptions, permits of such a wide range of treatment as that between the very frank realism of Courbet (q.v) and the «hieratic gloom» of Jean-François Millet (q.v.). Somewhere between these extremes are the rural scenes of Lhermitte (q.v.) and those of Jules Bréton (q.v.), in which realism is tempered with a certain style, with a strong desire to avoid the merely commonplace.

The latter half of the 19th century saw the rise of so many and so widely differing movements and tendencies in French painting that no general classification is possible. Under the Second Empire the official art, that of the

Académie and the Institut, included such celebrated names as those of Gérôme (q.v.), Jules Joseph Lefebvre (q.v.), Bonnat (q.v.), Cabanel (q.v.), Baudry (q.v.), Bouguereau (q.v.) and Henner. In Genre, characterized usually by excessive delicacy and accuracy of finish, the highest place was held by Meissonier (q.v.); and but little inferior was the work of Louis Leloir and Vibert (q.v). Something of the haunting antique influence appears in the work of Gleyre, Couture (q.v.) and Flandrin (q.v.), protesting against the rising flood of «realism»; something also in that of the so-called Neo-Grecs, of which the two most sincere and persistent were Hamon (q.v.) and Aubert. The most graceful of the Orientalists was Fromentin (q.v.), and the painters of Eastern subjects, in very varying methods, include many of the most celebrated names of this epoch, Gérôme, Henri Regnault (q.v.), Benjamin-Constant (q.v.), Belly, Boulanger and others. Of the mystical school, uninfluenced by any conventions or traditions, the most striking example is that of Gustave Moreau (q.v.); and one of the most distinguished and honored of the older men is Hébert (q.v.), whose delicate, melancholy art has not varied since 1850. Nearly all the French figure painters are portraitists. Military subjects have been rendered with a realistic accuracy and a dramatic force never before attained, by Yvon (q.v.), Detaille (q.v.), De Neuville, Aimé Morot, Roll and others; mural painting received a new inspiration from Puvis de Chavannes (q.v.); a warmer splendor of color than that of the Venetians was revived by Monticelli (q.v.); and the still-life of the early Dutch painters equaled by that of Dosgoffe and Vollon (q.v.) One of the most important manifestations of this contemporary school was that of the Impressionists (q.v.), with their new theories of presenting absolute realities, and of which the most uncompromising advocates among the leaders were Manet (q.v.), Monet (q.v.), Sisley, Pissaro, Caillebotte, and others. While the influence of this innovation still lingers, the contemporary art of the Salons shows but very little trace of it. It is to be noticed that the great decline in all artistic value of these annual Salon exhibitions, and of the national art generally, within the last 10 years, has been admitted by the French themselves.

In Great Britain, the influence of the Pre-Raphaelite movement of 1851 is considered to be still very strong, especially among the younger painters, but it is certain that that of the Newlyn school, much later, and even of the Glasgow school in landscape painting, has had very much more to do with the introduction of more purely artistic conceptions and a much sounder technique. A few of these younger colorists, as La Thangue and Clausen, have been officially recognized by the Royal Academy (q.v.), and the works of a number of the others, as Edward Stott, Alfred East, Alfred Parsons and J. M. Swan, the animal painter, appear at its annual exhibitions. Unlike the Pre-Raphaelites, who advocated the distinctly moral purpose of art — rejecting all but the sincerity and truth-seeking methods of Raphael's predecessors, and unlike the conventional characteristic art of the day with its insistence upon details and a subject, these modern innovators paint the simplest themes with breadth and with skilful rendering of atmosphere and color. At the head of the academical school stands the name of Sir Frederick Leighton, afterward Lord Leighton (q.v.); his immediate successors in the office of president, Sir John Everett Millais (q.v.) and Sir Edward J. Poynter (q.v.), sustain intelligently the traditions of an art whose greatest defect is generally in the brush-work. All forms of painting are represented in this school, historical, decorative, portrait, genre, landscape and marine. The British water color school has long been considered to be one of the most important branches of the national art; it likewise includes all subjects in its province and treats them with much the same seriousness of detail as the oil-painting. The most important of the official bodies after the Royal Academy are the Royal Scottish and the Royal Hibernian academies, and there are many minor societies representing various tendencies of the art.

Unlike England or France, northern Germany has never possessed one recognized centre of the arts — the conflicting claims of Berlin and Munich being mutually disallowed; but in Austria, the capital, Vienna, has long enjoyed this distinction — in the 18th century and in the 19th more particularly since the aggrandizement of the city following the razing of the outer walls in 1858. This period gave rise to a species of electicism in all the arts, in which a great variety of styles and influences prevailed. In Prussia and Bavaria, the second period of the great revival, led by Cornelius and Overbeck, began about 1810; and the third — the natural reaction against the mysticisms and devoutness of these «Nazarites» (q.v.), and hence considered to be naturalistic — about 1830. Still another regeneration is placed immediately after the close of the war of 1870–71. The development of this latter, however, was slow; the real leader in the modern movement is considered to be Franz Stück (q.v.), who first became widely known at the exhibition in Munich in 1889. This movement was particularly directed against the academic formulas of the historic painters of the school of Piloty (q.v.) and the rural genre of Defregger (q.v.) and Vautier (q.v.). Much of the influence of the older men, however, still survives and among those who escaped this general denunciation was the veteran, Menzel (q.v.). The three great «Secession» movements were those of Munich, Düsseldorf and Berlin, but the art of the latter capital is still largely official. The secession in Austria and the division of the painters into «the old and the new» dates from only about 1897. In Hungary, the national art, rising from the exhaustion and devastation of the numerous wars and revolutions, is considered to have taken form after the Revolution of 1848.

Contemporary Continental painting may be said to have been so greatly influenced by the art of France as to have fallen into a routine in which mere technical skill very frequently takes the place of any strong national or individual assertion. This is particularly true of Italy, Spain and Portugal. In the former, the Neapolitan painters, the chief of whom are Palizzi, Morelli and his pupil, Michetti, are the most interesting and the best known abroad; about 1887 a society of Roman painters was formed to combat the commercial art of the day, for which Fortuny (q.v.) was considered to be largely responsible. Among the few painters with international reputations, two of the most prominent are Segantini and Madame Romani-Carlesimo. In Spain, also, but few traces are left of the brilliant Roman-Spanish school (q.v.) of Fortuny, even in the genre. In much broader methods all the brilliancy of the contemporary cosmopolitan technique appears in the luminous canvases of Sorolla y Bastida (q.v.), and what are considered to be the qualities of Goya in the somewhat brutal scenes of daily life by Zuloaga. Dignified historical art is worthily represented by Pradilla (q.v.); and the small Venetian scenes painted by Rico are widely known. Portuguese art has suffered from many national ills; the list of contemporary painters is headed by the king, Dom Carlos I.

Painting in the Netherlands has not followed common lines of development in Holland and Belgium — in the latter, it has been susceptible to every new wind of doctrine from abroad, while the Dutch artists have remained faithful to what may be defined as the national principles for the last 30 years. This close appreciation of nature, the sense of the essential and intimate quality of things, differs from the famous national art of the 17th century, both in conception and in technical processes, but it seems to be rather an evolution than a revolution. The leaders in the movement against the undiscriminating assimilation of all other European methods, which prevailed in 1830, were Josef Israëls (q.v.) and Jacobus Maris (q.v.); the renown of the latter is shared by his two brothers, Matthys and Willem. The landscapes of Jongkind, Willy Martens, Blommers and Anton Mauve, the marines of Mesdag, the domestic genre of Albert Neuhuys, the church interiors of Bosboom, have given this art an international renown. Among the younger painters, a not very important independent movement was set on foot within the last few years — that of the «New Impressionists,» seeking the expression of greater vehemence, of more passion, in their works. The leaders in this were Isaac Israëls, the son of Josef, and Georges Hendrik Breitner. In strong contrast with this national art is that of a few denationalized painters who have gone abroad — as Kaemmere, in Paris and Alma-Tadema in London. The somewhat undiscriminating revolt against all the old traditions in Belgium was inaugurated by the founding of the Société libre des Beaux-Arts in 1868, followed by various associations, publications, manifestations and «discoveries.» So widely divergent are the principles of the modern school, however, that they include the historical paintings of Baron Leys (q.v.), the marines of Clays, the powerful and gloomy renderings of the life and labor of the poor by Constantin Meunier and the impressionism of Evenpoel, resembling that of the Spaniard Zuloaga. Of the mystical and imaginative painters, the most reticent and refined is Fernand Khnopff; one of the so-called realists, very hard in design and color and sacrificing all tones and values, is Léon Fréderic.

Scandinavian art, also, shows divergencies, following national characteristics — that of Norway being ruder, somewhat more direct; that of Sweden following more faithfully the varying currents of foreign art, as does the scanty art of Finland; that of Denmark, seemingly more intimate, with comparatively little variety. The emancipation from foreign domination, mostly German and latterly French, is recent and is not yet complete, dating in Denmark from the commencement of the 19th century, under Thorwaldsen (q.v.) the sculptor and Eckersberg the painter; and in Norway from only about 1890. The sound technical training that permits of the rendering of even the distinctively northern themes, the clear, cold, impressive aspects of nature, the sincere and intimate domestic genre, has in nearly all cases been acquired in foreign schools — Norway and Finland having none of their own; and of the most brilliantly equipped of these painters, as the Swede, Zorn (q.v.), and the Norwegian, Thaulow, it is to be said that their art, like their celebrity, is cosmopolitan. Many of the artists trained in Paris have identified themselves with the contemporary French school — the Norwegians generally excepted. Among the few painters who have remained distinctly national, one of the most original and most decorative in his work is Carl Larsson of Sweden; Gerhard Munthe of Norway, a good landscape painter, owes his international reputation to his very curious and novel renderings of ancient legends.

The art of Switzerland, like the best of all that of the minor countries, even the South American and the Danubian, reflects strongly the influence of the Parisian schools. In Basel, however, in 1897, was celebrated a double festival in honor of Holbein and Böcklin (q.v.), the latter a painter whose art was singularly free from all traditions whatever.

The art of western Europe was first introduced into Russia by Peter the Great; before him it was barbaric, or semi-Byzantine, like the civilization. The Saint Petersburg Academy of the Arts was founded by the Empress Elizabeth in 1757. In its curriculum the imitations of the various European schools of painting were taken up in turn, or simultaneously, from Carracci and Guido Reni to the classicism of David and Mengs. The reaction against these has naturally developed a number of painters who strive to give expression to the sympathy with their own race or their own ideals; many of them share the depression, the pessimism, which characterizes so much of the contemporary literature. This affects strongly the landscape sentiment, even in the works of artists who have returned from studying abroad. Of these figure painters, the most important are Répin, Wasnetzoff, Serof and some others, the first named being one of the boldest of the realists of any school or time. Verestchagin (q.v.) is well known abroad by his very numerous and very large canvases in which he has sought to depict the horrors of war. In the Russian school are included the two Finnish painters, Edelfelt, whose figures and portraits are rendered with all the excellence of Parisian technique, and Axel Gallen, whose strikingly original paintings depict weird scenes in the national legends. Of the painters of Poland, the most widely known are Matejko and Josef Brandt (q.v.).

In the United States, painting has developed along the lines of technical excellence, rather than in any striking or inspiring development of a great distinct national art. Even in the matter of technique, some of the early portrait painters, as Gilbert Stuart (q.v.) and the wood-engraver, A. B. Durand (q.v.), remain unsurpassed. Trumbull (q.v.) and Washington Allston (q.v.) were not only portraitists but also painters of historical and imaginative compositions, the former excelling in the small heads in his large historical canvases, and the latter displaying more of a painter's feeling for tone and color. The art of Benjamin West and C. R. Leslie belongs rather to England and is to-day quite alien. The modern landscape may be said to commence with the pictures of the visionary Thomas Cole (q.v.), and is rapidly developed in the work of the painters of the "Hudson River School," the most important of which were J. F. Kensett (q.v.), Sandford R. Gifford (q.v.), W. Whittredge (q.v.) (d. 1910), T. A. Richards (d. 1900) and Jervis McEntee (q.v.). The great panoramic canvases of Albert Bierstadt (q.v.) and the far more distinguished landscape compositions of Fred S. Church (q.v.), have no reflection in the work of to-day. This landscape art has culminated apparently in the renderings of tone and atmosphere, and the sentiment of nature in her quieter moods, in the works of such artists as George Inness (q.v.), Homer Martin (q.v.) and A. H. Wyant (q.v.) (d. 1892), and, of the stronger moods, Winslow Homer (q.v.), a painter of the clearest insight and most truthful rendering. William Page (q.v.) (d. 1885) and Daniel Huntington (q.v.) (d. 1906), each in his turn president of the National Academy of Design, enjoyed very considerable reputations as portrait painters, the former devoting himself to an effort to discover the secret of the color of the Venetians. At the present day, Blakelock, Ryder, Horatio Walker, Murphy, Dewey and Dearth represent the imaginative school of landscape; with them may be placed the more literal canvases of Tryon, R. Swain Gifford (d. 1905), Chase, Picknell, Bolton Jones and Theodore Robinson (d. 1896) — to mention only a few of a very long list. The portrait painters are also numerous; John S. Sargent (q.v.) enjoys an international reputation as one of the greatest of any school; Whistler (q.v.) (d. 1904; who resided in England), Eastman Johnson (d. 1906), Brush, Chase, Alexander (d. 1881), Vinton, Collins (d. 1903), George Butler, Wyatt Eaton (d. 1896), Beckwith, Tarbell, Benson, Vonnoh, Metcalf, Wiles and Fowler (d. 1910), at home, are among the most distinguished, as is Miss Cecilia Beaux. Most of these also paint genre, or semi-decorative figure pieces; some of them having commenced as illustrators, or still practising that art. Among the latter are Howard Pyle (d. 1911), A. B. Frost, W. T. Smedley and Hopkinson Smith (d. 1915). E. A. Abbey (q.v.) (d. 1911), originally an illustrator, had transferred his residence to England and painted both in historical and in large mural compositions.

John La Farge (q.v.) is in a way a link between the old and the new, having been a pupil of Couture, and the first, practically, to seek color for its own sake, in oil, in his very numerous water-colors and in his later monumental work both on walls and in stained glass. Another of the older men, Robert Weir (d. 1889), was noted for his important figure compositions, apparently influenced by the European schools; Alden Weir renders much simpler scenes in methods somewhat more affected by wholly modern processes; Thomas Moran, mountain landscapes and Venetian scenes inspired by the English painters of the early part of the century. A number of the figure and landscape painters have established themselves in Paris, MacEwen, Melchers, Julius Stewart, Edwin Lord Weeks (d. 1903), Johnston and others; Hitchcock in Holland, Ulrich in Germany, etc. The list of marine painters is also long; among the most talented are Arthur Quartley (q.v.) (d. 1886), Henry Snell, T. W. Richards, C. T. Chapman and some others, and, among the older men, James Hamilton (d. 1878).

In figure painting there has seemed to be a lack of popular appreciation for anything more ambitious than small examples of genre, usually familiar and domestic themes, rather than for the historic or the more purely imaginative or mystical — the most important exceptions of late years being the dignified, almost monumental canvasses of Abbot Thayer, and the Oriental interiors of Siddons Mowbray. The increasing use of large mural paintings in public and private buildings has, however, developed a school of truly decorative artists, of which the first in point of time was Wm. Morris Hunt, Frank Millet (d. 1912); the living painters are Mowbray, Dewing, Simmons, Blashfield, Vedder, C. Y. Turner, Robert Reid and a few others.

WILLIAM WALTON,
Painter; Author of 'Chefs-d'Œuvre, Exposition Universelle,' Paris.

POST-TERTIARY PERIODS, the last main division of the Geological Record, and which includes all the formations accumulated from the close of the Tertiary Periods down to the present day. No sharp line can be drawn at the top of the Tertiary groups of strata. On the contrary, it is often difficult, or indeed impossible, satisfactorily to decide whether a particular deposit should be classed among the younger Tertiary or among the Post-Tertiary groups. In the latter all the mollusks are believed to belong to still living species, and the mammals, although mostly of existing species, include some which have become extinct. These extinct forms are numerous in proportion to the antiquity of the deposits in which they have been preserved. Accordingly a classification of the Post-Tertiary strata has been adopted, in which the older portions, containing a good many extinct mammals, have been formed into what is termed the Pleistocene, Post-Pliocene, or Glacial group, while the younger deposits, containing few or no extinct mammals, are termed Recent. The Post-Tertiary periods are now generally termed Pleistocene and designate the units of geological time from the end of the Tertiary to the beginning of the Historic. This term was introduced by Sir Charles Lyell.

The gradual refrigeration of climate was prolonged and intensified in Post-Tertiary time. Ultimately the northern portion of the Northern hemisphere was covered with snow and ice, which extended into the heart of Europe, and descended far southward in North America. The previous denizens of land and sea were in large measure driven out, or even in many cases wholly extirpated by the cold, while northern forms advanced southward to take their places. The reindeer, for instance, roamed in great numbers across southern France, and Arctic vegetation spread all over northern and central Europe, and what is now the temperate zone of America. After the cold had reached its climax, the ice-fields began to retreat, and the northern flora and fauna to retire before the advance of the plants and animals which had been banished by the increasingly severe temperature.

The insensible gradation of what is termed the Pleistocene into the Recent series of deposits affords a good illustration of the true relations of the successive geological formations to each other. We can trace the gradual passage because it is so recent that there has not yet been time for those geological revolutions which in the past have so often removed or concealed the evidence that would otherwise have been available to show that one period or group of formations merged insensibly into that which followed it. The Recent formations are those which have been accumulated since the present general arrangement of land and sea, and the present floras and faunas of the globe were established. They are particularly distinguished by traces of the existence of man. Hence the geological age to which these belong has been spoken of as the Human Period. But there is good evidence that man had already appeared on earth during Pleistocene time, so that the discovery of human relics does not afford certain evidence that the deposit containing them belongs to the Recent series. Nevertheless it is in this series of the Post-Tertiary deposits that vestiges of man become abundant, and that proofs of his advancing civilization are contained.

During the Recent period the same agencies have been and are at work as those which have been in progress during the vast succession of previous periods. No trace can anywhere be detected of a break in the continuity of the evolution through which our globe has passed. See GEOLOGY (*Divisions of Geologic Time*) and consult the bibliography under that article. Consult also Fairchild, H. L., 'Pleistocene Geology of New York State' (in Bull. Geol. Soc. America, Vol. XXIV, Washington 1913).

POSTAGE STAMPS. See PHILATELY; POST AND POSTAL SERVICE; STAMPS, POSTAGE.

POSTAL MONEY-ORDER SERVICE. A governmental agency, operating through the post offices, to promote public convenience in remitting small sums of money, and to ensure greater security in the transfer of money through the mails.

Notwithstanding the fact that England has been successfully operating a money-order service since the year 1839, the need for such a facility in the United States does not appear to have been recognized until about 1857. On 31 January of that year Postmaster-General Campbell furnished the chairman of the Committee on the Post Office and Post Roads of the House of Representatives, on his request, with an outline of a plan for a postal money-order system such as might be put in operation in this country, but no action appears to have been taken in the matter. In the annual report of the department, dated 1 Dec. 1857, it was stated that the adoption of some method for the more convenient and safe remittance of small sums of money through the mails by means of orders had been frequently urged as a matter worthy of attention. The first definite recommendation made by the department, however, appeared in the annual report for 1862. Postmaster-General Blair in setting forth therein reasons for the exclusion as far as practicable of money from the mails recommended the adoption of a money-order system as one of the remedies for the evils resulting from the common practice of enclosing currency in letters.

No action having been taken upon the recommendation, it was renewed in the annual report of the department for 1863, Postmaster-General Blair expressing the opinion that such a system «would not only prove a great convenience to civilians and soldiers, but would almost entirely obviate the loss of many letters, the great majority of which enclose small remittances.»

The money-order service finally was authorized by Congress in the act approved 17 May 1864, and on 1 November of that year the system was put in operation. The service was inaugurated at 141 offices, which had been designated by the Postmaster-General in accordance with the authority conferred upon him by the money-order act. In making the selection of the new-fledged money-order offices, it was deemed expedient to designate first the larger post offices and then to extend the service to others as rapidly as possible. This method resulted in a register of 419 offices equipped for the transaction of money-order business at the end of the first year of operation.

Measures were early taken to extend the service to the army, and the fact that money-orders to the amount of $403,776.80 were drawn at the great centres of military operations during the first eight months of the system's existence is evidence of the extensive use to which it was put by the soldiers in sending money to their families and friends.

For a number of years following the close of the Civil War, the government itself was a patron of the system. Money-orders amounting to many thousands of dollars annually were issued on the application of the War Department for the payment of claims for bounty and back pay due by the United States to colored soldiers for services during the war, the organization of the money-order service rendering valuable assistance in insuring the proper payment of the claims.

One of the means provided by the act approved 13 June 1898 to meet expenditure caused by the Spanish War was the collection of a tax of two cents on each domestic order issued. The collections began 1 July 1898 and ceased 30 June 1901, by repeal of the law. During this period the system collected for and paid to the Internal Revenue Service $1,931,481.94, without any expense whatever to the Treasury Department and with practically none to the Post Office Department.

Aside from the ordinary service which it renders the citizen by affording him the practical result of a checking account in making purchases and settling financial obligations by mail, the money-order service of the United States is now used by the foreign-born population to send money to relatives and to the postal-savings banks in their own countries. Many persons in the past have found the money-order system a convenience for the temporary deposit of funds for safekeeping by having the order drawn on the office of issue and in their own names. The establishment of a postal-savings system in this country, however, served to reduce the amount of money sent to postal-savings banks abroad and to curtail the use of the money-order service for savings purposes.

The act of Congress establishing the money-order system limited the amount for which a single order could be issued to a maximum of $30 and a minimum of $1. It was stated by Postmaster-General William Dennison on 2 Nov. 1864, the day following the opening of the service, that «The limit of $30 is believed to be sufficiently large to include all that class of remittances now sent in money through the mails, but in exceptional cases more than one order can be procured.» As a basis for this statement it was shown that the average amount contained in «money» letters received at the dead letter office during the fiscal years 1862, 1863 and 1864 was $4.53, $4.20 and $5.18, respectively. However, before the service had completed its first year of operation, experience showed that so many applicants desired to send larger amounts through the mail that the labor imposed by the necessity of writing several orders to cover the remittances handicapped the economical operation of the system. This condition resulted in a recommendation to Congress by Postmaster-General Dennison on 15 Nov. 1865 for the increase of the maximum amount of orders to $50, which was accepted in the act approved 12 June 1866. The present restriction on the amount for which an order may be issued is $100. The reasons which led to this amount being fixed as the maximum were substantially the same as those already recited for increasing it from $30 to $50. The desirability of the present maximum was suggested as early as 1866, but it was not until 3 March 1883 that Congress authorized it.

The growth of the system and the continuous simplification of business methods are reflected in the reductions that have been made from time to time in the money-order fees, the principal source of revenue from the business. It is a noteworthy fact that with few exceptions the growing transactions of the system have permitted successive decreases in the charges to the public. These reductions were uniformly recommended to Congress whenever the receipts derived from the operation of the system were substantially greater than the expenses. The present low schedule is the result of the extensive patronage of the system by the public and the progress that has been made in handling the business economically.

It was prophesied by Postmaster-General Dennison on 2 Nov. 1864 that —

"The establishment of the (money-order) system in this country will no doubt lead to arrangements for the interchange of international money orders with the several foreign countries with which we have direct postal arrangements."

This prediction was fulfilled on 27 July 1868 when the President signed an act authorizing the Postmaster-General to make conventions for exchange of orders with countries with which the Department had negotiated postal conventions. It was not until over a year later, however, that the first convention was concluded.

The service was initiated with Switzerland, pursuant to the terms of a convention signed at Washington on 2 July 1869 by the Postmaster-General, under the authority given by the act of 27 July 1868 and at Berne on 26 July 1869 by the chief of the Federal Post Department of Switzerland. The new service commenced on 1 Sept. 1869, 150 post offices in this country being authorized to issue and pay the international orders.

Service was next established with Great Britain on 2 Oct. 1871. Germany and Canada were the next countries with which conventions were concluded. The service has gradually been extended to other countries until at the present time conventions for the exchange of money orders exist with more than 50 foreign postal administrations.

The year 1880 saw important modifications in the terms of the original conventions with the United Kingdom of Great Britain and Ireland, the German empire and the Dominion of Canada. At the time the original conventions with these countries were concluded the value of United States currency was below par of gold and was continually fluctuating, which made it impossible for the issuing postmaster to draw the order for a fixed sum in the money of the country of payment and confined the actual exchange of orders between the respective countries to certain «international exchange offices.» The postmaster at the ordinary international money-order office would draw on the exchange office and the latter would make the conversion from the money of one country to that of the other at the market rate of gold prevailing in New York. When the currency of this country became stable, therefore, a simplification of the mode of procedure in the exchange of orders was made possible. Under the new method the postmaster at the inland international money-order office was able to issue the order for a determinate amount by the use of conversion tables supplied him. The rate of commission to be paid by each postal administration was lowered and the cost of the interchange of orders between the contracting countries was further reduced by the diminution of the number and cost of the blanks and the amount of clerical labor required. These economies permitted the United States to lessen materially the fees charged for the issue of orders to the countries concerned.

In line with the increase in the maximum amount of domestic orders to $100, which was authorized on 3 March 1883 the limitation on international orders was raised to a like amount by the act of Congress approved 30 Jan. 1889. Besides the advantage in uniformity between the two services that was gained by this legislation, the change tended to reduce the expense of the international system because only a single order was then required for sums from $50 to $100 instead of two orders as theretofore. Following is a table showing the growth of the service from the time of its inauguration in 1864 to the close of the fiscal year which ended 30 June 1918:

FISCAL YEAR	Number of money-order offices	Domestic money orders issued [1]		International money orders issued in the United States [2]		Postal notes issued [3]	
		Number	Value	Number	Value	Number	Value
1865	419	74,277	$1,360,122 52	....	....	....	....

[1] Domestic money orders first issued, 1 Nov. 1864, under act of Congress approved 17 May 1864.
[2] International money orders first issued, 1 Sept. 1869, under act of Congress of 27 July 1868.
[3] Postal notes first issued, 3 Sept. 1883, under act of Congress approved 3 March 1883.

International money-orders are of two kinds — those issued on what is known as the «domestic basis» and the «international basis.» In the former class the orders are drawn on the ordinary domestic form and settlement is made between the two countries involved on the exchange of paid orders. In the latter class the orders issued in each country are recorded on descriptive lists at an exchange office designated for the purpose and accounts are settled on the basis of such lists, care being taken to give due credit to the country of origin for the amounts of orders not presented for payment within one year from the time of issue.

Following are tables showing money-orders exchanged between the United States and foreign countries during the fiscal year ended 30 June 1918:

Countries having postal money-order systems arrange themselves into two general groups:

1. The United States, Great Britain, her colonies, protectorates and dependencies, comprising Canada, the Commonwealth of Aus-

tralia, the Union of South Africa, Egypt and Hongkong.

2. The countries of Continental Europe — Austria, Belgium, Denmark, Germany, Greece, Hungary, Italy, Luxemburg, Netherlands, Norway, Russia, Sweden and Switzerland.

The general distinction between the two groups is that the countries named in the first (excepting the United States) rely upon an advice to facilitate and safeguard payment; those in the second use a card order sent in open mail by the issuing to the paying postmaster. In the first case, the intending remitter must file with the proper amount for order and fee a written application containing the full particulars of the remittance — amount, name and address of sender and of payee, from which the postmaster prepares the order, which is then handed to the applicant to be mailed at his own expense to the payee.

Card orders are printed on thin boards and supplied to applicants free or at a merely nominal charge. The remitter fills in the required spaces on the card and hands it with the needed sum to the postmaster. Postage stamps representing the amount of the fee are affixed to the card, which is then numbered, signed, stamped and mailed by the postmaster. No written application is required from the remitter who receives, however, for his protection, a coupon receipt corresponding to the order. (The foregoing statements refer particularly to Germany, but are believed to apply equally to the other countries named in the same class). When it reaches the office of delivery, the order is given to a letter carrier, who calls at the designated address, pays the amount to the payee and obtains the latter's signature to a form of receipt on the back of the card, which is then returned to the postmaster at the office of payment.

France uses both forms of money-order and is in a class by herself.

As a separate feature or adjunct of the money-order systems, many countries issue postal orders or notes for small sums, limiting the amount to the equivalent of $5 or $10. The notes of Great Britain and Canada are printed in fixed denominations from 6 pence to 21 shillings in the one case and from 20 cents to $10 in the other. Twenty-two separate pieces are needed to complete a set of British notes and 18 of the Canadian. Intermediate amounts may be represented by canceled postage stamps affixed to the notes.

In the French service, it is understood, fractions being excluded, the amounts are expressed in writing, from one franc to 20 francs.

In effect, card orders and postal notes are money-orders without advices, issued by the postmaster with the minimum expenditure of time and labor consistent with a reasonable degree of safety. As already explained, postal notes are for small amounts only and, as might be expected, greatly outnumber the issues of money-orders.

Alexander M. Dockery,
Third Assistant Postmaster-General.

POSTAL SAVINGS BANKS. See Banks and Banking — Postal Savings Banks.

POSTAL SAVINGS SYSTEM. The Postmaster-General's Annual Report for the fiscal year ending 30 June 1918 registered an increase during the 12 months of $16,516,803, at 6,678 depositories; the depositors numbering 612,188 and the total deposits amounting to $148,471,499, an average of $242.53 per depositor. Congress further amended the Postal Savings Act by increasing the amount that a depositor may have to his credit from $1,000 to $2,500, which largely accounted for the increase. The amendment also eliminated the 10-cent savings card, provided for in the original Postal Savings Act as one of the means of evidencing small deposits and stipulated that hereafter a card with 10 (instead of 9) savings stamps affixed shall be accepted as a deposit of $1, either in opening an account or in adding to an existing account or may be redeemed in cash, the card provided for by the new legislation being furnished free of charge. By eliminating the savings card as a means of evidencing deposits, the accounting made necessary by the maintenance of both the card and the stamp was reduced by one-half.

The system is self-supporting. The profit in 1918 amounted to $1,135,288.61. At the close of the year $3,963,440 of postal savings funds were invested in the postal savings bonds authorized by the Postal-Savings Act. The board also purchased for investment $14,000,000 third Liberty Loan bonds.

POSTAL UNION, The. See Post and Postage.

POSTER ART. Posters are a modern field for the artist, having been developed within the last 50 years, along with advertising art. They are usually conventional in form and any degree of exaggeration is permissible, if it attracts attention. The earliest example of the poster dates back to the days of Pompeian splendor. During the Middle Ages managers of theatres and officers recruiting for the army used pictorial advertisements. From these pictures, Jules Chèret of Paris (b. 1836), called the father of the modern poster, is said to have received his first suggestion of the possibility of adopting art to latter-day advertising. One of his first efforts was an announcement of a fairy play, 'La Biche au Bois,' in which Sarah Bernhardt was acting in 1867. Chèret's principles were conventionality, elimination of detail, arrangement and pure color. For a long time he was almost alone in his efforts and did not attain to the pre-eminence that has come in more recent years.

In order to produce a good advertising placard it must command the attention of the public. It should be attractive to the man in the street without being vulgar; sufficiently startling, but not aggressively so. Jules Chèret understood the requisites and limitations of this kind of art better than any other of his time and his work gained for him a world-wide reputation. He can justly lay claim to founding a new school. He has defined his idea of a perfect poster as follows: «It should be as simple as possible and I consider the introduction of one figure — and need I hardly say that of a lady for choice — is indispensable; whenever it is possible this figure should be life-size. My own posters are never smaller than 60 centimeters (two feet) by 86 (nearly three feet) and my favorite size is 250 by 90; the figure should, of course, be elegantly and brightly dressed in some striking costume not likely to go out of fashion as long as the poster is to be in use. I always make a point of designing the lettering of the actual advertisements. I do not believe in black and white letters, but have no objection to their being very dark blue, red or violet; this produces the effect of lack without giving a jarring note.»

Close rivals to Chèret are Grasset and Steinlen and by some critics the two are considered to be in many respects superior to the master. Eugene Grasset, a native of Switzerland, is a decorator and architect by profession. His work is characterized by a vital principle of design, effective yet subdued. His Napoleon and Jeanne d'Arc (Bernhardt) posters are superb creations. Grasset's work is always refined and harmonious, yet less bright and striking than Chèret's. There is more repose and it appeals more to the artist than to the public. The poster of the Sàlon des Cent in its tenderness, its exquisite lines and its spirituality, is worthy of Rossetti.

Of the other French artists De Feure, Guillaume, Ibels, Lautrec, Boutet de Monvel, Steinlen, Willette and Jossot are perhaps the most accomplished. Bossot is a great artist, essentially a caricaturist, who works with vagabond and artistic lines and in a morbid color-scheme — rusty greens and pale yellows. Steinlen is every way a charming artist. His «Lait Pur Sterilisé,» a child in a red dress drinking from a bowl, envied by three eager tabby cats, is perhaps one of the most attractive posters ever made. Lautrec has not the refinement of Grasset, not the sprightliness of Chèret, yet he possesses an individuality which makes his work peculiarly interesting. His posters are generally simple in composition and depend to a great extent for their effectiveness on the skilful arrangement of masses. Ibels is remarkably clever in drawings that are inimitably and effectively grotesque. Aristide Bruant has done some things that are strikingly forcible in their broad masses of color. In Great Britain, Audrey Beardsley and Walter Crane were early experts in the new art. They have been worthily followed by Gordon Craig, Will Owen, Hardy, Simpson, Bell and others.

In the United States the modern poster artists include Louis J. Rhead, Will H. Bradley, Kenyon Cox, W. H. Carqueville, Edward Penfield, Ethel Reed, A. Friedler, Walter Fawcett, Max Parrish, Hy Mayer, Hamilton King, Clarence Tilt, E. Haskell, etc. The war brought forth a great demand for inspiring patriotic posters and many new men entered the ranks. By long odds the most successful of these war posters was a picture of a Red Cross nurse with a miniature wounded soldier in her arms and the inscription «The Greatest Mother in the World,» this being by A. E. Foringer.

POSTING, in Europe, traveling by means of horses hired at different stations on the line of journey. Such a system appears to have been established by private enterprise on some of the main routes in England, at least as early as the reign of Edward II. It was afterward made a government monopoly. As letters were originally forwarded in the same manner, the name of post office has come to be applied to the institution charging itself with conveyance and delivering of letters. The custom still obtains in certain parts of the world where the railway has not penetrated.

POSTMAN POET, The. See CAPERN, EDWARD.

POSTMASTERS, National Association of, an organization formed in Detroit, Mich., in 1898, taking in first and second-class postmasters and higher postal officials. They aim to improve the postal service by an exchange of information. In 1917 the president was D. T. Gerow of Jacksonville, Fla., and the secretary, W. C. Markham of Baldwin City. Kan.

POSTULANT, the canonical term for one who desires to take holy orders in the Protestant Episcopal Church of America and whose name has been entered by the bishop upon a list of postulants, as required by Canon 2, Title 1 of the Digest. A postulant may in due course be recommended, by the Standing Committee of the diocese, to the bishop for admission as a candidate for holy orders. The term is applied in the Roman Catholic Church to those on probation before entering a religious order. It is a preliminary stage for the novitiate and existed in the early days of monasticism. With modern decrees the postulant has to wait from three months to two years or more, usually in the novitiate's house.

POSTULATES, or axioms, are sets of propositions belonging to mathematical disciplines from which the remaining propositions can be deduced. Thus the axioms of Euclid constitute a tentative set of postulates for ordinary geometry. The old-fashioned view was that these axioms constitute a set of self-evident truths, referring only to one system, that of the space in which we live. The work of Bolyai, Lobachevski and Riemann, however (see GEOMETRY, NON-EUCLIDEAN), cast grave doubts on the self-evidence of these propositions, and led to the more modern attitude, according to which the axioms are merely hypotheses concerning space. As far as the mathematician makes use of the axioms it is a matter of entire indifference whether they concern space or not; in other words, strictly speaking, postulates are not propositions concerning a definite subject matter at all, but are merely forms of such propositions. Once this view is accepted it becomes easy to see that sets of postulates can be formulated for systems as unlike ordinary geometry or any ordinary mathematical system as you please, and that these sets will have just as much intrinsic, underived right to exist as that of Euclid. This has led to a large number of sets of postulates for various mathematical systems, such as non-Euclidean geometry, line geometry, analysis situs, algebra, the theory of functions of a real variable, quaternions, symbolic logic, etc. (qq.v.).

Furthermore, various sets of postulates can be formed for the same system. Thus, one can describe all the entities of geometry in terms of points and their distance-relations, or in terms of spheres and their relations of inclusion. Accordingly there are at least two possible sets of propositions characterizing the properties of geometrical entities, or, in other words, two sets of postulates for geometry. Furthermore, it is possible to define all geometrical properties in terms of the same entities by different sets of postulates. As a consequence of these facts it becomes a desideratum to determine those sets of postulates which are in some sense the most practical or simple. The criteria of simplicity usually employed are (a) the *independence* of the postulates — no set of the postulates must imply another; (b) their *fewness* in number. Independence of the postulates is demonstrated by the exhibition of systems which fail to satisfy but one of the postulates, this postulate being each in turn. E. K. Moore of Chicago discusses a strengthened form of independence, in which not only are the postulates independent of one another, but no postulate or its denial is dependent on any combination of the other postulates or their denials. Many mathematicians, however, consider this a rather unnecessary refinement. As to the fewness of the postulates, for some purposes of analysis the opposite extreme seems desirable as indicating a greater degree of analysis. However, no really unequivocal definition of the number of distinct postulates in a set has yet been given.

Besides these properties of postulates that are more or less independent of the systems they define, there are others which are bound up with the latter. In the first place, though a set of postulates always defines a class of mathematical systems, this may be the null class (see LOGIC, SYMBOLIC). In that case the postulates are called *inconsistent*, otherwise they are *consistent*. The consistency of a set of postulates is demonstrated by the exhibition of a system which satisfies them. For all ordinary purposes the exhibition of a system formed from the natural numbers is regarded as sufficient. The policy of producing such a system in the case of all mathematical systems is called the *arithmetization of mathematics*.

Another desideratum of a set of postulates is that the systems they define be one from the mathematical standpoint — that is, that the set be *categorical*. A categorical set has the property that a one-one correspondence can be set up between any two systems which it defines; and that this correspondence will leave their structure invariant.

There is one set of postulates whose position in the theory is unique. This is the set of postulates for symbolic logic (q.v.). Symbolic or mathematical logic consists in the criteria and methods of logical and mathematical reasoning in all fields. It is consequently in essence an individual system, not a type of systems. Consequently, if it can be treated by the postulate method at all, its postulates are genuine individual propositions, and not propositional forms. It is by no means obvious that any finite set of postulates will suffice for symbolic logic, and the attempt of Whitehead and Russell to find such a set breaks down in certain details, yet is sufficiently close to complete success to give promise of even better results in the future.

In the course of any attempt to formulate postulates for logic, two propositions appear which are not indispensable for the development of the simpler and many of the more complicated propositions in logic and mathematics, but are continually involved in many processes of reasoning that were formerly accepted without question. There are the proposition that there are an infinite number of things in the world, and the proposition that given an aggregate A of aggregates B, some aggregate C exists containing one member of each of the B's, and only one. This latter is essentially due to Zermelo. See ASSEMBLAGES, GENERAL THEORY OF.

There is no book devoted to postulate-theory at large, although almost any of the mathematical works of the writers already named or of Huntington, Veblen, Sheffer, Peano, Vailati or of many other writers of the last quarter century approach mathematical problems with this attitude in mind. By far the largest part of the literature is contained in the *American Journal of Mathematics*, the *Transactions of the American Mathematical Society* and the *Annals of Mathematics* for the past 15 years. For the postulates of logic consult A. N. Whitehead and B. Russell, ‹Principia Mathematica› (1910–).

Consult the various articles on mathematical disciples for their peculiar postulates, and see especially LOGIC, SYMBOLIC; ASSEMBLAGES, GENERAL THEORY OF.

NORBERT WIENER.

POSTULATION, in canon law, an appeal to a competent authority to remove a disability by which one who has been appointed to a benefice is prevented from entering upon it. The term was also applied to the method by which a bishop was translated. The canon law declared that a person once elected to one see could not be elected to another; and when an electoral college desired the bishop of another see to occupy their own, they petitioned the bishop to make the change. No postulation could be made unless the electoral college were unanimous, while in the case of an election a majority was sufficient.

POT-HOLES. Cylindrical holes in rock ledges usually in or near beds of streams. They are caused by the wearing action of sand and pebbles whirled by the water. They have been called giant kettles, giant caldrons, Indian kettles, wells and the Spanish name, remolionos. Their size and character vary greatly, many of the larger ones being 10 feet in diameter and 25 feet deep. One in Saint Croix, Dallas, Wis., is 27 feet in diameter, another with diameter of 15 feet is 65 feet deep, and one 12 feet in diameter is 160 feet deep. The pot-holes of the «Glacial Gardens» of Lucerne in Switzerland are famous. In some cases, notably on Kickinghorse River, near Field, British Columbia, a small natural bridge has resulted from the coalescence of the lower parts of two or more pot-holes. The canyon at Watkins Glen, N. Y., consists partly of coalescing pot-holes. Pot-holes develop only in streams that are eroding in fairly well consolidated rock. They evolve from small hollows due to solution, removal of a lense or pebble or a joint-crack. Such hollows are necessary to hold the first few pebbles which begin the grinding. Too much sediment stops the process, but otherwise flood stages of the stream greatly facilitate the erosion. The nature and jointing of the rock and declivity and volume of the stream are important factors. Many holes, «moulins,» are of glacial origin, not caused by the ice, however, but by water falling over the edge of the ice or into holes extending to the rock floor. Irregular pot-holes or basins also occur along the coast, scoured out by tidal or other currents. Plunge pools are frequent at the foot of water falls and a notable one on the Canadian side of Niagara Falls according to J. W. Spencer is 72 feet deep. Small pits due to swirling of hard parts of sea urchins have been observed on sea coast in New Brunswick and at Biarritz, France. Consult article by E. D. Elson (in *Scientific Monthly*, Vol. V, pp. 554–567; Vol. VI, pp. 37–51, 1917–18); Gilbert, G. K., 'Bulletin, Geological Society of America' (Vol. XVII, pp. 317–370, 1906); Upham, W. (ib., Vol. XII, pp. 25–44, 1900).

NELSON H. DARTON.

POTAMIAN, pō'tā-my'ăn, **Brother** (MICHAEL FRANCIS O'REILLY), American physicist: b. County Cavan, Ireland, 29 Sept. 1847; d. New York, 20 Jan. 1917. He was educated in the public and Christian Brothers schools, New York City, London University, and the Christian Brothers Scholasticate, Montreal, Canada. In 1859 he entered the Order of the Christian Brothers; taught successively at Quebec and Saint Louis, Mo., professor at Saint Joseph's College, London, from 1870 to 1893, and professor of mathematics and experimental physics at De La Salle Normal College, Waterford, Ireland, in 1893–96, and from 1896 to 1917 professor of physics at Manhattan College, New York City. In 1893 he was appointed by the British government a member of the jury of awards at the World's Columbian Exposition, Chicago. His writings include 'Gleanings in Electrical History'; 'Franklin and De Romas, or the Lightning Kite'; 'Gilbert of Colchester'; 'The Rotation of the Earth.' He was joint author of 'Electric Illumination' (2 vols.); 'Letter of Peregrinus on the Magnet'; 'The Makers of Electricity'; 'The Makers of Astronomy'; and 'Catalogue of the Wheeler Gift' or a brief illustrated account of works on electricity and magnetism from the earliest times to the middle of the 19th century.

POTAMOGALE, the generic name of a strange West African animal (*P. velox*), which might be called the insectivorous otter. It is a true insectivore, representing the family *Potamogalidæ*, is somewhat larger than a stoat, perhaps two feet long being an average, and the appearance and habits are like those of an otter, save that it is not certain that it subsists on fish. A related smaller potamogale (*Geogale aurita*) inhabits the valleys of Madagascar.

POTASH, originally a vegetable alkali (so-called), obtained by leaching wood-ashes, evaporating and calcining, commonly called carbonate of potash or pearl-ash, K_2CO_3. Soda and potash were not distinguished by old-time chemists, but in 1807 Davy separated them. Various plants take up potash salts, and the refuse of beet-roots has been utilized as a source of potash. After the electrolytic production by Davy and others, it came to be understood that a metallic element was being dealt with and potassium (q.v.) was developed.

Commercial Potash.— Previous to the outbreak of the World War nearly the whole potash supply of the United States market was imported from Germany. A glance at the importations of 1913 shows the various forms in which the potash came in and the amounts consumed normally by the industries of the country. The figures are as follows: Kainit, 521,176 tons; manure salts, 250,529 tons; muriate of potash, 237,630 tons; sulphate of potash, 44,349 tons; argol or bitartrate of potash (mainly from France and Italy), 14,499 tons; carbonate of potash, 11,003 tons; nitrate of potash, 4,826 tons; ferrocyanide of potash, 1,706 tons; and much smaller quanties of other potash salts — cyanide, chlorate, permanganate, etc., a grand total of 1,092,588 short tons, having a content of actual potash amounting to 270,720 tons and valued at $18,073,865. Beside these. the figures of the imports of potash for 1917 indicate the remarkable change of conditions and values — 8,100 tons, valued at $7,788,406.

Although the world's supply of commercial potash had come almost wholly from mines in Germany and Austria, it was a matter of common knowledge to geologists everywhere that potash occurs very extensively in nature, being a component of granites and most other igneous rocks, and occurring in smaller amounts in the various sedimentary strata and soils. It is estimated to form 3 per cent of the earth's crust. In the dry saline matter from evaporated river waters there is generally about 2 per cent of K_2O (potassium oxide) and in the ocean from 1 to 2 per cent. Where these waters evaporate and the other saline components crystallize out, the potash accumulates in the remaining solution so that on the evaporation of the final "pan" the proportion of K_2O may be high. There are deposits of this kind in various lake basins, both recent and of various older geologic periods. Alunite, a hydrous potassium-aluminum sulphate ($K_2O.3Al_2O_3.4SO_3.6H_2O.$), contains when pure 11.4 per cent of K_2O which is made soluble by roasting.

The orthoclase feldspars which are of widespread occurrence in granite and gneiss contain from 16.8 per cent of K_2O in combination with silicic acid and some processes for separating this ingredient appear to be commercially practicable, especially when the residue can be utilized for making brick. Some of the younger igneous rocks contain much potash notably the rhyolites, trachytes and phonolites, some of which carry 8 per cent. The mineral leucite $KAlSi_2O_6$ contains a large amount of K_2O, the rock in Leucite Hills, Sweetwater County, Wyo., carrying from 9 to 11 per cent of potash. Sericite or altered mica schist in the southern Appalachians carries 10 per cent or more. Glauconite or greensand, which occurs in beds, notably in southern New Jersey, Maryland and Virginia, Kentucky, Tennessee and Georgia, contains up to 9 per cent, and in some cases 11 per cent of K_2O in form of silicate. These deposits are from five to 20 feet thick and easily worked. These various silicates are exceedingly difficult to resolve, but heat and admixture with lime and other agents liberates most of the potash.

The largest known potash deposits exist in the Permian in central Germany, the Oligocene in Alsace, the lower Miocene in Galicia, in the early Tertiary near Sauria in northeastern Spain and in beds of unknown age in India. They are associated with the great deposits of common salt, dolomite and gypsum such as occur in the Permian beds of the central United States, and it is hoped that domestic supplies may be derived from these beds. The potash deposits in central Germany have been very extensively developed by numerous mines, some of great depth. The annual production under ordinary conditions is about 7,000,000 metric tons valued at more than $30,000,000 and sold at a profit of about $4,000,000. The potash occurs in various compounds, the principal one being Kainite, $MgSO_4.KCl.3H_2O$, which is in the midst of a 3,500 foot succession of common salt and anhydrite, the products of long-continued desiccation of a water body. The potash salt was deposited at or near the end of one stage of desiccation, but there was a later incursion of waters from which finally there were deposited anhydrite and common salt. Fortunately a thin overlying sheet of clay was deposited which protected the potash from solution by the water which brought the anhydrite and salt now covering the potash.

The larger percentage of potash consumed by the world is used in commercial fertilizers, although considerable is made into chemicals for the arts and medicine and for explosives. In the latter case, however, it is not as important as it was formerly, as the high explosives do not contain it. Potash is essential to plant growth and in agriculture is rapidly depleted from the soil, and must be returned in fertilizers. It also has an important stimulating effect on soils naturally deficient in this component. The production of potash-bearing material in the United States in 1917 was 126,961 short tons, containing an average of 26.4 per cent of K_2O, an equivalent of 32,573 short tons of potash; that is, 13.6 per cent of the normal consumption of the United States. This production was three times the amount produced in 1916 and 30 times the amount in 1915. During the war the price rose from the normal rate of 50 to 75 cents a unit to about eight times as much. The average for 1917 was $4.26 per unit or a total of $13,791,922. The unit is 1 per cent K_2O per ton. The production in 1917 is shown in table below.

About 63 per cent of the total output was produced from brines in lakes, mainly from those in the Sand Hill district of western Nebraska and from Searles Lake in California. From the Nebraska lakes a total of 61,053 tons of crude potash material was marketed in 1917; equivalent to 14,588 tons of pure potash. The residue resulting from the burning of kelp, the great sea weeds on the Pacific Coast, is a potential source, but as the raw material contains 90 per cent of water the expense of handling and drying it is great. The char or clinker carries from 20 to 30 per cent of K_2O and valuable by-products, including iodine, help defray the otherwise prohibitive cost of treatment. Charred molasses residue at alcohol distilleries yields considerable potash, while waste liquor from one of the beet sugar processes is a minor source. Potash is extracted from the mineral alunite mined near Marysvale, Utah, the potassium sulphate being made soluble by calcining. Flue dust from cement mills is an important source, with constantly increasing product as mills utilize more material rich in potash and make provision to catch flue dust. The dust is leached and a high grade potassium sulphate is obtained by evaporation. In 1917 eight mills produced a total of 1,621 tons of actual potash. A very large amount of potash is given off as vapor in fumes from blast furnaces, but no provision is made to collect this material. The present small output (1917) reported from three steel companies was recovered from the dust which collected in flues and stoves. The loss of potash in the furnace gases is not less than 22 pounds for each ton of iron produced. It is believed that if the large furnaces installed suitable flues the supply would be sufficient for all domestic demands and at very low cost. A constantly increasing supply is derived from the old-fashioned source of leaching wood ashes. Considerable potash is extracted from the crude Chilian nitrate of soda. See Potassium.

In 1918 production increased to 192,587 tons of products, containing 52,135 short tons of K_2O. The producing capacity of American potash plants at end of 1918, classified according to sources of raw materials, is estimated roughly as follows:

Capacity of American Potash Plants.

Source	Available potash (K_2O) (tons)
Natural brines:	
Nebraska lakes	50,000
Other sources	28,000
Alunite	4,000
Dust from cement mills	3,500
Kelp	5,500
Molasses distillery waste	4,000
Steffens waste water	3,000
Wood ashes	1,000
Other sources	1,000
	100,000

This quantity is about 40 per cent of our ordinary consumption in pre-war times and the output that may be maintained if the demand con-

Sources	Number of producers	Total production	Available potash (K_2O)	Value at point of shipment
Mineral sources:		*Short tons*	*Short tons*	
Natural brines	10	79,876	20,652	$8,219,912
Alunite (refined salts and crude and roasted alunite)	3	7,153	2,402	892,763
Dust from cement mills	8	13,582	1,621	700,523
Dust from blast furnaces	3	2,133	185	68,841
Organic sources:				
Kelp	10	11,306	3,572	2,114,815
Molasses residue from distilleries	4	8,589	2,846	1,130,907
Wood ashes	36	700	424	406,856
Evaporated Steffens water from sugar refineries	5	*2,593	359	143,430
Evaporated wool washings and miscellaneous industrial wastes	3	645	305	113,875

* Includes 1,333 tons of material produced but not sold in 1917.

tinues and the industry is not crippled by foreign competition.

NELSON H. DARTON,
United States Geological Survey.

POTASH FERTILIZERS. See FERTILIZERS.

POTASH PRODUCTION IN THE UNITED STATES. See FERTILIZERS; POTASH.

POTASSIUM (from "pot-ashes," wood ashes being one of the best known sources of the carbonate of the metal), a metallic element, many of whose compounds have been known from antiquity, but which was first prepared in the metallic form by Davy, in 1807, by the electrolysis of fused potassium hydrate — a substance which had previously been supposed to be itself elementary. In 1808 Gay-Lussac and Thénard showed that the hydrate can be reduced by heating it with finely divided iron and in the same year Curaudan showed that the reduction can also be effected by carbon. Several methods of preparing metallic potassium are now in use. The best known of these and the only one that was in practical service for many years consists in the direct reduction of the carbonate of potassium by carbon, the reaction being carried out in an iron retort heated to redness. The chief products of the distillation are carbon monoxide gas and metallic potassium, the latter being volatile at a red heat. The production of potassium by this method is attended by more or less danger, not only because the vapor of potassium takes fire spontaneously upon contact with air or with water, but also because under certain conditions potassium and carbon monoxide combine to form a black, explosive compound, whose production has caused a number of fatal accidents. The potassium vapor should be permitted to condense before it issues from the neck of the retort, a cooling device being provided for effecting its liquefaction, and the molten metal should then be allowed to drip into a receiver containing petroleum oil or some other similar fluid that is free from oxygen. In Castner's process, the carbonate or (hydrate) of potassium is mixed with carbon and finely divided iron, or with carbon and a metallic carbide and the reduction is effected by the agency of heat, as before. A considerable part of the commercial supply of metallic potassium is now produced, however, by the electrolysis of the melted hydrate or chloride of potassium.

Potassium is a lustrous, silvery-white metal, brittle at 32° F., but soft and wax-like at ordinary temperatures, so that it can be easily cut with a knife. It melts at about 144° F., and boils at about 1,250° F. (when heated in an atmosphere of hydrogen), its vapor being green. It has a specific gravity of about 0.87 and, with the exception of lithium, is the lightest metal known. Its specific heat is 0.166 and its coefficient of linear expansion (Fahrenheit scale) is about 0.0000467. It conducts electricity much better than mercury does and it is soluble in anhydrous liquid ammonia (NH_3), forming a blue solution from which metallic potassium is again deposited upon the evaporation of the ammonia.

Chemically, potassium has the symbol K (from *kalium,* Latin for potash), and the atomic weight 39.15. It oxidizes in the air with great readiness, a freshly cut surface becoming almost instantly covered with a film of oxide. It also decomposes water vigorously, uniting with it to form potassium hydrate, KOH, in accordance with the equation

$$K + H_2O = KOH + H,$$

hydrogen gas being liberated at the same time. When potassium is thrown upon the surface of water it floats and the heat generated by the chemical action is sufficient to set fire to the liberated hydrogen and to part of the potassium. This experiment is a favorite one in the lecture room, since it is beautiful as well as instructive, the flame having the purple color that is used in the laboratory as a test for the presence of volatile potassium salts. (See BLOWPIPE ANALYSIS). Potassium never occurs in nature in the free state, but it forms an essential constituent of many minerals, among the most important of which are feldspar, nitre and carnallite. Chloride and sulphate of potassium are found in sea water and various springs. It also occurs in the animal body and in plants and in remote country districts its carbonate is still prepared (chiefly for the manufacture of soap) by leaching wood ashes. (See POTASH). Wool yields an organic potassium salt, which may be washed out from the natural grease or suint.

Troast and Heutefeuille's experiments show that when potassium is heated to over 200° C. it occludes hydrogen gas. In a vacuum, when diluted with hydrogen, the compound will lose hydrogen above 200° C., down to a certain point.

The potassium compounds are exceedingly numerous and many of them are of great importance both in the laboratory and in the arts. Two oxides of the metal are certainly known and others probably exist also. Potassium monoxide, K_2O, which is the oxide that is understood when "potassium oxide" is mentioned without qualification, is formed when thin slices of the metal are allowed to oxidize in cool, dry air. It may be prepared more readily on the large scale by heating potassium just to its melting point and then leading over it a stream of air that has been dried and freed from carbon dioxide. The monoxide is a gray, brittle substance, which has a specific gravity of 2.66 and melts at a strong red heat. It has a powerful affinity for water, with which it combines with the evolution of much heat, to form potassium hydrate, KOH. Potassium tetroxide (or peroxide) is formed when potassium is burned in a stream of pure, dry oxygen. It has the formula K_2O_4, and is a yellowish substance at ordinary temperatures, melting, at a red heat, to a black liquid, which crystallizes upon cooling. The tetroxide combines with water to form potassium hydrate and peroxide of hydrogen, oxygen being also set free at the same time. When heated to a white heat, the peroxide gives off oxygen and becomes reduced to the monoxid.

Potassium chloride, KCl, occurs native in large quantities at Stassfurt, Germany, chiefly in combination with magnesium chloride, with which it forms the mineral "carnallite," $KCl.MgCl_2 + 6H_2O$. Most of the commercial supply of potassium chloride is now prepared from this mineral by crystallizing its solution. In order to obtain a satisfactory product, however, many practical details must be carefully attended to, for which reference must be made to advanced works on inorganic chemistry and to treatises on alkali manufacture. Potassium chloride is very similar in its general properties to sodium chloride (common salt). It has a saline taste, is white in color and crystallizes in cubes. Its specific gravity is 1.94 and it melts at about 1,350° F. Potassium chloride is now extensively used as a source of potassium in the preparation of other salts of that metal.

Potassium nitrate or "nitre" (q.v.), KNO_3, occurs native, but the greater part of the commercial supply is now manufactured by acting upon the cheaper nitrate of sodium ($NaNO_3$) by means of potassium chloride; the reaction being as indicated by the equation

$$NaNO_3 + KCl = KNO_3 + NaCl.$$

Potassium forms two carbonates, known respectively as the "normal" carbonate and the "acid" carbonate. Normal potassium carbonate, K_2CO_3, may be obtained in an impure state by leaching wood ashes and evaporating the resulting solution to dryness. The residue is then strongly heated to destroy any organic matter that it may contain and is subsequently redissolved and redeposited by evaporation. The crude product as obtained from wood ashes is known as "pearl-ash" or often simply as "potash." Pure normal potassium carbonate is best prepared by heating ordinary monotartrate of potassium (see below), which is thereby resolved into a mixture of free carbon and potassium carbonate, from which the latter salt may be obtained by solution, filtration and subsequent evaporation. Acid potassium carbonate has the formula $HKCO_3$, and may be prepared by passing carbon dioxide over the normal carbonate or through its concentrated solution in water; the reaction being as indicated by the equation

$$K_2CO_3 + CO_2 + H_2O = 2HKCO_3.$$

The greater part of the commercial supply of normal potassium carbonate is now prepared by a method similar to the Leblanc process for the preparation of carbonate of sodium. (See SODIUM). Normal carbonate of potassium is quite strongly alkaline and is deliquescent and very readily soluble in water. It is used in the manufacture of soap and as a raw material in the manufacture of various compounds of potassium. The acid carbonate is much less soluble than the normal salt and its solution is nearly neutral to litmus paper.

Potassium hydrate, potassium hydroxide or "caustic potash," KOH, is formed when metallic potassium is dissolved in water; but the commercial supply is obtained either by the electrolysis of a solution of a potassium salt or by acting upon a solution of normal potassium carbonate by means of slaked lime, $Ca(OH)_2$; the reaction, in the latter case, being as represented by the equation

$$K_2CO_3 + Ca(OH)_2 = 2KOH + CaCO_3.$$

The calcium carbonate ($CaCO_3$) that is formed at the same time is practically insoluble and may be removed by filtration. The solution is then evaporated to dryness and the resulting hydrate of potassium is finally melted and cast into sticks in metallic molds. Potassium hydrate is a white substance, absorbing moisture from the air with great readiness and also taking up carbon dioxide gas from the air, being thereby converted into the acid carbonate. The hydrate dissolves in half its own weight of water, the solution being intensely alkaline. The solid hydrate has powerful cauterizing properties (whence the name "caustic potash") and destroys the skin when brought in contact with it. It is used in the arts and in the laboratory for a great variety of purposes.

The bromide of potassium (KBr) and the iodide (KI) are soluble, crystallizable salts, which are largely used in medicine and in photography. The bromide may be prepared by adding bromide to a solution of potassium hydrate, the reaction being

$$6KOH + 6Br = 5KBr + KBrO_3 + 3H_2O.$$

To remove the potassium bromate ($KBrO_3$) that is formed, the solution is evaporated to dryness after the addition of a small quantity of powdered charcoal and the dry residue is well pulverized and finally raised to a dull red heat. The carbon that is present then reduces the bromate to potassium bromide and free carbon dioxide gas. When this process is complete, the mass is cooled and redissolved in water, after which the pure bromide of potassium is prepared by evaporation and crystallization. Iodide of potassium may be obtained in a similar manner. Potassium chlorate, $KClO_3$, which is used in the laboratory for effecting oxidations and also as a source of free oxygen and which is likewise employed in medicine, may be prepared by passing chlorine gas through a warm, concentrated solution of potassium hydrate; chloride of potassium being formed at the same time, as is indicated by the equation

$$6KOH + 6Cl = 5KCl + KClO_3 + 3H_2O,$$

the reaction being entirely analogous to that given above for the formation of potassium bromide. As will be seen from the last equation, only one-sixth of the potassium of the original hydrate is converted, by this method, into the form of chlorate; the remaining five-sixths being converted into the chloride. The process as given is, therefore, wasteful; for, although the potassium chloride may be easily recovered, it is not available for the manufacture of further quantities of the chlorate until it has been reconverted into the hydrate. In practice it is, therefore, customary to prepare calcium chlorate, $Ca(ClO_3)_2$, as the first step in the process; potassium chlorate being then obtained by treating the calcium chlorate with potassium chloride, according to the equation

$$Ca(ClO_3)_2 + 2KCl = 2KClO_3 + CaCl_2.$$

Several sulphates of potassium are known, the most important of these being the normal sulphate, K_2SO_4, and the acid sulphate, $HKSO_4$. These may be prepared by the action of sulphuric acid upon potassium chloride; but the commercial supply is obtained in large measure from the mineral "kainite," which occurs in great quantities at Stassfurt and which consists of normal potassium sulphate in combination with the sulphate and chloride of magnesium. It is also obtained as a by-product in the working up of beet root, vinasse and kelp, and in other chemical industries. Normal potassium sulphate forms, with aluminum sulphate, a compound familiarly known as "alum" (q.v.) or "potash alum," which crystallizes in octahedra having the composition

$$Al_2(SO_4)_3 + K_2SO_4 + 24H_2O.$$

Three important salts of potassium, known respectively as the cyanide, ferrocyanide and ferricyanide, are described under HYDROCYANIC ACID, and the permanganate of potassium is described under MANGANESE. Several sulphides of potassium may be prepared, the best known being those having the formulæ K_2S, K_2S_3, K_2S_4, and K_2S_5. These are all soluble and evolve sulphuretted hydrogen when heated with an acid. Common «liver of sulphur» is a brown, ill-smelling substance, prepared by heating normal potassium carbonate with sulphur. It contains various sulphides of potassium, together with more or less of the normal sulphate and carbonate of potassium. When potash and pulverized quartz are melted together, a compound of potassium, oxygen and silicon is obtained, which is usually described as a silicate of potassium. This compound is soluble in water and is known in the arts as «potash water glass,» the corresponding compound of sodium being known as «soda water glass.» The residue left when a solution of water glass is evaporated has a glassy appearance, from which fact the popular name is derived.

With tartaric acid, $H_6C_4O_6$, potassium forms two compounds (the acid being dibasic) Monopotassium tartrate, or acid potassium tartrate, $KH_5C_4O_6$, is formed in the course of the fermentation of wine, and, as deposited by the wine in a crude state, is known as «tartar,» or «argol.» When purified, it constitutes the substance familiarly known as «cream of tartar,» which is used in the manufacture of various baking powders. The normal tartrate of potassium, $K_2H_4C_4O_6$, is not used in the arts to any great extent.

With the fatty acids (for example, stearic, palmitic, etc.), potassium combines to form salts that are familiarly known as «soaps»; the combination being usually effected by boiling potassium hydrate or carbonate with fat. The fats are composed of glycerine in combination with various fatty acids; and the potassium, being more basic than the glycerine, replaces it in the compound, the result being the formation of a soap, and the simultaneous liberation of free glycerine. See SOAP.

Sources of Potassium.— Since the largest deposits of potash salts are in Prussia, the United States experienced a scarcity as the war progressed; in fact there had been a shortage of supply in America and friction over the importation as early as 1909. The year before the war our importation of potassium salts from Germany was about 525,000 tons. When this was cut off we had to get along with less than a tenth of the usual supply, and potash as a fertilizer had to be foregone, as the price was prohibitive. These conditions caused active search for new sources of supply. Wood ashes were carefully saved for leaching. The Bureau of Soils, Department of Agriculture, obtained an appropriation for experiments as to the best methods of securing potassium in commercial quantities, and the United States Geological Survey also expended considerable time and money in searching for deposits. Small quantities were found in Arizona, Colorado and Nevada, but it was not until a large deposit was uncovered in Utah in 1915 that this source of supply assumed importance. In 1916 the Survey classified 24,656 acres of Indian lands as potash land and prospecting commenced. One of the most promising finds was Searles Lake, California, a dried-up salt lake with an area of 7,500 acres and a crust 50 to 100 feet deep, saturated with a brine rich in ash and borax. The salt lakes of Nebraska also yield a supply. Potash feldspar and silicate of potash have been located at a number of places, and only await practicable methods of extraction to become available: while a considerable group of inventors are striving to improve and cheapen methods of extraction. Investigation of the dust and waste of the blast furnaces has disclosed a source that should be conserved. The dust that gathers around the bases of hot-blast stoves in such quantities is now carefully saved and utilized. Cement mills also yield a dust rich in potash, which is being gathered more or less, and the distillery wastes have contributed a little more. The 1915 production of potash salts in the United States was 9,720 tons; for 1917 about 32,000 tons and for 1918 the estimate is 40,000 tons, which is only one-eighth of the normal consumption.

The prospective supply of potash within the United States is summarized by the Geological Survey as follows: The 7,000 to 8,000 acres of Searles Lake, California, are estimated to contain about 20,000,000 tons of actual potash, enough to supply the present demands of the country for 80 years. About 100,000 tons annually may be recovered from the dust of cement mills. Approximately 380,000 tons of potash are annually volatilized in the blast furnaces of the United States, and much of this could be recovered by installing proper apparatus, not unduly expensive. The numberless salt lakes of Nebraska, chiefly in the Sand Hill region, range from an acre to a square mile in area, with a crust varying from a few inches to three feet in thickness. It has been discovered that below the hard pan bottom of these lakes is a layer of sand saturated with a strong potash brine, resting on a second bottom of hard pan. The possibilities of this source have not been estimated, but they are large. At the Salduro salt marsh, in Utah, wells have been sunk, and the brine pumped from them is found to be closely similar to the artificial brines of the German potash works at Stassfurt. The dumps of old copper and gold mines now being reground for treatment by the flotation process are found to contain considerable amounts of potash easily recoverable. The present possibilities of the molasses distilleries is estimated at 30,600 tons per annum; and from the beet sugar works it is expected to get 16,000 tons of pure potash a year. The supply from kelp is not regarded as especially promising. The difficulty of drying the raw material before it can be calcined, and the tendency of the great kelp plantations to become diseased and disappear entirely from a given locality renders the kelp-potash industry hazardous. The green sands of New Jersey are estimated to contain not less than 2,000,000,000 tons of actual potash.

The costs of getting potash from these various sources is estimated as follows: From the brines of the Nebraska lakes, $120 per ton; from roasting alunite (as at Marysvale, Utah), $40 per ton; from cement mill dust (as at Hagerstown, Md.), $30 per ton; from the German mines at Stassfurt, $40 per ton. The German product was sold in the American market at (about) $80 per ton and the investment in the German mines is about $150 per ton of annual product. This is not much less than the investment at the Hagerstown cement mills, where the net cost per ton is $10 less than at the German mines. The market price of actual potash in the United States in 1917 averaged about $423.50 per ton. See also POTASH, COMMERCIAL.

Potassium in Medicine.— Caustic potash is a useful irritant and caustic and may be used to kill off warts and other morbid growths. Permanganate of potash is valued as an antiseptic and disinfectant. Where an old sore tends to gangrene it may be applied wet to oxidize the products of decomposition. A 1 per cent solution has been recommended for external use on snake-bites. Any potassium salts taken internally serve as cardiac depressants, and also reduce the nervous action. Very small quantities of potassium are administered by the medical profession, in a variety of forms, internally, for several ailments; but it should be taken only under a physician's advice, for it is properly classed as a poison. An overdose causes abdominal pain, burning, diarrhœa and vomiting and should be treated with emetics, followed by lemon juice, then vegetable oil and white of egg. Washing out the stomach is of course advisable. Nitre paper, made with potassium nitrate, is burned by asthmatic patients, that they may inhale the fumes and relieve the paroxysms. Acetate and citrate of potassium are sometimes employed to increase the flow of urine. Potassium salts will neutralize the gastric acid, and small doses may thus relieve an acid condition of the digestive tract, but the tendency to induce inflammation and gastritis should not be overlooked.

Consult Bulletins of the United States Geological Survey; also Bulletins, United States Department of Agriculture, and Cushman and Coggeshall (in 'Eighth Inter-Congress of Applied Chemistry,' Vol. V, 1912).

POTASSIUM PERCHLORATE. See PERCHLORIC ACID.

POTATO, a perennial herb (*Solanum tuberosum*) of the family *Solanaceæ*. It is a native of the Chilean and Peruvian Andes. Its tuberous roots send up weak stems which bear pinnate leaves and white or lilac flowers which in cultivation are rarely followed by fruits. When fruits are produced they are globular, yellow or purple, and about the size of a gooseberry. The plant is extensively cultivated in temperate climates for its tubers, which are used as a staple food for man, and to a less extent for animals. It was in cultivation before the discovery of America, and was taken to Europe (probably to Spain from Peru) in the early part of the 16th century. It seems that Sir Francis Drake introduced it into England in 1586, though Sir Walter Raleigh is said to have brought it with him the year previous. Gerarde mentions it in his *Herball* in 1597 under the name *Batatas Virginiana*, but it seems to have been regarded somewhat as a curiosity until the latter part of the 18th century, although the Royal Society of London had recommended it in 1663 as a possible safeguard against famine among the Irish peasantry. Owing to the failure of grain crops in 1772 the potato soon commenced to grow in popularity as a food-plant, but even as late as 1771 only two varieties, one white and one red, were listed. In 1900 it was no uncommon thing for agricultural experiment stations in the United States and Europe to test more than 150 varieties at one time. The crop is one of the most important in Germany, France, Ireland and the United States. In the last-named country the yield per acre averages less than 100 bushels (1917), but with proper attention to cultivation, etc., yields of 200 to 400 bushels are not unusual, and even 1,000 bushels have been obtained under the best conditions. By artificial methods 2,558 pounds of tubers have been grown from one pound of seed in one season; but this was in a competition for prizes. The crop in the United States for 1917 was 442,536,000 bushels. Besides being an important article of food the potato is largely used in the manufacture of starch, and in some countries for making alcohol, etc. For such purposes special varieties are generally grown; these are usually coarse and are little used for human food.

The culinary varieties have been found to contain about 78 per cent water, 18 per cent starch, 2.2 per cent protein, 1 per cent ash and 0.1 per cent fat. During storage these proportions change, since the tubers shrink nearly two per cent a month as an average for seven months. Since the potato is rich in starch and poor in protein it is valued chiefly as a carbohydrate food, the deficiency of protein being made up by eggs, meat, fish, beans, peas, etc., and that of fat being supplied by butter, fat, oat-meal, etc. During the process of cooking the cells are ruptured, the starch expanded and made «mealy,» and great changes in flavor and palatability are produced, either by the dissipation of raw flavors, the development of new ones, or both. In the cooked state more than 90 per cent of the nutritive substances are considered assimilable. Large quantities of potatoes are annually evaporated to supply the demand for provisioning expeditions, camps, cruises, etc. «Saratoga chips» are thin slices of potato which have been fried in fats or oils and sprinkled with salt. The potato is cooked in perhaps a greater variety of ways than any other vegetable, but fundamentally the various processes are baking, boiling and frying, the first being the most economical when properly performed.

Methods of Propagation.— The potato is propagated almost wholly by means of its tubers, which are cut in many ways intended to increase the amount of «seed.» Some growers plant the whole tuber, others half-tubers, and others «single-eye pieces.» Probably there is no one method which is best under all conditions of soil, cultivation, etc., but it seems as if the half-tuber of medium-sized, well-formed specimens is in most general favor. Extra large and little potatoes are not favored. In the propagation of new varieties seed-balls are used, and after the variety is proved to be worthy it may be increased rapidly by means of cuttings made from the sprouts. These are rooted under glass in the same way as geranium cuttings, etc., and the rooted plants set in good soil when the weather has become settled. Some growers expose their «seed potatoes» to the sun for about 10 days before planting in order to hasten the growth. During this period of exposure small rosettes of sprouts appear at the eyes, and it is claimed that some of the starch is converted into sugar, with the result that when the tubers are planted they make a more rapid growth than under ordinary conditions. With certain varieties and upon certain soils the period of growth may be shortened to eight weeks or even less.

The plants will thrive in the cooler tropics and even in the colder temperate regions; in moist and dry climates; and on many kinds of soil. But the mild-temperate regions, fairly dry climates and light loamy soils generally suit them best. Such produce earlier, mealier, more highly flavored potatoes than the other conditions. While Americans demand potatoes of this order, Europeans seem generally to prefer the harder, less mealy tubers, produced in cloudy climates and upon rather rich, moist loamy soils. The soil should be well supplied with organic matter, but this should not be added fresh in the form of stable manure. Such applications should be made to a previous crop, such as corn, since practice has shown that the quality of the crop is thus improved. Generous applications of commercial fertilizers should be given. Dried blood, sulphate of potash, superphosphate, ammonium sulphate and wood ashes are favorite fertilizers for this crop. The amounts to apply will depend largely upon the character and quality of the soil. The plowing should be as deep as the surface soil will permit, six inches or more. It should be done as soon as the weather becomes settled. The «seed» is dropped at intervals of 12 to 18 inches in rows about 30 inches apart. Generally this is done by hand in a furrow about four inches deep, but upon a large scale potato planting machines are used. These machines make their own furrows, sow the fertilizer, drop the «seed» at regular intervals, cover the row and mark the position of the next row.

Before the young plants appear a weeder is run over the field once or perhaps twice to keep the surface loose and to destroy spouting weeds; after the plants are up the cultivator is used between the rows until the vines cover and shade the ground. Flat cultivation is in general vogue, but ridging or hilling has its advocates, who claim that the practice dries and warms the soil, thus hastening maturity, and that the young potatoes are less likely to be exposed to the sun and thus become green. When the tops begin to turn yellow the tubers may be dug; but late kinds, which are generally planted three or four weeks later than the earliest crops and about two inches deeper, are allowed to remain in the ground until the vines have died or until the weather becomes cold in the autumn. The number of cultivations varies from a minimum of three for the earliest crops, to a maximum of eight or sometimes more for the late. Hand digging is usually practised upon small farms; a specially made plow is also often employed; but upon large plantations machines which sift the tubers from the soil and leave them at the surface are in common use. In the South a second crop of potatoes often follows the first in the same season; in the North the land occupied by early potatoes is often planted to winter wheat; that occupied by a late crop is left bare until spring when cereals frequently are sown. Potatoes are favorite crops for preparing the land for such crops as strawberries, raspberries and other small fruits, truck crops, etc.

Insects.— Among the insects which feed upon the potato are tortoise blister and flea beetles. The three-lined potato beetle (*Lema trilineata*) and the tomato worm (*Sphinx quinque-maculata*) are also frequently seriously troublesome. The most widely destructive enemy, however, is probably the potato-bug or properly the Colorado potato beetle (*Doryphora decemlineata*). Unlike most insect pests this beetle became troublesome first in the West and migrated eastward. When the potato was first cultivated in the West this insect left its original food plant the sand-bur (*Solanum rostratum*), and traveled from field to field, living upon potato vines. In 1860 it had become troublesome in Nebraska; in 1870 it was busy in Ohio and Ontario; and in 1875 it was well known in the Atlantic States as far south as Virginia. Its spread in the South has been less rapid probably because the potato is there less extensively grown than in the North. The hibernating adults appear in the spring and lay yellow eggs in clusters upon the foliage, sometimes even before it appears above the surface. In about a week the red larvæ appear, eat ravenously for about three weeks, pupate for about 10 days and emerge for feeding and egg-laying. From two to five broods appear in a season. This insect has a number of enemies, but farmers prefer to depend upon Paris green or other arsenites which are sometimes applied as a dust while the dew is on the plants, but usually as a spray. This is also more or less effective for the other species mentioned above.

Two stalk-borers are often troublesome; one, the larva of an owlet moth (*Gortyna nitela*), the other of a beetle (*Trichobaris trinotatus*). Wilting of the vines is generally the first indication of their presence and the only remedy recommended is the burning of the vines as soon as observed to be wilting.

Two so-called plant diseases are reported troublesome in the North; early blight (*Alternaria solani*) and late blight or rot (*Phytophthora infestans*). In the South *Bacillus solanacearum* is believed to be the cause of the brown rot. These three maladies are characterized by the destruction of the plants and are thought to be spread by insects which feed upon the foliage. Hence the remedies most in vogue are the control of the insects and the use of Bordeaux mixture, Paris green, and Pyrox. Care in selecting «seed» potatoes from non-infected districts and rotation of crops, the potatoes being moved to fresh soil each year, are also recommended. The scabbiness of tubers is thought to be prevented by soaking the «seed» in a solution of formalin or of corrosive sublimate, and by rotation of crops.

B., 'Economic entomology' (Philadelphia 1896); also bulletins of the United States Department of Agriculture and of the State Agricultural Colleges.

POTAWATAMI. See POTTAWATTOMI.

POTEMKIN, pŏ-tĕm'kĭn (Russ. pŏt-yŏm'-kĭn), **Gregory Alexandrovich**, prince of Taurida, Russian field-marshal: b. Smolensk, Russia, 1739; d. Bessarabia, Russia, 16 Oct. 1791.

He came of a noble Polish family, entered the Russian army, was distinguished for bravery in the war against the Turks in 1771–72 and was promoted lieutenant-general. He soon supplanted the brothers Orloff in the favor of the empress Catharine and for years was her acknowledged lover. When she found another more to her taste, choosing Zavadovsky as prime favorite, Potempkin was clever enough to retain his political supremacy with her, and she continued to rely on his advice, which permitted him to wield great power. He enlarged the Russian army, built a fleet on the Baltic Sea, annexed the Crimea, founded the cities Kherson, Kertch, Nikolaiev, Sebastopol, etc., was honored by Frederick the Great, Maria Theresa, Joseph II and other monarchs, and became recognized as an important factor in the politics of Europe. He was waging a successful war against Turkey at the time of his death. In his private life he was mean and avaricious, though loaded with wealth by the empress, and his public life, though eminently successful, shows little indication of high ability as a statesman. Consult Cérenville, 'Vie de Prince Potemkin' (1807).

POTENTIAL. In the third volume of the 'Mécanique Céleste,' Laplace, in 1784, determined the attraction exerted by a spheroid on a particle outside the mass, in the course of which he discovered the so-called potential function as the limit of the sum obtained by dividing every element of the mass of the attracting body by its distance from the point upon which the force is exerted. That is, in the case of gravitation, if Δm denotes the element of mass, r the distance from the particle at P and V the potential function, then

$$(1)\quad V = \lim_{\Delta m = 0} \Sigma \frac{\Delta m}{r}$$

where the numeration includes all the elements that compose the mass M. Laplace then proceeded to show that if the potential function of a mass was known at any external point, the attraction exerted in any direction by the mass upon that point could be found at once by performing a differentiation of the function in the required direction and, finally, that such a potential function would always be a solution of the differential equation

$$(2)\quad \nabla^2 V \equiv \frac{\delta^2 v}{\delta x^2} + \frac{\delta^2 v}{\delta y^2} + \frac{\delta^2 v}{\delta z^2} = 0$$

when ∇^2 is a symbol generally employed to denote the operator

$$\nabla^2 \equiv \frac{\delta^2}{\delta x^2} + \frac{\delta^2}{\delta y^2} + \frac{\delta^2}{\delta z^2}.$$

This is called Laplace's equation and V is a potential function.

Poisson (1813), a student of Laplace, gave the form of the equation which V must satisfy for all points, situated either within or without the attracting mass, as

$$\nabla^2 V = -4\pi\rho.$$

This equation must be satisfied by the potential function for every conceivable distribution of attracting matter at any point P, where ρ is the density of the attracting matter at P. Since $\rho = 0$ for points outside, Poisson's equation reduces to that of Laplace in such a case.

In 1827, George Green, a self-educated mathematician, before he took his degree at Cambridge in 1837, noted the peculiar property of V; namely, that it is a function of the initial and the final position only, thereby recognizing its universal application in dynamics in the treatment of a conservative system of forces, that is, a system that is independent of all intermediate conditions. For example, the work done in moving a mass against the force of gravity from P to Q is the same whether it is lifted directly up from P to Q or moved along any other path, as an inclined plane, provided always there is no friction. That is the earth, and every mass connected therewith constitutes a conservative system with respect to gravity. The work done is independent of the path. But if, as in practice, friction is involved, some energy is dissipated in overcoming this force and the system is no longer conservative. Green recognized, therefore, that, so far as natural phenomena are concerned, forces that are functions of distances only constitute a conservative system to which the theory of the potential is applicable and, in particular, that in addition to gravitation, forces exerted by electrified and magnetized bodies upon each other are of this nature. Green was the first to call V the potential function. Its peculiar property may be said to be this: that it measures the work done in moving a unit of mass, electricity or magnetism from one position to another by virtue of the forces in action.

Attraction.— Newton's law states that every particle of a body attracts every particle of another body with a force that varies directly as the product of the masses of the attracting particles and inversely as the square of the distance between them. Let P be any particle, or point, M any mass, ρ the average density of an element of mass, Δv, Q a point of the element whose co-ordinates are x', y', z' and take x, y, z as the coördinates of P. By definition the attraction at P in the direction PQ will be $\frac{\rho\Delta v}{PQ^2}$ and its components in the direction of the axes become $\frac{\rho\Delta v}{PQ^2}\cos\alpha$, $\frac{\rho\Delta v}{PQ^2}\cos\beta$, $\frac{\rho\Delta v}{PQ^2}\cos\gamma$, where α, β, γ are the direction cosines of PQ. But $QP^2 = r^2 = (x'-x)^2 + (y'-y)^2 + (z'-z)^2$, whence $\cos\alpha = \frac{x'-x}{r}$, $\cos\beta = \frac{y'-y}{r}$, $\cos\gamma = \frac{z'-z}{r}$. Denoting the components of the total attraction by X, Y, Z, we have, by Newton's law:

$$X = \iiint \frac{\rho(x'-x)dx'\,dy'\,dz'}{r^3},$$

$$Y = \iiint \frac{\rho(y'-y)dx'\,dy'\,dz'}{r^3},$$

$$Z = \iiint \frac{\rho(z'-z)dx'\,dy'\,dz'}{r^3},$$

when the integration is taken over the mass M. It follows that the resultant attraction at P due to M will be $R = \sqrt{X^2 + Y^2 + Z^2}$. But by definition, the potential function of P due to M, assuming as the element of mass

$dm = \rho dx'dy'dz'$ will be

$$V = \int\int\int \frac{\rho dx' dy' dz'}{r} = f(x, y, z), \text{ and } \frac{\delta v}{\delta x} =$$

$$\int\int\int \frac{\delta}{dx}\left\{\frac{\rho dx'\, dy'\, dz'}{[(x'-x)^2 + (y'-y)^2 + (z'-z)^2]^{\frac{1}{2}}}\right\} =$$

$$\int\int\int \frac{\rho(x'-x)dx'dy'\,dz'}{r^3},$$

differentiation under the sign of integration being possible when P is outside the mass M, since *r*, the radical in the denominator, can in that case never become infinite. By comparison observe that the last expression is the attraction X. That is

$$\frac{\delta v}{\delta x} = Y, \frac{\delta v}{\delta y} = X, \frac{\delta v}{\delta z} = Z; \text{ whence}$$

$$R = \sqrt{X^2+Y^2+Z^2} = \sqrt{\left(\frac{\delta v}{\delta x}\right)^2 + \left(\frac{\delta v}{\delta y}\right)^2 + \left(\frac{\delta v}{\delta z}\right)^2}.$$

That is, to find the component of the attraction in any direction for a point P, find the potential function at P and differentiate this function partially in the required direction.

Potential Function as Measure of Work.— By definition, the work done in moving a unit of mass along a path S against a force F is equal to the product $F \times S$. Let the attraction at any point of the path and opposing the force F be $-\frac{\delta v}{\delta s}$, negative since in the opposite direction from the motion, and let Δs be an element of the path. Then, if the unit mass moves from P_1 to P_2, the work done is given by

$$W = \lim_{\Delta s = 0} \sum_{P_1}^{P_2} F\Delta s = -\int_{P_1}^{P_2} \frac{\delta v}{\delta s}\, ds = V_1 - V_2,$$

when V_1 and V_2 are the values of the potential function of P_1 and P_2 respectively. That is, the difference or loss in potential measures the work done.

Since the difference of potential is the measure, we observe that the farther P_2 is from the attracting mass the less V_2 becomes. For, in general,

$$V = \lim_{\Delta m = 0} \Sigma \frac{\Delta m}{r_{\mu}},$$

and if r_0 denotes the distance of the nearest point in the attracting mass from P, then

$$V < \frac{1}{r_0} \Sigma \Delta m, \text{ or } V < \frac{M}{r_0}.$$

That is, when P is at infinity $r_0 = \infty$, and the potential is zero.

It follows that when P_2 is at infinity,

$$W = V_1 - V_2 = V_1.$$

That is, the potential function or the potential at any point P, due to an attracting system, is equal to the work done in moving a unit mass considered as concentrated at P, from P to infinity along any path. In most modern works on mathematical physics the word «potential» does not denote the value of the potential function at a point but measures the work done in moving a mass from a given position to infinity in the presence of the system considered. W is used by some authors as «the potential of the mass M′ with reference to the mass M.» Others use the negative of W as the equivalent of «the mutual potential energy of M and M′.»

Laplace's Equation.— It is not difficult to show that $\frac{\delta V}{\delta x}, \frac{\delta V}{\delta y}, \frac{\delta V}{\delta z}$ are everywhere finite and that, as a consequence, the potential function is always finite and continuous. Moreover, when P is outside the masses, the expression under the radical in $\frac{\delta V}{\delta x}$ is everywhere finite within the limits of integration and it becomes possible to differentiate under the signs of integration. That is,

$$\frac{\delta^2 V}{\delta x^2} = \int\int\int \frac{3(x'-x)^2 - r^2}{r^5}\, dx'\, dy'\, dz',$$

$$\frac{\delta^2 V}{\delta y^2} = \int\int\int \frac{3(y'-y)^2 - r^2}{r^5}\, dx'\, dy'\, dz',$$

$$\frac{\delta^2 V}{\delta z^2} = \int\int\int \frac{3(z'-z)^2 - r^2}{r^5}\, dx'\, dy'\, dz',$$

whence we derive by addition Laplace's equation as one to be satisfied by the potential function at all points outside the attracting mass

$$\nabla^2 V = \frac{\delta^2 V}{\delta x^2} + \frac{\delta^2 V}{\delta y^2} + \frac{\delta^2 V}{\delta z^2} = 0.$$

The generalized form due to Poisson requires an application of a form of Green's theorem due to Gauss and is applicable to all points. As stated, Poisson's equation is $\nabla^2 V = -4\pi\rho$.

For a clear treatment of the elements of the theory of the potential function, consult 'Newtonian Potential Function,' B. O. Peirce, 1886, from which the present article is in the main derived. Consult also the mathematical papers of George Green, reprinted by Ferrers; Thomson and Tait, 'A Treatise on Natural Philosophy'; Maxwell, 'An Elementary Treatise on Electricity'; Watson and Burbury, 'The Mathematical Theory of Electricity and Magnetism'; Clausius, 'Die Potentialfunktion und das Potential.'

J. Brace Chittenden, Ph.D

POTENTILLA, CINQUEFOIL, or FIVE-FINGER, a genus of herbs and shrubs of the order *Rosaceæ*. The numerous species are mostly perennials and widely distributed in the north temperate and Arctic zones. They have compound leaves and variously colored flowers like the strawberry, from which the species are readily distinguished by the dry receptacle: that of the strawberry is juicy. They blossom throughout the whole season with a climax in midsummer. They may be readily propagated by division and by seed, and thrive well upon heavy soil. However, they may become persistent weeds in favorable situations. *P. fruticosa* is especially troublesome upon moist soils when it has once become established. *P. tridentata* is an evergreen species which forms a dense carpet of verdure.

POTENZA, pō-tĕn'zä, Italy, a river, province and city. (1) The Potenza River lies in northern Italy in the province of Macerata, rising in Monte Pennino, about 4,800 feet above sea-level, crosses the province in a northeasterly direction, and empties into the Adriatic at Porto Recanati, near Potenza Picena, the ancient Roman colony of Potentia, founded 184 B.C., the site of the abbey of Santa Maria. (2) The province lies 200 miles south of the river, and was formerly called Basilicata, being described under that name; it has about 500,000 inhabitants. (3) The city, capital of the province, lies on the left bank of the Basento and on the railroad between Naples and Metaponto, is the seat of a bishop and of several important courts, has a cathedral church, a liceo, a technical school and a great prison It is near an older city of the same name, the old Roman colony of Potentia in Lucania, which was captured by the Emperor Frederick II, and by Charles of Anjou. An earthquake 16 Dec. 1857 nearly destroyed the modern city. Pop. about 17,938.

POTIDÆA, pŏt-ĭ-dē'ą, in ancient history, a city of the peninsula of Pallene in Chalcidice, founded as a Corinthian colony in the beginning of the 16th century B.C. It was successfully defended against the Persians under Artabazus in 479; in 432 revolted from the Athenian League, thus precipitating the Peloponnesian War, in which it was captured by the Athenians in 429 and occupied by Athenian colonists; was destroyed in 356 by Philip II of Macedon; and was replaced in 316 by Cassandreia, which prospered until its destruction by the Huns.

POTIPHAR PAPERS, The, a series of sharply satirical papers on New York society by George William Curtis, first published in *Putnam's Magazine* in 1853. The papers are somewhat in the manner of Addison's satires on the pretensions and insincerities of society; but at times the bitterness becomes more scathing, and reminds one of Thackeray in its merciless analysis of folly and ignorance. One of the enduring characters is the Rev. Cream Cheese, who sympathetically advises with Mrs. Potiphar as to the color of the cover of her prayer-book.

POTLATCH, among American Indians of the Pacific Coast, a feast often lasting several days, given to a tribe by one of its members who aspires to the position of chief. The word is from the Nootka, meaning a gift, and at the potlatch feast numerous and valuable gifts are distributed among the members of the tribe. The token given at a potlatch is a piece of engraved copper, whose value is usually estimated in blankets. At these feasts the guests are expected to accept whatever is offered, but there is a «string» tied to every gift in that it must be later returned with excess. The wealthy chief who gives a potlatch will sometimes show his distinguished disregard of material values by burning a few hundred blankets, also a few canoes or other property he may have; the more he destroys the bigger chief he is. They have even been known to break up and give away the fragments of a potlatch copper representing a value of many thousand blankets. Consult Barbeau, C. M., 'Du Potlatch en Colombie Britannique' (in Bull. Soc. de Geographic de Quebec, Quebec 1911–12).

POTOCKI, pō-tôts'kē, **Ignanzy**, Count, Polish patriot, cousin of S. F. Potocki (q.v.): b. about 1751; d. Vienna, 20 Aug. 1809. He was grand marshal of Lithuania, and united with Malachovski, Kolontady and other patriots in support of the constitution of 3 May 1791. He procured the declaration of the king in its favor, and in 1792 went to Berlin to induce the Prussian court to protect the Poles from Russia. When the Russian troops took possession of the country Potocki fled to Dresden, and was deprived of his estates. In 1794 he returned to Warsaw to engage in the attempt of Kosciusko, and was appointed general and member of the Supreme National Council. After the capture of Warsaw he remained in the city, but was arrested and confined as a state prisoner until 1796. In 1806 he again engaged in public affairs, and exerted himself to effect the abolition of serfdom, and to promote the progress of education among the people.

POTOCKI, Jan, Polish historian: b. 1761; d. Oladovka, 1815. At an early age he formed the resolution of clearing up the obscurity that rested on Slavonic history, and prepared himself for carrying out his resolution by a course of linguistic studies, and by traveling over the lands occupied by Slavonic nations. His chief works are 'Essai sur l'Histore Universelle et Recherches sur la Sarmatie' (1788); 'Histoire Primitive des Peuples de la Russie' (1802); 'Fragments Historiques et Géographiques sur la Scythie, la Sarmatie, et les Slaves' (1794).

POTOCKI, Stanislas Felix, Count, Polish patriot and statesman: b. 1745; d. 1805. He adhered pertinaciously to the old constitution of Poland, and exerted his influence against the constitution of 3 May 1791. (See Poland). Potocki so far forgot his duty to his country as to form connections with Russia, and on 14 May 1792 joined with Rzeuski and Branicki in the declaration at Targovice against the constitution. He then united himself with the Russian army, and was one of the leaders of the Diet of Grodno, which abolished the constitution, and subscribed the act for the partition of the country. He was thought to aspire to the crown, and received important appointments from Catharine II.

POTOCKI, Stanislas Kostka, Polish patriot and statesman, brother of I. Potocki (q.v.): b. 1752; d. 14 Sept. 1821. He distinguished himself greatly by his eloquence in the various diets which were held between 1788 and 1792. When the king acceded to the Confederation of Targovice, and by that false step consummated the ruin of Poland, Potocki retired to Austria; but was arrested there and imprisoned in a fortress. On his release he continued to live in retirement till the creation of the grand duchy of Warsaw in 1807, when he returned to his native country, and as President of the Council of Education applied himself to the promotion of intellectual culture among his fellow-countrymen. When Napoleon gave out that he meditated the restoration of the ancient kingdom of Poland, Potocki's talent and influence were called into action. In 1815 he was appointed Minister for Ecclesiastical Affairs and Public Instruction. He wrote a work on eloquence (1815) and an uncompleted Polish translation (1815) of Winckelmann's work on ancient art.

POTOMAC, pō-tō'măk, a river in the eastern part of the United States, formed by the junction of two rivers on the boundary between Maryland and West Virginia. The river called North Branch rises in the western Alleghanies and the South Branch in the central Alleghanies, and flowing northeast they unite about 15 miles southeast of Cumberland. The North Branch flows southeast from Cumberland for over 100 miles. From the junction of the two headstreams, the river flows generally east-southeast, forming the irregular boundary between Maryland and West Virginia and between Maryland and Virginia, and after a course of over 400 miles enters Chesapeake Bay about 73 miles from the Atlantic Ocean. The chief branches are the Shenandoah from Virginia, and the Monocacy from Maryland. At Harper's Ferry the river breaks through the Blue Ridge, forming a picturesque gorge. There are a number of falls, especially in that part of the course through the mountains. About 15 miles above Washington begins a rapid descent which in two miles is 80 feet and which ends with the Great Falls, a cataract 35 feet high. At Washington the river meets the tide, 125 miles from its mouth; and about 25 miles below it becomes an estuary from two to eight miles wide. It is navigable for large vessels to Washington. The Chesapeake and Ohio Canal is parallel to and near the river the whole length from Georgetown to Cumberland. The Potomac is the most important river in this section of the United States. It was the route whereby explorers journeyed to the interior in the early days, and it has been closely associated with many of the important events in the history of the country. The nation's capitol is on its bank, the home of the first President, and his grave, is a few miles below, and Arlington (q.v.), with its white tombs, may be seen from the Capitol. The drainage area is about 15,000 miles. See BOUNDARIES OF THE UNITED STATES.

POTOMAC, Army of the, a great Federal army in the Civil War, which operated in the East, mainly in the Virginias. It was organized in 1861 by Gen. George B. McClellan. Under him, in 1862, it served in the Peninsula Campaign (q.v.) and later in that of Antietam. Under Gen. A. E. Burnside, who took command in November 1862, it was defeated at Fredericksburg in the following month. In January 1863 command of the army passed to Gen. Joseph Hooker, and at Chancellorsville, in May, it met another defeat; but in July of the same year, under Gen. G. G. Meade, it won the decisive battle of Gettysburg. General Meade continued in command, under Gen. U. S. Grant, throughout the operations of the latter in 1864–65.

POTOMAC, Society of the Army of the, a military organization which grew out of the Civil War. It was founded in New York City 5 July 1869, since when it has held annual reunions. All officers and soldiers who served in the Army of the Potomac and in the 10th and 18th army corps, Army of the James, are eligible to membership.

POTOMAC COMPANY, The, in American colonial history, a land company chartered in 1784, with General Washington as president. It was organized for the purpose of connecting the Potomac Valley with the West by means of a canal, and for general land improvement. The Chesapeake and Ohio Canal Company succeeded it in 1828.

POTOMAC FORMATION, the lowest deposits of the Cretaceous period in America, so-called from the location of some of its typical beds. It is represented by a narrow belt in Maryland, running southward, east of Washington to North Carolina, by strips in New Jersey and in Alabama, Arkansas and Texas. The series has been found to be from 5 to 500 feet thick. It is made up of various sandstones, gravel, sand and clays. Portions of the formation have supplied glass sand, clay (at Amboy, N. J.) and iron ore for manufacturing purposes. Consult United States Geological Survey Bulletins.

POTOSI, pō-tō-sē', Bolivia, (1) city, capital of the department of Potosi, on the side of the Cerro do Potosi, at an elevation of over 13,000 feet; about 80 miles southwest of Sucre, and 300 miles from the Pacific. It is one of the highest inhabited places in the world. The city owes its origin to the silver discovered in the mountains and at the site of the present city about 1540. The first mine was opened in 1545; the city was founded in 1547; a royal mint was established in 1562 at a cost of over $1,000,000. From the time of the first discovery to 1864 these mines supplied silver to the value of often over $5,000,000 a year; nearly 2,000 shafts were sunk. If the smuggled silver could have been taken into account no doubt the amount would be much greater. The number of mines worked was formerly 300. They are now exhausted. The city is still one of the most important in Bolivia. It has a mint, a cathedral, numerous churches, convents and various public buildings, but the general appearance is dilapidated and unattractive. In the 17th and 18th centuries the population was over 160,000. There are two banks besides the National Bank of Bolivia. Pop. about 24,795. (2) A department of Bolivia, in the southwest, bordering on Chile and Argentina. Area, 45,031 square miles. It is crossed by long mountain ranges; but in the northwest is a low, saline marsh, called "Grandes Salinas." Many of the inhabitants are Indians. Since the silver mines ran out, there is little industry. Pop. 530,748.

POTOTAN, pō-tō'tän, Philippines, pueblo, province of Iloilo, island of Panay, on the Jalaur River, 17 miles north of Iloilo. It is well built and contains a large church and a convent. Pop. 14,500.

POTPOURRI, pŏt-poo-rē', (1) Foods of various kinds, of meat and vegetables, cooked together. (2) A mixture of rose leaves and various spices, kept in jars or other vessels as a scent. (3) A vase or bouquet of flowers used to perfume a room. (4) In music, a medley; a collection of various tunes linked together; a capriccio or fantasia on popular melodies. (5) A literary composition made up of several parts put together without any unity of plot or plan.

POTSDAM, pŏts'däm, Germany, a district and a city of the province of Brandenburg in Prussia. (1) The administrative district of Potsdam lies between Mecklenberg-Schwerin and Anhalt in the western part of the province of Brandenburg, and is well watered by lakes, and the rivers Oder, Havel, Spree and Ucker, with several connecting canals, and is marked by fine strips of forest and stretches of moorland, and has a flourishing commerce, good fisheries, agriculture and grazing. There are 18 administrative divisions in the district, and

10 electoral districts for the choice of deputies to the Reichstag. Area, about 8,100 square miles; pop. about 2,000,000, of whom 1,800,000 are Evangelical Protestants, 114,000 Roman Catholics, 9,250 members of other Christian bodies and 20,780 Jews. (2) The capital city of the province is situated in its most pleasant and beautiful part, on an island where the Nuthe and several canals and lakes join the Havel, 17 miles southwest of Berlin. Most of the city is well built, with broad straight streets, fine houses, and trees planted in the squares and streets; and the five different parts, the old city or Potsdam proper, and the Berlin, Nauen, Brandenburg and Teltow quarters are connected by bridges, steamers and tramways. Among the city's beautiful squares are the Wilhelmsplatz, with a bronze statue of Frederick William III, by Kiss; the Bassinplatz with Dutch architectural treatment; the Lustgarten with its parade-ground and park and a bronze statue of Frederick William I, by Hilgers, busts of the heroes of the War of Liberation and statues of the generals of the armies of Brandenburg and Prussia and cannons captured between 1680 and 1858; the Old Market with a red and white marble obelisk 75 feet high; and in the narrowest part of the river on the Freundschaftsinsel a place with a bronze equestrian statue of the Emperor William I, by Herter, erected in 1900. The churches of the city, five Protestant and one Catholic, include the Garrison Church planned by Gerlach in 1730 (and rebuilt in 1898), with a tower 295 feet high and the graves of Frederick William I and Frederick II; the Nicholas Church, begun in 1830 and finished in 1850, with a beautiful dome 240 feet high and four bell-towers; the French church, after the Pantheon; the church of the Holy Spirit, with a steeple as tall as the Garrison Church; and the fine Friedenskirche. Among the profane edifices the chief are the Brandenburg Arch, on the lines of the Roman triumphal arch, built in 1750, and leading to Frederick the Great's palace and French gardens of Sans Souci; the palace of San Souci is a low building on fine terraces, its historical associations quite out of all proportion to its poor appearance; the New Palace built at the close of the Seven Years' War; the Marble Palace, the former residence of the Kaiser, situated in a northeastern suburb; northwest of this palace the Pfingstberg, an ornate building with two towers and a fine view. In the extreme northeastern part of the city in one of the broadest expanses of the river lies the large Pfaueninsel (or Peacocks' Island) with a park and a hunting lodge. Woods, hills and the stretches of water everywhere make the city an ideal one.

The city is situated on the Berlin-Magdeburg branch of the Prussian governmental railroad system, and has other rail connections with Berlin. The commerce is comparatively unimportant; there are sugar factories, several breweries, etc. It is an important garrison post, and among the educational institutions of the city are a military school, a war-school for the training of officers and a military orphanage, in which there are 800 pupils. There are also excellent schools for girls, a normal school for women, training schools for gardeners, etc. Pop. 62,243, of whom 5,000 are Catholics and 500 Jews.

Potsdam was a Wendish fishing village founded about 1300, and attained no importance until 1660 when it was selected as a site for a palace by the Great Elector. In 1685 (8 November) by the terms of the Edict of Potsdam he opened the city to the French refugees and made the city his residence. He not only built the palaces mentioned above as his, but erected many private houses to keep up the tone of architecture. Frederick William IV did hardly less for the city's scenic features with the help of Lenné and Meyer. The Peace of Potsdam was signed here 3 Nov. 1805, ratifying an alliance between Russia and Prussia against France.

Consult the works cited under the article Berlin; also 'Geschichte der Königlichen Residenzstadt Potsdam' (1883) and 'Potsdam ein deutscher Fürstensitz' (illustrated, 1893).

POTSDAM, N. Y., village in Saint Lawrence County, on the Raquette River, and on the New York Central and Hudson River Railroad, about 20 miles from the Saint Lawrence River and 30 miles west of Malone. In 1786 the State of New York created a land commission to further the settlement of the unexplored northern part of the State. Ten towns were established, one of which was Potsdam. Later Garrett Van Horn and David M. Clarkson purchased the town of Potsdam. In June 1803 their agent, Benjamin Raymond, arrived at the place to sell the property. A number of persons from Vermont soon purchased land and settled here. The village of Potsdam was incorporated in 1831. It is in a productive agricultural region, which has had extensive lumbering interests from its foundation. The first industrial establishment built by Benjamin Raymond was a saw mill, and saw mills have been there for over 100 years. In a recent year, one Potsdam company alone had 1,000 men employed in lumber camps in the Adirondacks, and in spring floated down the Raquette River, to the Potsdam mills, 30,000,000 feet of log stock. The village has flour and lumber mills, paper mills, creameries and machine shops. An extension of the water power is being developed in the vicinity. It has an extensive trade in lumber, paper, farm and dairy products, and men's clothing. The celebrated Potsdam sandstone (q.v.) is quarried in the vicinity, and is used in nearly all the large buildings of the town. It has the Potsdam State Normal and Training School, which has a library of 8,000 volumes, the Clarkson School of Technology, founded in 1895, the Crane Institute of Music, a high school and public elementary schools. There are seven churches. The two banks have a combined capital of $200,000. The government is administered by a village president and a board of five trustees elected annually. The village owns and operates the waterworks. Pop. 4,036.

POTSDAM SANDSTONE, an American geological formation of the Cambrian Period of which a yellowish brown sandstone found at Potsdam, N. Y., is typical. The formation was long supposed to be the oldest of Palæozoic time in America, but is now placed at the top of the Cambrian group. It is found to the north of the Adirondacks in New York and in Canada, and in Michigan, Wisconsin and Virginia.

POTT, pŏt, **August Friedrich**, German philologist: b. Nettelröde, Hanover, 14 Nov. 1802; d. Halle, 5 July 1887. He studied at Göttingen, became a lecturer at Berlin in 1830 and in 1833 professor of the science of language at Halle. His reputation as a comparative philologian was established by his 'Etymologische Forschungen auf dem Gebiet der Indogermanischen Sprachen' (1833–36; 2d ed., 1859–76), and he soon took place with Grimm, Bopp and W. von Humboldt among the students of the newly developed science. His researches were peculiarly thorough; and this fact makes them yet of value despite the advances made in his subject in more recent times. His books, which have been compared, for their want of order, to the plain of Shimar upon the confusion of tongues, include further: 'Die Zigeuner in Europa und Asien' (1845); 'Die quinäre und vigesimale Zählmethode' (1847); 'Die Personennamen und ihre Entstehungsarten' (1853); 'Anti-Kaulen' (1863); 'Die Sprachverschiedenheit in Europa, an den Zahlwörtern Nachgewiesen' (1868); and 'Wilhelm von Humboldt und die Sprachwissenschaft' (1876).

POTT, Percival, English surgeon: b. London, 1713; d. 22 Dec. 1788. He was assistant surgeon in Saint Bartholomew's Hospital, 1745–49, and a chief surgeon there from 1749 to 1787. In spinal diseases he was a specialist, and won distinction by his investigation of angular curvature of the spine, the cause of which he found in a disease of the bones of the spinal column, called after him Pott's disease (q.v.). He wrote a number of works, including 'A Treatise on Ruptures' (1756); 'Fistula Lacrymalis' (1758); 'Practical Remarks on Hydrocele' (1762); 'Some Few General Remarks on Fractures and Dislocations' (1769); and 'Remarks on That Kind of Palsy of the Lower Limbs Found to Accompany a Curvature of the Spine' (1779).

POTT'S DISEASE, an affection of the spinal vertebræ characterized by tuberculous inflammation of their bodies; spinal caries. The nature and cause of the disease were first correctly described by the English surgeon Percival Pott (q.v.), after whom it was named. The inflammation is sometimes followed by total paralysis of the lower limbs. On the diseased parts tubercles form, resulting in disintegration of the vertebræ. A curvature or hump is formed by the visible projection of spinal processes beyond their normal situation. The treatment of the disease must always be hygienic and constitutional, and for surgical treatment special methods are now in general use whereby excellent results are often obtained.

POTTAWATTOMI (pŏt-ą-wŏt'ō-mĭ) **INDIANS,** an American tribe of the Algonquian family, early occupied what is now lower Michigan and upper Illinois and Indiana. Joining Pontiac, they surprised Fort Saint Joseph in 1763. During the Revolution they were hostile to the Americans, but joined in the treaty of 1795. The tribe was then composed of settled bands and the wandering prairie tribes. In 1812 they aided England. A few descendants are now living in Kansas and Iowa.

POTTER, Alonzo, American Protestant Episcopal bishop: b. Beekman, Dutchess County, N. Y., 6 July 1800; d. San Francisco, Cal., 4 July 1865. He was graduated from Union College in 1818 and became a tutor there in the following year. In 1821 he was made professor of mathematics and natural philosophy. Of Quaker parentage, he nevertheless studied for the Episcopal ministry and was ordained to the priesthood in 1824. He was rector of Saint Paul's Church, Boston, 1826–31, and then returned to Union College as professor of moral philosophy and political economy, which position he retained until his elevation to the episcopate. He was consecrated bishop of Pennsylvania 23 Sept. 1845, and became known as one of the most sagacious and practical prelates of his day, as well as a man of marked intellectual force and spiritual fervor. His plans of church extension and benevolence were large and costly but he found means to carry them into effect, and not a few flourishing institutions, including the Episcopal Hospital and the Philadelphia Divinity School, owe their origin chiefly to him. Among his published works are several educational treatises and 'Religious Philosophy' (1870), besides sermons and addresses, and the Lowell Institute lectures on natural theology and Christian evidences, delivered in Boston 1845–49. Consult memoir by Bishop Howe (1870).

POTTER, Cora Urquhart (Mrs. James Brown Potter), American actress: b. New Orleans, about 1872. She first appeared on the amateur stage in New York, where she was a society favorite; her professional début was made at the Haymarket, London, as Anne Sylvester, in 'Man and Wife,' in 1887. Later in the same year she played in New York. She made several world tours and assisted in raising funds for the comfort and nursing of British troops in the Boer War. In recent years she has played mostly in and near London. She has written 'My Recitations.'

POTTER, Edward Clark, American sculptor: b. New London, Conn., 26 Nov. 1857. He was educated at Amherst College; studied sculpture under Mercei and Fremo, Paris, 1888–89. He collaborated with D. C. French in sculptures for the Chicago Exposition of 1892–93; executed equestrian statues of Grant at Philadelphia in 1894; Washington at Paris in 1898; Hooker at Boston in 1904; and Derens at Worcester in 1905. The statue of General Slocum at Gettysburg and De Soto at the Saint Louis Exposition of 1904 are also by Potter. He is also represented in the Fulton Library, Washington, the Appellate Court, New York, and the Michigan State House. He executed four groups for the Buffalo Exposition of 1901, two animal groups for the library of J. P. Morgan, New York. Potter is a member of the National Institute of Arts and Letters and was elected a National Academician in 1906.

POTTER, Edward Tuckerman, architect, son of Alonzo Potter (q.v.): b. Schenectady, N. Y., 25 Sept. 1831; d. New York City, 21 Dec. 1904. He was graduated from Union College in 1853 and studied and practised architecture in New York City, giving his attention principally to collegiate and ecclesiastical architecture. He designed and superintended the building of the church of the Heavenly Rest, in Fifth avenue, New York City, the Colt Memorial

Church at Hartford, Conn., the church of the Good Shepherd and the Memorial Hall at Schenectady.

POTTER, Eliphalet Nott, American educator and Episcopal clergyman, son of Alonzo Potter (q.v.): b. Schenectady, N. Y., 20 Sept. 1836; d. City of Mexico, 6 Feb. 1901. He was graduated from Union College in 1861 and from Berkeley Divinity School in 1862, in which year he entered the Episcopal ministry. He was rector of a parish at South Bethlehem, Pa., 1862–69, and professor of ethics at Lehigh University in 1866–71. He then accepted the presidency of Union College and when the college was made a university in 1873 he was elected chancellor. In 1884–97 he was president of Hobart College and in the latter year became president of the Cosmopolitan University, a correspondence school. He wrote 'Parochial Sermons'; 'Washington a Model in His Library and Life' (1895), etc.

POTTER, Henry Codman, American Protestant Episcopal bishop: b. Schenectady, N. Y., 25 May 1835; d. 21 July 1908. He was the son of Bishop Alonzo Potter (q.v.), and was educated at the Episcopal Academy, Philadelphia, Union College and at the Theological Seminary of Virginia. In 1857 he was ordained deacon and in 1858 priest. He was rector at Christ Church, Greensburg, Pa. (1857–58); and at Saint John's Church of Troy, N. Y. (1859–66); then became assistant at Trinity Church, Boston, and in 1868 rector of Grace Church, New York City. In 1883 he was consecrated assistant bishop of New York, and on the death of his uncle, Horatio Potter, in 1887 became bishop. Under his energetic and successful administration, the site for Saint John's Cathedral on Morningside Heights was purchased and funds raised for building. In his decisions on theological questions and controversies he proved himself sagacious and tolerant. He took a deep interest in political life of the city and nation, and wrote and spoke forcefully and freely on a wide variety of educational and political subjects. He lent his influence to promoting friendly relations between labor and capital, and to assisting the reform movement in New York City. His views were extremely liberal. He held that the beer saloon as a poor man's club was a necessity in a great city like New York, and that the church should try to elevate it, and not work — ineffectively — to smother it. In 1904 he established a tavern which was designed to be run as an ethical saloon. It was not well patronized and the newspapers ridiculed it, so it had to be abandoned. He had a great big heart, and did able work among the poor. He published 'Our Threefold Victory'; 'Young Men's Christian Associations and Their Work'; 'The Church and Her Children'; 'Sisterhoods and Deaconesses' (1873); 'The Religion for To-day' (1877); 'The Gates of the East' (1877); 'The Scholar and the State' (1897); 'The East of To-day and To-morrow' (1902); 'Law and Loyalty' (1903); 'The Drink Problem' (1905). Consult Keyser, H. A., 'Bishop Potter, the People's Friend' (1910); Hodges, George, 'Henry Codman Potter' (1915).

POTTER, Horatio, American Protestant Episcopal bishop, brother of Alonzo Potter (q.v.): b. Beekman, Dutchess County, N. Y., 9 Feb. 1802; d. New York, 2 Jan. 1887. He was graduated at Union College in 1826, like his brother studied for the ministry, and was ordained deacon in 1827 and priest in 1828. In the latter year after having held one pastoral charge in Maine, he was elected professor of mathematics and natural philosophy in Washington (now Trinity) College, Hartford, Conn. He was rector of Saint Peter's Church, Albany, N. Y., 1833–54, and was then (1854) elected provisional bishop of New York. His predecessor, Bishop Benjamin T. Onderdonk, after trial before a court of bishops, had been suspended from his office on a charge of immorality, the truth of which, however, he never acknowledged. Thus the diocese remained for some time in an anomalous position, until finally a canon was passed authorizing the election of a provisional bishop. On the death of Bishop Onderdonk, in 1861, Bishop Potter assumed entire charge of the diocese, and ruled it prudently until his own death. The care of such a large and important diocese, especially in the trying times of the Civil War and the ritual controversy, required an unusual amount of courage, wisdom and impartiality. These qualities Bishop Potter exhibited in such a degree as to bring a large measure of unity and peace to New York diocese. His published writings are principally sermons, addresses and pastoral letters dealing with religious and occasionally with civic questions.

POTTER, John, English Anglican archbishop: b. Wakefield, Yorkshire, 1674; d. London, 10 Oct. 1747. He was educated at Oxford, and in 1694 became Fellow of Lincoln College, Oxford. In 1697 he printed an edition of 'Lycophron.' In 1697–99 appeared his 'Archæologia Græca,' or the 'Antiquities of Greece,' which has gone through many editions, and was long indispensable to the classical student. In 1708 he was appointed regius professor of divinity at Oxford, and in 1737 was appointed archbishop of Canterbury. His 'Theological Works' in three volumes appeared in 1753.

POTTER, Louis, American sculptor: b. Troy, N. Y., 1873; d. 1912. His art instruction was obtained under Charles and Montague Flagg. Potter went to Paris in 1896 and studied painting under Merson and Dampt. He executed a number of statuettes, including such excellent pieces as 'The Snake Charmer'; 'Young Bedouin'; 'Tunisian Jewess,' etc. About 1900 he returned to the United States and specialized in American Indian subjects. Of these the best known are 'The Taku Wind'; 'Spirit of the Night'; and 'The Clam Diggers.' Other works are the heroic groups 'Earth Bound'; 'Earth Unfoldment'; and the 'Earth Man'; busts of Mark Twain and de Monvel, and the Horace Wells Memorial, Hartford, Conn.

POTTER, Paul, Dutch artist: b. Enkhuizen, November 1625; d. Amsterdam, January 1654. He came with his father to Amsterdam in 1631, and in 1646 joined the Painters' Guild of Delft and three years later that of The Hague. In 1653 he settled in Amsterdam. Of exceedingly precocious genius he early won a reputation as a painter and etcher, and although he died early takes the first place in the

Dutch school of painting as an animal painter. His life-size pictures such as 'The Young Bull' in the museum of The Hague, and the 'Bear Hunt' in the museum at Amsterdam, have contributed less to his reputation than the smaller canvases, in which are represented cattle, sheep, horses and swine out at pasture. His clear and true color and the fidelity of his drawing and modeling are remarkable. His chief works are 'The Cow'; 'The Sentence of the Beasts upon the Hunters' (at the Hermitage, Petrograd); 'Horse Standing before a Cottage'; 'The Meadow' (Louvre); 'The Shepherd's Cottage'; 'Orpheus and the Beasts'; 'Shepherds with their Flocks' (Amsterdam Museum). The Dresden Gallery possesses two landscapes with cattle, of his, in which the flat fields, peculiar sky and pollard trees of the local scenery are depicted with singular felicity. Most of his pictures are in English galleries. He is also to be considered one of the best etchers of his day. Consult Westrheene, 'Paulus Potter, sa Vie et ses Œuvres' (1867).

POTTER, Paul Meredith, American dramatist: b. Brighton, England, 3 June 1853. He entered journalism, was foreign editor of the New York *Herald* 1876–83, and its London correspondent 1883–84. He was on the editorial staff of the Chicago *Tribune* in 1888 and in 1889 composed his first play, 'The City Directory.' Among his many later plays may be cited 'Our Country Cousin' (1893); a dramatization of 'Trilby' (1895); 'Under Two Flags' (1901); 'Notre Dame' (1903); 'Nancy Stair' (1905); 'Queen of the Moulin Rouge' (1908); 'The Girl from Rector's' (1909); 'Arsene Lupin' (1909).

POTTER, Robert B., American lawyer and soldier, son of Alonzo Potter (q.v.): b. Schenectady, N. Y., 16 July 1829; d. Newport, R. I., 19 Feb. 1887. He studied at Union College; began the practice of law in New York, became colonel of the 51st regiment New York volunteers upon the organization of that regiment, and served with distinction at Newbern, where he stormed the intrenchments on the Confederate left, and at Antietam, where he carried the stone bridge and saved the day. He fought also at Fredericksburg, was made a brigadier 13 March 1863, commanded the second division of the Ninth corps at Vicksburg, and the corps at the siege of Knóxville. Under Grant he commanded his division from the Wilderness to the final attack on Petersburg. He was brevetted major-general in 1863. Retiring from the army in 1866, he was chosen receiver of the Atlantic and Great Western Railway.

POTTER, William Parker, American rear-admiral: b. Whitehall, N. Y., 10 May 1850. Graduating from the Naval Academy in 1869, he rose steadily in the service, serving several years as flag secretary, both of the North Atlantic fleet and of the European squadron. He took part in the destruction of Cervera's fleet at Santiago, 3 July 1898, and was advanced five numbers for «eminent and conspicuous conduct.» Thereafter he served as commander and captain at several stations, being raised to the rear-admiralty in 1908, and placed in charge of the fourth division of the Atlantic fleet. Later he was chief of the Bureau of Navigation, and in 1912 he retired.

POTTER'S CLAY. See CLAY.

POTTER'S FIELD, the name commonly given a piece of ground usually adjoining a cemetery, and reserved as a burial place for strangers and the friendless poor. The name is derived from its use in the following passage from the Bible: «And they took counsel and bought with them (30 pieces of silver) the potter's field, to bury strangers in.» Matt. xxvii, 7.

POTTER'S WHEEL. The wheel as used by the potter ranks among the earliest mechanical contrivances. The Egyptians classed it among the inventions of the gods and claimed that Num, the creator, fashioned man upon it. As a broad principle the wheel consists of a flat disc, on an upright axle, rotating in a horizontal plane. The primitive form was simply a turn-table. The edge of the disc was made of heavy substance to secure momentum and steady motion. It was rotated by the hand. The Chinese improved upon this by driving by a cord running in a groove. In Europe the favorite device was a lengthening of the axle of the wheel, enabling a heavy disc some three feet in diameter to be placed at the bottom. The potter seated himself at the wheel and propelled it with his foot, working on the lower disc. This was the first form of the «kick» wheel. The next improvement was the application of a crank and handle which was kept in constant motion by one foot. The introduction of power gave rise to two forms of wheel. The special requirement is that the speed of the wheel shall be variable at the will of the workman. This is accomplished either by cones in contact or by a traveling disc, or some similar device. In the former case a cone with a slightly curved face is fitted to the axle, so that it forms the base of the machine. In contact with this is an inverted cone faced with paper or leather and so arranged that the potter can, by pressure of his foot, bring the large end of one cone into contact with the small end of the other or vice-versa. Thus the speed of rotation is completely under control. In the disc wheel the power is applied to a large steel disc revolving in a vertical plane. Upon the shaft of the wheel is a small disc faced with leather and free to move up and down the shaft, but rotating with it. A treadle enables the workman to place this either at the centre or the edge of the large steel disc, thus securing any desired speed. The potter's wheel is fast disappearing. It is now used mainly for shaping blanks, which are afterward pressed into molds, or is employed by the makers of artistic pottery for the sake of the individuality of the work. Stoneware makers also use it for the production of large jars. See POTTERY, MANUFACTURE OF.

POTTERY (from the Latin *potum,* a pot); any article made with clay and fired. The origin of the formation of vessels from clay is lost in antiquity. It was the product of no one nation or people, but resulted from the necessity which arose for articles of domestic use when humankind emerged from savagery to barbarism and communal life was instituted. It required the aid of no metal tool; the fingers of the primitive potter were sufficient to fashion it. Its history cannot be related chronologically and the stages that mark its progress are few. First came the knowledge that clay could be formed into any desired shape and that it hardened by exposure, that this hardness could be materially increased by fire and then some genius discovered the potter's wheel. How long ago is unknown. The Chinese and Egyptians claim its invention and to the latter at least it was legendary, for they represent their god Ptâh as creating the egg of the world upon it. There is a long hiatus before another stage is reached, the production of porcelain by the Chinese early in the Ming dynasty (1368–1644). Followed the use of flint by Astbury (1720) and printing from copperplates (1752).

Ceramic authorities differ considerably in their classification of pottery but it may broadly be divided into three groups: (1) Porcelain — (a) hard or natural; (b) soft or artificial. White and translucent with a vitrified break and a glaze not easily scratched with a knife. Examples: Chinese, Japanese and European porcelains; European potters, unaware of the composition of Chinese porcelain, tried by the mixing of various materials to imitate it, the Medici porcelain (1574) being the first of which we have specimens. The only artificial porcelain to survive is the English bone china. The glaze, fired at a less heat than the body, is softer and more velvety than that of hard porcelain, the colors applied to it sink in the glaze and have not the applied look of those on hard porcelain. Examples: Early Sèvres, Capo di Monté, English bone china. (2) Bodies made wholly or partially from clay, opaque with a non-vitrified break. This includes (a) wares made entirely from clays in their natural state which are found sufficiently pure to use without levigation, which, owing to the presence of iron, manganese or other impurities, cannot be used for white wares and which are termed unwashed clays. Examples: Terra cotta, yellow ware and some ornamental wares where the color of the body is concealed by a glaze or engobe; (b) Faience; the body covered with an opaque (tin) enamel, decorated on either the raw or fired enamel. The term came into use when Italians of Faenza introduced its manufacture at Nevers in the 16th century. When its manufacture ceased toward the end of the 18th century and earthenware made on the English plan took its place, the use of the term ceased, the new body being termed *terre de pipe* or *faiences fines*. Examples: French pottery from 16th to 19th century; Delft, Alcora, etc.; (c) Mezza-majolica and majolica. The former had an engobe of white clay on its surface, the latter corresponded to faience except that it was enriched with metallic lustres. It is so termed because of the supposition that it was made on the island of Majorca, but this is disproved by M. Van de Put, who claims that the trade between Spain and Italy was conducted by Majorcan vessels and traders, the ware taking its name from this fact. Examples: Hispano-Moresque, Italian 15th and 16th centuries. The term is now erroneously applied to wares covered with one or more colored glazes which might be properly called such; (d) white and decorated household wares masquerading as Queensware, white granite, semi-porcelain, ironstone, etc. 3. Stoneware: Opaque with a vitrified break. Examples: Gres des Flandres, Höhr and Grenzhusen wares. Doulton's Lambeth ware. Before quitting the subject it may be well to consider what part clay forms in these divisions. The lowest content is that in English bone china which rarely exceeds 30 per cent; hard porcelain about 40; earthenware from 50 to 60 and stoneware from 70 to 80.

Buried in the dust of untold ages, specimens of the potter's art have and continue to be unearthed, telling us of civilizations before undreamed of. Assyria and Babylon, in the immense library of Nippon, formed of clay cones and tablets, reveal the history and most intimate details of their existence 7000 B.C. The bricks of Babylon were coated with a stanniferous enamel, the secret of which was lost for ages, to reappear in the 13th century when the Moors drove the Arabs out of Spain and established the kingdom of Granada. Egypt on her painted walls at Thebes, 4000 B.C., depicts the whole process of the art, including the use of the potter's wheel, which even then as already said must have been of great antiquity for they represent their god Ptah as fashioning the egg of the world on it. Glazes were early known to them, no less than seven colors being in use about 1500 B.C. The Greeks had obtained a certain technical excellence 2500 B.C. and later proved themselves magnificent potters. There is nothing finer in fictile art than their vases with friezes of figures, each one telling some story of mythology or of their warlike prowess, whilst the exquisite little Tanagra figures are distinguished by an inimitable grace. The art was at its best from 700 to 200 B.C. Much of this pottery which was unknown to Europe until the 18th century was found in Etruria and was for some time regarded as the product of that country, but Etruscan antedated the Greek period, dating from 1000 to 300 B.C., and though toward the close it was imitative of Greece it never equaled it. Etruscan civilization was merged in that of Rome, the natural successors of Greece, and the art was carried on by the Romans until the 1st century of our era. By them it was carried to Gaul, Italy and England and though never equaling that of Greece is distinguished by a black ware obtained by manipulation of the heat during firing and which when made by them in England later became known as Upchurch ware from the site of its manufacture; and by the beautiful Arrentine, or Samian ware as it is erroneously called, a red body, the composition of which has never been determined. Mesopotamia, Crete, Syria possessed a knowledge of lustres, a Rakka bowl bearing a date equivalent to about 790 A.D. though probably later. Persian pottery exerted a far-reaching influence. Their Arab conquerors were not in themselves an artistic race but fascinated by the beauty of the Persian style they largely adopted it and with the modifications demanded by their religion it is known as Saracenic art, the Arabs being known as Saracens during the Crusades. Probably much of the work ascribed to the Arabs was executed for them by Persian workmen. To Persia we are indebted for the beautiful *reflets metalliques,* which possibly may have been the Murrhine vases, those priceless treasures of

Rome of which no positive trace remains. These beautiful lustres made their reappearance during the Renaissance, the secret of manufacture again disappearing until rediscovered in the 19th century.

Before telling how the art was carried into Europe by the Moors another civilization, that of the Orient, demands notice. The Chinese, those indefatigable workers, the acknowledged past masters of the ceramic art, claim an antiquity equal to that of Egypt which until very recent times was not verified by actual specimens, but examples are now appearing lending color to their claims. These examples differ little from those of other countries. The Han dynasty, 206 B.C.–220 A.D., furnishes examples of glazed pottery and from that time progress must have been rapid. Unlike European, Chinese civilization had not halted and the T'ang period, 618–906 A.D., was remarkable for the development of the ceramic and kindred arts. Even life size figures in pottery were made and which European potters a thousand years later considered a great achievement. The pottery of the Sung dynasty, 960–1280 A.D., had disappeared and became legendary in the 16th century, the Ch'ai and Ju wares made famous by Chinese writers. The period marked the introduction of kaolin in the body, not as yet a true porcelain but perhaps best described as a porcellaneous stoneware. It was then that pieces of alternate colors of clay were made, the prototype of the agate ware of Whieldon, Wedgwood and other English potters of the 18th century. We are but just beginning to emulate their elusive *flambé* glazes, the crackled ware and the wonderful colors such as *sang de bœuf* produced by a reducing fire. With their characteristic reverence for age the Chinese have always delighted in reproducing their own past triumphs and so skilfully has this been done that there are but few who may reasonably be classed as experts who can distinguish the difference. The beautiful celadons are also of the period and were the forerunners of true porcelain which was probably produced early in the Ming dynasty, 1368–1644. (See PORCELAIN). While the wares we have but hinted at continued to be produced, they were largely overshadowed by the new body. The great centre of production has since the 7th century been the town of Ching-tê-Chen and in spite of its having been several times destroyed, has always phœnix-like risen from its ashes. The Japanese learned much from the Chinese, as also they did from the Koreans who were responsible for the establishment of the industry at Karatsu (Hizen) end of the 7th century; Satsuma 1457–86; the Raku factories at Kioto 1550; Seto 1590, and later at Haji. It is difficult to understand the Japanese preference for these Korean wares, which in no wise excelled their own productions except for some supposed superiority for use at their tea ceremonies. What merits Satsuma wares possess is due not to Korean but to Japanese influence, the art instinct being prompted by the work of the Chinese, whom they soon began to rival. Practically no good pottery was made in Japan until Kato Shirozayemon, called Toshiro, finished his five years' studies in China and came to Seto in 1200. Porcelain was not made until about 1513. Having obtained mastery of the art it spread all over the kingdom and was patronized and encouraged by emperors, princes and potentates. Two distinct styles are apparent, that made for use at home and that intended for export. The so-called old Japan, imitated and copied by nearly every manufacturer in Europe, is an example of the latter. Japanese pottery is largely the work of an individual or at least of a family, while Chinese is the result of combined workmanship. This individual work of recent years has been largely superseded by that of factories which to the great debasement of the national art have been induced to copy European designs with a result, with the single exception of price, disappointing and regretable. There remains, however, a number of artist potters who refuse to prostitute their talents, such as Miyagawa, Kozan, Seifer, Sobei, Watano and others. Even this glimpse of Japanese ceramics would be incomplete without reference to the great Imari artist Kakiyemon whose isolated designs on a white ground inspired the beautiful productions of present day Copenhagen porcelain and to whom many of the early European factories were largely indebted.

African pottery was made at Bagdad in the 9th century and at Cairo in the 11th, the Moors having obtained their knowledge from the Arabs, largely adopting the style of the Saracenic potters. In the 8th century the Arabs conquered Spain but no ceramic specimens definitely assigned to them at this period are known. Five hundred years later, 1235 A.D., the Arabs were driven out of Spain by the Moors and the wares known as Hispano-Moresque began to appear, the most notable example being the Alhambra vase made about 1230 The production continued until the 15th century, though its Moorish characteristics were gradually disappearing through coming into contact with Christian art, the late examples consisting of decorations of mock Arabic characters, with borders and diapers of leaves, principally of the vine and briony. The Moors had found in Spain a plentiful supply of tin and abandoned the calcarous covering they had hitherto employed in favor of a tin enamel and which they enriched with brilliant lustres. As the wares lost their Moorish character, so the application of the lustre changed until finally it degenerated into a ruddy copper. Much of this pottery found its way into Italy and it is probable that a Moorish potter gave assistance to Lucca della Robbia who in 1440 produced the first white enamel made in Italy. This led the way to those later triumphs in Italian ceramics which culminated in the period 1470 to 1530, a period remarkable for its awakening from the oblivion of centuries and one of the most splendid epochs of the ceramic art. The painter had recognized in della Robbia's invention a material on which his art could be preserved for all time and loyally backed by the reigning houses, the princes of Urbino, of Pesaro and Florence, the Sforza, the Montefeltros, the Medici and the Fontanas, he found the opportunity to express himself. These artist potters were the heroes of the moment; they were created maestros, entitling them to rank with princes. Never was an art so honored, so worthily expressed, and from the great centres at Castel-Durante, Urbino, Faenza, Gubbio and many other places there was a constant producing stream. This

Italian majolica was practically an art expression confined to placques, vases, etc., and was not applied to utilitarian articles if we except the drug pots of the period. That came later when Italian workmen carried the art to France and in 1578 when the Nevers works were started. Except for the use of the tin enamel it had nothing in common with Italian majolica and in the early part of the 18th century had so degenerated as to become grotesque. Nevers pottery is important only on account of its extent. Toward the middle of the 17th century Rouen came into prominence and in the early part of the 18th century potteries had become very numerous. Several distinct styles of decoration were introduced, owing nothing to foreign influence, and the industry received an impetus which extended all over France, some of the principal places being Moustiers, Marseilles, Lille, Strassburg and Bordeaux, and literally hundreds of other places had their small potteries. The most original of those mentioned was Moustiers; for the rest they relied for inspiration on the parent factories — Rouen stands pre-eminent, the faience produced there being characterized by the loftiest art ideals, combined with perfect workmanship. Another important pottery centre owing its influence to the Normandy potteries was at Alcora in Spain, which was of great extent, but which seems to have been somewhat neglected by ceramic writers. Delft in Holland came suddenly into life at the commencement of the 17th century and a tremendous trade was built up. Some English potters are known to have worked there, but the inspiration was no doubt Italian, for as early as 1560 Peccol Passo of Urbino had established at Antwerp a pottery for making Italian majolica so that the use of the tin enamel would be known to the Low Country potters. The manufacture of white ware in England, its superiority for use and durability and in the case of France the lowering of the duties on its importation, brought the manufacture of faience to a close. Recent years have seen the reproduction of much of the faience of the 17th and 18th centuries, their incontestable artistic merit being highly valued by refined connoisseurs.

After the collapse of the faience industry the manufacture of earthenware on the English plan was introduced. Many English potters assisting in perfecting it. The principal factories were Choisy-le-Roi, Creil, Montereau, Chantilly and Sarreguemines. Ware of good quality was made for a time but gradually deteriorated and the industry faced extinction, but was rescued by a scientist, M de St. Amans, who with the assistance of Brongniart succeeded in again placing it on a sound basis. About the middle of the 19th century there was a remarkable art revival as applied to ceramics which has practically revolutionized the pottery of France. The stoneware of Claude Louis Ziégler (1840–54), so pure in form and decoration, was perhaps the first evidence, followed by the remarkable reproductions of Palissy ware by Charles Avisseau of Tours (1842), his example being followed by Barbezet (1850) and Pull (1855), both of Paris. From 1854 to 1871 Sèvres took the lead and a great impetus was given to the movement. In 1859 Theodore Deck, the greatest of French ceramists, demonstrated that the secrets of the Orient were secrets no longer and he appeared to be able to duplicate at will the lustres of the Persians, the celadons of the Chinese, the intricacy of Hispano-Moresque or the inlaid work of Oiron. Still more recently an apparent army of artist potters have given expression to their ideals in grès, the royal factory assisting in the movement and restoring France to the position she seemed in danger of losing. No account of French pottery would be complete without reference to the work of Bernard Palissy and the faience of Oiron, though neither appears to have exerted any influence on French ceramics — Faience d'Oiron was made under the direction of Hélène de Hangest by her librarian, Jehan Bernart, and François Charpentier and consisted mostly of small pieces, the decoration formed by inlaying different colored clays. The work was executed in a marvelous manner, so well, indeed, that for centuries it was impossible to reproduce it; and owing to many of the late pieces bearing the monogram of the Dauphin (Henry II) it was long known as Henry deux ware. Its manufacture extended from 1524 to the middle of the century but the late period is much inferior to the early one. Some 50 or 60 specimens are known, each worth more than its weight in gold. Bernard Palissy, a land surveyor, a glassmaker, a portrait painter, but poor withal, became obsessed with the idea of discovering the art of making enamel. Against difficulties and privations, disappointments without number, he struggled against a fate which threatened to overwhelm him, continuing his experiments for over 16 years, until at last success rewarded him and the secret of the enamel was discovered. The time of his triumph was also one of the greatest despair, for reduced to absolute penury, his credit exhausted, reviled by his neighbors as a madman, he could not procure fuel to finish the firing of his kiln and in a frenzy tore down the doors of his house, broke up and fed to the flames what little furniture was left him in the house, his mad act rewarded at last by success. He died in 1589.

In England tin enamel never seems to have obtained much popularity. No pottery worthy of record with the exception of the Encaustic tiles made by religious orders in the 14th and 15th centuries occurs until the awakening of the Staffordshire potters in the 18th century. We are not forgetting the quaint slip-painted wares of Wrotham and Staffordshire which were but the expression of the rude art of the old English potter who had no materials beyond his clay to work with, but rude as that art was it is the prototype of the most difficult and most beautiful ware of the end of last century, pâte-sur-pâte.

The advent of Elers who came to England in the train of William of Orange and had a small pottery at Bradwell Wood prior to 1698 is generally spoken of as the beginning of Staffordshire pottery, but as before his arrival there John Philip Elers is known to have been in litigation with some of these Staffordshire potters for infringing his rights there appeared at least to be an awakening for something better than the rude butter pots of their forefathers. Certainly Elers by his refined processes stimulated competition; and when his carefully guarded secrets had been mastered by Astbury and Twyford and by them freely communicated

to their brother potters, the establishment of an important industry was laid. Whether the Elers introduced salt glazing in England is a moot point, but the process became prevalent at this period. Unlike the *gres de Flandres* it was extremely light in weight, much of it was beautifully designed and although the glaze was soft and scratched easily it made excellent tableware. Not content with the successes achieved the Staffordshire potter was but spurred on to further effort. New clays were searched for and tested in an endeavor to produce a white body and when in 1720 Astbury discovered the invaluable use of flint, the end was practically obtained. It gives both strength and whiteness, the two qualities hitherto lacking. Other discoveries rapidly followed but it was given to one man, Josiah Wedgwood, whose forbears had played no unimportant part as pioneers, to systematize and turn into a manufacture. Much had been done already. Whieldon (1740–98) had greatly improved the body; Dr. Thomas Wedgwood (1731) had invented the agate ware; Booth (1750) introduced the dipping of ware in glaze held in suspension in water; plaster molds had superseded pitcher and brass ones and others had added their quota. Wedgwood (1730–95) organized and systematized all that had gone before; he labored assiduously to improve all existing processes as well as communications with the outside world which were in a deplorable state and in doing so not only enriched himself, but benefited the community at large. He invented a new body employing a material hitherto unused in pottery, barytes, and which he called jasper. In this body he produced a series of vases ornamented with classical designs for which at the time there was a great vogue and which generally are regarded as his greatest work. These designs made by the best artists obtainable were made in white clay in slight relief in molds and afterward applied on the colored jasper. They are marvels of skilled workmanship. From this time English earthenware has steadily advanced, such men as Spode, Minton, Davenport, Ridgway, Adams and a host of others worthily maintaining its prestige. With the exception of Davenport the descendants of these men are still in business and to them must be added the name of Doulton who first as a manufacturer of stoneware at Lambeth and later at Burslem shares honors with the older firms. Whilst «The Potteries,» the five towns of Arnold Bennett, Stoke, Burslem, Hanley, Tunstall and Longton, were the centre of production the manufacture generally extends all over the country, Liverpool and Leeds, which formerly produced extensively, are now extinct. In the United States nothing beyond spasmodic attempts had been made until the middle of the 19th century Taylor and Speeler starting to make white ware at Trenton in 1855 resulting in the establishment of a pottery centre there. At East Liverpool from 1840, yellow and Rockingham wares were extensively made and in 1872 Knowles, Taylor and Knowles commenced making white wares, many other manufacturers following their lead. The use of natural gas as a cheap fuel and other causes has centred the pottery industry to the detriment of Trenton, and potteries have cropped up in the surrounding neighborhood. Probably the largest in the world, Laughlins, is situated at Newall, W. Va., on the opposite side of the Ohio. Up to 1876 practically nothing but white ware was produced and that of a mediocre character, but of late years a decided change for the better has taken place and we now successfully compete with the products of the Old World. There is, it is true, a certain family resemblance in all makes owing to the extensive use of decalcomanies which of necessity are procured from sources open to all. By and by American manufacturers will recognize the value of originality and individuality and perhaps evolve a distinct American style. Mention must be made of the so-called hotel ware, a hard durable body possessing the best qualities of both porcelain and earthenware, first made by the Greenwood Pottery Company, Trenton, in 1863 and now extensively made by many firms. In art pottery the name Rookwood inevitably suggests itself. Born in the brain of a woman, Mrs Bellamy Storer, in 1880, it has been praised by critics the world over and it at its inception was worthy of such. Present-day Rookwood is much more so for it is dominated by a loftier art ideal. The naturalistic style of painting has given place largely to a more conventional one and the whole has become more ceramic. The Grueby pottery at Boston was responsible for some of the most artistic pottery conceivable, the restraint in ornament, the beauty of the matt glaze being beyond criticism. The manufacture is now principally confined to tiles. These are the only two art potteries in America, but the women have largely made up any deficiency, the pupils of the Sophie Newcombe College, New Orleans, producing wares almost on a commercial scale, so well designed and executed as to undoubtedly place them in the first rank. At Zanesville, Ohio, a large quantity of ornamented pottery is made, the best of which is the multi-colored glazes of the Roseville Pottery Company, extraordinary in the beauty of their color and challenging comparison with some of the best examples of Oriental art. Mention must also be made of the slip wares of the Pennsylvania Dutch of the last half of the 18th century; crudely conceived and executed but interesting for its individuality.

South America did not fail to contribute its quota, the truly remarkable pottery of Peru showing a civilization at a time so remote that it is doubtful whether it was the work of the Chinese or some older race of which we have no knowledge. In the 16th century Peru and other countries were sending to Portugal pottery impregnated with a delicate perfume which became known as Noble Buccaros and about which many fantastic properties were invented, among others that if ground up and eaten it was a sure cure for all ills. An English firm claims to be able to reproduce them but no specimens have come under our notice.

Germany has always been noted for its stoneware, much of the *gres de Flandres* being made there, gaining its name from the fact that it was shipped from Flemish ports. The Hirschvogels of Nuremberg, the numberless potters of Höhr and Grenzhusen were pioneers in the work and modern firms with added knowledge have continued the work. Ceramic literature is of a most voluminous character and only a few works can be indicated which will serve as an introduction to more intensive reading. Consult for Egyptian, South Kensington and Bristol Museum Catalogs; *Greek*, Walters, 'History of Ancient Pottery'; *Hispano-Moresque*, Van de Puts, 'Hispano-Moresque Ware of the 15th Century'; *Italian*, Fortnums, 'Majolica' and other works by the same author; *French*, Gasnault and Garniers; 'French Pottery'; *English*, Llewellyn Jewett, 'Ceramic Art in Great Britain'; M. L. WILLIAM P. JERVIS,
Author of 'The Pottery Marks of the World,' etc.

POTTERY, Manufacture of. Clay in itself is not sufficient to make good pottery. The materials used for mixing with it are flint; Cornish stone and feldspar. The first process is to reduce all these materials to a common fineness by means of grinding and levigation. These in their proper proportions are mixed with water, the resultant liquid mass being known as slip. If plastic clay is required the slip is pumped into a clay press. The press consists of a number of what are termed chambers lined with very heavy cloth into which the slip is forced, pressure is brought to bear on them and the water expelled, leaving the clay mass inside the cloth or «bags.» The presses are then opened, the clay taken from the bags, but as it may not all be of exactly the same consistency a further process is necessary. This was formerly done by cutting off pieces with a wire and dashing it down on another piece until the whole was of the same density and moisture, and was known as wedging. This is now done by the pug mill, a cylinder down which runs an axle to which are attached blades of iron set at such an angle that they not only cut the clay but force it forward at the same time until it comes out at the bottom in a solid block about 6 × 4 inches. It is now in a plastic state ready for either the thrower or the presser. Throwing is perhaps the most fascinating operation in all the industrial arts. Taking a ball of clay the thrower throws it on a revolving horizontal wheel and grasps it on the side with hands held rigid, which forces the clay to the exact centre. He then with an upward pressure raises it into a cone and when this has been repeated once or twice inserts his thumb in the top to make the aperture, and according to the shape required so guides and gently forces the clay to the proper contour entirely by the use of his fingers. Watching a skilled workman, the clay appears as if imbued with life, obedient to his slightest wish or thought. There is, however, a good deal of nonsense talked about the expression of the thrower's individuality, and whilst this may be true of the few craftsmen who have mastered the process, it is ridiculous as applied to commercial wares, for when the individual work of the thrower is finished it is passed on to the turner, who places it on a horizontal lathe and turns out all the marks of the potter's thumb and fingers until it assumes the exact size and shape required, no better and no worse than if it had come out of the mold. The process is very little employed to-day. For the presser much preliminary work must be done. An artist must design a shape, a model of it must be made and from this model must be made the molds, so constructed that the different parts of them lift cleanly away from the clay inside. Taking these molds, the parts held firmly together with a strap, the presser lines them with bats of clay, which he presses firmly down and then sponges the inside to make it smooth. Evaporation causes the clay to harden and the particles to shrink more closely together, and the piece can then be removed from the mold. If it requires a handle it is passed to the handler who presses the handles from molds and then with a little water or slip adjusts them to their proper place. Plates, saucers, etc., are made by machinery, but the principal is the same, the molds being fixed on a revolving disc, which greatly facilitates the work. The ware is now in the «green» state, and when thoroughly dry is ready for the first firing, after undergoing which it is called biscuit ware, the first form of pottery. If instead of the plastic clay slip is used it is poured into a plaster mold, which being made somewhat softer absorbs some of the water, the clay particles floating to the side. The mold is kept full of slip until the requisite thickness is attained, the surplus slip is emptied out and the mold put away until the piece frees itself by shrinkage. All mold-made pieces require fettling, that is, the mold marks are removed with a knife or sponge. Biscuit ware can be decorated either by painting with a brush or by printing. The former enables the artist to express himself just as on canvass, except that his colors will be absolutely permanent. For printing, the design is engraved on a copper plate; an impression on thin paper is obtained from this and transferred to the ware, the paper being afterward washed off. In both cases the colors are mixed with oil, and to remove this the ware is fired in the «hardening on» kiln before the glaze is applied. Biscuit ware may also be dipped in a plain or colored glaze, which simply requires the «glost» fire to complete. The glazing is done by immersion in a tub of glaze, the dipper holding the piece with the least possible contact with his finger and quickly and dexterously plunges it in the glaze, which covers it all over with a thin film. It is now ready for its final firing. In the biscuit kiln it is immaterial whether one piece touches another, but this would be fatal to glazed pieces, which are separated by means of separators called stilts, spurs, pins, etc., according to how they are used and which are easily removed when the firing is finished. A biscuit kiln will hold from 1,500 to 2,000 dozens of ware and takes from 45 to 50 hours to cool. A glost kiln does not take so long, the clay ware requiring a greater heat than the glaze. If the biscuit ware has been glazed and fired it can be decorated in a number of ways, either by painting with the brush, by applying decalcomanies or by printing. The colors used in this case are heavily fluxed and only require a fire of about 8 to 10 hours. The average Centigrade heat for biscuit ware is 1,270°, for the glaze 1,210° and for decorations on the glaze 840°. The heat conditions in the kiln were formerly determined by the color and the withdrawal of certain trials, but small triangular cones made to melt from the lowest to the highest heat are placed in the kiln within view of the fireman and when the heat they represent is reached they bend and melt, showing that the firing is finished.

William P. Jervis,
Author of 'The Pottery Marks of the World,' etc.

POTTSTOWN, Pa., borough, Montgomery County, on the Schuylkill River, and on the Pennsylvania and Philadelphia and Reading railroads, 40 miles northwest of Philadelphia. It was laid out as a town in 1752 and was at first named Pottsgrove, after its founder, John Potts; in 1815 it was incorporated as a borough and renamed Pottstown; the boundaries of the borough were increased in 1888. It is the trade centre of a fertile agricultural region. The immediate vicinity possesses considerable mineral wealth and as a result Pottstown has grown to be o. importance as an industrial centre. Though at the time of the last United States census Pottstown was only 39th in size amongst the cities of Pennsylvania, it was 18th in volume of products manufactured in its 78 industrial establishments. The total value of these products in 1909 amounted to $12,205,000, an increase of 68 per cent since 1899. The capital invested in these industrial establishments was almost $10,000,000, and the number of persons engaged in industrial pursuits was 4,123, more than 25 per cent of its total population. The borough is especially noted for its manufactures of iron and steel; it contains rolling mills, blast furnaces, steel mills, bridge works, boiler works, nail factories and manufactories of agricultural implements; also cigar factories, carriage works, planing mills and creameries. It has a public high school and library as well as a number of private educational institutions, the best known of which is High School, a non-sectarian secondary school for boys. Pop. 15,599.

POTTSVILLE, Pa., borough, county-seat of Schuylkill County, on the Schuylkill River, near its source, and on the Pennsylvania, the Lehigh Valley, the Philadelphia and Reading and the Central of New Jersey railroads, 95 miles northwest of Philadelphia. It was first settled in 1800, incorporated in 1828 and made the county-seat in 1851. It is situated among the Schuylkill anthracite coal fields and is one of the most important mining centres and shipping points of the region. Its manufacturing interests are also of considerable importance. The total value of products manufactured in 1909 in its 91 industrial establishments amounted to $9,138,000, an increase of 99 per cent since 1899. The capital invested was $13,982,000, and the number of persons employed 3,342, 16 per cent of the total population. Its industrial establishments include steel mills, blast furnaces, rolling mills, foundries, planing mills, cotton-velvet and silk mills. It was in Pottsville that anthracite coal was first successfully used in smelting iron ore. Among its more important buildings are the county courthouse and jail, a public hospital and the Pottsville Athenæum. The latter contains a library and the borough also has a public library as well as the county law library. There are a public high school, public and parish graded schools and some private educational institutions. The chief executive officer of the borough is a burgess, elected for three years; the legislative body is a borough council, possessing the power of appointing many of the city officers; the city auditor, city treasurer and the school directors, however, are elected by the people. Pop. 20,236.

POTTSVILLE CONGLOMERATE, the name by which the Millstone-Grit at the base of the Pennsylvania series (coal measures) is generally known in Pennsylvania, because it has its greatest development at Pottsville, near the eastern edge of the anthracite fields. It is there more than a thousand feet thick, but toward the west and north grows thinner. The rock is composed of sand and pebbles, chiefly of quartz, giving it considerable hardness.

POTVIN, pō-văṅ, **Charles**, Belgian author: b. Mons, Belgium, 2 Dec. 1818; d. Ixelles, 1 March 1902. He was educated at the Catholic University at Louvain, became professor of national literature at Brussels, in 1883 conservator of the Wiertz Museum there, and in 1881 a member of the Belgian Academy. He was editor of *La Nation* in 1850–53, and in 1862 became editor of the *Revue de Belgique*. For many years he was the recognized leader of the Liberal party in Brussels. His writings comprise volumes of verse, history, political philosophy and criticism, including 'L'Eglise et la morale' (1858, under the pseudonym Dom Jacobus); 'Le Roman de Renard' (1860); 'Marbres antiques et crayons modernes' (1862); 'Jacques d'Artevelde' (1861); 'L'Histoire des lettres en Belgique' (1882); and 'L'Art Grec' (1895).

POUCHED DOG. See Dasyure.

POUGHKEEPSIE, po-kip'si, N. Y., city and county-seat of Dutchess County, on the eastern bank of the Hudson River, 72 miles north of New York, midway between the Highlands and the Catskills, and on the New York Central and Hudson River and the Central New England railroads. A ferry connects it with the West Shore Railroad. A cantilever bridge carries the Central New England lines across to the west bank of the river. Poughkeepsie has an elevation of 200 feet and a mean annual temperature of 50°. The city is the seat of Vassar College (q.v.), of Glen Eden Seminary, Putnam Hall, Eastman Business College, Adriance Memorial Library, containing over 40,000 volumes, the Hudson River State Hospital for the Insane, Vassar Brothers' Institute, Vassar Brothers' and Saint Francis hospitals, Pringle Home, Columbus Institute and Riverview Military Academy. College Hill Park has an area of 100 acres and is finely situated, commanding a magnificent view of the Hudson. The Intercollegiate regatta is an annual event in June. There are four national banks, one trust company and one savings bank, with total resources of $30,000,000. There is also an active Chamber of Commerce of 822 members and having an annual income of over $22,000. The assessed value of property subject to taxation is as follows: Real property, $24,844,845; personal property, $956,650; special franchise, $1,387,680;

shares of bank stock, $1,573,047. The city's funded debt is $2,135,000. The total tax rate is $25.97 per $1,000 valuation. There are 55 lines of manufacture in the city with products having an estimated total value of $15,000,000 and employing over 5,000 people. There are, all told, 176 establishments, employing 5,580 persons; of the latter 147 are proprietors and firm members, 704 are salaried employees and 4,729 are wage-earners. The capital invested aggregates $13,935,000; wages, $2,284,000; salaries, $1,039,000. The cost of materials used aggregates $6,115,000, and the value added by manufacture, $6,676,000. The chief manufactures are mill supplies, underwear, trousers, cigars, candied fruits and preserves, cream separators, foundries, knitgoods, celluloid articles, skirts, infants' garments, ball bearings, auto specialties, children's dresses, machine-shop products, linen and cotton mesh, shoes, ivory buttons, piano and organ players, dyes, etc. In September 1917 the average wage of 44 concerns employing men in Poughkeepsie was $16.01, and the 25 concerns employing women $9.90 per week. There are 11 grade schools with 5,500 pupils, five parochial schools, a $250,000 high school with 1,100 students. About $150,000 represents the municipal annual outlay on education. Poughkeepsie has steamer connection with Albany, New York and other Hudson River points. It is also a terminal point on the State canal system. What is now termed the city of Poughkeepsie dates far back of definite records. Its name is found in an Indian deed of date 5 May 1683, granting to Pieter Lamsingh and Jan Smeedes each a farm, and to the latter also a waterfall near the eastern bank of the Hudson, to build a mill thereon. The waterfall is called *Peoghkepesingh* («the place where the water breaks through»). A Dutch settlement sprang up about 1698, and during the Revolutionary War the place was a base for the Continental armies. In 1778 it became the State capital and in 1788 the Federal Constitution was ratified at a State convention held here. In 1799 it was incorporated and in 1854 was chartered as a city. The present charter was granted in 1874. Under it the people elect a mayor, a common council of 14 members and an alderman-at-large, who is president of the council. Pop. 32,000. Consult Platt, E., 'Eagle's History of Poughkeepsie' (Poughkeepsie 1905).

POULSON, pōl'sŏn, **Niels,** Danish-American architect, ironmaster anl philanthropist: b. Horsens, Denmark, 1843; d. 3 May 1911. He studied architecture and building at Copenhagen and came to the United States in 1864. He was for two years employed in the United States government supervising architects' office at Washington and afterward was in charge of the architectural and engineering departments of the New York Architectural Iron Works. He engaged in business in partnership with C. M. Eger in 1876, the firm being incorporated as the Hecla Iron Works, New York, in 1897. Poulson was an active promoter of the welfare of his employees, a free technical school was established by the company and many of the men were enabled to establish themselves in business. He was also desirous of a closer understanding between the United States and Scandinavian countries and in 1910 gave $100,000 to be expended in an exchange of lecturers and students. His fortune, amounting to about $500,000, was left to the same cause and resulted in the establishment of the American-Scandinavian Foundation and the American-Scandinavian Society. Scholarships for Scandinavian students were established at Harvard, Yale, Columbia and the Massachusetts Institute of Technology; while those for American students were at Christiania, Copenhagen and Upsala.

POULTNEY, pōlt'nĭ, Vt., town, Rutland County, on the Poultney River and Lake Saint Catherine and on the Delaware and Hudson Railroad, 18 miles southwest of Rutland. It is in an agricultural region; slate is quarried in the town and vicinity and there are slate manufactures, a foundry and machine shops. It is situated in a picturesque country in the Green Mountains and the lake affords facilities for boating and fishing; consequently the town has become popular as a summer resort and contains several hotels. It has a public high school and is also the seat of the Troy Conference (Methodist) Academy. Pop. 3,644.

POULTON, Edward Bagnall, English scientist: b. Reading, Berkshire, 27 Jan. 1856. He was educated at Oxford and was demonstrator in the anatomical department of the University Museum 1877–79, and lecturer in natural science at Keble College 1880–89, as well as at Jesus College 1880–89. In 1889 he became a Fellow of the Royal Society and since 1893 has been Hope professor of zoology at Oxford. He was vice-president of the Royal Society 1909–10, president of the Linnæan Society of London 1912–16 and is a member or correspondent of many scientific societies. He delivered a course of lectures before the Lowell Institute, Boston, Mass., in 1894 on 'The Meaning and Use of Colors in Animals.' He is the author of 'The Colors of Animals' (1890); 'Charles Darwin on the Theory of Natural Selection' (1896); 'Essays on Evolution' (1908); 'Charles Darwin and the Origin of Species' (1909); 'Viriamu Jones and other Oxford Memories' (1911); 'Hope Reports' (Vols. I–IX, 1897–1913), etc.

POULTRY. A term designating collectively all birds which have been domesticated for their flesh, eggs or feathers, for fighting or for pets, including fowls, ducks, geese, swans, turkeys, guineas, peacocks and pigeons. The word «fowl» once included wild game birds but now applies only to the domesticated fowl (*gallus domesticus*) and does not properly include turkeys, guineas or pheasants which belong to a similar genus (*Phasianus*) which are now kept in semi-captivity and are only partially domesticated.

Origin.— The common fowl which makes up the largest class of domestic poultry is supposed to have originated in southwestern Asia. Darwin believed all domestic fowl to have sprung from a single species, the wild jungle fowl (*gallus bankiva*) which still is found in the jungles of India in the wild state. His belief was founded upon the fact that *gallus bankiva* closely resembled the common Black Breasted Red Game of to-day, one of the oldest varieties of domestic fowl known; that it crosses readily with the common hen, producing fertile offspring; that it resembles the domestic fowl

in voice and action; that it is readily domesticated and that according to his observations it produced sterile offspring when crossed with other species of wild fowl and that sterile offspring resulted when other wild species were crossed with domestic fowl. On the latter two points it is believed that Darwin was in error and that many varieties of common fowl have descended from several wild species and their crosses. In support of the belief it is known that several domestic varieties bear a much closer resemblance to other wild species than do *gallus bankiva*. The Oriental games, for example, resemble *gallus giganteus* much more closely than they do *gallus bankiva;* indeed, the *gallus giganteus* kept in domestication by the natives of the Malay Peninsula at the present time are so like the Malay breed of our domestic fowl that they might be considered the same. Among the wild fowl now in existence which may have contributed largely or in slight degree to the foundation of the common fowl are *gallus bankiva* or (*gallus ferrugineus*) from southern India only; *gallus sonneratii,* found in Hindustan; *gallus fercatus* from Java; *gallus stanleyi* from Ceylon; *gallus giganteus,* the Kulm fowl of the Malay peninsula, and others not so well known.

The principal characteristics of the domestic fowl are as follows: Beak, heavy; gullet enlarged to form a crop; small stomach; gizzard strong to crush hard seed; two long sæca; body temperature 105 to 106, varying slightly according to temperature of the environment; feet adapted to scratching, running and perching; wings not suited to long flight; gregarious; polygamous; domestic in the extreme; prolific; period of incubation 21 days; young covered with down and able to run about as soon as hatched; brave in defense; flesh and eggs prized as human food.

History.— Fowls are the oldest of our domesticated animals so far as history records. The earliest record is to be found in a Chinese encyclopedia compiled from ancient documents, where it says "fowls are creatures of the west." Fowls were introduced into China 1,400 years B.C. and the Chinese considered the Indian region as their source. They were also mentioned by Aristophanes between 400 and 500 B.C., and it is said are figured on Babylonian cylinders between the 6th and 7th centuries B.C. Mention of fowls is also made in the writings of the Greek and Roman authors Theognis, Aristotle, Diodorus, Æschylus, Plutarch, Plato and Pliny, and are supposed to have been taken into the British Isles by the Romans, who regarded them as sacred to Mars. The cock has in all ages occupied an exalted position as an emblem, symbolizing courage among the ancient Gauls and afterward among the French, who used it on their ensign after the Revolution. It figures also in the Bible and has been used in Christian art to symbolize the Resurrection. At the present day it is regarded by political parties as a herald of victory.

Extent and Importance of the Poultry Industry.— Poultry husbandry is an old art and a comparatively new science for it is only within the present century that special attention has been given to raising poultry as a commercial enterprise and only within the past generation has any real effort been made to classify the information on the subject into anything like a science. The explanation of this recent advance may be found, first, in the fact that this class of domestic animals supplies human food that is second only in importance and value to dairy products. The egg offers the most digestible form of meat known and one which can be cooked in the greatest number of attractive ways, and the flesh forms an article of diet universally prized for its attractive flavor, which is distinctly different with each kind of poultry. In addition to and perhaps of greater importance than the nutritive value of eggs is the vitamine value which eggs possess in large degree and which are essential to growth. The fact that eggs contain all of the nutritive qualities and also the life-giving vitamine principle complete and in proper proportions to sustain the developing embryo chick makes the egg superior even to milk in sustaining human life. The second reason is found in the fact that poultry, particularly fowls and pigeons, are variable and plastic in the hands of the breeder and can be rapidly and skilfully made to acquire new forms and colors. In no branch of animal husbandry have so striking results been accomplished as in poultry breeding. Observe the large number of varieties at the present time and note the contrast between the mammoth Brahma, weighing 12 pounds, and the diminutive bantam of the same name, weighing 20 ounces; the brilliantly spangled Hamburg and the sombre Orpington; the long tail of the Yokohama and the inconspicuous, cushion tail of the Cochin; the clean, close feathering of the Indian game and the abundant, fluffy feathering of the Asiatics; the smooth shanks of the Plymouth Rock and the feathered shanks of the Langshan; the great prolificacy of the sprightly Leghorn and the large, solid muscle of the unproductive, clumsy Indian Game. Also note the great variety of plumage, both in color, color pattern and form of feather in the different breeds and varieties of the domestic fowl. For example, the spangled, laced, penciled, striped barred pattern and the solid-colored feather, including red, buff, black, white and blue; and in feather forms — ragged in the Frizzles and downy in the Silky; varieties of fowls with eyes varying in color from black to pearl, bay or gray; fowls with rose combs, leaf combs, single or pea combs, spike combs; fowls with or without beards and crests and showing in their plumage every color of the spectrum.

Equal in variability to the domestic fowl is the pigeon with its vastly different types of colors, sizes, shapes and physical characteristics. Then realize that all of these have been produced within the history of man; in the case of the fowl from a single or, at most, a few wild species of jungle fowl, and in the case of pigeons, from the single rock pigeon; moreover, domestic fowls, including several hundred varieties, breed reasonably true.

Poultry Statistics 1910 and 1900 in the United States.— The tables on following page give the number of the various kinds of poultry reported in 1910 and 1900, together with their value, and the number of farms reporting each kind in 1910; the number and value of poultry by States, value of products, etc.

POULTRY STATISTICS 1910 AND 1900

KIND	1910 (April 15)				1900 (June 1)
	Farms reporting		Number of fowls	Value	Number of fowls
	Number	Per cent of all farms			
Total	5,585,012	88.1	295,876,176	$153,394,142	250,623,354
Chickens	5,577,218	88.0	280,340,643	140,192,912	233,566,021
Turkeys	852,679	13.4	3,688,688	6,605,640	6,594,695
Ducks	503,673	7.9	2,904,359	1,566,176	4,785,850
Geese	661,189	10.4	4,431,623	3,192,861	5,676,788
Guinea fowls	339,922	5.4	1,765,033	613,282	(1)
Pigeons	99,409	1.6	2,730,996	762,372	(2)
All other [3]	2,005	(3)	14,834	460,899	(2)

1 Included with chickens. 2 Not reported. 3 Less than one-tenth of 1 per cent.

The summary on poultry shows that the total number of farms reporting the different kinds in 1910 was 5,585,012, the total number of fowls being 295,876,176, and the total value $153,394,000. Of the total number of farms reporting, nearly all, or 5,577,218, reported chickens, numbering 280,340,643, valued at $140,193,000. The number of farms in the United States reporting poultry increased 489,732, or 9.6 per cent, during the decade. The total number of fowls increased 18.1 per cent; while the relative increase in their value was considerably over four times as great, amounting to 78.9 per cent. The average number of fowls per farm reporting increased from 49 to 53.

POULTRY STATISTICS FROM THE CENSUS REPORT 1910, UNITED STATES.

Number Poultry by States.

1.	Iowa	23,482,880
2.	Illinois	21,409,835
3.	Missouri	20,897,208

9.	Washington	.268
10.	New Jersey	.264

I. AMERICAN CLASSES OF POULTRY.

This class includes six breeds and varieties, as follows:

Plymouth Rocks, six varieties: Barred. White. Buff. Silver Penciled. Partridge. Columbian.

Wyandottes, eight varieties: Silver. Golden. White. Buff. Black. Partridge. Silver Penciled. Columbian.

Javas: Black. Mottled.

Dominiques.

Rhode Island Reds: Single Comb. Rose Comb.

Buckeyes.

1. History and Origin.— The oldest varieties in the American class are only about 55 to 60 years old. Youngest only 10 to a dozen years and new ones developing. All are of *mixed* origin. Composite breeds all originating in America.

2. Distinguishing Class Characteristics.— (a) Purpose. General purpose, *meat* and *eggs*, and *exhibition*.

(b) Size and weight. Medium to large.

(c) Type compact, blocky, meaty, symmetrical, graceful.

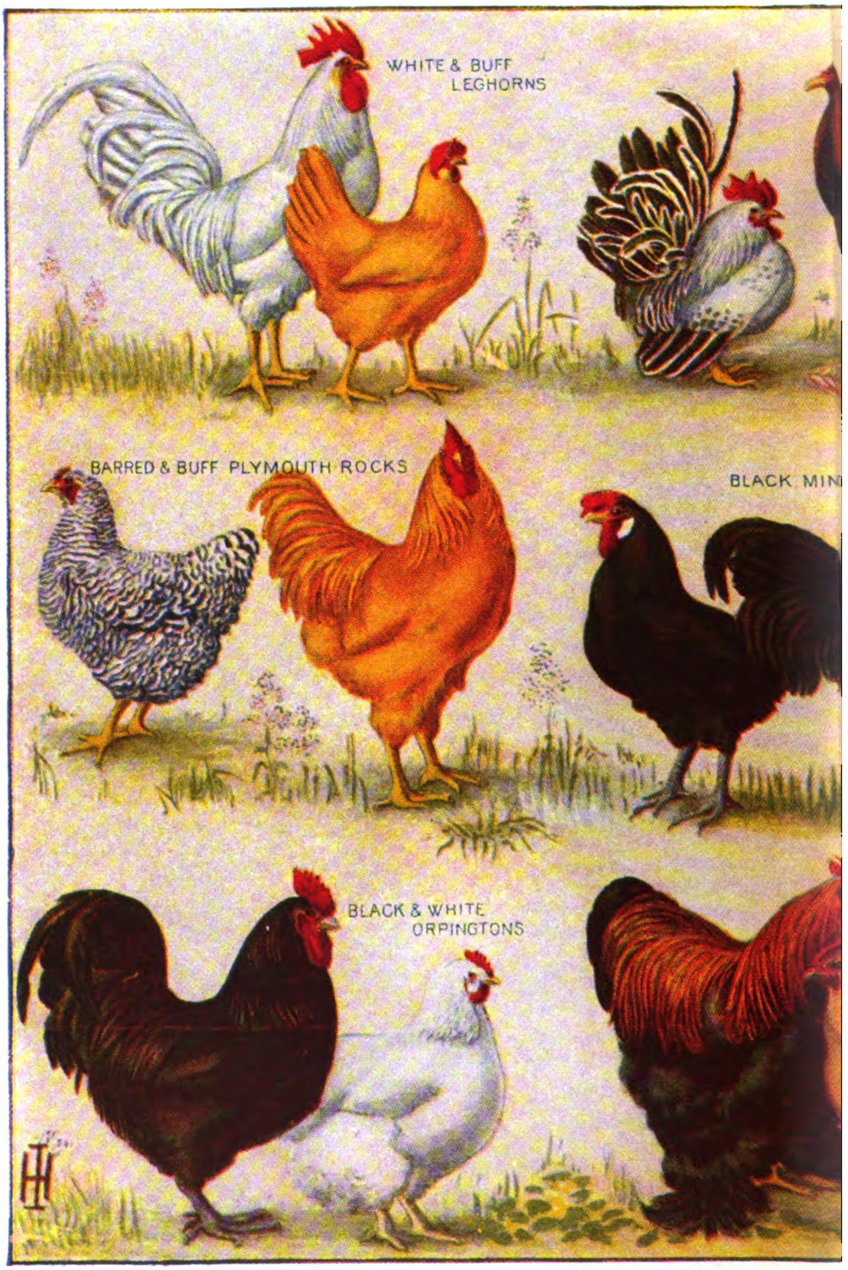
(d) Plumage. Moderate in quantity. Attractive in color patterns and types. Numerous colors to suit the fancy: Barred, Penciled, Laced, Mottled, Stripd, Red, White, Black, Buff.

(e) Skin. Yellow medium to coarse.

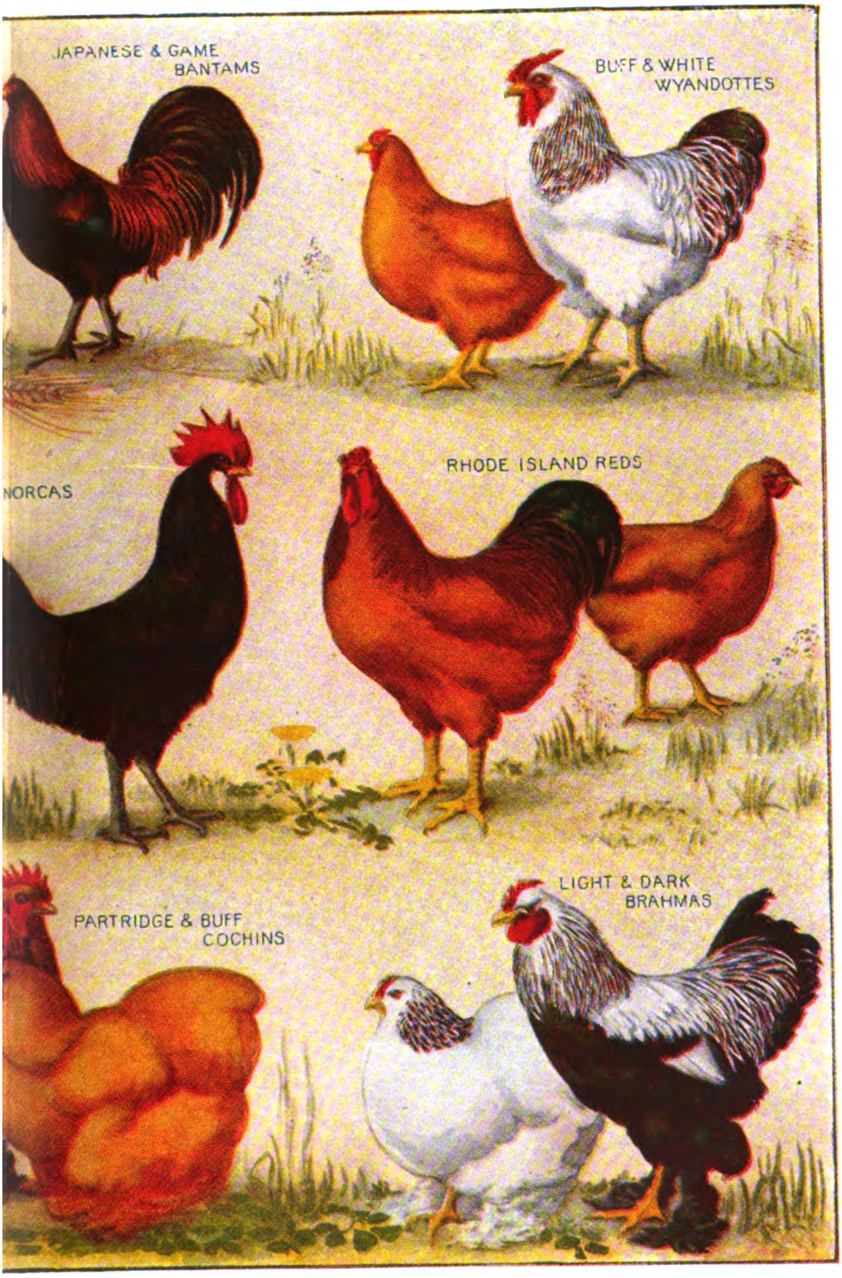
(f) Attractiveness. Attractive on account of type, carriage and color variations. "Style Plus."

(g) Rate of development. Moderately rapid, maturing three to four weeks later than Leghorns under normal conditions, and three to four weeks earlier than Asiastics.

(h) Habits. Non-flying, active, low to medium fences will retain them. Very best of foragers.



LEADING BREED



S OF CHICKENS

(i) Temperament. Active, but not sprightly, slow but not sluggish.

(j) Hardiness. Very hardy, small to medium comb and wattles. Well-protected bodies.

(k) Maternal qualities. The very best. Courageous and strong. Brooding instinct largely developed, intelligent, kind disposition, medium size, not clumsy. Occasionally bred small for hatching and brooding wild game birds. Smooth shanks are an advantage in brooding.

(l) Disposition. Kind, somewhat combative, but not vicious.

(m) Prolificacy. Except in some instances. The very best of winter layers. Good all-year-round producers. Superior to Asiatics, but inferior to Mediterraneans.

(n) Eggs. Slightly tinted to very dark brown, mostly lighter tints. Size medium to large. Thick, uniform shells.

(o) Meat production. Excellent. Medium as to quantity and also quality and rapidity of growth. Rocks for large roasters, Wyandottes for broilers or medium to light roasters, and Rhode Island Reds for small to medium roasters.

(p) Breeding efficiency. Most of the breeds are reliable in transmitting their characters, but are not as prepotent as Asiatic or Mediterraneans because a composite group and of more recent origin.

(q) Variable physical characters are: (1) Shanks smooth, yellow except Javas, and responsive; (2) Skin yellow (except Javas); (3) Comb and wattles medium to large; (4) Earlobes red; (5) Molting normal.

II. Asiatic.

This class includes three breeds and eight varieties as follows:

Brahmas	Dark. Light.
Cockins	Buff. Partridge. White. Black.
Langshans	Black. White.

For breeds and varieties consult the 'American Standard.'

1. History and Origin.— These are among the oldest known breeds. None are older except, perhaps, the games. They are of Chinese origin with a parentage too remote to be known. The size of fowl appeared to be a religious requirement in the country of origin. Have exerted the greatest influence of any class of fowl in the formation of new breeds in this country.

2. Distinguishing Class Characteristics.— (a) Purpose. Meat and winter egg production and for exhibition. Poor laying qualities. Among the best for heavy roasters and capons, particularly the Brahmas. Especially desirable for capons, especially for crossing for meat purposes. Rather coarse flesh. For village and general farm rather than large poultry plants, except on roaster farms. (b) Size and weight. The largest and heaviest class, weighing from 11 to 12 pounds for the cock; $7\frac{1}{2}$ to $9\frac{1}{2}$ for the hens.

(c) Type. Rangy, large bone, open organization. The shape of the breeds differs widely. Brahma erect, stately. Cochin squatty. Langshan tall and leggy.

(d) Plumage. Exceedingly heavy. The breeds are *parti-colored* and *solid buff, black* and *white*. The breed of feathers. Withstand cold weather.

(e) Skin. Yellow and coarse.

(f) Attractive because stately and large.

(g) Rate of development slow, late maturing both in growth and in egg production. Have a pronounced lank and bony state in development.

(h) Habits. Non-flyers. Do not scratch. Feet on ground all time. Low fences and small yards are sufficient. Naturally good foragers because not timid.

(i) Temperament. Phlegmatic and inactive. Not easily frightened.

(j) Hardiness. Very hardy naturally except when bred in too close confinement for the fancy. Resistant to unfavorable conditions. Not responsive to disturbing climatic conditions.

(k) Maternal qualities. Brooding instinct largely developed. Persistent sitters. Kind, but clumsy mothers. Because of their large size and abundance of feathers, they can cover many eggs and chickens.

(l) Disposition. Kind. Not quarrelsome or combative.

(m) Prolificacy. Poor producers. A large proportion of eggs in late winter.

(n) Eggs. Medium to large in size, but small in proportion to the size of fowls. Fairly uniform in shape and size. Color, light to very dark brown and fairly uniform.

(o) Breeding efficiency. Prepotent because characters long established and proven. Mating efficiency low — Brahmas, 1 male to 8–10 females. Langshan, 1 male to 12–15 females. Cochins, 1 male to 6–8 females.

(p) Meat quality. Considered coarse in texture but large in quantity for Brahmas and Langshans but to a less extent of which Cochins are not meaty. Brahmas and Langshans are among the best for meat production of any of the larger breeds. Not equal to Orpington or Dorking, Lafleche or Faverolles, Sussex, but as satisfactory as the American class, as Rocks or Wyandottes and better than the Mediterraneans, such as Leghorns, Anconas, etc., especially satisfactory for «roasters,» but not as broilers.

(q) Variable physical characters, as indicating laying condition and productive capacity. Less responsive to feed, fright and temperature: (1) Shanks yellow. Feathered; (2) Skin yellow; (3) Comb, pea comb and single comb, small. Wattles medium in size; (4) Earlobes red; (5) Molting habits similar to other breeds.

III. Mediterranean.

In this class are five breeds and 17 varieties as follows.

Leghorns	Single Comb Brown. Rose Comb Brown. Single Comb White. Rose Comb White. Single Comb Buff. Rose Comb Buff. Single Comb Black. Silver. Red Pyle.

III. Mediterranean — Continued.

Minorcas	Single Comb Black. Rose Comb Black. Single Comb White. Rose Comb White. Single Comb Buff.
Spanish	White Faced Black
Blue Andalusians.	
Anconas	Single Comb. Rose Comb.

1. Origin and History.— Next to the Americans they are the most popular breeds. All from Italy and Spain or in the neighborhood of the Mediterranean.

2. Distinguishing Characteristics.—Active, non-broody, prolific.

(a) Purpose. Special egg breeds.

(b) Size and weight. Generally light to medium except Minorcas, which are heavy.

(c) Type. Well-balanced proportions. Small boned, compact.

(d) Plumage. Light and close feathered, in many colors, white, buff, brown, red, pyle and black, in the native country; black predominating: mostly solid colors, mottled, penciled, striped.

(e) Skin. Fine in texture. Yellow except Minorcas and Spanish.

(f) Attractiveness. Graceful, sprightly, head points and plumage especially artistic.

(g) Rate of development. Rapid in both growth and reproduction, except Minorcas, which are like the breeds of the American class.

(h) Habits. Flyers. Only fair foragers because timid. Especially active and industrious in scratching and foraging. Exceedingly *active* in hunting for food but timid in foraging long distances.

(i) Temperament. Alert, nervous, flighty, quick acting; that is, easily frightened.

(j) Hardiness. Very adaptable to wide extremes but more suited to mild climates. Suffer from frozen head appendages, comb and wattles. Very responsive and sensitive to changes in climatic conditions, hence variable in production and physical characters due to environment.

(k) Maternal qualities. Unreliable, largely non-broody, except occasional individuals. Occasional individuals fairly satisfactory for brooding pheasants. Only about 5 to 10 per cent broodiness per year. Require artificial incubation and brooding. Kind but fickle and fussy as mothers.

(l) Intelligence. Especially intelligent, in learning to eat and return to hover when young.

(m) Disposition. Courageous, strong in defense but not quarrelsome.

(n) Prolificacy. The very highest in fecundity. Exceedingly precocious. The first eggs laid when four and one-half to five and one-half or six months.

(o) Economical production. Economical production is their strongest point as layers. Cost of production among the least per dozen, or per pound of eggs, due to small size of body.

(p) Feeding advantages. Easy to feed; not as likely to get too fat as heavier, less active breeds. (Except Minorcas).

(q) Egg quality. Eggs are medium to large. All white with but slight tendency to tintedness. Uniform in shape.

(r) Meat qualities. Generally too small. Lack economical dressing quality. Unsatisfactory except for squab broilers, at three-fourths of a pound to one and one-fourth pounds. Flesh fine grained. Large proportion of breast meat. The muscles used in flight.

(s) Breeding efficiency. Prepotent. A dominant race well established. Run out other less prepotent races. Mating qualities one to 25 or 40 hens. Mate most freely of any classes. Highest fertility and hatching power.

Variable physical characters. Most variable and hence most expressive of laying performance. (1) Shanks smooth, non-feathered and yellow (except Minorcas and the Mottled Anconas), and of great value in judging birds for quality of egg production; (2) Skin yellow, soft and fine; (3) Comb and wattles medium to large; (4) Earlobes white and very responsive to change in color pigmentation; (5) Molting quick and regular.

IV. English Class.

This class includes (1) White, Silver and Gray and Golden Duckwing; (2) Redcaps; (3) Orpingtons, Single Comb Buff, Black, White and Blue; (4) Cornish, Dark, White and White Laced Red; (5) Sussex, Speckled and Red. The English class are, for the most part, developed along meat-producing lines, although the general purpose idea of combining egg production has been attempted. The Orpingtons, the Cornish and the Sussex have been developed particularly for meat type which has materially decreased egg production qualities. They form the basis, however, of some of the most desirable of our varieties for the production of high quality meat.

V. Polish Class.

This family consists of one breed having eight varieties; namely, White-Crested Black, Golden, Silver, White, Bearded Golden, Bearded Silver, Bearded White and Buff Laced. They are medium in size, good layers of white eggs and non-sitters. All have large, showy crests owing to which they fall easy victims to hawks and enemies. They have, in some cases, beards; small V-shaped combs and slate and willow shanks. As they are chiefly ornamental they are not popular in the United States.

VI. Hamburgs.

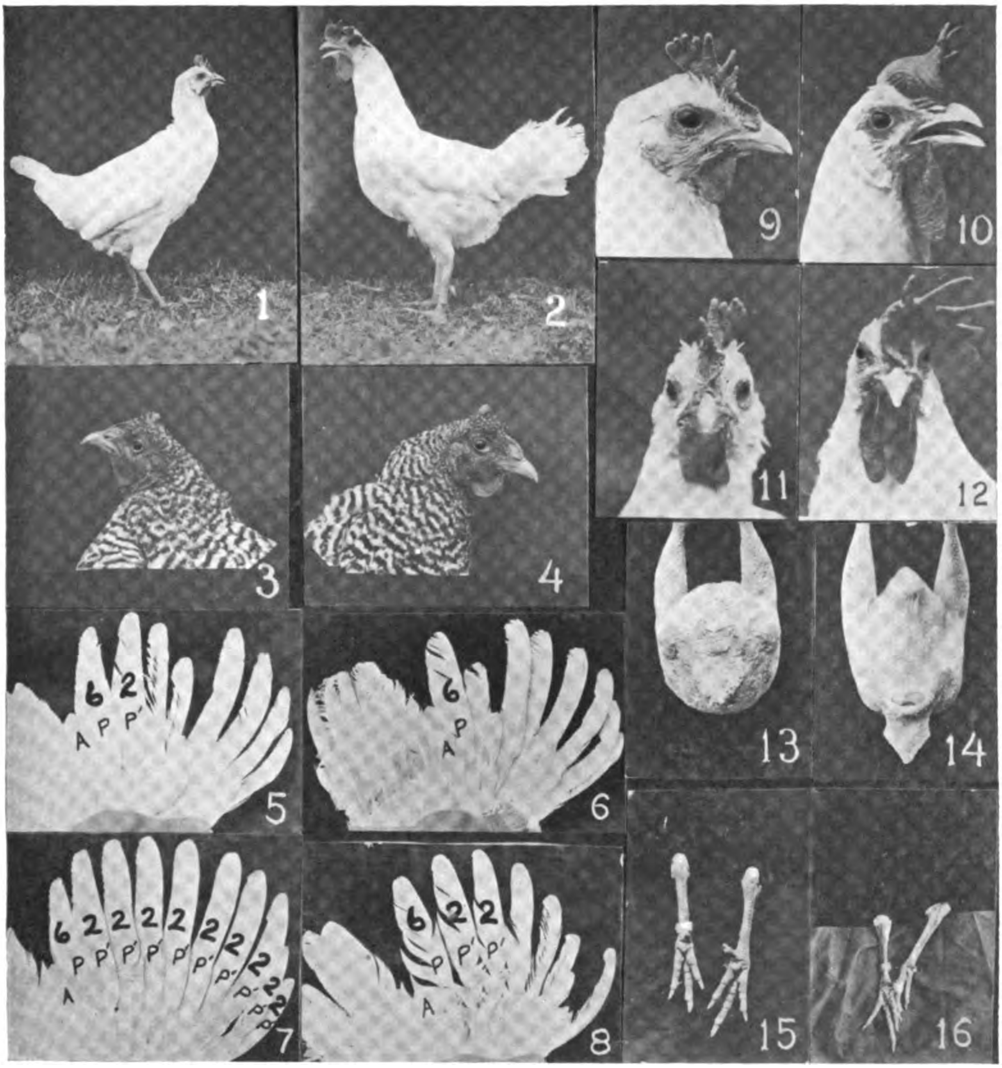
This is a Dutch family consisting of one breed and six varieties. Golden Spangled, Silver Spangled, Golden, Silver and White Penciled and Black. They are unsatisfactory for meat and generally considered too small for popular use for egg production.

VII. French.

This class consists of four breeds and five varieties. (1) Houdans, White and Mottled; (2) Crevecours, Black; (3) La Fleche, White; (4) Faverolles, Salmon. All of these varieties are distinctly of the meat-producing type, although bred as general purpose fowls having fairly satisfactory egg-producing qualities.

VIII. Continentals.

This class consists of Silver and Golden Campines. They are Belgian in origin and are of small size, distinctly of the egglaying type, very prolific and extremely hardy.



1 A POOR LAYER — (a) Yellow color of head, shanks and plumage. (b) New plumage. (c) Small, hard, dried, scale-covered comb. (d) Wrinkled ear lobes. (e) Tucked up abdomen. (f) Full face

2 A GOOD LAYER — (a) Pale color of beak, eye-ring, ear lobes, face, shanks. (b) Old, unmolted, ragged plumage. (c) Full, bright, waxy comb. (d) Full ear lobes. (e) Deep abdomen. (f) Intelligent head

3 and 4 HEAD PARTS — 3 (a) Wrinkled ear lobe. (b) Full face. (c) Face, eye-ring and beak yellow. 4 (a) Full ear lobe. (b) Thin face. (c) Pale color of beak, eye-ring and face

5 and 6 EGG PRODUCTION INDICATED BY THE LENGTH OF TIME OF MOLTING AS DETERMINED BY THE SHEDDING OF THE PRIMARY FEATHERS — It takes about six weeks to completely renew the primary feather (P) next to the axial feather (A) and an additional two weeks for each subsequent primary feather (P). (Photographs taken on 4 December). 5 AN EIGHT-WEEK MOLT (Two feathers completely renewed) — Estimated date stopped laying 9 October. Second year record 164 eggs. 6 A SIX-WEEK MOLT (Primary feather next to axial feather renewed) — Estimated date stopped laying 23 October. Second year record 186 eggs

7 A TWENTY-FOUR WEEK MOLT (Ten feathers completely renewed) — Estimated date stopped laying 21 June. Second year record 75 eggs

8 A TEN-WEEK MOLT (Three feathers completely renewed) — Estimated date stopped laying 25 September. Second year record 121 eggs

9 and 10 HEAD PARTS — 9 LOW PRODUCER (not laying) — (a) Small, hard, dried, scale-covered comb and wattles. (b) Fat face. (c) Yellow color of beak, eye-ring, ear lobes, face. (d) Wrinkled, shrunken ear lobe. (e) Dull, snaky eye. 10 HIGH PRODUCER (full laying) — (a) Full, bright, stiff, waxy comb and wattles. (b) Thin face. (c) Pale color of beak, eye-ring, ear lobes, face. (d) Full ear lobe. (e) Bright, round eye

11 and 12 HEAD PARTS — Same as above

13 POOR LAYERS (in non-laying condition) — (a) Vent yellow, small, hard and puckered. (b) Distance between blunt pelvic bones short. (c) Body full, hard and plump

14 GOOD LAYERS (in laying condition) — (a) Vent pale, large, full and moist. (b) Pelvic bones wide-spread. (c) Skin soft and flabby

15 and 16 SHANKS — 15. (a) Shanks yellow. (b) Shanks full, hard, round in the back. 16. (a) Shanks pale. (b) Shanks thin, and soft in the back

IX. GAMES AND GAME BANTAMS.

This class consists of 16 varieties, eight of which are Black Breasted, Red, Brow-Red, Golden Duckwing, Silver Duckwing, Birchen, Red Pyle, White and Black, and eight varieties of bantams, minatures of the above. Their purpose is primarily for exhibition and fighting.

X. ORIENTALS.

The Orientals are Sumatras, Black Malay, Black-Breasted Red Malay Bantams, Black-Breasted Red. The class is primarily kept for exhibition purposes.

XI. ORNAMENTAL BANTAMS.

The Ornamental bantam class consists of (1) Golden and Silver Sebright; (2) White and Black Rose Comb; White Booted; Light and Dark Brahmas; Buff, Partridge, White and Black Cochins; Black Tailed, White, Black and Gray, Japanese Bearded, White, Buff Laced, Non-Bearded Polish and Millefleur (booted).

XII. MISCELLANEOUS.

The miscellaneous class consists of the Silkys, Sultans and Frizzles which are produced as oddities and primarily for ornamental purposes and for exhibition.

Education and Research in Poultry Husbandry.— Among the 62 State agricultural colleges and experiment stations in the United States, only 10 offered courses of instruction in poultry husbandry in any form in 1904, whereas now nearly every State in the Union offers instruction in some form in poultry husbandry. To Cornell University is due the credit of having given the first regular course of instruction in poultry husbandry in the United States, which occurred in the winter of 1891 at Ithaca, N. Y. The first specialized short course where the students devote all of their time to poultry instruction occurred at Kingston, R. I., in 1898, at which time a six-weeks' poultry course was given. The first poultry investigational work in the United States devoted to poultry was at the Maine Experiment Station, Orono, Me., in 1885. In New York State, at the New York State agricultural experiment stations at Geneva, N. Y., and at Cornell University, experimental work with poultry was conducted in 1889 and 1890, respectively. At the present time practically every State in the Union provides facilities for experimental work in this subject and many States have made as large or larger provision for research work in poultry husbandry as for any branch of agriculture.

More than 75 poultry and pigeon papers are published in the United States alone, several of which report circulations of from 30,000 to 60,000 copies to each issue. In addition to this nearly all agricultural and livestock papers conduct poultry departments. In order to hatch the billions of chickens produced each year more than 50 kinds of incubators are manufactured in the United States, which leads all nations in this field of inventive skill. In 1890 a 500-hen poultry farm was an object of wonder, but now there are thousands of poultry plants having 2,000 hens and many which have from 5,000 to 10,000 or more, besides broiler and roaster farms, squab duck and squab pigeon establishments, some of which turn out more than 100,000 birds per year.

Evolution of Commercial Poultry Husbandry.—Among the more important discoveries which have had a profound influence upon the poultry industry may be mentioned: (1) The development of efficient hatching devices. Incubators and the increase in our knowledge of successful hatching have almost completely eliminated the natural methods of hatching by hens on the large commercial farms and has made possible a rapid and extensive expansion of the size of poultry enterprises; (2) The improvement of large flock-brooding systems which enables poultrymen to brood several hundred chickens in single flocks in portable buildings, which is a material saving in labor and provides for rearing under free range conditions; (3) Standardized methods of feeding for special purposes which results in larger and more economical production of healthier stock; (4) Large flock laying houses which reduce cost of construction per bird, economize labor and provide greater comfort, reduce mortality and increase production; (5) Improvement in the breeds as a result of discovery of methods of judging fowls for production by means of external characters and the perfection of methods of marking poultry for future identification, the use of trap nests and pedigree hatching trays which enables the breeder to connect up the performance of the progeny with that of the parents, has resulted in greater progress being made in efficient production in the past generation than in the preceding century; (6) The use of artificial light in the control of egg production is one of the most important discoveries in the efficient management of poultry. By our knowledge of this factor in the economical production of eggs it is now possible to materially increase the proportion of eggs that are normally laid in periods of scarcity and high prices in the fall and winter months in the north temperate climate and to do so without proportionately decreasing the normal production during the remainder of the year. The influence is far reaching in its effect upon the poultry industry due to the fact that by the control of production by means of artificial light, the poultryman increases the production of eggs laid during periods of high prices and reduces the cost of production without injury to the fowls.

Some of the more important variable physical characters used in determining the laying quality of fowls are shown in accompanying plate and explained in the descriptive statement of method of judging fowls for egg production, prepared at the Judging School, State College of Agriculture, Cornell University, and approved by the American Association of Instructors and Investigators in Poultry Husbandry.

Method of Judging Fowls for Egg Production.— In order to lay well a bird must have a sound body. As a first consideration a bird must be *vigorous and healthy* if it is to be able to lay well. Vigor and health are shown by a bright, clear eye, a well-set body, a comparatively active disposition and a good circulation. Further, the bird must be free from *physical*

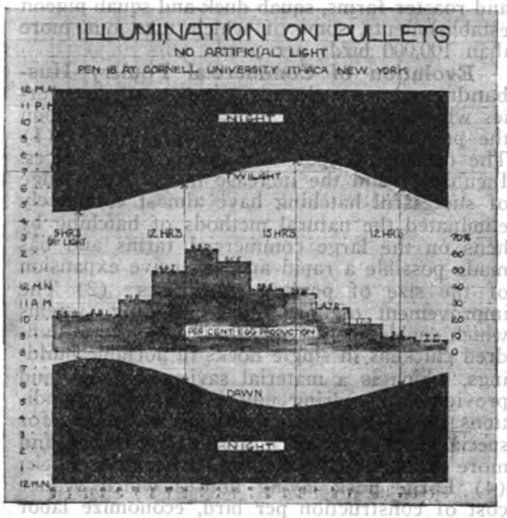


FIG. 1.—This graph shows the length of the light and the darkness each month of the year from 28 Nov. to 31 Oct. and the distribution of egg production each month stated in percentage. It will be seen that there is a very marked relationship between the egg production each period and the length of the day. It will be seen that on the 21st of Dec. in New York State the nights are approximately 15 hours long and the days 9 hours long, whereas on 21 March and 21 Sept. the nights and the days are equal and that on 21 June the nights are only 9 hours and the days 15 hours long. It has been found that the digestive system of the fowl has a capacity of about 12 hours between feedings and hence they cannot produce efficiently when the time between meals is more than 12 hours long. Under the normal day light conditions it will be seen that the largest production is in the months of April, May and June when eggs are cheapest, and least in October, November and December when eggs are highest.

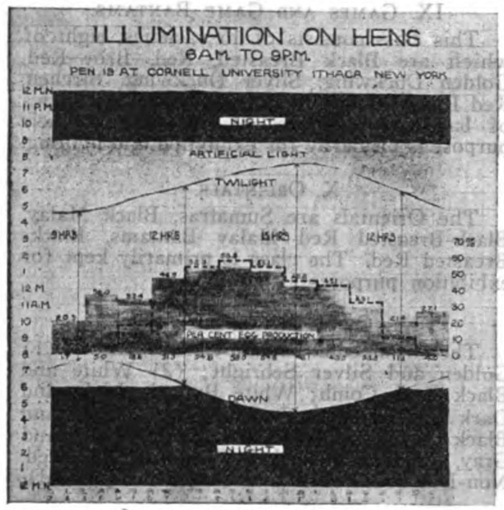

FIG. 2 shows the change in egg production brought about by the use of artificial flight from 6 A.M. to dawn and from twilight to 9 P.M. The dotted line plots the curve of production shown in Fig. 1. and which shows in Fig. 2 that a large increase in production was secured in periods of highest prices and with only slight reduction in production in periods of lowest prices, leaving a net gain of more eggs per year and a larger production of high priced eggs without injury to the hens.

defects such as crooked beak, excessively long toe nails, eyelids that over-hang so that the bird cannot see well, scaly leg or anything else that would keep the bird from seeing or getting an abundance of food.

Loss of Fat Due to Laying.—Color or pigmentation changes. (These should be observed by daylight). A laying fowl uses up the surplus fat in the body, especially it removes the fat from the skin. In yellow-skinned breeds this loss of fat can readily be seen by the loss of the yellow color. The different parts of the body tend to become white according to the amount of fat stored in the body and the amount of circulation of blood through that part. The changes occur in the following order: The *vent* changes very quickly with egg production so that a white or pink vent on a yellow-skinned bird generally means that the bird is laying, while a yellow vent means a bird is not laying. It should be recognized that all yellow color changes are dependent on the feed, coarseness of skin and size of bird. A heavy bird fed on an abundance of green feed or other material that will color the fat deep yellow will not bleach out nearly as quickly as a smaller or paler colored bird. The *eyering*, that is, the inner edges of the eyelids, bleach out a trifle slower than the vent. The earlobes on Leghorns and Anconas bleach out a little slower than the eyering, so that a bleached earlobe means a little longer or greater production than bleached vent or eyelid. The color goes out of the *beak* beginning at the base and gradually disappears until it finally leaves the front part of the upper beak. The lower beak bleaches faster than the upper, but may be used where the upper is obscured by horn or black. On the average colored, yellow-skinned bird a bleached beak means heavy production for at least the past four to six weeks. The *shanks* are the slowest to bleach out and hence indicate a much longer period of production than the other parts. The yellow goes out from the scales on the front of the shanks first and finally from the scales on the rear. The scales on the heel of the shank are the last to bleach out and may generally be used as an index as to the natural depth of yellow color of the bird. A bleached-out shank usually indicates fairly heavy production for at least 15 to 20 weeks.

The yellow color comes back into the vent, eyering, earlobes, beak and shanks in the same order that it went out, only the color returns much more quickly than it goes out. A vacation or rest period can sometimes be determined by the outer end of the beak being bleached and the base being yellow.

Body Changes Due to Laying.—A laying hen has a large, moist *vent* showing a dilated condition and looseness as compared with the hard, puckered vent of a non-laying hen. The whole *abdomen* is dilated as well as the vent so that the pelvic arches are widespread and the keel is forced down, away from the pelvic arches so as to give large *capacity*. The more eggs a bird is going to lay the following week the greater will be the size of the abdomen. The actual size of the abdomen is, of course, influenced by the size of eggs laid and by the size of the bird. Heavy production is shown by the quality of the skin and the thickness and stiffness of the *pelvic arches*. Fat goes out from the skin and body with production so that the heavy producers have a soft velvety skin that is not underlaid by layers of hard fat. The abdomen in particular is soft and pliable. The *sternal processes* are very prominent and are generally bent outward. The thicker and blunter the pelvic arches and the greater the amount of hard fat in the abdomen the less the production or the longer the time since production. One of the finer indications, but yet one of the most valuable in picking the high layer, is the fineness of the head and the closeness and dryness of *feathering*. The head of a high layer is fine. The wattles and earlobes fit close to the beak and are not loose and flabby. The face is clean-cut. The eye is full, round and prominent, especially when seen from the front. The high layer is trimmer, that is, the feathers lie closer to the body and after heavy production the oil does not keep the plumage relatively as sleek and glossy, but the plumage becomes worn and threadbare.

Changes in Secondary Sexual Characters. — *The Comb.* Wattles and earlobes enlarge or contract, depending on the ovary. If the comb, wattles and earlobes are large, full and smooth or hard and waxy, the bird is laying heavily. If the comb is limp the bird is only laying slightly, but is not laying at all when the comb is dried down, especially at molting time. If the comb is warm it is an indication that the bird is coming back into production.

Molting.— When a bird stops laying in the summer she usually starts molting. The later a hen lays in the summer or the longer the period over which she lays the greater will be her production, so that the high producer is the late layer and hence the late molter. The length of time that a hen has been molting or has stopped laying can be determined by the molting of the primary feathers. It takes about six weeks to completely renew the primary feathers next to the axial feathers and an additional two weeks for each subsequent primary to be renewed.

Temperament and Activity.— A good layer is more active and nervous and yet more easily handled than a poor layer. A high layer shows more friendliness and yet elusiveness than a poor bird. A low producer is shy and stays on the edge of the flock and will squawk when caught. While the characters discussed have dealt specifically with the current year's production, it should be borne in mind that a high producer one year is, generally speaking, a high producer in all other years.

JAMES E. RICE,
Professor of Poultry Husbandry, Cornell University.

POULTRY AS AN INDUSTRY. The information of the present article will be given under the following divisions: (1) The demand; (2) conditions of success; (3) details to be observed; (4) the necessary equipment; (5) the profit of the industry.

THE DEMAND.

There is a steady and constantly increasing demand for first-class poultry products, both in the form of eggs and poultry for the table and when the production of either of these commodities is combined with bure-bred poultry the producer has a doubly assured and considerably increased income.

There is certainly no danger of over-stocking the market, provided the quality be first-class. Statistics prove that the city of Greater New York consumes more eggs each year than the entire Empire State produces. The two States of New York and Pennsylvania consume five times as many eggs as they produce. The importation of poultry into these two States is even proportionately larger than that of eggs. The people who produce the choicest poultry for the tables of the more fastidious residents of our great Eastern cities realize prices more than double the average price of the average poultry products marketed in those same cities. The retail price of strictly first-class eggs during the fall and winter months is more than three times the average summer price of average eggs in those same markets. There is a constant demand at these high prices for a product that can be guaranteed strictly first class, while it is only the second-class or third-class products that are at any time a drug on the market. The people are being educated to the fact that there is a vast difference between fowls of the same age for table purposes, and that even fowls of the same variety and age vary largely in quality according to the methods by which they have been fatted and dressed.

CONDITIONS OF SUCCESS.

There are a few general principles, therefore, that he who hopes to succeed in the poultry business should become familiar with before embarking largely in this enterprise. 1. He must ever bear in mind that to acquire the greatest profit he must produce the finest quality. The market is generally glutted with the lower grades of poultry and eggs. These are supplied at an actual loss. 2. He must decide upon some one branch of the business which he will make his specialty, and, having made his decision, he must push that line to the limit, cultivating only as accessory the other minor branches of the industry. In making this decision he must give careful attention to his own adaptability to his chosen branch of the work, considering well his location and surroundings, his proximity to market and the demands of that market. 3. He must be prepared to apply the business principles of the business man to the poultry industry. He must apply the principles of industry, thrift and economy in poultry production with the same energy and persistence as they are practised in our great manufactories. In fact, he becomes a manufacturer, converting the raw materials of the farm crops into those finely finished products, eggs and poultry.

Details to Be Observed.

Having decided, for example, that egg production for the city markets shall be his chief aim, he must proceed in building up his business with that particular object constantly in view. In this work the following hints will be useful:

1. **Selection of His Variety.**— He must keep but one variety, so that his eggs may be as nearly uniform in color and size as possible. Boston calls for a brown egg; New York prefers a white egg. Each city will pay a few cents per dozen more for eggs of its favorite color. The Asiatics — Brahmas and Cochins — and the Americans — Plymouth Rocks and Wyandottes — produce the brown eggs. The Mediterranean varieties — Leghorns, Minorcas and Anconas — are the largest producers of the white eggs.

He must, however, in selecting his variety, remember that the Brahmas and Cochins will produce but few eggs until eight months old, while the Plymouth Rocks will lay at six months, and the Wyandottes and Leghorns at five months.

If he intends to grow his own young stock he must provide incubators and brooders for the non-sitting Mediterranean varieties, while the Asiatic and American varieties will hatch and rear their own young.

He must also calculate on building warmer and more comfortable houses for the Mediterraneans than will be necessary for the close-fitting rose-combs of the Wyandottes or the small pea-combs of most of the Asiatics. All the Mediterranean varieties have large combs and pendulous wattles, very susceptible to frost. The Plymouth Rocks, with their medium-sized combs, come between the extremes described, in this particular.

The time of year when he stocks his plant will decide whether he shall start by purchasing eggs for hatching or shall purchase fowls for his foundation. If he begins in the spring, and is equipped with incubators for hatching — and few now depend exclusively on the hens for hatching and rearing — then he will start more cheaply by purchasing eggs from some reliable breeder of his chosen variety. In the fall of the year it is best to start by buying pullets then four to six months old and ready to begin producing eggs.

2. **Care of the Stock.**— No hen can be a profitable egg producer unless she is kept comfortable and happy. More poultry plants have been wrecked and abandoned because of neglect in caring for the fowls than by any other cause. The questions of food and shelter will be considered under those headings, so we shall content ourselves here with merely mentioning two items:

(a) **Cleanliness.**— The hen is not an exacting tenant but she is naturally rather fastidious about some things, and she has a right to be. She must have her bath, and that bath is not a water bath, but a dust bath in which she can wallow occasionally and sift her feathers full of fine dust. This looks to be dirty, but it is not; simply dusty. Her quarters, furthermore, must be frequently cleansed. All droppings should be removed from the dropping-board at least once each week, and a little sweetening of the surroundings by a liquid disinfectant and insecticide is most advisable. Fresh straw as a litter for the floor of the house should be provided occasionally, and the nests — the receptacles for those fresh eggs so susceptible to any taint — should be renewed with fresh material frequently.

(b) **Water.**— Since an egg is two-thirds water, it seems useless to argue for a constant supply of pure, fresh water. If this is provided, a hen will drink 20 times a day. If it is not supplied, her natural thirst will compel her to drink from filthy pools wherever she can find them, even from the cow tracks in the mud of the barnyard. Is it strange that fastidious people are becoming so particular as to specify how the hens that produce their eggs shall be supplied with food and water?

3. **The Separation of the Sexes.**— This subject is attracting much attention of late, and properly. So soon as the cockerels can be determined from the pullets they should be separated. Both sexes develop much more satisfactorily when kept by themselves. The cocks should be removed from the yards at the close of the breeding season, say in June, not to return until January or February. This much for the best interests of the fowls themselves.

But it is for a better and more certain quality of the eggs that we urge a separation of the sexes. When a hen that has been mated produces an egg, that egg has been fertilized at a certain point in its passage down the oviduct. From the moment of said fertilization until it is deposited in the nest — under normal conditions about 12 hours — the heat of the hen's body has caused the process of incubation to progress. If some great excitement prevents the hen from depositing the egg until the next day, the egg shows bloody streaks. We have known eggs to be thus retained by the hen for 60 hours, so that at the time the egg was laid the heart beats of the embryo chick could be seen with the naked eye.

While the process of incubation practically ceases as soon as the freshly-laid egg reaches a temperature as low as 80°, yet succeeding hens coming on the nest, perhaps several of them the same day, each warm that fertile egg up above 90° and the process of incubation is resumed. Where eggs are gathered at irregular periods — too often only «every few days» — it can readily be seen that only absolutely infertile eggs, those laid by unmated hens, are safely fresh, and many institutions, and even private families, are now making their contracts for «virgin eggs.»

On the other hand, eggs that are absolutely infertile may be kept in almost any temperature without spoiling. We have placed such eggs in an incubator and kept them there for three weeks at a temperature above 100° all the time, and at the end of that period amateurs could not distinguish them from fresh eggs. Only the infertile egg will bear transportation in warm weather, and only those who will take care to have such can hope to realize the highest prices.

4. **Poultry Diseases.**— This subject is now very properly attracting much attention in our agricultural colleges. All desire to be excused from eating the eggs of a diseased hen. One's comfort comes, however, in the fact that diseased hens do not lay many eggs. There is a further satisfaction in the knowledge that the much-talked-of fowl cholera is a rare disease. Only a very few well-authenticated outbreaks of this disease have occurred in this country. There are a few other diseases with somewhat similar symptoms that are frequently mistaken for cholera.

(a) **Diarrhœa and Dysentery.**— These diseases are both usually brought on by neglect in the matter of food and drink. Pure water is one of the first essentials, and the fowls usually having an unnatural thirst, the pure water is an easy medium for administering some of the simple remedies, such as the Douglass mixture or a little carbolic acid in the water. With brooder chicks many of these irregularities of the bowels are caused solely by extremes of heat and cold. Chicks under three weeks old will scarcely endure day and night extremes of more than 15 or 20 degrees without manifesting bowel trouble, however carefully they may be fed. With mature fowls in confinement, a failure on the part of the attendant to provide them with grit, gravel, oyster-shell and broken bone is a fruitful cause of these two diseases. Sour and rancid food will also cause diarrhœa, while fowls nearby fed on sound grains will be free from it.

(b) **Roup.**— This is by far the most common disease to which our domestic fowls are subject. It is generally considered contagious, but the most careful experimenters have failed to identify the germ or to inoculate a well fowl from a diseased one. Still we advise caution, and recommend that affected birds be isolated. Roup being simply an aggravated cold which rapidly takes on the catarrhal form, prevention is most advisable. Under buildings we shall urge freedom from draughts and dampness, which are the most prolific causes. The bird taken in the early stages, kept warm and dry, fed liberally, and the throat and nasal passages sprayed with a weak solution of carbolic acid or an emulsion of unrefined petroleum, will generally recover. If he gets seriously ill, kill and bury him.

5. **The Kinds of Food.**— This is a subject on which volumes could be written. In brief, since analyses show that the egg and the body of the young bird are almost identical, we may conclude that the food that is best for egg production is almost the best also for the growing fowl. When the fowl is grown and is about ready to be fatted for market, then a different ration is best, as will be shown.

For either the growing chick or the egg-producing hen, in addition to the grits, bone and shell already referred to, the best results are obtained by a liberal supply, in large variety of form, of the three following classifications of food:

(a) **The Grains.**— These are the natural food of our domestic fowls. They grow in such a variety in this country that there is no excuse for limiting our fowls to a scanty variety. Many erroneously suppose that what a hen picks up first is best for her. Throw down a few handfuls of corn, wheat, oats and millet to a bunch of fowls and the corn will be taken first, the others in the order named. Notice that this is in the order of the size, instinct teaching them to take first that of which they can get the most in the shortest time. Now the corn is the grain that ordinarily should be fed the most sparingly. It is so rich in the carbonaceous, or fat-making, elements that it is neither a good egg-maker or a good flesh-producer. To feed to fowls thin in flesh or to feed on a very cold evening, to enable the fowls to keep up their temperature through a long night, corn is best.

Of all our grains we esteem oats the best. Fowls do not take so kindly to oats as to wheat which we rank as second. Use these two grains alternately. Do not mix your grains. Give them something different each time if possible. Kaffir corn is one of our very best poultry foods. Sorghum seed and broom-corn seed are very similar. Buckwheat and sunflower seed in moderate quantities are excellent. Never feed more grain than they will clean up in a few minutes, unless you bury it among the litter so that they must scratch and work for it. Better that your fowls be kept slightly hungry and in working condition than too fat.

There is not so much necessity for soft foods as most people imagine. With plenty of grit to do the grinding, fowls will do well a longer time on the grains fed whole than on any other rations. There are, however, two forms of the grains that are urged to be used freely, namely, common coarse bran constantly in boxes, dry, where the fowls, young and old, can get all they will eat of it, and ground oats. This last should be fed mixed with bran for the middle-of-the-day feed — the only time that it is advisable to feed soft, wet food.

(b) **The Greens.**— The hen at liberty, or in a state of nature, in summer consumes a large quantity of green, succulent food — clover, white clover, alfalfa, lawn-grass, plantain and a score of other forms of greenness will be found in her full crop as she comes up to the perch at night. On such a ration, together with the grains she picks up, she does her best at the egg-basket, or puts on good flesh the most rapidly. This should teach us, therefore, what to supply her in the cold weather if we wish her to do then the work of summer. We must supply these green things to her. Cabbages and mangel wurtzels, one each hung in her pen, are good. Clover and alfalfa, harvested before the stalks have become woody, cut into short lengths, steamed or wet with hot water, and then dried out in part with the bran or chopped oats — this is the most dependable of all green foods in winter.

(c) **The Meats.**—“As full as an egg is of meat” is an old-time proverb. The white of an egg is largely albumen, and this is best supplied to the laying hen in some form of meat. The hen at liberty gets many a bug and worm. The hen in confinement must have these supplied if she is to produce eggs. The growing and fattening fowl also needs the meat in some form.

Avoid as far as possible the meat-meals of the trade, of uncertain origin and quite likely to be adulterated. Use the coarse granulated beef-scraps whose contents can generally be discovered. These, having been prepared by steam cooking, keep well in any climate. Add to these an abundant supply of clean-cut bone and the combination is cheaper, richer and better than even the ground bone obtained by grinding fresh bones secured from the butcher.

(d) **Fattening Fowls.**— Where it is desired to quickly finish either young or old birds for the market, the crate-fattening process has no equal. Two birds are confined to a slatted coop two feet each way, and, for convenience in handling the droppings, the bottoms are slatted also. The most successful food is some skim milk or buttermilk, thickened to the consistency of batter with finely ground and sifted oats. Feed in a small trough in front of the coop all the birds will consume in 20 minutes, then remove the trough, returning it clean for the next feeding. Some give an occasional feed of grit and cut bone with advantage. Three weeks is as long as birds can be fed by this method; in that time many will gain 40 per cent, some 50 per cent. The improvement in the quality of the flesh is as noticeable as is the increase in quantity. To advance a cockerel weighing three and one-half pounds and worth 10 cents per pound, to one weighing five pounds, worth 15 cents per pound, in three weeks, at a food cost of eight cents, is to almost double one's investment, and many are doing this very thing. The yellow-skinned bird takes on a quality of flesh well distributed and having the white skin and white flesh so much desired by epicures.

Ration for Fattening Poultry.

The following fattening rations are recommended by the Cornell Department of Poultry Husbandry:

Ration with Milk.— 50 pounds corn meal; 20 pounds white wheat middlings; 10 pounds ground heavy oats. Mixed to a batter fresh at each feeding with buttermilk or skim milk. Will require approximately 1 quart (2 pounds) milk to 1 quart (1 pound) feed.

Ration with Meat Scrap.— 50 pounds corn meal; 20 pounds white wheat middlings; 10 pounds ground heavy oats; 20 pounds meat scrap. Mixed to a batter fresh at each feeding with water. Will require approximately 1½ quarts (3 pounds) water to 2 quarts (2 pounds) feed.

Methods and Practice.— *The Stock:* Rations recommended for both young and old stock. Birds "off condition" or of low vitality cannot be profitably fattened. Before putting in crates grease for lice below vent and under wings with equal parts of vaseline and "one-third strength blue ointment." *The quarters* must be clean. Mite-free quarters are necessary to ensure keen appetites — the keynote of successful fattening.

Crate Fattening.— Construct the crates 36 inches by 20 inches high of slats, using false bottoms of one-inch mesh wire poultry netting and suspend trough outside. The capacity of this crate is 6 to 8 fowls or 10 to 12 broilers, determined by the number that can eat from trough at once. Locate crates in comfortable temperature — outside in shade or open shed for summer use and in reasonably warm house for fall and winter.

Pen Fattening.— For best results limit flock to 20 or 30 birds, allowing two square feet of floor space per bird. To prevent dirt and waste feed in troughs so built that the birds cannot walk in them. The milk ration is to be preferred where milk is available or can be bought at a price not to exceed 45 cents per 40-quart can (55 cents per hundred weight). Feed all they will clean up readily twice daily for about two weeks, which is usually as long as fowls will "stand up" under such heavy feeding. Broilers may be held longer, especially in the case of pen-fattening, when they should be fed grain in the litter at noon. Birds should not be fed for the first 24 hours so they will eat the new ration greedily. Omit one feeding if at any time birds go "off feed"; clean pails and troughs will help to avoid this. Grit, shell, green feed and water are unnecessary except in hot weather when milk or water may be given at noon.

(e) **The Secret of Successful Feeding.**— To put it in a word, it is variety. Whether feeding for eggs or for growth, your aim must be to have the fowl consume and assimilate the largest possible quantity of food and then convert and manufacture this into eggs or flesh. With the hen as with the dairy cow, the individual with the best digestive apparatus is the one you can feed most profitably, and you must constantly cater to her appetite; when she gets tired of one thing, have something else more appetizing to tempt her to eat more of it.

The Necessary Equipment.

(a) **Houses.**— We have already intimated that the houses must be clean and comfortable. In order to be comfortable they need not be made warm with artificial heat. Fowls will endure intense cold if it is dry cold. Their bodies generate enough heat, if properly conserved, to keep them comfortable through the danger period — the night time. In the day they should have an opportunity to exercise and make their blood circulate in scratching in the litter on the floor for their grain ration.

The simplest and best houses are usually about 12 feet wide and of any length desired so as to be divided into compartments each 12 feet square. The rear posts are four and one-half feet high, the front posts five and one-half feet high, the rear rafter nine feet long, and the front rafters five feet long. This makes a house low at the back and only seven feet high at the apex of the rafters, which is about two-thirds of the distance from the rear to the front.

When the rafters are set, sheeting boards are put on the back and roof lengthwise. Over these the best quality of three-ply tarred paper is placed, running from the ground at the rear to the front eaves. This, if treated to a coat of hot gas tar, twice the first year and once each year thereafter, will last for a dozen years or more, and it will be a house "air-tight at the back." The front and ends may be covered with finished weather-boarding and painted, but if so the ends should be lined with the tarred paper.

Be sure that the house is only four and one-half feet high at the back. Build the dropping-boards three and one-half feet wide, exactly half way between the floor and the roof. Use 2 × 4-inch scantling, flat side up, and running lengthwise of the house, for perches. These, if placed six inches above the dropping-boards, will place your fowls at night 10 feet distance from the front or cold portion of the house and will give them a very limited space overhead, so the warmth of their bodies will not be scattered but will be retained where it will keep most combs from freezing in the coldest weather.

Put one window in the front of each compartment. Do not be too lavish of glass. It radiates the heat and makes the house cold at night. A window $2\frac{1}{2} \times 4\frac{1}{2}$ feet is large enough. If hung on hinges, it serves as a door through which one can step out from each compartment into its corresponding yard in front. A small exit hole, 8×14 inches, in the front for the use of the fowls makes sufficient ventilation in winter. In April the glass hinged windows may be removed and replaced until November or later with wire-screening doors.

All nest boxes, feed boxes, etc., should be attached to the front and sides of each compartment, one and one-half feet above the floor, so as to leave the entire floor area for scratching room for the fowls.

Each compartment being 12×12 feet, and each hen requiring a floor area of six square feet in order that she may have sufficient room for healthful exercise, it will be readily seen that 24 hens is the proper number of occupants for each compartment. A house of this kind, 120 feet long, divided into 10 compartments, holding 240 hens, should not cost more than $480, or $2 per hen. Do not be deluded into the idea of making the walls double and stuffing the space between with straw or sawdust. The thin walls, if made air-tight as directed, are better in every respect and the house will be dryer and more wholesome.

(b) **Incubators and Brooders.**— Better buy these from those who have learned how to make them. There are a dozen good incubators on the market. Purchase the one that seems to you simplest and best. After some experience you may learn to make large box brooders out of discarded piano boxes that will save you some money, and give greater area for the chicks than the brooders you buy. Those of the writer are $5\frac{1}{2} \times 5\frac{1}{2}$ feet, two feet high at the back, three and one-half feet high at the front, with a 2×3 feet window in the front. They are built on 12-inch plank set edgewise for a foundation, thus allowing room for the lamp-box underneath the back. When chicks no longer need artificial heat, the heating apparatus may be removed and this brooder used as a colony house for the youngsters until cold weather.

THE PROFIT OF THE INDUSTRY.

This must depend largely upon the intelligence, skill, energy and location of the operator. On farms the cost of food seldom exceeds $1.25 per hen per year. Where everything is bought, in most localities it need not exceed $2.25 per hen. It is a poor class of hens that cannot be made to average 120 eggs each, and it is a poor manager, anywhere east of the Missouri River, who cannot realize three cents each for those eggs. Deducting food cost of $1.25 the returns for labor and investment are $2.35 per hen. Many are averaging 180 eggs per hen and receiving four or more cents each for the eggs, which brings the income on the egg business up to approximately $5 per hen.

The best poulterers are combining the branches of the industry by raising pure-bred birds of some variety popular and saleable. They sell most of their surplus eggs for hatching during February, March, April and May, the price they realize varying with their reputations, from five cents to $1.00 per egg.

Their next sales are from the cull male birds of their early hatchings. These go for broilers, at from 75 cents to $1.50 each, from April to July. The early hatched chicks at one pound each bring more than those three times as large but later, in the Eastern cities.

The early hatched pullets become egg-producers by August and September, just in time to replace the hens that have quit laying on account of the molting. The choicest of both sexes are reserved for breeding, show or sale purposes and bring fancy prices. It is no unusual return for such a fancier to have an income of from $5 to $10 for every hen that he starts the year with, before that year closes.

For bibliography see article POULTRY; also consult Valentine, C. S., 'The Beginner in Poultry' 1912; id., 'How to Keep Hens for Profit' (1910).

POUNCE (a corruption of pumice), cuttlefish bone or gum sandarach. The resin of the sandarach tree, ground very fine, was used formerly to prevent the spreading of ink on the surface of vellum, parchment or paper where it had been roughened by erasures. In a more general way the term pounce was also used, previous to the invention of blotting paper, for the finely ground black sand which was generally used for the purpose of drying ink. The container in which this sand was kept and which was to be found on every writing desk was known under the name "pounce box" or "pouncet box." Finely powdered gum of the juniper tree or pipe clay, darkened by an admixture of charcoal, is also known as pounce when used for the purpose of transferring designs from the original to some other material. This is accomplished by punching small holes along the outline of the original design and shaking through these openings the darkened pounce which will fall thereby on the material onto which the design is to be transferred in such a manner that the original design can easily be traced in its complete form by means of a pencil, brush or similar instrument.

POUND, Ezra Loomis, American poet: b. Hailey, Idaho, 30 Oct. 1885. He was educated at Hamilton College and at the University of Pennsylvania. He later traveled in Spain, Italy and Provence, engaged in literary studies. He became known for his verse and has also produced several translations and some prose work. He was literary executor for Ernest Fenollosa's work on Japanese classical drama and on Japanese and Chinese poetry. He has contributed to the *Fortnightly Review*, the *Quarterly Review*, *Blast* and other publications, and makes his home in London, England. Author of, verse, 'Personæ' (1909); 'Exultations' (1909); 'Ripostes' (1912); 'Cathay' (1915); 'Lustra' (1916), etc.; prose, 'The Spirit of Romance' (1910); 'Gaudier Brzesha' (1916). His translations include 'The Sonnets and Ballads of Guido Cavalcanti' (1912–13); 'Certain Noble Plays of Japan' (1916). He edited 'The Catholic Anthology' (1915).

POUND, Roscoe, American college professor: b. Lincoln, Neb., 27 Oct. 1870. He was graduated at the University of Nebraska in 1888 and later studied at the Harvard Law

School. He was admitted to the bar in 1890 and engaged in practice at Lincoln, Neb. He was assistant professor of law at the University of Nebraska in 1899–1903, and dean of the law faculty there in 1903–07. He was professor of law at the Northwestern University in 1907–09 and at the University of Chicago in 1909–10. He was Story professor of law at Harvard in 1910–13, and has since been Carter professor of jurisprudence there. He was commissioner of appeals of the Supreme Court of Nebraska in 1901–03; and commissioner from Nebraska on uniform State laws in 1904–07. He was president of the Association of American Law Schools in 1911. Author of 'Readings on the History and System of the Common Law' (1904); 'Readings on Roman Law' (1906); 'Lectures on the Philosophy of Freemasonry' (1915), etc.

POUND, (1) an English weight of two different donominations, *avoirdupois* and *troy*. Since 1856 the legal original standard weight in Great Britain and her colonies has been the imperial pound avoirdupois, a cylindrical mass of platinum, grooved near the top and bearing the mark «P. S. 1844 1 lb.,» the two letters P. S. signifying «Parliamentary Standard.» The pound troy in Great Britain is defined as 5,760 grains and is divided into 12 ounces, being used almost entirely for weighing gold, silver and precious stones; the pound avoirdupois contains 7,000 grains, divided into 16 ounces, and is used for all ordinary commodities. The imperial standard troy pound constructed in 1758 was the only legal original standard weight between the years 1824 and 1856, but previous to these years certain weights, both troy and avoirdupois, had been the standards. These standards were not very accurately constructed, and through constant use became worn, but the pound avoirdupois probably contained as much as 7,002 of our present grains, while the pound troy weighed 5,759 grains. In the United States the British imperial pound avoirdupois has been copied to a great extent, but in theory the pound avoirdupois of Elizabeth is legal in this country. Edward III, from evidence in the official records, made the pound avoirdupois the standard, and Elizabeth probably copied her standard from his 56-pound weight, although standards had existed since 1497. The troy pound derives its name from the city of Troyes, where it was used as the standard of weight in the fairs held in that city. In 1497 it was made the legal weight for gold and silver and some authorities claim it was also used for bread, being known as the «old commercial weight of England,» and containing 7,600 grains. This troy pound displaced the monetary pound which had been in use from the times of the Saxons, and which contained 5,400 or 5,420 grains and was divided into 12 ounces or 20 shillings. At about the same time the merchant's pound containing 6,775 grains, divided into 15 ounces, came into considerable use. The apothecaries' pound is now obsolete. (2) Pound is also the highest monetary denomination used in British accounts, being equivalent to 20 shillings or 240 pence, and originally to a pound weight of silver (or of the alloy used). The pound (£) weighs 123.274 grains and contains 113.001 grains of fine gold. In the use of pound as designating money, the epithet *sterling* is generally affixed to discriminate from the pound weight. (See WEIGHTS AND MEASURES). (3) In law, an enclosed space for keeping cattle which have strayed on another man's ground, until they are replevined or redeemed. When cattle are put into pound it falls to the person impounding them to feed them, but he is entitled to charge the owner of the cattle the cost of keeping them in settling with him for the amount of damages to be paid. In England, an attempt to release from a pound cattle lawfully impounded is punishable by a fine. In Scotland the seizing of stray cattle and keeping them till damages are paid is called poinding of cattle.

POUND-NET FISHING, any fishing which is conducted by means of fixed enclosures of considerable size into which the fish are led by suitable guides, and within which they are confined by appropriate devices. Under this head will be included the pound-nets proper and trap-nets, as well as the simpler forms of weirs, which together constitute a class of automatic fishing gear quite distinct from the various forms of seines, gill-nets, etc., on the one hand, and the small fish-traps, baskets and eel-pots on the other. Devices of this sort are employed in the prosecution of the fisheries in many parts of the world, but the method, although not originating in the United States, has here been more highly elaborated and is more characteristic of our fisheries than elsewhere. The precise form and construction of pound-nets varies greatly in different localities, owing to the necessity of adapting it to local conditions of bottom, tides, currents, the kind and number of the fish sought, the available capital, resourcefulness of the fishermen, etc. The terms weir and pound in connection with the fisheries are to a great extent used interchangeably, according to local custom. The chief distinction between a weir and a pound-net seems to lie in the character of the enclosure within which the fish are confined. In the former this is more fixed and has no bottom which can be lifted; in the latter the pound is a netting bag which can be raised to the surface.

The most primitive apparatus of this sort in use in the United States is represented by the brush weirs employed in the herring fisheries of Maine and Canada. These consist of brush walls constructed of stout stakes driven into the bottom to a distance of about six feet and three feet apart. Between these brush, preferably of cedar or spruce for the bottom course, is woven in and out and held firmly in place by smaller stakes placed on the outside and bound to the large body-stakes. Toward the top a looser construction is adopted and the brush is placed vertically, as being less liable to be carried away by the current. Sometimes the brush is constructed in sections ashore and subsequently attached to stakes driven in the proper positions. This has the advantage that the brush sections can be removed and saved at the close of the fishing season, whereas the ordinary weirs, with the exception of such brush as can be removed from the tops, are likely to be totally destroyed by the winter's storms. When weirs are located on a bottom of solid rock into which no stakes can be driven, recourse is had to the construction of a platform of solid plank, which serves as a bottom to which the poles are fastened.

The whole is heavily weighted and held in place by loading it with stones.

A pound-net in the more restricted sense of the term is constructed entirely of cordage netting, supported and held in place by stakes, and consists of three essential parts; the pound or bowl, the wings and the leader. The pound is located off-shore, usually in from two to four fathoms of water and consists of a bag of very stout netting of about one inch mesh, the margin of which is supported above the level of the water by stout upright stakes driven into the bottom at suitable intervals which vary with the character of the ground and the force of the waves and currents. Where the bottom is rocky further security is found by the attachment of anchored guy ropes to some of the stakes. The only opening in the pound is the slit-like entrance, usually about six feet across, on the inshore side. At this point the walls of the net are carried inward, in order to render the opening less conspicuous from the inside, and are so arranged that by means of suitable ropes they may be used to close the opening when the net is drawn. The bottom of the pound is spread and secured by means of ropes which pass through loops or pulleys near the bottom of the stakes.

The wings are vertical fences of netting, diverging from the entrance to the pound and having a length of 100 feet or more. The ends directed toward the shore are carried toward one another in the form of a semi-circle, but leaving a wide opening between the two wings. The netting of which the wings are constructed is lighter than that forming the pound, and of about one and one-half inches mesh. It is supported by stakes and reaches from the bottom to the surface, the lower border being weighted with a heavy chain.

Any form of enclosure employed in the capture of fish may be called a trap, and trap-net is frequently used as an equivalent of pound-net. The best usage of the term, however, is to indicate those forms of pound-nets which are especially adapted to deep waters or a considerable tidal rise and fall by the attachment to the upper margin of the nets of floats which keep it always level with the surface. When surface-swimming fish only are sought, the parts which correspond to the leaders and wings of pound-nets frequently hang suspended above the bottom. The whole is of course held in position by a suitable system of ropes, anchors and moorings. This type of apparatus is an approach to the floating gill-net, the sets of which are often arranged in the form of leaders and enclosures. Much information relating to all phases of the use of pound-nets in the American fisheries will be found scattered through the ‘Annual Reports’ of the United States Bureau of Fisheries and of the commissions of the various States in which these fisheries are located, and especially in the ‘Fisheries Industries of the United States’ (Washington 1884–87).

POUNDAL. See FORCE; MECHANICS.

POURBUS, poor-büs, **Frans,** THE ELDER, Flemish painter: b. Bruges, 1545; d. Antwerp, 19 Sept. 1581. He was a pupil of his father Pieter, the Younger, and of Frans Floris, and became a free master of the Guild of Saint Luke at Antwerp in 1564. He died of a malignant fever caught in the guard house of the civic guard of which he was standard bearer. His wife, the daughter of Frans Floris, married Jordaens, the painter, after the death of Pourbus. He painted historical subjects, landscapes, animals and portraits; in the last-named department his work is best known. Several religious subjects are to be found in the cathedral of Ghent and in churches of Antwerp and Oudenarde. Other works by him are in museums of Antwerp, Berlin, Brussels, Ghent, Petrograd and Vienna.

POURBUS, Frans (THE YOUNGER), Flemish painter: b. Antwerp, 1569; d. Paris, 1622. He was a pupil of his father Frans Pourbus, the Elder, and doubtless studied with others, for his father died when he was 12. He was a free master of the Guild of Saint Luke in 1591. After 1600 he resided at Brussels, then in Italy at the court of the Duke of Mantua, and after 1610 was court painter to Henry IV of France. Of the latter monarch he painted several portraits; he painted also Marie de' Medici, the Louvre portrait of the queen being accounted his greatest work. Works by him are to be found in museums at Hampton Court, Madrid, Munich, Paris, The Hague and Vienna. His portraits are inferior to those of his father in warmth of color.

POURBUS, Pieter, THE ELDER, Flemish painter: b. probably Gouda, 1463. He is supposed to be the father of Pieter the Younger and grandfather of Frans the Elder. A portrait of a goldsmith, now at Vienna, is assigned to him.

POURBUS, Pieter (THE YOUNGER), Flemish painter: b. probably Gouda, 1510 or 1513; d. Bruges, 1584. He was a pupil of his father and probably of Lancelot Blondeel whose daughter he married. In 1540 he entered the Serment des Arbaletriers de S. George and in 1543 became a free master of the Guild of Saint Luke, of which he was «doyen» in 1569 and 1580. As he did not buy his citizenship at Bruges it is argued that his father may have moved thither from Gouda before his birth. He worked as decorator and surveyor, having remarkable gifts as a geometrician; but he is known chiefly as a portrait painter. His portrait of Dr. Ambroise Paré is owned by the New York Historical Society. Other works by him are in churches of Antwerp and Bruges and in museums of Brussels, Paris, Rotterdam and Vienna.

POURTALÈS, poor'tą-läs', COUNT **(Graf) Friedrich von, German diplomat:** b. 24 Oct. 1853. He is descended from a noble French Huguenot family domiciled in Switzerland since the revocation of the Edict of Nantes. Three brothers were made Prussian counts in 1815, and members of the family have long served Germany in bureaucratic, military and diplomatic capacities. The subject of this sketch served as lieutenant of Hussars in the German army and was attached to the Foreign Office in 1880. After serving in secretarial positions in Vienna, at The Hague and Saint Petersburg (Petrograd), he became Ambassador to Holland in 1899, to Munich in 1902, and to Russia in 1907. In the last-mentioned post he handled the negotiations preceding the European War. He did not figure prominently in the diplomatic history of that war, though the British Ambassador in Petrograd telegraphed to Sir Edward Grey on 29 July 1914: "I fear that the German Ambassador will not help to smooth matters over, if he uses to his own government the same language as he did to me to-day."

POURTALÈS, Louis François de, Swiss-American naturalist: b. Neuchâtel, Switzerland, 4 March 1824; d. Beverly Farms, Mass., 17 July 1880. He studied engineering but turned to natural science; was a pupil of Louis Agassiz (q.v.), whom he assisted in 1840 in an exploration of Alpine glaciers; and in 1847 came with him to America, where the next year he entered the United States coast-survey. He was the first in this country to attempt deep-sea dredging. Among his important researches in this field were those conducted during the Hassler expedition from Massachusetts Bay to California by way of the Straits of Magellan. From 1854 until his resignation from the survey in 1873, he was in charge of the office and field work of the tidal division. His chief work was accomplished in marine zoology, and the large collections accumulated by him in connection with that subject were deposited in the Harvard museum of comparative zoology in which he was for a number of years an assistant, and as keeper of which he succeeded Agassiz in 1873. The genus *Pourtalesia* of sea-urchins was named after him. His writings include, besides articles in scientific journals and contributions to the survey reports, the following works among several published by the Cambridge museum: 'Contributions to the Fauna of the Gulf Stream at Great Depths' (1863–69); 'List of the Crinoids Obtained on the Coasts of Florida and Cuba in 1867–69' (1869); 'Deep-Sea Corals' (1871); 'The Zoological Results of the Hassler Expedition' (with A. Agassiz, 1874); 'Corals and Crinoids' (1878); a report on 'Corals and Antipatheria' (1880).

POUSHKIN. See PUSHKIN.

POUSSIN, poo-săṅ, **Gaspar,** Italian painter: b. Rome, 1613; d. there, 15 May 1675. He was the son of a Frenchman named Dughet, who had settled at Rome but in signing his etchings he Italianized the paternal name into Duche. When his sister married Nicolas Poussin he took the name of his brother-in-law, whose studio he entered as pupil. The standard landscape of his day was that of Claude Lorraine, but Poussin was not so conventionally classical but more true to the animalism of nature than his great rival, the transparent lucidity of whose aerial perspective he never attained to. As he painted on a red background his pictures have so darkened by age that it is hard to imagine their effect when first produced. It can, however, be seen that he discerned the true lines of a landscape; that he composed with natural grace his groups of forest trees and antique ruins; and that his land storms, in which the trees seem to quiver and bend, are genuine transcripts from tempest-harried plain and mountain. He was imitated by many painters of his day. The best of his pictures are at Rome. They are painted in tempera or oil, and examples of both styles may be seen in the Palazzi Doria, Colonna Barberini, Borghese and Corsini and in the gallery of the Accademia di San Luca. At Rome he executed the frescoes 'History of Elijah and Elisha' in the church of San Martino a' Monti. There are pictures of his to be found in the galleries of Paris, Petrograd, Florence, Munich, Stockholm, Vienna, London, Madrid and Dresden, and a great number are scattered through the private galleries of England and through the public galleries of many small European cities. He was one of the most prolific and finished painters of his time so that to-day more than 200 of his pictures are to be found in various European galleries and collections. Two of his landscapes are in the New York Metropolitan Museum of Art.

POUSSIN, Nicolas, French painter: b. Les Andelys, Normandy, 15 June 1593; d. Rome, 19 Nov. 1665. He studied first in his native place, and then at Paris. He had already acquired considerable reputation when, in 1624, he went to Italy, where at Rome, Marini, the poet, inspired him with a taste for the Italian poets, in whose works Poussin found many subjects for his art. After the death of Marini (1625), though left without patronage, he continued the study of geometry, perspective, architecture, anatomy, as well as the practice of his art. His conversation, his walks, his readings were also almost always connected with it. He copied antiques, modeled statues and reliefs, diligently painted from nature; and all his works show the results of this study. At last he was attacked by an illness brought on by his labors. He was, however, taken care of by a Frenchman, Jacques Dughet, the father of Gaspar Poussin (q.v.). In 1630 Poussin married the daughter of his benefactor. About this time his affairs began to improve. He found patrons in Cardinal Barberini and the Cavaliere Cassiano del Pozzo, for whom he painted the celebrated 'Seven Sacraments.' These works likewise gained him celebrity in France; and Cardinal Richelieu invited him to Paris to paint the great gallery of the Louvre. Louis XIII appointed him his first painter, with a pension of 3,000 livres. Poussin arrived in Paris in 1640, and executed numerous works, particularly historical pieces from the Old Testament, but was much harassed by his enemies. The painter Jacques Fouquières had been employed to decorate the gallery and the architect Mercier had overloaded it with ornament. Poussin found himself under the necessity of removing their labors. He also had to contend with the whole school of Simon Vouet. Harassed on every side he determined to leave Paris. In September 1642 while employed on cartoons of the 'Labors of Hercules' for the gallery of the Louvre, he returned to Rome (ostensibly for the purpose of bringing his wife to France) and never again quitted that city. The second period of his life in Rome was even more productive than the first. Many of his works were the result of orders that came to him from admirers in Paris, especially from de Chantelou, an influential courtier, for whom he painted, between 1644 and 1648, a second series of 'The Seven Sacraments.' As a painter his drawing is remarkably correct; his composition dignified and noble; his invention rich; his style grand and heroic. His expression approaches that of Raphael, and he has been called the Raphael of France. He has been censured for a too studied arrangement and a too great propensity to episodes; too much uniformity in the attitudes, air and expression of his figures; an excessive fulness in the drapery and too small proportions in his figures — faults which may have been owing to his close imitation of the ancients. But notwithstanding these faults Poussin may be compared with the greatest Italian masters. Among his most celebrated works are 'Seven Sacraments'; 'Deluge'; 'Death of Germanicus'; 'Capture of Jerusalem'; 'Plague of the Philistines'; 'Rebecca'; 'The Adulteress'; 'The Infant Moses'; 'Moses bringing Water from the Rock'; 'The Worship of the Golden Calf'; 'John Baptizing in the Wilderness,' etc., and many fine landscapes. The largest collection of Poussin's works is to be found in Paris, the Louvre alone containing 39. London, too, holds many of his paintings, and practically every one of the more important European galleries owns specimens of his work. Only comparatively few, however, have remained in Rome. Three of his pictures may be seen in the New York Metropolitan Museum of Art.

POUT, or HORNED POUT. See BULLHEADS.

POUTER, a variety of fancy pigeon, the chief character of which is its projecting highly inflatable breast. See PIGEON.

POUTRINCOURT, Jean de Biencourt. See BIENCOURT DE POUTRINCOURT, JEAN.

POW-WOW, an American Indian term meaning (1) a ceremony, with conjurations, held for the curing of diseases; (2) a consultation of chiefs or leaders; a deliberation over important tribal matters. In colloquial use pow-wow is used in American politics as applied to any noisy meeting or gathering.

POWDER, a general name applied to explosive as gunpowder, giant powder, etc. See EXPLOSIVES.

POWDER-DOWN FEATHERS. See PLUMAGE.

POWDERLY, Terence Vincent, American labor leader and lawyer: b. Carbondale, Pa., 22 Jan. 1849. His early education was obtained in the public schools and he then (1862) became a railroad switch tender. At 17 he became a machinist's apprentice, settled in Scranton, Pa., in 1866, and there worked as a machinist until 1877. He was elected mayor of that city on the labor ticket in 1877 and re-elected in 1880 and 1882. He was General Master-Workman of the Knights of Labor in 1879–93, but resigning in the last-named year took up the study of law and was admitted to the bar of Lackawanna County in 1894, and in 1901 to that of the Supreme Court of the United States. He was United States commissioner-general of immigration 1897–1902, special representative of the Department of Commerce and Labor to study causes of emigration from Europe 1906 and since 1907 has been Chief of Division of Information in Bureau of Immigration to distribute immigrants throughout the United States. He has lectured frequently, made many Republican campaign speeches in 1896 and 1900 and published 'Thirty Years of Labor 1858–89' (1899–1900); 'History of Labor Day'; and articles on economics in numerous magazines. In collaboration with S. C. T. Dodd he published 'Trusts' (1892) and also contributed with others to 'The Labor Movement' (1887).

POWELL, Baden, English Anglican clergyman and mathematician: b. Stamford Hill, London, 22 Aug. 1796; d. London, 11 June 1860. He was graduated from Oriel College, Oxford, in 1817, took orders in the English Church and became vicar of Plumstead, Kent, in 1821. He was elected a Fellow of the Royal Society in 1824, and in 1827 was appointed Savilian professor of geometry at Oxford, on which occasion he resigned his living of Plumstead. He was the father of the famous English general, Sir Robert S. S. Baden-Powell (q.v.). He contributed many papers on optics, radiant heat and other physical subjects to the 'Philosophical Transactions'; and published a 'History of Natural Philosophy' (1834); but he is better known by his essay "On the Study of the Evidences of Christianity" (in 'Essays and Reviews,' 1860). Earlier theological works of a similarly liberal character are 'The Connexion of Natural and Divine Truth' (1838); 'Tradition Unveiled' (1839); 'The Unity of Worlds' (1855); 'The Study of Natural Theology' (1856); 'Christianity without Judaism' (1857); and 'The Order of Nature' (1859).

POWELL, Edward Payson, American Unitarian clergyman and author: b. Clinton, N. Y., 9 May 1833; d. Sorento, Fla., 14 May 1915. He was graduated from Hamilton College in his native town and from Union Theological Seminary, New York, in 1858. Entering the Congregational ministry he was pastor at Adrian, Mich., 1861–71, and of the Mayflower Congregational Church, Saint Louis, 1871–74. From 1874 to 1877 he held a Unitarian pastorate in Chicago and has since been editorially connected with secular and religious journals to which he has contributed numerous articles on outdoor life and kindred subjects. He has published 'Our Heredity from God' (1886); 'Liberty and Life' (1890); 'Nullification and Secession in the United States' (1896); 'Wind-breaks, Hedges and Shelters' (1900); 'The Country Home' (1904); 'In the Orchard and Fruit Garden' (1905); 'How to Live in the Country' (1910).

POWELL, Frederick York, English historian: b. London, 14 Jan. 1850; d. Oxford, 8 May 1904. He was educated at Rugby and

Christ Church, Oxford, and was appointed regius professor of modern history at Oxford, in 1894, succeeding Froude. He also acted as the University's delegate to the Clarendon Press. He was especially known as an Icelandic scholar. Together with Dr. Gudbrand Vigfússon he edited 'Icelandic Antiqua' (1876); 'Icelandic Prose Reader' (1881); 'Corpus Poeticum Boreale: The Poetry of the Old Northern Tongue from the Earliest Times to the Thirteenth Century' (1883); and 'Origines Islandicae' 1905. Although not possessing as great or as wide a reputation as some of his predecessors at Oxford, he was a scholar of deep learning and a man of broad sympathies. He was an extensive contributor to newspapers and journals on historical and literary subjects. He published a number of historical books, the most important of which are 'Early England up to the Norman Conquest' (1876); 'Old Stories from British History' (1882); 'History of England from the Earliest Times to the Death of Henry VII' (1885); 'The Tale of Throud of Gate' (1896); and 'Quatrains from Omar Khayyâm' (1901). He also acted as editor of 'English History by Contemporary Writers' (1887); and 'Scottish History by Contemporary Writers' (1890). Consult Elton, Oliver, 'Frederick York Powell' (Oxford 1906).

POWELL, John Wesley, American geologist: b. Mount Morris, N. Y., 24 March 1834; d. Haven, Maine, 23 Sept. 1902. He was educated at Illinois and Wheaton colleges, studied also at Oberlin and made researches in natural history and geology. At the outbreak of the Civil War he enlisted as a private in the 20th Illinois volunteers. As a result of a severe wound, suffered in the battle of Shiloh, he lost his right arm. At the expiration of his term of service in the spring of 1865 he returned to civil life, after having been promoted to the rank of major. In 1865 he was appointed professor of geology and curator of the museum at Illinois Wesleyan University at Bloomington, and in 1867 lecturer and curator at the State Normal University. He conducted in 1868 a perilous exploration of the grand canyon of the Colorado, and in 1870 took charge of the newly established geological and topographical survey of the Colorado River of the West. By this survey nearly 100,000 miles of the Colorado Valley were carefully explored. The work was subsequently transferred to the Interior Department. By 1874 there were four surveys in the field, and this led in 1879 to the establishment of the organization known as the United States Geological Survey, in the formation of which Powell was largely instrumental. From 1881 to 1894 he was director of the survey. He also made a particular study of American ethnology and obtained the organization of the Bureau of Ethnology, of which he was the director until his death and which he trained to a high plane of scientific efficiency. His studies of the Indians are deemed of great value. As administrator of the survey, which included also economic geology, geography and palæontology, he was very successful. Later in his life he devoted considerable attention to philosophy and psychology. He secured valuable legislation in connection with the land laws affecting the development of the arid West. In May 1918 a memorial in form of a stone altar supporting a bronze tablet engraved with a brief account of Powell's expedition to the Grand Canyon of Colorado was erected on the brink of the Grand Canyon in commemoration of the explorations accomplished by the expedition. Among his writings are 'Exploration of the Colorado River' (1875); 'Report on the Geology of the Uinta Mountains' (1876); 'Introduction to the Study of Indian Languages' (1877); 'Studies in Sociology' (1887); 'Indian Linguistic Families of America, North of Mexico' 1891); 'Canyons of the Colorado' (1895); 'Truth and Error; or the Science of Intellection' (1898); and 'First Through the Grand Canyon' (1915).

POWELL, Lyman Pierson, American college president: b. Farmington, Del., 21 Sept. 1866. He was educated at Johns Hopkins University and the University of Wisconsin and in 1893–95 he was a Fellow of the University of Pennsylvania. He was ordained deacon in the Protestant Episcopal Church in 1897 and priest in 1898; was rector at Landsdowne, Pa., in 1898–1903, and at Northampton, Mass., in 1901–12. In 1912 he became professor of business ethics at New York University and since 1913 he has been president of Hobart College and William Smith College. He edited 'American Historic Towns' (4 vols., 1898–1902); 'Current Religious Literature' (1902); 'Devotional Series' (3 vols., 1905–07); 'Religion in Our Colleges and Universities' (1912); and is author of 'The History of Education in Delaware' (1893); 'Family Prayers' (1905); 'Christian Science — the Faith and its Founder' (1907; 'Heavenly Heretics' (1910).

POWELL, Maud (MME. H. GODFREY TURNER), American violinist: b. Peru, Ill., 22 Aug. 1868. She received her musical education at Chicago, Leipzig, Paris and Berlin, studying under William Lewis, Henri Schradiech, Dancla and Joachim and made her début at Berlin in 1885. She was married to H. Godfrey Turner of London in 1904. She has been soloist with many great orchestras, including those of Thomas, Siedl, Gericke, Nikisch and Damrosch. She toured Germany and Austria with the New York Arion Society in 1892; the British Isles and European countries in 1899–1901, and in 1903–05; and also toured South Africa in 1905. Since 1903 she has appeared in America every musical season. She attained a high reputation and holds a large and appreciative following. She is noted for her interest in new compositions and in arousing her audiences to appreciation of them, and she is likewise keenly on the elert for excellence in the work of American composers.

POWELL, William Byrd, American physician and cerebral physiologist: b. Bourbon County, Ky., 8 Jan. 1799; d. Henderson, Ky., 3 July 1867. He became noted by reason of his work, 'The Natural History of the Human Temperament' (1856), announcing the theory known as Powell's life-line, and his novel views concerning the results of marriage within near or prohibited degrees of consanguinity. He was graduated from Transylvania University, at Lexington, Ky., in 1820, and from the Transylvania Medical School in 1823. In 1835 he was appointed professor of chemistry in the Medical College of Louisiana, holding that position for several years. In 1843 he began a sojourn among the American Indians, adopting their dress and manners in order to study their habits, dispositions, longevity, etc., and secured the crania of many warriors and chiefs. In 1849 he organized at Memphis, Tenn., the Memphis Medical Institute, heading its department of cerebral physiology. He held a similar position in the Cincinnati Eclectic Medical Institute 1856–59. In 1865 he was made professor emeritus of cerebral physiology in the New York Eclectic Medical Institute. He bequeathed his head to his literary executor to be preserved with his collection of crania containing some 500 specimens. He was a member of many domestic and foreign scientific societies and a frequent contributor to medical journals. Beside 'The Natural History of the Human Temperament' (1856) he published 'Eclectic Treatise on the Diseases of Children' (1857); and, with Dr. Robert S. Newman, 'The Eclectic Practice of Medicine' (1857).

POWELSON, Wilfred Van Nest, American naval officer: b. Middletown, N. Y., 15 Sept. 1872. He was graduated from the United States Naval Academy in 1893 and was then sent by the government to study naval architecture at the University of Glasgow. While serving on the *Fern* at Key West he was ordered to pursue examinations regarding the destruction of the *Maine* in the harbor of Havana and his published report stating that the *Maine* was sunk by an exploded mine was much discussed by scientific periodicals. He was promoted lieutenant in March 1901 and retired in 1902. After becoming general manager of the Union Electric Light and Power Company of Saint Louis, Mo., in 1904, and president and treasurer in 1906, he has been, since 1908, a member of a New York firm of consulting engineers and managers of public utilities corporations.

POWER, Frederick Belding, American chemist: b. Hudson, N. Y., 4 March 1853. He was graduated at the Philadelphia College of Pharmacy in 1874 and at the University of Strassburg in 1880. He was professor of analytical chemistry at the Philadelphia College of Pharmacy in 1881–83; professor of pharmacy and materia medica at the University of Wisconsin in 1883–92; director of the laboratories of Fritzsche Brothers in 1892–96; and in 1896–1914 was director at the Wellcome Chemical Research Laboratories, London, England. He was awarded the Ebert Prize of the American Pharmaceutical Association in 1887, 1902 and 1906; and received gold medals at the Saint Louis Exposition, 1904, at Milan in 1906, at the Franco-British Exposition in 1908; grand prize at Brussels in 1910; the gold medal at Turin in 1911, and the Hamburg gold medal in 1913. He was a member of the Committee of Revision of the United States Pharmacopœia in 1890; and United States delegate to the International Congress for the Unification of the Formulæ of Potent Medicaments at Brussels in 1902. With Dr. Fred Hoffmann he edited 'Manual of Chemical Analysis' (1883).

POWER (William Grattan), Tyrone, Irish actor: b. near Kilmacthomas, County Waterford, 1795; lost at sea, 1841. He made his début as Orlando in 'As You Like It' in 1811 at Monmouth, Wales. In 1822 he appeared in London, where he made a hit as Larry Hooligan O'Halloran in 1824, and henceforth devoted himself to impersonations of Irish characters in which he was inimitable. He visited the United States in 1833, 1836 and in 1840, and in 1841 embarked for Europe on the *President*, which was never heard of. He published two novels, 'The King's Secret' and 'The Lost Heir'; a number of plays; and 'Impressions of America' (1836). Consult Winter, William, 'Tyrone Power' (New York 1913).

POWER, *in arithmetic*, and in the algebra of real numbers, the product obtained by multiplying a given number by itself a specified number of times. If x is the given number, and n is the number of times that x is taken as a factor in forming the product, then the product that is finally obtained is

$$x \times x \times x \times \quad . \quad . \quad . \quad . \quad \times x \times x \times x$$
$$(n \text{ factors altogether})$$

This is called the "nth power" of the number x, and is represented by the symbol x^n. Assuming for the moment that n (which is called the "exponent" of the power) is positive and integral (since this is the only case in which the foregoing definition is applicable), we easily obtain the following general laws which the powers of numbers must fulfil:
x^{m+n}; $(x^m)^n = x^{mn}$; $(xy)^n = x^n y^n$. To extend the conception of a "power" so as to permit of the use of fractional and negative exponents, we may assume that the foregoing laws hold true of all real exponents, and from them we may seek the interpretations that must be given to an expression of the form x^n, when n is fractional or negative. First, if we make $m = 0$ in the equation $x^m . x^n = x^{m+n}$ we have $x^0 . x^n = x^n$; and hence we conclude that the symbol x^0 must be interpreted as representing unity in all cases. Again, if we make $n = -m$, we have, from the first of the general relations given above, $x^m . x^{-m} = x^{m-m} = x^0 = 1$ and hence we must interpret the expression x^{-m} as signifying the reciprocal of x^m. We may ascertain the significance of a fractional exponent by means of the second general relation, above. Thus in the identity $(x^m)^n = x^{mn}$, let us put $m = 1$. Then we have $\left(\frac{1}{x^n}\right)^n = \frac{1}{x^n} = x^1 = x$. Hence $\frac{1}{x^n}$ must be interpreted as representing one of those quantities which, when raised to the nth power, will yield x itself. That is, we must interpret $\left(\frac{1}{x^n}\right)$ as equivalent to $\sqrt[n]{x}$. In general, this will be a many valued function. If x is real, $\sqrt[n]{x}$ is often interpreted as the positive real number which when raised to the nth power gives x. This is only one of the values of $\frac{1}{x^n}$. In a similar manner it is easily shown that the symol $\frac{m}{x^n}$ must be interpreted as equivalent to $\sqrt[m]{x^m}$.

The significance of a power. when the exponent is irrational or imaginary, is considered in the theory of functions, but these generalizations are too difficult for sound treatment in the present article. For this aspect of the subject, and for the discussion of the development of functions of a variable in a series whose terms are powers of that variable, consult Harkness and Morley, 'Introduction to the Theory of Analytic Functions' (London 1898).

POWER, *in mechanics and physics,* the rate at which work is performed; or (what is the same thing), the quantity of work that is performed *per unit of time.* In ordinary engineering practice in the United States and England, the unit of work is the "foot-pound;" a foot-pound being defined as the quantity of work that is performed when a force equal to the weight of one pound of matter is exerted through a distance of one foot. (See MECHANICS). Nothing is here specified, it will be observed, as to the *time* in which this work is done. A small motor, for example, might require 10 seconds to accomplish it, while a more powerful one might perform it in a very small fraction of one second. The work that is performed by a given motor or engine in one second, or in one minute, is therefore the true measure of the "power" that is being developed. James Watt adopted the "horse power" as the unit of power for steam engines and other large motors, and this has been universally adopted, since his time, in all English-speaking countries. He estimated that a strong horse is capable of performing 33,000 foot-pounds of work per minute; and although it is known that the horse cannot work continuously at this rate, his definition has never been modified, and in steam and hydraulic engineering a "horse power" is still understood to signify the performance of 33,000 foot-pounds of work per minute, or (what is the same thing) 550 foot-pounds per second. The horse power of an engine or a water-wheel is therefore determined by observing how many foot-pounds of work it is performing per minute, and dividing this number by 33,000. In the centimeter-gram-second system of units, which is in extensive and increasing use in modern physics, the unit of work is the "erg," and the unit of power is the "watt"; a watt being defined as the power that is developed when 10,000,000 (that is 10^7) ergs of work are performed per second. The watt is employed in practical electrical engineering, as well as in experimental physics; it being then defined as the rate at which work is being done in a circuit in which the current is one ampere, and the electromotive force is one volt. This change in definition is merely a matter of convenience, since it may be shown that the two definitions amount to precisely the same thing. A horse power is approximately equal to 746 watts. Consult Everett, 'Units and Physical Constants.' See also the article UNITS OF MEASUREMENT.

POWER, Utilization of. The economical production of manufactures and the convenient adaptations of time- and labor-saving devices in all the various lines of constructional work have exerted a wonderful influence in the upbuilding of American industries. Among other significant features the present tendency is marked by the adaptation of compressed air and the application of electric power to machine driving. In the use of compressed air, the facility of adaptation to various requirements which are in many cases additional to the supply of motive power, is a valuable feature peculiar to this system and one which is susceptible of extension along many lines. The labor cost in most machine shops and other works is so much greater than the cost of power that any expedient by which the labor cost may be appreciably reduced is justified, even though the efficiency of the agent itself be low. Whenever new methods or agencies cause an increased production with a given outlay for labor, these methods will supersede the old, even though the cost of the power required be greater than before. The saving of power is a consideration secondary to the advantages and economical output obtained by its use. While economy in the use of power should therefore be secondary to increased output, yet careful attention to details will often greatly reduce the useless waste of power. Engineers have recognized that there is a very great percentage of loss due to shaft friction, which, in railroad and other shops where the buildings are more or less scattered, may be as great as 75 or even 80 per cent of the total power used. In the ordinary machine shop this loss will probably average from 30 to 50 per cent. No matter how well a long line of shafting may have been erected, it soon loses its alignment and the power necessary to rotate it is increased.

Manufacturers are realizing the loss of power which ensues from the present system of mechanical transmission, and there is an increasing tendency to introduce different methods by which a part of this loss will be obviated. Among these are the adoption of hollow and lighter shafting, higher speeds and lighter pulleys, roller and ball bearings in shaft hangers, and the total or partial elimination of the shafting.

Subdivided Power.— Independent motors are often employed to drive sections of shafting and isolated machines, and among these are found steam and gas-engines, electric motors, compressed air and hydraulic motors, although the latter have not been used for this purpose to any appreciable extent. In the choice of motors, until quite recently the steam engine has generally been used, especially where the units are relatively large, but the advantages possessed by electric driving has caused the electric motor to displace the steam engine in many cases. An interesting example of this is noted in the Franklin Sugar Refining Company of Philadelphia, in which there were formerly some 90 Westinghouse engines about the works, many of them being of 75 and 100 horse power each; others of 5 and 10 horse power only. At the present time these have all been replaced with electric motors. A similar subdivided-power plant involving nearly 50 steam engines was erected some years ago at the Dunnell Print Works of the United States Finishing Company at Pawtucket, R. I. More recently many of the steam engines have been replaced by electric motors, but there are still 27 engines in use in this plant. It was not so many years ago that several large and economical Corliss engines were replaced at the Baldwin Locomotive Works by a greater number of small, simple-expansion engines, which actually required about 15 per cent more steam per horse-power hour than the Corliss engines. This loss, however, was only apparent, for by increasing the number of units and locating them at convenient centres of distribution much of the shafting and belting could be dispensed with and an actual saving of power was obtained. Later, the simple engines were replaced by a number of compounds, some 18 being in service and these showed a saving of 36 per cent over that obtained by the use of the simple engines. Subsequently, however, the electric motor (q.v.) has superseded the steam-engine for this work, as its economy and convenience over the latter are now thoroughly recognized.

Water Power.— It is estimated that there are available in this country about 61,000,000 water horse power that could be profitably utilized, of which it appears that only 6,500,000 horse power have been developed; that is, practically 54,000,000 water horse power is now going to waste. Nor does it seem likely that this power will soon be developed unless more satisfactory legislation be enacted which will afford a greater security and permit a better return to the investor in water-power development.

Electric Power.—The statistics of American manufacturing, compiled for the 1900 United States census, show that at that time electric power was less than 5 per cent of all that was in use in such plants, or about 500,000 horse power out of a total of 11,000,000. During the decade from 1899 to 1909 the total amount of primary power used in the industries throughout the United States has increased from 11,000,000 horse power to nearly 19,000,000, of which 76 per cent or a little over 14,000,000 horse power is derived from steam engines; the rest being distributed between water power, electric power and gas and internal combustion engine power. At the time of the last census there were in use in the industries nearly 5,000,000 horse power in electric motors, of which over 3,000,000 horse power, or 63 per cent, was generated by the particular establishment using the power. That is, 63 per cent of the electric power used in the industries is generated by the user, and 37 per cent is purchased. The introduction of electric power in machine shops and factories was at first looked upon with disfavor and was opposed by many manufacturers, but the innovation obtained a foothold, and advantages which were at first unforeseen were found to attend its use, so that now it is being very generally adopted for a wide variety of work. A considerable difference of opinion exists as to whether individual motors should be used with each machine, or whether a number of machines should be arranged in a group and driven from a short line shaft. There are well-defined conditions to which each system is best adapted, but there are wide limits between which there appears to be no general rule, and both methods are occupying the same field. For isolated machines and for heavy machines that may be in occasional use, the individual motor is particularly well adapted, as it consumes power only when in operation. It is, however, necessary that each motor thus connected shall be capable of supplying sufficient power to operate its machine under the heaviest as well as lightest loads. In certain cases, moreover, the load is liable to very great irregularity, as for instance in metal-working planers, in which the resistance offered by the machine at the moment of reversal of the platen is far higher than at other times, and may be so great as to endanger the armature of the motor. Under these conditions it is necessary to use a motor of much larger capacity than the average load would indicate. Ordinarily in machine driving the motor is shunt-wound, and the current through the field coils is constant under all conditions of load; but to obtain the best results with that class of machinery in which the load is intermittent and subject to sudden variations, the motor should be compound-wound so as to increase the torque without an excessive increase of current in the armature. In many cases with individual motors, owing to wide variations in power required, the average efficiency of the motor may be very low; for this reason a careful consideration of the conditions governing each case indicates that for ordinary machine-driving, especially with small machines, short lengths of light shafting may be frequently employed to good advantage, and the various machines, arranged in groups, may be driven from one motor. By this method fewer motors are required, and each may be so proportioned to the average load that it may run most of the time at its maximum efficiency. When short lengths of shafting are employed the alignment of any section is very little affected by local settling of beams or columns, and since a relatively small amount of power is transmitted by each section, the shaft may be reduced in size, thus decreasing the friction loss. Moreover, with this arrangement, as also with the independent motor, the machinery may often be placed to better advantage in order to suit a given process of manufacture; shafts may be placed at any angle without the usual complicated and often unsatisfactory devices, and setting-up room may be provided in any suitable location as required, without carrying long lines of shafting through space. This is an important consideration, for not only is the running expense reduced and the lighting increased thereby, but the clear head-room thus obtained, free from shafting, belts, ropes, pulleys and other power-transmitting devices can be more easily utilized for hoists and cranes, which have so largely come to be recognized as essential to economical manufacture.

Distribution.— In arranging such a system of power distribution the average power required to drive is of as much importance as the maximum, for in a properly arranged group system the motor capacity need not be the equivalent of the total maximum power required to operate the several machines in the group, but may be taken at some value less than the total, depending upon the number of the machines and the average period of operation. On the other hand, as already shown, the motor capacity of independently driven machines must not only equal the maximum power required to drive the machine at full load, but it must be capable of exerting a greatly increased momentary torque. In any case large units should be avoided, for the multiplication of machines driven from one motor entails additional shafting, counter-shafts and belting which may readily cause the transmission losses to be greater than those obtained with engines and shafting alone, besides frustrating some of the principal objects of this method of transmission.

As far as the efficiency of transmission is concerned, it is doubtful whether, in a large number of cases, motor-driving *per se* is any more efficient than well-arranged engines and shafting. The principal thing to be kept in mind is a desired increase in efficiency of the shop plant in turning out product, with a reduction in the time and labor items, without especial reference to the fuel items involved in the power production. On account of the subdivision of power which results from the use of many motors, there is less liability of interruption to manufacture, and in case of overtime it is not necessary to operate the whole works, with its usual heavy load of transmitting machinery. Another advantage is the adaptability to changes and extensions; new motors may always be added without affecting any already in operation, and the ease with which this system lends itself to varying the speed of different unit groups is a very potent factor in its favor. When power is delivered to the machine by direct connected motors, a serious difficulty is often experienced in obtaining speed variation, which is so necessary with a large proportion of the machines in common use. A certain amount of variation can be obtained by rheostatic control — a wasteful method; or by using a single voltage system with shunt field regulation; but the variation in either case is very limited. This, however, may be increased by using a double commutator if space will permit. The three-wire, 110–220-volt system, offers many advantages for both power and lighting systems, and is very frequently employed. Variations of speed may be obtained with this system by using a combination of field regulation with either voltage, and, in rarer cases, by the use of a double commutator motor. A method which has been used with considerable satisfaction involves the use of a three-wire generator, with collector rings connected to armature winding similar to that of a two-phase rotary converter. Balancing coils are used, and the middle points of these are connected to the third wire, which is thus maintained at a voltage half way between the outer wires. This system is simple and economical, and possesses all the advantages of the ordinary three-wire method; it permits similar variations in speed by field regulation with either voltage; and if still wider ranges are desired a double commutator motor may also be used.

In other installations the four-wire mutiple voltage system is used, which permits of very wide variations of speed in the operation of the tool. This system gives excellent results and removes one of the objections urged against direct-connected motor-driven tools, namely, that such machines are not sufficiently flexible in regard to speed variation, and that such variation can only be obtained by throwing in resistances which cut down the efficiency of the motor or by varying the strength of field which reduces the torque. The multiple voltage system, however, has some serious disadvantages. It cannot usually be operated from an outside source of power without rotary transformers; the generating sets and switchboard are complicated, and the total cost of installation is expensive; yet with these drawbacks the system is growing in favor, as it has manifest advantages which outweigh the objections. Storage battery power has been used to some extent to obtain multiple control and is suggestive of interesting possibilities, but in its present form it is not altogether desirable for this purpose. In many of the larger sizes of certain metal-cutting machines marked changes in design have taken place, and these machines are now built with direct-connected motors incorporated in them, possessing wide variations of speed and power.

Improvements in the manufacture of tool steel have shown indisputably that the older designs of machine tools are not sufficiently heavy to stand up to the work in order to obtain the economy of operation which results from the use of such steels. Higher speeds, heavier cuts and greater feeds may be obtained if the machines will stand the strain, but in most cases the capacity of the machine is not commensurate with the ability of the tool to remove metal. With cutting speeds of 100 to 200 feet per minute, it is evident that the power requirements will be much greater than for those machines which use ordinary carbon steel with cutting speeds of from 10 to 30 feet per minute. Here then is an interesting field for the direct-connected motor with ample power and speed variation for any work which it may be called upon to perform.

Compressed Air.—Reference has been made to the use of compressed air power, and its facility of adaptation to various requirements, but it is evident from an inspection of some of the devices in use that enthusiasm for new methods, rather than good judgment, has controlled in many of its applications. For some years compressed air was used only in mines, where it produced marked economics in underground work. Later, compressed air was introduced into manufacturing lines, and to-day its use in railroad and other machine shops, boiler shops, foundries and bridge works is being widely extended. In the Santa Fé Railroad shops at Topeka there are over five miles of pipe in which compressed air is carried to the different machines and labor-saving appliances throughout the works. In such shops air is used to operate riveting machines, punches, stay-bolt breakers, stay-bolt cutters, rotary tapping and drilling machines, flue rollers, rotary grinders, rotary saw for sawing car roofs, pneumatic hammers, chisels and caulking tools, flue welders, boring and valve-facing machines, rail saws, machine for revolving driving-wheels for setting valves, pneumatic painting and whitewashing machines, dusters for car seats and the operation of switching engines about the yard. It is also used in the foundry for pressing and ramming molds, and for cleaning castings by the sand blast; but its greatest field of usefulness lies in its application to hoisting and lifting operations in and about the works. More recently its use has been extended to include the sand blasting of steel passenger coaches. In mines, where exhaust steam or gas engine exhaust would interfere with proper ventilation, compressed-air engines and motors, which discharge pure air directly into the workings, are used for a variety of purposes, such as locomotive haulage, hoisting, pumping, cutting and drilling. Probably nothing has called wider attention to the possibilities of the use of compressed air than the recent installation of a system of compressed air deep-mine hoists in the Butte, Mont., mines. This is especially remarkable in view of the fact that the compressors are operated electrically from transmitted water power; it was found to be better to use electricity to operate compressors discharging into storage reservoirs from which the air passed through heaters on the way to hoisting engines than to operate the hoists electrically. One factor in this conclusion is the special construction of the engine, which as the cage descends operates as a compressor, storing air by the energy of the falling hoist, and acts as a brake at the same time.

New applications of compressed air are constantly being made, and each new use suggests another. This has a tendency to increase the number of appliances which are intended to be labor-saving devices, but in many cases the work could be done just as well and much more cheaply by hand. The success and economy which has attended the use of compressed air in so many lines of work has led to its adoption in fields which are much better covered by electrically operated machines. While compressed air has been used under certain conditions very satisfactorily to operate pumps and engines, printing-presses, individual motors for lathes, planers, slotters, dynamos and other work, it does not follow that it is always an economical agent under these various uses or that other methods could not be used even more satisfactorily. It has been proposed to use individual air motors in machine shops and do away with all line shafting, except possibly for some of the heavier machinery. This use of compressed air seems entirely outside the pale of its legitimate field; the general experience thus far indicates that rotary motors are not at all economical and generally are not as satisfactory as electric motors. Exceptions are to be found in the small portable motors for drilling and similar operations to which electricity is not so well adapted and where compressed air has been found to give excellent results. Although these tools are very successful, they are still rotary motors, not exempt from some of the objectionable features which seem to be inseparable from them. It is not surprising, therefore, to find a tendency to employ reciprocating pistons and cranks in these portable machines, and such tools are now in use weighing only 40 pounds capable of drilling up to two and a half inches diameter. In most cases no attempt has been made to use compressed air power efficiently; its great convenience and the economy produced by its displacement of hand labor have, until recently, been accepted as sufficient, and greater economies have not been sought.

In the matter of compression, very inefficient pumps are still in use, but manufacturers generally have found that it pays to use high-grade economical compressors. The greatest loss is that in the air motor itself. In a large number of cases it is impracticable or, at most, inconvenient to employ reheaters, and the air is used very generally at normal temperature for the various purposes to which it is applied. To obtain the most satisfactory results, the air must be used expansively, but usually where the demand for power is intermittent no attempt has been made to reheat the air, and as a result the combined efficiency of compressor and motor is quite low, varying in general from 20 to 50 per cent. While low-working pressures are more efficient than high, the use of such pressures would demand larger and heavier motors and other apparatus which is undesirable.

The advantages of higher pressures in reducing cost of transmission are also well recognized, and the present tendency is to use air at 100 to 150 pounds instead of the 60 or 70 pounds formerly used. By reheating the air to a temperature of about 300° F., which may often be accomplished at small expense, the efficiency is greatly increased; in some cases this has been shown to be as high as 80 per cent.

A remarkable development of compressed air power, in which very high compression is used, has recently been accomplished in the Porter compound compressed-air locomotive for use in mines, lumbering operations, powder works or other places where fire is much feared; also in hauling cars about the yards of large manufacturing plants, where cleanliness as well as avoidance of fire risk is important. In this case the air is stored in the locomotive tanks under a pressure of 800 pounds per square inch; this air thoroughly dried by the high compression then passes through a reducing valve, where it produces kinetic energy due to expansion, which it immediately loses by impact, thus avoiding temperature drop when falling from 800 to 250 pounds per square inch. At this pressure and practically atmospheric temperature the air is admitted to and expanded in the high-pressure cylinder of the locomotive, exhausting into the receiver at as low a temperature below atmosphere as practicable. Atmospheric air is blown through a series of tubes in the receiver, so that the working air takes up heat from the atmosphere and, subsequently expanding in the low-pressure cylinder, converts some of the atmospheric heat into work. This process is peculiarly interesting, in that it provides a means of reheating the working air directly from the atmospheric air and obtaining thereby an increase of 30 per cent in the economy.

While the lower pressures are in general more efficient, the loss due to higher compression is not serious. If the compressed air be used without expansion, it will be seen that there is a material loss in efficiency; but, on the other hand, if it be used expansively without reheating, trouble may be experienced, due to the drop in temperature below the freezing point. When moisture is present, this will cause the formation of ice, which may clog the passages if proper precautions are not taken to prevent it. The low temperature will not in itself cause trouble; if, therefore, the moisture which the compressed air holds in suspension be allowed to settle in a receiving tank, placed near the motor or other air apparatus and frequently drained, less trouble will be experienced from this cause. The greater adaptability of compressed air to various purposes causes its use to increase along with that of the electric motor, for it has a different field of usefulness, independent of power transmission; at the same time, when the requirements are properly observed in its production and use, its economy as a motive power in special cases compares favorably with other systems. But compressed air possesses so many advantages that, however inefficient it may be as a motive power, its application to shop processes will be continually extended as its usefulness becomes better known. See PNEUMATIC TOOLS.

Hydraulic Power.— Mention has been made of the use of hydraulic motors as a factor in the subdivision of power but these are being used to such a limited extent for this purpose that they will not be considered here. There is, however, a growing field of usefulness for hydraulic power in manufacturing operations which is peculiar to this agent alone, namely, its use in forging and similar work. Where hydraulic power exists for this purpose it is also generally used for a variety of work which could be accomplished just as well, and often more economically, by steam or compressed air; but in forging operations where heavy pressures are required hydraulic power is infinitely better than either. The compressibility of air is an objection in many lines of work, and it is now well recognized that the effect of a hammer blow is oftentimes merely local. As H. F. J. Porter has so ably shown, the pressure applied in forging a body of iron or steel should be sufficient in amount and of such a character as to penetrate to the centre and cause flowing throughout the mass; as this flowing of the metal requires a certain amount of time, the pressure should be maintained for a corresponding period. Hydraulic pressure, instead of a hammer, should, therefore, be used to work the metal into shape. Under its influence the forging is slowly acted upon and the pressure is distributed evenly throughout the mass, whereas under the high velocity of impact of the hammer the metal does not have time to flow, and thus internal strains are set up in the mass, which may cause serious results, especially with certain steels which have not the property of welding. Moreover the quality of the steel is very much improved by the processes of hydraulic forging. There exists at present a marked tendency to substitute this method in a wide variety of work in which presses are employed varying in capacity from 20 tons to 14,000 tons.

It is an interesting fact that the magnificent hammer, designed and built by the Bethlehem Steel Company, of a nominal capacity of 125 tons and an actual of 145 tons falling weight has been superseded by hydraulic presses for forging purposes. This hammer is no more in existence. The largest hammer at the Bethlehem plant to-day is a 10-ton hammer. Among the numerous hydraulic presses at Bethlehem under which forgings are made they have one of 14,000-ton capacity, operated by the world's largest land engine of 16,000 horse power.

The different hydraulic systems are as follows: (1) A pump or continuous intensifier using pressure corresponding to the resistance of the press. This pressure runs up to 7,000 pounds per square inch; (2) single stroke steam or air intensifiers where the hydraulic cylinder is filled with water, under a pressure of 2 to 50 pounds per square inch and then the pressure increased by means of the intensifier from 3,000 to 9,000 pounds per square inch.

The latest development at Bethlehem has been in high speed processes where the water is pumped, electrically, to an accumulator and from there used in the presses. This is the most economical. In presses of this nature, the cylinder is filled from a tank through a valve of very large dimensions (to date up to 16-inch in diameter) withstanding a pressure of 10,000 pounds per square inch. A water intensifier is then used; this may be one, two or three-pressure intensifier. The nominal pressure used in the lines for operating auxiliary parts of the press, together with the intensifier, is 2,500 pounds per square inch line pressure. A line pressure lower than this makes the machinery bulky and cumbersome and does not take advantage of modern steel construction, nor does it give high speed.

Any one of these presses will run up to 100 or more strokes per minute when needed. A press at Bethlehem has been tested up to 60 strokes of three feet length per minute. Most die forging presses are made of this last type. The speed of these presses may be understood when it is stated that as many as 10 projectiles are turned out per minute.

Presses are now built at the Bethlehem plant of 10,000 and more tons capacity for the manufacture of die forgings, such as car wheels, which may be produced at the rate of one a minute.

The high efficiency of the presses has chiefly been accomplished by means of the large valves and the high initial pressure in the lines, the cushioned accumulator, and the shifting tables (both in top and bottom platen). These have all been developed by the Bethlehem Company, which, at the present time, stands practically alone in the building of these enormous machines, a single one of which will weigh as much as 1,000 tons. All handling of pieces under these presses is done mechanically by hydraulic or electric power. The success which has attended the use of hydraulic power in forging is causing it to be applied to other and similar work to an increasing extent. In boiler works, railroad and locomotive shops, bridge works and shipyards it is used along with compressed air, but where heavy pressures are desired hydraulic power is greatly to be preferred; hence we find it operating machines for punching and shearing heavy plates and sectional beams, riveting machines, stationary and portable, flanging and bending machines, tube upsetting machines, wheel and crank-pin presses, lifting jacks and hoists of all kinds. For heavy boiler work hydraulic riveting seems especially well adapted, since an intensity of pressure can be brought to bear upon the plates which is obtained by no other method.

Transmission.— In the transmission of power by compressed air, within reasonable limits, the loss in transmission if the pipes be tight need not be considered, for although there is a slight loss in pressure due to the frictional resistances of the pipes, yet there is a corresponding increase in volume due to drop in pressure, so that the loss is practically inappreciable. It has already been stated that compressed air as now used without reheating is not at all efficient as a source of motive power, since the combined efficiency of compressor and motor, even under favorable conditions, is not more than 50 per cent of the available energy put into the compressor. In other cases the efficiency is as low as 20 per cent. There should be no comparison between the cost of power by compressed air and its brilliant rival, electricity, since each has its own field of usefulness. With a three-wire 220-volt-system, which is very suitable for ordinary shop transmission when both light and power are to be taken off the same circuit, the combined efficiency of generators and motors working intermittently with fluctuating loads will be about 60 per cent of the power delivered to the engine. For greater distances than those which obtain in plants of this character the loss in transmission will be greater, and higher voltage must be employed in order to keep down the line loss. While it is possible to put in conductors sufficiently large to carry the current with any assumed loss, yet the cost of the line may become prohibitive with low voltage. Where cheap fuel is available it is found in many cases that electric power can be generated at the works more cheaply than it can be purchased from a central station; especially is this the case if the exhaust steam be used for heating purposes. In isolated plants the cost of transmission is very small as compared with the total cost of generation; whereas in the average central station the cost of transmission, which includes interest and depreciation on pole line, may constitute a large percentage of the operating cost.

As already stated the last census shows that 63 per cent of the electric power used in the industries is generated by the user. In those localities where the cost of fuel is high, electric power can often be purchased more cheaply from a central station which possibly obtains its current from a water-power development many miles distant and transmits it electrically to a convenient distributing centre, where it is used for power and light. The recent advances in electrical transmission are very marked, and one constantly hears of some new achievement more wonderful than anything previously accomplished. Distances have been gradually increased until it is now not uncommon to transmit electrical energy economically and in commercial quantities up to 150 or 200 miles; in one recent case the transmission extends from the Sierras to Los Angeles, Cal., a distance of 240 miles.

If the available power cannot be utilized near at hand by centralizing the industries near the source, there is no reasonable limit to the distance to which it can be transmitted if occasion should require. The problem resolves itself largely into a question of voltage, which has steadily increased from the 4,000 to 6,000 volts in use not so many years ago to 40,000 and 60,000 volts which are now quite commonly employed; but it appears that even 60,000 volts which was regarded as a high value a few years since has been far exceeded in the most recent developments. The Los Angeles transmission line for instance uses 150,000 volts, and the hydro-electric development at Victoria Falls, in South Africa, contemplates a line pressure of 200,000 volts through a distance of 700 miles. The possibility of electrical transmission thus permits the utilization of available sources of power at great distances from the centre of distribution; but while it is interesting to know that a certain amount of power may be transmitted a given distance with a high degree of efficiency, it is more important to know whether the same amount of power could be obtained at the objective point more economically by other means.

Petroleum Fuel.— It has been suggested that the future of long-distance transmission depends largely upon the development of oil as a fuel; but at the present time the outlook for oil fuel in general competition with coal or long-distance transmission is not encouraging. While the development of the Texas and Southern California oil fields has increased the visible supply and brought about increased activity in the use of liquid fuel, yet it is doubtful whether the advantages would be sufficient to cause it to come into general use as a fuel, since with a limited production and an increased demand for this and other purposes the cost would be correspondingly increased.

A number of railroads contiguous to the oil-producing centres have equipped their locomotives to burn this fuel, and it is used to an increasing extent for marine and naval boilers, with great satisfaction,— since its displacement for a given heating value is only about one-half that of coal and the labor cost is materially reduced. It is also used quite extensively in certain sections of the country as a steam producer in power plants, but it is hardly possible that liquid fuel will be a serious competitor of coal for steam generation. At present, as far as power for manufacturing plants is concerned, it is largely a question of transportation, whether oil can be laid down and handled at a given point more cheaply than coal. It is probable, however, that oil fuel will supply a local demand in certain sections where transportation charges, and possibly insurance, will permit its use at a low cost, and it is in this connection that it may become a competitor of electrical transmission.

Internal Combustion Engines.— One interesting phase of the power problem which forcibly presents itself at the present time is the vast possibilities possessed by the modern combustion engine, which includes the various types of gas and oil engines. While its use as a motor in industrial establishments has been somewhat limited, yet there is a marked tendency to employ the gas engine in manufacturing works, and consideration of its advantages and cost of operation, together with its high thermal efficiency and possibility of still further improvement, indicates that, for a great many purposes, both steam engines and electric motors may be ultimately replaced by some form of internal combustion engine. That the gas engine in both large and small sizes has reached a point in its development where it can fairly rival the steam-engine in reliability and satisfactory running qualities there can be no question. In point of fuel economy, a gas engine of moderate size is on a parity with the largest triple-expansion steam engines, and will give a horse power on less than one pound of fuel. The high price of gas in this country has contributed largely to those causes which have prevented a more common use of the gas engine as a motor. For this reason the gas engine has generally been used, not so much because of its high efficiency as a thermo-dynamic machine, but rather on account of its convenience and saving in labor. It is true that natural gas is cheap, but it is equally true that natural gas is not generally available. Fortunately the manufacture of producer gas has reached a high state of development, and there are now in successful use several processes by which power gas can be made from cheap bituminous coals as well as anthracite and coke. The leanness of such gases renders them less effective per cubic foot of gas, as compared with the richer coal gas or even water gas; but this difference is more than compensated for by the low cost of production.

A prominent factor in gas engine practice which has attained a high degree of development in European practice is the small gas producer. These generators are very simple in operation, and furnish a convenient and economical means of obtaining power at a much lower rate than with the ordinary city lighting gas. The economy of these small producers is shown by tests which give one horse power on a 16 horse-power engine with a consumption of only 1.1 pounds of fuel. For engines above 40 horse power one horse power can be obtained on seven-eighths pound of fuel. The successful employment of large combustion engines with blast furnace gases as the explosive medium utilizes vast sources of power which a few years ago were allowed to go to waste or, at most, were used very inefficiently. The high thermal efficiency of the gas engine has long been recognized and the possibility of further development is a promising factor in this field. The accomplished efficiency of 38 per cent reported by Professor Meyer, of Göttingen, greatly exceeds the maximum theoretical efficiency of the steam engine. With higher compression even greater efficiencies may be expected. But with high compression there is danger of premature explosion, due to the generation of heat in compressing the gas in the presence of oxygen; for this reason Herr Diesel compresses the air separately. Under a pressure of 500 pounds or more, which is used in the Diesel motors, the air becomes very hot and readily ignites a charge of liquid fuel which is injected into the compression chamber. There is no explosion; combustion occurs while expansion goes on, and the heat generated disappears in the form of work. The United States census report for 1900 shows that about 135,000 horse power derived from gas or internal combustion engines were used in the industries, whereas, according to the latest (1910) report 750,000 horse power from gas and internal combustion engines were so used. That is, an increase of more than 500 per cent had taken place during the decade. The present development is toward the improvement of the internal combustion engine similar to the Diesel type, and this is accompanied by a marked tendency to use this type in marine engines; especially is this noticeable in European practice where it is employed in sizes up to 2,500 horse power per cylinder. In the larger sizes these engines are of vertical construction double acting two-cycle, and usually with six cylinders; but the fuel consumption is slightly greater in this type than in the four-cycle. The experience already obtained with Diesel engines in scores of vessels indicates that they may be made as reliable and that they are as suitable for ship propulsion as steam engines, which in a number of cases they have displaced. In many locations the crude oil used as fuel is available and cheap, and since its value in heat units per pound is from one-third to one-half greater than that of steam coal, the space occupied by the fuel in the vessel is greatly reduced; moreover remarkably high thermal efficiencies are obtained in this type of engine and even greater may be expected in the future since tests with various oil fuels have shown that thermal efficiencies of 45 to 48 per cent are possible. At the present time one ton of oil will accomplish approximately as much work in a Diesel engine as four tons of coal converted into steam power. In addition to the greater economies due to the fuel there is a marked saving in space and weight in the power plant, since the internal combustion engines weigh only about half as much and occupy only two-thirds of the space of the steam engines and boilers, which saving may be profitably used for cargo. These advantages and others indicate that internal combustion engines using crude oil, especially those of the Diesel or semi-Diesel type, must inevitably be used to an increasing extent both for land and marine engines.

Although this country has lagged somewhat behind Europe in adopting large gas engines, there is evidence that this state of affairs will not exist very long, for a number of firms are now in the field building gas engines from 1,000 to 6,000 horse-power capacity. The uses to which these large engines are put are about equally divided between the operation of blowing engines for blast furnaces and the driving of dynamos for general power distribution. While the gas engine in the larger sizes is thus used extensively for the generation of electric light and power, a growing tendency is observed to use the gas engines direct as motors. A number of railroad and other machine shops have been equipped with moderate sized gas engines suitably located about the works, and in addition, thousands of horse power are used in the smaller sizes for a wide variety of purposes, including village waterworks, isolated lighting stations and manufacturing plants of all kinds.

The gas engine, usually adapted to consume gasoline or other oil fuel, has invaded the agricultural field and is being used to an increasing extent for a variety of purposes and in many forms, not the least important of which is the gas tractor, which is especially adapted to agricultural service in that it is conveniently mobile in the field and on the road, nor is it burdened with steam boiler nor gas producer.

In the field of transportation in addition to its use in the familiar automobile and motor truck, the oil engine constitutes the power plant in motor cars, in submarine vessels, in aeroplane service and also to a limited though increasing extent in railway motor cars.

Gas Engine Central Power Stations.— With the possibilities of high thermal efficiencies still higher development of cheap fuel gas processes may be expected that will bring the gas engine into close competition with the electric motor for power purposes, for it will doubtless be found that gas transmitted from a central gas-making plant at a manufacturing works into engines located nearby, combined with the recovery of by-products from the fuel will produce a very cheap form of power. Where large amounts of power are involved, as in the various electro-chemical industries, it is quite feasible to locate such works near a cheap fuel supply; in which case the recovery of ammonia and liquid hydrocarbons from the solid fuel, and the use of the residual gas in internal combustion engines combined with the generation and distribution of electrical energy should effect a material saving in the utilization of power over any existing method. It is not to be presumed that the gas engine will displace either the electric motor or the steam engine; each has its legitimate sphere of usefulness, and each will be more highly developed as the result of direct competition. Yet the economies already obtained indicate that the field of the gas engine will be gradually extended into that of the steam engine and the electric motor.

Steam Turbines.— Many of the questions involved in this consideration are at the present time in a transitional stage. The reciprocating steam engine has reached a high state of development, but it is not probable that it has attained its highest degree of perfection. While an economy of less than eight and one-half pounds of steam per horse-power hour has been obtained, even better results may be anticipated; the use of high pressure super-heated steam in compound, jacketed engines involves more perfect lubrication, and this may demand modification in existing valve types; however this may be, the outlook is promising for still higher efficiency.

Experiment demonstrates that both piston engines and steam turbines gain more in efficiency with a reduction in back pressure than they do with a corresponding increase in initial pressures; and further that steam turbines gain more than reciprocating engines. Superheat is another important element in steam engine and turbine economy. A gain in thermal efficiency very nearly proportional to the superheat is to be expected, but since maintenance costs increase rapidly beyond a moderate degree of superheat practice has confined itself to values of about 100°; occasionally going as high as 200° or 250° as the economic limit for reciprocating engines. These amounts depend upon the boiler pressure so that the initial temperature of the steam usually runs from 450° to 550° F. In steam turbines, owing to the absence of rubbing surfaces in contact with the steam, the superheat may be higher and temperatures of 650° F. are not uncommon. With back pressures reduced to less than one-half pound per square inch absolute which are now in use, it is reasonable to assume that any increased gain in efficiency in the future must result from higher initial temperatures and pressures. In this respect it is significant to note that steam boilers have recently been constructed for initial pressures of 400 pounds per square inch, and even 600 pounds pressure is being considered. At the same time high degrees of superheat have recently been adopted in special cases in which final temperatures of 800° F. and 1,000° F. have been attained. Whether this will mean cheaper power than can be obtained in other ways will depend upon many conditions. In any case, and especially with intermittent or variable loads, it is not so much a question of maximum efficiency as it is economy of operation.

From this point of view the present activity in the construction and development of the steam-turbine is of interest to engineers and power users. The steam consumption of a modern steam-turbine of moderate size compares very favorably with that of the better class of large reciprocating engines, but what is of greater importance is the evident superior steam economy under variable loads. The steam consumption per horse-power hour varies little from one-third to full load; at over-loads the economy, as shown by numerous tests, may be even better. This feature predestines the steam-turbine to the special field of electric lighting and power generation, where it must inevitably become a formidable rival of the larger-sized, slow-speed reciprocating steam-engine.

The turbine is not only able to utilize a fairly large fraction of the possible gain due to reduction of back pressure, but is generally much cheaper to build than piston engines, especially for very low back pressures which require in piston engines abnormally large low-pressure cylinders. Thus the practice has been established of using turbines for the low ranges of pressure in preference to piston engines, and of combining reciprocating engines and turbines to work together — the turbine taking the exhaust steam from the engine at whatever release pressure it is discharged, usually from atmospheric to 25 pounds absolute. This practice has been found especially valuable in adding capacity to existing overloaded reciprocating engines. In some cases the power has been doubled by this arrangement.

The high rotative speed of the steam-turbine is a prominent factor in favor of its adoption in connection with electrical generators, since the cost of the generator end of the equipment ought eventually to be very materially reduced; but for many lines of work the high rotative speed of the present types of steam-turbine is prohibitive, nor can it be adapted successfully to belt-driving, except by the use of gearing.

The economies already obtained with both the steam-turbine and the gas-engine have brought each into a prominence which is at least suggestive of the important developments that are taking place in methods of obtaining and using power.

Professor of Mechanical Engineering, University of Minnesota.

POWER OF ATTORNEY. See Attorney.

POWER OF DARKNESS, The (Vlast' t'my). Leo Tolstoy had made in his youth several abortive attempts at writing dramas, but he scored a remarkable success when, in the eighties, under the influence of his moral regeneration, he published his first drama, 'The Power of Darkness.' His intention was to strike terror into the hearers, not through the action of inexorable fate, but through the possibility of being engulfed by the Power of Darkness; hence the subtitle, "The bird is lost if its claw is caught." This is illustrated in the case of the hero, Nikita, who pays no attention to the advice of his simple-minded father, the cesspool-cleaner Akim, but allows his wily mother, Matrena, who has been compared to Lady Macbeth, to kill Anisya's husband, in order that he may marry her and live at ease. The terrible scene in which Nikita, at the insistence of his mother and wife, kills his illegitimate child, by Akulina, had such a crushing effect upon audiences that Tolstoy was obliged to write a less terrible variant for its performance. The Divine voice in the tragedy is represented by Akim, who encourages his son to stand at the street corner and make his confession to the people and his peace with God.

Although passed by the press-censor, the dramatic censor prohibited the performance of the play. It was later performed first in private houses, and in 1895 in Suvorin's Theatre, where it produced a deep impression. However, on account of the surcharge of peasant details it was not a success at the Little Theatre or at the Moscow Art Theatre, where it was given later. In France it was performed as early as 1888 in Antoine's Theatre Libre and elsewhere, and in Berlin in the Deutsches Theater in 1900. It has been translated into English as 'The Dominion of Darkness' in Sergel's Columbia Library, Chicago 1890, and several times since by the translators of Tolstoy's complete works.

LEO WIENER.

POWER HOUSES. With the growth of electrical distribution, the generating station has become a highly specialized structure which demands consideration both from the electrical and mechanical viewpoints. In the first instance it presents peculiar requirements as to location, differing widely according to its purpose. Broadly, one may divide power houses into two general classes, those designed for the utilization of water power and those using heat engines as prime movers. The former are nearly always power transmission stations connected by high tension lines with the centre of distribution and not themselves burdened with direct distribution of energy to consumers. The latter are generally within the area of distribution, and the centres of distributing net works. In the cases where power is transmitted considerable distances from stations of the second class they are still generally to be regarded as distributing stations as regards the requirements of location.

Location.— The location of hydro-electric power houses is usually determined by purely hydraulic considerations. The area within which they may be economically placed is limited by the topography, and the chief requirements are as follows: First, the location must be such as to keep the power house free of floods under all conditions of stream flow. Second, within this limitation the location must be such as to utilize the maximum possible proportion of the available head. Third, in the interest of regulation the station must be placed so that it may be subject to the minimum variation of head. In plants working under high hydraulic heads, high enough to utilize impulse wheels conveniently, these conditions are easily met. At low heads there is often difficulty in placing the power house clear of floods and above any possible backing up of the tail water.

The location of a station driven by heat engines of one sort or another is usually kept as nearly as may be at the centre of the electrical distribution. Since for the delivery of any given load at a fixed percentage of loss the weight of conductor required varies directly with the square of the distance from the load, the reason for a central location is obvious. Assuming, for example, an electrical load uniformly distributed over a circular area, the most economical location of the power station, so far as the conductors are concerned, is at the centre. Transference of the station to a point at the edge of the area approximately doubles the cost of the distributing system. The causes which may justify removal from the central position are local conditions as to cost of real estate, of fuel and of water. The first item is part of the capital charge which may be taken as an offset to change in the cost of distribution; the last two affect the operating expense, and the change in these with change of location must be capitalized for comparison with the concurrent change in the cost of distribution.

Fuel.— Fuel is by far the largest single item of expense in ordinary electrical power production, and a power house must be so located, on a railway spur or waterway, that it can receive its supply and secure proper storage space without incurring serious charges for cartage or other handling of fuel. This necessity usually compels a location somewhat out of the centre of distribution. Water supply is more easily secured, but occasionally it becomes an important factor in location. In cases where the principal office of the power station itself is to furnish energy at high voltage for a distribution from substations, the cost of conductors is relatively a smaller consideration and commonly a location meeting the requirements just laid down can be secured without serious increase in the cost of the conducting system.

Equipment.— The electrical equipment of a modern power station usually consists of a small number of electric generators directly coupled to their prime movers, whether hydraulic, steam or gas operated. Except in small plants generators driven through intermediary belts, ropes or gears are rare, since these introduce added complications, cause some loss of energy, cannot well be used for large power, and serve no useful purpose of themselves, save now and then in giving the generators some specially valuable advantage in speed. In such case they should be used without hesitation if the conditions permit. The day of stations equipped with numerous small dynamos has passed, and for good cause, since the small machines are more costly and less efficient for a given total output, and they require also more space and more care.

Hence the number of generating units should generally be reduced to the minimum that will satisfy the following condition, viz.: that the total number should be such that one unit can go out of service without seriously overloading the others, dividing its load among them. Good modern generators usually are able to carry 25 or 30 per cent over their normal rated loads for some hours without serious heating, so that ordinarily four or five generators suffice. If the load upon the plant is normally moderate, two or three generators may serve admirably until such time as the normal full load nears the rated capacity of the machines.

In the case of a transmission or distributing network fed from several stations the total output rather than the individual output of the separate plants should be considered in determining the size of units to be used, for as regards reserve capacity it makes little difference whether it is in one location or another. Thus in some of the large hydro-electric networks 8 or 10 plants co-operate and the size of the units in each is determined not by the possession of a theoretical reserve capacity in a particular station, but by considerations of convenience, though some of the stations may have only one or two generators where such an arrangement suits the hydraulic conditions, and any station is called into or out of action by the load dispatcher just as if all the generators were concentrated under a single roof.

In steam-driven stations past practice has tended toward great aggregation of capacity, but more recently, since widespread distributing networks have become fairly common, the advantage from the standpoint of distribution of several generating plants has gradually been recognized and in planning these it is again the total capacity on the system which counts. The vital point is to avoid on the one hand putting too large a proportion of the possible output into a single unit, and on the other splitting the output into a number of units too small for the most economical operation. Stations with more than five or six generators are now generally relics of an early stage of design, except in certain cases of hydro-electric plants where the hydraulic conditions are such as to introduce the dilemma of choosing between relatively small units of normal design, or large units of special and sometimes disadvantageous design. Such cases arise in working at low heads where the available power from a single wheel or pair of wheels is comparatively limited. Cases may also arise in which generators for different purposes, as for general transmission, railway and electro-chemical service, may have to be installed in the same plant. In this case the number of machines for each use would be determined as if the other machines were located somewhere else. In plants including raising transformers the capacity of these is determined on the principles already laid down for the generators. Recent practice tends toward the installation of a single three-phase transformer or bank of three single-phase transformers for each generator without further subdivision. As between the two, practice is drifting toward the latter on account of the more convenient size of the separate units in large output and from the fact that in case of need two of them can be operated on open delta connection, thus giving an additional element of reserve capacity. Broadly, large stations should differ from small ones only in the capacity of individual units, so that if a 2,000 kilowatt plant is equipped with four 500 kilowatt units a 20,000 kilowatt plant would be equipped with four 5,000 kilowatt units and so on.

In either case the same allowance for reserve capacity would naturally be made, but evidently the larger plant would have the advantage not only of greater economy in the larger units but of reduced attendance cost per unit of output, and would also cost less per unit of output.

Large power plants then evidently can produce electrical energy at a lower cost than small ones. As the size is increased, however, the relative gain is diminished so that a size will finally be reached at which further increase in capacity ceases to be beneficial. Indeed since a very large station usually implies a large area served, the average distribution losses will be reduced by serving it from several interconnected power houses, so that the maximum economical capacity of a single power house is less than would be determined by considering only the effect of size on fuel and labor.

For example, if a certain considerable district requires 200,000 kilowatts, it is altogether probable that two 100,000 kilowatt plants will serve it more economically than a single gigantic power house and unless the district is of moderate area, four 50,000 kilowatt stations would probably do even better, provided they could all be well located. In other words a power plant of 50,000 kilowatts or thereabouts comes so near to giving maximum economy of operation that the difference is easily offset by lessened losses in distribution. The only cases in which size may be economically increased without limit are those in which the plants must for one reason or another lie far without the area served, as in great hydro-electric plants like those at Niagara, or in plants using coal at the mines for transmission of power on a colossal scale.

In any power house adequate provision for reserve capacity evidently can be most easily made if the equipment throughout is of a single kind so that everything may be as far as possible interchangeable. Similar units of uniform size are, therefore, advisable throughout the entire plant unless there is some good reason to the contrary.

The equipment of a power house may be divided into four parts: the prime movers, the electric generators, the accessory apparatus, and the switchboard, from which the output is regulated and distributed. The power-house structure must be planned for advantageous location of all of these and in addition, if steam is the motive power, there must be ample provision for the storage of fuel.

Design and Arrangement.— In point of design hydro-electric power houses present by far the simplest problem. In these the prime movers are the water wheels, which are relatively simple and compact, the generators are directly coupled to the shafts of these, and the output is delivered to a small number of lines so that the switchboard is relatively simple. As most such plants are for high voltage, the power house must often provide place for the transformers which raise the voltage from that of the generators to that of the line. Less frequently such transformers are found in steam-driven plants.

Structurally the ordinary power house consists of two parallel halls with a common dividing wall, one containing the generating units, the other water wheels or boilers as the case may be. The generator room contains or has annexed to it space for the switchboard connections and for the transformers, if any, while the boiler or wheel room has annexed to it space on the one hand for fuel, on the other for the hydraulic connections. Usually the plant comprises only a single story, although more rarely ground space is gained by superimposing some of the parts.

One may now pass to consideration of the concrete arrangements usually adopted, the hydro-electric case being taken up first, as the simpler in design.

Fig. 1 shows the small plan of a typical hydro-electric power station using as prime movers water wheels under high head. Here A is the receiver terminating the supply pipe and provided with branches to the several wheels. At very high heads these branches are sometimes made farther back, spreading finger-wise from a terminal chamber to secure a straighter run to the wheels. B, B, B are the water wheels, directly coupled to and on the same level with the generators C, C, C. The pipes from the water supply enter the lower part of this case the inner tail-race wall would usually carry a partition wall separating the wheel room from the dynamo room proper and provided with water-tight fittings for the turbine shafts to pass through.

In case raising transformers were to be used in such a plant the generators would be for perhaps 2,300 volts, the switchboard would preferably be turned around, facing the exciters, and the station would be extended far enough to the left of the cut to accommodate the transformers and the necessary accessories; or, if more convenient from the nature of the ground, space could be gained by widening the power house enough to accommodate the row of transformers. The size of the power house of Fig. 1 is about 40 feet by 85 feet and slight modifications of this simple design serve

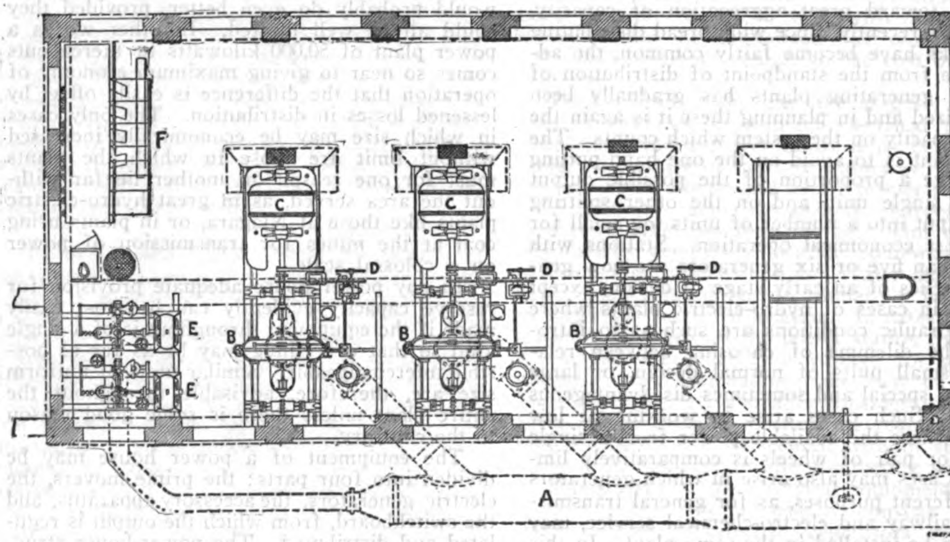

FIG. 1.

the wheel cases and discharge into the tail race below the power-house floor. The wheel gates are controlled by the governors D, D, D. The generators are revolving-field, 400 kilowatts, three-phase machines, giving 13,000 volts at the terminals at 500 revolutions per minute. Their fields are excited by two 25-kilowatt direct-driven exciters, E, E, each of which is regulated by a separate hydraulic governor. The switchboard is located on the floor level at F, and the line wires leaves the power house just above and behind the switchboard. Room is provided for a fourth generator and a traveling crane running lengthwise the power house is available for handling the machinery if necessary. The material of this power house is brick, on concrete foundations, with a steel truss roof covered with reinforced concrete slabs and then with roofing felt and asphalt, as the location is in a cold climate.

The design here followed is thoroughly simple and normal. At higher hydraulic head the somewhat unusual turbines here used would be replaced by impulse wheels in the same situation; at lower head by considerably bulkier turbines, which would require a wider tail race and power house for their accommodation. In well up to very much larger capacities. In case the necessary width becomes too great to be conveniently covered by a single roof, separate roofs are placed over the wheel rooms and generator rooms and in mild climates the wheel cases and tail race may sometimes be left uncovered.

In case of hydraulic plants operating at rather low heads one is often driven to the use of vertical shaft turbines, which results in a somewhat different arrangement of power house from that shown in Fig. 1. In such cases the forebay usually comes fairly up to the power-house wall instead of the water being received from a reservoir at the end of a pipe line. The generators like the water wheels are vertical shaft machines, the weight of the revolving fields being carried by a combination of water pressure and step bearing. Fig. 2 shows a cross-section through one of the four 6,000 horse-power units in a recent hydro-electric plant operating under a head of 49 feet. The design is an interesting one from the fact that the wheels have but a single runner which operates at 116 revolutions per minute, while the spiral wheel case and its entrance and the discharge draft tube are smoothly molded in the concrete foundation of the power house, which is really built as a sort of annex to the massive forebay wall, and in the monolithic foundations, of which the wheel cases and the water channels are a part. The bus bar and switchboard galleries occupy in this structure their wonted position, but the power-house interior is otherwise very simple, containing around, instead of containing, the hydraulic units.

It is necessary even in hydraulic plants to make the power station as nearly fireproof as possible and hence brick, steel and concrete are the most suitable materials of construction. Wood, even if treated by some fireproofing process, should be sparingly employed. For

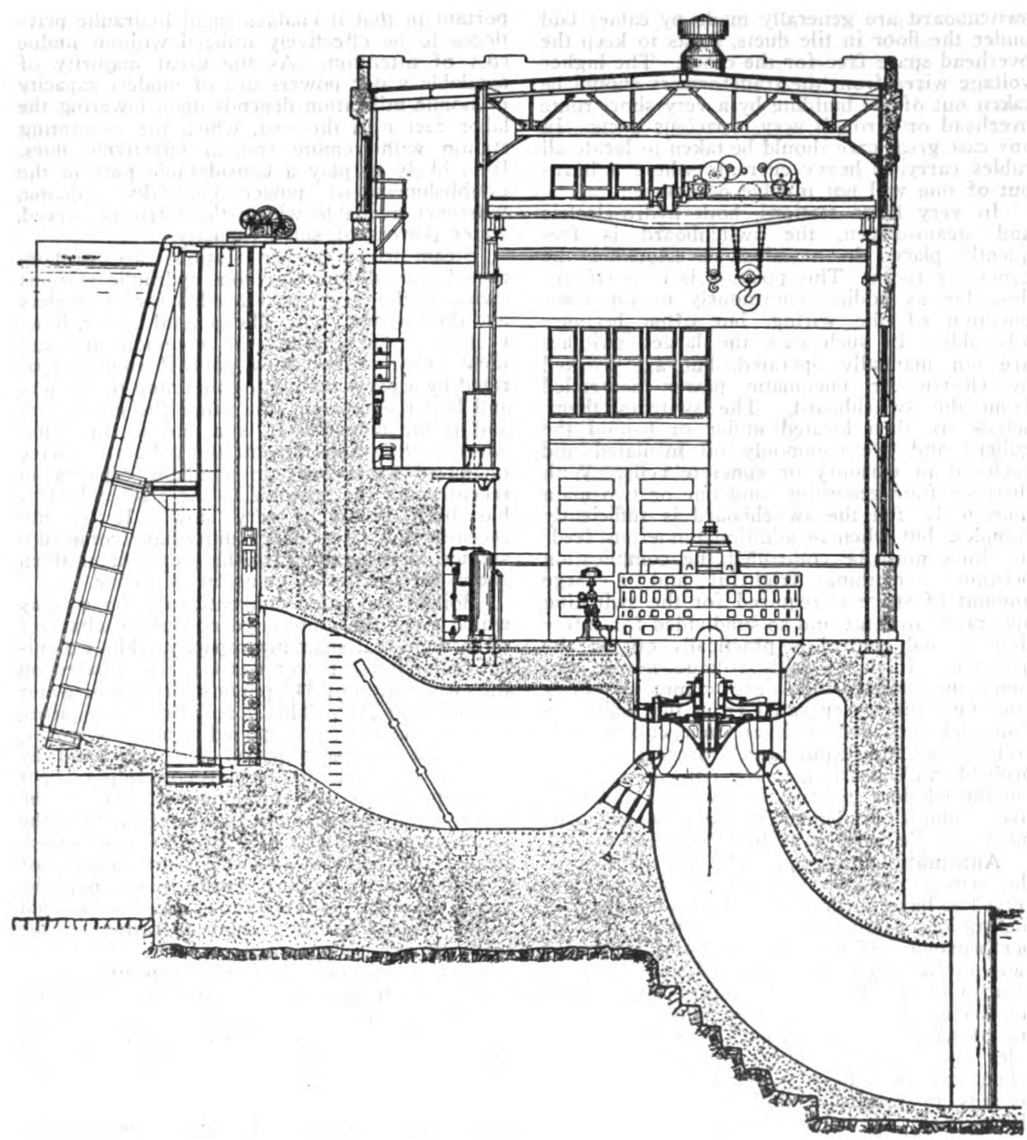

FIG. 2.—Section through power house No. 2, Appalachian Power Company, showing 6,000 horse-power hydraulic turbines and generators in place.

merely the four great vertical-shaft units rising above the floor over the wheels, the water-wheel governors and a few other auxiliaries. This power-house design is the latest type of those designed for the utilization of large powers at fairly low head. The hydraulic construction has the advantage of combining very high efficiency with compactness and extreme simplicity. It is really a power house built floors, concrete, reinforced when necessary, is probably the best material. The transformers and switchboard are the danger points, from the standpoint of fire risks. The former should be placed so that even if they burn out no exterior damage will result. If, as is usual in high voltage plants, they are oil-insulated, provision should be made for disposing of the oil harmlessly in the rare case where it ignites from an extreme short-circuit. Transformer oil is very difficultly inflammable, but it can be fired, and oil transformers should be guarded by pits with drains, so that the oil may not run about if it escapes from the cases. Generally the transformer cases are provided with drain valves from which the oil can be quickly run off outside the station.

The connections between generators and switchboard are generally made by cables laid under the floor in tile ducts, so as to keep the overhead space free for the crane. The higher voltage wires from the transformers should be taken out of the building by a very short route overhead or through very capacious ducts. In any case great care should be taken to locate all cables carrying heavy currents where a burn-out of one will not involve others.

In very large stations, both hydro-electric and steam-driven, the switchboard is frequently placed in a gallery overlooking the generator room. This position is in itself undesirable as adding enormously to the complication of the wiring, but often becomes advisable. In such case the larger switches are not manually operated, but are worked by electric or pneumatic power controlled from the switchboard. The switches themselves are then located under or behind the gallery and are commonly oil insulated and enclosed in masonry or concrete cells. With three or four generators and one or two main lines to be fed the switchboard is sufficiently complex, but when in addition numerous feeding lines must be controlled the complication becomes something frightful and a large amount of space is required for the switching apparatus, so large and so subdivided for safety that manual control is practically out of the question. In large high voltage power stations the transformers are commonly in a building entirely separated from the main station and provided with an independent high voltage switching equipment, a procedure which probably adds nearly as many risks as it avoids. On the whole a plant with few units and relatively simple equipment is likely to give the most reliable service at the lowest cost.

Automatic Stations.— The possibilities of the remote control switching system just referred to have borne fruit in hydraulic generating stations partly or wholly automatic in their performance. If the switching of a generator can conveniently be accomplished, as is the case, from a distant part of the power house without seeing the apparatus controlled, the working of which is signaled back by electrical telltales, then it is evidently possible to work a wheel gate or a main switch or any other apparatus in precisely similar fashion from a distance of rods or miles. There have, therefore, been introduced auxiliary generating stations started and stopped from the main switching station and regularly operated without other attendance than the occasional visit of an inspector. The generators used in such case are commonly of the induction type, which do not require separate excitation by direct current and are consequently simpler to operate without attendance. When desired to start the station the motor-driven wheel-gate is opened by remote control of the circuit and the subsequent necessary operations of switching the generator fully into circuit are performed either by other remote control apparatus or by a drum switch thrown into operation when the generator is at speed and performing the necessary switching operations in their proper sequence. In stopping the plant the same operations are gone through with in reverse order. Most stations of this type are of relatively small power and contain but a single generator, but the system is important in that it enables small hydraulic privileges to be effectively utilized without undue cost of attention. As the great majority of available water powers are of modest capacity economic utilization depends upon lowering the labor factor in the cost, which the generating station with remote control effectively does. It is likely to play a considerable part in the establishment of power networks utilizing, wherever available within the territory served, water powers of small capacity.

Steam-driven power stations are proportioned very differently from hydraulic stations owing to the large space needed for the boilers and their accessories. The general layout, however, is quite similar, the common arrangement being in two long parallel rooms separated by a party wall, one containing the boilers and boiler equipment, the other the generators and prime movers. It is a curious fact that whereas the prime movers and generators have increased enormously in available capacity in recent years the advance in the size of boilers has been relatively very slow. It is only recently that large boiler units have come into service, despite the fact that tests upon them show very material gains in efficiency.

Boilers are rated conventionally on a basis which gives the uninitiated no notion whatever as to their real steaming capacity. The canonical boiler horse power has long been based on the evaporation of 34.5 pounds per hour of water from and at 212°. This nominal rating requires, when a boiler is to be applied to a prime mover, wholesale modification, on the one hand by reason of the actual steam consumption per horse power of the prime mover, and on the other hand on account of the fact that the steam is generally at high pressure and superheated. In point of fact the steam capacity of a boiler in a modern steam plant may be counted as two to three times the conventional rating so far as the actual operation of the prime mover is concerned.

But, even so, the boiler capacities have grown much more slowly than the capacities of the steam engines or turbines, the latter being almost invariably used in plants of any size. It is, however, a fact that boilers of large capacity may be counted on for considerably higher efficiency than those of small capacity, as in many other cases, so that larger and larger units are quite certain to come into use. At present boilers of more than 1,000 horse power nominal rating are rather unusual, although units of more than double that size have been successfully used for some years past. The chief difficulty in employing very large boiler units is in adapting the setting to withstand the extremely high furnace temperatures which result in added efficiency. It is usual, therefore, to find each large prime mover in a modern station supplied with steam by a group of four or more boilers, a number which a few years back would have been doubled.

There is a collateral advantage in thus subdividing the boiler units, inasmuch as the boiler is the part of a steam plant which requires, probably, the most frequent repairs, and there is some advantage in having enough units for each prime mover group so that one can be cut out without seriously lowering the capacity, inasmuch as a boiler can at a pinch, particularly by help of forced draft, be driven temporarily 30 to 50 per cent above its working rate. A single boiler group of three or four units can readily be made an independent source of steam supply for its prime mover under ordinary circumstances. Generally, however, the steam piping in a modern plant is so arranged that in case of withdrawing a single boiler from service its place can be filled from steam from the general supply without exceptional forcing at any point.

here shown are almost universal, as is the use of mechanical stokers for feeding the boilers, which are almost invariably of the water-tube type. This particular boiler plant delivers steam at 200 pounds' pressure and 160° F. super-heat, which is a fair example of present practice. There is a strong tendency, however, toward the use of higher pressures and super-heat in the interest of economy.

The generators in this instance are for 6,600 volts, a figure convenient where there is to be local distribution beside possible feeding of transmission lines and which is besides a convenient voltage in the design of large generators. Smaller machines are often wound for 2,300 volts and 6,600 is rarely exceeded. The reciprocating engine has practically passed out of existence in large electric generating plants owing to the lower cost, greater compactness and higher efficiency of the turbines, particularly at loads below the normal. The

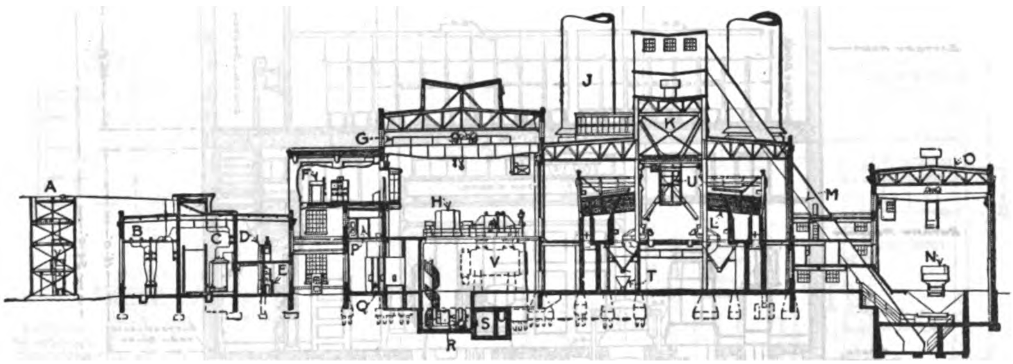

FIG. 3.— A — 42,000-volt arresters; B — 42,000-volt reactance circuit breakers; C — three 4,000-kva. transformers per generator; D and E — 6,600-volt circuit breakers and bus structure respectively; F — control room; G — 50-ton crane; H — 12,500-kva. turbine-generator; J — smokestack; K — 420-ton coal bunker; L — 1,050-hp. boilers; M — 60-ton elevator; N — coal cars; O — coal shed; P — lavatory; Q — humidifiers for ventilating air; R — condenser circulating pump; S — cooling water tunnel; T — ash car; U — 5-ton lorry; V — condenser.

Fig. 3 shows in elevation the layout of a typical modern steam plant of fair size designed for feeding high-tension lines. It includes a boiler room with typical provision for receiving and distributing the fuel, a turbine room parallel thereto containing the generators, with adjacent provision for switchboard transformers and auxiliary apparatus, while next to the boiler room is a coal shed for the reception of fuel. This particular plant is planned for an ultimate capacity of 75,000 kva. in six 12,500 kva. generators. The location of the equipment is clearly shown in the cut. In larger plants the turbo-generators often run to 20,000 or 30,000 kilowatt units and occasionally higher. At the present time as here shown these turbo generators are built with horizontal axis, the vertical type of a decade since being now obsolescent. Very commonly the coal shed with its track for the reception of coal cars is replaced by a storage yard equipped with automatic conveyers for the maintenance of a large fuel supply, and crushing apparatus for dealing with run-of-the-mine coal is a not uncommon accompaniment. In small plants the transformers and circuit breakers would often be installed under the switchboard gallery instead of, as here, in an adjacent building.

The capacious coal bunkers above the boiler room with distributing apparatus similar to that

boiler units here employed are of 1,050-rated horse power each and can readily be forced to three times their nominal rating which is, as in the case of all boilers based on a conventional steaming capacity, long obsolete.

Each turbo-generator has its own bank of boilers, but the piping is so arranged that one set of spare boilers is sufficient for the entire plant. At Q will be noted an equipment for purifying and cooling an air-blast for the artificial cooling of the turbo-generators. As the size of such generating units has increased artificial cooling has been very generally adopted, the air being forced through the ventilating slots in the machines. The capacity of the individual boilers here noted is now a common one in plants of fair size, such boiler units having replaced very extensively those of a few hundred horse power generally in use until very recent years. In larger plants boiler units up to and exceeding 2,000 nominal horse power have been introduced to material advantage in economy. In many plants the familiar tall stacks are replaced by rather short ones supplemented by forced draft. This arrangement is not particularly advantageous in plants working at moderate and fairly steady load, but gives great capacity for forcing the output when abnormally heavy peak loads have to be dealt with.

As steam turbines for efficient operation demand a rather high vacuum, 28 inches to 29 inches, they are usually fitted with highly-developed surface condensers and the power required for delivering water to these and for other auxiliary purposes is considerable. One of the moot points in station design is the source of this auxiliary power, whether it should be derived from steam turbines or from electric motors operated from the generating system. Practice is about equally divided in this matter with a frequent tendency to adopt a combination of the two systems. It will be noted that the switching apparatus in this typical plant is somewhat intricate and occupies considerable space. cost and generally in complication, with the size of the station, particularly if as usual the number of feeders is greatly increased. In view of this switchboard apparatus and connections should be protected with the utmost care, special pains being taken to locate cables and apparatus so that injury to one may not involve others and this injunction extends to all apparatus which from its connections can conceivably cause a short-circuit. It has repeatedly happened that large stations have been put out of action by apparently trivial accidents occurring at an unexpected and unprotected point.

The fundamental principles at the basis of modern station design are so to arrange the

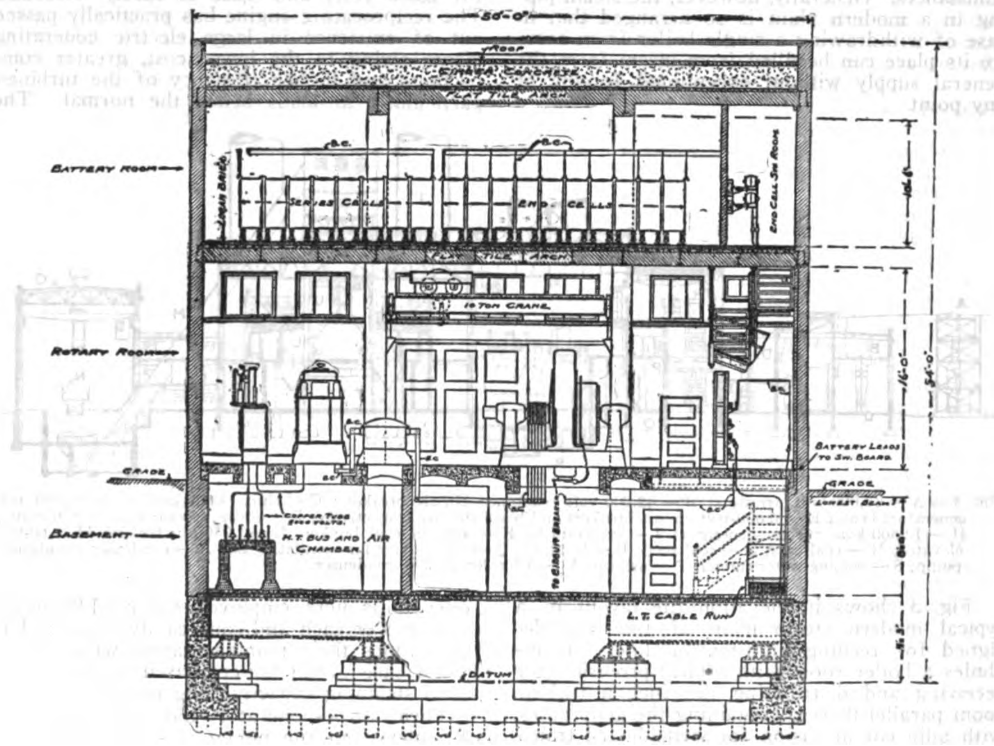

Fig. 4.

This arises from two causes, first, the absolutely large amount of switching apparatus required, and second, from the fact that it is desirable and usual to install high-power switches and circuit breakers in independent concrete cubicles, from which a burn-out will not extend. As plants have increased in size the switching problem has become a very serious one. It is usual and sometimes necessary to operate all the generating units in parallel. In this case any unit which is the victim of a short-circuit may receive the aggregate output of all, so that each main protective switch has practically to be able to handle successfully the whole output of the station. In long-distance transmission plants this difficulty is often minimized by putting the high-tension transformers in parallel only at the far end of the line, but within the station and in ordinary distribution plants the difficulty remains. Hence the switchboard equipment increases in relative apparatus that nothing need be done by manual labor which can better be done by mechanism, and that no heat shall be lost which can be made to serve a useful purpose. In the station of Fig. 3, for example, the fuel is dealt with mechanically from the time it drops by gravity from the cars to the moment when it drops as ashes into the ash cars beneath the grates, save for such attendance as is necessary to see that the mechanical stokers are functioning properly and to lend what little aid may be needed. The steam piping is relatively short, simple and well jacketed, the surface condensers are immediately beneath the turbines and the waste exhaust from the auxiliary turbines goes to heat the feed water.

Sub-Stations.—An account of power houses would be incomplete did it not take notice of sub-stations. The modern power house is almost always fitted with alternating current generators which transmit current either for general distribution or for conversion into direct current for supplying electric railways or the old direct current lighting systems. Such conversion must probably be regarded as a makeshift, but at present a necessary one. The high voltage current from the power house is transmitted through cables or over aerial lines to the sub-stations, and there the voltage is lowered by reducing transformers to the amount appropriate for the synchronous converters. The sub-station must, therefore, accommodate the reducing transformers, the converters, regulating apparatus, switchboards for both alternating and direct currents, and sometimes a storage battery and its accessories. The structure, therefore, becomes practically a power house for general service, less only the prime movers. Fig. 4 shows in elevation a sub-station for city lighting and power service which is a masterpiece of compactness. It is a modern steel building two stories above grade and with a basement for the cable entrances and exits. The main floor contains, as Fig. 4 shows, arranged in order, the high-tension bus and main switches, the three-phase transformers, the regulators, and the rotary converters, of which there are four, each of 1,000 kilowatt capacity. The same room contains the booster set for charging the batteries at a variable voltage somewhat higher than that of the rotaries, and the switchboard, also a blower set for ventilation. Large apertures are left under the rotary converters and transformers so that a liberal air supply may be drawn in from below and exhausted by the blower. The second floor contains the storage batteries and their special switching arrangements. On account of possible leakage of acid from the batteries the floor construction is peculiar. The basis is tile arch over steel beams. Then comes a layer of concrete coated with asphalt, then a floor of hard-baked brick, glazed all over, laid with narrow interstices which are finally filled with hot asphalt.

Sub-stations for railway service do not so commonly have the storage battery, and are generally less compactly arranged, but after about the same general plan. The sub-station shown here covers only 3,150 square feet for its 4,000 kilowatts capacity. Ordinarily the switching arrangements in a sub-station are so intricate as to require a rather liberal allowance of space. The same principles of location and subdivision of units hold for sub-stations as for power houses in general, with the advantage that the location is not dependent on water and fuel supply. Sub-stations for the receiving ends of power transmissions for general service differ from those just described in the lessened importance of synchronous converters. The ordinary distribution from a high voltage transmission service is very largely by alternating currents, and is accomplished by substations designed accordingly. The high voltage current is received in large reducing transformers which in number, size and location are to be treated as so many alternating current generators fortunately exempt from the necessity of rotation. Regulating apparatus is an important feature of stations of this class, and being inductive can be applied with very small loss of energy to the exact regulation of voltage on individual feeders.

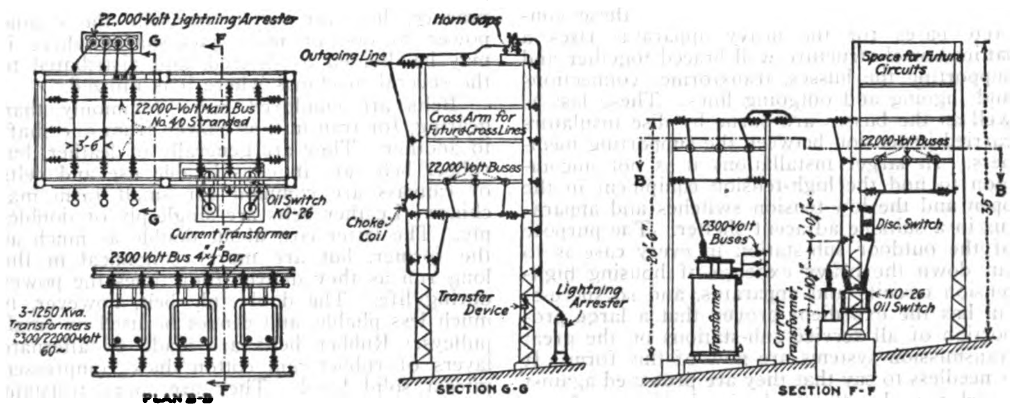

FIG. 5.

For arc light service constant current transformers are very widely used, taking energy from the lower voltage side of the reducing transformers. This service requires a special switchboard, and is generally set apart in the sub-station. Owing to the absence of rotating machinery in any considerable amount the sub-station for general service is compacter and requires less in the way of foundations and special construction than the sub-station of Fig. 4. Otherwise the principles of location and design are unchanged.

Out Door Sub-stations.—The needs of high voltage transmission have evolved in recent years an interesting and important form of sub-station which is coming into very wide use. One of the main difficulties of high tension practice is the large space required for switching apparatus and the great difficulty of getting high voltage wires into and out of buildings while retaining adequate insulation. The result is that a sub-station building and equipment rises to very burdensome cost in case the output required is not large. There has, therefore, been evolved the outdoor sub-station derived by natural process of growth from the transformer mounted on a pole, and supplied with the necessary auxiliaries for protection and switching. To meet these requirements weatherproof apparatus has been designed which can be safely left in the open under all climatic conditions. The common form taken by the outdoor sub-station is a concrete platform to bear the weight of the transformers and above it a quadrilateral of steel or wooden poles braced together and carrying switches, cut-outs and other auxiliary apparatus, as well as serving to support the incoming and outgoing circuits. In stations of the larger capacities electrolytic cell or similar lightning arresters, and oil switches form part of the platform equipment, while in the smaller stations air-break switches with very long swing and protected by horn-gaps, and horn-gap lightning arresters often take the place of the more expensive apparatus. Fig. 5 shows in section and plan a typical station of this kind and of medium capacity. Here the transformers are of the usual oil-filled type, cooled by natural draft, and the lightning arresters are of the electrolytic form installed on a platform by themselves. The switching equipment is of oil switches carried on a platform like that which supports the transformers. Above these concrete bases for the heavy apparatus rises a latticed steel structure well braced together and supporting the busses, transformer connections and ingoing and outgoing lines. These last as well as the busses are borne by disc insulators carried in tension between the supporting members. In larger installations it is not uncommon to find the high-tension equipment in the open and the low-tension switches and apparatus in a suitable adjacent shelter. The purpose of the outdoor sub-station in every case is to cut down the heavy expense of housing high-tension circuits and apparatus, and so successful has the expedient proved that a large proportion of all service sub-stations on the great transmission systems are now of this form. It is needless to say that they are protected against interlopers by thorough fencing in, and are otherwise treated with the respect due to their voltage.

Consulting Electrical Engineer, Boston, Mass.

POWER SIGNALS. See Block Signal System.

POWER TRANSMISSION. It is rarely convenient to develop power at exactly the point where it is to be utilized, and hence the necessity of devices and systems for conveying it from place to place without loss, or with the minimum of loss. These systems of power transmission separate naturally into two groups: one in which the motion produced by a power is transmitted mechanically; the other where the power generated by one engine is used to operate another engine, the motion developed by the second engine being employed in work. To the first group belong the mechanical devices known as shafting, belts, chains, rope and cable drives, friction gearing, toothed gearing, link work and the like. To the second group belong the transmissions of power by compressed air, steam, hydraulic pressure and electricity.

Shafting.— Between the different parts of a given machine, or of a given mill, the transmission is often effected by means of a rotating shaft, which is subjected to a torsional moment. In mill work the shaft is rigid, and is made of solid steel, or of steel tubing; while in small machines (as in dental drills and the like) the shaft is often flexible, so that the point of application of the power can be varied at will, without disturbing the source from which the power is drawn. In mill practice it is essential that the alignment of the shafting shall be as good as possible,— that is, that the centre line of each shaft shall be as nearly straight as it can be made. It is also essential that the "journals," or bearings which support the shaft, shall be properly designed and well lubricated. If attention is paid to these points, transmission by shafting may be quite efficient; but if the alignment is poor, or the journals are poorly designed, or the lubrication is inadequate, a great deal of energy may be absorbed by the shaft, and dissipated in the form of frictional heat. In transmission by shafting, the speed remains invariable, that is, that of the engine as controlled by its governor, and if (as is usually the case) a change of speed is desired, it must be effected by the use of gearing or belting, or some similar device. The more common practice, however, is to transmit the engine power to one or more jack-shafts where it may be divided as desired, and distributed to the several machines where it is utilized.

Belts are employed more commonly than gearing, for transmitting power from one shaft to another. They are generally of leather, but rubber belts are in considerable use and belts of canvass are common for small farm machines. Leather belts are single-ply or double-ply. The latter cost about double as much as the former, but are more economical in the long run as they deliver four times the power during life. The double-ply belt, however, is much less pliable, and cannot be used on small pulleys. Rubber belts are máde of alternate layers of rubber and cotton duck compressed into a solid band. They are more resistant than leather to heat, cold and moisture but are easily ruined by lubricating oils and greases. If kept strictly clean they will long outlast leather, and are considered to give a better grip on the pulleys. Canvas belts are cheap, and are readily affected by the weather. They are much improved by waterproofing paints and dressings. Steel belts have been used with success. They are simply flat bands of tempered steel. For an equal power they are about one-fifth the width of a leather belt, and show only one-tenth the slip. They are run at speeds up to 10,000 feet per minute. The resistance of a belt to slipping is independent of the width of the belt, so long as the total stress upon the belt is constant. It depends chiefly, in this case, upon the arc of contact between the belt and the pulley; and a belt will slip just as readily upon a pulley four feet in diameter as upon one that is two feet in diameter, if the arc of contact (measured in degrees) is the same in both cases, and the surfaces of the two pulleys are in the same condition. The laying out of a successful system of belting, for use in mill work, calls for practical experience with belts, since it must be admitted that the formulæ that have been given do not correspond with experience. The performances of belts have made all the carefully devised rules seem ridiculous. There are too many variables in the problem. In most cases it is customary to make a computation according to Webber's rule for ordinary leather belting of single thickness: A belt one inch wide will safely transmit one horse power, when run at a speed of 600 feet per minute; and the power transmitted will be proportional to the width of the belt, and to the speed at which it is run. This rule gives no information with regard to the proper tension; but it implies that the tension may be safely increased until the belt actually does transmit the computed horse power. For efficient operation, that is, the economical transmission of the power, the driver and driven pulleys should not be too close together. A large percentage of power is transmitted if a distinct sag in the driving side of the belt is arranged for. For narrow belts the pulleys should be at least 10 to 15 feet apart and the sag about 2 inches; and for wide belts from 20 feet upward and the sag up to 5 inches. Where the distances between shafts are necessarily less than these either rope or chain drives may be more effectively employed. The angle at which belting is placed with reference to the horizontal should never exceed 45 degrees. With a very stiff belt vertical belting is practicable if necessary. In placing belt pulleys on the jack shaft they should be so arranged that the pull alternates in different directions. Unless absolutely impossible, the motion should be from the top of the driver to the top of the driven pulley: in this case the sag increases the arc of contact. The pulleys should be as large as practicable to lessen the abruptness of bending in the belt but the speed (except for steel belts) should not exceed 4,800 feet per minute. If the pulleys are faced with leather, the tension of the belt may be reduced, with a larger transmission of power and an increased durability of the belt. The greatest efficiency in belt transmission of power is secured with narrow belts on large pulleys, run with low tension at high speed (4,000 feet per minute).

Rope and Cable Drive.— Rope drives are used where the shaft centres are too close together or too far apart for the economical use of belting, and generally where very large power is to be transmitted. The faces of the pulleys are scored with deep grooves narrow at the bottom, so that the rope will be gripped by the wedging of the sides of the groove. The width of the pulleys is governed by the power to be conveyed, ranks of 30 ropes being not uncommon for large powers. There are two methods of fitting out such a drive: the English and the American. By the former method each complete wind of the rope is individual, and is spliced in its place. In the American system the entire drive consists of one continuous rope, with but one splice. The slack of so long a rope is large, but is taken up by a tension carriage around which the rope makes a single turn. After a new drive has run a few minutes all the slack has been gathered upon this carriage, and the tension of all the coils of the drive is uniform, and is kept so by the tension regulator. In the English drives, on the contrary, it is rarely that any two coils are of the same tension, and a lack of efficiency results. The speeds at which rope drives are run vary from 2,000 to 4,000 feet per minute. They are most effective when run under full load. The rope used in such drives is preferably a four-strand rope of long-fibre Zebu manila twisted upon a core. This rope is not only soft and pliable, but very durable. Cotton ropes have made remarkable records in some cases. In a certain Scottish cotton mill a rope drive of 24 cotton ropes one and three-fourths inches in diameter ran continuously at a speed of 4,400 feet per minute for 26 years without repair. This drive transmitted 826 horse power from a driving pulley 28 feet in diameter.

Wire ropes or cables are useful in very long horizontal transmission. They work acceptably up to 6,000 feet, if relay pulleys are provided at least every 500 feet, transmitting about 80 per cent of the power. They are generally woven of six strands upon a cotton core, each strand being a cable of from 7 to 19 wires of charcoal iron or low steel: the 7-wire cables make a stronger rope, but less pliable. On account of its great liability to rust a wire cable used in power transmission is usually treated with boiled linseed oil, which has also the effect of improving its grip on the pulleys. The pulleys for wire cables should have a leather bed in the bottom of the groove to save wear of the cable.

Chain Drive.— For speeds of less than 1,000 feet per minute the chain and sprocket drive is highly efficient. The disadvantage with it is that the teeth of the sprocket wheel become worn so that the pull is not evenly distributed upon the wheel. In extreme cases the entire pull may fall upon a single tooth. The sprocket wheel should never have less than 12 teeth. The usual top limit is 60 teeth. This form of drive is particularly adapted to situations where the driving shaft and the driven shaft are necessarily close together. For very heavy powers the gear-chain is effective. It is so constructed that the ends of the links form a series of cogs on the inner side of the chain-belt, to engage with the cogs of a broad spur-geared wheels. Because of their noiseless running these chains are sometimes called «silent chains.»

Friction Gearing.— In some circumstances friction gearing is desirable, but as it depends for its efficiency upon strong pressure, with the excessive strains which accompany it, this form of power transmission is generally avoided. Where used the driving wheel is usually of iron and the driven wheel of leather, or faced with leather. It has been found, however, that the friction of aluminum on leather is 40 per cent greater than that of iron on leather.

Wheel gearing is discussed at length in a special article under that title, to which the reader is referred. This form of power transmission is effective in overcoming resistances in which belts, ropes and chains would be insufficient. The efficiency of toothed gears ranges up to 98 per cent when the teeth are comparatively small and the speed low, or very fast, medium speeds showing a lower efficiency. The breaking pressure on the teeth of toothed gears increases up to a certain speed, and above that speed decreases.

Link work includes the mechanical devices known as cams, eccentrics, cranks, connecting-rods, levers and the like. They serve to transmit motion from one part of a machine to some other part.

The second group of power transmissions depends upon the elasticity of fluids. Air, steam or water are put under pressure, and this pressure is available for work at the farther end of the pipe-line which confines and conveys the fluid. In the case of electricity the condition is somewhat different, but is comparable to a hydraulic current flowing in a pipe.

Compressed air (q.v.) is employed in the transmission of power in many cases, especially in the operation of rock drills, and in mining generally, the air serving, in such cases, not only to operate the machinery, but also to aid in the ventilation of the mine. While the efficiency of the mains is 98 per cent that of the motors varies from 40 to 67 per cent. The compressed air may be delivered to the point at which the power is wanted by means of pipes directly from the compressors, or it may be stored at high pressure in tanks, from which it is drawn as wanted. For example, in mining locomotives are used which derive their power from large tanks of compressed air that take the place of the ordinary steam boilers of other locomotives; these tanks being charged at convenient points along the line of travel. Steam is used in the same way but with much less efficiency as enormous amounts of heat are lost from naked steampipes and they are very rarely insulated. Power is also transmitted hydraulically, when, as in cranes, presses and elevators, it is desired to exert great force in some slow-moving piece of machinery. In London and other European cities there is a regular public service of water under high pressure for use in small shops as a cheap source of power.

A great deal of attention has been given, in recent years, to the economical transmission of power by electricity, and the various problems that are involved have been solved so satisfactorily that enormous quantities of power are now transmitted electrically, in some instances to a distance of upwards of 200 miles. The mechanical energy that is to be transmitted is first converted into electricity by means of a dynamo; and the electricity thus generated is led along a conductor (usually of copper) to the point where the power is to be used, it being there reconverted into mechanical energy by means of electric motors. In certain shops and mills, the power is transmitted in this way from the engine room to the various machines that are to be operated, each machine being provided with its own separate motor. Installations of this kind are especially successful when the work is of such a nature that the machines are idle for a considerable part of the time, because there is no loss, in electrical transmission systems, when the circuit is interrupted and no current is flowing; whereas in a mill that is fitted up with shafting and belts the shafting runs all the time, and the losses due to its friction go on all the time, whether the machines are running or not. The use of individual motors, as described, is also advisable in plants where the machines are run at high speeds, since the desired speeds can be attained electrically, without the losses incident to the use of pulleys and belts, of trains of gears, or any other method of direct mechanical multiplication.

In the transmission of power by electricity to considerable distances, the chief losses are those due to direct leakage of electricity along the line, and to the dissipation of energy in the form of heat in the conductor. The losses due to the former cause can be kept down to a reasonable limit by paying proper attention to insulation, though the problems that are here involved are very serious, when the potential of the conductor is maintained at 60,000 volts or over. The loss due to the development of heat on account of the resistance of the conductor can theoretically be diminished as much as we please, by merely increasing the size of the conductor; but conductors sufficient in size to render the heat loss negligible are too expensive to be commercially practicable. Lord Kelvin, in an attempt to determine the most economical size of conductor for electrical transmission, came to the conclusion that the maximum economy is attained when the conductor is of such a size that «the annual interest on the capital outlay is equal to the annual cost of energy wasted.» Under ordinary conditions, this is found to lead to the conclusion that the most economical current-density in the conductor is about 380 amperes per square inch of sectional area of the conductor. For the case in which a given horse power is to be delivered at a given distance, the condition is somewhat different, and not so simple. Professors Ayrton and Perry, who have investigated this case, have given somewhat complicated formulæ for determining the most economical cross-section of the conductor. (Consult Kent, ‹Engineer's Pocket Book,› and the references there given). In long distance transmission it is customary to adopt, for the transmission line, a far higher potential than is desired for the operation of the machinery at the delivery end, since this artifice makes it possible to transmit a given quantity of electrical energy over a given conductor with a smaller heat loss than would be involved if the transmission were effected at a lower potential. When the transmitting current is alternating, the reduction of potential at the delivery end may be effected by means of a transformer; but when the transmitting current is direct, it is customary to employ a «motor-generator,» which consists of a motor, actuated by the transmission current, coupled on the same shaft with a dynamo, which gives out a current adapted to the work to be done. The motor-generator is also used to transform an alternating transmission current into a continuous current, when the continuous current is desired for delivery purposes. Some of the problems of electrical transmission have been solved on a very large scale at Niagara Falls, where the water power is partially utilized for mechanical purposes. A portion of the power that is developed in the turbine houses is transmitted electrically to Buffalo, for the operation of electric railways and for other purposes, and the remainder is utilized, also in the electrical form, in factories in the more immediate neighborhood of the falls. The modern electric transmission line for high voltages is of aluminum cable on a steel core — to give it strength and lessen the sag between towers — or of copper-clad steel, known to the trade as «Monnot metal.» The latter is an ingeniously devised steel core which is first alloyed with copper on its surface, and then covered with a heavy coating of pure copper. The aluminum cable has to be 61.6 per cent larger in volume than a copper cable to obtain an equally low resistance. As the weight of aluminum is 30.2 per cent that of an equal volume of copper, the weight of aluminum required for a stated conductivity is 48.8 per cent of the weight of copper having the same conductivity. An aluminum line is, therefore, much cheaper than a copper line. For voltages up to 66,000 the «petticoat› type of insulators, set upon iron pins, are commonly used. The «petticoats» or porcelain «bells» are nested one within another until the insulation is sufficient to prevent the current from the cable from leaping to the supporting pin. The protective power ranges about 15,000 volts to each bell; that is, for a current of 44,000 volts, three bells nested are required; for 66,000 volts, at least four bells in the nest. The great weight of these porcelain masses limits their use to the smaller voltages, so that above 66,000 volts the suspension type of insulation is used. This consists of a series of porcelain discs hanging in horizontal positions one below another and suspended through their centres. As many discs may be added to the «string» as are needed to insulate the particular current. On 110,000-volt lines five or six discs are used. On 140,000 volt lines the number of dics is increased to 10 and the space between the horizontal cables is not less than 12 feet. On lines of low voltage wooden poles of white cedar (arbor vitæ) or chestnut are generally used. They have a «life» of from 10 to 12 years. Concrete poles are practically indestructible, but very expensive to set, on account of their great weight. For high voltage transmission lines the steel tower of lattice construction is favored. These are set from 400 to 1,000 feet apart. The longest known span is one reaching across the Saint Lawrence River at Three Rivers (Canada) which is a clear span of 4,800 feet from towers 315 feet high; the cable carrying 140,000 volts. Underground conduits are common for electric transmission in cities. They are variously constructed: of artificial stone — made by mixing limestone and Portland cement; or of fibre pipe — made of woodpulp saturated with a bituminous compound. The cables used in underground transmission are usually three-phase, three-conductor cables of the so-called «clover-leaf» pattern, the conductors being insulated by manila-rope paper of the finest quality saturated with resin and resin oil. This type of insulation is as durable as the lead sheath in which the cable is encased; which is all that can be desired. The voltage which such an underground cable can carry without loss, or perforation of the insulation, ranges up to a maximum of 300,000 volts.

POWERS, Hiram, American sculptor: b. Woodstock, Vt., 29 July 1805; d. Florence, Italy, 27 June 1873. He received his education at the district school, and on the removal of the family to Ohio in 1819 was employed as assistant to a clock-maker. At the same time he learned the art of modeling in clay from a German sculptor. He was subsequently appointed director of the waxwork department of the Western Museum of Cincinnati, an employment he pursued for seven years. In 1835 he went to Washington, and was for some time employed in modeling busts of distinguished men. With the proceeds derived from these efforts, and the aid of Gen. John Preston, he was enabled to visit Italy. In 1837 he established himself at Florence, where he resided until his death. His statue of ‹Eve Tempted,› which excited the approval of Thorwaldsen, was produced in 1838; in 1843 was modeled the still more popular ‹Greek Slave,› of which six copies in marble and innumerable casts and reduced copies are in existence. Among his other statues the most notable are ‹The Fisher Boy› (1846); another ‹Eve Tempted› (1850); ‹America› (1854), destroyed by fire in 1866; ‹Il Penseroso› (1856); ‹California› (1858); and ‹The Indian Girl› (1872); and statues of Washington for the State of Louisiana, of John C. Calhoun for South Carolina, of Daniel Webster for Boston, and of Franklin and Jefferson. He also executed several ideal busts, such as ‹Ginevra› (1840–65); ‹Proserpine› (1845); ‹Psyche› (1849); ‹Diana› (1852); ‹Christ› (1866); ‹Faith› (1867); ‹Clytie› (1868); ‹Hope› (1869); and ‹Charity› (1871); besides busts of Jackson, John Quincy Adams, Edward Everett, Van Buren, Longfellow, John Marshall, Philip Sheridan and others.

POWERS, Le Grand, American statistician: b. Preston, N. Y., 1847. He was graduated at Iowa State University in 1872 and was engaged in active ministerial work 1874–90. He was commissioner of labor in Minnesota 1891–99, and has since been chief statistician of the United States census, in charge of agriculture. He has published ‹Minnesota Bureau of Labor Biennial Reports› (1890–99); ‹Farmer Hayseed› (a reply to ‹Coin's Financial School›) (1895) Twelfth Census of the United States (Vols. V–VI); Census Report on wealth, debt, taxation and other statistics of cities. He is also a frequent contributor to newspapers, American and English reviews and financial and statistical juornals.

POWERS OF CORPORATIONS. See CORPORATIONS, LEGAL.

POWHATAN, pow-hạ-tăn', Indian sachem: b. about 1550; d. 1618. This was the name of his tribe; his own was Wahunsonacook. Originally he was at the head of eight tribes, but being a man of great natural abilities he raised himself from the rank of a chieftain to the command of 30 tribes, numbering about 8,000. (See POWHATAN INDIANS). His dominions included the country between the James and Patuxent, and extended into the interior as far as the falls of the chief rivers. One of his abodes was a village of a few wigwams near the present site of Richmond. A large guard of warriors usually attended him, and his dwelling was watched at night by sentinels. After the extension of his power northward, he dwelt mainly at Werowocomoco, on York River, in the present county of Gloucester, a few miles from Jamestown. He was disposed to look with dislike upon the coming of the whites. Capt. John Smith, in 1607, was held for some time by Powhatan as a prisoner, and according to the tradition, when Smith had been condemned to death, the sachem yielded to the entreaties of his daughter Pocahontas (q.v.) and spared his life. Two years later Powhatan was crowned «Emperor of the Indies» by Smith and Capt. Christopher Newport, during a visit which they paid him in quest of supplies. Smith afterward made an unsuccessful attempt to capture Powhatan in order to obtain a supply of corn, and in revenge for this Powhatan prepared to exterminate the English, but was foiled by the watchfulness of Pocahontas. The quarrels between Powhatan and the English did not cease until the marriage of his daughter to John Rolfe (q.v.), after which he was their firm friend. Smith's description of Powhatan represents him as a «tall, well-proportioned man, with a sour look, his head somewhat gray, his beard so thin that it seemed none at all, his age near sixty, of a very able and hardy body to endure any labor.» Powhatan died in 1618 and was succeeded by his brother Opitchapam, who was soon supplanted by a younger brother, Opechancano (q.v.) already a very noted warrior.

POWHATAN, Indian «pawatan» «falls in a current of water,» a confederacy of southern Algonquian tribes resident at one time within the territory now occupied by the State of Virginia and a part of Maryland. They were surrounded by the Monacan, Manahoac, Chowanoc, Nottoway and Meherrin. When the Powhatan first came into contact with the whites they were one of the most numerous and powerful tribes in America east of the Mississippi. On his map of their territory Capt. John Smith gives 160 of their villages, which were only a part of the territory under the control of their high chief. The Powhatan were among the first tribes on the continent and north of Mexico visited by the early explorers. As early as 1570 the Jesuits established a mission among them; and a few years later reports of them reached the English who finally came into contact with them on the foundation of the Jamestown settlement in 1607. The Indians were alternately friendly and hostile until finally a unity of interest was created between the whites and the natives through the marriage of Pocahontas (q.v.), the daughter of the high chief, to John Rolfe, an Englishman of middle-class family. On the death of Powhatan, father of Pocahontas, in 1618, he was succeeded by his brother Opechancano who had always been an enemy of the white settlers. On 22 March 1622 he attacked, at the same time, all the settlements in Virginia, killing 347 English and destroying all the settlements except Jamestown. The settlers declared war to the death against the Powhatan and made arrangements to render them helpless by sending against them three yearly expeditions with a view to molesting them in every way and especially of destroying their plantations. For 14 years the war continued during which both sides suffered severely. In 1625 General Wyatt defeated a force of 1,000 Powhatan at the battle of Paumunkey and destroyed their villages and crops. The Indians continued the struggle fiercely, but at a great disadvantage owing to the better arrangement of the whites. A peace made in 1636 lasted seven years, when the aged Opechancanough headed another massacre in which over 500 whites were killed in one day. The settlers retaliated and finally captured and shot Opechancanough and broke up the confederacy (1642), after which each tribe made its peace as best it could with the whites. Again the Indians rose in revolt, but their stronghold, near Richmond, was stormed and men, women and children were put to the sword (1676). Some 46 years later a treaty was signed in Albany between the whites, the Powhatan and the Iroquois in which they mutually agreed to keep the peace. From this time on they gave no further trouble. They gradually mixed with the negroes and whites, and from time to time individuals, or even whole decimated tribes, joined other tribes not of their own tongue until finally they disappeared as a tribal organization. The Powhatan are supposed to have numbered at one time at least 8,000. They lived in community houses which were well built and varying in length from about 35 to over 100 feet. Most of their villages were fortified with post-palisades about twice the height of a man. There were from one to three of these walls, one within the other. They had gone a considerable way along the road to the sedentary life that leads to civilization. They had extensive plantations of corn, beans, pumpkins, melons, squashes, vegetables, tobacco and fruits; and they kept account of time and their business transactions on knotted strings much as the ancient Peruvians did. They are represented by a considerable number of Mestizos, most of whom are either farmers or fishermen; and they are as expert to-day as in olden times in the making and management of canoes and fishing nets. See POCAHONTAS; OPECHANCANO; VIRGINIA. Consult Eggleston, E., 'Pocahontas' (New York 1879); Hamor, R. A., 'True Discourse of the Present Estate of Virginia' (London 1915); Hodge, W. H., 'Handbook of the American Indians' (Washington 1910); Price, W. T., 'Historical Sketches of Pocahontas County, West Virginia' (Martinton 1901); Waston, V. C., 'The Princess Pocahontas' (Philadelphia 1916).

POWNALL, Thomas, English statesman, colonial governor and author: b. near Lincoln, 1722; d. Bath, 25 Feb. 1805. He was graduated at Cambridge in 1743. In 1753 he went to America as private secretary to Sir Danvers Osborn, governor of New York, and in 1757 was made governor of the colony of Massachusetts Bay. He showed considerable disinclination to carry out the policies of his superiors in London and as a result he was transferred to South Carolina in 1760 as governor of this colony. Without having gone to South Carolina he returned to England in June 1760 and soon after his arrival resigned the governorship. In 1762–63 he was comptroller-general of the expenditures of the army in Germany, and in 1768 was elected to Parliament. He earnestly opposed the measures of the government against the colonies. After being three times returned to Parliament, he retired in 1780 and passed the remainder of his life in antiquarian studies. In the sphere of scholarship he achieved a greater reputation than that which he won in the field of politics. His writings have a wide range of subjects, and among his principal works are 'Administration of the Colonies' (1764); 'A Memorial to the Sovereigns of America' (1773); 'A Topographical Description of the Middle Colonies' (1776); 'A Memorial to the Sovereigns of Europe on the State of Affairs between the Old and the New World' (1780); 'Notices and Descriptions of the Antiquities of the Provincia Romana of Gaul' (1788); 'Intellectual Physics' (1795); 'A Treatise on Old Age' (1801); 'A Memorial to the Sovereigns of Europe and the Atlantic' (1803), and numerous monographs on antiquarian subjects. Consult Pownall, Chas. A. W., 'Thomas Pownall' (London 1908).

POYNINGS, poin'ingz, Sir **Edward**, English statesman: b. 1459; d. 1521. As a result of his activity in the Kentish revolt against Richard III in 1483 he had to flee to the Continent. In 1485, however, he returned to England in the train of the Earl of Richmond, afterward Henry VII. During the life of this monarch he was one of the most favored and trusted members of his entourage, a position which he also occupied under his successor, Henry VIII. In 1493 he was made governor of Calais. He went as lord deputy to Ireland in 1494 and there defeated Perkin Warbeck at Waterford. During his administration of Ireland he summoned a Parliament at Drogheda, which, at his instigation, gave to the English Crown and the king's Privy Council direct control of Irish administrative affairs. The act by which this was accomplished became known as the Poynings' Law (q.v.; also see Ireland, History). After his recall in 1496 he was made warden of the Cinque Ports. Henry VIII, immediately upon his succession to the throne after the death of Henry VII in 1509, made him a member of the King's Council. During the following years he was frequently entrusted with important diplomatic missions and military commands, and in 1520 he was especially active in arranging and preparing for the Field of the Cloth of Gold (q.v.), the famous meeting between Henry VIII and Francis I of France.

POYNINGS' LAW, or STATUTE OF DROGHEDA, an act of the Irish Parliament, passed in 1495, whereby it was provided that no Irish Parliament should be summoned and no act passed without the previous approval of the English king and his Privy Council under the great seal of England. At the same time all laws that had so far been enacted and were in force then in England were declared of force in Ireland. It was so named from Sir Edward Poynings (q.v.). It was repealed in 1782. Consult 'The Policy of Poynings' Law' (Dublin 1770).

POYNTER, point'ẽr, Sir **Edward John**, English painter: b. Paris, 20 March 1836; d. London, 26 July 1919. He received his early education in Westminster School and in Ipswich, and was the pupil of Gleyre in Paris from 1856 to 1859. In 1860 he returned to London and was elected Royal Academician in 1876. From 1894 to 1905 he was director of the National Gallery. On the death of Sir John Millais in 1896 he was elected president of the Royal Academy and the same year was knighted. He was created a baronet in 1902. His paintings in oil and water colors are distinguished by originality of conception, faultless drawing and strong color qualities, and the most remarkable of them are 'Israel in Egypt' (1867); 'The Catapult,' an incident in the siege of Carthage (1868); 'Faithful unto Death'; 'Proserpine'; 'Perseus and Andromeda' (1872); 'The Fortune Teller' (1877); 'Rhodope'; 'The Golden Age'; 'Zenobia in Captivity' (1878); 'The Meeting of Solomon and the Queen of Sheba' (1891); 'Horæ Serenæ'; 'Idle Fears' (1894); 'The Ionian Dance' (1899); 'The Cave of the Storm Nymphs' (1903); 'The Nymphs' Bathing Place' (1904); 'The Cup of Tantalus' (1905); 'Lesbia and Her Sparrow' (1907); 'Brewing a Storm' (1909); 'A Naval Disaster' (1912); 'At Low Tide' (1913); 'The Sea Bath' (1914); and portraits of King Edward VII and of numerous persons of prominence as well as many water colors, figures and landscapes. Also two sets of designs for the new coinage of 1894 and cartoons for mosaics of Saint George and Saint David in Westminster Palace. During the years 1872–73 he was engaged in frescoing the walls of Saint Stephen's Church, Dulwich. He also furnished designs for the decoration of the interior of the dome of Saint Paul's Cathedral with subjects from the Apocalypse, as well as for the mosaics in Westminster Palace. He also published 'Ten Lectures on Art' (1879); 'Classic and Italian Painting' (with P. R. Head, 1880); 'German, Flemish and Dutch Painting' (with H. J. Wilmot Buxton, 1881). He acted as editor of 'The National Gallery' (1899), containing reproductions of all pictures in the National Gallery acquired up to the end of 1899. Du Maurier in 'Trilby' draws a delightful sketch of Poynter in their old student Paris days and of his passionate study and admiration for all the great masters.

POYNTING, poin'tĭng, **John Henry**, English scientist: b. Monton, Lancashire, 9 Sept. 1852; d. Birmingham, 30 March 1914. He was educated at Owens College, Manchester, and Trinity College, Oxford, was assistant to Prof. Balfour Stewart in the physical laboratory at Owens in 1876–79, and in 1880 was appointed to the chair of physics at Mason College (now Birmingham University). In 1905 the royal medal of the Royal Society was conferred upon him. He has contributed papers on electrical theory, gravitation, radiation and the mean density of the earth to the 'Philosophical Transactions' and the 'Proceedings' of the Royal Society; published his Adams prize essay on 'The Mean Density of the Earth' (1891); and 'A Text-book of Physics' (with Sir J. J. Thomson, 1902–14).

POZZO DI BORGO, pŏt'sō dē bōr'gō, **Carlo Andrea**, Count, Russian diplomat: b. Alata, Corsica, 8 March 1764; d. Paris, 15 Feb. 1842. He was educated at Pisa and became an advocate. In 1791 he was elected to the National Assembly. In his youth he was friendly with Napoleon Bonaparte and his family, but later joined Paoli in his opposition to Napoleon and became the bitter enemy of the latter. As a result he had to flee from France. In 1794, when the English instituted a protectorate over Corsica, he became president of the council, holding this position until the withdrawal of the English forces in 1796. At that time he was specifically excluded by Napoleon from the amnesty which he extended to his other Corsican opponents and he, therefore, went for his safety to England where he resided for a number of years, working to the fullest extent of his power against Napoleon. In 1804 he entered the Russian diplomatic service and was employed in various missions of importance, continuing at all times his activities against Napoleon. As a result of this attitude he resigned from the Russian diplomatic service in 1807 after Emperor Alexander I had concluded a treaty with Napoleon. Again he retired to England where he resided until 1812 when he was recalled by Emperor Alexander. He now devoted himself more than ever to the prosecution of the war against Napoleon. He succeeded in persuading Bernadotte and Sweden to turn against Napoleon and was most active in forming the coalition against the French emperor. He played an important part at the Congress of Vienna. Throughout his whole diplomatic career he openly and constantly displayed his friendship for France, which country honored him in 1818 by making him a count and peer of France. From 1830–35 he was Russian Ambassador at Paris and from 1835–39 at London. Consult Uvarov, S. S., 'Stein et Pozzo' (1846); Maggiolo, A., 'Corse, France et Russie, Pozzo di Borgo' (Paris 1890); 'Correspondance Diplomatique du Comte Pozzo di Borgo et du Comte de Nesselrode' (Paris 1890–97).

POZZUOLI, pŏt-soo-ō'lĕ, Italy, a city on the bay of the same name, six miles west of Naples, at the western foot of the Solfatara and in a volcanic country known to the Romans as the Phlegræan Fields. Near by is the Avernian Lake famed as the entrance to hell both in Virgil's sixth Æneid and in early Christian legend, which pointed out here the place where Christ descended into hell. Remains of Cicero's villa are near the town, which is particularly famed for its amphitheatre, where 30,000 spectators could sit and in which there were naval battles as well as the ordinary gladiatorial contests. The so-called Serapeum is an archæological puzzle and may have been a town-hall; traces of the action of sea water on several pillars not now touched by high water seem to prove that the coast, possibly from volcanic disturbances, has undergone marked and recurrent changes. The only other ruin of importance is that of the temple of Augustus, the site of which is occupied by the cathedral, which preserves six of the original Corinthian columns. Pozzuoli is a good fishing-port; exports the volcanic sands called pozzolana, which are used in making cement; has important mineral baths in the vicinity, and is the site of an ordnance factory, a branch house of Armstrong and Company, which makes armor plate and cannon for the Italian government.

Pozzuoli was founded by Greek exiles from Samos in the 6th century B.C., as Dicæarchia, but the Italians called it Puteoli, "the wells," because of the sulphurous cavities in the earth, and the city continued to be known under this name after it was made a Roman colony in 194 B.C. The city became the greatest port of Italy and on entrepôt for Oriental commerce; goods were sent overland hence to Rome and the dangerous navigation of the coast of Latium avoided. Even after Ostium was built the port retained its importance, and its beautiful coast and curative springs and baths made it a famous resort. During the Middle Ages it suffered a great deal from frequent convulsions caused by nearby volcanos. Pop. (1910 census) 28,167. Consult Loffredi, F., 'Antiquas Peteolorum' (in 'Thes. Antiq. et Hist. Ital.,' Vol. IX, part 4, 1723); Paoli, P. A., 'Avanzi delle Antichita che Esistano a Pozzuoli, Cuma e Baja' (Florence 1768); Stefani, Carlo de, 'La Villa Puteolana di Cicerone' (in 'R. Accad. d. Lincei. Rendic. 'Classe d. Sci. Fis.,' Ser. V. Vol. X, part 1, p. 128, Rome 1901); Huelsen, Christian, 'Inschrift von Pozzuoli' (in Kaiserliches Deutsches Archæologisches Institut Mitteilungen, Roemische Abteilung, Vol. XXIII, p. 71, Rome 1908).

PRADIER, prä-dē-ā, **James**, French sculptor: b. Geneva, 23 May 1792; d. near Paris, 14 June 1852. In his youth he was apprenticed to a jeweler in his native city where he engraved rings and watch cases. At this work he showed so much ability that he was placed in the Geneva School of Design. In 1809 he went to Paris where he studied design under Meynier, and sculpture in the studio of Lemot. In 1813 he gained the prize of the Academy for a bas-relief of Philoctetes and Ulysses, and this work procured his admission to the French Academy at Rome. Here he studied the antique and returned to Paris with two statues, one of Bacchante and the other of a son of Niobe, now in the Luxembourg. In 1821 he went again to Rome, where he remained till 1823 and brought back a statue of Psyche, which he had made out of part of the shaft of an ancient marble pillar found at Veii. This work, too, is now in the Luxembourg. From this period he worked constantly at Paris and produced a great number of larger and minor sculptures, including a Venus, a group of the Three Graces (now at Versailles), a plaster statue of Jean Jacques Rousseau, after which the casting at Geneva has been made, and Cyparissus with his goat and a huntress. Admitted to the Institute in 1827, he afterward executed, among other works, a Prometheus, a Faun and Bacchante, a Phidias (now in the Tuileries Gardens), the bas-reliefs on the pediment of the Chamber of Deputies, the allegorical figures of Lille and Strassburg in the Place de la Concorde at Paris, the Industry in front of the exchange, the Flora, which he considered one of his most successful works, the 12 colossal Victories on the monument of Napoleon in the Hotel des Invalides, the Atalanta in the exhibition of 1851 and the Sappho exhibited in 1852. The colossal fountain at Nimes is another example of his work, as is also the monument of the Duc de Berry in the church of Saint Louis at Versailles. The execution of his works ranks him a sculptor of the first order, but he is deficient in originality of conception, his monotone borders on insipidity and he sometimes strives to give life to his creations by a touch of meretriciousness.

PRADILLA, Francisco, frän-thēs'kō prä-dēl-yä, Spanish painter: b. Villanueva de Gallego, in the province of Saragossa, 24 July 1848. His parents were very poor, and the young Pradilla, who early in his youth showed a remarkable gift for drawing, had to undergo a hard struggle before he could find the ways and means to devote himself to the development of this gift. In 1863 he came to Madrid where he devoted himself zealously to the study of the old masters and became a pupil of Serri. Before long he was sent to the Spanish Academy of Fine Arts at Rome, of which he was one of the first pupils. His first signal achievement was 'The Rape of the Sabines'; this was followed in 1878 by 'Joanna the Mad, following the Coffin of Philip the Fair, her Husband.' The latter was exhibited at the World's Exposition at Paris in the same year, where it created quite a sensation and was awarded a medal. It is now in the Prado at Madrid. His next important work was 'The Surrender of Granada to Ferdinand and Isabella,' a picture remarkable for spirited delineation of character, lifelike action and grandeur of style. It was awarded a first medal at the exposition in Munich (1883) and may now be seen in the Senate Hall in Madrid. Still another picture of the same type is the 'Last Sigh of the Moor.' In addition to these large canvasses he has produced many small genre pictures. Most of these illustrate modern life, especially amongst the peasants, and show keen observation, subtle power of individualization and a remarkable genius for realism. These small canvasses are masterpieces of their kind and have won for him an international reputation. The best known amongst them are 'High Mass in the Pilgrims' Chapel at Guia' (1891); 'Markef Day at Vigo' (1892), and 'Pilgrimage to the Shrine of Our Lady of Good Counsel' (1895). He has also painted some mural decorations of great beauty in the Murgo Palace in Madrid. In 1892 he was made a member of the Berlin Academy and in 1896 he became director of the Royal Museum in Madrid.

PRADO, prä'thō, **Mariano Ignacio,** Peruvian politician: b. Huanaco, 1826; d. Paris, 1902. He engaged actively in a revolution which in 1854 overthrew General Echenique and led the opposition to President Pezet in 1865 which resulted in Pezet's resignation and his own designation as supreme chief. He then formed an offensive and defensive alliance with Chile, and declared war against Spain. A Spanish attack upon Callao was repulsed 2 May 1866, but his own position having been declared unconstitutional, he was obliged to leave Peru in January 1868 and went to Chile. Returning several years later he was elected President in 1876 and in 1879 declared war against Chile. Prado went to Europe in the same year, for the purpose, as was then stated, of obtaining a loan and ironclads, and in his absence the Presidency was seized by Pierola. He returned to Lima in 1886, but ceased to be active in politics. Consult Markham, C. R., 'A History of Peru' (Chicago 1892).

PRAED, präd, **Mrs. Campbell Mackworth.** See PRAED, ROSA CAROLINE MURRAY-PRIOR.

PRAED, Rosa Caroline Murray-Prior, Australian novelist: b. Bromelton, Queensland, 27 March 1852. In 1872 she was married to Campbell Mackworth Praed (d. 1901) and in 1876 went to London where her Australian stories soon made her well known. She has been a prolific writer of popular fiction and many of her books have reached large editions. Amongst the most important of them are 'An Australian Heroine' (1880); 'Policy and Passion' (1881); 'Nádine' (1882); 'Moloch' (1883); 'Zero' (1884); 'The Head Station'; 'Affinities'; 'The Brother of the Shadow' (1885); 'The Bond of Wedlock'; 'Miss Jacobsen's Chance' (1887); 'The Romance of a Station' (1889); 'The Romance of a Chalet'; 'The Soul of Countess Adrian' (1891); 'December Roses' (1892); 'Outlaw and Law Maker' (1893); 'Christina Chard' (1894); 'Mrs. Tregaskiss' (1896); 'The Scourge Stick' (1898); 'Madame Izan' (1899); 'As a Watch in the Night' (1900); 'The Insane Root'; 'Dwellers by the River' (1902); 'Fugitive Anne' (1903); 'Nyria' (1904); 'A Maid of the River' (1905); 'The Lost Earl of Ellan' (1906); 'The Luck of the Leura' (1907); 'By Their Fruits' (1908); 'Opal Fire'; 'The Romance of Mademoiselle Aissé' (1910): 'Body of His Desire' (1912); 'Lady Bridget of the Never-Never Land' (1915). She also published 'My Australian Girlhood' (1902), an autobiography; with Justin McCarthy (q.v.), 'The Right Honorable' (1886); and with Justin McCarthy and M. Menpes, 'The Gray River' (1889). Consult McCarthy, Justin, 'Our Book of Memories; Letters of Justin McCarthy to Mrs. Campbell Praed' (London 1912).

PRAED, Winthrop Mackworth, English poet: b. London, 26 July 1802; d. there, 15 July 1839. He was educated at Eaton and Trinity College, Cambridge, was elected to a Trinity fellowship in 1827, and in 1829 was admitted to the bar. In Parliament he sat for Saint Germains in 1830–32, for Great Yarmouth in 1834–37 and for Aylesbury from 1837. Praed made some successful speeches in the House and was requested by Wellington to write for the *Morning Post* a defense against certain attacks on the Duke in the *Times*. He showed a remarkable gift for versification comparatively early in life, writing considerable poetry of the lighter sort even during his public school and college days. His political writing was too restrained wholly to reach its mark; but his verse is marked by a lightness of touch and a metrical ease and finish which in more recent times finds its closest resemblance in the work of Austin Dobson. He excelled in *vers de société*, though he displayed, as in the 'Red Fisherman,' an imaginative force which suggests broader fields. Of his writings the following have been published in book form: 'Charades' (New York 1852); 'Essays' (London and New York 1887); 'Poems' (London 1865). Consult 'Kraupa, Matilde, 'Winthrop Mackworth Praed' (in 'Wiener Beitraege Zur Englischen Philologie,' Wien and Leipzig 1910).

PRÆFECT, the title of various civil and military officials of ancient Rome. Of these the most important was the *præfectus urbis*, or warden of the city, originally called *custos urbis*. The name *præfectus urbi* does not seem to have been used till after the time of the decemvirs. During the kingly period and the early years of the republic the *custos urbis* exercised within the city all the powers of the chief of the state in his absence; he convoked the senate, held the comitia, and on any emergency might take such measures as he thought proper. When the office of *prætor urbanis* (see PRÆTOR) was instituted the wardenship of the city was merged in it; but the conservative spirit of the Romans still induced them to appoint annually a *præfectus urbi* for the time during which the consuls were absent from the city to celebrate the Feriæ Latinæ, a festival held on the Alban Mount. Under Augustus, however, the office ceased to be a sinecure. The *præfectus urbi* was a permanent magistrate whom the emperor invested with all the powers necessary to maintain peace and order in the city. He had under him a sort of police called *milites stationarii;* and the powers of the office were gradually so far extended that at last there was no appeal from his sentence except to the emperor. The *præfectus prætorio* was the officer who commanded the troops who guarded the emperor's person. (See PRÆTORIAN GUARDS). The office was first instituted by Augustus, and was at first only military and had comparatively little influence attached to it; but under Tiberius it became second only to that of the emperors. From the time of Severus to that of Diocletian the præfects had the superintendence of all the departments of the state — the palace, the army, the finances and the law; they also had a court in which they decided cases. In addition to these functionaries there were the *præfectus aquarum,* charged with the regulation of the water supply of the city; the *præfectus ærarii,* who had charge of the public treasury; the *præfectus vigilum,* who commanded the night-watch; with others of less importance.

PRÆMUNIRE, prē-mū-nī'rē, the opening words of the writ issued preparatory to the prosecution of certain offenses supposed to imply legal contempt toward the sovereign or the government — *præmonere* or *præmunire facias* A. B. (Cause A. B. to be forewarned that he appear before us, etc.). Gradually the word acquired a wider meaning, being used to denote both the offense and the penalties incurred. The first statute of præmunire was passed during the reign of Edward I in 1306 and was intended to repress the papal encroachments on the rights of the Crown, and several subsequent statutes before the Reformation greatly extended the number of penal acts under this title. By still later statutes acts of a very miscellaneous nature were rendered liable to the penalties of præmunire, as knowingly and wilfully solemnizing, assisting or being present at any marriage forbidden by the Royal Marriage Act; asserting by preaching, teaching or advisedly speaking that any person other than according to the acts of settlement and union has any right to the throne, or that the sovereign and Parliament cannot make laws to limit the descent of the Crown; to assert that both or either of the Houses of Parliament have or has a legislative authority without the sovereign; and so on. Cathedral chapters in England which refused to elect the bishop nominated by the Crown were liable to be prosecuted on præmunire. The punishment was forfeiture and imprisonment during the sovereign's pleasure. Prosecution by writ of præmunire has been obsolete, however, for a long time. Consult 'Statutes of the Realm'; Reeves, John, 'History of the English Law' (London 1869); Stubbs, William, 'Constitutional History of England' (Oxford 1875–78); Holdsworth, W. S., 'A History of English Law' (London 1903–09); Jenks, Edward, 'A Short History of English Law' (Boston 1912).

PRÆNESTE, prē-nĕs'tē. See PALESTRINA.

PRÆTOR, originally the official title of the consuls at Rome. When the patricians were compelled to acquiesce in the consulship being thrown open to the plebeians, they stipulated that a new curule magistrate should be appointed from the patricians exclusively, to act as supreme judge in the civil courts. On this magistrate the title of prætor was bestowed. In 337 B.C. the prætorship was thrown open to the plebeians. About 240 B.C., the number of aliens residing in Rome had increased to such an extent that it was found necessary to appoint a second prætor, who should decide suits between aliens or between aliens and citizens. He was known as the *prætor peregrinus,* the other prætor, *prætor urbanus,* having cognizance of suits between citizens only. In 227 B.C., the number was increased to four, the two additional prætors to act as governors of provinces. By Sulla the number was augmented to eight, by Julius Cæsar to 10, 12 and eventually to 16. The prætors held their offices for one year and were afterward sent out by lot as governors of provinces.

PRÆTORIAN GUARDS, a body of permanent troops, established by Augustus as Imperial Life Guards, in imitation of the *cohors prætoria,* or bodyguard attached to the person of the commander-in-chief of a Roman army. The Prætorian guards were kept up by successive emperors and, being under special organization and enjoying several privileges, they became in time so powerful that they were able to raise and depose emperors at their will. They were reorganized by Septimius Severus and were finally suppressed by Constantine the Great.

PRÆTORIUM, (1) the official residence of a prætor or governor of a Roman province: hence, a hall of justice; a judgment-hall; a palace. (2) That part of a Roman camp in which the general's quarters were.

PRAGA, prä'gä, Russian Poland. See WARSAW.

PRAGMATIC SANCTION (*Sanctio Pragmatica*), a public edict relating to important state business, pronounced by the head of a state and differing from the simple rescript, in that the latter was a declaration of law in answer to a question propounded on behalf of an individual. The pragmatic decree was considered irreversible and formed part of the fundamental law of the country. In European history the following are the most important pragmatic sanctions: (1) The ordinance of Charles VII of France, drawn up at Bourges in 1438, conformably to the decrees of the Council of Basel and on which rest the claims of the Gallican liberties. It was repealed by Francis I. (2) The instrument published in 1713 by which the German emperor, Charles VI, being without male issue endeavored to secure the succession to his female descendants. It was in accordance with this instrument that he settled his dominions on his daughter Maria Theresa. He induced most of the European sovereigns to guarantee it; but Charles Albert, elector of Bavaria, the next heir to his dominions, refused; this caused the Austrian War of Succession after the death of the emperor in 1740. In the Peace of Füssen (1745) Bavaria acknowledged the pragmatic sanction. (3) Charles III of Spain, when he ceded the throne of Naples to his third son and his successors in 1759, called the law of succession which he prepared for this branch of his family *sanctio pragmatica.* Consult Wolf, A., 'Die Geschichte der Pragmatischen Sanktion bis 1740' (Wien 1850); Turba, De Gustav, 'Die Grundlagen der Pragmatischen Sanktion' (in 'Wiener Staatswissen-Schaftliche Studten,' Vol. X, part 2, and Vol. XI, part 1, Leipzig and Wien 1911–12).

PRAGMATISM. The term pragmatism, as employed in philosophy at the present time, denotes the general tendency to subordinate logical thinking to the ends of practical life and to find the test of the truth of ideas in their practical consequences. There are thus two somewhat distinct sides to the doctrine, which we find differently emphasized by different writers. On the one hand, this view points out that thought owes its origin to the needs and demands of the practical life. Thought is thus a tool or instrument that is always invoked to meet a particular crisis or problem resulting from a concrete situation. Thought, therefore, does not aim at truth in general. Its business is to discover, in concrete circumstances, the best means to the realization of some practical end that life demands.

This side of the doctrine has been chiefly elaborated by Prof. John Dewey and those associated with him at the University of Chicago as colleagues or students. These writers have connected their theory with the doctrine of evolution and support it mainly by arguments and analogies drawn from this source. On the other hand, to decide regarding the truth or falsity of any theory or conception, we must also appeal to the practical consequences that result from it. A theory is demonstrated in the only possible way when it is shown that it will "work"; that is, that the results that we wish to obtain in a given situation follow from it. It is only in the light of these results that a conception has meaning. Apart from its practical consequences, a conception is an abstraction without meaning or significance and consequently without truth or falsehood.

This practical test of the truth of a theory through an appeal to its consequences is the element in pragmatism that has been mainly emphasized by C. S. Peirce and Prof. William James. Peirce first employed the term and outlined the doctrine in an article in *The Popular Science Monthly* (January 1878), though he put it forward merely as a practical method of avoiding abstractions by making clear to oneself the consequences in terms of action of general logical conceptions. The present currency of the position in America and England is, however, largely due to Professor James, who has elaborated and enforced it in his psychology and in a number of popular works and articles. The names of Peirce and James are so closely connected with pragmatism that we quote here the formal definitions of the term which they have written for Baldwin's 'Dictionary of Philosophy.' Peirce describes the doctrine as follows: "The opinion that metaphysics is to be largely cleared up by the application of the following maxim for attaining clearness of apprehension: 'Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object.'" James defines pragmatism: "The doctrine that the whole 'meaning' of a conception expresses itself in practical consequences, consequences either in the shape of conduct to be recommended, or in that of experience to be expected, if the conception be true; which consequences would be different if it were untrue, and must be different from the consequences by which the meaning of other conceptions is expressed. If a second conception should not appear to have other consequences, then it must really be only the first conception under a different name. In methodology it is certain that to trace and compare their respective consequences is an admirable way of establishing the differing meanings of different conceptions."

JAMES E. CREIGHTON,
Professor of Logic and Metaphysics, Cornell University.

PRAGUE, prăg (German Prag; Bohemian Praha), Austria-Hungary, the capital of Bohemia and the third largest city of the empire, 217 miles by rail northwest of Vienna and 118 miles southeast of Dresden. Its site is a regular basin, traversed by the river Moldau, from the banks of which the city's buildings rise in terraces, till they are terminated and enclosed by hills of considerable height. Of nine bridges including two railway viaducts the most striking is the Karlsbrücke, dating from 1357–1503, and reconstructed after damage by a flood in 1892; it is 543 yards long with tower gateways at each end and buttresses adorned with statues of Saint John Nepomuk, the patron saint of Bohemia, and other saints. The mediæval fortifications and ramparts have been gradually demolished since 1866 and their sites occupied by pleasure grounds, boulevards, dwellings, etc. The city is divided into eight districts, the Altstadt, Josephstadt, Neustadt, Vysehrad and Lieben on the right, and the Kleinseite, Hradschin and Holeschowitz-Bubua on the left bank. Outside the line of the old walls lie the suburbs Karolinenthal, Smichow, Weinberge, Zizkov and others. The Altstadt and Josephstadt, the latter formerly the Jewish Ghetto, lie along the right bank toward the north. The streets of the Altstadt are narrow; it is the principal seat of trade and business and contains some of the best stores, besides numerous churches, ecclesiastical and educational establishments. The Neustadt encloses the Altstadt on the northeast, east and southeast. Though newer than the other, it is still very ancient, having been built by the Emperor Charles IV in 1348. On the opposite side the Kleinseite forms the aristocratic quarter, the chosen abode of the Bohemian nobles and the site of several remarkable palaces. The Hradschin, to the west of the Kleinseite, occupies the side of a steep hill, is of less extent and contains fewer houses than the other quarters, but the chief public edifices. Among these are the royal palace, formerly palace of the Bohemian kings, situated in the Hradschin, parts of which date back to the 14th century; the Gothic cathedral, begun in 1344 and still uncompleted, also in the Hradschin; the Clementinum, the seat of the theological and philosophical faculties of the university, erected by the Jesuits in 1653–1726; the Carolinum, the seat of the university since 1383 and still devoted to the faculties of law and medicine; the Teynkirche, a Gothic church, begun in 1370, historically interesting as the place where the Bohemian estates made George Podiebrad their king, and containing the grave of the celebrated Danish astronomer, Tycho Brahe, who spent his last years at Prague; the palace of Wallenstein, originally a structure of great magnificence, but now much dilapidated; the Alte Rathaus (old town hall), an irregular Gothic edifice, partly of the 15th century and partly of the early 19th century, with a fine old clock dating back to 1490; the chief synagogue of the Jews, rebuilt in 1338 after the burning of the Jewish quarter; the military hospital, a large and magnificent edifice, originally erected by the Jesuits as a college; German and Bohemian theatres, the opera house, the national museum, museum of natural history, picture gallery, the German and Bohemian technical colleges, Landesbank (1896), municipal savings bank (1894), central market hall (1896), the new Ritterakademie (1896), the Municipal Museum, the Museum of Industrial Art (1899), etc. Besides the cathedral there are a number of other smaller churches of considerable interest and antiquity, such as the Karlov church (1351–77), church of Saint Mary the Virgin (1348–72), church of Our Lady of the Snows (about 1347), Saint Thomas' Church (14th century), Saint George's Church (1142–50), etc. The university, founded in 1348, had 10,000 students at the beginning of the 15th century; but subsequently as a result of the Hussite disturbances it had a long period of inactivity. It received a new constitution in 1881, having now two co-ordinate sides or sections, one German and one Czech, with respectively 184 and 249 teachers, and 2,067 and 4,713 students (1914). It possesses a library of 370,000 volumes and 3,920 manuscripts, a fine observatory, museums of zoology and anatomy, a botanical garden, etc. The manufactures consist of gold and silver embroidery, silk, woolen, cotton and linen goods, buttons, hats, leather, paper, soap, refined sugar, vinegar, liqueurs, refined salt, gloves, sugar of lead, stearine and tallow candles, machines, musical and mathematical instruments, firearms, porcelain, jewelry, etc. The trade is of great importance; Prague, owing to its central position, and to its facilities of transport by river, roads and railway, being the great entrepôt for all the traffic of the kingdom. There are seven railroad stations and two river steamship lines. It has also several important fairs, particularly one for wool, which lasts seven days, and during which a great amount of business is done; that of Saint Wenceslas, the old patron saint of Bohemia; and that of Saint John Nepomuk, though these two are rather religious festivals than fairs, and are more crowded with devotees than dealers.

Prague is supposed to have been founded in 722 by the Duchess Libussa. In 1348 Charles IV founded the university, the first which Germany possessed, and it soon acquired such celebrity through the teachings of such zealous rectors as Huss and Jerome that it was resorted to from all quarters of Europe. In 1424 Prague was taken by the Hussites and almost destroyed, but after their submission to the emperor in 1433 the town was rebuilt. It reached its greatest prosperity and importance during the times of George Podiebead and his successors. It suffered severely in the Thirty Years' War, which, indeed, started in Prague, and in 1620 a battle was fought at the White Mountain in the neighborhood, in which the Elector-palatine Frederick V was defeated by the Emperor Ferdinand II and compelled to renounce his crown. In 1631 the city was captured by the Saxons, who were driven out a few months later by Wallenstein. In 1741 it was taken by the French and Bavarians, and three years later capitulated to Frederick the Great. After the Seven Years' War the city made rapid strides and enjoyed peace and prosperity until 1848, when the Austrian government caused it to be bombarded for two days, owing to the marked democratic demonstrations excited by the meetings of the Slavonic Congress within its walls. During the Austro-Prussian War in 1866 the city was occupied by the Prussians and here the treaty of peace was signed on the 23d of August.

Prague is the seat of the Imperial government and a Roman Catholic prince-archbishop. The city is governed according to a charter dating back to 1850. At the head of its government is a burgomaster. The citizens elect a board of aldermen of 90 members from whom a second body of 24 members, the Stadtrat, are chosen. The city owns three of its four gas works, several waterworks, the electrical powerworks and street railways and the slaughterhouse.

Besides the two universities and technical colleges there are numerous public, normal, high, manual training, trade and grammar schools, both for German and Bohemian children, as well as a number of private educational institutions. There are also nine public hospitals, a state insane asylum, orphan asylums and a large number of other charitable institutions. A number of newspapers are published daily in both German and Bohemian. Of the total population 90 per cent were Bohemians and 8 per cent Germans. Almost 90 per cent were members of the Roman Catholic Church and about 8 per cent Hebrews. Prague has shown the least increase in population of all Austrian cities during the decade 1900–1910, namely, less than one-half per cent. Pop. (1910 census) 223,741. Consult 'Privilegia Civitatum Pragentum' (Prague 1886); Tomek, W. W., 'History of the City of Prague' (in Bohemian, Vols. 1–12, Prague 1855–1901); 'Oesterreichisches Staedte-Buch' (Vienna 1899, to date); Neuwirth, J., 'Prag' (Leipzig 1901); Luetzow, F. H. H. von, 'Story of Prague' (New York 1902); Symons, Arthur, 'Cities' (London 1903).

PRAHRAN, prā-răn', Australia, a town in the state of Victoria, four miles southeast of and suburban to Melbourne (q.v.). It is a separate municipality and in 1879 was made a city. Pop. (1911 census) 45,367.

PRAIA, prä'yä, or La Praia, Cape Verde Islands (q.v.), since 1770 capital of this group of 14 Portuguese islands; on the southeast coast of the island of São Thiago, the largest and most populous of the 14. It has a good harbor and commercial relations with all the cities of the islands. It is the seat of the governor-general, whose palace is located there; has a meteorological observatory; and is an important cable station between South America, Europe and West Africa. Pop. 21,000.

PRAIRIE, a treeless region in the Mississippi Valley, adjacent to the forested area, so called since the time of the early French explorers. The eastern border of the prairie region is an irregular line crossing Minnesota and Wisconsin in a southeasterly direction and extending into western Indiana, thence crossing Illinois and Missouri southwesterly to the borders of Oklahoma and eastern Texas. From this forest line the prairies extend westward from 200 to 600 miles to the Great Plains, into which they merge quite imperceptibly. In general we may say that the characteristics of the prairies are intermediate between those of the adjacent forests on the east and the plains on the west. The soil, climate, rainfall, etc., of the prairies are much like those of the western edge of the forests. As we go westward the soil becomes more sandy, the climate more «continental» and the rainfall less, approaching the conditions which prevail on the plains.

The soil of the prairies is usually dark in color and rich in organic matter. It is composed of very fine particles, and when dried after wetting becomes very hard. It contains much finely divided sand, and is generally somewhat deficient in clay. While very rich and often of great depth, it is by no means inexhaustible, and the better classes of farmers have found it profitable to add fertilizers from time to time.

The climate of the prairies is somewhat more severe than that of the adjacent forest areas, on account of the free sweep of the winds which intensify the cold of winter as well as the heat of summer. The annual rainfall is about 30 inches, diminishing somewhat as we go westward, and this is so distributed that by far the greater portion falls in the spring and summer.

Although the prairies are usually spoken of as treeless, this is not strictly true, since the streams are always fringed with trees, the treeless areas extending over the higher lands from stream to stream. Yet since these forest fringes are often confined to the deep narrow valleys in which the streams flow, they are often scarcely noticeable as one looks over the landscape. The vegetation of the prairies naturally divides itself into that of the open country and that of the woodlands. In the open country the grasses constitute the dominant vegetation, since they are mostly perennial, and very tenacious of life. The species which are most common are grama (*Bouteloua oligostachya, B. curtipendula, B. hirsuta*), buffalo grass (*Bulbilis dactyloides*), dropseed grass (*Sporobolus*, of several species), wild June grass (*Koeleria cristata*), blue-stem (*Andropogon*, of several species), switch grass (*Panicum virgatum*), beard-grass (*Aristida*, of several species), Muhlenberg grass (*Muhlenbergia*, of several species), sand-grass (*Calamagrostis*), porcupine-grass (*Stipa spartea*), Eaton grass (*Eatonia*), spear-grasses (*Poa*), fescue grasses (*Festuca*), brome-grasses (*Bromus*), wheat-grasses (*Agropyrum*), and wild-rye (*Elymus*), each of many species. Altogether about 150 native species of grasses grow upon the prairies, affording fine pasturage and hay for stock. In those portions of the prairies where the rainfall is abundant these grasses constitute a continuous sod which completely covers the surface, but where there is less rain they are in isolated clumps or bunches, and are then called «bunch grasses.» In all prairies there are other plants which grow intermingled with the grasses, the most conspicuous of which are the golden-rods (*Solidago rigida, S. serotina, S. canadensis*, and other species), asters (*Aster patens, A. sericeus, A. multiflorus*, and other species), sunflowers (*Helianthus annuus*, and other smaller species). A few shrubs are found scattered over the prairies, adding to the variety of the vegetation, most noticeable the wild roses, redroot (*Ceanothus*), and shoe-string (*Amorphia canescens*), the last so-called on account of its long tough roots which trouble the plowman.

The woodlands are usually found bordering the water courses. In some cases they constitute broad areas extending for many miles on each side of the streams, while in others they are narrow belts but a few rods in width, or even mere fringes along the stream-banks. The trees of the prairies are all of species which have wandered away from the eastern forests, and pushed up the streams to a greater or less distance. There are more species along the eastern side of the prairies, and their number decreases as we go westward. The common species are oaks, hickories, walnuts, willows, cottonwood, elms, maples and ashes. As a rule these trees are not as tall as those which occur in the heavy forests eastward, and they generally grow with more spreading tops. Occasionally, however, trees of gigantic dimensions are found in sheltered situations. Careful observation of the trees on the prairies shows that where they are protected from fires, stock and other adverse influences, they generally reproduce so rapdily as gradually to extend the forest areas. In many places the forest belts along the streams are widening, and also pushing up the valleys. Since the stoppage of prairie fires this natural spreading of the forests has gone on rapidly, so that there is to-day more forest-covered land in some parts of the prairie country than when it was first visited by white men. The prairie lands are from 300 to 1,400 feet above sea-level and are broken by river channels which have been cut in places to depths of over 100 feet.

PRAIRIE CHICKEN, or PINNATED GROUSE, a familiar western gamebird (*Tympanuchus americanus*). The genus *Tympanuchus* (or *Cupidonia*) is particularly well characterized by a large patch of naked yellow skin on each side of the neck, ordinarily concealed by a tuft of narrow-pointed feathers attached to the skin at its anterior border. Beneath this patch is an air-sac connected with the respiratory system and which can be inflated until the skin is distended to the size and form of half an orange. The head-crest is small, the tail is rather short, rounded and formed of 18 rather stiff quills, and the tarsi are incompletely and lightly feathered to the toes, which are naked and conspicuously webbed at the base. The plumage is plain, the colors being various browns and yellows with white and black, finely mottled above and more boldly barred transversely below. The neck-tufts of the male are two and one-half to three and one-half inches long, those of the female being considerably shorter. A full-grown male prairie-chicken is fully 18 inches long, but the females are smaller.

The changes in the centre of population of the prairie chicken as related to human settlement of the country are interesting and still in progress. Formerly it ranged throughout all open country between the Appalachian and the Rocky Mountain systems, and from Manitoba to the Gulf Coast. As the country has become more thickly populated it has disappeared from many regions and the eastern limit of its range has moved more and more westward. At the same time the clearing of the forests has provided much new open country which it has been prompt to occupy, replacing other species of grouse less adapted to life on bare prairies, and becoming abundant in many places where, as in parts of Minnesota, the land is cultivated in large tracts. In this way its range has extended westward and northward as it has been curtailed eastward. Like most of the grouse the prairie chicken is gregarious, living in flocks which become very large in the winter, when the birds show a disposition to wander. Throughout most of its still wide range this species is not in any true sense migratory; but a definite northward and southward movement takes place in the upper part of the central Mississippi Valley, although according to some experienced gunners and ornithologists, this is limited to the females, the males being quite stationary. In the spring parties of the males congregate at dawn on knolls, perform various antics, and from time to time inflate and empty the air-sacs, thus producing a loud booming noise which is said to be audible, in the stillness of the time and place, for a mile. In a few days the females gather, when the cocks engage in fierce battles for the possession of mates, before whom they strut and swell, with drooping wings and spreading tail, with their Cupid's wings elevated and air-sacs inflated almost to bursting, until the conquest is complete. They are monogamous and the nest of grass and weeds is built in a concealed spot on the ground and from 12 to 20 eggs, of a grayish or buff color and either unmarked or speckled with brown, are laid. They are said to hatch in about 25 days and the young, which run at birth, are cared for chiefly by the female, which has also performed the labor of incubation. Throughout the summer and early autumn they remain in family parties, but later gather in larger flocks. The food consists of various kinds of berries, nuts, seeds, shoots and buds and insects. With the development of the prairie region as a great grain-growing country the prairie chicken has come to be especially abundant in the cultivated districts and to adopt wheat and other grains as special articles of diet. The vast numbers of grasshoppers which they destroy should, however, more than compensate the farmer for any loss of grain which he suffers.

The prairie chicken is so prolific, that, in spite of the enormous numbers destroyed annually by cold rains, hawks, skunks and other natural influences, and by man, it has held its own and continues to be abundant in many parts of the grain-producing prairie States. It is, therefore, of far greater commercial importance than all other species of our native grouse combined, and not only are immense numbers consumed within those States but many thousands are shipped to New York and other eastern markets, where its rich and delicate flesh is in demand for table use. Most States have seen the expediency of establishing close seasons and of prohibiting the use of snares and traps in its capture, so that it is now hunted almost exclusively with the shot-gun. Many States have also prohibited its shipment for sale and have limited the number which a gunner is permitted to shoot in one day, usually to 25 or 50. Naturally it is the great game bird of its range. Its great popularity with the masses, however, is probably due to the size of the bag which results from a day's shooting rather than to its gaming qualities, for in speed and other attributes which test the true metal of the sportsman the prairie chicken cannot compare with the ruffed grouse. Early in the season, when the young are not yet strong of wing and when better cover and warm weather cause the birds to lie close, bags of 50 or even 100 may be made by a good shot on the best hunting-grounds, but with the advance of the season and cooler weather the birds become more alert, harder and swifter of wing, the long quick shots which are now necessary testing the skill of even the most experienced gunner. Still later nothing but the rifle and much hard tramping is likely to yield any returns. As in the case of all similar gallinaceous birds, a strong shooting gun and good dogs are required. Whether the latter be setter or pointer is generally immaterial, as both may be equal in speed, ruse and training. For this work on the wide, little watered prairies, endurance is a prime qualification and many hunters use their dogs in relays. The best time for the sport is in the early morning and late afternoon, not only because tramping under the noonday sun is very wearying to hunters and dogs, but also because the birds cease feeding at that time and retire to sheltered gulleys and ravines. The species is easily domesticated.

It is very commonly stated that the prairie chicken was found throughout the New England and Middle States a century ago; but ornithologists are now practically agreed that the eastern heath hen is a distinct species, properly called *T. cupido.* At one time it was common, but became practically extinct 75 years ago. At the present time the only colony known to be in existence is one which inhabits the wooded hills and scrubby plains of the island of Martha's Vineyard, where the birds are seldom seen in the thick coverts which this region affords. In general habits the heath hen differs little from its western relative. This remnant of its race is absolutely protected by the Massachusetts game law and a generally sympathetic local sentiment. A third species (*T. pallidicinctus*) is found in the region from Kansas to Texas, and along the Gulf Coast the common prairie chicken develops a distinct local race in Texas and Louisiana. In parts of the northwest the sharp-tailed grouse (*Pediocætes phasianellus*) is called prairie-chicken. See GROUSE.

Biological Survey, United States Department of Agriculture, Washington 1902.

PRAIRIE DOG, a name given to either of the two species of marmot-like rodents of the western plains of the genus *Cynomys*, but especially to *C. ludovicianus*. It is about a foot long, reddish-brown above, lighter beneath. Its habits are eminently social. It forms large communities on the higher and drier parts of the plains, each burrow having a little hillock at its entrance, forming a firm curb about the shaft, which leads steeply down to a series of chambers a dozen feet or more underground, where the animals spend the winter in comfort, sustained by a store of the stems and seed-heads of sunflowers and similar plants.

These colonies were naturally several acres in extent, forming "towns" of crowded burrows; and were frequented by weasels, wolves, badgers, snakes and birds of prey, which preyed upon the rodents and their young, and kept down their numbers. Since the general settlement of the borders and river-valleys of the plains region, the prairie dogs have been so favored by the decrease of their natural enemies and by the spread of irrigated cultivated lands, supplying them with both water and food in vast abundance, that they have increased enormously, so that at the opening of the present century areas of thousands of square miles in northern Texas, and in the region between the upper Arkansas and Platte rivers, were so infested with the animals as to be practically useless to man. The question of practical relief from this condition has been a subject of much discussion among naturalists, not only, but both general and local governments have been forced to act in assistance of the farmers and cattlemen. The most successful means of extermination seems to be suffocation in their holes by means of bisulphide of carbon, which is placed upon balls of absorbent material and rolled down their burrows. Consult publications of the United States Department of Agriculture since 1891.

PRAIRIE DU CHIEN, Wis., city, county-seat of Crawford County, on the Mississippi River and on the Chicago, Missouri and Saint Paul and the Chicago, Burlington and Quincy railroads, about 90 miles in direct line west of Madison. In the vicinity of the city of mineral springs. Previous to its settlement the ground on which the city stands now was open prairie land. It is said that it was then the seat of an Indian chief named "The Dog," from which the French gave it its present name. Prairie du Chien was settled in 1783, but a French fort was built here in 1685 and abandoned a few years later. Another fort was built in 1755. In 1786 the British surrendered this place to the United States, but captured it again in 1814 and retained possession for two years. In 1872 it was incorporated. Prairie du Chien is the trade centre of a fertile agricultural section. The chief manufactures are pearl buttons, barrels, veneer, egg cases, woolen goods, pickles, dairy products. The trade is chiefly in eggs, poultry, farm and dairy products, buttons and its own manufactures. The principal public buildings are the churches and schools; the ruins of Fort Crawford (1830) still remain. The educational institutions are College of the Sacred Heart, for boys and young men; Saint Mary's Institute, for girls; a high school, public and parish schools and a public library. The population in 1910 was 3,149. Consult 'State Historical Society of Wisconsin Collections' (Madison 1855–1916).

PRAIRIE FOX, the swift or kit fox (*Vulpes velox*) of the western American plains. See FOX.

PRAIRIE GROVE, Battle of, an engagement between the Confederates under General Hindman and the Federals under Gens. F. J. Herron and J. G. Blunt, at Prairie Grove, Ark., 7 Dec. 1862. Blunt had been stationed for some time at Cane Hill, when he received information that Hindman, with a force of about 25,000, was advancing northward to enter Missouri. He immediately summoned Herron and his two divisions, then near Springfield, Mo., to his aid. Herron reached Fayetteville, about 12 miles from Blunt's position, in the morning of 1 December, and the Confederates at that time lay between the two Union camps. Early that morning Hindman, with 11,000 men, moved against Herron; the Confederate cavalry at first had the advantage, but were in turn driven back by Herron, whose entire force came up; Hindman then took up a strong position and awaited attack. Meantime Blunt hastened to Herron's aid, and Hindman thus faced a force superior to his own in both numbers and equipment. The battle lasted the greater part of the day, and the Confederates were finally forced to retreat. The Confederate loss in killed, wounded and missing was 1,317; the Federal loss, 1,251. The battle was of importance as checking the further advance of the Confederates into Missouri. Consult 'The War of the Rebellion' (Series I, Vol. XXII, Part 1, pp. 67–158, Washington 1888).

PRAIRIE HEN. See PRAIRIE CHICKEN.

PRAIRIE PIGEON, name given in the prairie region of the western United States to both the golden plover and the upland plover. See PLOVER; SANDPIPER.

PRAIRIE RATTLESNAKE, a name applied to one of several rattlesnakes to be found on the prairies of North America, the massasauga (*Sistrurus catenatus*). See RATTLESNAKE.

PRAIRIE SCHOONER, a type of covered wagon, used by the pioneers in transporting their chattels across the western prairies. As a type they have vanished, but the covering of the modern army motor truck is arranged in many respects similarly to that of the early prairie-schooner — more or less of a horseshoe shape with openings in front and back.

PRAIRIE SQUIRREL, or GOPHER, a name for several animals of the genus *Spermophilus*, found in the American prairies in great numbers. See GOPHER.

PRAIRIE STATE, a name applied to Illinois from the fact that the face of the State is mostly a level table-land, elevated from 300 to 800 feet above the sea.

PRAIRIE WOLF, the coyote (q.v.).

PRAISE OF FOLLY, The ('Moriæ Encomium'), «the wittiest of all Erasmus's writings» (Froude), was written at Sir Thomas More's house in Bucklersbury immediately after Erasmus's return from Italy in 1509, but was not published until two years later when Erasmus went to Paris to see it through the press. At least 12 editions followed within the next 10 years; and several English translations quickly appeared, so that Milton in 1628 speaks of it as being «in everyone's hands» at Cambridge. In a dedicatory letter to More, Erasmus tells us that «the first hint (of the work) was your own surname of More, which comes as near the literal sound of the word (*Moria*) as yourself are distant from the signification of it, and that in all men's judgments is vastly wide.» From a subsequent letter to John Botzheim (1523) it appears that Erasmus had intended at the same time to write three essays in praise of Folly, Nature and Grace, respectively, but that the carping disposition of certain persons made him change his mind. 'The Praise of Folly,' which is very entertainingly written and is filled with proverbs, classical allusions and quotations from the poets, scourges the abuses and follies of the various classes of contemporary society, although not by lashing particular persons by name. «I did not,» Erasmus tells us, «so far imitate Juvenal as to rake into the sink of vices to procure a laughter rather than create a hearty abhorrence.» The entire work is put into the mouth of Folly herself, who, after describing her descent, education and attendants, proceeds to show that no class of human beings is free from her influence. In this process, it is shown tc what extent grammarians and poets, philosophers and theologians, religious and monks, princes and courtiers, popes, cardinals and bishops and all other classes of men are under Folly's sway. The work is comparatively free from the coarseness of speech prevalent at the time, and men like More said that it needed no defense. It has been charged, however, that it was a deliberate attempt to discredit the Church, but this charge is unfounded, unless by the words «the Church» one means «the wicked and unfaithful ministers of the Church.» Among these indeed it produced consternation, although its author did not incur the disfavor of secular princes, many fellow-clerics and even Pope Leo X. Hard as he had struck at the existing evils he had said nothing for which the Church courts could openly punish him. When it is remembered that 'The Praise of Folly' appeared after the pontificates of such Popes as Alexander VI and Julius II, at a time when simony and similar abuses had made such an inroad into the Church that plans were laid for convening the great reformatory Council of Trent, it is not difficult to imagine that such outspoken works as the one under discussion were needed to speed the day.

HERBERT F. WRIGHT.

PRAISES OF THE CREATURES, The. See CANTICLE OF THE SUN.

PRAJĀPATI, Hindu divinity, having the character of a creator; at various periods this name was given to different Hindu deities, such as Indra, Brahma, etc. Thus there were many Prajāpatis, and the Puranas contain many legends concerning them. Consult Monier-Williams, Sir M., Brahmanism and Hinduism' (4th ed., London 1891); Barth, A., 'The Religions of India' (Boston 1882); Hopkins, E. W., 'The Religions of India' (Boston 1895); Macnicol, N., 'Indian Theism' (London 1915).

PRĀJÑĀ PARAMITĀ, the principal Sutra (body of rules or precepts) of the Mahayana School of Buddhists. The words mean in Sanskrit «absolute or transcendental wisdom.» Consult Walleser, M. G. L., 'Prajña Pāramitā; Die Voll Korumeubeit der Erkeuntris' (in Quellen der Religions-Geschichte,' Vol. VI, Göttingen and Leipzig 1914).

PRAKRIT LANGUAGES AND LITERATURE. The term Prakrit is applied to the vernacular languages of India, in distinction from the literary idiom, the Sanskrit (*samskrita*, purified, refined; *prakrit*, natural, common), and it is a sign of the venerable age of Prakrit that we find traces of it even in some very early Vedic hymns. Prakrit again is subdivided into primary, secondary and tertiary, according to the period when each of these three forms of the vernacular was in general use. There are two main groups of primary Prakrit, namely, the Aryâvarta, or that spoken in the central part of India, the Mâdhya-dêsa, and that current in the zone beyond, the so-called «Outer Band.» That of the Midland developed in its turn into literary Sanskrit about B.C. 300. Irrespective of that process, however, the primary Prakrits arose and grew in accordance with the usual courses of phonetics, with a general tendency to simplify the different idioms, eliminating harsh consonants and diphthongs and also complicated grammar forms. Side by side, however, with the literary Sanskrit there developed in the central region of India a vernacular, though this was somewhat hampered in its growth by the literary tongue. One of the secondary Prakrits at least, the Pâli, grew into the literary vehicle of Buddhism and became a highly articulated tongue. Besides, other Prakrits in a measure went through the same process and blossomed out into literary languages, both for profane and sacred uses. Thus, Jainism (or the Jaina religion, a regenerated Brahmanism) was propagated by three distinct Prakrits, and in the Indian drama and in other branches of literary production some of the common dialects were likewise employed. Singularly enough, in such dramas the Brahmans, heroes and persons of high lineage and the female personages, the celestial nymphs, courtesans, etc., only, spoke generally in Sanskrit to the audiences, all the others in the various forms of Prakrit. In fact, our knowledge of the older Prakrits has been greatly enhanced by this Indian stage convention, because the vernaculars thus employed in plays by acting persons varied greatly, partaking as they did of the provincial character assumed by each. Often as many as 10 different forms of Prakrit are thus introduced in a single play to the audiences, and of some of the less prominent Prakrits, notably of those possessing no literature of their own, we should not have a single trace without the aid thus given our understanding. Distinguished again from Prakrit proper, or perhaps rather as its lowest expression, is the *Apabhramsa* («corrupt» language, or «patois»), a name given to the wholly unliterary form of Prakrit, the one quite devoid of grammatical niceties and ingenious refinements of speech. However, it might happen that the Apabhramsa itself grew into a literary vehicle and received a grammatical construction, while a coarser form of the same vernacular remained as the speech of the totally uncultured masses. The secondary Prakrits again attained a double growth, that of the Mâdhya-dêsa, or Midland region of India, which was named *Saurasêni*, and that of the surrounding country district. Saurasêni extended as far as Lahore, overrunning Rajputâna and Gujerât. Its vocabulary was nearly identical with the primary Prakrit, but phonetically there was considerable change. The Prakrits of the Outer Band comprised the Mâgadhi, Ardhamâgadhi and Mâhârâstri. Pâli grew out of Mâgadhi. Ardhamâgadhi (half Mâgadhi) developed by itself. Mâhârâstri was spoken and cultivated in the large kingdom of that name, reaching from the Nerbudda to the Kistna and including parts of Bombay and Hyderabad, all of it south of the Saurasêni territory. At one time the prevalence of Prakrit of the Outer Band extended up to and including Benâres. As a general point it ought to be noticed that there was an Apabhramsa (corruption) to each proper form of Prakrit. But uniform with them all, Prakrit and Apabhramsa both had the inclination to do away with certain harsh consonantal sounds that existed in literary Sanskrit itself, and with as much grammatical restriction as possible. Thus, for example, the Sanskrit *bratam* (brother) develops into *vatam* in Pâli and into *vaam* in Mâhârâstri. A number of the Prakrits, too, cast out the Sanskrit *r*. Of all these Prakrits it is Mâhârâstri that deserves most mention. In the Indian texts it usually stands for Prakrit *per se*. It obtained literary prominence quite early, epical, lyrical and dramatical literature being alike cultivated. Ardhamâgadhi also produced much literature, though of a somewhat inferior texture. However, the early Jaini books were composed in it. Saurasêni is, on the other hand, the usual prose dialect of the plays and is also used exclusively by one of the Jaini sects in their writings. There is, then, a plentitude of material from which to study the earlier as well as the later Prakrits, and there are grammars, too, to help. Throughout one notices a steadily proceeding decay of grammatical rules and forms in all the Prakrits, until, as in the Hindustani of to-day, a purely analytical vernacular is the result. In their general phonetic effect there was a flattening of the vowels and a pruning away of superabundant consonants. To be more explicit as to the poetical and literary uses made of the Prakrits, the holy writings of the Jaina religion, the *sûtras*, etc., were in Ardhamâgadhi; the non-canonical books of the Svêtâmbara sect were in Mâhârâstri, and the canon of the Digâmbâras was in Saurasêni. In lyrics, which all are of a highly artificial type, the Prakrit reigns supreme. Most admired by Indians is Hâla's «Sattasaī,» a collection of lyrics compiled some time before the 7th century A.D. There is much grace and playful fancy displayed in this collection, though in range of subjects and thought somewhat narrow. Many imitations inspired by this volume have appeared in India, the best being probably the «Satsaí,» of Bihâri Lâl (17th century). The sources whence Hâla drew are, unfortunately, lost. It has been contended that the «Mahâbhârata» also owed much to Prakrit, and that it had first been written as a folk-epic in the early vernacular before being done over into Sanskrit proper. Mâhârâstri was employed for lyrics, even in Sanskrit dramas, as Saurasêni was for most interspersed dialogue. In Prakrit epic poetry the «Ravânyavâha» (Death of Ravâna), based on the «Rāmāyana» of Pravarasêna (about A.D. 700) occupies first place. Since then the «Gaūdavaha» by Vākpabi (about 750 A.D.), telling of the taking of Bengal by Yasōvarman, and the «Kumārapāla-carita» (A.D. 1150) are the most pretentious. Of Prakrit dramatic literature may be mentioned the «Karpûra-mānjarī,» a lively comedy of intrigue (A.D. 900) by Rājasekhara; in fiction «Kathâsaritsâgara,» a tale of adventures by Somadra, and «Gitagôvinda» by Jayadeva, a fanciful narrative may be cited.

Author of 'America, Asia and the Pacific'; 'Germany: the Welding of a World Power'; etc.

PRAM, präm, **Christen Henriksen**, Danish poet, critic and economist: b. Gudbrandsdalen, Norway, 4 Sept. 1756; d. island of Saint Thomas, West Indies, 25 Nov. 1821. He studied at Copenhagen and in 1781, as a member of the agricultural and commercial college of Copenhagen, he undertook several tours, the results of which were published in the *Commercial Journal*, founded by him in 1782. In 1815 he was discharged from his office with a small pension, and in 1819 became collector of customs on the island of Saint Thomas. His numerous writings embrace a great variety of subjects, both in political and natural science. Among his poetical productions are 'Heroide an Erich'; and 'Starkodder' (Copenhagen 1785), a heroic poem, in 15 cantos. He also edited J. H. Wessel's 'Collected Writings' (1787). Besides the *Commercial Journal* he founded another, the *Minerva*, a critical monthly which rendered essential service in the formation of literary taste in the Scandinavian kingdoms. As editor of the latter he was succeeded by K. L. Rahbek, who edited and published his 'Works' (six vols., 1824–29). Consult Host, J. K., 'Til Christensen Henriksen Prams Amindelse' (Copenhagen 1820).

PRANG, präng, **Louis**, German-American engraver and publisher: b. Breslau, Germany, 12 March 1824; d. Los Angeles, Cal., 15 June 1909. His part in the revolutionary movement of 1848 compelled him to leave Germany and he came to this country in 1850. He established himself as a wood engraver in Boston, later becoming a lithographer, and in 1861 engaged in publishing, making a specialty of color printing. He was especially known for his well-executed reproductions of famous paintings. He invented the Prang method of art instruction and published the drawing books and materials used in that course. He was president of the Prang Educational Company of Boston and of the Taber-Prang Art Company of Springfield, Mass. He published 'The Prang Standard of Color' (1898); and with John S. Clark and Mary D. Hicks, 'Suggestions for Color Instruction' (1893).

PRASE. See QUARTZ.

PRATER, prä'tĕr, the most famous promenade of Vienna. See VIENNA.

PRATI, Giovanni, jō-vän'nē prä'tē, Italian poet: b. Dasindo, near Trent, 27 Jan. 1814; d. Rome, Italy, 9 May 1884. He studied law at the University of Padua, from which he was graduated in 1834, but soon turned to literature. Strongly anti-Austrian and deeply in sympathy with the movement for national independence and unity under the rule of the royal house of Savoy, he was frequently in political difficulties during the period of Italy's unification. He lived successively in Milan, Turin, Florence and Rome. His first major work, 'Edmenegarda' (1841), a narrative poem of the Romantic school, was received with extraordinary favor. Several volumes of lyric poetry still further increased the poet's reputation, but during the last years of his life he wrote but little. In 1862 he was elected to the Italian Parliament and in 1876 became senator. He was a prolific writer of rather uneven merit. Endowed with rich imagination and facility of style and expression, he was lacking in originality and depth. Some of his lyric poems are amongst the best of his time, but much of his work is mediocre. His works include 'Canti Lirici, Canti per il Popolo e Ballate' (2 vols., Milan 1843); 'Lettere a Maria' (Turin 1843); 'Memorie e Lacrime'; 'Nuovi Canti' (Turin 1844); 'Poesie' (Palermo 1844); 'Nuovi Versi' (Venice 1848); 'Poesie Politiche' (Italia 1850); 'Rodolfo' (Turin 1853); 'Satana e le Grazie' (Pinerolo 1855); 'Ariberto' (Turin 1860); 'Armando' (Florence 1868); 'Psiche' (Padua 1876); 'Iside' (Rome 1878). A collection of his works was published as 'Opere Varie' (5 vols., Milan 1875). Consult Zanichelli, D., 'La Rivoluzione de 1848 e le Poesie Politiche di G. Prati' (Bologna 1895); Cavalluzzi, C., 'La Poesia del Prati' (Citta di Castello 1898); Emmert, Bruno, 'Saggio Bibliografico; Giovanni Prati' (in 'Atti della R. I. Accademia di Scienze Lettere ed Arti degli Agiati in Rovereto,' serie III, Vol. 17, pp. 173 and 285, Vol. 18, p. 89, Rovereto 1911).

PRATINAS, Greek poet: flourished about 500 B.C. He was a native of Phlius in the Peloponnesus and became famous as a lyrical and dramatic poet. He is credited with originating the satyric drama which he introduced at Athens. Fragments of his lyrical poetry have been collected and published by T. Bergk in 'Poetæ Lyrici Græci' (Leipzig 1843); Nauck, A., 'Tragicorum Graecorum Fragmenta' (Leipzig 1856).

PRATINCOLE, a genus *Glareola* of wading birds of the family *Glareolidæ*, allied to the plovers, inhabiting the temperate and warmer regions of the Old World. About half a dozen species are described in Europe, Asia, Africa and Australia, frequenting the borders of rivers, lakes and marshes in low and high regions; the food consists of worms and insects, which they pick from the ground or aquatic plants or take on the wing like swallows; they fly and run very swiftly; the nest is a slight structure on the ground, among the thick herbage of the marshes, and the eggs three or four in number. All scream noisily. The collared pratincole (*G. pratincola*, Pall.), plentiful in southern Europe, is about the size of a blackbird, nine inches long; it is brown above, white on the rump and below; the throat surrounded by a black circle; the base of the bill and the feet reddish.

PRATIQUE, prat'ēk, a term used to signify the permission given to a vessel to hold communication with the land after the port authorities have been satisfied that the ship is free from infectious diseases. See QUARANTINE.

PRATO, prä'tō, Italy, city in the province of Florence, on the Bisenzio, 11 miles northwest of Florence, with which it is connected by a railroad and a street railway. It is surrounded by ancient walls and is a well-built, cheerful-looking place. The cathedral, begun in the 12th and finished in the 15th century, with a very beautiful open air pulpit by Donatello and Michelozzo, contains also some very fine frescoes by Fra Filippo Lippi (q.v.). Amongst the other memorable buildings are a court of justice, several other churches, monasteries, convents, an old castle, an ancient prætorium (Palazzo Pretorio), a college, called after its founder Cicognini, a public library, a theatre and several hospitals. Its extensive manufactures of woolen, silk, straw hats, paper, candles, olive oil, crackers, clothing and furniture, together with its iron and copper works have made Prato a prosperous, up-to-date city. It is the seat of a bishop. Pop. (1910) 20,360 (city proper); 56,715 (commune).

PRÄTORIUS, prā-tō'rē-ŭs, **Michael**, German composer: b. Kreuzberg, Thuringia, 15 Feb. 1571; d. Wolfenbüttel, Brunswick, 15 Feb. 1621. Details concerning his life are very meagre. He began his career as kapell-meister at Wolfenbüttel, was secretary to the Duke of Brunswick, and later was appointed prior of the monastery of Ringelheim, near Goslar, with the privilege of making his residence where he chose. He was one of the most prominent composers of his time and also an able writer on musical topics. His most noted literary work is 'Syntagma Musicum' (Wolfenbüttel 1614–20), and his compositions include 'Musæ Sioniæ' (published in 16 volumes, containing 1,244 vocal numbers, Wolfenbüttel 1605–10); 'Musa Aonia' (9 vols.), etc. His works are now exceedingly rare. A detailed description of the contents of 'Syntagma Musicum' may be found in 'Grove's Dictionary of Music and Musicians' (Vol. III, p. 806, New York 1911).

PRATT, Ambrose, Australian journalist and author: b. Forbes, New South Wales, 31 Aug. 1874. He was graduated in law from Sidney University, but he soon left his profession to join the editorial staff of the Melbourne *Age* (1905). His published works include the following: 'King of the Rocks' (1900); 'The Loot of the Tien-ti-Hway' (1900); 'Franks, Duellist' (1901); 'The Great Push Experiment' (1902); 'Vigorous Daunt, Billionaire' (London 1903; New York 1904); 'Three Years with Thunderbold' (1905); 'The Countershake' (1906); 'The Remittance Man' (1907); 'The Emperor and his Double'; 'First Person Paramount' (1908); 'The Veiled Man' (1909), and many short stories.

PRATT, Anne, English botanist: b. Strood, England, 5 Dec. 1806; d. London, England, 27 July 1893. She made a life-study of the nature of plants and her writings reveal a wide knowledge as well as a deep love of nature. Her books are illustrated with her own excellent sketches and achieved great popularity. She had the happy faculty of combining a popular style with a considerable amount of scientific accuracy, so that her books served not only the purpose of increasing popular interest in botany, but also added considerably to the sum total of knowledge regarding English plants, grasses, etc. The most important of her books, all of which were published in London, are 'The Field, the Garden and the Woodland' (published under the pseudonym 'A Lady,' 1838); 'Flowers and their Associations' (1840); 'Dawnings of Genius, or the Early Lives of Some Eminent Persons of the Last Century' (1841); 'The Pictorial Catechism of Botany' (1842); 'Chapters on Common Things of the Seaside' (1850); 'Our Native Songsters'; 'The Green Fields and their Grasses'; 'Wild Flowers' (2 vols., 1852); 'Flowering Plants, Grasses and Ferns of Great Britain' (5 vols., 1854); 'The Ferns of Great Britain, etc.' (1855); 'The Poisonous, Noxious and Suspected Plants of our Fields and Woods, etc.' (1857); 'The British Grasses and Sedges, etc.' (1859); 'Haunts of the Wild Flowers' (1863). She also translated Ottilie Wildermuth's 'Im Tageslicht' and published it in 1865 under the title 'By Daylight.'

PRATT, Bela Lyon, American sculptor: b. Norwich, Conn., 11 Dec. 1867; d. Boston, 19 May 1917. He studied at the Yale School of Fine Arts under Niemeyer and Wier, and at the Art Students League in New York under Augustus St. Gaudens, F. Edwin Elwell, William Chase and Kenyon Cox, working under St. Gaudens in his studio. Later he studied in Paris under Chapu and Falquière and at the École des Beaux Arts. He received two medals and two prizes while in Paris and in 1892 he returned to the United States. He has been instructor of modeling at the Boston Museum of Fine Arts since 1893. He has produced many works in sculpture, including statues, memorials, portrait busts, tablets, medallions and other works. He is a member of the National Institute of Arts and Letters, the American Academy of Arts and Sciences and of the National Sculptors Society. He was awarded a gold medal at the Panama Exposition in 1915. Among his works may be mentioned two colossal groups on the Water Gate of the Peristyle at the Chicago Exposition: the Eliot medal for Harvard University and the Yale Bi-centennial medal; six seven-foot spandrel figures for the main entrance of the Library of Congress, as well as a 12-foot figure of 'Philosophy' and a series of four medallions, 'The Seasons' there; recumbent figure of Dr. Coit, Saint Paul's Church, Concord, N. H., which received honorable mention at the Paris Salon in 1897; 'Study of a Young Girl,' second medal at the Buffalo Exposition in 1901; statues of Bishop Brooks, Gov. John Winthrop, Jr., General Stevenson and others; portrait busts of Gen. C. J. Paine, Bishop Huntington, Dr. Homans, Dr. Richard Hodgson; the Harvard Spanish War Memorial; statue of Nathan Hale, Yale Campus, etc.

PRATT, Charles, American philanthropist: b. Watertown, Mass., 2 Oct. 1830; d. New York, 4 May 1891. He obtained a portion of his education at Wesleyan Academy, Wilbraham, Mass., after having saved the money needed by working as a machinist, and in 1851 removed to New York where he engaged with a paint and oil firm, of which he became a member in 1854. When the firm dissolved in 1867 he retained the oil interests and under the firm name Charles Pratt and Company organized a most successful business. He grasped the possibilities of the petroleum trade when the oil fields of Philadelphia were being developed in 1860 and devoted himself to producing the best quality of refined petroleum on the market, Pratt's astral oil becoming world-famous. He acquired an enormous fortune and in 1874 his business was merged in the Standard Oil Company, with which concern he was, therefore, affiliated almost from its beginning and in the prosperity of which he shared to a very considerable extent. He afterward devoted himself to philanthropic enterprises and contributed generously to various religious, charitable and educational causes. His greatest philanthropic work was the founding of the famous Pratt Institute (q.v.) in 1886, in which he embodied his ideas of a thorough and practical education. It was opened in 1887 with 12 students, a number which at the time of his death had increased to over 3,000. The entire cost of the buildings, equipment, grounds and ample endowment was borne by Mr. Pratt and at his death he left a further endowment of $2,000,000. He was public-spirited in every way but firmly declined public office.

PRATT, Daniel, the «Great American Traveler,» American eccentric: b. Prattville, Chelsea, Mass., about 1809; d. Boston, Mass., 21 June 1887. He was a carpenter by trade, but became mentally unbalanced and wandered about, a pensioner on general charity. Contributions of his, including certain «proclamations,» appeared from time to time in print; and for several years he made annually a grand tour of New England colleges, delivering in each grandiloquent orations. He believed himself unjustly deprived of the Presidency, asserting he had been duly elected.

PRATT, Ella Farman, American writer for young people: b. New York; d. Warner, N. H., 22 May 1907. With C. S. Pratt, for a series of years she edited the juvenile periodical *Wide Awake* and later *Little Folks.* Among her books, many of which were published under her maiden name, are ‹Good-for-Nothing Polly›; ‹How Two Girls Tried Farming›; ‹A Girl's Money›; ‹The Cooking Club of Tu-Whit Hollow›; ‹A Little Woman›; ‹Grandma Crosby's Household›; ‹Mrs. Hurd's Niece›; ‹Anna Maylie›; ‹A White Hand›; ‹Sugar Plums›; ‹Happy Children›; ‹The Play Lady› and ‹The Little Cave-Dwellers.›

PRATT, Enoch, American philanthropist: b. North Middleborough, Mass., 10 Sept. 1808; d. near Baltimore, Md., 17 Sept. 1896. He was educated at the Bridgewater (Mass.) Academy, entered a commercial house in Boston and in 1831 removed to Baltimore where he became a wholesale iron merchant and engaged in various financial enterprises which gained for him great wealth. He presented to the city of Baltimore in 1882 the Enoch Pratt Free Library, endowing it to the extent of $1,145,000. He was one of the first amongst American millionaires to devote part of his wealth to the founding of public libraries. He also gave generously to different churches, libraries and schools, especially to the House of Reformation and Instruction for Colored Children at Cheltenham, Md., and the Maryland School for the Deaf and Dumb at Frederick. The residue of his large estate was left to the trustees of the Sheppard Asylum, a hospital for mental diseases near Baltimore, which is now known as the Sheppard and Enoch Pratt Hospital.

PRATT, George Du Pont, American conservation commissioner: b. Brooklyn, 16 Aug. 1869. He was graduated at Amherst College in 1893 and entered the employ of the Long Island Railroad, eventually becoming assistant to the president of that company. In 1915 he became conservation commissioner for the State of New York and rendered important service in prevention of forest fires and by an education campaign in the field of hunting and forest laws has made great progress in his conservation of the natural resources of the State. Mr. Pratt is also well-known for his philanthropic interests.

PRATT, John Francis, American scientist: b. Pomfret, Vt., 18 June 1848. He was graduated from Dartmouth College in 1871; studied civil engineering and in 1871 became connected with the United States Coast and Geodetic Survey, being made an assistant in 1884. He led the expedition to Chilcoot, Chilkat, Skagway and Dyea to determine the southeast boundary of Alaska; conducted an expedition to the east side of Bering Sea and the lower portion of the Yukon River in 1898. Has commanded several different vessels of the United States Coast and Geodetic Survey in conducting various expeditions to Alaska, Bering Sea, Hawaiian Islands, central portion of the Pacific Ocean and the Philippine Islands. He has recently been appointed on inspection duty in Oregon, Washington and Alaska.

PRATT, Orson, American Mormon apostle: b. Hartford, N. Y., 19 Sept. 1811; d. Salt Lake City, Utah, 3 Oct. 1881. After a common-school education, he followed the lead of his brother, Parley P. Pratt (q.v.), and joined the Mormons in 1830, accompanied them in the westward migration and in 1835 became one of the original 12 apostles. With Erastus Snow he was the first to enter the valley of the Great Salt Lake. From 1840–78 he accomplished eight missions to Great Britain and in 1864–65 one to Austria. During his visits to England he edited at various times *The Millennial Star,* the circulation of which he increased greatly. He began in Washington in 1852 the publication of *The Seer,* a monthly, of which 18 numbers appeared. From 1874 until his death he was historian and general church recorder. He was also for many sessions a member of the Utah Territorial legislature and seven times its speaker. In spite of the lack of educational opportunities which he had experienced in his early life, he became a well-versed scholar of higher mathematics, astronomy and Hebrew. In 1854 he announced his «law of planetary rotation» to the effect that the cubic roots of the densities of the planets are as the square roots of their periods of rotation. Among his works are ‹New and Easy Method of Solution of the Cubic and Biquadratic Equations› (London 1866); ‹Key to the Universe› (1879), and a large number of tracts and pamphlets dealing with the Mormon doctrine. He also edited and published in Salt Lake City *The Doctrine and Covenants of the Church of Jesus Christ of Latter-Day Saints, Containing the Revelations Given to Joseph Smith, Jr., the Prophet.*›

PRATT, Parley Parker, American Mormon apostle: b. Burlington, N. Y., 12 April 1807; d. near Van Buren, Ark., 13 May 1857. He adopted the Mormon faith in 1830 and in 1835 was elected a member of the first quorum of the 12 apostles. He traveled in this country, Canada, South America and in England, engaged in missionary work and in 1840 established at Manchester, England, the *Millennial Star.* At various times he was put in charge of the Mormon churches and missions in Great Britain, New England and the Middle States. He was one of the party which explored the valley of the Great Salt Lake in 1847 and 1849 and Parley's Peak and Parley's Cañon were named in his honor. He assisted in forming a constitution for the Provisional Government of Deseret, the name then applied to the present State of Utah, served as a member of its senate and later, when Deseret became the United States Territory of Utah, as a member of its legislative council. Throughout the early days of Mormonism he suffered all the hardships and persecutions which were then inflicted upon members of his sect and had many narrow escapes from injury and death. At last, while engaged in one of his frequent missionary tours, he was murdered by three men near Van Buren, Ark. He wrote 'A Voice of Warning' (1837); 'History of the Persecutions in Missouri' (1839); 'Key to the Science of Theology' (1854), etc. His 'Autobiography' edited by his son, Parley P. Pratt, was published in 1874.

PRATT, Samuel Jackson («Courtney Melmoth»), English author: b. Saint Ives, Huntingdonshire, 25 Dec. 1749; d. Birmingham, 4 Oct. 1814. He was ordained in the English Church, but later went on the stage where his career was not notable and then turned his attention to literature. He was a very prolific writer and his works cover a wide range of subjects. Though undoubtedly possessing considerable literary talent, force of circumstances prevented him from giving sufficient time and effort to his work so that very little of it proved of lasting value. He is by some authorities credited with a translation of Goethe's 'Sorrows of Werther,' which, in 1809, was published by a Dr. Pratt. Of his works, many of which were published anonymously, the most important are 'Tears of Genius' (1774); 'Liberal Opinions Upon Animals, Man and Providence' (6 vols., 1775–77); 'Apology for David Hume' (1777); 'Tutor of Truth' (3 vols., 1779); 'Emma Corbett, or the Miseries of Civil War. Founded on some events in America' (1780); 'The Fair Circassian,' a tragedy (1781); 'Sympathy,' a poem (1788); 'Gleanings through Wales, Holland and Westphalia' (1795); 'John and Dame, or the Loyal Cottagers,' a poem (1803); 'Harvest Home: Consisting of Supplementary Gleanings, etc.' (3 vols., 1805). In 1808 he edited and published the 'Cabinet of Poetry,' containing selections from the poets (Milton to Beattie) with short biographical notices (6 vols.). He also edited 'Specimens of the Poetry of Joseph Blacket' (1809) and 'The Remains of Joseph Blacket' (2 vols., 1811), and with Dr. Mavor 'A Collection of Classical English Poetry' (1813). The epitaph on Garrick's monument in Westminster Abbey is likewise from his pen and perhaps has been criticised and condemned to a greater extent than any of his other writings. Selections from his works were published as follows: 'Pity's Gift' (London 1801) and 'The Paternal Present' (London 1810). Consult *Blackwood's Magazine* (January 1895, pp. 121–125); *Gentleman's Magazine* (1814, pt. II, pp. 398–399).

PRATT, Silas Gamaliel, American pianist and composer: b. Addison, Vt., 4 Aug. 1846; d. Pittsburgh, Pa., 31 Oct. 1916. He studied in Berlin in 1868–71 with Kullak, Bendel and Kiel and with Liszt and Heinrich Dorn in 1875–76. His first symphony was performed in Berlin in 1871 and in the following year he organized the Apollo Club of Chicago. His opera Zenobia' was well received on its presentation in 1882; in 1884 he was director-general of the Chicago Grand Opera Festival. In 1890 he accepted an appointment as professor of piano at the New York Metropolitan Conservatory. In 1906 he became president of the Pratt Institute of Music and Art, Pittsburgh, Pa., and in the same year he also organized there the Pittsburgh centre of the American Music Society. He has published numerous songs, part-songs, symphonies, etc., the operas 'The Triumph of Columbus,' 'Lucille,' 'Ollanta' and the symphonic poems 'America' and 'A Tragedy of the Deep.' He has also written 'Lincoln in Story' (1901) and 'Pianist's Mental Velocity' (1903).

PRATT, Kan., city and county-seat of Pratt County, 80 miles west of Wichita, on the Atchison, Topeka and Santa Fé and on the Chicago, Rock Island and Pacific railroads. The city is situated in a rich agricultural and stock-raising district and a State fish-hatchery is located here. The population is increasing. Pop. 3,302.

PRATT INSTITUTE, a polytechnic school in Brooklyn, N. Y., established in 1887 by Charles Pratt (q.v.). Its aim is to promote manual and industrial education as well as cultivation in literature, science and art. Its organization includes the following departments: (1) School of Fine and Applied Arts; (2) School of Science and Technology; (3) School of Household Science and Arts; (4) School of Library Science; (5) Department of Education; (6) Department of Physical Education. The regular courses of the institute vary in length; mostly they cover two or three years; the general course in domestic science is only one year, and the general art course four years. Normal courses are given in the schools of Fine and Applied Arts and of Household Science and Arts, evening classes in these two schools as well as in the School of Science and Technology. The library is open for the free use of the public, has a large children's room, and in equipment and management is considered a model library. It contained 114,775 volumes in 1918. The library school offers a one-year general course and provides practice work for students in the library (See Library Schools). The institute confers no degrees, but grants diplomas for the completion of any of the normal courses, and gives certificates attesting the completion of the full-time day courses. It occupies 12 large buildings, the main building, the science and technology building, the electrical building, the chemistry building, the machinery building, the household arts building, the practice house, the men's club house, the women's club house, the rest home, the library and the gymnasium. The endowment is large and the tuition fees are small. The productive funds consist of the original endowment made by the founder, to which large sums have been added at various times by members of the Pratt family. The students in 1918 numbered 3,799, including all those in the special and evening, as well as the regular courses. The faculty consisted of 195 members.

PRATZ, Le Page du, lė päzh dü präts, French explorer in the New World: b. Holland, about 1690; d. 1775. Entering the French army and serving in Germany for a time he was subsequently a member of the French Compagnie d'Occident which acquired a grant of territory near New Orleans, La. Du Pratz led an expedition there in 1718 and made unsuccessful attempts to found a colony. In 1720 he went up the Mississippi and settled among the Natchez Indians. Later he explored the region bordering the Mississippi and Arkansas and was for some years treasurer of the land company at New Orleans. He returned to France in 1734. He wrote a valuable and detailed account of his life in Louisiana which was published under the title 'Histoire de la Louisiana' (3 vols., Paris 1758). It was translated into English as 'History of Louisiana' (2 vols., London 1763).

PRAWN, a small decapod crustacean of the family *Palæmonidæ*, allied to the shrimps, in which the beak or «rostrum,» which projects in front of the carapace, is large, toothed and of compresed shape. The common British prawn (*Palæmon serratus*) is three to five inches long, shrimp-like in form, half-transparent and often beautifully tinted, and is taken for market in great quantities by means of nets operated on sandy shores. When boiled, prawns become of a pale pink color, and are highly esteemed as table delicacies in this and in other shapes. Several species occur on the eastern coast of the United States, but are little used.

PRAXEAS, a teacher of the errors of the Antitrinitarians or Monarchians. Data concerning his life are meagre and uncertain. It is claimed that toward the end of the 2d century, after suffering persecution in the reign of Marcus Aurelius for his open confession of the Christian faith, he came to Rome from his native Phrygia to acquaint Pope Victor with the erroneous teachings and vicious practices of the Montanists, and prevailed upon Victor to recall the letters of communion which he had given to those sectaries. But while at Rome and afterward at Carthage he became an apostle of the doctrine of the Monarchians, teaching that in the Godhead is but one Person, who proceeding forth of his own divine essence and called Son, entered the Virgin's womb, was born of her and suffered on the cross; hence the distinctive name of the sectaries who followed Praxeas — Patripassians. See ANTITRINITARIAN; MONARCHIANS; SABELLIUS; UNITARIANS.

PRAXITELES, prăks-ĭt'ĕ-lēz, Greek sculptor: b. probably, about 400 B.C. He was an Athenian by birth, the contemporary of Scopas (q.v.), and one of the greatest sculptors of ancient times. The date of his death is unknown; but his life must have been long, since nearly three score works are mentioned as executed by him. He lived in the age of greatest opulence in Greek art, an age succeeding that of Phidias and one which had outgrown the austere vigor displayed in the works of the earlier master. During the time of Praxiteles the life of the individual was less merged in that of the body politic, and became more highly developed. This fact consequent upon the growth of wealth in private possession made the work of the sculptor in demand for the adornment of private houses instead of temples of worship. Praxiteles worked for private buyers, and many of his statues went to Asia Minor as well as Greece. Antiquity placed the highest estimate upon his statue of Aphrodite, and people traveled in large numbers to Cnidus to see it. Lucian records seeing it there about 150 A.D. The statue has disappeared, but an idea of its form may be derived from a Cnidian coin, bearing its effigy, struck in honor of Plautilla. The greatest of his extant works is the statue of the youthful Hermes bearing on his arm the infant Dionysus. This statue, described by Pausanius, was discovered in 1877 by German excavators, at Olympia, where it now remains. The face, which is perfectly preserved, gives to posterity a revelation of the exquisite beauty of the Greek face. The mutilated statue of Demeter from Cnidus, now preserved in the British Museum, is probably by Praxiteles; but the Hermes is the only unquestionable one. Pausanias records that Praxiteles regarded his statue of Eros and one of a satyr as his greatest works. This Eros was presented to Phryne, the courtesan, who posed for the Cnidian Venus, and was afterward placed in the temple at Thespiæ. There was another Eros at Parium on the Hellespont. The Satyr, represented leaning gracefully with his arm on a support, is preserved in reproduction in the Capitoline Museum at Rome, and furnished Hawthorne with his inspiration for his romance, 'The Marble Faun.' The 'Apollo Sauroktonos' (Lizard-Killer), a motive original with Praxiteles, is also known to posterity in reproductions in the Louvre and elsewhere. Reproductions of other works of Praxiteles, the authenticity of which, however, is frequently very doubtful, may be found in many museums and private collections, especially in Athens, Berlin, Dresden, Florence, London, Naples, Paris and Rome. Good casts of his most important works are to be seen in practically every art museum in this country, especially in the New York Metropolitan Museum of Art and in the Boston Museum of Fine Arts. Praxiteles produced in addition to statues portrait busts and genre-scenes, the latter being in the form of sculptured reliefs. His work, which exercised a great influence upon the further development of Greek art, charms by its perfection of grace and its refined and noble expression of human emotions. Consult Kekulé, R. von S., 'Der Kopf des Praxitelischen Hermes' (Stuttgart 1881); Amelung, W., 'Die Basis des Praxiteles aus Mantinea' (München 1895); Furtwaengler, A., 'Masterpieces of Greek Sculpture' (ed. by E. Sellers, London 1895); Klein, W., 'Praxiteles' (Leipzig 1898); 'Praxiteles' (in 'Masters in Art,' Vol. III, Boston 1902); Gardner, E. A., 'Six Greek Sculptors' (London 1906).

PRAY, Isaac Clark, American journalist, dramatist and theatrical manager: b. Boston, Mass., 15 May 1813; d. New York, 28 Nov. 1869. He was educated at Harvard and at Amherst and entered journalism in Boston, where he was at various times editor of the *Pearl*, the *Daily Herald*, the *Sunday Morning News*, the *Dramatic Guardian* and the *Ladies' Companion*. He early engaged in play-writing and in 1836 became manager of the National Theatre where he produced some of his own plays. In 1846–47 he played the leading parts in 'Hamlet,' 'Othello,' and other productions in London, Liverpool and Cork. He went to New York in 1850 as an editorial writer on the *Herald*, and he was afterward a theatrical manager. He wrote about 30 plays and was also author of 'Poems' (1837); 'Book of the Drama' (1851); 'Memoirs of James Gordon Bennett' (1855), etc.

PRAY, James Sturgis, American landscape architect: b. Boston, Mass., 26 Feb. 1871. He was educated at Harvard and in 1903 engaged in independent practice. Since 1906 he has been senior member of the firm Pray, Hubbell and White. He was assistant professor of landscape architecture at Harvard in 1905–14, was appointed chairman of the School of Landscape Architecture there in 1908, and since 1914 he has been Charles Eliot professor. He is author of various articles in the periodicals devoted to his profession and of 'City Planning' (1913).

PRAYER, a religious act taking the form of an entreaty for the grant of favor or the forgiveness of trespasses, and directed toward an object of worship in whose power the answer of this entreaty is supposed to reside. Since prayer is an act almost universal among the religions of the world, it is but natural that it should exhibit a vast range of variation in its form and its spiritual level. The savage may beseech his fetish like a human king, or he may bribe it by offerings and promises, or he may bully it into granting the favors desired. In any case, he is likely to adopt toward it an attitude no more spiritual than that which he adopts toward his fellow savage. His prayer is used for the same purposes as magic, and indeed only differs from magic in that the desired very immediate and very material benefit is accomplished through the mediation of a supernatural person, and not by virtue of the mere wish for the benefit itself. It is rain, or the death of an enemy, or the fertility of his crops, for which he prays, and all notion of the purification from sin is likely to be absent. This awaits the coming of a morality less hand-to-mouth, and the formation of a more or less unified ideal of conduct. While the germs of this inhere in the religion of many races of a low civilization, it is only in such faiths as Buddhism, Judaism and Christianity, which combine a background of vigorous intellectual activity with a fervent exaltation of goodness, that religion habitually expresses itself in «peccavi.»

Religion, however, does not run a continually ascending course. The transition from a religion of morality to fetishism, demonology, and magic, easily takes place through the formalism of religious senescence. The faith that has lent dignity to its prayer through a set formula of noble words, or the sonorous cadences of an ancient language, ultimately finds that the formula, the cadences are retained long after all memory of their significance is dead. A condition supervenes — as in many Christian denominations — where the objects of religious worship are held firmly enough in mind, but the prayer, understood but in part by the priesthood and by the laity not at all, has come to be but an induction of the worshipper into a state of devotion. This does not mark the end of the process, which culminates in the mechanical prayer-wheels of the Buddhists of Tibet, who have all but lost their Buddhism in a degraded devil-worship. Here the idea of the object of the prayer has practically vanished, so that religion is about to be resorbed into the magic from which it has emerged with such difficulty.

Even in Christianity, and in cases where the prayer has undergone no significant degree of formalization, the nature of prayer varies between wide limits. It may be like that of the savage, objective in trend, and directed primarily toward an almighty Deity, with the purpose of receiving definite physical benefits. On the other hand, as has been seen among those of a more sensitive religious constitution, prayer is rather an entreaty that the merciful God shall aid a sinner in his avoidance of temptation. This entreaty passes over into a state where full reliance is placed in the goodness and wisdom of God; and entreaty gives way to an inner confession. In these instances the emphasis is not so much on the Deity and the answer expected of him as in the purging of the moral consciousness encompassed by the act of prayer itself. It is this awareness of previous sin and rejection of it, this turning over a new leaf, that lends to prayer its chief value. As William James says, the object of prayer is by far the least important feature of it. The prayer becomes a resolution of good works, accompanied by a faith that this resolution can be realized. The Deity who receives this prayer enters into the prayer merely as a symbol and tangible object serving to fix this faith. (See FAITH). Consult Frazer, J. G., 'The Golden Bough' (London 1911–15); James, W., 'Varieties of Religious Experience' (New York 1902).

PRAYER, Week of, a special period of devotion set apart as a result of a resolution adopted at Manchester, England, in 1846 at a conference of the Evangelical Alliance (q.v.) which urged «members and friends of the Alliance throughout the world to observe the week beginning with the first Lord's day of January in each year as a season for concert in prayer on behalf of the objects contemplated by the Alliance.» An appeal from missionaries in India some years later resulted in broadening this scope. The week of prayer has become a settled institution among Evangelical Christians of different churches and countries and has been successful to a considerable extent in promoting Christian union.

PRAYER BEADS, the polished seeds of a West Indian leguminous plant (*Abrus precatorius*) called wild licorice. These seeds were formerly much used for stringing into rosaries, necklaces, etc.

PRAYER BOOK. See BOOK OF COMMON PRAYER.

PRAYER BOOK, Common. See COMMON PRAYER, BOOK OF.

PRAYER FOR THE DEAD. The practice of prayer for the dead prevails in the Roman Catholic, Greek and other Eastern churches. Its purpose is the remission of punishment for sin. The custom seems to have existed in most of the ancient religions, especially in those of India, China and Egypt. The doctrine and practice came to the Christian Church through the Jews (2 Maccabees xii, 44, 45). The first of the Christian fathers who mentions prayer for the dead is Tertullian; but he speaks of the usage as well known and long established in the Church; such prayers are frequently alluded to by Saint John Chrysostom, Cyril of Jerusalem and Saint Augustine. The Roman Catholic practice of prayer for the dead stands of course in a close relation with the doctrine of purgatory, and was discarded with the latter by Protestantism. In the burial service of the first Book of Common Prayer of the English Church some prayers for the dead appeared, but they were deleted from the second book, and are not found in the subsequent revision. Nevertheless, many Anglican clergymen of all periods have approved of such prayers. Consult Boggis, R. J. E., 'Praying for the Dead' (New York 1913); Lucock, H. M., 'Eucharistic Sacrifice and Intercession for Departed' (ib. 1907).

PRAYER RUGS, the Mohammedan rug used for prostration during prayer. In considering anything to do with the Moslem we have to remember that of the many Oriental tribes most of them are nomadic or were so. Hence their customs. Their tent is their home, their furniture consists of rugs. Before the warmth of the fire they sit on the *odjaklik*; their floor is carpeted with the *sedjadeh*; they separate the tent into individual spaces with hangings (*berdelik*). But each devout Moslem (practically the entire population) must have his "prayer" rug (*namazlik*). Being the chief piece of religious furniture his prayer rug is as valuable as his financial condition affords, and on it he prostrates himself five times each day at the prescribed hour. First he spreads his rug in correct orientation, assisted by his compass, seeing that the niche (*mihrab*) points due toward Mecca, the grave place of Mohammed. Next he removes all valuable belongings, such as jewelry, money, etc., from his person to symbolize his abject humility before Allah; he combs his beard as symbol of cleansing, then he brings forth his rosary of 99 beads and a piece of earth or stone taken from Mecca, placing them below the niche. Now he bows his head to the earth, stretches out his arms and in this pose carries out his devotions. The *mihrab* or niche is a point, or projection, extending from the central field of the rug, and represents the niche in which the Koran is preserved in the temple at Mecca. Prayer rugs vary in size from two and one-half to four feet in width by four and one-half to six feet in length. Some are made specially for the owner and have his name in wool on it; these are, of course, of the finest weave. Now and again we come across prayer rugs with a design of three or more niches for combined family or children's worship; mostly they are Caucasian. Some have three small medallions in place of the prayer niche; these spaces are for the knees and forehead of the devout.

Technique.—As each tribe follows closely the traditional designs (*tereh*), handed down through the centuries, more especially in its prayer rugs, they are the more easily assigned to the different localities of origin. The field of the prayer rug is divided into sections as follows: When a single panel (square) only appears it is always above the prayer space; Kulahs have generally but one, also Anatolians; but Bergamos generally have two panels, Ghiordes (see RUGS, ORIENTAL) nearly always, Kulahs seldom. When two panels are in the design one each is placed at the upper and the lower end. We find on some rugs emblems of the equipment crudely defined: a compass, a comb, sometimes the 99 beads of a rosary. A small rhomboidal motif is found on some prayer rugs of Asia Minor designating the place for the devotee to put the earth or stone. Odd motifs figure at the sides of some niches showing where to place the hands in worship. A characteristic of the Ghiordes prayer rug is the shoulder on either side of the base of the niche (see illustration). Pilasters used to support

1. Mirhab or Niche.
2, 3. Upper and Lower Panels.

these in the old specimens; some had scroll or floral decoration, but they gradually lost resemblance to pilasters evolving into floral motifs, disappearing altogether in some. Suspended from the niche was a lamp motif or a floral piece, also later disappearing often. Some plant life is usually depicted inside the niche and on the inner side of the border. In the upper panel may be a floral decoration, a scroll or a verse from the Koran. The reclining S (~) or pothook also occurs in panels. A large palmette or rosette partly enclosed by foliage, somewhat like the Herati motif (see RUGS, ORIENTAL) is common in the central border stripe, or square flowers and fruit. The wide stripe is at times represented by several narrow ones decorated with small floral figures. Tekke rugs differ so much from the carpets (*sedjadeh*) they would not be known as of the same tribal make. The glaring reds are not there (in antiques), but are replaced by sober, soft tones of wonderful richness; mahogany color with deep copper bronze tones as relief are usual. The motif in the border is a «multiplied tree pattern» with thin lines of pure white as high lights. The design of the field corresponds with the borders in its tree form motifs. A horizontal band runs midway across the field and a perpendicular traversing it divides the field into four parts, a tree in each. So much does the Tekke *namazlik* differ from others that some of the experts have put them under a different heading, terming them *Hardjli* or Princess Bokhara, and the term of the Armenians is *Khatchli Bokhara* or Cross Bokhara, because of the cross dividing the field. Tekke *·zliks* are wider compared with their length ·her prayer rugs with the exception of ınd Bergamos. Prayer rugs owned by collectors are rarely Persian as Per- ıammedans cannot bear the thought of ıristians trampling on the sacred field *azlik*, but other Moslems are less strict. rayer rugs» in America were made to : Western markets.

PRAYING INDIANS, The, in American colonial history the name given those New England Indians who were early won to the Christian faith. During Philip's War they remained friendly to the colonists, a company of them enlisting under Major Gookin in July 1675. They acted as scouts and spies and rendered valuable service against Philip. Consult Gookin, Daniel, 'An Historical Account of the Doings and Sufferings of the Christian Indians of New England' (in 'Transactions and Collections of the American Antiquarian Society,' Vol. II, p. 423, Cambridge, Mass., 1836); Markham, Richard, 'A Narrative History of King Philip's War' (New York 1883).

PRAYING INSECTS. See MANTIS.

PRE-ADAMITES, those supposed inhabitants of the earth prior to the creation of Adam. The legendary traditions of the East speak of nations and empires existing before Adam's creation, and of a line of kings who ruled over them. In Europe the subject was taken up by Isaac de la Peyrère, who, in a work published in Paris in Latin in 1655, maintained that the Jews were the descendants of Adam, and the Gentiles those of a long anterior creation, founding his opinions on Genesis iv, 14, 17; and Romans v, 12–14. Others maintain that only the white and dusky races descended from Adam, but that the black races existed before him. In modern times the question became again a matter of extensive controversy. Consult 'The Genesis of the Earth and of Man' (ed. by R. S. Poole, London and Edinburgh 1860); M'Causland, D., 'Adam and the Adamite' (London 1872); Winchell, Alexander, 'Preadamites' (Chicago 1880).

PRE-CAMBRIAN FORMATIONS. Those geological formations included in the systems below the Cambrian are sometimes grouped under this name. In America they include the earliest formations, namely, those of the Archean Period (q.v.), and those immediately succeeding them, namely, those belonging to the Algonkian System (q.v.). According to the earlier, European, nomenclature all the Pre-Cambrian formations fell within the Archean Period, their lower series being called the Laurentian and the higher the Huronian. The latter practically correspond to the Algonkian.

The time occupied by the deposition of the Pre-Cambrian formations extended from the solidifying of the crust of the earth to the beginning of the Cambrian period (q.v.) and as the first traces of life are found in these formations, and as they already show in the variety of their types evidences of long development, the length of time that elapsed during the building up of these formations must have been very great. See GEOLOGY; ARCHEAN; ALGONKIAN; PROTEROZOIC.

PRE-EMPTION LAW, United States. The first pre-emption act was passed 3 March 1801; it was a special act affecting the Symmes colonization scheme on the Miami River. Between that time and 1841 about 18 pre-emption acts were passed, all of a more or less special nature. The first general law was passed in 1830. That of 1841 granted, upon considerations of residence and improvement, freedom of entry upon 160 acres of public lands to any person over 21 years of age, provided he was a citizen or had declared his intention to become one. By act of Congress of 3 March 1891 the various pre-emption laws then in existence were repealed. All bona-fide claims or rights under them, however, were saved. There are now no pre-emption laws on the statutes of the United States. Consult Mallory, John A., comp., 'Compiled Statutes of the United States, Vol. II, pp. 1854–56 (St. Paul 1914).

PRE-EXISTENCE, the doctrine that the soul of an individual had an existence previous to that of the body in which it appears. This opinion was very prevalent in the East, and was held by the Greek philosophers, Pythagoras, Empedocles and Plato himself. A similar doctrine has found some countenance in Christian times among those who were anxious to explain how the soul becomes united to the body, but could not divine any more plausible hypothesis than that all souls were created before the world, and that each has its proper body allotted to it at the time of birth. In opposition to the doctrine of pre-existentism is that of traducianism, which teaches that the soul, like the body, is propagated; and creationism, in accordance with which a new soul is immediately created out of nothing by God for each newly propagated body. Consult Müller, Julius, 'The Christian Doctrine of Sin' (Edinburgh 1852–53); Howison, G. H., 'Limits of Evolution' (New York 1901).

PRE-RAPHAELITES, members of the «Pre-Raphaelite Brotherhood» and their followers. The original brotherhood was founded by the association of three painters, Dante Gabriel Rossetti, William Holman Hunt and John Everett Millais. The inspiration, however, which gave life to the Pre-Raphaelites was derived from an artist who never joined the brotherhood, Ford Maddox Brown. In 1848 Rossetti became the pupil of Ford Maddox Brown, a great and original artist whose work was quite neglected at a period when Victorian art in England had sunk to its lowest condition of commonplace prettiness, conventionality and utter want of mysticism or spirituality. Ford Maddox Brown, the practical originator of the new school of English painting, and the bringer-in of a new English Renaissance, had attracted the notice of Rossetti by his powerful picture, 'Parisina's Sleep,' which was exhibited at the British Institution 1845 and was conspicuous for marvelous atmosphere, finish and fidelity of expression. Rossetti became the devoted disciple of this master. Rossetti was a poet, full of dreams and desires, and passionately striving after the true and the beautiful. At the academy schools he met William Holman Hunt, a man of profound religious feeling, yet reserved, hard working and bound on notable and original achievement in art. With them was eventually associated John Everett Millais, already a brilliant and successful artist, and far in advance of his confrères of equal age in all the skill that comes from knowledge and practice. These men, strangely different in artistic temperament, formed a powerful trio devoted to making a fearless protest against the shallow and insincere banalities of the day. They called themselves Pre-Raphaelites; but, as W. Holman Hunt has said, «Neither then nor afterward did they affirm there was not much healthy and good art after the time of Raphael; but it appeared to them that afterward art was so frequently tainted with the canker of corruption that it was only in the earlier work they could find with certainty absolute health. Up to a certain point the tree was healthy: above it, disease began; side by side with life, there was death.» Their artistic doctrines were indeed to be summed up in the one word *sincerity;* the bond of union between them, as enunciated by one of their number, was (1) to have clear ideas to express; (2) to study Nature attentively, so as to know how to express them; (3) to sympathize with what is direct and serious and heartfelt in previous art, to the exclusion of what is conventional and self-parading and learned by rote; and (4) most indispensable of all, to produce thoroughly good pictures and statues.

The three founders of the association which Ford Maddox Brown had inspired were subsequently joined by Thomas Woolner, sculptor; James Collinson, painter, who eventually left the brotherhood; Walter Howell Deverell, painter; Frederick George Stephens, painter and art critic; and William Michael Rossetti, younger brother of Dante Rossetti, and like the latter, a poet. Ford Maddox Brown declined to join simply because he disliked coteries, and it certainly was not he who gave the doctrine its name of Pre-Raphaelitism. But, as his own work was an embodiment of this artistic creed, so his association with the members of it was always close and his sympathy with their work enthusiastic. Millais remained in the brotherhood 10 years (1849–59); he then dropped out, became a fashionable portrait painter and famous for his power in painting children, and such textures as satin and velvet. W. Holman Hunt kept on an uncompromising adherent to the principles of the brotherhood. But before the work the Pre-Raphaelites had to do was accomplished, they were compelled to run the gauntlet of criticism and ridicule from those whose system and method of painting they were attacking. In the *Times* of 5 May 1854 a letter appeared signed by John Ruskin, boldly praising and defending the new school. It is doubtful, however, whether Ruskin understood the principle of Pre-Raphaelitism, and it is a mistake to think that his writings gave the first suggestion for the formation of such a league.

Pre-Raphaelitism has become a permanent influence in English art. The generation of English artists which succeeded that in which Ford Maddox Brown lived has followed the guidance of the Pre-Raphaelites, either as to romantic motif, mystic religiousness or drawing and technique; sometimes in all of these. In certain quarters, however, there appeared a tendency in a somewhat perverted manner to carry out the traditions of the brotherhood, by an exaggerated mediævalism, a deliberate crudeness or grotesqueness of design and an insistence on minute detail. The most important English artists who were influenced by Pre-Raphaelitism were: William Morris, W. S. Burton, M. J. Lawless, Robert Martineau, Walter Crane, Sir Edward Burne-Jones and E. De Morgan.

PREACHERS, Orders of. See Dominicans.

PREACHING FRIARS. See Dominicans.

PRÉAULT, prā-ō, **Antoine-Auguste,** French sculptor: b. Paris, 8 Oct. 1809; d. there, 11 Jan. 1879. He began his art studies with a decided tendency toward romanticism and entered the studio of David d'Angers, but soon left it and ever afterward aimed at a naturalistic treatment of art themes. This was proved by the first works he exhibited at the Salon (1833) — 'Misery,' a group representing a girl dying in the arms of her mother; and two reliefs, 'Death of the Poet Gilbert in Hospital' and 'Famine.' In the following years he exhibited numerous works, among them the statue 'Undine'; and the relief 'River Amazon'; 'Queen of Sheba'; a sitting figure of Hecuba; the colossal statue 'Charlemagne'; and the statue 'Carthage.' None of these works were admitted to the Salon, but in 1849 the opinion of his merits had changed and the doors of the exhibition in the Champs Elysées were opened to him. After this he was represented there by his ‘Christ on the Cross’ (now in the church of Saint Gervais); the relief ‘Ophelia’; the statue of ‘General Marceau’ at Chartres; the statuette ‘French Comedy’; and many other works, amongst which there were many sepulchral monuments. The most famous of these, perhaps, is ‘Silence’; now in the Père-Lachaise cemetery. As a sculptor his workmanship was fine, but he sometimes failed to control his fancy and strong feeling for realistic form within that reserve and restraint prescribed by the canons of strictly plastic art. He was a tireless worker and one of the most ardent and powerful representatives of the new realistic school of sculpture. Consult Chesneau, E., ‘Auguste Préault’ (in ‘L'Art,’ Vol. XVII, p. 3, Paris 1879); Chesneau, E., ‘Pedutres et statuaires romantiques’ (Paris 1880).

PREBEND, a stipend paid to an ecclesiastic from the foundation funds of a cathedral or collegiate church. Prebendary is the person who holds a prebend. A simple prebend has no more than the revenue which is assigned for its support; but if the prebend has a jurisdiction annexed, the prebendary is styled a dignitary. Prebendaries, as such, have no cure of souls; but a prebendary may, and frequently does, hold a parochial benefice as well. The prebendal stall is the seat of the prebendary in the church, into which he is inducted by the dean and chapter.

PREBLE, prĕb'l, **Edward,** American naval officer: b. Portland, Maine, 15 Aug. 1761; d. there, 25 Aug. 1807. When about 16 he ran away from home and joined a merchantman, on which he went to Europe; on his return in 1779 he entered with his father's approval the Massachusetts State marine as midshipman on the *Protector* and participated in the attack on the British ship *Admiral Duff* which was destroyed. In 1780 he was captured on board the *Protector* and imprisoned on the prison-ship *Jersey* in New York Harbor. Upon his release he served on the *Winthrop,* another Massachusetts State ship, and with 14 men boarded an armed British brig and took her out of Penobscot Harbor in the face of the enemy's battery. At the conclusion of peace the Massachusetts navy was disbanded in 1782. For the next 16 years he devoted himself to commercial pursuits and made a number of journeys to various parts of the world. On the organization of the United States navy in 1798 he was one of the first five to be commissioned lieutenant, and in 1799 was promoted captain in command of the *Essex* with which he convoyed a fleet of 14 valuably laden merchantmen from China. In 1803 he was assigned to the *Constitution* and given command of the squadron against the Barbary powers. He arrived at Tangiers in October 1803 and speedily forced from the Sultan of Morocco a renewal of the treaty of 1786. The *Philadelphia* of his squadron was captured while pursuing Tripolitan gunboats and Preble blockaded Tripoli for several months endeavoring to regain or destroy the ship. In July 1804 he bombarded Tripoli and subsequently conducted six vigorous attacks in which he captured three gunboats and sunk three others. In September the relief squadron under Preble's senior officer, Captain Barron, arrived and Preble returned to the United States early in 1805. The treaty was signed in 1805 without further fighting and Preble received a gold medal and the thanks of Congress. After his return his health showed signs of serious impairment. And, without again assuming active duty, he died after much suffering in his 47th year from consumption. Consult ‘Naval Operations against Tripoli’ (in ‘American State Papers,’ Class VI, Naval Affairs, Vol. I, 1794–1825, p. 133, Washington 1834); Waldo, S. P., ‘Biographical Sketches of American Naval Heroes in the War of Revolution’ (Hartford 1823); Sparks, Jared, ed., ‘The Library of American Biography’ (Series II, Vol. XII, Boston 1847); Preble, G. H., ‘First Three Generations of Prebles in America’ (Boston 1868).

PREBLE, George Henry, American naval officer: nephew of Edward Preble (q.v.), b. Portland, Maine, 25 Feb. 1816; d. Brookline, Mass., 1 March 1885. He entered the navy as midshipman in 1835, served in the Mediterranean on the frigate *United States* in 1836–38, on various boats of the West Indian and Gulf squadron in 1839–40, was engaged in the war against the Seminoles in 1841–42, and in 1843–45 circumnavigated the world on the *Saint Louis,* attaining the distinction of landing the first American force in China. In the Mexican War he participated in the battles of Alvaredo, Vera Cruz, Laguna, Tampico, Panuco and San Juan de Ulloa; in 1848 he was commissioned a lieutenant; from 1853–56 he was in Japan and China with the Perry expedition and in 1854–55 he was engaged in several actions with Chinese pirates. In 1862 he commanded the steam gun-boat *Katahdin* under Farragut at the capture of New Orleans, was commissioned a commander in that year and for failure to capture the Confederate cruiser *Oreto* was dismissed from the navy. Investigation proved him blameless, however, and in 1863 he was restored to his rank, placed in command of the *Saint Louis* with which he engaged in pursuing Confederate rovers in foreign waters. In the latter part of 1864 he blockaded the North Edisto River, and a little later was placed in command of the fleet brigade organized by Admiral Dahlgren at Port Royal for the purpose of co-operating with General Sherman. Under his command the brigade engaged on 30 Nov. 1864, in the successful battle of Honey Hill. In April 1865 he was put in command of the steamer *State of Georgia.* From October 1865 to July 1867 he was inspector general of supplies at the Charlestown navy yard. From August to December 1867 he acted as chief of staff of the North Pacific squadron, commanding the flagship *Pensacola* and in March 1867 was commissioned a captain. He was commissioned commodore in 1871, and in 1873–75 had charge of the navy yard at Philadelphia. In 1876 he received rank as rear-admiral, was in command of the South Pacific station in 1877–78 and in 1878 was retired. He wrote ‘Chase of the Rebel Steamer of War Oreto’ (Cambridge, Mass., 1862); ‘Genealogical Sketch of the First Three Generations of Prebles in America’ (Boston 1868); ‘Our Flag. Origin and Progress of the Flag of the United States of America, etc.’ (Albany 1872); ‘History of the Flag of the United States of America, and of the Naval and Yacht-Club Signals, Seals and Arms, etc.' (1880); 'A Chronological History of the Origin and Development of Steam Navigation' (Philadelphia 1883).

PRECEDENCE, in official life, the order in which men and women follow each other according to rank and dignity in a State procession or on other public occasions. In England the order of precedence depends partly on statutes and partly on ancient usage and established custom. Questions arising on matters of precedence depending on usage are hardly considered as definitely settled and are in a great measure left to the discretion of the officers of arms. The sovereign, of course, is always first in order of precedence, after whom in descending order follow the Prince of Wales, younger sons of the sovereign, grandsons of the sovereign, brothers of the sovereign, uncles of the sovereign, nephews of the sovereign, ambassadors, the Archbishop of Canterbury, the Lord High Chancellor, the Archbishop of York, the Prime Minister, and so on through the high state dignitaries, the various ranks of the peerage, etc. The order of precedence among women follows the same rules as that among men, except that wives and daughters of men possessing official precedence do not participate therein and are ranked entirely by whatever personal standing they may possess by virtue of inherited titles or dignities. By the acts of Union of Scotland and Ireland the precedence in any given degree of the peerage has been established as follows: (1) Peers of England; (2) Peers of Scotland; (3) Peers of Great Britain; (4) Peers of Ireland; (5) Peers of the United Kingdom and Peers of Ireland created subsequent to the Union. The question of precedence in recent times has lost much of its former importance as a result of the spread of democratic institutions. England is, perhaps, still more interested to-day than any other country and has more extensive and detailed regulations concerning it, though, of course, rules governing precedence are in existence in practically every civilized country in the world.

In the United States the most generally accepted order in Washington official life is as follows:

The President,
The Vice-President,
President of the Senate,
Foreign Ambassadors,
Chief Justice of the Supreme Court,
United States Senators,
Speaker of the House,
Representatives in Congress,
Associate Justices of the Supreme Court,
Secretary of State,
Diplomatic Corps (other than ambassadors),
Secretary of the Treasury,
Secretary of War,
The Attorney-General,
The Postmaster-General,
Secretary of the Navy,
Secretary of the Interior,
Secretary of Agriculture,
Secretary of Commerce and Labor,
General Staff of the Army,
Admirals of the Navy,
Governors of States.

Then follow the judiciary, diplomatic representatives of the United States, army and navy officers, chiefs of departments, foreign consuls, secretaries of legations, etc.

Questions of international precedence arising as a result of international commissions or of the signing of treaties by several countries, are solved usually by arranging the names of the countries in alphabetical order. The precedence of diplomatic representatives is determined by the date of the presentation of their credentials, except that ambassadors outrank envoys and ministers plenipotentiary. Consult Burke, 'Peerage'; MacKenzie, Sir George, 'Observation Upon the Laws and Customs of Nations as to Precedency' (Edinburgh 1680); Hellbach, J. C. von, 'Handbuch des Rangrechts' (Ansbach 1804).

PRECENTOR (Latin, *præ*, before; *canere*, to sing), a leader of singing. In cathedrals of ancient foundation of the Established Church of England the precentor is a member of the chapter and in dignity ranks next after the dean; in cathedrals of the new foundation, that is, those of sees created by Henry VIII or formed in later times, the precentor is only a minor canon and is removable at the pleasure of the dean and chapter. During solemn functions the precentor's place is on the north side of the chancel, while that of the dean is on the south side. In the Presbyterian churches of Scotland it was formerly the custom that half an hour before the arrival of the minister, the precentor would read to the congregation lessons from the Scripture; when the minister entered, the precentor would give out a psalm and lead the singing; hence his desk, below the pulpit, is still called lectern, or in Scotch dialect *lettran*, that is, reading-desk. In the rural districts of Scotland it is still customary for the precentor to read each verse of a psalm before it is sung.

PRECEPTORS, College of, London, England, a training school for teachers founded in 1846 and granted a Royal Charter in 1849 «for the purpose of promoting sound learning and of advancing the interests of education, especially among the middle classes, by affording facilities to the teacher for acquiring a knowledge of his profession.» The college established examinations for teachers and for students in the secondary schools, issuing diplomas and certificates; and performed pioneer work in the training of teachers for the secondary schools. The school examinations, established in 1853, served as standards by which teachers could guide their work. The first examination in the theory and practice of education was held in 1867 and in 1873 the first professorship in education in England was established by the college. There are practical examinations for certificates of ability to teach as well as the written theoretical examinations; and there are, as well, winter meetings and short courses for teachers. The examinations conducted for pupils in secondary schools have proved of value as the marks obtained are recognized by the board of education and by many professional associations. The college has power to inspect schools and decide upon their suitable housing and equipment, as well as upon the adequacy of the teaching staff and the general organization. Membership in the college is open to persons over 18 years of age who have passed the examination prescribed by the council and been thereafter elected. The college is located in Bloomsbury Square and has a library of 10,000 volumes. The organ of the college is the *Educational Times*, published monthly and one of the oldest educational journals in

England. Consult 'Annual Calendar, College of Preceptors'; Board of Education of England's 'Report of the Consultative Committee on Examinations in Secondary Schools' (1911); 'Schoolmaster's Year Book' (London, annual).

PRECESSION OF THE EQUINOX. See EQUINOX.

PRÉCIEUSES RIDICULES, Les, lā prā-sē-ė rē-dē-kül, a comedy by Molière (q.v.), produced for the first time 18 Nov. 1659. No one of Molière's comedies is better known than this famous satire on the «Précieuses,» which can almost be entitled a farce, being an exaggeration of an exaggeration. It is in one act and is a satire on a style of speech and an affected taste in art and literature, prevalent among a certain class at that time. When writing it Molière had in mind the literary lights who assembled at the Hôtel de Rambouillet, the residence of the Marquise de Rambouillet (q.v.). Consult Lang, Andrew, ed., 'Les Précieuses Ridicules' (Oxford 1890); Davis, W. M., ed., 'Les Précieuses Ridicules' (Boston 1895).

PRECIOUS METALS. Gold and silver are commonly included under this term, though platinum and quicksilver have sometimes been added. However, on the basis of their having sufficient value and being abundant enough for coinage, gold and silver are more accurately described as precious metals. America has contributed largely to the total amount of the precious metals in circulation in the world. The United States, Mexico and Australasia are the three countries which rank highest in annual total production of these metals according to their monetary value.

Fine ounce of gold, $20.671834 +; fine ounce of silver, $1.292929 +, coining rate in United States silver dollars.

The United States, therefore, while greatly surpassed in the amount of gold produced by Africa, and in silver by Mexico, far surpasses every other country in the total value of precious metals produced. It is estimated that the total production of gold in all countries since the discovery of America amounted to 825,000,000 fine ounces in 1919, while the total production of silver in the same period was 12,000,000,000 fine ounces. See COMMERCE, *History of*; GOLD; MINERAL PRODUCTION IN THE UNITED STATES; PLATINUM; SILVER; and consult Smith, E. A., 'Sampling and Assay of the Precious Metals' (Philadelphia 1914).

PRECIOUS STAR, Order of. See ORDERS, ROYAL.

PRECIOUS STONES. A substance to be precious must possess variety, beauty, durability and portability. Precious stones, phenomenal stones and semi-precious stones are such as may be used for ornamental jewelry. Strictly speaking the term precious stone is reserved to designate the diamond, the ruby, the sapphire and the emerald, the others being called «phenomenal» and «semi-precious,» but the designation «precious» has been loosely used to indicate all stones used for the jeweling of choice objects of adornment. The following are those which chiefly claim attention:

Diamond.— See the special article describing this gem.

Spodumene has a hardness of 6.5 — 7, and a specific gravity of 3.13 — 3.19. The rich green variety, ***hiddenite,*** named after the late William Earle Hidden, was found at Stony Point (now named Hiddenite), Alexander County, N. C., in crystals furnishing gems weighing up to five carats each. A yellow variety which occurs in Brazil is called triphane. *Kunzite* (q.v.) is a rich, lilac-hued variety of spodumene, of which fine examples come from Pala, San Diego County, Cal., It also occurs in crystals weighing up to 100 carats in Madagascar. Spodumene was at an earlier time called «triphane,» a name given it by the great crystallographer Haüy.

Titanite (or sphene) is a calcium silicotitanite, having a hardness of 5.5 and a specific gravity of 3.5. It furnishes the most brilliant yellow and brown gem except the diamond. Fine examples have been found in Bridgewater, Bucks County, Pa., from which gems weighing from 10 to 20 carats could be cut. Other sources are the Tilly Foster Mine, New York, and the Pfitschtal and Zillertal, in Tyrol.

Tiffanyite.— A name given to a hydrocarbon assumed to be present in certain diamonds, namely those which on that account exhibit fluorescence and phosphorescence. The substance apparently has a bluish-white color. The blue white diamonds of Brazil are called Tiffanyite diamonds.*

Moissanite.— A natural carborundum, a carbon silicide, of which the French chemist, Henri Moissan, found, in 1905, small blue or bluish-green crystals in the meteorite of Cañon Diablo, Arizona, in association with microscopic diamonds. It belongs to the rhombohedral division of the hexagonal system. The cleavage is poor; the fracture conchoidal; the hardness is next to that of the diamond. The refractive indices are higher than 1.75. As many as 44 varieties of the crystal forms have been observed. The name was given in honor of the discoverer.†

Rubies and Sapphires.— The ruby and the sapphire are transparent varieties of corundum (q.v.), the first being carmine-red, and the second bright blue and velvet blue. Other colors also occur, as yellow, green and purple, called, respectively, Oriental topaz, Oriental emerald and Oriental amethyst. Corundum crystallizes in the hexagonal system, and consists of alumina nearly pure. In hardness it ranks next below the diamond, being rated as nine on the scale. The finest rubies are found in Burma, in the Mogok Valley, northeast of Mandelay. They are also mined in Siam, where they are of a darker shade, and in Ceylon, where they are of lighter hue and often of great brilliancy. The finest Burmese rubies have a peculiar tint, called «pigeon's blood.» Rubies of large size are extremely rare, and when they weigh four carats or more they are worth from two to five, and formerly 10 times the price of diamonds of the same size. Sapphires come principally from Ceylon, Cashmere and Siam, the finest tints being known as the «cornflower» and the «velvet blue.» In Australia, especially at Anakie in Queensland, many dark-blue sapphires are found, too deep in hue to be of

* Appendix I, Dana 'System of Mineralogy,' p. 68, 1899; citing George F. Kunz, N. Y. Acad. Sciences, Vol. XIV, p. 260; 1895.

† Second Appendix to the 6th ed. of Dana's 'System of Mineralogy,' New York 1909, p. 70.

value if cut into large gems, so they are generally cut as calibre or small stones. Queensland has furnished some wonderful golden-yellow corundums, these being the centres of blue crystals. Sapphires are also found in Montana at several points, generally under two carats each; the choicest are mined at Yogo Gulch, in Fergus County. These are of a rich blue color. Other mines are at Rock Creek, Granite County, where there is a great variety of shades; examples also occur at Cottonwood Creek, and along the bars of the Missouri River, not far from Helena, Mont. Fancy colors are of little value compared to the blue.

Beryl, Emerald and Aquamarine are the same mineral, a silicate of aluminum and glucinum. The hardness is eight and the crystals belong to the hexagonal system. Beryl varies from blue through light green to yellow, when it is called «golden beryl,» and forms a gem resembling topaz. If colored a rich green by a little oxide of chromium, it becomes the emerald, a stone which is rarely flawless, but ranks in value with the diamond. The chief source of fine emeralds has long been the mines at Muzo, about 70 miles on a direct line from Bogotá, Colombia, where they occur in a black limestone rock. The mine has been worked by Europeans for three centuries, and was previously exploited by the native peoples of the region. The emeralds known to the ancients came principally from Upper Egypt, near the Red Sea. These mines were long abandoned and left unworked, but are now being operated on a small scale. Light sky-blue, rich ocean-blue, sea green or greenish beryls are known as aquamarines; the finest examples have come from Brazil and Madagascar. A Brazilian crystal weighed 246 pounds. They also occur in the Urals and Siberia, as well as in Maine, North Carolina and Colorado. Golden beryls are found in Maine, Connecticut and Pennsylvania. A variety of golden beryl found at Rössing in the former German Southwest Africa has been given the trade name «heliodor.»

Phenomenal Gems.— The name applied to precious stones which change in color or else have a change of light or exhibit some phenomena other than the color itself. Notable among these are the sapphire asteria and ruby asteria; the ruby asteria or star ruby is found in Ceylon and in the ruby mines of Burma, and is a phenomenal gem in high favor. Then come the alexandrite, a variety of chrysoberyl changing from a dark green by daylight to a columbine red by artificial light; the chrysoberyl cat's-eye, changing from pale honey yellow to dark brown, and, occasionally, the alexandrite cat's-eye, green by day and red by artificial light; moonstone, a white feldspar exhibiting the phenomena of lustre, and a white or bluish play of light; sunstone, in which there are brilliant reflections from the interior of the feldspar or quartz; labrador spar, labradonite feldspar, which has a rich play of blue, blue-green and yellow, resembling a peacock feather. All of these are surmised to bring good fortune to the wearer.

Chrysoberyl, which has a hardness of 8.5, is a glucinum aluminate. It is a rare mineral, of various shades of yellow, brown, light green and dark green. One variety contains minute impurities distributed between the layers of the crystal, and these layers are so arranged, by what is termed the «twinning» of the crystal, that when the stone is cut across them light is reflected or condensed into a transverse bright line; such a gem is called a chrysoberyl cat's-eye.

Alexandrite is a variety of chrysoberyl, colored by chromium. This name was given by Nordenskjöld because the gem had been found on the day the Czarevitch, later Alexander II, came of age, in 1833. It was first discovered in the Ural Mountains at Takowaya, but now occurs in larger gems, up to 70 carats each, in the gem-gravels of Ceylon. It possesses the property of changing from a dark green to a columbine red when exposed to artificial light, thus displaying in turn what were the Russian national colors at the time it was first discovered.

Morganite is a rose red silicate of beryllium containing manganese, found in Madagascar, being the same in composition as the aquamarine and the emerald, differing only in color. It possesses the property of becoming phosphorescent as does kunzite, a mineral with which it is associated. It appears in beautiful gems up to 200 carats each. It occurs, also, at Pala, in San Diego County, Cal., in crystals of some size, and example, small and not of good color, are met with at Haddam, Conn,, but not in gem form. The name was given in honor of the late J. Pierpont Morgan.

Zircon, or Hyacinth (jacinth), sometimes called jargon, is a gem of 7.5 in hardness and having a specific gravity of 4.1 to 4.7, occurring brown, yellow, blue, green and white; it is a zirconium silicate. Frequently the white gem is the result of the decolorization of a darker stone. These were frequently rose-cut in the East, and in the 18th century were called «Matura Diamonds.» The color sometimes returns after decolorization. The chief source of supply has been Ceylon, although many fine gems have been found in Australia and Tasmania.

Topaz is a rather complex silicate of aluminum, occurring in rhombic prisms and possessing a hardness of eight. It is generally yellow, but other examples are pale blue, pale green, pale brown and white or colorless. The favorite tint is a peculiar yellow known as sherry color. The finest come from Brazil or from the Ural Mountains, but some very handsome ones have been found in Colorado and Utah. The sherry-colored variety, if heated in vacuo, changes to a rich, almost magenta pink, then to a light pink and finally becomes colorless. White topaz is often found in large masses in Ceylon, and in Brazil, where a 23-pound mass was found. Fine blue and cinnamon colored crystals occur in the Urals, in Siberia, Japan, Mongolia and in Colorado, Texas and Maine; the cinnamon-colored variety changes, upon exposure to daylight, to colorless topaz. (See also QUARTZ; nearly all the so-called topazes are really citrines — decolorized smoky quartz).

Tourmaline is a complex silicate of aluminum, occurring in prisms of six, nine or 12 sides. It is usually black, but also of transparent red, green and other colors, often singularly mingled in the same crystal. The gem is found in Brazil and Siberia, and examples of great beauty are met with at Paris and

Auburn, Me., Haddam Neck, Conn., and especially in San Diego County, Cal. Mineralogically it occurs in a great variety of colors and forms; the red is known as rubellite, the blue as indicolite, the white as achroite and the green is called «Brazilian emerald» in Brazil. Wonderful red tourmalines rubellite are found in the Ural Mountains, Russia, and red and other colors in Madagascar. At times the crystal is green on the exterior with a white zone and a red interior, the iron which causes the green hue being neutralized by the manganese in the red color; this strange combination forms the so-called «watermelon crystal.» Tourmaline is probably the most varied interesting mineral, with the exception of quartz, occurring in magnificent gems of green, blue, red, yellow, brown, white and frequently three or more colors are present in distinct zones in various parts of the crystal. Its electric properties, discovered in the 18th century, was discussed in most of the European learned societies at that time, the name «Aschentrekker» («Ash-attractor») being given to the mineral in Amsterdam.

Garnet is the name of a group of minerals closely related in form and properties, but presenting a number of varieties. They are all very complex aluminum silicates, in which various metallic oxides enter as components. The principal gem varieties are almandine, or precious garnet, the carbuncle of the ancients, containing considerable oxide of iron; its color is a deep, rather purplish or brownish red; pyrope, or Bohemian garnet, containing much magnesia, of a fine dark crimson, almost a ruby color. These two are the red garnets of jewelry; when cut *en cabochon,* that is, not facetted, but dome-shaped, they are called carbuncles. Manganese garnet, or spessartite, is sometimes of a very beautiful orange-brown color; elegant gems of this kind have been found at Amelia Court House, Va. Uvorovite, or chrome garnet, is a rare variety, of a brilliant dark green color, but the crystals are very small. Another green garnet of somewhat different composition, and with very brilliant lustre, from the Ural Mountains, is called demantoid, or Uralian emerald. Much fine garnet is found in the United States. North Carolina yields a beautiful variety that has been called rhodolite,— a brilliant light red garnet, between almandite and pyrope in composition; these are largely mined in the Cowee Valley, in Macon County. New Mexico and Arizona produce fine pyropes, often misnamed «Arizona rubies,» and equalling those of any other known locality. They are found where ants and centipedes have carried them out in making the galleries of their hills. In South Africa similar pyrope garnets found with the diamonds are termed «Cape rubies.»

Quartz is pure silica, the crystalline, rock crystal type occurring as six-sided crystals. It embraces a great number of the commoner gem stones, specific gravity about 2.6. These fall into three distinct groups,— The transparent colorless variety, rock crystal, then the purple amethyst which is colored by manganese, and finally the smoky topaz or smoky crystal, the ordinary black variety, and the intensely black «morion.» When the black variety can be decolorized by heat, it changes first to a deep brown and then to a transparent yellow, sometimes becoming almost colorless. The original smoky quartz, deep brown in color, is called «cairngorm»; it is mostly used in Scotland and is the Scotch national stone. The lighter colors produced by decolorization by heat are known as Spanish topaz and citrine. Nearly all the so-called topaz of commerce is a quartz variety, not true topaz.

The cryptocrystalline variety, agate, is usually banded, and is generally the result of deposition of silica in the amygdules of a volcanic rock. The structure is in thin layers, even though they may not be visible to the eye. The principal varieties are chalcedony, gray and blue-gray, the apparently unbanded variety; when banded it is called «banded agate.» When this banded material has been broken and recemented, it bears the name of «ruin agate»; if the bands are irregular in outline it is denominated «fortification agate.» Chalcedony, when treated with iron salts and then highly heated, becomes red and is known as «carnelian»; if there be one or more layers, one of which is compact and impervious, it forms the «onyx» (from Greek word signifying «nail»). Should any one of two layers be pink, reddish or brown, it is termed «sardonyx.» The latter name has been applied to an artificially colored variety, from pale brown and pale red to brown; when black with a thin white, copper-colored layer, it appears gray, and is called «nicolo.» The name onyx is also applied to chalcedony saturated with boiling honey or blood, and then treated with sulphuric acid, the blood or honey becoming carbonized and making the entire stone a deep black. When chalcedony is stained a translucent red or brown it is also called sardonyx, although it is really not an onyx, as it has only one layer.

The uncrystalline, or slightly crystalline, varieties are notably red jasper and green jasper. When jasper is green with red spots, due to the oxidation of the iron in the stone, it is called «bloodstone.» When the stone is yellow, brown or black, the term jasper is also used.

Opal is silica containing from 5 per cent to 10 per cent of water. When it contains more than 5 per cent of water, the opal is liable to fracture; with 5 per cent or less, it is a stone of considerable durability. Magnificent specimens of the white variety have been found in the mines of Hungary and in New South Wales, the white opals in New South Wales occurring in sandstone in which they occasionally replace wood, shells and the bones of reptiles. The black variety offers a velvet black field broken with the most intense red, green, yellow, blue and other colors. This is greatly prized and highly valued; it is found in the Lightning Ridge region in New South Wales. Many thousand fine gems have been brought from this locality, single stones selling for $5,000. The fire opals are a rich, red, honey or honey-red variety, containing a high percentage of water. The fire opal, or flame opal, found in Queretaro and other parts of Mexico is a rich honey-red—a brilliant variety with prominently large flames of light color, possibly due to inclusion of rutile (oxide of titanium). A colorless variety is also found, in which the play of color is in small flecks. This is known as the harlequin opal. Interesting opals replacing wood have been found in Humboldt County, Nev., brown, black and colorless.

Peridot, Chrysolite, or **Olivine,** deriving its name from its olive-green color, is a silicate of magnesia, found in magnificent examples in Egypt. Many magnificent specimens brought from the East are found in the church treasuries, dating from the time of the Crusades, notably at Cologne. They were then called emeralds. After a close study of the peridots here and in other ecclesiastical jewels, the opinion is expressed that almost if not quite all the fine examples in modern jewelry had been derived from this source. In 1900, gem chrysolites were found on the small volcanic island Seberget (also called Zebirget or Saint John) near the Egyptian coast of the Red Sea, an interesting discovery as it serves to confirm the ancient tale in early Greek and Latin authors that their chrysolite (which they called topaz) came from a mysterious «Serpent Isle» in the Red Sea. They are also found in the Navajo Reservation in New Mexico, in small gems of considerable beauty; in Hawaii, as honey yellow and small gems; and at Lac La Hache, British Columbia.

Jade.— This name is commonly used to designate both *nephrite* (a silicate of magnesium and calcium), and *jadeite,* named by Damour in 1863 (a silicate of aluminum and sodium). Nephrite has a hardness of 6.5, its specific gravity being 2.8, while jadeite's hardness is 7 and its specific gravity 3.3. The Chinese name for jade is *yu,* or *yu-shi;* the most prized variety of jadeite is termed *fei-tsui,* «kingfisher-plumes,» jewel jade or imperial jade. The jade brought by the Spaniards from the New World was named by them *piedra de ijada,* «stone of the flank,» whence our «jade»; it was asserted (and believed) to be a highly efficient remedy for diseases of the kidneys. This belief was reflected in the later name *lapis nephriticus* (kidney-stone) from the Greek *nephros,* «kidney,» the origin of our nephrite. A third stone of the jade group is *chloromelanite,* discovered by Damour in 1865. This mineral, with a hardness of over 6.5 to 7 and a specific gravity of 3.4, is of a darker green than jadeite (with which it is very closely related) because in its composition iron supplants a part of the alumina in the latter. A number of prehistoric ornamental objects of *chloromelanite* have been found in France, and a few in the lake-dwellings of Switzerland, as well as in Mexico, Guatemala and Colombia. The chief source of supply for nephrite has been in modern times the Kuen-lun Mountain in eastern Turkestan, while the jadeite now mined comes from the Kachin Hills, about 120 miles from Mogaung, Upper Burma. The nephrite of New Zealand, called by the natives *punamu,* or «green-stone,» is also well known. Numerous jade artefacts made in prehistoric times have come to light in almost all parts of the world, although the source whence the stone was obtained has not often been determined. For a time it was rather generally believed that none of it could be found *in situ* in Europe, and that the material for the European artefacts and for those discovered in the Americas as well was strictly of Asiatic origin. This erroneous idea has been entirely dissipated by several discoveries of nephrite in its original place at various European localities. The largest mass ever extracted was found by the present writer in 1899 at Jordansmühl, Silesia; it weighed 4,718 pounds (2,140 kilograms). This is in the Heber R. Bishop Collection in the American Museum of Natural History, New York City.

The fondness of the Chinese for jade is proverbial, and the finest ornamental objects (both of nephrite and of jadeite) have been produced by Chinese lapidaries, although to Hindu and other Asiatic artists also may be credited admirable work, and in New Zealand, as well, the native nephrite has been quite skilfully carved, as in the case of the curious *hei-tikis,* grotesque ancestral heirlooms with which some superstitious fancies are associated. In hue, jade runs through the gamut of the different shades of green, from the darkest to the lightest; some specimens are quite white. Jadeite is occasionally almost transparent, of a rich emerald green Jewel jade or Imperial jade, when containing a greater quantity of iron or chromium with a specific gravity up to 3.6 is called chloromelanite.

The color, translucency, hardness, toughness and fine structure are the properties that have rendered jade a very attractive material for the most artistic lapidaries of China, India, ancient Mexico, France, Russia and other countries. The Chinese have been the most pre-eminent in carving jade as is testified by the wonderful, beautiful and interesting carved objects in the Heber R. Bishop Collection in the Metropolitan Museum of Art, New York, and in the collections of the museums of Boston, Chicago, Paris, Berlin and Petrograd. The Russian objects are usually of stupendous size; the Chinese objects scarcely ever a foot high; some of the Russian works are from two to six feet long. Notable are the sarcophagus of Tsar Alexander II, and other work in the Imperial collections or among the Imperial gifts of the Russian tsars.

Nephrite is much tougher than jadeite, and as an illustration of its extraordinary toughness Dr. Heinrich Fischer relates* that he placed a large block of jade under a steam hammer, and that as a result of the blow the anvil on which the stone rested was broken, while the stone itself was unharmed. This illustrates the great difference between hardness and toughness, for although the diamond has a hardness of 10 against 6.5 of nephrite, the former would have been broken to splinters by such a test.

Owing to the shutting down of the European lapidary works due to the World War, the eastern Chinese lapidaries were called upon to supply the deficiency. The chromium-colored jadeite, because of its great beauty, has come into high favor, especially the rich translucent emerald green and yellowish green jewel-jade for bead necklaces, some of which have been sold for $20,000. Carved ornaments of jadeite have sold for from $500 to $2,000. Jade thumb-rings were formerly bought by wealthy Chinese for from a few dollars to $15,000 each. The exports of Burmese jadeite in worked form from China during the five-year period 1914–18 have been valued at about $2,000,000.

Turquoise is a phosphate of lime colored with copper, found for many centuries in the

* Tschermak's 'Mittheilungen' (1872, 2. Heft, p. 135); consult also Fischer's 'Nephrit und Jadeit', (Stuttgart, 1880, pp. 294, 299).

Nishapur district, near Meshed, Persia, where it is highly valued and is sold in great quantities, from gems weighing many carats each to minute, round discs not more than one or two millimeters in diameter. It is found also in the Sinai Peninsula, where the mines were worked by the Egyptians almost as far back at 4000 B.C. The color is a more intense blue than that of any other stone. In China, where it is worked into Oriental objects, it is found in great masses, weighing many pounds each, but impure. Gem turquoise occurs also in New Mexico, Arizona, Nevada and California as well as in Mexico, and it was used by the pre-Columbians for ornament as well as in mosaics in combination with various colored shells or obsidian and for the decoration of human skulls, daggers, clam shells and other objects. Many of these are of great beauty. As a ring stone the beautiful color of the best turquoise makes it a great favorite. In order to preserve the color, it is desirable to exercise care in subjecting turquoise to contact with liquids. In the Middle Ages, and later, the superstition prevailed that the wearer of a turquoise would be protected from injury by falls. In the 16th century this was called the Turkey stone, as it came to Europe from Persia via Turkey; the name was then converted to turquoise.

Benitoite, a titano-silicate closely related to titanite, a deep blue gem from California, is so named from its occurrence on the Mount Diablo Range in San Benito County. When cut, its beautiful blue color resembles that of the sapphire, which it exceeds in brilliancy because of its higher refractive power.

Lapis-lazuli was valued as gem-material at a very early date and is mentioned as an article of tribute on Assyrian tablets of the second millenium before Christ. The stone is of a rich blue color and is a complex mixture of minerals, the most important constituent being lazurite. It was originally used to produce the pigment ultramarine. Its average hardness is only about 5.5. Many of the old Egyptian scarabs and amulets are made of it and a proof that its beauty was greatly prized by the Assyrians is given in a hymn addressed to the moon-god Sin, where he is said to be «bright as lapis-lazuli» (*uknu*). Some of the earliest Babylonian cylinders were of this stone and down to the present time it has been highly valued for its rich and beautiful color. One of the chief sources has been the mines of Badakshan, in the northwest part of Afghanistan, near the upper reaches of the Oxus. Still more ancient mines have been discovered in the valley of the Kokcha, a tributary of the Oxus. These mines have been worked for about 6,000 years and are evidently the oldest mines in the world. Near Lake Baikal in Siberia, especially along the river Malaya Bistraya, there are also productive mines and material of a somewhat inferior quality has been found in the Chilean Andes of Ovalle near the watershed between Chile and Argentina. At this locality masses of several hundreds of pounds each have been found, but much white limestone permeates the lapis-lazuli. The stone designated «sapphire» by the ancient Greek and Roman authors was probably lapis-lazuli.

Malachite is a basic carbonate of copper, with a hardness of three and one-half to four. It is an aggregate of minute crystals, is opaque in the mass and is capable of taking a very good polish. Ornamental objects of various kinds have been made of this material, its wonderful variety of rich green hues and its artistic markings enabling the lapidary to produce most attractive effects. Most of the fine work in this stone has come from the Imperial Russian lapidary works at Ekaterinburg, where a wealth of vases, bowls, table-tops, etc., have been made. The Medno-Rudiansk mine at Nizhni-Tagilsk furnished in 1836 the largest block of malachite that has ever been extracted. Its dimensions were: length, 10½ feet, width, 8 feet, height 3½ feet; the estimated weight was from 25 to 30 tons. As many as 125 horses were used to haul this mass from the mine to Ekaterinburg.

Amber, which the ancient Greek poets derived from the tears annually shed over the death of their brother Phaëthon by the Heliades, is not a mineral but a vegetable substance, the fossilized resin of pine trees of far distant times; it has been and is still used in a variety of ways for decorative purposes, more especially in the form of beads to be strung as necklaces or rosaries. Example of such beads have been found among the remains of the most ancient civilizations and they have been worn by almost all races and at all periods. The hardness of amber slightly exceeds that of gypsum, being about two and one-half, and it is thus easily shaped. It is quite strongly electric and this quality may have given rise to the supposed curative effects to be secured by wearing amber necklaces and to the belief of luxurious Romans that a cooling sensation was experienced by holding an amber ball in the hand. In Mohammedan countries many of the long rosaries carried or worn by the followers of Islam are composed of 99 amber beads. The broad distinction between «clear» and «cloudy» amber, the former of a pure, light yellow hue and quite transparent, the latter, passing through different degrees of opacity, variously marked and shaded and ranging in hue from whitish-yellow to light-yellow, is that commonly employed, but a number of special designations are used in the amber industry. An interesting feature in some amber specimens is the inclusion in the fossil resin of insects or plant forms, that must have become imbedded in the substance while in a fluid state and thus have preserved for us the exact appearance of insects that died thousands of years ago. Cloudy amber can be clarified by heating it in oil, the latter being absorbed through the pores of the amber and rendering it more highly refractive. Another method of clarifying is by burying the amber in sand and subjecting it to a heat of over 100° C. for a long period.

Phenomenal Feldspars. *Aventurine.*—There are three phenomenal feldspars: Sunstone (Aventurine), Moonstone and Labrador Spar or Labradorite. Of these the sunstone owes its peculiar beauty to the presence of spangles of either hematite, göthite or mica. The name has also been applied to a compact quartzite, usually red, brownish or white, with spangles of mica. This aventurine quartzite is found in several parts of Siberia, sometimes in masses weighing more than a ton and is called by the Russians «orletz.» Numerous vases, cups and ornaments are made of this material by the Russians and two great vases formed of it were presented, one to Sir Roderick Murchison and one to Baron Von Humboldt, when they visited Russia in 1850. A greenish or white quartzite, having spangles of mica, or a greenish chlorite, or both, is said to come from India and is occasionally sold as jade.

Californite is a compact variety of *vesuvianite*, named by George F. Kunz and is found in Siskiyou County, Cal. A somewhat similar variety was discovered in 1889, on the Piz Longhin, Canton Grisons, Switzerland. When cut *en cabochon*, its bright green hue acquires great brilliancy and resembles that of the nephrite variety of jade, for which it is occasionally mistaken.

Among the finest gem collections in the United States are the Tiffany-Morgan collection and the Bement-Morgan collections at the American Museum of Natural History, New York; the Isaac Lea collection, at the United States National Museum, Washington, D. C.; the Tiffany collection of the Field Museum of Natural History, Chicago; the Tiffany collection of the Golden Gate Museum, San Francisco, and the Kunz collection at the New York State Museum, Albany, N. Y. The foreign collections contain many fine gems and are in the collections of the British Museum; the Musée d'Histoire Naturelle, Paris; the National Mineralogical Collection at Vienna, Austria; the Mining Institute, Petrograd, Russia.

Spencer; Smith, ‹Catalogue of the Gems of the British Museum›; Streeter, ‹Precious Stones and Gems›; Kunz, ‹Reports of the Department Mining Statistics›; United States Geological Survey, Bul. 1883–1905 in ‹Reports on Precious Stones,› in the annual Mineral Industry (Vols. I–XXVII, 1882–1918, New York).

GEORGE F. KUNZ.

PRECIPICE, The, by Iván Aleksándrovitch Goncharóf, had for its chief purpose, even more distinctly than ‹Oblómof› (q.v.), to present the eternal struggle between the East and the West — the contrast between the lethargy or indolence of the Russian and the enterprising spirit of European energy. The protagonist of the story suffers not so much from constitutional laziness as from vacillation, from lack of resolution. Raïsky had a good education and served for a time as a civil *chinovnik* at Saint Petersburg; but left his position as casually as he had accepted it. He had great ability as an artist but he never had the patience to finish the innumerable sketches that he began. He might have been a talented musician but his masters could not induce him to practise. He had no ambition and if he found nothing to interest him in reading he would lie all day in bed as if exhausted by hard labor. He owns a pretty estate on the banks of the mighty Volga and thither he goes to visit his Aunt Tatiana, who has managed it for him with remarkable ability. There the action of the story unfolds, especially connecting itself with a high bluff (*Obruif*) overlooking the wide stream, gliding peacefully between its overgrown banks, with here and there a bush-covered island. The bluff, or precipice, was once the scene of a murder and was believed to be haunted by a ghost. It occurs to Raïsky to make the place the scene of a novel and he writes at it in his usual desultory way, not realizing that the passion and the dramatic color which he is seeking to impart to his imaginary characters are all about him. He finds himself interested in Viera, the elder of the two young girls reputed to be his aunt's grandnieces, but in reality her grandchildren, the daughters of her own illegitimate child. Viera is under the almost hypnotic influence of Mark Volokóf, a political suspect, interned in the village and enjoying an evil repute as a thief and monster of iniquity. Volokóf can hardly be regarded as a type of revolutionist like Turgénief's Bazárof. He is an exceptional character, somewhat overdrawn in his moral obliquity, but not impossible. In spite of Viera's appeal to Raïsky to save her from this human wolf, Volokóf succeeds in his dastardly purpose; but the girl finds an unexpected sympathy in Aunt Tatiana, whose own tragic story is revealed, bringing redemption to both of them. Raïsky, finding his love for Viera hopeless through his own fault, throws aside his unfinished novel and goes to Italy to take up sculpture as a consolation. The minor characters are admirably drawn and the subordinate strands of the romance are woven in with skill against a charming background of the Volga. ‹Obruif› was published in the *Vyestnik Yevropui* (*The European Messenger*) in 1868–69, just 20 years after ‹Oblómof.› An English translation by M. Bryant was published in London in 1916.

NATHAN HASKELL DOLE.

PRECIPITATE, in chemistry a solid body produced by the mutual action of two or more liquids. Thus if sulphuric acid be added to an aqueous solution of barium chloride, barium sulphate is produced, and being insoluble in the menstrua present it precipitates or sinks as a solid to the bottom of the liquid in the vessel. So again, if a solution of potassium iodide be added to a solution of lead chloride, a reaction takes place resulting in the formation of lead iodide and potassium chloride, and inasmuch as the former of these bodies is, under the circumstances, a solid, it is precipitated. As a general rule it may be laid down that if it is possible to produce an insoluble solid substance by the action of two liquids on one another, that solid will be produced when these liquids are mixed, and that therefore a precipitate will be formed.

PRECOCITY, prē-kŏs'ĭ-tĭ, an early mental development, surpassing the normal. Generally speaking the precocious child differs from the prodigy in that his attainments constitute an actual acquirement rather than an intuitive possession of knowledge; and the precocious child presents a general development of the mental faculties instead of a supernormal development in a special line, as music, mathematics or other arts and sciences. Precocity may be the result of either training or natural endowment and the course of the educator toward it is usually that of fostering a general development, at the same time exercising care in avoidance of physical overstrain. Precocity has sometimes been held an indication of general physical weakness or inherent physical infirmity and likewise as having a deleterious influence upon adult attainments. As a rule, however, such unfortunate results may be ascribed to undue forcing, although the precocious child is no more immune to physical ills than any other. When due discretion is observed in its training the trait may generally be welcomed. It by no means presages genius, but on the other hand a preponderance of geniuses have possessed it. The need for modifying educational methods to meet the requirements of the supernormal individual so as not to retard his natural development and at the same time avoid overstimulation is one that has for some time engaged the attention of educators and physicians. Consult Donaldson, H. H., 'Growth of the Brain' (London 1895); Sully, J., 'Genius and Precocity' (1886); Galton, F., 'Hereditary Genius' (London 1892); Constable, F. C., 'Poverty and Hereditary Genius' (London 1905).

PREDESTINARIANS. See Religious Sects.

PREDESTINATION is the doctrine of God's will and counsel as revealed in the decreed redemption of mankind. It includes in its scope two significant facts, namely, his beneficent and allwise purpose and plan in reference to those who are fore-known and forechosen to the enjoyment of eternal salvation; and his fixed, determinate attitude toward those who are permitted to perish in their sins. This doctrine, as thus defined, has been the subject of intense theological controversy, because of the many essential and apparently contradictory personal features involved in it. And yet its history, as it appears in the rise and development of Calvinism over against Pelagianism, gives evidence of the logical connection which it has with biblical and metaphysical truth.

The sources of this tenet are set forth in the Old and New Testament Scriptures. From the earliest times of the human race, the God who "upholds, directs, disposes, and governs all creatures, actions, and things, from the greatest even to the least," is manifestly a potent personal factor in the world. His wisdom and might, his love and grace, are wondrously and sublimely illustrated in the lives and movements of his chosen people. Every stage of their history, in the genesis and growth of their civil and religious institutions, to the closing tragedy of the life of Jesus Christ, furnishes a series of pictures of the divine method of government, as they are painted by his artist hand. Indeed, so evident is his own mind and purpose throughout the execution of his salvatory plan, that his nature, life and love at once and forever become inseparable elements within the domain of the human universe. And this is fully indicated (1) by the perfection of his nature; (2) in the marks of his infinite wisdom, power, holiness, etc.; (3) in the operations of his will, thought and counsel; (4) in prophetic utterances and their fulfilment; (5) in the coming of Jesus Christ, the true representative of God; (6) in the unchangeable provisions of the redemption wrought out through him; (7) in the actual salvation of men from their sins; (8) in the establishment, upon a sure foundation, of the *Fact* of eternal life!

The historic birth of this doctrine can be traced to the fertile brain of Origen, who possibly was its first supporter, although he did not fully accept the second portion of it, which consigns the unsaved to conditions of everlasting reprobation. From his time to the Augustinian Age there was little controversy over the sovereignty of God in its relation to man's freedom and salvation. But during Augustine's sway, in the Western Church, the doctrine of man's inability to save himself and his absolute dependence upon God's eternal decree to be saved, was so strongly and vigorously taught that Pelagius, who represented opposite theological tendencies, declared that the true fundamental conception of sin involved man's capacity of choice to be good or evil, apart from God's plan and grace. This controversy was waged with great earnestness — especially in the Greek Church — for half a century, till it was modified under the form of Semipelagianism.

Later theologians divided themselves into two groups, the Infralapsarians and the Supralapsarians. The former taught that the decree of predestination had no effectiveness until after man's fall, while the latter class held that the ultimate end which God had in mind was his own glorification in the salvation of some and in the reprobation of others.

During the Reformation the strongest exponents of the true predestination idea were the Calvinistic thinkers under the leadership of John Calvin (1509), though the Lutherans and Arminians also accepted the doctrine in a less rigid form. Calvin's doctrinal ideas were incorporated in his greatest masterpiece, 'Institutes of the Christian Religion' (1535). The main features of this scholarly production, aside from the dissertations upon church, state and religion, are embodied in the doctrines of plenarv inspiration of the Bible, free-will and predestination. Here God is the centre and man the object of his voluntary interest and love. But in this relation he is confessedly to be dealt with according to his Creator's established order. Everything in and about him which is out of harmony with that order must be adjusted or rejected. In this process of correction or of salvation God acts alone. Man is a passive agent without the power of free-will. His predestined salvation or reprobation depends upon the unlimited might and wisdom of God. Hence predestination is a divine necessity.

This view of predestination was presented more philosophically and clearly by Calvin in his catechism published at Geneva (1545). And it was this treatise, without a doubt, that, a century later, furnished the Westminster divines the foundation outlines for the Standards which they drew up in England's great Abbey of Westminster during the years 1643–48. The three products of that representative body called by the English Parliament and made up of the most eloquent, pious and scholarly divines, Lords, Commoners and commissioners from every county of England and the universities of Oxford and Cambridge, are the Westminster Shorter and Larger Catechisms and the Westminster Confession of Faith.

In each one of these the doctrine of predestination is set forth, but more especially so in the 3d and 10th chapters of the Confession of Faith, which respectively treat "Of God's Eternal Decree" and "Of Effectual Calling." The paragraphs in these chapters that most pointedly outline the doctrine read as follows:

III. By the decree of God, for the manifestation of his glory, some men and angels are predestined unto everlasting life and others foreordained to everlasting death.

IV. Those angels and men, thus predestined and fore-ordained, are particularly and unchangeably designed; and their number is so certain and definite that it cannot be either increased or diminished.

As early as in the year 1831 the general assembly of the Presbyterian Church was confronted with the demand for more liberty in the interpretation of the Creed of the Fathers. The marshaling of the forces who stood for a change in the form of statement, involving the doctrines of election and predestination, continued, as shown by the famous heresy trials of Drs. Barnes, Swing, Smith and Briggs. After their deposition from the Presbyterian fold, the consideration of a revision of its standards became a matter of serious importance. In view of this the general assembly of 1889 resolved to transmit an overture to the presbyteries, asking them to consider the propriety of a revision of the Confession of Faith. The result of this action brought about the sentiment in favor of a revision. The assembly of 1891 now asked the presbyteries for more suggestions. Again the answer came by a large majority of Presbyterial votes for a revision.

In 1893 the assembly was importuned once more for a new and shorter creed, but it voted to lay the matter aside. The battle of the theological giants did not cease at this. Again they pressed to the front. In consequence, the general assembly of 1900 appointed a large committee to reconsider the matter of revision. After seven months they reported that "the returns indicated plainly that no change is desired which would in any way impair the integrity of the system of doctrine contained in the Confession of Faith." In spite of this negating motion, the general assembly of 1902–03 added the Declaratory Statement to chapters III and X, which reads as follows:

"With reference to chapter III of the Confession of Faith: that concerning those who are saved in Christ, the doctrine of God's eternal decree is held in harmony with the doctrine of his love to all mankind, his gift of his Son to be the propitiation for the sins of the whole world, and his readiness to bestow his saving grace on all who seek it. That concerning those who perish, the doctrine of God's eternal decree is held in harmony with the doctrine that God desires not the death of any sinner, but has provided in Christ a salvation sufficient for all, adapted to all, and freely offered in the Gospel to all; that men are fully responsible for their treatment of God's gracious offer; that his decree hinders no man from accepting that offer; and that no man is condemned except on the ground of his sin."

PREDICABLES, term of the Aristotelian system of logic, denoting a class of concepts which may be predicated affirmatively of several others; it is now obsolete. The predicables are five in number, namely, *genus, species, differentia, proprium* and *accidens*, and were used in classifying objects on a systematic plan. Every object was conceived of as belonging to some species and that to some genus; objects in the same genus — a dog and a wolf, for example, would belong to different species because of the *differentia* between their characters — the specific *differentia;* a property (*proprium*) would form a ground of difference between members of the same species, *proprium* expressing, not an ultimate distinction, but one resulting from some other character, for example, the peculiarity of the shepherd dog, which is founded in the dog's natural sagacity; *accidens* is something not inherent in the nature of the object, but incidentally present in it, for example, the high value of the diamond. See LOGIC.

PRE-ESTABLISHED HARMONY, The Doctrine of, the philosophical theory of Leibuity as presented in his doctrine of the monads, which has as its purpose the explanation of the universe as composed of various orders of self-active beings. His belief is that the forces of nature are not externally controlled and that the action of no single monad is influenced by another but was destined by God from the beginning to work out its individual progress unaffected by any other and toward an end of perfect harmony which is preëstablished. The monads include the physical elements with their chemical affinities and plants with their sentient life, up to the class of humans with souls and power of thought. The soul becomes the dominating monad in human existence, while God is the *monad monadum*. The theory involves a progressive independent development of the monads toward ultimate perfection and regards evil as an evanescent quality in no way conflicting with sure progression of God's original plan. The theory obviates any necessity for interference by the Deity. While of necessity conjectural in its conclusions it is regarded as one of the most profund treatises of philosophical theology in existence. Leibnitz left no elaborate exposition of his theory, its most complete summary being that he prepared for Prince Eugene of Savoy in 1714. See LEIBNITZ, GOTTFRIED WILHELM.

PREFECT, or **PREFET**, the title of a high civil official in France, created by a law of the 28th Pluviôse in the year VIII (17 Feb. 1800). It was derived from the old Roman title Praefect (q.v.). There were 86 prefects in modern France, each at the head of the civil administration of a departément. The prefect is an official of considerable power, although his prerogatives have been curtailed at various times since they were first established. He is appointed by the President and must be a French citizen. There are three classes of prefects, according to the size and importance of their departément, with salaries ranging from 18,000 to 35,000 francs. The prefect is the chief representative of the government, whose decisions, laws and regulations he executes. Though directly responsible to the Minister of the Interior, he supervises all governmental institutions and services in his départément. He exercises considerable control over the conseil général, mayors and municipal councils of his departément and possesses great power in respect to the administration of the police and of public institutions, both charitable and otherwise. Formerly he enjoyed almost unlimited powers in regard to the management of his departément's local interests. These, however, have now been transferred to a great extent to the conseil général and to a departémental committee, elected by the former for the interval between its sessions. Under the prefects serve sous-préfets of which there are 362, each at the head of an arrondissement, a subdivision of the departément. Various attempts to discontinue these officials, made on the part of the Chamber of Deputies by refusing to vote the amounts required for their salaries, have failed. Consult Haas, C. P. M., 'Administration de la France' (Vol. II, Paris 1861); Larroque, P., 'De l'Organization du Gouvernment Republicain' (Paris 1870); Monnet, Emile, 'Histoire de l'Administration en France' (Paris 1885); Dethan, Georges, 'De l'Organisation des Conseils Généraux' (Paris 1889); Lowell, A. PREFORMATION, a theoretical view of embryological development widely held in the 17th century, and especially advocated by Haller. It asserted that the germ held in infinitesimal proportions all the parts and organs of the being, which were simply unfolded by growth. Hence this theory came to be known in England as the "evolution" theory and in French literature as the *emboîtement* theory. One class of thinkers regarded the egg as containing the whole of the embryonic material; another class thought it all contained in the spermatozoon. This whole baseless fabric of philosophy was overthrown by the microscopical researches of Wolf and the other founders of the science of embryology (q.v.).

PREGNANCY. See ABORTION; MENSTRUATION; OBSTETRICS.

PREHISTORIC MAN. See MAN, PREHISTORIC RACES OF.

PREHNITE, or EDELITE, a mineral, allied to zeolites and usually found with them, white or pale-green with a vitreous lustre, crystallizing in the orthorhombic system. It is a hydrous silicate of aluminum and calcium, having the formula $H_2Ca_2Al_2Si_3O_{12}$. It is most frequently found in rocks of the basaltic type

and is obtained from a wide area, being found in the copper region of Lake Superior, at Paterson and Bergen Hill, N. J., in Scotland, France, China and South Africa. It was first found by Colonel Prehn in the 18th century at the Cape of Good Hope. It is cut into gems and slabs, resembling chrysoprase in appearance. Its hardness is 6–7, its specific gravity 2.8–3.

PRELATE, a term used generally of bishops and archbishops of the Anglican communion, but bearing a more precise and specific meaning in the Roman Catholic Church, where it is applied to secular or regular clergy, who have a jurisdiction inherent in their office, and not merely delegated by a superior. The title is especially used of the prelates of the pope's court and household; prelates of the Curia, who hold higher rank than other prelates, have the title "Monsignore" and may wear apparel of violet color.

PRELL, prĕl, **Hermann,** German painter and sculptor: b. Leipzig, 29 April 1854. He studied at Dresden and Berlin under Grosse and Gussow respectively, supplementing this by a course of study in fresco painting in Italy. He soon became one of the foremost German fresco painters of historical subjects. Returning home he was commissioned to paint the frescoes in the banquet hall of the House of Architects, in Berlin, and for this hall he executed in 1881–82 a series of 11 paintings on the 'Main Epochs of the History of Architecture.' His other mural paintings are to be found in the City Hall of Worms ('Justice,' 'Valor' and 'Henry IV Granting Privileges to Worms in 1074,' painted in 1884); the City Hall of Hildesheim (1887–81); City Hall of Dantzic (1892); the Breslau Museum (1893–94); Palazzo Caffarelli in Rome (1895–98); the Albertinum, Dresden (1901–05); the City Hall of Dresden (1908–12); sculptures by him are in the new Dresden City Hall and in the Albertinum, Dresden. He has also done some mosaics in the Cotton Exchange and in the North German Lloyd Building in Bremen (1911), and in the Staendehaus in Dresden (1907). The Dresden Gallery and the Breslau Museum contain specimens of his easel pictures. He has taught in the academies of Berlin and Dresden. In 1893 he received the Great Gold Medal at the Berlin Exhibition. He has published 'Die Fresken im Rathause zu Hildesheim' (Hildesheim 1894). Consult Ianitsch, 'Die Fresken im Treppenhause des Schlesischen Museums der Bildenden Kuenste' (Berlin 1895); Meissner, F. H., 'Hermann Prell' (Wien 1897); Rosenberg, A., 'Hermann Prell' (in 'Kuenstler Monographien,' Vol. LIII, Leipzig 1901).

PRELLER, prĕl'lĕr, **Friedrich,** German painter, son of the following: b. Weimar, 1 Sept. 1838; d. Dresden, 21 Oct. 1901. After studying under his father and later in Rome, he traveled much in Switzerland, France and Italy and painted landscapes. His wall-paintings in the new theatre at Dresden (especially his 'Prometheus' and 'Iphigenia') and in the Albertinum at Dresden ('Olympia'; 'Pergamus'; 'The Acropolis at Athens,' and 'Ægina') have been much admired. He also produced a series of landscapes, scenes from Italy and Greece, in oil. His 'View of the

Monastery of Santa Scholastica' and some other landscapes are in the Dresden Gallery, his 'Sappho' in the museum at Leipzig. In 1867 he became professor in the Art Academy at Dresden.

PRELLER, Friedrich Johann Christian Ernst, German painter: b. Eisenach, 25 April 1804: d. Weimar, 23 April 1878. In the same year in which he was born, his parents moved to Weimar where he became acquainted with Goethe in his youth, and received encouragement and finally a pension from the Grand Duke Karl August of Weimar which enabled him to travel and study from 1826–31 first in Holland and later in Italy where he imbibed more from the classic than the Renaissance art and formulated a pictorial philosophy in which he saw man as the culmination of all earthy beauties. His important works, especially the series suggested by Homer's Odyssey, now in the Museum of Weimar, are bold and vigorous landscapes forming a setting for nude figures of heroic mold. To paint such subjects was the necessity of his artistic creed; yet he frequently turned to other fields, partly for financial reasons, partly because of his deep interest in and love of all phases of nature. In 1840 he made a sketching trip to Norway, and frankly adopting the naturalism of Ruysdael, of whom he had been an ardent admirer since his early youth and one of whose pictures he copied when he first began seriously the study of painting, he painted landscapes for sale. Even these were vigorous and meritorious in execution, if not fully representing his genius. He made unremitting sketches from nature and left behind him a long series of remarkable drawings. In later years he made other journeys to Italy, though most of his time was spent in Weimar where he taught at the Art Academy. Besides the Odyssey landscapes he also painted frescoes in the Wieland room of the Weimar palace showing scenes from Oberon. Paintings from his brush are to be seen in the National Gallery at Berlin and in museums at Weimar, Dresden, Leipzig, Stuttgart and Munich. He was also interested in etching and etched many of his own paintings. Consult Gensel, J., 'Friedrich Preller d.Ä.' (in 'Künstler Monographien,' Vol. LXIX, Leipzig 1904); Roquette, 'Friedrich Preller' (Frankfurt a.M. 1883).

PRELUDE, in music, a short introductory strain preceding the principal movement, performed on the same key as it, and intended to prepare the ear for the piece that is to follow. It may consist of a series of unconnected chords when the intention is simply to attract the attention of an audience, or to fill a singer's ear with the key in which the piece is written, in which case it is generally improvised. It is, however, usually composed of part of the leading theme, more or less varied toward the close, and is not left to the invention of individual performance. Among classic models are the preludes to Bach's fugues and the preludes written by Chopin and Mendelssohn. See Music.

PRELUDE, The. 'The Prelude or Growth or a Poet's Mind,' a blank verse poem in 14 books, was written by Wordsworth between the years 1799 and 1805, and was published posthumously in 1850. The work was intended to be introductory to a long philosophical poem, 'The Recluse,' of which the second part alone, viz., "The Excursion," was completed. In 'The Prelude' Wordsworth, addressing his friend, Samuel Taylor Coleridge, passes in review his own development as a poet, taking account of the circumstances which influenced him and analyzing the spiritual changes through which he passed. From the point of view of content the work may be classed with such autobiographies as Goethe's 'Dichtung und Wahrheit' and Coleridge's own 'Biographia Literaria.' Throughout the work Wordsworth is chiefly occupied with defining the influence of nature as a determining factor in his spiritual life. As in 'Tintern Abbey,' he distinguishes several stages in his relation to nature. In his early youth he is a thoughtless boy, using nature as the companion of his sports. There is no conscious nature love, but at intervals amid his sports there come to him moments of vision, "gleams like the flashing of a shield," and nature seems to him a living thing. A second stage is reached when nature, hitherto secondary in his thoughts, is sought for her own sake, with conscious love; his imagination now leads him to see in nature the reflection of his own soul and to feel "the sentiment of being spread o'er all that moves and all that seemeth still." His residence in Cambridge comes as a partial interruption of his communion with the divinity in nature, but on his return to the scenes of his childhood during a summer vacation he experiences a renewal of his old affection and reverence, and now, too, he begins to interest himself in the human life about him. The incorporation into his thought of the sense of humanity marks a third step in his spiritual evolution. He becomes conscious also at this time of his mission as a poet. During the years which follow, Wordsworth passes through the great crisis of his life. He is caught up by the revolutionary enthusiasm while in France, and for the time being entirely loses sight of the earlier vision in his devotion to the new movement for the regeneration of society. But as the revolution progresses, Wordsworth, like other idealists of his time, begins to lose faith in it. He turns to abstract reason for comfort, becomes hopelessly entangled in the mazes of fruitless speculation, and ends in intellectual despair. From this condition he is rescued by renewed contact with the soothing influences of nature and by his sister, who leads him gently back to the life of feeling and restores in him the spirit of joy and love. The emotions are now more precious to him than the intellect, and he regains possession of the creative vision of his youth. But henceforth humanity occupies a position in his heart higher even than that of nature.

'The Prelude' is very important for the understanding not only of Wordsworth himself but of the spiritual history of his generation. It is, moreover, a poem of great beauty, abounding in descriptive and philosophical passages written in Wordsworth's most exalted manner, and containing a relatively small proportion of the pedestrian element which is apt to mar his longer works. Consult 'Poetical Works,' edited by W. Knight, 1882–89; 'The Prelude,' edited by G. C. Moore Smith [Temple Classics]; other editions are common. The best commentary on 'The Prelude' is E. Legouis' 'The Early Life of Wordsworth,' translated by J. W. Matthews. A selected bibliography of Wordsworth criticism may be found in Page's 'British Poets of the Nineteenth Century,' also in 'Cambridge History of English Literature' (Vol. XI).

JAMES H. HANFORD,
University of North Carolina.

PREMIUM PLAN, a system of wage bonus awarded a worker for completing a certain amount of work in less than the standard time allowed for it. The plan has been adopted in very many industrial establishments where there is a wage scale fixed by collective bargaining such as are becoming general under modern trades-union conditions. Henry R. Towne was the first to promote the plan in the United States in 1889 calling it "gain sharing." Two years later it was adapted to specific industries by F. A. Halsey. Since that time many modifications have been introduced, nearly all of which had regard to the proper adjustment of the standard time to be allowed for a specified task. James Rowan, of Glasgow, introduced a system of making the time saved on a task a percentage of the standard and then applying the percentage to the actual time. Under the Rowan plan the total earnings of a worker cannot be more than twice the regular fixed day-rate. See WAGES.

PREMONSTRATENSIANS, or **NORBERTINES,** a religious order, founded by Norbert, canon of Xanten in Cleves, who on account of his zeal as archbishop of Magdeburg in 1127 was canonized. In the forest of Saint Gobain, in a meadow pointed out to him, as he said, by Heaven (*prémontré, pratum monstratum*; thence the name of the order), he collected his first disciples (1120). The original establishment was built by the bishop of Laon. It contained 40 members who wore the white habit and cloak of canons regular and lived, according to the rule of Saint Augustine, a strict conventual life. In 1125 they were formally approved by Pope Honorius II. The order is composed of three classes: (1) priests and clerics under an abbot or provost; (2) nuns who embrace the rule of Saint Norbert; (3) lay members. Their order increased rapidly; several nunneries were established with the same rigid rules. The abbot of the original monastery Prémontré, near Coucy, was general, and with three other abbots formed the great council of the fathers of the order. The order was introduced into England in 1143 at Newhouse in Lincolnshire and its members were there regularly known as the White Canons. Some time before, in 1125, King David of Scotland had brought a colony to his kingdom. Before the Reformation they are said to have had 1,300 monasteries, among which were 500 nunneries, mostly in Germany, the Netherlands, France, England and the north of Europe; but the Reformation diminished this number by more than one-half in the 16th century. In the 18th century the order lost many of its houses as a result of the French Revolution and at the end of the century there were only 27 houses in existence. It now consists of eight houses in Holland and Belgium, seven in Austria, two in Hungary, three in England, one in the United States and one in Canada. There are also eleven nunneries in Holland, Belgium, Spain, Austrian and Russian Poland, Switzerland and Bohemia. Some of these monasteries have founded priories in Brazil to which colleges are attached, others are doing missionary work in the Belgian Congo and in Madagascar. The entire order is divided into five circaries. At its head is a superior-general, the most recent one being Norbert Schachinger, abbot of Schläge, one of the Austrian monasteries of the order." In 1913 the membership of the order was made up of one bishop, 17 vicars, one apostolic praefect, 789 priests, 129 scholastics, 51 novices, 91 lay brothers and three lay novices. In modern times the order has become very active in teaching boys in high schools and academies. It possesses a college for its own members at Budapest and one at Rome, the head of the latter being the procurator of the order. The provincial house of the Premonstratensians in the United States was founded at West De Pere, Wis., by fathers from the abbey of Heeswijk, Holland. The very Rev. B. H. Pennings, O. Praem., is the present prior. The fathers conduct missions in the archdiocese of Chicago and the dioceses of Green Bay, Grand Rapids, Marquette and Helena, as well as a flourishing classical and commercial college. The membership in 1918 consisted of 28 clerics, six scholastics, four novices and four lay brothers. Consult 'Statuta Sacri et Canonici Præmonstratensis Ordinis, Renovata Jussu Regis Christianissimi, et Auctoritate Capituli Nationalis, Anni 1770' (Paris 1773); Currier, 'History of Religious Orders' (New York 1894); Gasquet, Rev. PRENCE, prĕns, or **PRINCE, Thomas,** American colonist: b. Lechdale, Gloucestershire, about 1600; d. Plymouth, Mass., 29 March 1673. He was one of the Leyden band of Pilgrims which arrived at Plymouth on the ship *Fortune* 9 Nov. 1621, and his wealth soon gained for him considerable influence. In 1634 and in 1638 he was elected governor and was one of the assistants in 1635-37 and in 1639-56. He assisted in the settlement of Nansett or Eastham and from 1657 until his death was governor of Plymouth, the law requiring the residence of the governor in Plymouth being waived in his favor. He was also one of the commissioners from Plymouth at various times after the confederacy of the four colonies of Plymouth, Massachusetts, Connecticut and New Haven had been formed in 1643. He was zealous in the religious affairs of the colony, an active promoter of educational matters, and was the real founder of the public schools in New England. Consult Baylies, F., 'An Historical Memoir of the Colony of New Plymouth' (Boston 1866); Morton, N., 'New England's Memorial' (Cambridge, Mass., 1669); 'Mourt's

Relation or Journal of the Plantation at Plymouth' (London 1622).

PRENDERGAST, Edmond Francis, American Roman Catholic prelate: b. Clonmel, Ireland, 3 May 1843; d. Philadelphia, Feb. 1918. He came to the United States in 1859; was educated at the ecclesiastical seminary of Saint Charles Borromeo, Philadelphia, and was ordained to the priesthood in 1865. He was successively at Saint Paul's, Philadelphia, Susquehanna Depot and rector of Saint Mark's, Bristol, Pa., for four years. Until 1874 he was rector at Allentown, Pa., and from 1874 to 1897 was rector of Saint Malachy's, Philadelphia. In February 1897 he was consecrated auxiliary bishop of Philadelphia and in May 1911 became archbishop in succession to Dr. Ryan.

PRENDERGAST, Maurice Brazil, American artist: b. Boston, Mass., October 1861. He studied at Julien and Colorossi academies and at the École des Beaux Arts, Paris, under Joseph Blanc, Courtois, Jean Paul Laurens and Jerome. He returned to the United States and settled in Boston, removing to New York in 1914. He works both in oil and in water color, and his favorite subject is a grouping of figures against a landscape background. He is noted for his vivid coloring, his joyous vision of nature and his unconventional but truthful presentation. His strength in design and individuality in execution are remarkable. Among his works may be mentioned 'Crepuscule,' 'Chrysanthemum Market,' 'On the Cliffs,' 'The Merry Maidens,' 'Seashore,' etc.

PRENTICE, prĕn'tĭs, **George Dennison,** American journalist: b. Preston, Conn., 18 Dec. 1802; d. Louisville, Ky., 22 Jan. 1870. He was graduated from Brown University in 1823; studied law, but did not practise, and was editor of the *New England Weekly Review* at Hartford, a literary journal, 1828–30. He then removed to Louisville, Ky., where in November 1830 he founded the Louisville *Journal* and became its first editor, in which position he won widespread reputation for political ability, wit and satire. For many years the *Journal* was a leading advocate in the West of the policy of the Whig party, and at the outbreak of the Civil War maintained with zeal the cause of the Union. A collection of his poems appeared in 1876 and a selection from his newspaper paragraphs under the title of 'Prenticeana' in 1860.

PRENTISS, Benjamin Mayberry, American military officer: b. Belleville, Va. (now W. Va.), 23 Nov. 1819; d. Bethany, Mo., 8 Feb. 8 Feb. 1901. He removed with his parents to Missouri in 1835, and in 1841 settled in Quincy, Ill., where he entered the commission business. He served in the Mexican War with rank of captain, and received honorable mention for services at Buena Vista. At the outbreak of the Civil War he reorganized his old company, was appointed colonel of the Seventh Illinois regiment and in May 1861 was made brigadier-general of volunteers. He routed a band of Confederates at Mount Zion, southern Missouri, 28 Dec. 1861, joined General Grant a few days before the battle of Shiloh and was taken prisoner in that battle on 6 April 1862, together with most of his command, while stubbornly holding the position to which he had been assigned. He was released in October 1862, promoted major-general of volunteers in November 1862, served as a member of the court-martial which tried Gen. FitzJohn Porter, and in July 1863 defeated the Confederate forces under Holmes and Price at Helena, Ark. He resigned his commission in October 1863 and settled in Bethany, Mo., where he practised law.

PRENTISS, Elizabeth Payson, American author: b. Portland, Maine, 26 Oct. 1818; d. Dorset, Vt., 13 Aug. 1878. She was married to George Lewis Prentiss (q.v.) in 1845 and after the death of two children turned her attention to literary work. Her most popular work, 'Stepping Heavenward' (1869), reached a sale of over 150,000 in this country besides being translated into French, German, Norwegian and Italian, where it met with great success. Many of her other books, too, achieved great success and were translated into foreign languages. Among her other works are 'The Susy Books' (1853–56); 'The Flower of the Family' (1856); 'Little Threads' (1868); 'Fred, Maria and Me' (1868); 'Nidworth and His Three Magic Wands' (1869); 'The Percys' (1870); 'Six Little Princesses and What They Turned Into' (1871); 'Aunt Jane's Hero' (1871); 'Golden Hours' (1873); 'Urbane and His Friends' (1874); 'The Home at Greylock' (1876); 'Pemaquid' (1877); 'Gentleman Jim' (1878); 'Avis Benson' (1879). Consult Prentiss, G. L., 'Life and Letters of Elizabeth Prentiss' (1882).

PRENTISS, George Lewis, American Presbyterian clergyman: b. Gorham, Maine, 12 May 1816; d. New York, 18 March 1903. He was graduated from Bowdoin College, Brunswick, Maine, in 1835, which gave him the degree of D.D. in 1854, studied theology in the universities of Halle and Berlin in 1839–41, and was ordained to the ministry in 1845. He was pastor of the South Trinitarian Church, Boston, 1845–50, of the Mercer Street Presbyterian Church, New York, 1851–58, when ill health compelled his resignation. In 1862 he established in New York the Church of the Covenant, and was its pastor until 1873, when he accepted the chair of pastoral theology, church polity and mission work at Union Theological Seminary. He published 'A Memoir of S. S. Prentiss' (2 vols., New York 1855); 'A Discourse in Memory of Thomas Harvey Skinner' (New York 1871); 'Life and Letters of Elizabeth Prentiss' (New York 1882); 'The Union Theological Seminary in New York, Historical and Biographical Sketches of Its First Fifty Years' (New York 1889); 'The Agreement between Union Seminary and the General Assembly' (New York 1891); 'The Union Theological Seminary in New York; its Design and Another Decade of its History' (Asbury Park 1899), etc. He also edited 'Faith and Philosophy: Discourses and Essays by H. B. Smith' (New York 1877).

PRENTISS, Sergeant Smith, American orator, brother of G. L. Prentiss (q.v.): b. Portland, Maine, 30 Sept. 1808; d. Natchez, Miss., 1 July 1850. He was graduated from Bowdoin College, Brunswick, Maine, in 1826, removed to Natchez, studied law, taught school, and in 1829 was admitted to the bar, after which he established a law practice, first in Natchez and later in Vicksburg, Miss., and rapidly gained high rank in his profession. In 1835 he was elected to the Mississippi legislature, where he won a reputation as an orator, and in 1837 he was elected to Congress, but upon arriving at Washington to take his seat found it occupied by the Democratic candidate, Colonel Claiborne. In a speech of great brilliancy and power, which continued for three days, he argued his case before the House, attracting the attention of the country to the «Mississippi Election Case.» The controlling vote was cast by the speaker, James K. Polk, and Prentiss was defeated, but at the polls in the election following was triumphantly elected. His speech against the sub-treasury bill sustained his reputation as an orator, but at the close of his term he declined re-election. In the campaign of 1840 he actively supported General Harrison, and in 1845 he strenuously opposed repudiation. In the same year, after suffering serious financial reverses, he removed to New Orleans, La., where he spent the balance of his life in the practice of law. Consult Prentiss, G. L., 'Memoir of S. S. Prentiss' (New York 1855).

PRENZLAU, prĕnts'low, or **PRENZLOW**, Germany, town in the province of Brandenburg, in Prussia, on the Ücker and Lake Ücker, 57 miles north by east of Berlin. It is divided by the river into an old and a new town, is well built and has among its buildings a handsome Gothic church (erected 1325–40), monuments of Emperor William I, Moltke, Bismarck and Grabow, some old city gates and a gymansium. Of interest is also the Ukermär Kósche Museum. It has a number of manufacturing establishments, machine shops, woolen mills, tanneries, sugar works, etc. In 1806 a Prussian corps under Prince Hohenlohe surrendered here after the battle of Jena to Murat. Pop. 21,431.

PREPOSITION. See GRAMMAR.

PREROGATIVE, in British law a term used to denote an exclusive privilege of the Crown, the expression the prerogative being employed for the whole or any part of such exclusive privilege. The prerogative may be confined or limited by the supreme legislative authority and has in fact been much restricted, notably by Magna Charta (1215), the Habeas Corpus Act (1679), and the Bill of Rights (1688). In a wider sense the term is used to denote a right attached to a rank or office to exercise certain powers or privileges to the exclusion of others. Consult Allan, John, 'Inquiry into the Rise and Growth of the Royal Prerogative in England' (2d ed., London 1849); Blackstone, Sir William, 'Commentaries' (4th ed., Chicago 1899); Chitty, Jos., the Y., 'A Treatise on the Law of the Prerogative of the Crown, etc.' (London 1820); Holdsworth, W., 'A History of English Law' (3 vols., London 1903–09); Stubbs, W., 'The Constitutional History of England' (3 vols., Oxford 1875–78).

PRESBYOPIA. See VISION, DEFECTS OF.

PRESBYTER. See BISHOP; PRESBYTERIANISM; etc.

PRESBYTERIAN CHURCH IN THE UNITED STATES OF AMERICA. The history of Presbyterianism in the United States is closely interwoven with that of the country at large. The early colonists were, for the most part, those who had crossed the ocean to find a home in the New World, in order to enjoy religious freedom. They came for conscience's sake, rather than for the advancement of their fortunes. They claimed the right to worship God according to the dictates of their own consciences and to govern themselves in the administration of church order and discipline. They were bitterly opposed to the claims of prelacy. Alike among the Congregationalists of New England, the Dutch of New York, the Scotch-Irish of Pennsylvania and the Huguenots of the Carolinas, the Calvinistic or Reformed system of doctrine was the prevailing belief. The Shorter Catechism of the Westminster Assembly, embodied in the New England Primer, had a more profound influence in the training of successive generations than any other book of that period, except the Bible. It was the working creed of the men who laid the foundations of free institutions in America. The organization of the church among the colonists was determined largely by their previous associations in the Old World. The New England colonists were mostly of English-Puritan extraction and favored the Congregational polity. There were, however, two parties among them; one zealously favoring Independency, the other leaning toward the Presbyterian polity. The former belonged to the school called Brownists, the latter to Barrowism. A strictly Presbyterian colony was established in Salem, Massachusetts Bay, under Roger Conant in 1625. Among those who held to Presbyterian views was Rev. Richard Denton, who came from England in 1630, and settled in Watertown, Mass. Driven out by opposition to his views, he removed in 1644, with some of his congregation, to Hempstead, Long Island, where a church was organized in accordance with the Presbyterian form. The earliest organization of Presbyterianism in the New World was made in the Dutch settlement of New Amsterdam, in New York, in 1628. It was a Reformed Dutch church and the first Protestant church in America. Other churches of this denomination were organized at an early date among the Dutch settlements. (See REFORMED DUTCH). While the Presbyterian element was found in all of the colonies from New England to Georgia, circumstances prevented its separate organization. In New England the prevailing form of government was Independency or Congregational; in New York Presbyterianism was of the Dutch type and only Episcopacy was allowed among the English. In Virginia, Episcopacy was established by law and was intolerant toward all forms of dissent. Conditions were more favorable to Presbyterianism in the provinces of Pennsylvania, New Jersey, Delaware and Maryland. To these colonies came a large number of emigrants from the North of Ireland and from Scotland. The religious intolerance prevailing under the reign of Charles II led them to seek refuge from it in the New World. It was among these emigrants that Presbyterianism took its organized form. In answer to a request from one of the scattered groups of Presbyterians, the Presbytery of Laggan, Ireland, sent as its missionary, Rev. Francis Makamie, in 1683. He journeyed in his missionary work as far south as the Georgias, and as far north as New York. He finally settled in Rehoboth, in eastern Maryland, where he organized the churches of Rehoboth and Snow Hill. In 1704 he returned to London, seeking aid for his work, returning in 1705, and bringing with him two additional ministers.

There was also, before the opening of the 18th century, a Presbyterian church in Philadelphia. Rev. Jedediah Andrews was its pastor, in 1701. In 1705 seven ministers, Makamie, Davis, Wilson, Andrews, Taylor, MacMish and Hampton, met by appointment in the city of Philadelphia and organized a Presbytery. It was the first Presbytery in America and the beginning of the American Presbyterian Church in its organized form. The original minutes of this Presbytery are in the archives of the Presbyterian Historical Society in Philadelphia. This Presbytery was subsequently divided into three, which were included in a Synod. The Synod held its first meeting 17 Sept. 1717, in Philadelphia. In 1741 a division occurred in the Synod resulting, not from doctrinal differences, but from those ecclesiastical passions and unregulated zeal which have so often disturbed the church. One party under the leadership of the Tennents, father and son, and greatly helped by the minister of the renowned evangelist, Whitfield, was earnestly solicitous for a revival in the church, charging it with formalism and world conformity. The other party, the conservative, resisted the charge, and sought to restrain by ecclesiastical action what they considered the immoderate zeal of the revivalists. The parties were known respectively as the New Side and the Old Side. The result of these controversies was the establishment of two independent synods, the Synod of New York, composed mainly of those favoring the New Side, and the Synod of Philadelphia, favoring the Old Side. Both synods unanimously affirmed their adherence to the Westminster Standards. This division lasted 17 years and was healed by the reunion of the two synods in 1758, under the name of the Synod of New York and Philadelphia. With the reunion came renewed effort and enlarged prosperity. Churches were organized in the Carolinas, Georgia, Kentucky, Tennessee, Virginia and Western Pennsylvania. This enlargement of the Presbyterian Church had an important bearing on the subsequent efforts of the colonies to secure their independence. The Presbyterians everywhere were foremost in resisting civil and religious oppression and when the period of the Revolution came, were unanimously in favor of independence and the establishment of a government on republican principles. Thirteen months before the signing of the Declaration of Independence, in Philadelphia, the Presbyterians of Mecklenburg County, North Carolina, had drawn up and signed a Declaration of Independence from England and also framed a system of local government. The Scotch-Irish Presbyterians in Western Pennsylvania declared for independence in May 1776. The Presbyterian element was everywhere a determining factor in the War of Independence.

In England, the rebellion was attributed especially to the Presbyterians. Walpole said in the English Parliament, «Cousin America has run off with a Presbyterian parson.» At the close of the Revolutionary War, the Synod of New York and Philadelphia met, May 1788, and revised the Confession of Faith and the Form of Government in some minor matters, which were required by the change of allegiance in civil affairs. At the same meeting it was resolved to create a General Assembly, in which all the presbyteries should be represented by their commissioners. This General Assembly held its first meeting in the Second Presbyterian Church of Philadelphia, Thursday, 22 May 1789. At this time the church had 16 presbyteries, four synods, 177 ministers and 431 churches. Among the first acts of the General Assembly was one directing that efforts should be made to send missionaries to the frontier. Before the close of the century, numerous churches had been established in the West and South. To prevent collision with the missionaries who went out from the Congregationalists in New England, the General Assembly, in 1802, entered into the Plan of Union with the associated churches of Connecticut, providing for the orderly organization of churches in mission fields. This Plan of Union continued in force until 1836, when it was abrogated by the General Assembly. It provided, in brief, that Congregational churches might settle Presbyterian ministers and the reverse; and that if a congregation was composed partly of Congregationalists and partly of Presbyterians, this fact should be no obstacle to their uniting in one church and settling a minister; and that such a church, though not presbyterially organized, should have a representative in Presbytery. Its operation led to most favorable results in the extension of the church. The opening of the 19th century was a time of widespread religious revivals. «The Great Awakening» began in Kentucky and it was attended there with some manifestations which met the disapproval of the more conservative element in the Church. In view of the great demand for ministers, some were authorized to preach who had not received a regular classical and theological education. There were also a few who held that the Confession of Faith taught fatalism. This led to the withdrawal of the Cumberland Presbytery, from which has sprung a large and influential body of Presbyterians known as the Cumberland Presbyterian Church. This separation took place 1810. (See PRESBYTERIANISM). The first quarter of the century was one of rapid growth for the Church. The tide of emigration poured westward, and new settlements and towns were founded. In all these, the missionaries of the Church found a hopeful and fruitful field for their labors. During this period, the Board of Home Missions was organized (1816). Theological Seminaries for the education of ministers were also established; Princeton (1812); Auburn (1820); Western Theological Seminary, Allegheny, Pa. (1826); Union Seminary, Virginia (1828); Columbia, South Carolina (1828); Lane (1834); Hanover, subsequently removed to New Albany, thence to Chicago and now known as McCormick Theological Seminary (1829). In 1825 appeared the beginnings of a controversy which ultimately resulted in the disruption of the Church. Various causes led to the formation of two parties, known subsequently as the Old School and the New School. Chief among these causes was the spread of New Haven Theology, or Hopkinsianism, which was supposed to be contrary to the doctrine of the Confession of Faith. It was also charged that through the Plan of Union, Presbyterian order had been subverted and that innovations in worship were permitted in certain parts of the Church. In 1836 Dr. Albert Barnes, who sympathized with the new theology, was tried for heresy before the General Assembly and acquitted. The previous year, Dr. Lyman Beecher, professor in Lane Theological Seminary, had been tried for heresy by the Presbytery of Cincinnati and ultimately acquitted. All these things produced intense excitement in the Church and widened the breach between the conservatives and the liberals. The Assembly of 1837, which met in Philadelphia, in response to a memorial signed by a large number of ministers and elders representing the Old School party, dissolved the Plan of Union with the Congregational Church, and exscinded the synods of Western Reserve, Utica, Geneva and Genesee.

At the meeting of the Assembly in Philadelphia, 1838, the commissioners from the exscinded synods presented themselves and asked to be enrolled; this being denied them, they with their friends proceeded to organize the Assembly and withdraw to hold its sessions in the First Presbyterian Church of Philadelphia. With the Old School party remained 140 commissioners, while 136 gave their adhesion to the newly organized Assembly. Thus began the unhappy division which lasted 32 years. Both Assemblies had the same name and claimed to be the General Assembly of the Presbyterian Church in the United States of America; both held to the same confession and form of government. Both Assemblies engaged zealously in the work of home and foreign missions and in the establishment of institutions of learning. Both, also, were troubled by questions concerning slavery. As early as 1787, the Presbyterian Church had declared itself in favor of the education of the slaves and for the adoption of such «prudent methods as would procure eventually the final abolition of slavery.» In 1815 the General Assembly adopted a strong antislavery document, in which it expressed regret for the existence of slavery in the United States, urged the duty of educating slaves and expressed the hope for their speedy emancipation. It further declared the buying and selling of slaves to be «inconsistent with the spirit of the Gospel.» These views were more clearly and positively avowed in the New School General Assembly than in the Old School General Assembly. In 1858, in consequence of some decided action taken with reference to slavery and emancipation, six Southern synods withdrew from the New School Assembly and constituted themselves the «United Synod of the Presbyterian Church.» In 1864 this Synod united with the General Assembly of the Presbyterian Church in the Confederate States. The passage of the «Spring Resolutions» by the General Assembly (Old School) in 1861 led to the withdrawal from that Assembly of a number of synods, all of which were within the bounds of the Southern Confederacy. This resolution was directed against the rebellion in the South and called upon all of the members of the Church to support the government in defense of the integrity of the Union. It was bitterly opposed by the commissioners from the synods in the South and by a small number from the Northern States, on the ground that in passing it the Assembly transcended its prerogatives. The objectors urged that the Assembly had no right to define civil duties. The vote on the resolution stood 156 in the affirmative and 66 in the negative. The action resulted in the withdrawal of the synods in the seceding States and the subsequent formation of the Presbyterian Church in the Confederate States of America. In 1866 the General Assembly Old School and the General Assembly New School met at the same time in Saint Louis, when steps were taken with reference to the reunion of the two bodies, by the appointment of committees to consider a plan of union. These negotiations terminated favorably and the basis of reunion, which was the Confession of Faith, after being approved by the presbyteries, was ratified by the Assembly in 1869. In May 1870, the first General Assembly of the reunited Church met in Philadelphia. In 1837, the year preceding the disruption, the ministers numbered 2,140, the churches 2,865 and the membership 220,537. At the time of the reunion, there were 4,238 ministers, 4,526 churches and 446,561 members. Since the reunion, the progress of the Church has been marked and steadfast. Two notable trials threatened for a time to disturb its peace. The first was that of Rev. David Swing, 1874, for alleged heresy with reference to the divinity of Christ. This case was settled by the withdrawal of Dr. Swing from the Church. The second was the trial of Professor Briggs of Union Theological Seminary, for his advocacy of those views of the «higher criticism» which it was claimed affected the fundamental doctrines of the Christian faith. This trial resulted in the condemnation of his views, his suspension from the ministry and his subsequent withdrawal from the Church.

Since these ecclesiastical trials the Church remains conservative, but with an increasing tendency toward liberal interpretation of standards. Though the General Assembly has repeatedly stressed the inerrancy of Scripture and has made belief in such inerrancy requisite of teachers in seminaries and candidates for the ministry, in 1902 the Assembly adopted a brief statement of the Reformed faith, not as a legal standard but as an interpretation of the Confession. It repudiated the doctrine of infant damnation, insisted on the consistency of predestination, of God's universal love, and incorporated new chapters on the Holy Spirit, the love of God and missions.

During a number of past years repeated advances have been made looking toward a union with the Southern Presbyterian Church, but so far without success. The Southern Church, while expressing the most cordial relations toward the Church of the North, has felt that the interests of Presbyterianism may be better conserved by their holding for the present to their ecclesiastical organization.

The last few decades have been remarkable in the extension of the missionary work of the Church. Up to the time of the separation between the Old and New School, the foreign mission work was carried on by the American Board of Commissioners of Foreign Missions. After the division, the Old School was established as the Board of Foreign Missions — the New School continuing as the American Board.

After the reunion in 1869 the separate Board was continued, embracing all the foreign mission work of the Church. The extent of the foreign mission activities in 1918 is indicated by the fact that the total contributions amounted to $2,131,387. The foreign missionary work is carried on in all parts of the world.

The home missionary work was carried on in early times by a committee of the General Assembly, but in 1816 the present Board of Home Missions was organized. The total home mission contributions for 1918 was $2,268,925. Its home mission work extends from Alaska to Porto Rico. The woman's home mission work was conducted as a branch of the Board of Home Missions until 1915, when it became incorporated as a separate Board. The Minutes of the General Assembly for 1918 show a roll of 9,902 ordained ministers and 9,928 churches, with a Sabbath-school membership of 1,386,928, the number of communicants being 1,631,748. Its contributions for all purposes in 1918 were $33,148,407. Other Boards caring for its other branches of Christian service are Education, Publication and Sabbath-school Work, Church Erection, Ministerial Relief, Freedmen and Temperance.

The development of the modern American life has given it within the last 15 years new fields of service in immigration, social work, city evangelization and country church work.

It has also in connection with it numerous schools, colleges, universities and theological seminaries. The national churches of Mexico and Brazil, both Presbyterian, have been established largely through its instrumentality. It has synods in India and China, and its mission operations are carried on in all parts of the world.

The Cumberland Presbyterian Church.— The origin of this branch of the Presbyterian Church is to be found in the great religious revival which swept over Kentucky and Tennessee at the beginning of the 19th century. The demand at that time for an additional number of ministers in that region led the Presbytery of Cumberland, in connection with the General Assembly, to license and ordain a number of young men of the Presbyterian Church, who had not received the required classical and theological training, for the gospel ministry. This proceeding was contrary to the rules and traditions of the Church, and was strenuously opposed by those who stood for the old ecclesiastical order. The Synod of Kentucky refused to sanction the acts of the Presbytery, and this decision was finally confirmed in part by the General Assembly. There were also among those engaged in this controversy some divergencies in doctrinal belief, especially with reference to what were claimed to be the fatalistic teachings of the Confession of Faith. The result was the withdrawal of those who were dissatisfied, and the formation of an independent presbytery, called the Presbytery of Cumberland. Those who organized it recognized as their standard of doctrine the Confession of Faith of the Presbyterian Church, but made provision for those who objected that fatalism was taught in it. The growth of this Presbytery was rapid. In three years it grew into a synod, composed of three presbyteries, and numbering 60 churches.

Its first meeting was held 5 Oct. 1813, when it proclaimed a summary of its doctrines. A year later it revised the Confession of Faith to meet its views regarding the articles to which exception had been taken. These were, specially, the third chapter with reference to the decrees of God, and the article with reference to the salvation of infants. The new Church, filled with the revival zeal of its origin, made rapid advances. In 1827 it established at Princeton, Ky., an institution of learning, with a view to securing educated men for the ministry. In 1829 the General Assembly of the Cumberland Church was organized, consisting of five synods. At that time the field occupied by the Church embraced eight States, in which there were 18 presbyteries.

In 1906 it was adjudged that the doctrinal differences which had separated the Cumberland Church from the Presbyterian Church in the United States of America had been largely composed. A union of the two Churches was affected. At the time of the reunion the Cumberland Church had a roll of 1,514 ordained ministers serving 2,869 churches, with a total membership of 185,212 and annual contributions aggregating $933,920. A small part of the Cumberland Church, however, refused to enter into the reunion and has continued the organization of the Cumberland Presbyterian Church. The principal reason given for refusing to enter the union was that the revision of the Westminster Confession had not brought the two Churches sufficiently into doctrinal accord to justify the cessation of the separate existence of the Cumberland Presbyterian Church. The question of property and institutions was carried into the courts; but in almost all cases it was decided in the court of final appeal in favor of the body which had gone into the union. The number of ministers in the continued organization is 996 and the total number of Church membership, resident and non-resident, is 63,735. They carry on their benevolent work through Boards of Missions, Education, Publication and Ministerial Relief. They have a theological seminary — the Cumberland Presbyterian Theological Seminary — located at McKenzie, Tenn., and the Cumberland College located at Leonard, Tex. During its history, various attempts have been made to restore its union with the Presbyterian Church in the United States of America, but they failed on account of doctrinal differences until 24 May 1906 when, in convention assembled, the former at Decatur, Ill., the latter at Des Moines, Iowa, the reunion was accomplished.

The Colored Cumberland Presbyterian Church.— Prior to the Civil War the number of colored people in connection with the Cumberland Church amounted to 20,000. In times of slavery, they worshipped in the same buildings with their masters, a particular portion of the church being assigned to them; but they were not allowed to participate in the government of the church. After the Civil War, it was deemed expedient that these members should be associated in a separate organization. Accordingly presbyteries and synods were formed, which met in a General Assembly 1 May 1874. This organization, whose statistics are rather indefinite, now reports a membership of 25,000. It has one educational institution, but the poverty of the people has prevented them from obtaining a thoroughly educated ministry.

The Presbyterian Church in the United States (Southern).—This Church had its origin at the beginning of the Civil War, and from causes connected with it. The action of the General Assembly, Old School, in 1861 was one of the leading causes. By the passage of the "Spring Resolutions" concerning the Civil War, it had determined for all under its jurisdiction that their allegiance was due to the national government. A minority held that this action, whether true or false, was beyond the jurisdiction of the General Assembly, and that in making it the Church was transcending her sphere, and usurping the duties of the state, which alone had the power to define civil duties. A protest was presented against this action, in which it was urged that the Assembly in thus deciding a political question, and in making that decision binding upon those under its care, practically made a condition of church membership which violated the constitution of the Church, and usurped the prerogative of its divine Head. Presbyteries in the seceding States generally coincided with this view, and concluded that a separation from the General Assembly was demanded for the defense of a great truth, and for the protection of the liberty with which Christ had made them free. The organization of the Confederate States furnished another reason. It was, in brief. that the changed condition of civil affairs made it expedient and necessary that the presbyteries within the bounds of the Confederacy should be organized as a separate and independent body. Accordingly 93 ministers and elders, representatives from presbyteries, met in Augusta, Ga., 4 Dec. 1861, and constituted a General Assembly, under the name of the General Assembly of the Confederate States of America. They adopted at the same time, as their standards of doctrine, the Westminster Confession of Faith, and the Form of Government as held in the old Church. At the close of the war, the name of the Church was changed to the Presbyterian Church in the United States. In 1864 the United Synod of the South, composed of the presbyteries and churches which had seceded from the General Assembly (New School), on account of its action concerning slavery, was admitted into the General Assembly of the Confederate States. It consisted of 120 ministers, 190 churches and 12,000 communicants. In 1869 that portion of the Synod of Kentucky which had separated from the General Assembly (Old School) in 1867 was received into connection with the Southern General Assembly, bringing with it 13,540 communicants. In 1874 the independent Synod of Missouri, which had separated itself from the Northern Assembly on account of its action concerning civil affairs, united with the Southern Assembly. The churches in connection with this Assembly are almost exclusively in what is known as the Southern States, and for that reason it is commonly called "the Southern General Assembly" in distinction from the Assembly, North. Its missionary and benevolent operations are not conducted by organized boards, but through committees elected annually by the General Assembly, directly responsible to it, and acting under its instruction. It carries on mission work in China, Africa, South America, Greece, Italy and Mexico. Its home mission work is conducted with vigor and efficiency, and includes work among Indians and negroes, as well as the white population. It has under its care Union Theological Seminary at Richmond, Va.; the Theological Seminary at Columbia, S. C., and the Theological Seminary at Louisville, Ky. The last-named institution, having been joined with Danville Seminary, is now under the joint control of both synods of Kentucky, one in connection with the Northern and the other with the Southern Assembly.

In addition to these, the Southwestern Presbyterian University at Clarksville, Tenn., has a theological department, and there is also a theological seminary at Austin, Tex. For the education of the colored ministry there is the Stillman Institute at Tuscaloosa, Ala., making a total of six theological seminaries. This branch of the Church, while holding in common with other Presbyterian churches the Westminster Confession and Cathechisms, Larger and Shorter, lays special emphasis upon the spirituality of the Church in its functions. It insists that church courts shall be governed by the articles of the Confession, which says, "synods and councils are to handle or conclude nothing but that which is ecclesiastical."

The latest statistics for this Church are as follows: Number of ministers, 1,861; number of communicants, 348,223; number of Sunday-school pupils, 328,252; and total contributions, $4,967,852.

The United Presbyterian Church of North America.— This organization is the result of a union between the Synod of the Associate Reformed Church and the Associate Synod, commonly known as the Seceders. This union took place in Pittsburgh 26 May 1858. The basis of it was the Westminster Confession of Faith, with a modification of the chapter on the power of the civil magistrate, the Catechisms, Larger and Shorter, and a Judicial Testimony. Most of the articles in this testimony are held in common by all Evangelical churches, but there are five which are special to this denomination. The first declares that slave holding is a violation of the law of God and contrary both to the letter and spirit of Christianity. The second declares that all secret and oath-bound societies are inconsistent with the genius and spirit of Christianity, and that church members ought not to have fellowship with such associations. The third is a declaration in favor of close communion; none are to be admitted to the sealing ordinances of the Church except such as give their assent to its doctrines. The fourth declares the duty of public social covenanting at special times. The fifth affirms that it is the will of God that the songs contained in the Book of Psalms should be used exclusively in public worship, and that hymns, the composition of uninspired men, should not be employed in such service. In all other respects, the laws, government and discipline of this Church are the same as those of other branches of the Presbyterian Church. It has been distinguished for the careful training of its ministry. It has in its connection two theological seminaries and six colleges. For the execution of its work the United Presbyterian Church has seven boards, namely: Home, Foreign, Freedmen's Mission, Church Erection, Publication, Education and Ministerial Relief.

Its foreign mission work is now carried on in India, Egypt and the Soudan. In home missions it has been progressive in work in the mountains of the South, among the foreigners and the Mormons and the freedmen of the South. It also has departments of work in Bible schools, evangelism, social service and industrial conditions. The latest statistics give 1,143 ordained ministers and 1,150 congregations. The communicants in America are 156,954. The total membership, including the foreign field, is 200,879. Its contributions in 1916 were $3,006,508.

The Reformed Church in the United States (German Reformed).— Previous to the Revolutionary War a considerable number of emigrants from the Palatinate, a district of Germany, emigrated to America and settled in Pennsylvania. They were members of the Reformed Church in Germany and were men of sterling character and devoted piety. They became important factors in the settlement of middle and western Pennsylvania, and also took part in the Revolutionary War. The first German Reformed minister settled among these emigrants was Philip Boehm, who came to America in 1720. In 1747 there were five ordained ministers and 46 organized churches. In 1793, at which time the Synod was divided into classes, there were 22 ordained ministers and about 150 churches. Subsequently affiliated synods were organized in Ohio and in the neighboring States; but it was not until the year 1863 that organic union was established between them. The General Synod was organized 18 Nov. 1863 in Pittsburgh, Pa. It holds its sessions triennially. It is a delegated body composed of an equal number of ministers and elders, elected by the several classes, constituting eight synods. The General Synod has under its control the various boards to which are entrusted the work of home and foreign missions, and also that of the Sunday school. The membership of the Church is located in the northern belt of the country extending from the New England States to the Pacific slope and southward as far as North Carolina.

The last statistics give the number of ministers as 1,245 and of congregations 1,773, with a communicant list of 326,112 members. Their gifts for benevolence during 1916 were $687,446. Its principal foreign mission work is in China and Japan, where evangelistic, educational and hospital work is conducted. It conducts a growing home mission work at an expense last year of $162,349.

The Reformed Presbyterian Church in North America.— This organization traces its ancestry to the Covenanters and claims to be a lineal descendant of the Kirk of Scotland. Its name has a twofold significance and is a résumé of its history. It is called Reformed, to indicate that it was founded on the principles of the Reformation, and Presbyterian because of its adoption of and long struggle to maintain that form of government. The first presbytery of the Reformed Presbyterian Church in America was organized in 1774. In 1782 the majority of this presbytery united with the Associate presbyteries and formed the Associate Reformed Church. A few refused to accept the union and maintained their organization in what was called "praying circles." Ministers having been obtained from Scotland, in 1798 the presbytery was again constituted. In 1809 the Synod of the Reformed Church was organized with three presbyteries, in Philadelphia; through the increase of churches and presbyteries a General Synod was in time organized. But in 1833 a division occurred by which it was separated into two branches, known respectively as the Synod of the Reformed Church and the General Synod of the Reformed Church. The distinctive features of the Reformed Church are, first, the kingly office of Christ in the sense that nations as well as individuals are his subjects and should acknowledge his authority. Hence Reformed Presbyterians "decline to hold office or to exercise the right of suffrage in any government that does not clearly own Christ as king and his law as supreme." Second, the exclusive use of the Psalms in praise. Third, opposition to secret and oath-bound societies. Fourth, communion restricted to church membership. The cause of the division of the Synod into two branches was a difference of opinion concerning the application of these distinctive principles, one party demanding a rigid and the other a liberal interpretation.

The Synod maintained that voting under the Constitution of the United States involves immorality. The General Synod maintained that voting does not involve morality, a position that makes it so near like several other American denominations as to dim its individuality. The General Synod has 20 ministers, 17 congregations and about 3,000 communicants. The Synod of the Reformed Church, representing the "Old Side," is the stronger of the two branches. It now has 8,481 communicants.

The Christian Reformed Church.— The organization of this Church took place in 1857. It is lineally descended from the Reformed Church of Holland. About the year 1847 a large number of Hollanders, connected with the Christian Reformed Church of the Netherlands, emigrated to America and settled in Michigan. For a short time they became associated with the Dutch Reformed Church, now the Reformed Church of America; but after a time withdrew on account of what they deemed laxity in doctrine and discipline, and formed an organization of their own. Its membership is to be found mainly in the States of Michigan, Illinois, Iowa and New Jersey, with a few scattered congregations in New York, Ohio, Indiana, Wisconsin and Minnesota. It is rigidly Calvinistic in its doctrines, accepting as its standard the articles of the Synod of Dort, and the Heidelberg Catechism. It is opposed to secret oath-bound societies and uses almost exclusively the Psalms in the service of praise. It uses also a liturgy in the administration of the sacraments and in the ordination of ministers and elders. Its theological school is in Grand Rapids, Mich. It numbers about 160 churches and 36,296 communicants. Its General Synod meets biennially at Grand Rapids, Mich. Its ministers officiate in the English, German, French, Bohemian and Hungarian languages.

The Welsh Calvinistic Methodist.— This branch of the Presbyterian body is derived from the Calvinistic Methodist Church of Wales. The first church of this denomination in the United States was organized in Remsen, N. Y., and three years later the first presbytery was constituted. On 22 Sept. 1869 the General Assembly was organized and held its sessions in Columbus, Ohio; and it has met triennially ever since. Its standards of doctrine are the same as those of the parent church in Wales. Its system of government is presbyterian. The Church exists among the Welsh in 13 States of the republic, and in 1916 had 14,326 members.

The Associate Reformed Synod of the South.— The origin of this synod dates back to the year 1821. It was the result of a secession from the Associated Reformed Church on account of differences concerning psalmody and communion questions. Its membership is confined principally to the Southern States and numbers about 15,112. Its doctrinal symbols are the same as those of other Reformed churches.

There are also in the United States several organizations of Presbyterians known respectively as The Associate Church of North America, The Reformed (Covenanted) and The Reformed in the United States and Canada. The number of their adherents is small, not exceeding 2,000.

Presbyterian Churches in Canada.— Presbyterianism in Canada is of Scottish origin, and in it are to be found representatives of every shade of Presbyterianism that has appeared in the British islands. Its early history is marked by divisions, which in course of time have been overcome. In 1831 the Synod of the Presbyterian Church of Canada, in connection with the Church of Scotland, was organized. Meanwhile other Presbyterian ministers, chiefly of the Associate Church of Scotland, organized themselves as the United Synod of Upper Canada. These two bodies were united in 1840. Previous to this union another church had been formed under the name of the United Presbyterian Church of Canada. On 10 July 1844, 25 ministers, in connection with the Church of Scotland, who were in sympathy with the Free Church movement in Scotland, withdrew from the Synod and constituted themselves a separate body, under the name of the Presbyterian Church of Canada. For 17 years these three bodies maintained a separate existence; but in 1861 a union was effected between the United Presbyteries and the representatives of the Free Church, under the name of the Synod of the Canada Presbyterian Church. This synod entered upon a prosperous career, and in 1870 the supreme court of this Church was for the first time constituted as a General Assembly. In 1866 a union was accomplished between the churches of Nova Scotia and New Brunswick; and in 1868 the synods of Nova Scotia and New Brunswick, in connection with the Church of Scotland, formed one synod. A general union of all the churches took place in the year 1875, into which union, under the name of the Presbyterian Church of Canada, came the Presbyterian Church in Canada, in connection with the Church of Scotland, the Canada Presbyterian Church, the Church of the Lower Provinces and the Church of the Maritime Provinces in connection with the Church of Scotland. This union was cordial, and it has been followed by marked progress and substantial prosperity. The united Church has 1,899 ministers, 1,675 congregations and 333,457 communicants. The total contributions for all purposes in 1916 amounted to $5,460,133. The home mission work is comprehensive, embracing such fields as evangelism, moral and social reform, congested city districts, church and rural life and church and industrial life. It is carrying on foreign missions. The 182 missionaries are engaged in China, Korea and India. It has five theological seminaries. See PRESBYTERIANISM.

CHARLES L. THOMPSON, D.D.,
Ex-Moderator, Presbyterian Assembly.

PRESBYTERIAN COLLEGE BOARD, an organization formed by the General Assembly in 1883, for the purpose of establishing colleges for the education of ministers, especially in the sparsely-settled Western States. Colleges must be of professed Christian purpose and desirous of converting all students under their tutelage in order to receive assistance. Fifty-one colleges are now co-operating with this board. See PRESBYTERIAN CHURCH.

PRESBYTERIAN COLLEGE OF SOUTH CAROLINA, a South Presbyterian institution of learning at Clinton, S. C., founded in 1880. The faculty numbers 10; the average annual enrolment of students is 120. The library contains over 3,000 volumes.

PRESBYTERIAN SYSTEM, Alliance of the Reformed Churches Throughout the World Holding the. Previous to 1870 the desire had been frequently expressed that the various branches of the Presbyterian churches could be united in some general alliance which would express the generic unity of Presbyterianism. Some attempts had been made in this direction, but the first official step in this country was taken by the General Assembly of the Presbyterian Church, U. S. A., at its sessions in Baltimore 1873. As a result of this action, the alliance was formed by representatives from different Presbyterian churches in London, England, in the year 1875. The alliance is composed of representatives from different branches of the Presbyterian Church throughout the world. The action of its General Council is not legally binding upon any of the churches, but only advisory in its character. It has, however, been enabled through its counsels to regulate the mission work of the Church, and to bring different branches of the

Presbyterian family into closer relations, for mutual support. The alliance has held seven General Councils: the first was in Edinburgh, Scotland, 1877; the second in Philadelphia, U. S. A., 1880; the third, in Belfast, Ireland, 1884; the fourth in London, England, 1888; the fifth in Toronto, Canada, 1892; the sixth in Glasgow, Scotland, 1896; the seventh in Washington, D. C., 1899; the eighth in Liverpool, England, 1904. The churches connected with the alliance number more than 90, and are located in all parts of the world. The adherents of the Presbyterian and Reformed churches represented in the alliance number at the present time about 30,000,000.

PRESBYTERIANISM, a term derived from the Greek word πρεσβύτερος, meaning «an elder,» defines, primarily, a system of church government. As such, it stands midway between Episcopacy or Prelacy and Independency or Congregationalism. It affirms that the Church, as to its government, is a theocracy under law to Christ, its supreme and only Head and Lawgiver; but the powers of government are vested in the body of believers, and are to be exercised through their chosen representatives called «elders.» It denies the claim of one man, or of a special class of men, to rule the Church by virtue of a divine right. In opposition to papacy and prelacy, it asserts the right of the Church to govern itself through its chosen representatives, administering rule and discipline according to the word of God. «The radical principles of Presbyterian Church government and discipline are: that the several different congregations of believers, taken collectively, constitute one church of Christ, called emphatically, The Church;— that a larger part of the church or a representation of it, should govern a smaller, or determine matters of controversy which arise therein; that in like manner a representation of the whole should govern and determine in regard to every part, and to all the parts united; that is, that a majority shall govern; and, consequently, that appeals may be carried from lower to higher judiciaries, till they be finally decided by the collected wisdom and united voice of the whole church. For these principles and this procedure, the example of the Apostles and the practice of the primitive Church are considered as authority.»

The Presbyterian form of government is essentially republican. It differs from Congregationalism in that it asserts the visible organic unity of the Church in the sense that all local or individual churches are included under one government, in which the majority governs. In accordance with its representative form of government, it has a succession of church courts or judicatories. First in order is the session, or consistory, of the local church, chosen by its members. Next is the presbytery, having jurisdiction over the ministers and churches within a certain limited district. It is composed of the ministers, and one elder from each church in the district. The synod, likewise a representative body, has jurisdiction over the presbyteries; and there must be at least three presbyteries to compose a synod. The boundaries of synods in America are usually, and for the sake of convenience, coterminous with the boundaries of the States in which they are located.

The highest court is called the General Assembly, or General Synod. It is a representative body, composed of an equal number of ministers and elders elected by the presbyteries. The number of representatives from each presbytery varies according to the membership of the presbytery; but each presbytery is entitled to be represented by one minister and one ruling elder. The General Assembly represents all the churches under its care. It exercises administrative, legislative and judicial powers, and its decisions are final and binding upon all the lower courts, when made in accordance with the constitution of the Church. Another characteristic of Presbyterianism is the parity or equality of the ministry. According to its teachings, there are but two permanent official orders in the Church, bishops or elders and deacons. The first includes both teaching and ruling elders. The term deacon includes the two-fold distinction of male and female. The deacons are those to whom is especially committed the administration of the charities of the Church (Acts vi, 3).

Presbyterians claim for their order and form of government apostolic and scriptural sanction. Some among them have gone so far as to assert that the Presbyterian form of government is *jus divinum,* and that none other can be allowed in the Church. This extreme position, however, has had but very few advocates.

The general view is, that it is an ancient form of government having apostolic sanction, and that it is agreeable to Holy Scripture. The main argument by which this view is supported is in brief this: The office of elder was established in the Old Testament Church in the earliest time. The elders were a distinct class of office bearers in the Hebrew commonwealth, and ruled in the synagogue or local church. In biblical history they are mentioned as representatives of the people (Exodus iii, 16 and iv, 24; 1 Samuel viii, 4; 2 Samuel v, 3; 1 Kings viii, 1). They were especially prominent in the synagogue worship, familiar to the Jews from the time of the return from the Babylonian captivity. Each synagogue had a bench of elders, with a presiding officer known as the «chief ruler,» to which was entrusted the oversight of the congregation. The «rulers» of the synagogue, mentioned in the gospel narrative, were these elders. The government of the synagogue, with its system of appellate courts terminating in the Sanhedrin, was Presbyterian (Edersheim, ‹Life of Christ,› Vol. II, p. 552). Jesus Christ and His chosen apostles, the founders of the Christian Church, had been trained in the synagogue and were accustomed to no other form of church government. They knew that it had been previously sanctioned by prophets, priests and kings, all through the history of the chosen people. It was but natural that the same form of government should be adopted in the new church or «Ecclesia,» the body of those «called out» from the synagogue.

That the synagogue furnished the model for the government of the Christian Church is confirmed by the statements of the apostles. Acts xiv, 23 and xx, 17–18; 1 Peter v, 1; 1 Timothy iv, 14 and v, 17. It is further claimed that the terms *episcopos* and *presbyteros,* signifying respectively bishop and elder, are equivalent terms designating the same office. Elders and deacons constituted the office bearers of the early Church. In course of time the «chief ruler» came to be known as *episcopos*, the bishop of the church; but each church had its own bishop or overseer. They were what the Presbyterian pastor is at the present time. Such in general are the grounds upon which Presbyterians claim that their form of government is both primitive, apostolic and conformed to the New Testament Church order. Whatever may have been the primitive form of church government in the Christian Church, it is a historical fact that from the 3d century what is known as prelacy became the prevailing order, culminating in the papacy. At the time of the Reformation (1692–1700) all the reformers desired to restore to the people their primitive rights, but there was considerable diversity of opinion as to methods. John Calvin, in Geneva, was the first to organize a representative government in a practical form, by restoring the eldership to the church.

His conception of the eldership was adopted in the Reformed churches of Scotland, France, Holland and practically in Germany. It was through the struggle to maintain a representative form of government, as against the claims of prelacy, that the term «Presbyterian» was applied to the churches holding that form of government. The Church of Scotland and the Reformed churches of France and Holland are Presbyterian as to their form of government. Most of the Reformed churches have adopted, with slight modifications, the Presbyterian polity. The Methodist Episcopal Church in America, the largest of the Protestant bodies, while Episcopal in name, has become Presbyterian in fact, so far as polity is concerned. In the Protestant Episcopal Church there is now representation from the laity, and the powers of the presbyters have been greatly enlarged. The Lutheran Church in the United States is also presbyterian in policy.

The Doctrines of the Presbyterian Church. — While the term «Presbyterian» defines, primarily, a polity or form of church government, it is also definitive of a system of doctrine, known as the Calvinistic or Reformed. So far as doctrine is concerned, Presbyterianism and Calvinism are synonymous. It is a popular mistake to suppose that Presbyterians accept all the teachings of the great Genevan reformer, John Calvin; but his statement of the Pauline or Augustinian system of theology is generally accepted by all branches of the Presbyterian family, and is embodied substantially in their Confessions. The five distinguishing features of the Calvinistic doctrine are: the absolute sovereignty of God in creation, providence and redemption; the fall of man and his utter inability to save himself from the consequences of his transgression; the election from this fallen race by the sovereign grace of God of a certain number unto eternal life; the provision made for their salvation in Jesus Christ; their effectual calling by the Holy Spirit; and their perseverance in divine grace, assured by the indwelling of the Holy Spirit.

The accepted symbols of the Presbyterian faith are, the Canons of the Synod of Dort, 1619 A.D., the Westminster Confession of Faith with the Catechisms, Larger and Shorter, 1648 A.D., and the Heidelberg Catechism, 1563 A.D. (See DORT, SYNOD OF, and WESTMINSTER ASSEMBLY). These symbols are regarded as subordinate standards. Presbyterians receive the Scriptures of the Old and New Testament as the supreme standard, «the only infallible rule of faith and practice.» In America, the most widely accepted symbol of faith is the Westminster Confession, slightly modified from its original form. In the year 1900 a movement was inaugurated in the largest denomination of the Presbyterian Church for a revision of the Confession of Faith. This movement resulted in the adoption in the year 1903 of an explanatory statement with reference to the third chapter of the Confession of Faith, and in sundry minor amendments. The Assembly also adopted a Brief Statement of Doctrine to be used in the churches under its care. The Confession of Faith as revised still remains the authoritative standard of the Church. Ministers and office bearers are required to subscribe to it in the following terms: «Do you sincerely receive and adopt the Confession of Faith of this Church as containing the system of doctrine taught in the Holy Scriptures?» But the only requirement for admission to the communion of the Presbyterian Church is faith in the Lord Jesus Christ, as the divine Saviour of men.

While claiming that their polity is lawful and agreeable to the Word of God, and that their system of doctrine is that taught in Holy Scripture, Presbyterians recognize all other churches holding to the essential doctrines of Christianity as parts of the one Catholic Church.

History of the Presbyterian Church.—The history of Presbyterianism begins with the reorganization of the Church in the Reformation period, at a council held in Zürich, 26 Oct. 1523, at which the principles of primitive Presbyterianism were formally adopted, and thereafter became the distinctive features of the Reformed churches in Switzerland, France, Belgium, Holland and Prussia. They were adopted by the Church of Scotland which, under the leadership of John Knox, separated herself from the papacy. They were also introduced into England about 1572 by Cartwright. In Scotland, and in the north of Ireland, Presbyterianism has continued to be the dominant faith; and from these great centres it has exerted an influence extending throughout the world.

The Church of Scotland.— Presbyterianism in Scotland is divided into different branches, chief of which is the Church of Scotland, commonly known as the Established Church. It is the state church, supported by the government. It was organized in 1560 and legally established in 1592 by the Scottish Parliament. It is, numerically, the largest Church in Scotland, and its various enterprises, which are many and important, are carried on with great energy and liberality. According to the statistics of 1916 the Church of Scotland has 718,719 communicants.

The Free Church of Scotland.— This branch of Presbyterianism originated in a separation from the Established Church in the year 1843. The immediate cause of the disruption was diversity of views on the subject of patronage. One of the principles of Presbyterian government is, that «no minister should be intruded upon a congregation contrary to its will.» By act of Parliament, the right to appoint ministers to vacant churches had been conferred on certain landed proprietors connected with the parishes. The General Assembly for many years protested against this enactment, but to no avail. The exercise of this legal right in a particular case led ultimately to the withdrawal of a large number of ministers and churches from the establishment, and to the organization of the Free Church of Scotland. But the great underlying reason for this movement was, the determination to maintain the spiritual independence of the Church from the civil power, and her liberty to obey the Lord Jesus Christ as the Supreme Head of the Church. The new organization grew rapidly and took a foremost place in missionary and educational work.

The United Presbyterian Church of Scotland.— This organization originated 13 May 1847 in a union between the United Secession and the Relief Churches. These churches had originated from doctrinal differences in the past, and the harsh exercise of discipline in the establishment. The United Church has been distinguished for its missionary zeal and progressive spirit. It has been said of it, that it has done more for the diffusion of the gospel throughout the world than any other denomination of its size, except the Moravians.

As early as 1862 negotiations for a union of this branch of the Church with the Free Church were begun, and they were continued from time to time till 1873 without any manifest results. In 1896 the United Presbyterian Church again took up the matter of union with the sister body, and the following year the Free Church responded by appointing a committee of conference. The United Presbyterian Church did the same and a remarkable and happy agreement was discovered between these two bodies both as to doctrinal standards and their methods of work. A common constitution was adopted and in 1900 the way for a complete union was open. The general assemblies of the two bodies met in their respective places on the thirtieth of October and the next day the «United Free Church» was constituted and entered upon its career. The small body claiming for themselves the title of the «Free Church of Scotland» resisted the union and the contest for the property was carried through various courts and up to Parliament, with the final decision which deprived the «United Free Church» of all the property of the original Free Church and left it in the control of the very small body claiming to be the «Free Church of Scotland.» That body in 1901 had only 25 ministers and 63 congregations. They were largely the churches of the Highlanders and protested against all relaxation in the terms of subscription, against the disestablishment of the Church, against the use of hymns and organs, against the toleration of Glasgow professors in their chairs.

While the general decision of the highest court remained, final arrangements for the use of the property of the «United Free Church» were made, by which, in cases where the «Free Church» could not use or occupy, it might go to the United body. Under the decision of the appointed commissioners the Assembly Hall with new college buildings and the High Church were to be the property of the «United Free Church.» The allocation of the churches from the one body to the other has been slow, but in 1908 over 100 churches had been assigned to the use of the «United Free Church.» That body now carries on missions in India, Manchuria, Africa, Melanesia and in the West Indies. It has three divinity halls at Glasgow, Aberdeen and Edinburgh, is progressive in all its educational and missionary work. By the latest available statistics the «United Free Church» has 512,000 communicants.

The Presbyterian Church of England.— Presbyterianism in England is associated with the great Puritan movement in that country. It manifested itself in the famous Westminster Assembly, 1643. When prelacy was abolished by the Long Parliament, Presbyterianism was established in its stead, 29 June 1647, and for 20 years it was the national church of England. But opposed by Cromwell and Independency, on the one side, and by the Episcopal Church on the other, it was destined to lose its position. After the restoration of Charles II, and on Saint Bartholomew's Day, it was disestablished and 2,000 ministers, most of them Presbyterian, were ejected from their parishes. In 1686 Presbyterianism was, by act of Parliament, denied civil and religious rights. The passing years brought some amelioration, as a more tolerant spirit pervaded legislation; but from that time until 1850 it had only a feeble existence. Since the latter date, through the union of various scattered churches, Presbyterianism has greatly revived in England.

Thus, in 1876, the English congregations of the United Presbyterian Church of Scotland, which was strong in the three districts of Northumberland, Lancashire and London, were gathered into one synod with the Church of England and known as the Presbyterian Church of England. In 1897 it founded the Westminster College at Cambridge for the purpose of securing a home-bred ministry for its churches. In recent years there has been some revision of its standards but without setting aside its Westminster Confession. Twenty-four Articles of Faith have been adopted. In these, however, there is no essential change of doctrine, but rather of emphasis. According to the statistics of 1916, the Presbyterian Church in England and Wales numbers 88,166.

Welsh Calvinistic Methodist (Presbyterian).— This Church represents Presbyterianism in Wales. The movement which resulted in the establishment of this Church began in 1736 and owes its origin to the evangelical revivals which were spreading throughout the country at that time. In 1864, the two synods, that of North Wales and that of South Wales, united in one General Assembly, whose decisions are binding upon churches in all matters of controversy between them. This Church maintains cordial fellowship with the Presbyterian Church of England. Its Confession of Faith in all essential articles is in harmony with the Westminster Confession, and with the Thirty-Nine Articles of the Church of England. Its leading theological seminary is at Bala, North Wales. It has also under its care a college at Trevecca, South Wales. It has both Home and Foreign Missionary societies, and a fund for the support of aged and infirm ministers. The above-named churches are the principal branches of the Presbyterian Church in the United Kingdom of Great Britain. In addition to these there are in Scotland the Reformed Presbyterian Church, and the original Secession Church of Scotland, with a combined membership of about 10,000, and in England a branch of the Church of Scotland.

The Irish Presbyterian Church.— Presbyterian ministers began their work in Ireland as early as 1594, but on account of persecution Presbyterianism did not obtain a permanent footing there until 1642. It found its home in the northern part of the island, and in the province of Ulster. Its progress was at first hindered by divisions, and by the presence of Arianism which was openly avowed by some of its ministers. In 1840 the various churches were united in one body under the name of the General Assembly of the Presbyterian Church in Ireland. Since this union the Irish Presbyterian Church has occupied a commanding position in the country. It has at present more than half a million people under its care, 560 congregations, over 600 ministers, 5 synods and 37 presbyteries. For a time its ministers were supported by the *Regium Donum* — a grant from the state. About 33 years ago this grant was commuted into a general fund amounting to $3,000,000. This is the basis of the Sustentation Fund, the income from which, increased by voluntary contributions from the churches, supports the ministry. The Church has large foreign missions, and has under its care the Assembly's College at Belfast, and the Magee College, Londonderry. For the last 150 years there has been a constant stream of emigration from the north of Ireland to America and the British colonies, so that the Irish Presbyterian Church has been largely instrumental in establishing Presbyterianism in other parts of the world. Three small communities in Ireland have failed to go into the United Irish Presbyterian Church and retain their separate autonomy under the names of the Reformed Presbyterian Church, the Eastern Reformed Church and the Secession Church.

Presbyterian Churches in Europe.— The Reformed churches of the Reformation period in Switzerland, France, Germany, Bohemia and the Netherlands were generally presbyterian as to their form of government. In addition to these is the ancient church of the Waldensians, dating from primitive times and now established in various parts of Italy and Switzerland. In later years the Presbyterian Church has been extended to Spain, Hungary, Austria, Russia and Norway. The number of adherents in Europe is somewht over 14,000,000.

There are also scattered groups of Presbyterians in Africa, Asia, Australasia and South America, numbering all told about 2,600,000.

CHARLES L. THOMPSON, D.D.,
Ex-Moderator, Presbyterian Assembly.

PRESBYTERY, in Presbyterian churches, a court of judicature consisting of all the ministers of the denomination within a given district, and of ruling elders, one from each church session. Each meeting is opened with prayer by the moderator. The functions of the court are purely executive, not legislative. It has supervision of all the congregations within its territorial limits, hears appeals from decisions of the several sessions, examines candidates for the ministry, issues licenses to probationers, ordains ministers, and in general guards the spiritual interests of the congregations under its charge in matters of doctrine or of discipline.

PRESCOTT, Albert Benjamin, American chemist: b. Hastings, N. Y., 12 Dec. 1832; d. 1905. He took his M.D. at the University of Michigan in 1864 and in 1864–65 was assistant surgeon of the United States volunteers. He was appointed assistant professor of chemistry at the University of Michigan in 1865, where he subsequently became professor of organic and applied chemistry in 1870, dean of pharmacy in 1876 and director of the chemical laboratory in 1884. He was president of the American Association for the Advancement of Science in 1891, and of the American Pharmaceutical Association in 1900. Author of 'Qualitative Chemical Analysis' (1874; 5th ed., 1901); 'Chemistry of Alcoholic Liquors' (1875); 'Nostrums in Relation to the Public Health' (1881); 'Manual of Organic Analysis' (1888), etc.

PRESCOTT, George Bartlett, American electrician: b. Kingston, N. H., 16 Sept. 1830; d. New York, 18 Jan. 1894. He studied electricity and telegraphy and from 1847–58 was manager of several telegraph offices in Connecticut and Massachusetts, becoming in the latter year superintendent of the American Telegraph Company and in 1866 accepted the same position with the Western Union Company. He was electrician of the International Ocean Telegraph Company in 1873–80, was actively interested in various telephone and telegraph companies and was one of the promoters of the former. He discovered the electrical origin of aurora borealis in 1852, invented several improvements in telegraph and telephone instruments, was engaged with Edison in the invention of the duplex and the quadruplex telegraph which he successfully launched on the market and introduced in this country the European system of dispatching messages through pneumatic tubes. He published in the *Boston Journal* and in the *Atlantic Monthly* accounts of his discoveries concerning the aurora borealis and also wrote 'History, Theory and Practice of the Electric Telegraph' (Boston 1860); 'Electricity and the Electric Telegraph' (New York 1879); 'The Speaking Telephone, Electric Light and Other Recent Electrical Inventions' (New York 1879); 'Dynamo-Electricity; Its Generation, Application, Transmission, Storage and Measurement' (New York 1884); 'Bell's

Electric Speaking Telephone: Its Invention, Construction, Application, Modification and History' (New York 1884).

PRESCOTT, Oliver, American soldier: b. Groton, Mass., 27 April 1731; d. there, 17 Nov. 1804. He was a brother of Col. Wm. Prescott (q.v.). He was graduated from Harvard in 1750 and engaged in the practice of medicine, becoming one of the most successful and popular general practitioners. He was a charter member of the Massachusetts Medical Society, incorporated in 1781. In 1780 he became a Fellow of the American Academy of Arts. He was also for many years one of the trustees of Groton Academy. He was an officer in the State militia with rank as major, lieutenant-colonel and in 1776 became a brigadier-general and a member of the board of war. In 1777 he was elected to the supreme executive council of his State and in 1778 received rank as third major-general of militia. He resigned soon after his promotion to second major-general in 1781 and was empowered by the government to cause the arrest of any person whom he should consider dangerous to the Commonwealth. In 1779 he was made judge of the Probate Court of Middlesex County, Mass., and played an important part in the suppression of Shay's rebellion in 1786-87. Consult Prescott, W., M.D., 'The Prescott Memorial' (Boston 1870).

PRESCOTT, William, American soldier, brother of O. Prescott (q.v.): b. Groton, Mass., 20 Feb. 1726; d. Pepperell, Mass., 13 Oct. 1795. He served with the rank of lieutenant in the expedition against Nova Scotia under Wilson in 1755 and was offered a commission in the British army. He declined the honor and lived in retirement until the battle of Lexington in 1775 when he joined the Continental camp at Cambridge with a regiment which he had organized in 1774 and of which he was colonel. At the battle of Bunker Hill he was very conspicuous, really commanding the patriot forces and displaying the greatest courage and ability. He served in the Continental army until the end of 1776 and then retired from active duty with the exception of a short service as a volunteer at Saratoga in 1777. After his retirement from the army he served as town clerk and selectman of Groton and for three years represented his town in the General Court of Massachusetts. For the balance of his life he was an acting magistrate. Consult Gardner, F. A., 'Colonel William Prescott's Regiment' (in *Massachusetts Magazine,* Vol I, pp. 149 and 235, Salem 1908); Green, S. A., 'Colonel William Prescott and Groton Soldiers in the Battle of Bunker Hill' (Cambridge, Mass., 1909); Parker, F. J., 'Colonel William Prescott, the Commander in the Battle of Bunker Hill' (Boston 1875); Prescott, William, M.D., 'The Prescott Memorial' (Boston 1870).

PRESCOTT, William Hickling, American historian: b. Salem, Mass., 4 May 1796; d. Boston, 28 Jan. 1859. In 1811 he entered Harvard College and was graduated in 1814. He long had trouble with his eyesight, which eventually became so weak that during the latter half of his life he could read only for a few moments at a time, and could scarcely see to write at all. He had early resolved to devote himself to a literary life and soon after leaving college went to Europe and spent two years in traveling through England, France and Italy. The subject for which his inclination and abilities more especially fitted him was history and he published his 'History of the Reign of Ferdinand and Isabella the Catholic' in three volumes in 1837 in Boston. The success which this achieved was most decisive. It was received with the utmost enthusiasm both in America and Europe; was soon translated into French, Spanish and German; and its author was elected a member of the Royal Academy of History of Madrid. Prescott's next work was the 'History of the Conquest of Mexico, with a Preliminary View of the Ancient Mexican Civilization and the Life of the Conqueror Hernando Cortez' (3 vols., New York 1843), which was received with equal favor; and next appeared the 'History of the Conquest of Peru, with a Preliminary View of the Civilization of the Incas' (3 vols., New York 1847). Prescott now began the 'History of the Reign of Philip II.,' and no pains nor expense were spared by him to render the result commensurate with the undertaking. He received the most liberal co-operation from all quarters, public and private, and everywhere both public and private collections were thrown open to his inspection. In 1855 the first two volumes of the work appeared entitled, 'The History of the Reign of Philip II, King of Spain,' and in 1858 the third volume. In 1857 Prescott published an edition of Robertson's 'History of the Reign of Charles V,' with notes and supplement, containing an account of the emperor's life after his abdication.

The labors of Prescott afford a remarkable instance of the success of indomitable industry and perseverance carried out in the face of what might otherwise appear almost insurmountable obstacles. Partial blindness preventing him from consulting personally the authorities from which he drew his materials, he had them read aloud to him. His first reader knew, however, no language but English. The historian "taught him," as he says, "to pronounce the Castilian, suited, I suspect, much more to my ear than to that of a Spaniard." He afterward obtained the services of a reader acquainted with several of the Continental languages. Prescott's contemporaries laid strong emphasis and not unjustly, on the thoroughness of his research. But unfortunately modern discovery had done much to correct his pictures of early American civilization, for his information on which he had no recourse save the Spanish chroniclers. Hence 'The Conquest of Mexico' and 'The Conquest of Peru' are now to be valued less for their historical accuracy than for the sweep of the narrative and unfailing interest of the style. Indeed, this "easy flow of language" and "faultless lucidity," praised by Bancroft, is everywhere apparent in Prescott's work. He has not escaped the charge of too highly coloring his scenes for the sake of dramatic effect. He was not an analytical investigator, but rested content with a splendid synthetic arrangement of the concrete facts which he sincerely labored to obtain. This artistic sense and breadth of scope gave to his work an interest and a popularity not known in the case of many historians. A collection of eminent opinions on Prescott may be seen in the familiar 'Dictionary of Authors,' by Allibone. That his reputation was international is proven by the long list of literary honors which were showered on him. Besides being made a member of some 16 State historical societies in his own country, he was also elected to membership in the American Philosophical Society, Royal Academy of Science of Naples, American Antiquarian Society, American Academy of Arts and Sciences, Herculaneum Academy of Naples, National Institute, French Institute, Royal Society of Berlin, Royal Society of Literature of London, Mexican Society of Geography and Statistics and Royal Irish Academy. He received honorary degrees from Columbia College, South Carolina; Harvard; Columbian College, Washington, D. C.; Oxford University, England. His contributions to periodicals were collected under the title of 'Biographical and Critical Miscellanies' (New York 1845; London 1861). A complete edition of his work has been published in 15 volumes (new ed. 1890). Consult Ogden, R., 'William Hickling Prescott' (Boston and New York 1904); Peck, H. T., 'W. H. Prescott' (New York 1905); Ticknor, G., 'Life of W. H. Prescott' (Boston 1864); Bassett, J. S., 'The Middle Group of American Historians' (New York 1916).

PRESCOTT, Ariz., city, county-seat of Yavapai County, on the Santa Fé, Prescott and Phœnix and on the Atchison, Topeka and Santa Fé railroads, about 135 miles north of Phœnix, the capital of the State. The plateau upon which the city is situated has here an altitude of 5,347 feet. Prescott was named in honor of the historian William Hickling Prescott (q.v.) and was formerly the capital of Arizona when it was still a Territory. It is in the midst of a rich mining region; the chief minerals mined in the vicinity are copper, silver and gold. Considerable attention is given to stock raising and farming, and there is some lumbering. Prescott has a hospital, a Carnegie library, a courthouse, four banks with total deposits of over $6,000,000, and three newspapers. The educational institutions are Saint Joseph's Academy, public and parish schools. Pop. 5,092.

PRESCOTT, Ark., city and county-seat of Nevada County, 30 miles southwest of Arkadelphia, on the Saint Louis, Iron Mountain and Southern and on the Prescott and Northwestern railroads. It is located in a cotton-growing district, has a large trade in this article and also in lumber, livestock, eggs and poultry, butter, furs and wool. Pop. 2,705.

PRESCOTT, Canada, town and county-seat of Grenville County, Ontario, on Saint Lawrence River, opposite Ogdensburg, N. Y., 50 miles southwest of Ottawa, on the Canadian Pacific Railway. There are iron foundries, breweries, distilleries and creameries; and manufactories of starch, emery-wheels and caskets. Pop. 2,801.

PRESCRIPTION, *in medicine,* a statement or formula, usually in writing and made by a physician, containing directions for the preparation and use of medicines or remedies for a patient. Formerly prescriptions were written altogether in Latin, but in this country and in Scotland, English is now chiefly used for the directions, Latin being reserved for the names of ingredients. In England both prescriptions and directions are still usually written in Latin. In prescribing the physician may, from the nature of the case, use an officinal or extemporaneous preparation. Prescriptions are now much more simple than formerly. The parts of a regular prescription are four, as follows: (1) The superscription, with the date, name of patient and the sign ℞, an abbreviation of *recipe* (take); (2) the inscription, that is, the body of the formula, containing names and quantities of ingredients, the former in Latin, the latter according to apothecaries' measure or the metric system; (3) the subscription — directions for the apothecary; (4) the signature, comprising directions to the patient regarding the use of the medicines or remedies prescribed, and followed by the signature (sometimes initials) of the physician. In former times, when frequently very complicated prescriptions were used, every prescription was supposed to consist of four classes of ingredients. The most active of these is called the base; the *adjuvant* is meant to promote the action of the first; the *corrigent* or corrective is intended to modify that action; and to these is added the *excipient,* also called the *vehicle* for the purpose of imparting to the whole a form or consistency convenient and agreeable for use. Consult Barton, W. M., 'Therapeutic Index and Prescription Writing Practice' (Boston 1917); Maitland, L., 'How to Read and Write Prescriptions' (Chicago 1914); Mann, M. D., 'Manual of Prescription Writing' (6th ed., New York 1906); Prichard, A. H., 'Practical Prescribing with Clinical Notes' (Oxford 1914); Swan, J. M., 'Prescription Writing and Formulary' (Philadelphia 1910); Wall, O., 'Prescriptions' (4th ed., Saint Louis 1917).

PRESCRIPTION. *At common law,* right or title to incorporeal interests in land, as easements, acquired by possession for the time and in the method required by law. In some systems of jurisprudence, as in the civil law, the term has a much more extensive signification.

At common law prescription was originally based on the legal fiction that open, peaceful and uninterrupted possession for a long term of years raised a presumption of a grant, with the further fiction that this grant had been lost, so as to avoid the rule of pleading requiring profert. The fiction of a lost grant has now to a great extent been superseded. The doctrine is governed largely by statute in the United States. Formerly the period of possession necessary to acquire title by prescription was from time immemorial, or "from the time whereof the memory of man runneth not to the contrary." Today the period is usually fixed at 20 years, both in England and the United States, but by statutory regulation in the latter country it may be less and in rare cases even more. In Louisiana, however, which follows the civil law, the period varies with the subject, and the important distinction is made that the right is not restricted to incorporeal hereditaments. By the Prescription Act passed in England in 1832, later extended to Ireland, rights of common and other profits *à prendre* vest after 30 years, and the right ordinarily becomes absolute after 60 years. The period of prescription does not run against an owner of land while he is under legal disability, as insanity. Rights of way and drainage may be acquired by prescription in the United States, but not to lateral support or light. In some States it is denied that easements by prescription may be acquired against a railroad, but in other States this right is declared to exist. As prescription is founded on the theory of a grant, the use or possession on which it is founded must be adverse. It is, therefore, a well-settled principle of law that use by express or implied permission, irrespective of the length of time continued, cannot ripen into an easement by prescription. In the United States generally evidence of adverse user must be clear and positive, and usually it is a question of fact for the jury. In England, however, the Prescription Act renders the possession a bar or title of itself, without the necessity of the intervention of a jury.

The term had several distinct meanings in Roman law. In procedure a prescription was a legal plea sent by the prætor to the referee to be examined before other disputed issues. The term was also applied to a right or title acquired by uninterrupted possession of property. In the case of movables the period required was fixed at three years by the legislation of Justinian, while for immovables it varied, being 10 years where the parties were domiciled in the same province and 20 years where domiciled in different provinces. However, title by prescription could not be secured to public property nor to property acquired by theft or violence. At one period it required continued possession varying from 40 to 100 years to give title by prescription to church property. Later the same rule was applied to church property as to public property. The term was also used in Roman law to apply to lapse of time after which actions were barred, first limited to equity, but later extended to all cases.

In the law of Scotland, the term is used in a broader sense than in England or the United States and includes limitation in English law. Though originating in the common law, it is governed by statute in Scotland.

Statutes of prescription are statutes of repose. Prescription is justified on the ground that public policy and convenience require that long possession should not be disturbed, and also because there is a social need of settling controversies and of affording relief to those who necessarily find it exceedingly difficult to furnish proof of title on account of great lapse of time. Concerning corporeal interests in real property and title to personal property by lapse of time, see ADVERSE POSSESSION; LIMITATION OF ACTIONS.

EDWARD F. DONOVAN.

PRESENTATION, *in ecclesiastics,* means the nomination of one or several candidates to a vacant office in the church. In ecclesiastical benefices the usual rule is that if the patron fails to present within six months after a vacancy has been intimated to him, the *jus devolutum* takes place; in other words, the patron loses his right, which in consequence devolves on the party before whom the presentation should have been laid, as the bishop under Episcopacy and the presbytery under Presbyterianism.

PRESENTATION AT COURT. See COURT, PRESENTATION AT.

PRESENTMENT, *in law,* is properly speaking the notice taken by a grand jury of any offense, from their own knowledge or observation, without any bill of indictment being laid before them at the suit of the government; as the presentation of a nuisance, a libel or the like, upon which the officer of the court must afterward frame an indictment before the party presented can be put to answer it. The term is also used to include inquisitions of office and indictments by a grand jury; the Constitution of the United States uses the terms «presentment,» «indictment» and «charge» interchangeably and as referring to the first step in the prosecution of a crime.

PRESERVATION, Fort. See OSWEGATCHIE.

PRESERVATION OF FOOD. See FOOD PRESERVATION.

PRESERVATIVES. See ANTISEPTIC.

PRESIDENCY. See PRESIDENT; UNITED STATES — PRESIDENT'S OFFICE.

PRESIDENT, signifying he who presides. The title is used for: (1) the principal member of a society or association, who takes the chair when present at meetings; (2) the chief official of a company or board; (3) the head of a university or college or of a learned faculty; (4) the elected chief magistrate of a republic. At the present time the following countries, all having some form of democratic government, have Presidents as chief magistrates: Andorra, China, France, Liberia, Portugal, Russia, San Marino, Switzerland. All the Central and South American countries, not any longer colonies of European countries, are now republics with a president at the head of their administrations. To this group belong Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, Guatemala, Haiti, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, El Salvador, Uruguay, Venezuela. The powers, duties, etc., of the presidents of these countries are, of course, regulated by their several constitutions and differ to a considerable extent. Further details will be found in the articles on each country. In the United States the President is the chief executive of the government. His duties, rights and election are defined by the Constitution of the United States, article II, sections I, II and III, and article XII of the amendments. He is commander-in-chief of the army and navy of the United States and of the militia of the several States when called into the actual service of the United States. He has the power to grant reprieves and pardons for offenses against the United States except in cases of impeachment. With the advice and consent of the Senate he has the power to make treaties and to nominate and appoint ambassadors, consuls, judges of the Supreme Court, most of the executive offices of the government and a large number of judicial and administrative functionaries. He is elected for a term of four years and is eligible for any number of re-elections, though, in conformity with the precedent set by George Washington, no President has yet been elected more than twice. The President has a veto power. His salary was originally placed at $25,000. In 1873 it was increased to $50,000. In 1907 he was allowed an additional $25,000 for traveling expenses and in 1909 the salary itself was increased to $75,000. His residence during his Presidency is the White House in Washington. He is elected by an electoral college, the composition and procedure of which is regulated by the Constitution, article II, section I, paragraph II, and article XII, amendments to the Constitution. He may receive a minority of the popular vote and yet be legally chosen to the office. He can be removed from office on impeachment for and conviction of treason, bribery or other high crimes and misdemeanors. On the entrance of the United States in the war in April 1917 the regular powers of the President, as defined by the Constitution, were extended and enlarged temporarily in various directions by means of special legislation. These extra powers, however, were given to the executive only for the duration of the war. In case of his death or total disability the functions of the office devolved on the Vice-President, who is elected coincidently with the President and is the presiding officer of the Senate. (See PRESIDENTIAL SUCCESSION). The following is the list of Presidents up to the present: George Washington, 1789 and 1793; John Adams, 1797; Thomas Jefferson, 1801 and 1805; James Madison, 1809 and 1813; James Monroe, 1817 and 1821; John Quincy Adams, 1825; Andrew Jackson, 1829 and 1833; Martin Van Buren, 1837; William Henry Harrison (died 4 April 1841), 1841; John Tyler (elected as Vice-President), 1841; James Knox Polk, 1845; Zachary Taylor (died 9 July 1850), 1849; Millard Fillmore (elected as Vice-President), 1850; Franklin Pierce, 1853; James Buchanan, 1857; Abraham Lincoln (assassinated 14 April 1865), 1861 and 1865; Andrew Johnson (elected as Vice-President), 1865; Ulysses S. Grant, 1869 and 1873; Rutherford B. Hayes, 1877; James A. Garfield (died by assassination 19 Sept. 1881), 1881; Chester A. Arthur (elected as Vice-President), 1881; Grover Cleveland, 1885; Benjamin H. Harrison, 1889; Grover Cleveland, 1893; William McKinley, 1897 and 1900 (assassinated 6 Sept. 1901); Theodore Roosevelt (elected as Vice-President) 1901 and 1905; William H. Taft, 1909; Woodrow Wilson, 1913 and 1917.

PRESIDENT, The, the name of an American frigate of 44 guns, built in New York in 1794, and playing an important part in the early part of the War of 1812 (q.v.). In the summer of 1812 she was made the flagship of a small squadron under the command of Capt. John Rodgers, and in June of that year she had a fight with the British ship *Belvidere*. The latter, after having been hit a number of times, just managed to make her escape. In the summer of 1814 Commodore Decatur was transferred to the *President*, the command of which he assumed. On 15 June 1815 the *President*, then lying in the Hudson, successfully ran the English blockade of New York Harbor with the intention of making a cruise to the East Indies for the purpose of attacking English shipping there. However, before she got very far she was attacked by four British ships-of-war of superior speed and strength. With one of these, the *Endymion*, she had a running fight lasting for two and a half hours. At the end of that time the other three British ships came up and made a simultaneous attack on the *President*. Appreciating the impossibility of further resistance Decatur struck his colors. The *Endymion* with her prize sailed for Bermuda, but before arriving there both ships were dismasted in a heavy gale.

PRESIDENT AND ENDYMION, Battle of the, in the War of 1812. The blockade of the American coast by British ships was very strict and so effective that the frigates *United States* and *Macedonian* were dismantled in April 1814 at New London, and Stephen Decatur (q.v.) and his crew were transferred to the *President*, then at New York. On the night of 14 Jan. 1815 Decatur decided to run the blockade and as a severe snowstorm and heavy gale had driven the blockading fleet out of sight he attempted to make for the open. Through a mistake of the pilot the *President* grounded while crossing the bar but the wind forced her across and despite her injuries she was compelled to proceed. Decatur hugged the Long Island shore for 50 miles, but at early dawn ran into the British squadron consisting of the *Baltic*, 56, the *Endymion*, 50, the *Pomone* and the *Tenedos*, 38's. These three promptly gave chase but being the fastest sailer the *Endymion* left the others in the rear and at 2:30 P.M. exchanged shots from her bow chasers with the stern guns of the *President*. At 5 o'clock the *Endymion* crept up on the *President's* starboard quarter, raked her for half an hour and punished her so severely that Decatur attempted to board his antagonist with the idea of capturing her, scuttling his own ship and escaping on the British ship. But the British captain yawed his ship, whereupon Decatur poured such a galling fire into her that she was reduced to a wreck. He then attempted to escape but at 11 o'clock the *Pomone* and *Tenedos* came up and opened fire. «Thus situated,» says Decatur, «with about one-fifth of my crew killed and wounded, my ship crippled and more than four-fold force opposed to me, without a chance of escape left, I deemed it my duty to surrender.» The loss on the *President* was 25 killed and 60 wounded; on the *Endymion*, 11 killed and 14 wounded. Consult Adams, Henry, 'The United States' (Vol. IX, pp. 65–70); Barnes, James, 'Naval Actions of the War of 1812' (pp. 219–227); Cooper, J. F., 'Naval History' (Vol. II, pp. 235–238); James, William, 'Naval Actions' (pp. 82–94); Maclay, E. S., 'History of the Navy' (Vol. II, pp. 64–70); Roosevelt, 'Naval War of 1812' (pp. 402–405); Spears, J. R., 'History of Our Navy' (Vol. II, pp. 215–228), and biographies of Decatur by T. C. Brady, S. P. Waldo and MacKenzie.

PRESIDENT AND LITTLE BELT, Affair of the. Prior to the War of 1812 British ships were accustomed to hover off American ports and commit depredations on American merchantmen. Accordingly Com. John Rodgers (q.v.) was ordered to sail with his flagship, the *President*, 44 guns, to stop this unlawful interference. On 10 May 1811 Rodgers sailed from Annapolis and at noon of the 16th sighted a ship supposed to be the British *Guerrière*. At 2 o'clock he set a broad pennant and ensign whereupon the stranger began to make signals and stood to southward. Rodgers gave chase and at 8:30 came within speaking distance, but the stranger answered his hail with a solid shot in the mainmast. Before Rodgers could prevent it, a lieutenant on the *President* replied in kind; the two ships then fought for 20 minutes when the stranger was completely disabled. She proved to be the British corvette *Little Belt*, 22, Capt. A. B. Bingham. The British lost 32 men killed and wounded and the Americans 2 wounded. Consult Dawson, 'Battles of the United States' (Vol. II, chap. XIII); the official records and evidence of the court-martial of Rodgers in 'American State Papers, Foreign Relations' (Vol. III, pp. 473–498); Annals of Congress, 12th Congress, 1st session, Pt. II, pp. 1874–1930; Lossing, 'War of 1812' (pp. 181–184); Paullin, Charles O., 'Commodore John Rodgers'; Wiley and Rines, 'The United States' (Vol. V, pp. 246–247).

PRESIDENTIAL ELECTORS. See ELECTORS, UNITED STATES PRESIDENTIAL.

PRESIDENTIAL SUCCESSION, the order in which a vacancy in the office of the President of the United States can be filled pending a new election. The 49th Congress passed a measure entitled «An Act to provide for the performance of the duties of the office of President in the case of removal, death, resignation or inability both of the President and Vice-President.» The measure was approved by the President 19 Jan. 1886. The text is as follows:

§ 1. Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That in case of removal, death, resignation, or inability of both the President and Vice-President of the United States, the Secretary of State, or if there be none, or in case of his removal, death, resignation, or inability, then the Secretary of the Treasury, or if there be none, or in case of his removal, death, resignation, or inability, then the Secretary of War, or if there be none, or in case of his removal, death, resignation, or inability, then the Attorney-General, or if there be none, or in case of his removal, death, resignation, or inability, then the Postmaster-General, or if there be none, or in case of his removal, death, resignation, or inability, then the Secretary of the Navy, or if there be none, or in case of his removal, death, resignation, or inability, then the Secretary of the Interior, shall act as President till the disability of the President or Vice-President is removed or a President shall be elected: Provided, That whenever the powers and duties of the office of President of the United States shall devolve on any of the persons named herein, if Congress be not then in session, or if it would not meet in accordance with law within 20 days thereafter, it shall be the duty of the person on whom said powers and duties shall devolve to issue a proclamation convening Congress in extraordinary session, giving 20 days' notice of the time of meeting.

§ 2. That the preceding section shall only be held to describe and apply to such officers as shall have been appointed by the advice and consent of the Senate to the offices therein named, and such as are eligible to the office of President under the Constitution, and not under impeachment by the House of Representatives of the United States at the time the powers and duties of the office shall devolve upon them respectively.

Consult Hamlin, C. S., 'The Presidential Succession Act of 1886' (in *Harvard Law Review*, Vol. XVIII, p. 182, Cambridge 1905); Willoughby, W. W., 'Constitutional Law of the United States' (2 vols., New York 1910).

PRESIDENT'S MARCH, the title of a popular American national air, most likely composed about 1793 by Philip Phile, a Philadelphian musician, although it is claimed by some authorities to have been played for the first time on Trenton Bridge as Washington rode over it on his way to be inaugurated. In 1798 Joseph Hopkinson of Philadelphia wrote the words of 'Hail Columbia' to the air and it became immensely popular. Consult Sonneck, O. G. T., 'Report on the 'Star-Spangled Banner,' 'Hail Columbia,' etc. (Washington 1909).

PRESIDENT'S OFFICE. For the history of the President's office, see UNITED STATES — PRESIDENT'S OFFICE.

PRESIDENTS OF THE UNITED STATES, Family Coats-of-Arms of. One-half of our 28 Presidents possess either through the paternal or maternal side heraldic bearings, while four additional executives come into heraldic relationship by marriage. The study of these heraldic symbols is not only interesting, but profitable, since they suggest much which is of historic importance and bring to the surface accurate genealogical connections between them and great families of the past.

The grants of arms were not given in recognition of royal blood, but were honors conferred on the ancestors of our Presidents because of some special merit, achievement, heroism or patriotic valor. Hence, the pride we have in their shields, crests or supporters is «born of high record.» The frequent association of aristocracy with this meritorious form of heraldic bearings is an error and none so often has this misconception as the American. While the former pertains to regal blood the latter, an entirely different mode of distinction, relates to honor and personal worth and they have nothing in common other than the expression of heraldic emblems. No relationship exists between these two branches of armorial devices, the latter antedating the caste or titled aristocracy by generations, centuries and decades, for family arms and national insignia are of most ancient conception, as papyrus, stones, edifices and scripture will attest.

George Washington's people came from England, where centuries ago they were known as De Wessingtons and their immediate ancestors came from France, with William the Conqueror, and the original family name was William de Hertburn and he was knighted in the 12th century. In the «Balden Book» a record is made of all the estates of the people of Durham; in 1183 is found the entry that William de Hertburn of Hertburn, France, took the manor Wessington in exchange for soldierly service. With this grant Sir William de Hertburn became Sir William de Wessington. In these olden times «when knights were bold and barons had their sway» this Wessington served his king, being among the preux chevaliers, fighting, hawking, gaming, conspiring, conquering and feasting, the king granting him a silver shield upon which were two golden bars, surrounded by three spurs of the knight in red with a crest of the black raven emerging from a ducal coronet.

In the great struggle of Charles I, the Washingtons remained loyal to the king and upon the promotion of Cromwell the Washingtons eagerly sought refuge in the Virginia colony, where they prospered and were men of great estates. Washington, our first President, devoted considerable attention to the investigation of his pedigree. The public is familiar with his frequent blazoning of the family arms on carriages, books, plate, mirrors, private seal, dishes, pictures and practically every memorable family token was decorated with the old shield of the English Washingtons. As a book plate all the Washingtons employed the family arms, both in England and America.

John Quincy Adams in a communication writes: «That the fact of my father securing this high position and rank at Harvard was due rather to the position of the maternal branch of the family than to the Adamses.» This is strange reading to Americans of this day. The coat of arms of the Adams family was a red shield with a silver cross upon which were five mullets of gold; the crest, a demi-lion emerging from a ducal crown.

Jefferson was eager about knowledge of the early Jeffersons and was well acquainted with the lineage. On 20 Feb. 1771 he wrote Thomas Adams of London (Vol. 81, p. 205, *Harper's*) a letter, in which the following request appears: «One further favor and I am done; to search the herald's office for the arms of my family. I have what I have been told were the family arms, but on what authority I know not.» Jefferson's book-plate and personal seal consisted of his monogram, about which were the words: «Rebellion to tyrants is obedience to God.» A distant relative in preparing the domestic «Life of Thomas Jefferson,» by Sarah V. Randolph, had the Jefferson arms prominently blazoned on the cover of the volume and Jefferson's private seal decorates the title-page. The coat-of-arms of the Jeffersons was a deep red, upon which blazoned three leopards base with cross of Saint Andrew entwined with a lozenger and field blue crest a demi-lion proper. See GREAT SEAL OF UNITED STATES.

The next stratum of American history brings us to the administration of James Monroe, of the ancient Monroe or Munroe family, noted for their studiousness and mildness of character. The family escutcheon of gold was of English origin and contained a spread eagle. In beak a sprig of laurel proper; crest same as arms; motto, «Dread God.» Crest eagle's head erased gules.

The ancestors of Andrew Jackson were Scotch by blood, though they came from the geography of Ireland and in 1765 we find the Jackson family. Generations ago these people were prominent in the wars of Great Britain and the mark of distinction which came to them consisted of a silver shield with a fess or bar, with three birds blazoned; the helmet had perched upon it a bird and a shell supported the shield. The motto, «I move carefully.»

Then comes John Quincy Adams with an armorial device. He inherited a love for the heraldic and early in his life used the Adams crest as a book mark, but later in life he employed in connection with the crest a shield, upon which were blazoned the arms of his ancestors, both paternal and maternal. He was a deep student of things heraldic and while he was Secretary of State he devised and used — contrary to any authority — a private device as the seal of the Department of State. It was his heraldic idea of the constellation Lyra, infrequently referred to in the act creating our national flag, the lines reading «Thirteen stars, representing a new constellation.» See FLAG OF UNITED STATES.

The name Harrison throughout national life is redolent of patriotic intellectual greatness. The family insignia was «a golden shield upon which were two ermine bars and, spangled on shield, five silver stars, with a lion as a crest.»

President Tyler's wife was a Miss Julia Gardiner, of a distinguished family who owned by kingly grant the island of Gardiner of New York. Their coat-of-arms, which can at this day be seen on the walls of this colonial manor house, was «Arms of silver with three hunters' horns and chevron (roof shaped), red crest, an armor with visor surmounted by an arm holding a baton.»

Millard Fillmore family arms were Sable, three bars in chief, three cinquefoils.

President James Buchanan was a descendant of James Buchanan, who came from Ireland just as the American Revolution closed, settling in Pennsylvania. From a book-plate and also from a tombstone at Christ Church Cemetery, Philadelphia, the coat-of-arms of his family is obtained a golden shield blazoned with lion, the helmet is surmounted by a rose, the mottoes «Supported by Courage» and «Honorable Reflection.»

In our backward journey we find Rutherford Birchard Hayes as one of an heraldic family. Little, indeed, is known of the ancestry of Mr. Hayes, though the family has cherished a purple shield, upon which are blazoned three lesser shields of silver. He was of Scottish ancestry, the first member of the family in America being George Hayes, who settled in Windsor colony of Connecticut in 1682. The Scottish ancestry were granted the arms early in the 15th century as a distinction for profound ability at the bar, a heritage which made the branch of progress easy for the scholarly Hayes.

Garfield's shield of gold, with its three bars of red and its right canton with cross and left canton with heart, is symbolic of the armorial ancestral device. As a crest the arm clasping a sword and for a motto those significant words «In the cross I conquer.» The name and the arms are possibly of Saxon origin, for the name occurs in the Teutonic heraldic insignias as meaning «Garfeld» or «watch of the field» and the crest is of crusade origin, the remote Garfields having been a part of the noble army of religious patriots.

Benjamin H. Harrison was the 23d President and his armorial device the same as William Henry Harrison.

The name Cleveland is, in truth, not the name of this great American family, but rather the designation of the immense estate they once possessed in England, where these folks were known as «De Cleveland» of Durham, England. This French nobiliary predicate «de» formed a part of this family name up to the 13th century, some genealogists claiming their ancestry French and hence the French word «of» prefacing the name. The Clevelands have an armorial bearing which dates back to the remote period of the 12th century and the crest, which represents a spearman, is in token of Sir Guy de Cleveland, who commanded the spearman at the famous battle of Poiclien-Poitiers of 19 Sept. 1356. The Cleveland shield, with its black chief and silvery base spangled with stars and its argent chevron (roof) with stars, once formed the book-plate of Stephen Cleveland, father of the Hon. Grover Cleveland. The motto in this coat-of-arms is especially appropriate, meaning «For God and Fatherland.»

The Roosevelts were in old New York when the Pilgrims of Massachusetts were banishing men and women for freedom in religious worship and executing so-called witches and tyrannizing the wilderness with self-destruction. At this same time the Dutch of New York were welcoming the world and laying the foundation of our present public-school system. In this atmosphere the Roosevelts flourished as early as 1649. The Roosevelt coat-of-arms in its heraldic colors was painted on the dining-room wall of old Jacobus Roosevelt and opposite in oils in a heavy frame was the likeness of Klaas Roosevelt, the first emigrant Roosevelt, who came as early as 1649 when New York was still New Amsterdam. The Arms are a silver shield charged with red roses and Latin motto, meaning «God who has transplanted it will protect it.»

The ancient Dutch grant of arms is interesting, though too lengthy to reproduce. Suffice the statement that this shield of honor was conferred upon his kin early in the 1500's, during the campaign leading up to the founding of the Dutch Republic. Needless to say, these Roosevelts or Van Roosevelts, as they were entered in record, were of the Republican party and of the Protestant army.

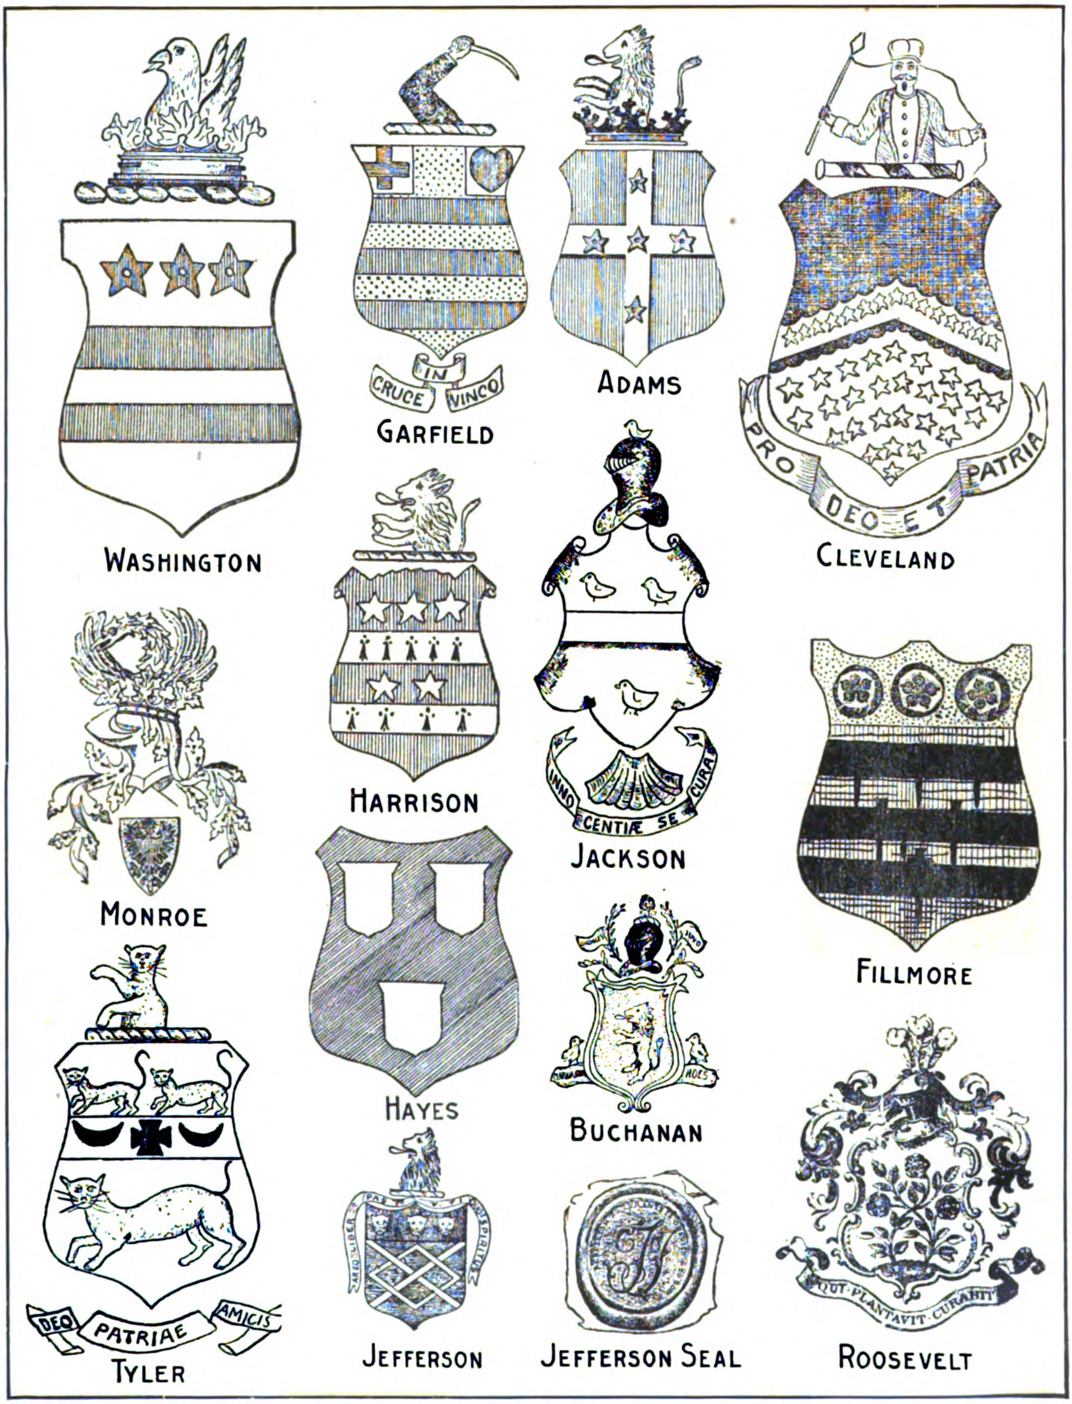
B. J. Cigrand,
Author of 'Our Presidents' and 'Heraldic Americana.'

PRESIDENTS OF THE UNITED STATES, Graves of the. Some writers and distinguished citizens have advocated bringing to the capitol the remains of all the Presidents and depositing same in a huge mausoleum patterned after the Westminster Abbey of London. This would be a mistake, since State pride and individual requests rebel against such procedure. Let the States have their spots of historic interest. This will impel people to visit various parts of the Union. Besides, a certain «love of home» induces men, even of broad and liberal minds, to choose a burial spot, or God's acre, within the precincts of youthful days or within the vicinity of faithful friends. This latter sentiment was the one uppermost in our Presidents selecting their own last earthly home and Washington's notion on this theme was borne out by many of his successors.

While there are innumerable magnificent memorials, monuments, statues and tablets to the eminent dead who filled the highest chair in the gift of a republic, these are for the most part distant from their graves and though these markers in stone, metal or wood represent a form of gratitude, yet the actual tomb, its surroundings and general care is the emblem of our affections.

Washington.

The one of Washington, at Mount Vernon, is commonplace. It does not reflect the sentiment of our people. The national treasury could very fittingly unlock one of the gold boxes and contribute toward the shrine of him who, when living, was «first in war, first in peace,» and, in life or in death, «first in the hearts of his countrymen.» Thousands are the men, women and children who annually make the pilgrimage to this patriot's grave. It is indeed a shrine worthy of national regard, and while the entire republic in all its material grandeur is as a monument to his wisdom and heroic patriotism, yet his immediate tomb de-



COATS OF ARMS OF AMERICAN PRESIDENTS

serves a more extravagant materialization to be an equivalent to the popular regard.

Miss Alice Longfellow, youngest daughter of New England's beloved poet, told the story to the Warren and Prescott chapters, Daughters of the American Revolution, of how Mount Vernon was saved to the nation by a woman. Miss Longfellow told of Miss Ann Cunningham, a gentle woman of old Virginia, who, when passing up the Potomac River one day in 1853 and hearing the steamer bell toll when passing the grave of Washington, became possessed with the desire to restore it. The place was then occupied by a great-grandnephew of the first President, John Augustine Washington. It was in a state of decay and the generous hospitality of the owner, who treated every passing stranger as a guest, made the expenditure of money for repairs utterly impossible. When Miss Cunningham ventured to tell him of her plans he was filled with horror that women should do that which should so emphasize the degeneracy of men. But the determined woman sent out urgent appeals.

Her first call was to the women of the South and on 12 July 1854 the first meeting was held. Edward Everett was one of the first to offer his services and as the result of his lectures $68,000 was contributed to the fund.

In addition to the actual price of the plantation $300,000 had to be raised for repairs and when matters were progressing finely the Civil War broke out and confusion was the result. Mount Vernon was neutral ground throughout the bitter struggle. When the strife was ended Miss Cunningham went there to live, received the aid of Sumner in getting an indemnity from the government and went on with the noble work she had undertaken.

It may not be generally known, but such is the case nevertheless, that when the capitol of the United States was planned and erected at Washington a crypt was constructed in the basement of the capitol, directly underneath the rotunda. This final resting place was designed for the body of Gen. George Washington. Considerable mystery surrounds the delay or refusal of the entombing of the first President in the foundation of the national capitol. Some claim that neglect of action on the part of our national Congress is responsible for the empty crypt, while others, equally good authority, states that Washington's wish dictated his present grave on the premises of old Mount Vernon, the spot of all others he so devotedly loved.

John Adams.

The death of John Adams and of Thomas Jefferson 4 July 1826 is the most remarkable necrological coincident in the history of our country. Adams married a minister's daughter and he was a devout Christian, affiliating with the Unitarians of Braintree, Mass., and under the pulpit of this antique religious structure reposes all that is earthly of the eloquent gentleman who made the Declaration of Independence an accepted national decree. He is incased in a leaden coffin, which is sealed in a stone sarcophagus. His son, John Q., placed a huge marble tablet at the right of the pulpit, with these inspiring words:

From lives thus spent
  Thy earthly duties learn;
From fancy's dreams
  To active virtue turn.

Let Freedom, Friendship, Faith
  Thy soul engage,
And serve, like them,
  Thy country and thy age.

Thomas Jefferson.

Thomas Jefferson, whose labors so thoroughly complemented those of John Adams, rests in Williamsburg, Va., beneath a plain and unassuming obelisk of granite, in the small family cemetery on the road leading to his famous homestead, Monticello. He did not regard having been twice elected to the Presidency the height of his accomplishments, as is shown by the burial tablet he wrote for his own tomb, the character of which he designed. The lines he wished blazoned on the granite read: «Here lies buried Thomas Jefferson, author of the Declaration of Independence, of the statute of Virginia for religious freedom, and father of the University of Virginia.»

The Democrats, aided by Republicans, will erect at Washington, D. C., the most elaborate memorial to Jefferson ever erected to any famed person. But his body will not be disturbed from its present resting place because of Jefferson's request to lie at the side of his loved ones. The spot he selected when yet a young man. On a fly-leaf of one of his old books was found this regarding his burial: «Choose some unfrequented vale in my park, where is no sound to break the stillness, but a brook that, bubbling, winds among the woods. Let it be among the ancient and venerable oaks.» The obelisk has been practically destroyed by crazed relic hunters, who have beaten and battered the granite until only a few letters tell whose grave it is. Vandalism of an insane origin only could be responsible for such desecration. Why does not the central government awaken to the duty it owes to the dead national Presidents? An infinitesimal fraction of the protective tariff revenues would make these graves truly shrines for the inculcation of national patriotism.

James Madison.

He lies buried on the centre of his old farm at Montpelier, Va. A brick fence encloses his bier, a lot measuring about 100 square feet. A granite obelisk 20 feet high marks the spot, and on its base are these words: «Madison, born March 16, 1761.» The lovable and gracious Dolly Madison, his wife, has an obelisk of smaller dimensions near by.

James Monroe.

New York City for 27 years had the body of James Monroe, but on 4 July 1858, it was removed to the capital of Virginia, where it now rests in Hollywood cemetery. The monument is unique and patterned after the windows of a Norman abbey. The General Assembly of Virginia looks after this grave, and it is kept up with reverential care.

John Quincy Adams.

In the crypt at Braintree, Mass., is the body of John Quincy Adams. He loved his parents dearly, and it was his wish to be buried at their side. He was religious, and when President he prayed the prayers of his childhood days. He related at a Cabinet meeting that the sweetest lines in the English language were those of the prayer which begins: "Now I lay me down to sleep; I pray thee, Lord, my soul to keep." On his tomb tablet are these lines: "A son worthy of his father, a citizen shedding glory on his country, a scholar ambitious to advance mankind. This Christian sought to walk humbly in the sight of God."

Andrew Jackson.

Eleven miles from Nashville, Tenn., is the famous shrine, "The Hermitage," the home of Andrew Jackson, and in the garden of this notable farm is the quiet resting place of the stern and fearless "Old Hickory." On the base covering the graves of Jackson and his wife are erected eight fluted columns which support a circular cope surmounted by an urn. This old plantation, with its sacred remains, was cared for by the women of Tennessee, and they have now presented this estate to Tennessee, hence the State is guardian. The words "General Andrew Jackson, born March 15, 1767, died June 8 1845," are all that relate to the soldier President, while a lengthy inscription, written by himself, is engraved into the stone above his amiably tempered wife.

Martin Van Buren.

The grave of Martin Van Buren is at Kinderhook, N. Y., and is marked by a plain granite obelisk with simple inscription stating he was the eighth President of the United States.

William Henry Harrison.

Fifteen miles west of Cincinnati, Ohio, lies all that was mortal of W. H. Harrison. The old brick vault was recently replaced by stone, the inscription is wanting and patriotic societies contemplate improving the surroundings.

John Tyler.

The American people have lost track of the grave of John Tyler. Church records place it near the grave of James Monroe. A magnolia tree serves as a marker; neither stone, flowers nor urn indicate the place of his burial. While it is true that he did not remain loyal to the Union — taking up the cause of the Confederacy, and being an ardent advocate of State's rights — he nevertheless was a dutiful and respected Virginian, and held the office of President. The government might appropriate the regulation soldier marker — costing about $5. This would serve to give designation to the spot until future generations more befittingly recognize it.

James K. Polk.

Within the capitol grounds at Nashville, Tenn., rest the remains of James K. Polk. He certainly has a beautiful resting place. The high hill on which it is located overlooks the great landscape of Tennessee, and miles away can be seen with fieldglass the grave of Jackson, and Nashville, the Athens of the Southland, is proud of these two graves and reveres the sacred remains there deposited. A lengthy and praiseworthy inscription graces the Grecian Doric pillared grave.

Zachary Taylor.

A curious oversight regarding the death of General Taylor comes to light in the truth that the 12th President, who died in the office as President, has never received burial services. Gen. Richard Taylor, nephew of the President, writes: "General Zachary Taylor has never been buried, notwithstanding the many stories to the contrary. He died in 1850 and his remains were immediately brought to Kentucky by his brother, Commissary General J. P. Taylor, and placed in a vault in the Taylor cemetery." This cemetery is about five miles from Louisville, Ky. On the monument are these splendid words from the General: "My only regret is for the friends I leave behind me."

Millard Fillmore.

About two miles from Buffalo, N. Y., is Forest Lawn cemetery, and here a plain obelisk rises into the sky to designate the final home of President Fillmore. The word "Fillmore" is on the base, but it does not state that he was an American President. The grave is kept in most befitting manner.

Franklin Pierce.

Far north in the hills of old New Hampshire, near the famous town of Concord, in Minot cemetery, a delicately designed pillar monument marks the grave of Franklin Pierce. A strange mistake on the tomb shows: "Francis Pierce, born Nov. 23, 1804; died Oct. 8. 1869." On the same lot are buried his two sons, Robert and Franklin, hence the entire family is dead.

James Buchanan.

Pennsylvania, with all its glorious history, with its thrilling scenes in Philadelphia, has had but one man in the White House. This "fortunate son" was James Buchanan, who "rests in peace" at Lancaster in Woodward Hill cemetery. No wife lies at his side. He was a bachelor President. Disappointed in love he remained single to the end of life. The magnificent block monument, with presidential reference, is pointed out with pride by the Pennsylvanians.

Abraham Lincoln.

To us the name of Lincoln is justly associated with all that stands for truth and justice, and to his fair name time only can add the laurel. His great and grand character will be more thoroughly understood as time rolls on. His life will appear in clearer light and be more fully appreciated by the generations yet to come. And the hour is close at hand when the name Lincoln will be nearer that of Washington than that of any other in the long calendar of fame.

The massive granite structure in which he "sleeps the eternal sleep" is of a Masonic character, and upon its four fortlike bays rest copper figures representing the heroic charges of the men who saved the Union. Like for Jefferson, the American people have contributed toward erecting on the old "Lincoln home" in Kentucky, where he was born, an elaborate memorial to be in the form of the White House, as that structure was at the time of his tragic death.

ANDREW JOHNSON.

Several years before the death of Andrew Johnson he chose the spot where he hoped to be buried. This place was on the heights of Greeneville, Tenn. It is not generally known that he had two sons in the Civil War. Charles was killed at Nashville and Robert, a colonel of a Tennessee regiment, died in 1869. Both are buried near the graves of the parents.

ULYSSES S. GRANT.

A most imposing structure on the banks of the Hudson marks the final resting place of Gen. U. S. Grant. Its grand proportions and its matchless location attract thousands annually. No President's death was made into such an expensive burial. It has been estimated that over $1,000,000 were expended. His funeral was the first real evidences that the North and South had become more than friendly; yea, the brotherly spirit here came to the surface. The Southland remembered the generosity of Grant at the surrender of Lee. They recalled how modestly, how tenderly and how fraternally he greeted General Lee on the day of Southern defeat. The death of the great Illinoisan brought not only wreaths of Southern posies, brought not only eloquence from Southern lips, but, more and better, tears from the defeated Southern hosts. No man received such universal homage, and he grows dearer and his character becomes nobler as time moves on. His tomb is a credit to the nation.

RUTHERFORD B. HAYES.

The Hayes tomb or monument was designed by President Hayes, and erected over his wife, who died in 1881, and near it he, too, was buried. Its splendid proportions are well known to the visitors at Oakwoods cemetery, Fremont, Ohio.

JAMES A. GARFIELD.

The tragic death of James A. Garfield brought forth general sympathy, and his costly tomb at Lakewood, Cleveland, Ohio, is evidence of his popular regard. Before his death he expressed the wish of being buried in this scenic cemetery. The structure cost $150,000, half of which was donated by his personal friends in Cleveland — a remarkable witness of his lovable character.

CHESTER A. ARTHUR.

Chester A. Arthur, the quiet, graceful and diplomatic New Yorker, sleeps in Rural cemetery, Albany, N. Y. Arthur and the scholarly gentleman who preceded him represented the two factions of the Republican party, but during the official life both were friendly.

WILLIAM MCKINLEY.

President McKinley, whose tragic assassination took place at a time when the country was just emerging from a cruel war and enjoying the calm, quieting words of a man who represented the «peace traits» of a happy people. His tomb at Canton, Ohio, and its speedy erection was due to the earnest and faithful co-operation of President Roosevelt and his praiseworthy Cabinet. The mammoth mausoleum cost $600,000.

The heroic statue of McKinley graces his mausoleum erected at Canton, Ohio. The statue of McKinley is depicted as he made his last public speech, just before his assassination at Buffalo, when he urged that «our real eminence rests on the victories of peace, not those of war.» The pose of the statue is familiar to the public, as it is taken from the photograph of President McKinley as he made this address. Instead of the awkward setting, however, that a balcony afforded for a statue, the sculptor has introduced a chair of state, over which the folds of an American flag appear.

GROVER CLEVELAND.

A handsome memorial is planned for Cleveland though a simple marker now shows where he is buried at Princeton, N. J.

BENJAMIN HARRISON.

Lies buried at Indianapolis, Ind., and a plain stone marks his resting place.

THEODORE ROOSEVELT.

Theodore Roosevelt was buried on 8 Jan. 1919 at Oyster Bay Cemetery, overlooking the beautiful landscape and waterflow of historic New York. There amid giant trees, wild fern and ocean breeze he chose to rest; great nature lover that he was it was but natural that the wildwood would claim his body. Quietly and without elaborate ceremonials he was deposited in the soil of his native State.

B. J. CIGRAND,
Author of 'Our Presidents' and 'Heraldic Americana.'

PRESIDIO, prę-sĭd'ĭ-ō, a Spanish word which means «a fort.» It is applied especially to four fortified Spanish forts on the coast of Morocco: Alhucemas, Ceuta, Melilla and Peñon de Velez. The military settlements made by the Spaniards in California were also known as presidios. In 1729 there were 20 presidios in New Spain, some of them founded as early as 1680 and most of them in what is now Mexico. The chief presidios of Spanish California were massive forts at San Francisco, Monterey, San Diego and Santa Barbara. Of these two, at San Francisco and Monterey, continued to be military posts after California was acquired by the United States. They are known officially as Presidio of San Francisco (q.v.) and Presidio of Monterey. The latter was founded in 1772 by the Spanish and at the present time contains 398 acres. Consult Richman, J. B., 'California under Spain and Mexico' (Boston and New York 1911).

PRESIDIO OF SAN FRANCISCO, Cal., a United States military reservation in the northwest suburbs of the city of San Francisco. It contains 1,542 acres. It was established as a military post by Spain about 1776, and Mexico continued it until it was ceded to the United States in 1848. It was established as a United States military post in 1850, and is United States army headquarters for the Department of California.

PRESQUE ISLE, Me., town in Aroostook County, near Aroostook River, 135 miles, direct, northwest of Bangor, on the Bangor and Aroostook and the Canadian Pacific railroads. The town is situated in an agricultural district and manufactures starch and lumber. The population is increasing. Pop. 2,938.

PRESS, *in mechanics,* see METAL-WORKING MACHINERY; *in printing,* see PRINTING PRESS.

PRESS, Freedom of the, the right of every citizen to print whatever he chooses. The freedom, however, does not prevent his being amenable to justice for abuse of this liberty. The right of printing rests on the same abstract grounds as the right of speech, and it might seem strange to a man unacquainted with history that printing should be subjected to censorship, as it is still in some countries and has been at one time or another in all, any more than speaking, and that the liberty of the press should be expressly provided for in the constitutions of most free States. But when we look to history we find the origin of this, as of many other legislative anomalies, in periods when politics, religion and individual rights were confusedly intermingled. It is only since men's views of the just limits of government have become clearer that the liberty of the press has been recognized as a right; and to England and the United States the world is particularly indebted for the establishment of this principle. The existence of a censorship of the press was for centuries, however, deemed essential to the safety of all European governments. Liberty of printing, as we understand it, is a comparatively modern notion: Milton's plea for a free press met with no response from his own party, nor for many years later was it the cue of any party in the English commonwealth to refrain from suppressing the writings of their political opponents. In England the liberty of the press, soon after printing was introduced, was regulated by the king's proclamations, prohibitions, charter of license, etc., and finally by the court of star-chamber. The Long Parliament, after their rupture with Charles I, assumed the same power. The government of Charles II imitated their ordinances, and the press did not really become free till the expiration of the statutes restricting it in 1693, after which it was found impossible to pass new laws in restraint of it, and it has remained free ever since, the last restriction being done away with on the abolition of the newspaper stamp duty, in 1856. Such legal checks as remain are merely intended to prevent outrages on religion or decency, to protect individuals from defamation and to conserve the copyright of authors. The Constitution of the United States specifically prohibits Congress from passing any law abridging the freedom of the press. The constitutions of most of the United States declare, as we should expect, for the liberty of the press. The same may be said of all the South American republics. In other countries the amount of freedom enjoyed by the press varies considerably and is frequently regulated by executive laws. At the outbreak of the European War in 1914 the freedom of the press in all countries was involved, and even in some of the neutral countries, was greatly restricted, though these restrictions did not apply so much to the essential right of freedom as to details in connection with the printing of war news.

As recently as 1919 a decision of the Supreme Court of Mexico in a contempt case against the editor and publisher of a local journal cleared up several points concerning the freedom of the press and the law of contempt of court. The editor of the publication was found guilty of contempt of court by the judge whose actions he had criticized in an editorial, concerning a legal proceeding which affected the publication. An appeal taken to the Supreme Court contended «that the criticism made did not concern the official acts of the jurist, but merely his private act,» and this contention was upheld by the Supreme Court.

While adhering to the rule that criticism calculated to obstruct the course of justice may be punished as for a contempt of court, the court held that cases of constructive contempt are criminal proceedings and that, therefore, the information, the authority of the court, the weight of the evidence (including all presumptions and proof) and the regularity of the proceedings are governed by the rules of criminal law. The information must be strictly construed as well as the article alleged to be contemptous,» and the court further savs «the defendant is presumed to be innocent until proved guilty beyond a reasonable doubt, the same as a defendant in any criminal case. There are no presumptions taken against him, but the presumptions are all in his favor.» This is a wide departure from the attitude of those courts which seem to have presumed that their critics were guilty and to have thrown upon them the burden of proving the innocency of their intent. Certainly in contempt proceedings, where the offended judge sits substantially as accuser, judge and executioner, the rule announced is much more consonant with free press and free speech guarantees. The opinion handed down by the Supreme Court asserts «it is not the personal dignity nor the personal feelings of the court that justify contempt proceedings,» and that «attacks on the character or conduct of a judge as an individual may, in some cases, be so gross as to amount to a contempt,» but «only when they tend to influence the course of justice.» A most important holding of the court, especially at a time when the rights of free speech and free press have been so much clouded by voluntary and involuntary censorship and by so much public concern as to the effect of governmental control of many of the means of communication, is the reaffirmation of the principle that «under our theory of government the right of the freedom of speech and of the press are essential to public welfare.» While holding that these do not afford license to indulge in unwarranted attacks upon the courts, the opinion notes that «public opinion has greatly restrained the courts in the exercise of contempt powers, and that even false and unwarranted criticisms of judges affords them no greater remedy than those given to private citizens, unless they encroach upon the rights of litigants and tend to obstruct justice in pending matters or embarrass the judge in the discharge of judicial functions.» See LIBERTY OF THE PRESS; CENSORSHIP OF THE PRESS.

PRESS ASSOCIATION OF LONDON, a subsidiary organization of the Reuter Agency, established in London in 1868 to furnish daily news to the povincial newspapers of the United Kingdom. See PRESS ASSOCIATIONS.

PRESS ASSOCIATIONS, organizations for the gathering and distribution of news. The association of newspapers for the collection of news began before the invention and use of the telegraph. In London the great dailies and other agencies supplied the interior press of the country with stereotyped news, and more especially with reports of the doings of Parliament; and in the United States, the shipping and other news, especially foreign, to be had at the Atlantic ports, was collected and distributed, by agencies, to subscribing newspapers, by fast boat and other means of transportation; and fast pony express was made use of for the conveyance of news from the national and State capitals to the larger and most important centres of population. A system of arbitrary signs was established at important harbors for the fast transmission of news to the great dailies. But the coming of the telegraph gave to these earlier news associations a sudden impetus which was destined to increase with wonderful speed. The great newspapers of New York City formed an association, in 1848, to pay jointly the expenses of the transmission, by telegraphy and other means, of comprehensive reports of the operations of the American forces in the Mexican War. Owing to the fact that the telegraph lines were then not extended throughout the South, the news was generally from a week to 10 days old when it appeared in print; but even with all this delay newspaper enterprise generally outstripped the government in the securing of early reports of war operations. The gradual extension of telegraph lines to the South rapidly widened the field of these early news-gatherers. The monthly news service of the Cunard Line between Europe and Boston was sent on to New York by wire; and from there it was transmitted to all parts of the country by various means of conveyance. With this European news went local market reports and other important information to the press of interior cities and towns. The rapid organization of the news features of the great cities followed; and to the current daily service were added full reports of happenings of general and national interest. The handling of news became a business of experts.

The Reuter Agency.— In the meantime Julius Reuter, a Prussian government messenger, conceived the idea of a great associated press service that could be extended to all papers desirous of making use of it. In 1849 he opened an office in Paris; but the French government discouraged him. This and the fact that the German government was rapidly extending its telegraph lines induced him to go to Aix-la-Chapelle where there was a gap between the telegraph line which ended there and the French-Belgian line terminating at Verviers. Reuter opened a news-collecting and distributing agency at each of these points and forwarded the news by carrier pigeon and other means of fast transmission. He extended his news service and finally removed his headquarters to London in 1851. This he had been induced to do owing to the fact that the Dover-Calais submarine cable had just been laid. Reuter's London office began the transmission of news by wire from London to Paris, at first, as correspondent for various newspapers on the Continent; for he had not been able to induce the great London dailies to purchase his news service. He used the wires wherever they existed and where they did not he employed special agents to transmit his news by carrier pigeon or fast messenger to all his subscribers. In his work of extending the news facilities of the press he overcame, by his tireless energy, countless difficulties, and soon the Reuter News Agency became known to every newspaper in Europe. Its first important conquest was the London *Morning Advertiser*, the second greatest newspaper in England in 1858. The *Times* and other British dailies soon fell into line and the Reuter Agency extended its news facilities still more rapidly than the rapidly extending telegraph lines. Reuter correspondents were to be found in all parts of the world.. In 1866 Reuter connected Cork with Crookhaven by private submarine cable in order to be able to beat his competitors in furnishing news of the American situation. He also secured a concession for a submarine cable to Cuxhaven from the king of Hanover, and another for a cable between France and the United States, both in 1865. Reuter's Agency and the Anglo-American Telegraph Company made mutual use of this latter line. In 1868 the Press Association of London, a subsidiary affair, was formed to serve the provincial newspapers of the United Kingdom with daily news.

The Havas Agency.— Among the other news agencies that had already sprung into existence by this time were the Central News Agency, the Continental Agency, the Exchange Company, Dalziell's Cable News, the National Press Agency and the Havas Continental Agency. The oldest of these was the latter which dated back to 1835, when Charles Havas, a translator, opened an agency in Paris for the translation from English and Continental newspapers of interesting news for the French press. In 1840 Havas established a carrier pigeon news service between Paris, London and Brussels. This being the first attempt at the rapid transportation of news it naturally attracted much attention to the Havas Agency. Between this date and 1850 the name Havas became well known to the newspaper world, and more especially to the capitals of Europe; for the Havas Agency had kept abreast of the times and had made use of telegraph and railway transportation as rapidly as they had developed. Already, at this early date, Havas furnished daily news reports of a commercial, financial and political nature; and this had completely changed the nature of the news offered by the daily press. In 1856 the Havas Agency was amalgamated with the Bullier Advertising Agency; and among the patrons of the new concern were the foremost French dailies. Subagencies were opened in Madrid, Rome, Vienna, Brussels and, a little later, in various American cities. Working agreements were entered into with the Wolff Agency in Germany and the Reuter in London. This was followed by the planting of Havas correspondents in all the important news centres of Europe and America and in almost every town and city of any importance in France; for the Havas Agency has always made a specialty of local French news. It was the first to make use of the principle of the mutual exchange of news between a central news bureau and the newspapers taking its service. It was also the first to furnish syndicated material to subscribers in the form of special news features; and this part of the business it has developed very extensively. It furnishes *feuilletons* of a literary character, feature stories and novels written by the best-known and most popular of French writers. Fully 75 per cent of the typesetting of the French country press has been done away with through the «patent» material furnished it in the form of «mats» or stereotyped metal plates. Yet this local work has not prevented the Havas Agency giving much attention to the gathering of international news, a business which it has organized on a labor, money and time-saving basis. Special trained Havas correspondents are stationed in all the capitals and other great news centres of Europe, Asia and Africa; and whenever there is a sudden need for a correspondent the nearest Havas man is wired from Paris to go at once to the place where his services are required. All these correspondents are carefully educated in the ways of the agency and they know exactly what is expected of them. When it is necessary to depart from this routine they are so instructed by wire. The Havas Agency was the first to establish and perfect a very contracted figure and word code for the transmission by wire of routine news to countries to and from which the cable rates for news were excessively high. In 1879 Havas Agency was reorganized as a joint-stock company with a capital of $1,700,000, divided into 1,700 shares of $100 each.

The Wolff Bureau and the Oversea News Service became, in 1917, a part of the advertising machinery of the German government which purchased a controlling interest in each of them. To strengthen this strong news and advertising medium control was also secured of more than 50 per cent of the stock of some of the foremost daily papers in Germany and Austria. Among these were the *Deutsche Zeitung*, *Frankfurter Nachtrichten* and the *Lokal Anzeiger*. This new combination of news agencies also secured control of the greater part of the advertising patronage of Germany, and through this control of advertising it secured a powerful influence over the policy of the most important dailies in Austria.

The Associated Press of New York was organized prior to 1860, and the Western Associated Press was formed during the Civil War period. The latter was a strong coöperative organization, and for many years it was an important factor in the business of news gathering in this country. For 20 years the New York Associated Press and the Western Associated Press worked together in harmony. The wires of the Western Union Telegraph were utilized for transmitting reports, and thousands of miles of leased wires were constantly in use. In 1882 the United Press was formed, using the Postal Telegraph wires for the transmission of news, and in 1883 a third and smaller rival, the Press News Association, entered the field. Meanwhile dissensions arose over contracts between the New York and the Western associations, and the disputes were carried into the courts. The evidence showed that the Western Associated Press had made contracts for franchises between January 1883 and January 1893 with newspapers in the Far West, calling for payments under the contracts of $118,410. Of this amount the books showed that $85,294 had actually been paid in. One-half of this amount was claimed by the New York Associated Press as its share of the money collected from such sales of franchises. Suits and counter suits were commenced and the Western Associated Press was finally dissolved. A new Associated Press was organized under the laws of Illinois and for several years a close rivalry existed between this company and the United Press. Then dissensions arose and in 1900 the Associated Press was reorganized and reincorporated under the laws of New York State. In the meantime the Press News had died from financial mismanagement and soon afterward the United Press was wrecked. The Associated Press now began a prosperous career with no rival worthy of the name. The New York City Press Association, a local concern, was incorporated as a part of the Associated Press, which also began an exchange arrangement with Reuter's Agency in Europe. All the New York newspapers with the exception of the *Sun* received their foreign and domestic reports from the Associated Press. The *Sun* organized an independent news-gathering service, called the Laffan Bureau, and from the ruins of the

United Press co-operated with a number of newspapers between New York and San Francisco, thus building up a creditable organization independent of the Associated Press. A third organization, the Scripps-McRae Press (Western service) and the Publisher's Press (Eastern service) in 1903, was serving news to several hundred newspapers. These two companies, practically one, divide the eastern and western fields between them. The three press associations were strenuous rivals during the Spanish-American War, and special correspondents were sent with the American fleets and the armies in the field. Reporters were also stationed at every port on the Southern coasts. An Associated Press correspondent was with Dewey at the battle of Manila Bay. All three associations maintain resident correspondents in the larger American cities, and in London, Paris, Rome and the foreign capitals. Throughout the European War correspondents of the Associated Press were maintained at the front in France, where Reuter's, Havas and other news agencies were also represented either directly or indirectly. Correspondents were also maintained in all centres where war or important political news was to be had.

Newspaper Syndicate.— Closely allied with the press associations is the newspaper syndicate which instead of furnishing current daily news supplies special articles, correspondence, fiction and miscellaneous literary material to thousands of daily and weekly newspapers throughout the country. S. S. McClure was the pioneer in this field, followed by the American Press Association, the Bacheller and Johnson syndicate, the A. N. Kellogg Newspaper Union, the Leslie Syndicate, the Bulletin Press Association and numerous others. The syndicate is enabled, by its sales of the same article to many customers, to purchase matter quite out of the reach of the individual newspaper, and to sell it on terms that each can afford. The scheme is found to be so advantageous that practically all the leading newspapers use syndicate matter to a considerable extent. Besides the firms engaged primarily in the syndicate business, several leading metropolitan daily newspapers, notably the New York *Herald* and the *American*, dispose of their own matter to papers published in other cities. In addition to these there are now in the United States news syndicates for almost every kind of newspaper enterprise. If one wishes to start a local magazine, for instance, he can secure 32, 64 or 96 pages of material already printed and ready to bind in handsome cover, with or without advertising, at a very nominal price, if he publish the advertising; and all that is necessary is to add a few pages of local to have a finely printed and illustrated publication.

J. H. Cornyn.

PRESS CENSORSHIP. See Censorship of the Press.

PRESS-GANG, the name given in England to a detachment of seamen who (under the command of a naval officer) were empowered, in time of war, to take any seafaring men and oblige them to serve on board the king's ships. Consult Fletcher, W. J., 'The Press-Gang' (in 'The 19th Century and After,' Vol. L, p. 761, London 1901). See Impressment.

PRESSBURG, prĕs'boorg, or **PRESBURG** (Magyar, *Pozsony*), Czecho-Slovakia, (1) free city in the west, capital of a county of the same name, on the left bank of the Danube, 35 miles east of Vienna. The site of the town is remarkably fine, being in the form of a semi-circle, bounded on the south by the Danube, from the banks of which it gradually ascends to the west and north toward ramifications of the Carpathians; and an extensive plain, covered with gardens, vineyards, meadows and corn-fields, forms its boundary on the east. The houses are built of brick and stone, and of two or three stories. The edifices most deserving of notice are the Landhaus, or Hall of the Diet, in which the chambers of the kingdom used to meet, but now used as a courthouse; the cathedral, a huge Gothic pile with a lofty steeple, begun in 1090, consecrated in 1452 and rebuilt in 1845–67, less remarkable as a church than as the place where the kings of Hungary were formerly crowned; a number of churches and monasteries, the Jesuit church, a synagogue, the city hall, begun in 1288, theatre, archbishop's palace, orphan hospital and barracks. The city possesses a number of interesting monuments, fountains and bridges. The old castle, formerly residence of the king of Hungary and located on a rock about 275 feet above the Danube, is now a ruin. Of educational institutions there are a law school, gymnasiums for boys and girls, a military academy, Protestant and Catholic lyceums and a well-equipped library. The industrial establishments are devoted especially to the manufacture of wooden ware, musical instruments, gloves, tobacco, silk ribbons, alcohol and woolens. There are also flour and sawmills and, in the suburbs, a sulphur factory and slate quarries. The trade, chiefly in corn, is extensive. Outside the town there used to be an artificial mound called the Coronation Hill, to which the newly-crowned kings of Hungary rode in grand procession and brandished the sword of Saint Stephen toward the north, south, east and west, signifying thereby that they undertook to defend the kingdom from danger, come from which quarter it might. Pressburg is a place of very great antiquity, being first mentioned in the 9th century. In 1541, when the Turks captured Buda, it became the capital of Hungary, till the Emperor Joseph II restored this dignity in 1784 to Buda. Pressburg, however, continued to be the seat of the Diet until 1848. The peace by which Austria ceded Venice to France and the Tyrol to Bavaria was concluded here in 1805. Soon after the establishment of this new republic of Czecho-Slovakia, the name of the city was changed to Bratislava. Pop. 78,223, of which 32,790 are Germans, 31,700 Hungarians and 11,600 Slovaks; 59,200 are Roman Catholics, 10,500 Protestants and 8,200 Jews. (2) The county of Pressburg, area, about 1,700 square miles, is traversed by part of the Carpathian chain in the north; in the south it is flat and fertile. It is watered by the Danube, March and Waag, and yields corn and grapes. The large forests furnish abundance of timber. Pop. 389,750. Consult Kiraly, J., 'Geschichte des Donau-Mauth- und Urfahrt-Rechtes der Freistadt Pressburg' (Pressburg 1890); Ortvay, T., 'Geschichte der Stadt Pressburg bis 1526'

(6 vols., Pressburg 1892–1903); 'Pressburg's Strassen und Plätze' (Pressburg 1905).

PRESSED GLASS. See GLASS, VARIETIES OF.

PRESSENSÉ, Edmond Dehault de, ĕd-môn dė-ōlt dė prā-sŏn-sā, French Protestant theologian: b. Paris, 3 June 1824; d. there, 8 April 1891. He studied theology under Vinet, Tholuck and Neander and in 1847 was appointed pastor of the independent Chapelle Taitbout in Paris. Throughout his whole career he was an eloquent opponent of the connection of church and state and an able supporter of evangelical Christianity. He also took part in politics, in 1871 was elected to the National Assembly by the department of the Seine, and thenceforward constantly sought to consolidate the republic on a thoroughly liberal basis. He was elected a life senator in 1883. He founded the *Revue Chrétienne* in 1854 and conducted it till his death. In spite of his many activities he found time for the publication of a large number of works: 'Du Catholicisme en France' (Paris 1851); 'Histoire des trois premiers siècles de l'Église Chrétienne' (6 vols., Paris 1858–77; new ed., 3 vols., Paris 1888–89); translated by Harwood-Holmden, A., as 'The Early Years of Christianity' (2 vols., London 1877–78); 'L'Ecole Critique et Jésus-Christ' (Paris 1863); translated by L. Corkran as 'The Critical School and Jesus Christ' (London 1865); 'L'Église et la Révolution Française' (Paris 1864); translated by J. Stroyan as 'The Church and the French Revolution' (London 1869); and by J. P. Lacroix as 'Religion and the Reign of Terror' (New York 1869); 'Le pays de l'evangile' (Paris 1864); translated as 'The Land of the Gospel' (London 1865); 'Jésus-Christ, son temps, sa vie, son œuvre' (Paris 1865); translated by Harwood-Holmden, A., as 'Jesus Christ: His Times, Life and Work' (London 1866); 'Études évangéliques' (Paris 1867); 'Rome and Italy at the Opening of the Œcumenical Council' (translated by George Prentice, New York 1870); 'Le concile du Vatican, son histoire et ses conséquences politiques et religieuses' (Paris 1872); 'La liberté religieuse en Europe depuis 1870' (Paris 1874); 'Études contemporaines' (Paris 1880); translated by Harwood-Holmden, A., as 'Contemporary Portraits' (London 1879); 'Les Origines' (Paris 1883); translated by Harwood-Holmden, A., as 'A Study of Origins' (London 1883); 'Variétés morales et politiques' (Paris 1885); 'Les Énglises Libres de France et la reforme française du XVIe siècle' (Paris 1887); 'Alex. Vinet, d'après Sa Correspondance inédite' (Paris 1890). Of his sermons quite a number have also been published, the most important of which are 'Le Rédempteur, etc.' (Paris 1854); translated as 'The Redeemer' (Edinburgh 1864); 'Discours religieux' (Paris 1859); 'The Mystery of Suffering and other Discourses' (translated by A. Harwood-Holmden, London 1868); 'Le devoir' (Paris 1875). Consult Loyson, H., 'Edmond de Pressensé' (Paris 1891); Roussel, Th., 'Notice sur la vie et les Œuvres de Pressensé' (Paris 1894); Thieme, H. P., 'Guide Bibliographique de la Littérature Française' (pp. 324–325, Paris 1907).

PRESSURE. See FORCE; POWER.

PRESSURE FIGURES, *in mineralogy,* are certain radiating lines developed by the pressure of a point on a crystal or cleavage surface. They are diagonal to the percussion figures.

PRESTAGE, Edgar, English litterateur: b. Manchester, 20 July 1869. He was educated at Radley School, Abingdon, and Balliol College, Oxford. In 1902–08 he was engaged as law student and solicitor and at different periods was special lecturer in Portuguese literature at the University of Manchester, examiner in Portuguese to the universities of Manchester, London, Liverpool, Leeds and Sheffield and the civil service commission. He is corresponding member of the Lisbon Academy of Sciences, the Institute of Coimbra, etc., and commendador of the Portuguese order of São Thiago. Mr. Prestage's works are 'Cincoenta documentos ineditos relativos a D. Francisco Manuel de Mello'; 'Cartas de D. Francisco Manuel de Mello escriptas a Antonio Luiz de Azevedo'; 'Portuguese Literature to the End of the XVIII Century'; 'Registo da Frequesia de Santa Cruz do Castello de Lisboa'; 'Letters of a Portuguese Nun'; 'Sixty-four Sonnets of Quental'; 'Short Stories,' and contributions to encyclopedias and periodicals.

PRESTER JOHN (Priest or Presbyter John), a semi-legendary character of the Middle Ages. It was reported by travelers that there was a Christian prince who reigned in the interior of Asia under his name, and the same story was also known to the Crusaders. Albert of Aix and Otto of Freisingen speak of him in the 12th century; the Franciscan Rubruquis, in the 13th, attributes the name of Prester John to a Nestorian prince, Ung Khan, who had reigned in Karakoram over two Mongol tribes and perished in a war against Genghis Khan, above half a century before the time of his journey. Other travelers of the 13th century also mention this personage. Who this Prester John was cannot be determined. The supposition that he was one of the chief priests of the Lamaites does not agree with the position assigned to his residence by the travelers, nor do any etymological explanations seem satisfactory. The Portuguese in the 15th century, hearing a story of the Christian prince in the interior of Africa, whose name was Ogan, and who was in fact the negus (king) of Abyssinia, and being misled by the resemblance of the names Ogan and Ung Khan, made the mistake of transferring the throne of Prester John from Asia to Africa and giving the name to the Abyssinian prince. Consult Baring-Gould, S., 'Curious Myths of the Middle Ages' (2 vols., London 1867–68); Brunet, G., 'La Légende du Prêtre-Jean' (Bordeaux 1877); Hakluyt Society, 'The Book of Sir Marco Polo' (2 vols., London 1874); Oppert, G., 'Der Presbyter Johannes in Sage und Geschichte' (2d ed., Berlin 1870); Yule, Sir Henry, 'Cathay and the Way Thither' (2 vols., London 1866); Zarncke, F., 'Der Priester Johannes' (in 'Abhandlungen der Koenigl. Saechsischen Gesellschaft der Wissenschaften,' Vols. XVII and XIX, Philologisch-Historische Klasse, Vol. VII, pp. 827–1030, Vol. VIII, pp. 1–186, Leipzig 1879–83).

PRESTON, Ann, American physician and educator: b. West Grove, Pa., 1 Dec. 1813; d. Philadelphia, Pa., 18 April 1872. She was the daughter of Amos Preston, a Quaker, and her first knowledge of medicine was gained in many years of care for an invalid mother. Upon the opening of the Women's Medical College of Philadelphia in 1850 she enrolled as a student and was graduated in 1852. She engaged in practice in Philadelphia, achieving marked success, and in 1854 she became professor of physiology and hygiene at her alma mater, occupying the office of dean after 1866. She was instrumental in the establishment of the Woman's Hospital in Philadelphia, which she later served as consulting physician. Her lectures and addresses were strikingly able, and her defense of her sex as medical practitioners when in 1867 the Philadelphia County Medical Society decided to make public objection to them resulted in a reversal of the decision. She wrote several essays on medical education for women and was author of a volume of verse, 'Cousin Ann's Stories for Children' (1848).

PRESTON, Harriet Waters, American translator and novelist: b. Danvers, Mass., 6 Aug. 1836; d. Cambridge, Mass., 3 June 1911. At an early age she became noted as a linguist and has since achieved a brilliant reputation as a translator from the Latin and Provençal languages and as an essayist. Much of her work was published in the *Atlantic Monthly*. Her translations comprise Count de Falloux's 'Life and Letters of Madame Swetchine' (1867); Mistral's 'Miréio' (1873); C. A. Sainte-Beuve's 'Memoirs of Madame Desbordes Valmore' (1873); Paul de Musset's 'Biography of Alfred de Musset' (1877); C. A. Sainte-Beuve's 'Portraits of Celebrated Women' (1880); Virgil's 'Georgics' (1881); F. M. A. de Voltaire's 'Contes de Voltaire' in 'Oxford Modern French Series' (1912). Of her own original works the following have been published: 'Aspendale' (1871); 'Love in the 19th Century' (1873); 'Is That All?' (1876); 'Troubadours and Trouveres, New and Old' (1876); 'A Year in Eden' (1887); with Louise Dodge, 'The Guardians' (1888); and 'The Private Life of the Romans' (1893).

PRESTON, John Smith, American politician and soldier: b. near Abington, Va., 20 April 1809; d. Columbia, S. C., 1 May 1881. He was a younger brother of William Campbell Preston (q.v.) and was graduated from the Hampden-Sidney College in 1824, studied at the University of Virginia and at Harvard, and after an extended tour of Europe settled in Columbia. He was a member of the South Carolina legislature in 1848–56 and gained a high reputation as an orator. He openly and ardently upheld the secession movement, headed his State's delegation to the Charleston Convention in 1860, and in the following year became one of the commissioners to Virginia, where he made a brilliant speech, urging secession upon that State. He served in the Confederate army throughout the entire war. He was engaged at the first battle of Bull Run and afterward was assigned chief of the conscription department with the rank of brigadier-general. After the war he lived in Europe for a time, and after his return to the United States remained a bitter opponent of the government until his death.

PRESTON, Margaret Junkin, American author: b. Milton, Pa., 19 May 1820; d. Baltimore, Md., 28 March 1897. She was the daughter of George Junkin (q.v.), a well-known Presbyterian clergyman, who in 1829 moved with his family to Germantown, Pa., and in 1832 to Easton, Pa., where he became the first president of Lafayette College (q.v.). From 1841–44 she lived at Oxford, Ohio, where her father had moved after accepting the presidency of Miami University. In 1844 he became once more president of Lafayette College, necessitating the removal of his family again to Easton. In 1848 her father accepted the presidency of Washington College, now Washington and Lee University, at Lexington, Va., at which place the family continued to reside from then on. In 1857 she was married to John T. L. Preston, one of the founders and a member of the faculty of the Virginia Military Institute. Later on he served on the staff of Stonewall Jackson, who had married Mrs. Preston's younger sister. Mrs. Preston continued to reside in Lexington until 1892, two years after her husband's death. She then moved to Baltimore, Md., where until her own death she made her home with her oldest son. In 1855 she translated the Latin hymn 'Dies Iræ' and in 1856 published her first book, a novel entitled 'Silverwood.' Her subsequent work is almost entirely in verse and is characterized by deep religious feeling and an ardent espousal of the Confederate cause. She published 'Beechenbrook; a Rhyme of the War' (Baltimore 1866); 'Old Songs and New' (1870); 'Cartoons' (Boston 1875); 'Centennial Poem for Washington and Lee University, Lexington, Va., 1785–1885' (New York 1885); 'For Love's Sake' (1886); 'A Handful of Monographs, Continental and English' (New York 1886); 'Colonial Ballads, Sonnets and Other Verse' (Boston 1887); 'Semi-Centennial Ode for the Virginia Military Institute, Lexington, Va., 1839–89' (New York 1889); 'Chimes for Church Children' (Philadelphia 1889); 'Aunt Dorothy; An Old Virginia Plantation Story' (New York 1890). Her diary, giving an interesting and valuable history of her life in the South, is published in part in Elizabeth Preston Allan's 'Life and Letters of Margaret Junkin Preston' (Boston 1903). Consult also Picket, L. C., 'Literary Hearthstones of Dixie' (Philadelphia 1912).

PRESTON, Thomas Scott, American Roman Catholic clergyman: b. Hartford, Conn., 23 July 1824; d. New York, 4 Nov. 1891. He was graduated from Washington (now Trinity) College in 1843, from the General Theological Seminary of the Protestant Episcopal Church in 1846 and held assistant rectorates in New York. In 1849 he entered the Roman Catholic Church, and after study at Saint Joseph's Seminary, Fordham, N. Y., was ordained priest in 1850. He became chancellor of the archdiocese of New York in 1853, and in 1863 rector of Saint Ann's, New York. In 1872 he was made vicar-general of the New York archdiocese, in 1881 he was made monsignor and in 1888 prothonotary apostolic. He vigorously opposed the land and labor movement of Henry George (q.v.) and was active in urging the excommunication of Dr. McGlynn (q.v). He founded and for many years directed the Sisters of the Divine Compassion. As a preacher he enjoyed considerable popularity. Among his many controversial and devotional works are 'The Ark of the Covenant; or, A Series of Short Discourses Upon the Joys, Sorrows, Glories and Virtues of the Ever Blessed Mother of God' (New York 1860); 'The Life of Saint Mary Magdalene' (New York 1860); 'The Life of Saint Vincent de Paul' (New York 1866); 'Lectures on Christian Unity' (New York 1867); 'Lectures on Reason and Revelation' (New York 1868); 'Christ and the Church' (New York 1870); 'Vicar of Christ' (New York 1878); 'The Divine Paraclete' (New York 1879); 'The Protestant Reformation' (New York 1879); 'Protestantism and the Bible' (New York 1880); 'Christian Unity' (New York 1881); 'Protestantism and the Church' (New York 1882); 'God and Reason' (New York 1884); 'The Sacred Year' (New York 1885); 'The Watch on Calvary' (New York 1885); 'The Divine Sanctuary' (New York 1887); 'Gethsemane' (New York 1887). Consult Brann, 'The Rt. Rev. Thomas S. Preston, Vicar General' (New York); Preston, 'Remembrances of My Brother Thomas.'

PRESTON, William, soldier, lawyer: b. near Louisville, Ky., 16 Oct. 1806; d. Lexington, Ky., 21 Sept. 1887. He was educated at the Harvard College Law School, from which he was graduated in 1838. He then entered upon the practice of law in Kentucky and took much interest in politics. During the Mexican War he served as lieutenant-colonel of a Kentucky regiment. In 1851 he was a Whig representative in the Kentucky legislature, but when the Whig party broke up he became a Democrat. During Buchanan's administration he was Minister to Spain. He returned to America in time to see the beginning of the Civil War. In 1861-62 he was colonel on the staff of Albert Sidney Johnston. In 1862 he was made brigadier-general. He was engaged in the campaigns of the Western army, notably at Vicksburg, Baton Rouge, Murfreesboro and Chickamauga. In 1864 he was sent to the Trans-Mississippi Department and in 1865 was made major-general. After the war he settled in Lexington, where he practised law until his death. In 1867 he was a member of the Kentucky legislature and in 1880 a delegate to the National Democratic Convention.

PRESTON, William Campbell, American legislator and educator: b. Philadelphia, Pa., 27 Dec. 1794; d. Columbia, S. C., 22 May 1860. He was graduated from the South Carolina College in 1812, studied law and was admitted to the bar in 1820. He established a law practice in Columbia, S. C., in 1823, and speedily became prominent in his profession, excelling as a jury lawyer. He sat in the State legislature in 1828 and in 1830-32, where he boldly advocated nullification and won a high reputation as an orator. In 1833 he was elected to the United States Senate, but refused to act with his colleague, Calhoun, in the latter's support of Van Buren, and resigned his office in 1842. In 1845-51 he was president of the South Carolina College and a trustee of it from 1851 to 1857 and proved an able and successful administrator. He established the Columbia Lyceum, which he endowed with his own library of 3,000 volumes. Consult Miller, W. L., 'William Campbell Preston' (in *The Green Bag*, Vols. XI and XII, Boston 1899-1900); O'Neall, J. B., 'Biographical Sketches of the Bench and Bar of South Carolina' (Charleston 1859).

PRESTON, Canada, town in Waterloo County, Ontario, at the confluence of the Speed and Grand rivers, 55 miles, direct, southwest of Toronto, on the Grand Trunk and Canadian Pacific railways. It is an outport for Ontario and has flour and saw mills as well as manufactories of iron castings, woolens, shoes, furniture, piano-players and other industries, including machine shops. The population is steadily increasing. Pop. 3,882.

PRESTON, England, an important manufacturing town of Lancashire, 28 miles northeast of Liverpool, on a height above the north bank of the Ribble, near the head of its estuary, and on the London and North-Western and the Lancashire and Yorkshire companies railways. The river is spanned by five bridges. The handsome central railway station cost about $1,000,000. Other important buildings are the Gothic town-hall; courthouse, in the Doric style; a new infirmary, the house of correction, the custom-house, corn-exchange, new gas offices, large and handsome market-shed, extensive barracks, workhouse, theatre and assembly-rooms; the Literary and Philosophical Institution, provided with a library and museum; the Harris Institute of Literature, Art, Science and Technical Instruction (formerly the Mechanics' Institute, and now greatly enlarged); The Free Public Library and Museum, in the Grecian style, with many valuable paintings, etc. The ecclesiastical edifices include a number of Established churches, beside Roman Catholic and other chapels. Among the former Christ Church is admired for the purity of its Norman architecture; and the parish church, which has been rebuilt in the decorated style of the 14th century, with a spire 196 feet high, is also a fine building. Saint Walburge's Roman Catholic Chapel, which has a beautiful spire 306 feet high, ranks as the most splendid place of worship in Preston. The town is supplied with water from reservoirs situated near Longridge, 18 miles northeast of Preston with a capacity of 405,000,000 gallons. On the south side of the town are two beautiful public parks, and on the north side is the Moor Park. The original staple manufacture of the town was linen, which is still woven, but has been completely eclipsed by the cotton manufacture, especially spinning, first introduced in 1777. There are engineering works, machine-shops, iron and brass foundries, boiler works, breweries, malt-houses, roperies, tanneries, etc. A considerable shipping trade is carried on, though it was long obstructed by the condition of the Ribble. Since 1884 the river has been canalized and large docks have been built and a very considerable increase in the trade has taken place. Preston and Lancaster are connected by canal.

Preston is said to have risen on the decay of Ribchester, the Roman Rigodunum, situated about 11 miles farther up the river. Its name, originally Priest's town, it owed to the number of religious houses which it contained. About 600 it was a Saxon settlement; in 1322 it was taken and burned down by Robert Bruce; in the great Civil War it espoused the Royalist cause, and suffered severely during the contest, having been twice captured by the Parliamentarians, who on the latter occasion were headed by Cromwell in person; in the rebellion of 1715 it was occupied by the Jacobite forces, who erected barricades and made a brave resistance, but were ultimately obliged to surrender. Modern Preston is a Parliamentary borough, returning two members. Its municipal government is in the hands of a mayor, 12 aldermen and 36 councillors. Pop. about 117,113. Consult Clemesha, H. W., 'A History of Preston in Amounderness' (in 'Publications of the University of Manchester, No. 67, Historical Series No. 14,' Manchester 1914); Fishwick, H., 'History of the Parish of Preston' (Rochdale 1900); Whittle, P., 'History of the Borough of Preston' (2 vols., Preston 1837).

PRESTONBURG, Engagements at and near. In September 1861 Col. John S. Williams began to organize a Confederate force at Prestonburg, in eastern Kentucky, to operate in the interior of the State. On 8 November Gen. William Nelson, who had advanced against him with three Ohio regiments, detachments of Kentucky infantry and cavalry and two sections of artillery, with a part of this force encountered a detachment thrown forward by Williams to cover his withdrawal. After a well-contested engagement at Ivy Mountain, Williams was forced from his position and retreated through Pound Gap into Virginia, with a loss of 10 killed, 15 wounded and 40 missing. Nelson was recalled to Louisville, and Williams returned to Prestonburg. Gen. Humphrey Marshall had been ordered, 1 November, to the command of the Confederate forces in eastern Kentucky, including those of Williams, and soon had in addition two Virginia regiments and a battery of four guns, making a total force of about 2,400 men, who were badly clothed, many of them barefooted, and generally badly armed, many of the men having only shotguns and squirrel-rifles. In the beginning of January 1862 Marshall had the greater part of his command intrenched near Paintsville, on the main branch of the Big Sandy River, a few miles north of Prestonburg. On 17 December General Buell assigned Col. James A. Garfield to the command of a brigade of about 3,000 men, partly cavalry, and sent him against Marshall and to clear the valley of the Big Sandy. On the 23d, when Garfield began his march up the course of the river, the greater part of the brigade was concentrated at Louisa, on the Big Sandy. On 6 Jan. 1862, after driving in several scouting parties, Garfield arrived within seven miles of Paintsville. Marshall, well informed of his approach, fell back from Paintsville on the night of the 5th to the forks of Middle Creek, about three miles above Prestonburg. Garfield advanced through Paintsville, defeated Marshall's cavalry at the mouth of Jennis' Creek on the 7th, and on the morning of the 10th attacked Marshall on Middle Creek with cavalry and was repulsed by artillery alone. Garfield now attacked with infantry and the fight continued from noon to near dark with varying success, several Union advances being repulsed; but Marshall finally abandoned his position, though not retiring from the field until next morning, when, being out of food for his men, he marched to Martin's Mill. Garfield did not pursue. He crossed the river on the 11th and occupied Prestonburg, and on the 12th and 13th withdrew to Paintsville. Both sides claimed the victory. Garfield had 1,700 men on the field, and his loss was two killed and 25 wounded. Marshall had 1,500 engaged, and lost 11 killed and 15 wounded. Consult 'Official Records' (Vol. VII); The Century Company's 'Battles and Leaders of the Civil War' (ed. by R. U. Johnson and C. C. Buel, Vol. I, New York 1887); 'War of the Rebellion: Compilation of Official Records of the Union and Confederate Armies' (Series 1, Vol. VII, p. 21; Vol. XX, Pt. 1, p. 31; Vol. XXI, p. 1065; Washington 1882–88).

PRESTONPANS, prĕs-tŏn-pănz', Scotland, a small town in Haddingtonshire, on the Firth of Forth, nine miles east of Edinburgh, celebrated for the battle fought in the vicinity, 21 Sept. 1745, when the Highlanders, headed by Prince Charles, defeated the royal troops commanded by Sir John Cope. Pop. 1,923. Consult M'Neil, P., 'Prestonpans and Vicinity' (Tranent 1902).

PRESTWICH, Sir Joseph, English geologist: b. London, 12 March 1812; d. Shoreham, Kent, 23 June 1896. He spent one year at University College, London, continued his geological studies though at the age of 18 he entered his father's office and for many years he was a prominent wine merchant. The Geological Society conferred a medal upon him in 1849, and he received like honors from the Royal Society in 1865. In 1864 he became a member of the Water Commission and in 1866 of the Royal Coal Commission. In 1870 he became president of the Geological Society and in the same year married. In 1872 he retired from business. He became professor of geology at Oxford 1874 and though advanced in years for the adoption of a new profession his vast learning and the vigor with which he approached his new task enabled him to fill the position with great success. His most important researches relate to the Tertiary deposits, which he rearranged and reclassified, and evidences concerning the existence of the prehistoric man. He also applied his knowledge to the practical question of obtaining from underground waters a better supply for cities. He retained his professorship at Oxford until 1888, was connected with various important scientific societies and in 1896 was knighted. He was a Fellow of the Geological Society, the Royal Society, the Chemical Society, the Geological Society of France, an associate of the Institute of Civil Engineers and an honorary and corresponding member of a number of English and foreign scientific societies. Oxford University gave him the degree of D.C.L. in 1888. His writings reached the large number of 140. Of these the following were published in book form: 'A Geological Inquiry respecting the Water-bearing Strata of the Country around London, etc.' (London 1851; new ed., 1895); 'The Ground beneath Us: Its Geological Phases and Changes, etc.' (London 1857); 'An Index Guide to the Geological Collections in the University Museum, Oxford' (Oxford 1881); 'Geology, Chemical, Physical and Stratigraphical' (2 vols., Oxford 1886–88); 'Collected Papers on Some

Controverted Questions in Geology' (London 1895); 'On Certain Phenomena Belonging to the Close of the Last Geological Period, and on their Bearing upon the Tradition of the Flood' (London 1895). The balance of his writings was published in scientific journals and magazines. Consult Lady Prestwich, 'Life and Letters of Sir Joseph Prestwich' (Edinburgh 1899).

PRESUMPTION, *in law,* is a supposition held as good or real before it is shown or certainly known to be so. Presumptions are either *juris,* or *juris et de jure.* A legal presumption in law is one established in law till the contrary be proved. Thus, a person who has the possession of goods is presumed to be the owner, or a man is assumed to be innocent unless the contrary be proved. Presumptions are adopted from the necessity of arriving at some conclusion or other in most cases where the evidence is general or inconclusive. Thus, where a person has disappeared and has not been heard of, the law will in general presume that he is still alive, unless after a lapse of time considerably exceeding the ordinary duration of human life; but if there be evidence of his continuous unexplained absence from home, and of the nonreceipt of intelligence concerning him for a period of seven years, the presumption of life ceases.

PRETENDER, The. See STUART, JAMES FRANCIS EDWARD.

PRETENDER, The Young. See STUART, CHARLES EDWARD.

PRETORIA, prę-tō'ri-ą, South Africa, administrative capital of the Union of South Africa (q.v.) and the province of the Transvaal (q.v.), situated on the banks of the small river Aapies, a tributary of the Limpopo, 4,500 feet above sea-level, 46 miles northeast of Johannesburg, 349 miles by rail west of Delagoa Bay and 1,003 miles by rail northeast of Cape Town. The town is regularly laid out and many of the streets are planted with splendid willow trees. The most important public buildings are the government buildings, in Church Square, surmounted by a statue of Liberty; the post office; the Dutch Reformed church, formerly in the centre of Church Square, destroyed in 1905; the Anglican cathedral of Saint Alban; a Roman Catholic church, with school and convent buildings; a new Dutch Reformed church; the former presidency and residence of the late Paul Kruger (q.v.); the Jewish synagogue, a handsome building; the new market buildings; the law courts; a public library, containing English and Dutch books; the National Museum adjacent to the Zoological Gardens; a new opera-house. Pretoria, since 1916, is the administrative seat of the newly constituted University of South Africa, consisting of six colleges in various parts of the Union with a total of 87 teachers and 560 students in 1915–16. The town is lighted by electricity, and public waterworks were opened in 1891. Just outside the town are the barracks, and near them the prison is situated. In 1896 the Boer authorities began the construction of a circle of six forts round the town, which since the Boer War have been dismantled. Pretoria was founded in 1855, and was named in honor of Andries Pretorius, the first President of the South African Republic. In 1864 it replaced Potchefstroom as the seat of the central administration. In December 1880 the British garrison in Pretoria was besieged by a force of Boers, and on the retrocession of the country in the following year the town was evacuated by the British troops. The gold-rush which began about 1886, and the working of the natural wealth of the neighboring Witwatersrand, had a great influence upon the condition of Pretoria, which was rapidly improved in respect of architecture and sanitation. On 5 June 1900 the town was occupied, practically without opposition, by a British force under Lord Roberts, after President Kruger, who had for many years been the dominant figure of the town, had fled in May, and then became the headquarters of the British operations in the South African War (q.v.). It was at Pretoria that on 31 May 1902 the peace articles were signed. In 1907 the first Parliament of the Transvaal (q.v.), which by that time had become a self-governing part of the British Empire, met at Pretoria. It was later displaced by a Provincial Council. Since 1903 Pretoria is a municipality, controlling its sewers, water and electric-light systems, as well as its trolley lines. There are a number of attractive suburbs, in one of which, Bryntirion, is located Meintjes Kop which has become the site for the public offices of the Union. In the cemetery at the western end of the town are buried Paul Kruger and many of the British who fell in the Boer War. Nearby is also the big new Central Railway station and workshops. The world-famed Premier Diamond Mine is about 30 miles northeast of Pretoria. The population, which before the war was about 12,000, has increased to over 29,618. Consult Berthold, H., 'Pretoria, die Hauptstadt des Neuen Suedafrika' (in 'Zeitschrift für Kolonialpolitik, Kolonialrecht, und Kolonialwirtschaft' (Vol. II, pp. 826–835, Berlin 1909); Hillegas, H. C., 'Pretoria Before the War' (in *Harper's New Monthly Magazine,* Vol. C, pp. 548–557, New York 1900); 'Pretoria. News of the Camp. A Journal Published in the Military Camp of Her Majesty's Forces Defending Pretoria, 25 Dec. 1880 to 9 April 1881' (ed. by C. Du-Val and C. Decker, Pretoria 1880–81).

PRETORIUS (Dutch, prā-tō'ri-ŭs), **Marthinas Wessels,** Boer soldier and politician: b. Natal, 1827; d. Potchefstroom, South Africa, 19 May 1901. He took part in the «Great Trek» of 1836, and in 1852 became commandant-general of the Boers. He made a name for himself in his capacity as commander of the forces making war upon the Kafirs, and shortly afterward (in (1860) he was elected President of the Orange Free State; in 1864 of the South African Republic. Re-elected in 1869, he soon afterward resigned. After the Boer trouble in 1877 and following years Pretorius formed part of the provisional Transvaal government in 1880. After Kruger's election in 1883, Pretorius took small part in the affairs of the republic, being persistently opposed to the war policy against Great Britain as destined eventually to subvert the independence it sought to secure. Pretoria, the capital of the Transvaal, was named in his honor.

PREVENTIVE MEDICINE. Generally the term "preventive medicine" has been regarded as almost synonymous with public hygiene and its application has been confined to the operations of the sanitary authorities in the prevention of the infectious and communicable diseases. These operations have not in the past included even all of the more important communicable diseases, although the list in recent years has been considerably extended. Formerly cholera, plague, yellow fever, typhus fever, epidemic dysentery, smallpox, scarlet fever, diphtheria and typhoid fever practically comprised all of the diseases which came specifically under the supervision of the public health authorities. Recently this list has been considerably increased by some sanitary boards. Many of the diseases referred to — for example, cholera, plague, yellow fever, epidemic dysentery — have practically passed from the supervision of the authorities, at least in the temperate zones, because either they no longer occur at all in these regions or only occasionally a case or a group of cases appears and calls for specific action and supervision. The eradication of these epidemic diseases may be regarded as the greatest triumph of preventive medicine. It will of course be noted that public hygiene or preventive medicine, in this restricted sense, has taken little or no cognizance as yet of many exceedingly important communicable diseases, such as syphilis, gonorrhœa, puerperal fever and, generally speaking, even of tuberculosis.

Preventive medicine in the proper sense has a very much broader scope than that indicated and may be defined as the sum of all medical knowledge applicable to the prevention of disease — of all disease in the broadest sense and not simply of the communicable diseases. It presupposes the widest knowledge of medicine and has its essential foundation in our knowledge of the anatomy and causation of disease. Preventive medicine comprises, therefore, the prophylaxis of disease; it is general, comprising those measures which are applicable to the prevention of disease in the community (including especially the communicable diseases), and it is individual, as applied to the prevention of disease of all kinds in the individual members of the community. General prophylaxis refers to what are spoken of as preventable diseases and these in the broad sense may be regarded as all of the infectious diseases which are communicable. Individual prophylaxis has a still wider scope and includes the whole sum of medical knowledge as applied to the prevention of diseases (of all varieties) and the prolongation of life. General prophylaxis and individual prophylaxis do not always run along wholly parallel lines; for what is best for the individual is not necessarily best for the community. Preventive medicine is an applied science and includes all purely medical knowledge applicable to the attainment of its aim. In securing its aim preventive medicine necessarily improves the general physical well-being of the individual and thus life is rendered not only longer, but happier.

General prophylaxis attains its purposes in different ways. Through the establishment of sea quarantine it attempts to exclude infectious diseases which are endemic. These are spoken of as "quarantinable diseases" and they of course must differ with locality, depending upon what communicable diseases are endemic in a locality. In the United States, plague, cholera, typhus fever, yellow fever and leprosy are the diseases which the authorities especially attempt to exclude from the country. Scarlet fever, measles, diphtheria and smallpox, being endemic, are not held at quarantine, but are referred to isolation hospitals for supervision until their termination. During recent years the quarantinable diseases have been almost completely excluded from this country. Occasionally a case has been admitted at some point and a group of cases or a localized epidemic has followed; but in almost all instances the outbreaks have been of a restricted and local character. It does not seem probable that in North America there will ever again be any serious danger of the prevalence of cholera, plague, typhus fever or leprosy. In dealing with the other communicable diseases specific methods have been devised, depending upon the nature of the disease and the method of its transmission. In some instances the attempt is made to destroy the cause or prevent its entrance into the body; in other instances, to render the individual insusceptible to the cause and at the same time protect him from exposure to infection. For example, the cause of smallpox not being known, it is vain to attempt to destroy it in the individual; but as vaccination renders a person insusceptible to smallpox, it proves an absolutely efficient means for preventing the prevalence of this disease. In cities and countries where vaccination and revaccination are enforced smallpox rapidly disappears, and even when cases are introduced from without, the disease does not extend. Thus in Prussia, where there is compulsory vaccination in infancy and revaccination at different intervals later in life, smallpox practically does not exist. In different portions of the United States the prevalence of smallpox in epidemic form is determined in each instance by the thoroughness with which different communities have been vaccinated. In the recent Great War less than a dozen deaths from smallpox took place in an army of 4,000,000 men.

In typhoid fever the methods followed in prevention are of a different character. The typhoid bacilli which cause typhoid fever are practically always taken into the body through the mouth, usually in drinking water or food. The commonest sources of infection are contaminated water, milk and oysters and also the direct infection of those in immediate contact with typhoid fever cases, by the transfer of the typhoid bacilli to the mouth on soiled hands or from eating or drinking utensils. Aerial infection plays a small part in the causation of this disease. The prevalence of typhoid fever has been very greatly restricted by the protection of the sources of water-supply, by the application of sanitary measures to the collection of milk, by proper disposal of sewage and in recent years by preventive inoculation, which, in large armies, have made what was a formidable disease almost non-existent. Sewage is the medium through which the typoid infection reaches the water-supply. Milk is infected, not when derived from the animal, but subsequently, from the washing of utensils with contaminated water or in some similar way. As yet no active measures have been adopted by the sanitary authorities to prevent the contamination of shellfish through the sewage-pollution of the water in which the shellfish beds are situated. This is probably a much more common source of infection than has been generally supposed. In the case of scarlet fever, measles, diphtheria, chickenpox, whooping-cough and mumps, prophylactic measures comprise the removal of the sick if possible to special isolation hospitals designed for this purpose and the adequate disinfection of clothing, rooms, furniture, bedding, etc., which may have become infected by contact with the sick. At present no other means are available, except in diphtheria, largely because of the lack of knowledge as to the exact causes of these diseases. In diphtheria, besides these measures, there is now a method for rendering the individual insusceptible to the disease for short periods by administering immunizing injections of diphtheria antitoxin. By these injections the individual may be rendered insusceptible to the disease (as in smallpox by vaccination), but the immunity is of short duration.

Many sanitary authorities are now adopting measures for the prevention of tuberculosis, which causes more deaths throughout the civilized world than any other single disease. Here again the problem of prophylaxis differs from that applicable to any of the other diseases mentioned. In tuberculosis the tubercle bacilli, which are the cause of the diseases, are solely contained in the discharges from the diseased tissues, but the only form of tuberculosis (the disease may affect any organ or tissue of the body) in which the discharges containing the tubercle bacilli are likely to be a source of danger to others is tuberculosis of the lungs or pulmonary consumption. In this form, tubercle bacilli are frequently present in the expectoration in almost incredible numbers. The prophylaxis of tuberculosis is, therefore, practically comprised in the destruction of the expectoration of persons suffering from pulmonary tuberculosis at the time of its exit from the body. If this could be absolutely accomplished the transmission of tuberculosis from one person to another would be almost completely avoided. A common source of infection is probably present in the minute drops of atomized expectoration which are forcibly discharged into the air in coughing and sneezing, unless the mouth and nose are covered during these acts. The prevention of tuberculosis only requires the exercise of scrupulous care with regard to the expectoration, the removal to isolation hospitals of those who are unwilling, too ignorant or unable because of weakness, to adopt proper precautions and the disinfection of rooms, with their contents, which have been occupied by tubercular patients. There remain to be considered, aside from this prophylaxis as applicable to the human being the measures necessary because of the possible transmission of the disease from animals, especially through the meat and milk of tubercular cows. But while this is a real danger, its importance has probably been greatly overestimated. It is now well known that tuberculosis very rarely exists at birth. It is never inherited, in the strict sense, and only in very exceptional instances does intra-uterine infection occur.

General prophylaxis has as yet scarcely touched upon many of the other infectious and probably, to some extent at least, preventable diseases. The venereal diseases have been ignored because the problem is so largely a social one. No preventive measures even promising in their character have been suggested for dealing with them. The prevalence of the puerperal diseases has been very largely reduced through individual prophylaxis at the time of childbirth.

The diarrhœal diseases of infancy are not as a rule properly to be regarded as communicable, but their prevalence has been greatly restricted through the work of health authorities in the sanitary control of milk and, to a less extent, of the water-supply. The reduction during recent years in the death-rate from diarrhœal diseases of children under two, which has taken place almost everywhere in this country, is almost phenomenal, and indirectly the reduced prevalence of these diseases has materially decreased others brought on by them — diseases of malnutrition, such as rickets, etc. The results which have thus been accomplished have been due almost entirely to increased medical knowledge and its intelligent application to preventive medicine.

Preventive medicine, however, in the truest, broadest and best sense, includes not only this work in the general application of medical knowledge to restricting the prevalence of the infectious diseases in the community, but also the application of medical knowledge to the protection of the individual from disease of all kinds at every stage in life from birth to old age, and it is this individual prophylaxis which has received the least attention either from the medical profession or from the people. Here is a very large field for intelligence work. A moment's consideration shows at once the impossibility of formulating general rules or of applying the same rules to all individuals, for it is a matter of common observation that individuals differ widely in their physical and mental characteristics, susceptibilities and tendencies. The occurrence in different families of certain similar types of disease in successive generations is a matter of general observation, and the influences which are injurious at one period in life may be not only not harmful but beneficial at another. It is most unfortunate, from this point of view at least, that the family physician of former times is so generally disappearing. The ideal family physician knew thoroughly the family histories of his patients, their tendencies, susceptibilities, weaknesses; he watched every stage in the life of the child from birth; he knew where to restrain, where to encourage and what to prohibit, where dangers to the physical well-being lay and how to advise them for self-protection. In earlier days when the knowledge of disease was less extensive than at present, it was not within the power of the physician to advise as wisely as at present. It is well known now that disease as such is never inherited. It is too much the custom to think of disease as a definite entity, whereas it is really only an abnormal process. It is not possible to see or examine disease, as it has no existence as such, but in some instances the causes of disease may be studied, as is the case in the infectious diseases due to known micro-organisms. In these may be investigated the micro-organisms causing the disease and the changes in the organisms produced by the germs; so also may be studied the abnormal manifestations of life which these changes produce, those manifestations, which are called the symptoms of disease. The so-called inherited diseases which are of an infectious nature are simply instances of infection during intra-uterine life, as tuberculosis and syphilis. The diseases of metabolism, such as gout, diabetes, adiposity, etc., are not instances of inherited disease, when they occur in different generations in the same family, as is frequently the case, but are the result of the transmission from parent to children of functionally inefficient organs, which break down under the demands laid upon them.

Among the more recent additions to general prophylaxis are the movements now actively going forward to prevent mental diseases. This whole movement of mental hygiene is one of the most important of modern times. While it has been recognized for years that a healthy mind can exist only in a healthy body, it is being more and more emphasized that there can be no healthy body without a sound mind.

An absolutely efficient prophylaxis applied to the individual would permit the conduct of a physiological life from birth to its termination in a physiological death, occurring when the vital resistance with which the individual was endowed at birth was exhausted. With advancing medical knowledge and a higher civilization there should be a closer approximation to this condition in a larger and larger percentage of the population and a material prolongation of the mean lifetime.

HERMANN MICHAEL BIGGS, M.D.,
New York State Public Health Commissioner.

PREVIOUS QUESTION, a question put to a parliamentary body with the object of suspending debate on the subject under consideration, the question being put upon a member's motion in order to ascertain if the assembly desire to vote upon the subject at once. The form of the question is: "Shall the main question now be put?" Any member may demand the previous question and if the vote be in the affirmative, the main question as ordered, whether a single motion or all the motions necessary to put the measures through all its stages to final passage, is put to a vote. If the previous question be ordered on a question on which there has been no debate, then 40 minutes of debate are permitted, but if there has been even a brief debate before the previous question is ordered, an immediate vote must follow the ordering of the previous question. The 40 minutes are divided equally between the supporters and opponents of the measure. In practice the member having charge of a measure and having the floor usually calls for the previous question at the end of his speech unless the measure is being debated under a special order. (See CLOSURE; PARLIAMENTARY LAW). Consult Hinds, A. C., 'Digest and Manual of Rules and Practice of the House of Representatives' (Washington 1908).

PREVOST, prĕ-vō', **Augustine,** English soldier: b. Geneva, Switzerland, about 1725; d. England, 5 May 1786. He entered the army, served under Wolfe at Quebec as captain of the 60th regiment. He was promoted to the rank of lieutenant-colonel in 1761, and four years later he was made commander of the troops in the Southern Department and was stationed at Pensacola, and in 1778 captured the fort at Sunbury, Ga., for which service he was brevetted major-general. He then commanded the forces which defeated Gen. John Ashe at Briar Creek in 1779, but failed in an attempt to capture Charlestown in that year. He distinguished himself by his successful defense of Savannah against the Americans and French in October 1779, and received full rank as major-general in recognition of his services. His son was Sir George Prevost (q.v.).

PRÉVOST, prā'vō', **Eugene Marcel,** French novelist: b. Paris, 1 May 1862. He was educated at the Polytechnic School in Paris and until 1891 he was engaged in tobacco manufacturing at Lille. His conceptions are clever and well worked out, his style easy and usually graceful, but his later work, though brilliant, shows a tendency to the delineation of morbid emotional types. His first book, 'Le Scorpion' (1887), attracted great attention from its attack on the Jesuit system of education). His later works include 'Chonchette' (1888); 'Mademoiselle Jaufre' (1889); 'La Cousine Laura' (1890); 'La confession d'un amant' (1891); 'L'Automne d'une femme' (1892); 'Lettres de femmes' (1893); Nouvelles lettres de femmes' (1893); 'Demivierges' (1894); 'Le moulin de Nazareth' (1894); 'Notre compagne' (1895); 'Le jardin secret' (1897); 'Dernieres lettres de femmes' (1897); 'L'Heureux ménage' (1901); 'Nimba'; 'Le mariage de Julienne'; 'Les vierges fortes' (1901); 'Lettres à Françoise' (1902); 'La pas relevé' (1903); 'La plus faible' (comedy 1904); 'La princesse d'Erminge'; L'Accordeur aveugle' (1905); 'Monsieur et Madame Moloch' (1906); 'Femmes' (1907); 'Lettres a Françoise mariée' (1908).

PREVOST, SIR **George,** English soldier, son of Augustine Prevost (q.v.): b. New York, 19 May 1767; d. London, England, 5 Jan. 1816. He entered the army in early youth, distinguished himself in the West Indes, was promoted major-general in 1805 and created a baronet later in the same year. In 1808 he was appointed lieutenant-governor of Nova Scotia and in the autumn of that year he conducted a division of troops to the West Indies where he participated in the capture of Martinique as second in command. He was made lieutenant-general in 1811, and appointed governor-in-chief of British North America, a position he held throughout the war that followed. In the War of 1812 he rendered important service to his government, but his defeat at Plattsburg in 1814 forced him to abandon his attempt to invade New York and brought him under censure. He died before a verdict of the court-martial had been rendered.

PRÉVOST D'EXILES, prā-vō dĕg-zēl, **Antoine François,** French author: b. Hesdin (Artois), 1 April 1697; d. near Chantilly, 23 Nov. 1763. He was at first a Jesuit, then enlisted in the army, after a brief return to the order again turned soldier, and still later joined the Benedictines of Saint Maur. Subsequently he lived in Holland and England, and in 1735 became almoner and secretary of the Prince de Conti. He was a great admirer of England and things English and his writings, his influence and his translations from English into French created a great interest in English literature; and this in its turn helped to pave the way for the democratic and liberal tendencies which later took possession of the literature of France. Rousseau was the first great writer notably to exhibit this tendency. 'Manon Lescaut,' which became immensely popular, influenced most of the great writers from the days of Prévost to Victor Hugo. He founded *Le Pour et le Contre,* a journal patterned after the *Spectator,* which ran through 20 volumes (1733–40); translated Richardson and Hume's 'History of England'; and wrote a 'Histoire des Voyages' (1747–80), and several works of fiction, including 'Le Doyen de Killérine' (1732–35); 'Mémoires et Aventure d'un Homme de Qualité qui s'est Retiré du Monde' (1728–56), which includes 'Manon Lescaut,' a story of some celebrity in French literature, frequently reprinted, and the basis of a drama (1851) by Barrière and Fournier and 'Contes, Aventures et Faits Singuliers' (1764). A selection from his works appeared at Paris in 1810–16. (See MANON LESCAUT). Consult Harisse, 'L'Abbé Prévost' (Paris 1896); Schroeder, V., 'Un romancier français XVIIe siècle, l'abbé Prévost' (Paris 1898); 'Rousseau and the Cosmopolitan Spirit in Literature' (New York 1899); 'Sainte-Beuve,' 'Causeries de lundi' (Vol. IX, Paris 1862).

PRÉVOST-PARADOL, prā-vō pä-rä-dŏl, **Lucien Anatole,** French writer: b. Paris, France, 8 Aug. 1829; d. Washington, D. C., 11 Aug. 1870. He was educated at the Collège Bourbon and the École Normal, was editor of 'La Revue d'Histoire Universelle' in 1854 and in 1855 accepted the chair of literature at the University of Aix, but resigned in 1856 to become editor of the Paris *Journal des Débats.* As a journalist, his keen irony, his brilliant, forcible style rendered him a formidable adversary. A believer in constitutional government he was opposed to Napoleon III. His articles were instrumental in recalling the French army from Mexico, but his contributions to the *Courier du Dimanche* caused the suppression of that journal in 1866. After the formation of the Ollivier ministry in 1870 he became reconciled to the empire and accepted the post of Ambassador to the United States. The trying conditions of the war had generally, preyed upon his mind and he committed suicide shortly after his arrival. His editorials are still considerable models of journalistic style and his books include 'Du Rôle de la Famille dans l'Education' (1857); 'Quelques Pages d'Histoire Contemporaine' (4 vols., 1862–66); 'La France Nouvelle' (1868). Consult Gérard, 'Prévost-Paradol' (Paris 1894).

PREWITT, proo'it, **Theodore Frelinghuysen,** American surgeon: b. Fayette, Mo., 1 March 1832; d. Saint Louis, Mo., 17 Oct. 1904. He was graduated at the Saint Louis Medical College in 1856 and engaged in practice at Utica, Mo., but in 1863 removed to Saint Louis where he remained. He was resident physician and surgeon at the City Hospital, chief surgeon of Saint John's Hospital and dean of the Missouri Medical College. After the consolidation of the Missouri Medical College with the Saint Louis Medical College as the medical department of Washington University he occupied the chair of surgery. He was president of the Saint Louis Medical Society, the Missouri State Medical Society and of the American Surgical Association.

PREYER, prī'ĕr, **Wilhelm Thierry,** German physiologist: b. Manchester, England, 4 July 1841; d. Wiesbaden, Germany, 15 July 1897. He was educated in the universities of Bonn, Berlin, Heidelberg, Vienna and Paris, took degrees in both philosophy and medicine and in 1869 was appointed professor of physiology at Jena. In 1888 he became privat-docent at Berlin. He has made valuable investigations in the fields of quantitative spectral analysis, the perception of sound and the precise qualities of the senses. He carried on important researches relative to the blood, respiration and similar subjects. Of his books the most famous is 'Die Seele des Kindes' (1881), and especially deserving of mention are 'Ueber Empfindungen' (1867); 'Ueber die Grenzen der Tonwahrnehmung' (1876); 'Elemente der allgemeinen Physiologie' (1883); 'Der Hypnotismus' (1890).

PRIAM, prī'ạm, the last king of ancient Troy, was the son of Laomedon and Strymo or Placia. He was the 6th of the Trojan kings and reigned 40 years. His territory included Lesbos, Mysia and the Hellespont. When a youth he marched with the Phrygians against the Amazons, and went as ambassador to the Thracians. After the death of his father he reigned in Troy. By his first wife, Arisbe, daughter of Merops, he had Æsacus. He afterward gave Arisbe to Hyrtacus, and married Hecuba, by whom he had, according to Homer, 19 children, among whom Hector, Alexander or Paris, Creusa, Laodice, Polyxena, Cassandra, Deiphobus, Helenus, Pammon, Polites, Antiphus, Hipponous, Polydorus and Troilus were the most distinguished. By four concubines he also had 30 sons and four daughters. When he was extremely old the Greeks demanded of him the restoration of Helen, who had been carried away by Paris, and on his refusal to give her up they made war against Troy, took and destroyed the city, after a siege of 10 years, his son Hector having already fallen. According to later legends, when the Greeks entered the city he armed himself, to seek death in the midst of the enemy; but Hecuba prevailed upon him to take shelter at the altar of Zeus. Here he saw his son Polites fall by the hand of Pyrrhus; and, unable to contain himself, hurled his javelin at the youth, who dragged the old man by the hair from the altar and plunged a sword into his breast. See TROY.

PRIAPUS, prī-ā'pŭs, in Greek mythology, a field and garden god especially honored in Lampsacus, a town of Mysia, situated in a rich wine country. Aphrodite bore him to Dionysus when the latter was returning from India, though his father unwillingly acknowledged him on account of his ugliness. The first fruits of the crops were offered to him as the god of the fields, the protector of gardens, bees, goats and sheep. Homer and Hesiod do not mention him and it was only in later times that he was honored with divine worship. He was represented with horns and goat's ears, and large phallus, having in his lap all kinds of fruit; in his hand he held a sickle, and usually a horn of plenty. His worship spread from Lampsacus to Greece and thence to Rome. He represents the productive power of nature and is the god of sensual pleasure. His image was set up in gardens and fields to scare away birds; and this was probably the origin of the modern scarecrow; at any rate the «scare-crow» idea had begun to take possession of the more educated before his worship disappeared; and his name was made the subject of many coarse jests by the poets and writers.

PRIBER, prē-bār, **Christian,** French Jesuit in America. He came among the Cherokee Indians in 1736 and took up his residence with them in Great Tellico Town in what is now East Tennessee. Intending to make a dictionary and grammar of the Cherokee language he adopted the dress of the Indians to lessen their feeling of his being a stranger, meanwhile striving to civilize and convert them. His influence among the Cherokees grew to such an extent that they adopted a code of laws he prepared for them thereby exciting the distrust of the English government of South Carolina. Fearing French influence the English demanded Priber from the Indians, who refused to surrender him, and the safety of the English envoy was secured only by Priber's interference. But while traveling in Alabama in 1741 he was seized by the English authorities and cast into prison in Frederica, Ga., where he soon died.

PRIBILOF, prē'bē-lŏf, or «**FUR SEAL ISLANDS,**» a group of islands in Bering Sea, belonging to the United States, about 200 miles north of the Aleutian Islands and 320 miles west of Bristol Bay. The largest islands of the group are Saint George, Saint Paul, Walrus and Otter, while the others consist of a number of islets, all of volcanic origin. The total area is about 180 square miles. This group is of great importance as here is the breeding place of the fur-seal, sea-bear, otter and blue-fox. About May the seal come to Pribilof Islands, where the fog hangs over the land almost continuously. The islands were discovered toward the end of the 18th century by Gerassim Pribylof (or Pribyloff), a Russian, and first mate on the boat *Saint George*. He had been drifting about in the Bering Sea, looking for the breeding place of the fur-bearing seal, and at last he found it. He took possession of the island for Russia, and named it Saint George after his boat. Later the second island was discovered and called Saint Paul and the whole group was named after its discoverer. There are on the islands about 600 permanent residents. Saint Paul, the largest island of the group, has an area of about 35 square miles and a population of over 200. Saint George has about half this population and an area of 27 square miles. In 1868 the Pribilof Islands were made a fur-seal reservation by the American government; and since then schools and churches have been built on the islands, reindeer have been introduced and the condition of the natives has been very materially improved. Consult Elliott, H. W., ‹Our Arctic Province› (New York 1887); Greely, A. W., ‹Handbook of Alaska› (New York 1914); Jones, E. L., ‹Report of Alaska Investigations in 1914› (Washington 1915).

PRICE, Bonamy, English economist: b. Saint Peter Port, Guernsey, 22 May 1807; d. London, 8 Jan. 1888. He was educated at Worcester College, Oxford, and in 1830–50 he was assistant master at Rugby. He then engaged in business and literary work in London and from 1868 he was Drummond professor of political economy at Oxford. He was popular as a lecturer on political economy and was an advocate of free trade. He lectured in the United States in 1874. Besides numerous pamphlets he was author of ‹Principles of Currency› (1869); ‹Currency and Banking› (1876); ‹Chapters on Practical Political Economy› (1878).

PRICE, Ira Maurice, American Orientalist: b. Welsh Hills, near Newark, Ohio, 29 April 1856. He was educated at Denison University, the Baptist Union Theological Seminary at Morgan Park, Ill., and at the University of Leipzig. He was professor of Greek and modern languages at the University of Des Moines (now Des Moines College) in 1879–80; and subsequently was connected with the faculties of the Morgan Park Military Academy, the Wheaton (Ill.) Theological Seminary and Harper's Hebrew Correspondence Schools. He was instructor and later professor of Hebrew and cognate languages at the Baptist Theological Seminary in 1886–1900. In 1900 he became professor of Semitic languages and literature at the University of Chicago, and since 1910 he has also been secretary of that department. He has been associate editor of the *Biblical World* and of the *American Journal of Semitic Languages and Literature* since 1892, and of the *American Journal of Theology* since 1867. He was a contributor to Hastings' ‹Dictionary of the Bible› and ‹Dictionary of Religion›; ‹The Jewish Encyclopedia›; ‹Standard Bible Dictionary›; and the ‹Encyclopedia Americana›; author of ‹Introduction to the Inscriptions Discovered by M. De Sarzec› (1887); ‹A Syllabus of Old Testament History› (1890; 9th ed., 1915); ‹The Ancestry of Our English Bible› (1907; 5th ed., 1911).

PRICE, Julius Mendes, English traveler: b. London, England. He was educated in Brussels and at the École des Beaux Arts, Paris; entered journalism and was a special artist-correspondent of the *Illustrated London News*. In 1884–85 he served in the army with the Bechuanaland campaign in South Africa when he enlisted, for journalistic purposes, as a trooper, in Methuen's Horse, serving with the regiment until its disbandment. He went with the expedition to open up the Nordenskiold route to the interior of Siberia via the Kara Sea, the Arctic Coast of Siberia and up the Yenesei River. He became so interested in the country that he afterward traveled alone through Siberia, Mongolia, and the Gobi Desert via northern China, to Peking (1890–91). Four years later he visited the western Australian goldfields. He was with the Greek army in the Græco-Turkish War in 1897, was engaged in an expedition in the Northwest Territory, Canada, and down the Yukon River to the

Klondike in 1898 and was in China in 1900–01. He served as special artist for the *Illustrated London News* and war correspondent of the *Daily Telegraph* during the Russo-Japanese War (1904–05). In the European War he was with the French army at first and later with the Italian Headquarters Staff, where he was official war correspondent to the Italian government in 1917. He has published 'From the Arctic Ocean to the Yellow Sea' (1892); 'The Land of Gold' (1896); 'From Euston to Klondike' (1898); 'Dame Fashion' (1913); 'My Bohemian Days in Paris' (1913); 'My Bohemian Days in London' (1914); 'Six Months on the Italian Front' (1917). He has also written many magazine and newspaper articles illustrated with his own sketches and drawings.

PRICE, Langford Lovell, English political economist: b. England, 20 July 1862. He was educated at Trinity College, Oxford; was lecturer to the Toynbee Trust in 1886–87 and in 1895–96; Nuomarch lecturer in statistics at University College, London; governor of Dulwich College, 1897; examiner at Victoria University in 1898 and in 1903 was called to that position at the University of Wales. He has published 'Industrial Peace' (1887); 'West Barbary' (1891); 'A Short History of Political Economy in England' (1891); 'Money and its Relation to Prices' (1896); 'A Short History of English Commerce and Industry' (1900); 'The Study of Economic History' (1908): 'Co-operation and Copartnership' (1914): 'Ely and Wicker's Elementary Principles of Economics' (1915).

PRICE, Richard, British Unitarian clergyman and political economist and moral philosopher: b. Tynton, Glamorganshire, Wales, 22 Feb. 1723; d. London, 19 April 1791. In 1743 he became pastor of a Unitarian congregation at Stake Newington, where he continued most of his life. He published in 1758 'Review of the Principal Difficulties in Morals,' which was followed by 'Four Dissertations on the Importance of Christianity, the Nature of Historical Evidence and Miracles, etc.' (1767). In 1771 appeared his 'Observations on Reversionary Payments and Annuities,' succeeded by the celebrated 'Northampton Mortality Tables,' and other valuable works relating to life assurance and annuities. He also published 'Appeal to the Public on the Subject of the National Debt'; and during the contest with the North American colonies, 'Observations on the Nature of Civil Liberty' and the 'Justice and the Policy of the War with America' (1776). This work was widely circulated in this country, and Congress, through Franklin, expressed its desire to receive his assistance in regulating the national finances. When Pitt became Prime Minister he consulted Price in his schemes for the reduction of the national debt, and the establishment of the sinking fund was by his recommendation. Consult Morgan, William, 'Memoirs of the Life of Richard Price' (London 1815).

PRICE, Sterling G., American soldier: b. Prince Edward County, Va., 11 Sept. 1809; d. Saint Louis, Mo., 29 Sept. 1869. He was educated at Hampden-Sidney College, studied law, removed to Chariton County, Mo., in 1831, and in 1840 was elected to the Missouri house of representatives, of which he was speaker until 1844 when he was elected to Congress. He resigned on the outbreak of the Mexican War and organized a cavalry regiment of which he was commissioned colonel. Under General Kearney he marched with his men from Fort Leavenworth to Santa Fé where he was left in charge. Attacked by the Mexicans he repulsed them severely and completed the conquest of California. In 1847 he was promoted brigadier-general of volunteers, became military governor of Chihuahua, and in 1848 won a decisive victory over the Mexicans at Santa Cruz de Rosales. In 1853–57 he was governor of Missouri, and in 1861 presided over the convention called to decide the secession question. He was a «Conditional Union» man but later joined the Confederacy, and in 1861 was appointed major-general of State forces, participating under Gen. Ben McCulloch, in the defeat of the Union forces at Wilson's Creek in August of that year. He then captured Lexington on the Missouri, but was forced to retreat before Frémont. He served under Van Dorn at Pea Ridge in 1862 and was promoted major-general in the Confederate army. He commanded one wing of Van Dorn's army at Corinth. He was defeated by Rosecrans at Iuka, Miss.; accompanied Beauregard in his retreat to Tupelo, and afterward serving in the Trans-Mississippi department, was there engaged in the unsuccessful attempt to capture Helena in 1863. In 1864 he succeeded in preventing General Steele's advance toward Red River, and later made a raid into Missouri. He was driven into southwestern Arkansas toward the close of the war and after the surrender he became interested in a colonization scheme in Mexico. Consult Snead, T. L., 'The Fight for Missouri' (New York 1886).

PRICE, Thomas Randolph, American educator: b. Richmond, Va., 18 March 1839; d. New York, 7 May 1903. He was graduated from the University of Virginia in 1855, studied at the University of Virginia and at Berlin and Kiel. In 1861 returned home to enlist in the Confederate army in which he served through the war on the staff of General Stuart. In 1867 he became professor of Latin and Greek at Randolph-Macon College, being later transferred to the Greek and English chair; and in 1876 he was appointed to the chair of Greek and Hebrew in the University of Virginia. In 1882 he was called to Columbia University as professor of English language and literature and remained at the head of the department until his death. He published 'The Teaching of the Mother-Tongue' (1877); 'Shakespeare's Verse Construction' (1889); edited 'Othello' in the Bankside Shakespeare (1890).

PRICEITE, a friable chalky mineral $3CaO.4B_2O_3.6H_2O$. A source of borax in Oregon.

PRICES. Price is value expressed in money. Thus, price is not identical with value. It is an expression of value in terms of some one commodity, which commodity is called money. Value is thus the more fundamental term; it is the thing expressed, whereas price is the expression of the thing.

The general scale of prices may rise or fall without any material change in the supply of or the demand for commodities in general. The forces of supply and demand, however, operate upon money as well as upon other commodities. It is quite possible for money to become cheap, in which case considerable quantities of money will be given in exchange for small quantities of other commodities. This makes what we call «high prices.» On the other hand, money may become dear, in which case small quantities of money are given in exchange for large quantities of the other commodities. This is what we call «low prices.» The causes of high or low prices therefore may operate on money alone or they may operate on the other commodities for which money is exchanged.

It is commonly assumed that money is cheap or dear according as it is abundant or scarce. The abundance or scarcity of money is undoubtedly a factor in determining its cheapness or dearness; but with money, as with all other commodities, demand is as important as supply. The supply or the quantity, therefore, is only one factor in the problem. With an abundance of money, if there is a general desire to hold on to it and a reluctance to spend it or to let it go, it may remain dear and its purchasing power may remain high. That is, when every one who lacks money is anxious to get it, and every one who has it is reluctant to part with it, large quantities of other commodities may be offered in exchange for small quantities of money. On the other hand, when there is no great eagerness to acquire money except as a means of purchase, no general disposition to hold on to it or reluctance to part with it, it is likely to be cheap; and when every one who lacks money desires to possess it solely for the purpose of spending it quickly, and every one who has it is anxious to spend it for the purpose of getting other commodities as quickly as possible, the result is cheap money or high prices. Large quantities of money are freely spent in order to get small quantities of the other commodities.

If we assume, even for a short period of time, that no change has taken place in the quantity of money or in the desire to possess it, then such change of prices as occurs will be due to factors affecting other commodities. Any change of fashion with respect to dress goods, or change of habit with respect to food, will of course bring about a considerable readjustment of prices. Under such conditions, these changes in the price list become a fairly accurate expression of the desires of the people. That which is most desired will command the highest price. That which is least desired will command the lowest price, whether it be in material commodities or the services of labor which are under consideration. The price list is therefore a pretty safe guide to the desires or wants of the community, and he who is anxious to give the community what it desires could scarcely do better than to follow the price list, whether he be producing commodities or selling his labor. Consult Laughlin, J. L., 'Money and Prices' (New York 1919).

THOMAS N. CARVER.

PRICHARD, James Cowles, English ethnologist and physician: b. Ross, Herefordshire, 11 Feb. 1786; d. London, 22 Dec. 1848. He studied medicine at Bristol, London and Edinburgh, began practice at Bristol in 1810, and in 1814 became physician to the Bristol infirmary. In 1813 he published 'Researches into the Physical History of Mankind' (extended to five vols., 1836–47); 'The Eastern Origin of the Celtic Nations' (1831); 'Natural History of Man' (1843); 'Insanity and Other Disorders Affecting the Mind' (1835); 'Different Forms of Insanity in relation to Jurisprudence' (1842); 'The Relation of Ethnology to other Branches of Knowledge' (1847). In 1845 he was appointed one of the London commissioners of lunacy.

PRICKLY ASH, any of several prickly shrubs of the United States of the rue family (*Rutaceæ*) and genus *Xanthoxylum*, especially *X. clavaherculis*, whose aromatic and pungent bark is used in the Southern States as a rustic remedy for toothache. In the south this bush is therefore known as toothache-tree and pepper-wood.

PRICKLY HEAT. See MILIARIA.

PRICKLY PEAR, a genus (*Opuntia*) of American cactus. About 130 species have been recognized in the region they occupy from British Columbia through the western States, Central America and West Indies to southern South America. They are very variable in their specific characters, and the lines between species are very indistinctly marked. Some are very dwarf prostrate plants; others are tree-like in height and spread of top. They have club-shaped, cylindrical or flat spiny or hairy, fleshy stems, and except upon the youngest joints bear no leaves. These leaves drop off very soon. The flowers, which are borne near the upper parts of the joints or stems and on the most bristly parts, are solitary or in corymb-like panicles and are usually yellow and very showy. The fruit is a modified stem, the ovary being sunken in its apex. It varies with different species from dry to fleshy and succulent, in many species being edible. Prickly pears were in cultivation among the natives when America was discovered, and were introduced by the Spaniards to the Mediterranean region, and finally to Asia, South Africa, Australia, etc. In all these places they are now regarded as troublesome weeds, though in many they are valued for their fruit. In Sicily they are one of the chief crops, the peasants living mainly upon the fruit from July to November. Since some of the varieties will produce about nine tons of fruit to the acre upon land too rocky, thin or poor for other crops; since this production can be counted upon for a long series of years without any cultivation after the plants become established (in three years or less, usually); and since they are highly nutritious, their value is not over-estimated in climates adapted to their culture; namely, dry and frostless. They contain about 14 per cent of sugar and nearly 2 per cent of fat. A crop of nine tons per acre would, therefore, be equivalent to about 2,500 pounds of sugar.

In view of these statements it seems strange that attention has not been directed to improvement of varieties, etc. They have not been ranked with horticultural fruits, though they are of far more economic importance than many that are. In many sections they are used for stock feeding, especially in seasons of drought. The spines are generally rubbed or burned off, but cattle often eat them without this treatment, and frequently suffer death because the spines pierce their intestines. Of late, however, spineless varieties have been cultivated successfully and are used chiefly for stock feed. The plants are most used for fodder in the western States, Africa and Australia. In Tunis, dairymen are rarely without a plantation of prickly pear for their herd. The plants are also planted for ornamental purposes in gardens and greenhouses in many parts of the world not adapted to their cultivation; and in places adapted to them they are favorite hedge plants. The most esteemed species are probably the Indian fig (*O. ficus-indica*), the tuna (*O. tuna*), *O. engelmanni*, and *O. fulgida*, the first two being especially valued for the fruit, the last two for their fodder. *O. vulgaris* is a common species in the eastern States and is hardy as far north as Massachusetts.

PRIDE, Thomas, English Parliamentary officer: d. Nonsuch, 23 Oct. 1658. Early in life he was a brewer and began service in the Civil War as ensign under the Earl of Essex; he was finally promoted colonel. As a soldier he won considerable distinction, being conspicuous at Preston (17–19 Aug. 1648), and commanding a brigade in the Scottish campaign. An extreme anti-Royalist, he was selected by the army to exclude the Royalist members from the House of Commons. (See PRIDE'S PURGE). He was one of the judges of Charles I, whose death-warrant he signed. During the lord-protectorship of Cromwell, he was knighted and made a member of the newly organized House of Lords. See FAIRFAX, CROMWELL, and CHARLES I.

PRIDE OF INDIA, PRIDE OF CHINA, a tree (*Melia asedarach*), of the mahogany family, a native of Lebanon, Syria, Persia and the north of India, and cultivated in different parts of the world as an ornamental tree. It is known in different localities as CAPE LILAC; PERSIAN LILAC; CHINA TREE; PARADISE OR PARAISO TREE; and in Southern America frequently, but incorrectly as PEPPER TREE; and in Australia as WHITE CEDAR. It grows to the height of 30 or 40 feet with a trunk of 20 inches diameter; but in open spaces it is spreading and not so high. Its leaves consist of smooth, pointed, dark green leaflets, arranged in pairs with an odd one at the end. The flowers, hanging in clusters at the ends of the branches, are of lilac color and agreeable perfume. They give place to bunches of berries about as large as cherries, and yellow when ripe. The fruit is sweetish, and edible, though generally supposed to be poisonous. In the cities of the Southern States where the tree was introduced by the elder Michaux early in the 19th century, and upon many of the plantations, rows of Pride of India trees are very common, and in autumn the branches and the ground beneath are covered with their berries. One of its most attractive forms is known as the TEXAS UMBRELLA TREE. A decoction of the bark of the root is administered as a cathartic and vermifuge. In large doses it is said to produce narcotic effects, and such appears to be the action of the ripe berries upon the robin redbreasts, which are very fond of them, and eat them until they become stupefied and fall to the ground. From this state, however, they soon recover.

PRIDE AND PREJUDICE. An admirer of Jane Austen's novels is certain to regard as the best the one he happens to be reading, so admirable are they all in those qualities which make for perfect work; but on reflection he will probably give the palm to 'Pride and Prejudice,' if for no other reason, because he remembers it the longest. This novel, with its clean-cut, logical plot, was published in 1813, though its first draft dates as far back as 1796–97, when Jane Austen was in her 22d year. It is the novel of a girl — a clergyman's daughter — who had been bred in the country among the minor gentry. The scene, except for a few excursions, is laid in two English villages named Longbourn and Meryton. Within these narrow limits, Jane Austen studies the Bennet family — consisting of Mr. and Mrs. Bennet and their six daughters — in relation with their neighbors, and especially with the tenant of Netherfield Park, the young Mr. Bingley and his friend Mr. Darcy. In the end Jane, the eldest daughter of the Bennets, is married to Mr. Bingley; and Elizabeth, the second daughter, to Mr. Darcy; while a younger sister, Lydia, elopes with Mr. Wickham, the villain of the story, who holds a commission in the militia stationed at Meryton.

The novel takes its title from the two leading characters — Mr. Darcy, who is proud of his birth, fortune and attainments, and Elizabeth Bennet, who resents his apparent condescension and superciliousness, and, not understanding his true character, becomes inordinately and unjustly prejudiced against him. Elizabeth's prejudice is first awakened at a village ball, where she overhears a remark of Darcy's in disparagement of herself and the other girls; it is strengthened by Darcy's attempt to detach Bingley from Jane, and by a false story about his dishonorable treatment of Wickham. All the time Darcy is falling in love with Elizabeth, attracted by her very fine eyes, her vivacity, her frankness, her keen intelligence and genuine charm. The climax is reached when Darcy proposes and Elizabeth spurns him. Thereupon Elizabeth soon learns why Darcy has cast off Wickham, the spendthrift and libertine; she is made to understand why he has interfered in the match between Jane and Bingley; and she discovers that but for Darcy, who patched up a marriage between Lydia and Wickham, lasting disgrace would have fallen upon the entire Bennet household. Elizabeth and Darcy come to understand each other perfectly. Pride and prejudice vanish: and the conclusion is as logical as a mathematical demonstration.

In tone and atmosphere, 'Pride and Prejudice' is the novel that approaches nearest to Shakespeare's 'Much Ado About Nothing' (q.v.) Elizabeth and Darcy give us much the same delight that we feel when we read of the wit combats between Beatrice and Benedict. All the other characters are also carefully differentiated. The novel is pervaded with pure comedy, which Jane Austen occasionally allows to approach farce in the delineation of Mrs. Bennet, the match-making mother, and in the Rev. Mr. Collins, who would marry Elizabeth in order to promote his own happiness at the expense of hers. There is no tragedy in the novel. Over all the domestic affairs of life Jane

Austen lets her mind play, diverting the reader with «follies and nonsense, whims and inconsistencies.» Scott despaired of ever attaining to her delicate protrayal of character; and her art has had a potent influence upon Trollope and other later novelists down to Mr. Howells, who writes of her as «the divine Jane.»

WILBUR L. CROSS.

PRIDEAUX, prid'ō, **Humphrey**, English scholar and divine; b. Padstow, Cornwall, 2 May 1648; d. Norwich, 1 Nov. 1724. He was graduated from Christ Church, Oxford, in 1672 and was appointed rector of Saint Clement's, Oxford, in 1679, prebend at Norwich in 1681, archdeacon of Suffolk in 1688, and in 1702 became dean of Norwich. He was a man of studious habits, a deep thinker, acquired a vast store of knowledge, and a wide reputation for judgment, integrity and wisdom. His greatest work was entitled 'The Connecticut of the History of the Old and New Testaments' (4 vols., 1715–18). Among his other works are 'Marmora Oxoniensia' (1676); 'Life of Mahomet' (1697). Consult Thompson, E. M., for his letters to John Ellis, Under-Secretary of State, (published by the Camden Society in 1875); the 'Bibliotheca Cornubiensis' (Vols. II and III); and a 'Life of Humphrey Prideaux' (published anonymously in 1748).

PRIDEAUX, John, English soldier: b. Devonshire, 1718; d. near Fort Niagara, N. Y., 19 July 1759. He entered the army in early youth, and attained the rank of brigadier-general in 1759. In that year he was given command of one of the four divisions which were sent to conquer Canada, and while Amherst, Wolfe and Stanwix co-operated in the north, Prideaux attempted the reduction of Fort Niagara, one of the strongest fortresses in possession of the French. He landed before the fort on 7 July and opened an attack, repelled a sortie on 11 July and on the 19th prevented the landing of the French reinforcements sent by Frontenac, but was killed in the trenches on the same day by the premature bursting of a shell. His work was not without results, however, as the fort surrendered on the 24th. Consult Parkman, Francis, 'Montcalm and Wolfe' (Boston 1884).

PRIDE'S PURGE, the familiar name for the forcible exclusion of Royalist members from the House of Commons in 1648 by Col. Thomas Pride. See PRIDE, THOMAS.

PRIENE, pri-ē'nē, in ancient history, a city of Ionia at the mouth of the Gæson in early times, but because of the alluvial deposits of the Mæander finally lay several miles from the coast. One of the 12 cities in the Ionian League, Priene was conquered by Ardys, a Lydian king, in the latter part of the 7th century B.C. It was mixed up in several revolts against the Persian power, notably the Ionic trouble (500–494 B.C.). Shortly after Priene fell into the hands of Athens. During the power of Alexander in Asia Priene flourished. A new city was laid out and it and the old beautified by additions of the best art of the day. Sometime during the reign of the Byzantine rulers, the city was deserted and it was subsequently covered by débris caused principally by earthquakes, and on Crœsus' overthrow became the property of Persia. The great temple of Athena Polias, the scene of the festival called the Paniona, was here; a dedication upon it by Alexander the Great is now in the British Museum. In 1868 the temple of Athena Polias (erected under the direction of Pythias) was excavated for the Dilettanti Society by Pullan and Newton, who have shown that it was one of the finest pieces of Ionian architecture ever built. The plan of the ancient city has been made plain by explorations in 1895–99 under the management of the Royal Museum in Berlin. These show that the city had been planned with great care and had been looked after as the best of the Greek cities were. The excavations, therefore, have made of the ruins one of the most important sources of information concerning the Greek city life of the period. The market place, theatre, temples and other public buildings, together with a vast amount of sculpture and inscriptions, were unearthed. Consult Bædeker, 'Konstantinopel, Balkanstaaten, Kleinasien' (Leipzig 1914); Frothingham, A. L., 'Priene' (*Century Magazine*, Vol. LXII, 1901); Gärtringen, H. von, 'Inschriften von Priene' (Berlin 1907); Lenschau, 'De Rebus Prienensibus' (Leipzig 1890); Leutner, 'Priene' (*Classical Weekly*, Vol. V, 1911); Pullan and Newton, 'Antiquities of Ionia' (London 1881); Wiegand, 'Priene' (Berlin 1898).

PRIESSNITZ, prēs'nits, **Vincenz**, founder of the Kaltwasskur, or system of hydropathy (q.v.): b. Gräfenberg, Austrian Silesia, 4 Oct. 1799; d. there, 28 Nov. 1851. Having effected by the application of cold water a cure of a severe injury he had received, he subsequently employed it in local cases as a healing agent. Two English physicians, Sir John Floyer and Dr. Currie of Liverpool, had anticipated him in advocacy of the method, and a Silesian, Hahn, had published a book on it derived largely from a work by Floyer. But Priessnitz was the first to develop hydropathic practice. He established with the permission of the government an institution at Gräfenberg which was much frequented, among the guests being many physicians who came to study his claims. He wrote nothing himself, but many records of experiences of his cure, most of them favorable and many enthusiastic, were written by others. Consult the study by Selinger (1852); and Philo von Walde, 'Priessnitz als Begründer des Wasser- und Naturheilfahrens' (1897).

PRIEST, Josiah, American author: b. New York, about 1790; d. western New York, about 1850. He was a harness-maker, but became self-educated and published several books, some of which became very popular. Among them were 'Wonders of Nature' (1826); 'View of the Millennium' (1828); 'Stories of the Revolution' (1836); 'American Antiquities' (1838); and 'Slavery in the Light of History and Scripture' (1843).

PRIEST, one who performs the sacred rites of any religion, especially the sacrificial rites, and who is thus a mediator between the Deity and men.

In primitive times the function of priesthood was inherent in the head of a family, the *pater familias*; but as states were organized priesthood on behalf of the people was assumed by the chief or king, or was exercised, under him, by a special order of men; but still the rites of domestic religion would continue to be performed by the head of the household. In early Greece and Rome when kings were banished and the power of the state came into the hands of elected magistrates the priestly office of the king, or his headship in religious affairs, was vested in the *archon basileus* as at Athens, or the *rex sacrorum* as at Rome; the term king (*basileus, rex*) being retained after kingship had been done away, doubtless because of some religious scruple, lest the gods should resent the lowering of the appellation of the head of the state religion. The priests of the state religion were now appointed by the public authority, whether their functions were general or were restricted to the service of special gods in special temples.

In Rome there never was in pagan times anything like a priestly order or priestly caste or class, as the order of knights (*equites*) or patricians (*patricii nobiles*), nor was priesthood hereditary. In Greek states the priestly service in certain temples and places was restricted to certain families; for the rest the priesthood was a function of the state. In Egypt the priesthood was a very close corporation, the members of which, with the king at their head, were the supreme arbiters of civil and even military as well as of religious affairs; the priesthood alone possessed whatever science existed of the mysteries of religion or of the secrets of statecraft, or the laws of nature.

In primitive Israel, as in other primitive societies, priesthood was the attribute of the father of the family: the priest by vocation, as a man set apart to minister on behalf of the people in their relations to the Deity, does not come into view till the Mosaic epoch; and the fully developed priestly system of Israel did not come into existence till the time of Solomon or even, perhaps, till after the return of the people from Babylon and the building of the second temple at Jerusalem by Zerubbabel in 520 B.C., nearly 500 years after Solomon's reign. Before the building of Solomon's Temple there were in Israel several temples or sanctuaries with oracles that were consulted to ascertain the will and pleasure of Jehovah, and with priests as their interpreters; and the priests and the Levites constituted a distinct order of society; but after the secession of northern Israel every devout king of Judah earnestly sought to suppress religious worship or sacrifice everywhere save in the central national temple: this end was not achieved till after the return of the captives from Babylon. Henceforth the worship even of the true God elsewhere than in the temple at Jerusalem was denounced as impious and little different from worship of false gods. The entire priestly order was massed in Jerusalem and its neighborhood; the priests were distributed into 24 classes, each presided over by a chief priest, and each class of priests ministering in the temple one week in rotation. Over the whole priesthood presided the high priest, believed to be always a lineal descendant of Aaron, the brother of Moses.

The ministers of the several religions mentioned, as well as those of Phœnicia, Babylon and other countries, are styled in English «priests»: in Hebrew, Greek and Latin, respectively, the priest is *Kohen, hiereus* and *sacerdos*. But the English word priest, derived from the Greek *presbyteros,* an elder person, has not in itself any denotation of sacrifice or of priestly function but only of maturity of age.

In the Greek New Testament the priest of the Jewish law is always called *hiereus* and in the Latin Vulgate version *sacerdos,* never *presbyteros,* or *senior* (elder). On the other hand, neither in the Greek original nor in the Vulgate Latin version of it is *hiereus* or *sacerdos* ever said of the minister of the religion of Jesus Christ, but always *presbyteros* and *presbyter*; and in the authorized English version *presbyteros* is invariably rendered elder, never priest. Nevertheless, in the Book of Common Prayer of the Anglican Church and in that Church's Articles of Religion the word priest is everywhere employed instead of elder; but this «priest» of the Prayer Book is not *hiereus, sacerdos,* a sacrificing priest; for in the Articles the sacrificial function of the priest of the Catholic Church is classed with «blasphemous fables and dangerous deceits.» Hence for the Anglican Church, as for all the other Protestant churches, the priest, presbyter or elder is not the minister of a sacrifice. It is different in the Catholic Church and in the numerous Christian churches of the East. Those churches teach, with the Church of Rome, that in the Christian dispensation it is the chief office of the priest to offer sacrifice, namely, the eucharistic oblation, which is a perpetual representation of the offering made on Calvary. In the belief of those churches the mass is the selfsame sacrifice which Christ offered — the victim the same, the priest the same: for the victim is Jesus Christ, his body and blood; and the priest is the incarnate Son of God in Heaven, the High Priest, who is represented in the mystic offering by the priest who ministers at the altar.

It is worthy of mention that till the middle of the 3d century no extant writing of any of the fathers employs the Greek or the Latin word for priest (*hiereus, sacerdos*) to designate the *presbyteros*. In the Roman pontifical the order of the priesthood is called both *presbyteratus* and *sacerdotium*.

PRIEST OF KIRCHFELD, The. The folkplay in Viennese dialect, 'Der Pfarrer von Kirchfeld,' produced 5 Nov. 1870, in Vienna, is Anzengruber's most popular drama even if in the opinion of the critics it is not his best. It raised a struggling unknown author to fame, partly because of its freshness and inherent excellence, but more because it voiced popular feelings in regard to the celibacy of the clergy, mixed unions, enforced civil marriage and the relation of church and state as affected by the declaration of papal infallibility in 1870.

The scene is laid just outside of Austria in the most conservative portion of Old Bávaria among a simple peasantry «whose passions, expressed without reservation or but clumsily concealed» were a novel revelation of human nature to theatregoers. Priest Hell and his feudal adversary, Count Finsterberg, reveal by their very names the nature of the conflict which is precipitated by Hell's innocent gift of a little gold cross to his ward, the orphaned, penniless Annerl. This gives the vagabond Wurzelsepp an opportunity to ruin the Priest with his parish as an expression of hatred caused by ecclesiastical prevention of his union to a Lutheran girl 20 years before. In the best scene of the play Hell converts and wins the friendship of this enemy when he permits the burial of Wurzelsepp's suicide mother in consecrated ground. But this employment of his own judgment against the law of the Church loses for him his parish.

Though a member of the «church militant and regnant» he had sought like the 'Monk of Wittenberg' for a way short of the requirement to inquire «May I do it, just as I mean it?», a way which makes men «indifferent or apostate.» Herein lies a part of the tragedy of his position. However, he becomes no champion of the «Away from Rome» movement, which later gained such strength. He conquers self, and submits. More tragic, almost to the point of suicide, is his love for Annerl, who also learns resignation like all Austrians, by giving hand and allegiance to the peasant, Michel. It is this soul conflict, more than its politico-religious purpose, which makes the play great. First produced in the Folktheatre «an der Wien,» it gradually found its way over all German-speaking lands, being played 632 times between 1899 and 1905. Text Vol. VI of Gesammelte Werke (1898). Criticism Sigismund Friedmann, 'Ludwig Anzengruben' (Leipzig 1902).

CARL E. EGGERT.

PRIESTLEY, prēst'lĭ, **Joseph,** English physicist and Unitarian divine: b. Fieldhead, Yorkshire, 13 March 1733; d. Northumberland, Pa., 6 Feb. 1804. After a secondary education he accepted an invitation to become Presbyterian minister of Needham Market, Suffolk, on an average salary of £30 a year. After three years he took charge of a congregation at Nantwich, Cheshire, to which he joined a school. Here his reputation increased, and in 1761 he was invited by the trustees of the Dissenting academy at Warrington to occupy the post of tutor of languages and *belles-lettres* under Dr. Aiken. A visit to London having introduced him to Drs. Franklin, Watson and Price, he was encouraged to compose a 'History of Electricity,' which appeared in 1767. In the same year he became minister, at a salary of £100 a year, of the Mill Hill chapel at Leeds, where his religious opinions grew decidedly Unitarian. At Leeds his attention was first drawn to the properties of «fixed air» (carbonic acid gas); and about this time he completed his 'History and Present State of Discoveries relating to Vision, Light and Colors.' In 1771 he agreed to accompany Captain Cook on his second voyage in the capacity of astronomer, but his appointment was canceled, as the Board of Longitude objected to his theology.

After six years at Leeds he accepted an invitation from the Earl of Shelburne, afterward Marquis of Lansdowne, to reside with him as a companion in the nominal capacity of librarian. While forming a part of the establishment of this nobleman, he occupied himself in scientific pursuits, and in 1773 gave to the 'Philosophical Transactions' a paper on the different kinds of air, which obtained the prize of Copley's gold medal. On 1 Aug. 1774 he discovered oxygen or «dephlogisticated air,» as he called it, a result quickly followed by other important discoveries, such as nitrous gas, nitrous oxide gas, sulphurous oxide gas, fluoric acid gas, muriatic gas and ammoniacal gas, etc. By these exploits he may be said to have been almost the first to render chemistry a precise science. In 1775 he published 'Examination of the Doctrine of Common Sense, as held by Drs. Reid, Beattie, and Oswald,' and soon after the treatise of Hartley. He had already declared himself a believer in the doctrine of philosophical necessity, and in a dissertation annexed to his edition of Hartley expressed some doubts of the immateriality of the sentient principle in man. This doctrine he still more forcibly supported in his 'Disquisitions on Matter and Spirit' (1777). Probably because of his «materialistic» views, the connection with Shelburne was dissolved in 1780, Priestley retaining an annuity by original agreement. He next removed to Birmingham, where he became once more minister of a Non-Conformist congregation, and occupied himself on his 'History of the Corruptions of Christianity' (1782), and 'History of the Early Opinions concerning Jesus Christ' (1786). With Erasmus Darwin, Watt, Boulton, Wedgewood and other famous men he founded the now celebrated Lunar Society, which rendered Birmingham for the time of its existence almost the intellectual centre of England. His 'Familiar Letter to the Inhabitants of Birmingham' was written in support of the claims of Dissenters for a repeal of the test acts. The era of the French Revolution, whose principles Priestley vindicated, added to the usual animosity of theological dispute. The anniversary of the capture of the Bastile being celebrated at Birmingham, a mob assembled, and although Priestley was not present, burned his house, and nearly all his library, manuscripts and apparatus. The outrage was countenanced by too many exercising both lay and clerical influence, and the legal compensation which he obtained fell short of his real losses by about £2,000. On 1 Aug. 1874, Birmingham made some amends for the wrong done to her greatest citizen, by the erection of a marble statue of him in front of the town-hall. On quitting Birmingham (1791) he succeeded his friend Price as preacher in the Gravel Pit Chapel, Hackney, where he remained some time in the cultivation of his scientific pursuits, until finally goaded by party enmity to seek an asylum in the United States, which he reached in 1794, and took up his residence at Northumberland, Pa. In America he dedicated his whole time to his accustomed pursuits. Some discourses of his led to the formation in Philadelphia of a Unitarian congregation and he held private meetings in his own house. He was never naturalized; and, curiously enough, never learned to make change in United States coinage. Priestley was an ardent controversialist, chiefly in consequence of extreme simplicity and openness of character; but no man felt less animosity toward his opponents than he did, and many who entertained the strongest antipathy to his opinions were converted into friends by his gentleness and urbanity in personal intercourse. As a man of science he stands high in the field of invention and discovery, and to few has pneumatic chemistry been so much indebted. On his own admission his researches in his favorite science were superficial, and his great discoveries to a considerable extent accidental. But this should detract nothing from the honor due to the earnest pioneer. As a metaphysician his elucidation of Hartley's theory of association, his works upon philosophical necessity and upon materialism will always insure attention. As a theologian Priestley, who followed his convictions wherever they led him, passed through all changes, from Calvinism to a Unitarian system in some measure his own; but to the last remained a zealous opposer of infidelity. Of his theological and controversial productions, those most generally esteemed are his 'Institutes of Natural and Revealed Religion' (1772–74), and 'Letters to a Philosophical Unbeliever' (1780–82). He also wrote many works of practical divinity. There is an edition of his 'Theological and Miscellaneous Works, with Memoirs and Correspondence' (1817–32).

PRIGG CASE, The, in American history, a famous slave case tried in 1837. Edward Prigg caused a fugitive Maryland slave-woman to be returned to her mistress, in violation of a Pennsylvania statute forbidding the carrying of any negro out of the State in order to enslave him. The case was finally brought before the Supreme Court of the United States, where it was contended that the statute was unconstitutional since it conflicted with the National Fugitive Slave Act of 1793. The opinion was handed down that the national law must be carried out by national authorities alone.

PRIM, Juan, hoo-än' prēm, COUNT DE REUSS, MARQUIS DE LOS CASTILLEJOS, Spanish general and statesman: b. Reuss, Catalonia, 6 Dec. 1814; d. Madrid, 30 Dec. 1870. Destined for the law, he entered the ranks of the volunteers in the cause of the infant Queen Isabella on the outbreak of the civil war, which in 1833 followed the death of Ferdinand VII. At its close in 1839, Prim threw himself into politics, and when Queen Maria Christina quitted Spain, worked in behalf of the Progresista party against Espartero, who, 8 May 1841, had assumed the regency. In May 1843 he led the insurrectionist forces against Espartero, and upon the downfall of the Espartero ministry was rewarded by the queen by being created successively brigadier-general, Count de Reuss, and in 1843 governor of Madrid. Suspected later of conspiracy against the government in 1844, he was sentenced to six years' imprisonment but was released after six months, and made governor of Porto Rico. Distinguishing himself in the war against Morocco at the battle of Los Castillejos, 1 Jan. 1860, he was given the title of Marquis de los Castillejos. He commanded the Spanish expedition, which acting jointly with the French and English landed in Mexico early in 1862 to enforce claims of indemnity against that country, but withdrew his troops almost immediately. Again accused of conspiracy, he was banished in 1864, but headed an uprising in January 1866 against the government and was compelled to flee to England in 1867. From there he gave support to a revolution started in Spain that summer and in September suddenly appeared in Cadiz and fought against the government in the military revolution headed by Topete and Serrano. Upon the defeat of the government Serrano appointed Prim Minister of War in his provisional government. He became head of the Cabinet and procured the election of Amadeo, Duke of Aosta, second son of the king of Italy, as king of Spain. He was shot by unknown assassins while driving through Madrid. Consult Jimenez, F., 'Historia Militar y Politica de D. Juan Prim' (1860); Leonardson, 'Prim' (1901).

PRIMARY, Direct. A direct primary is an election held by political parties at which candidates for nomination are chosen directly by the voters of those parties. Under this method, voters select their nominees directly, whereas under the delegate or convention system the voters send their delegates to a convention at which the party candidate is nominted (see CONVENTION, POLITICAL). The convention system was so indirect in its methods and so many times accompanied by sharp practices on the part of rings of professional politicians and office-holders that a more effective method of nominating candidates was sought in order that nominees should represent the will of the rank and file of the party who cannot make politics their business. Moreover, the argument was advanced that the mass of the party members would regain control of the government of the party and the electors would exhibit a greater interest in party nominations. This has proven to be the case, the vote at the primaries as a rule being larger than under the delegate system, while the party electorate expresses its will more directly and effectively, thus making the party rulers more amenable to the party will. Even though the bosses may prepare a nomination "slate" or list of candidates at a preliminary or pre-primary caucus, the rejection of these candidates or the elimination of the unfit is an easy task, since the primary practically amounts to a referendum on the caucus nominees. Hence, party leaders are directly responsible for the personal qualities and principles of the candidates presented, and would scarely run the risk of discredit and overthrow by having the party electorate repudiate their candidates. In Oregon and some other States each candidate is afforded an opportunity to give widespread publicity to his platform or principles; the pictures and statements of all the candidates are printed and bound in a publicity pamphlet, which, for a small consideration, is distributed to the voters before the primary. In Wisconsin a candidates' convention frames the platform, the convention consisting of all party candidates for State offices and for the legislature and of any members of the senate who have held over. Thus the voter receives a concrete statement of the policy by both the legislative and executive departments. In Missouri the State central committee, together with the party nominees for State office, for the legislature and for Congress, formulate the platform. In Oregon, when the petition is filed, the candidate may set forth his principles in a paragraph of not more than 100 words, and he is also allowed a 12-word sentence upon the ballot. If 10 per cent of the party voters in Texas petition, a question of party policy must be submitted to the voters at the primary and the party cannot be pledged to any policy which has not been endorsed by a majority of the voters.

In most States a mere plurality of votes cast determines the nomination, but in the Southern States a clear majority is often required and if no candidate should receive the necessary number of votes a second primary is held at which only the two leading candidates are considered. Some States use the minimum percentage plan, Iowa requiring 35 per cent of the total vote, while Michigan requires 40 per cent for governor and lieutenant-governor. Idaho, North Dakota, Wisconsin and a few other States have adopted a system known as preferential voting, under which first and second choices for a given office are indicated and if no candidate receives a majority of first choice, the lowest candidate is dropped and the second choices are then distributed. The object of the preferential vote is to eliminate a second ballot and to prevent the choice of a candidate by plurality only. In some cases even third choices may be indicated.

The advent of the direct primary has had a large influence on the personnel and character of the national government, since it affects the choice of senators, representatives, Presidential electors and delegates to national conventions. The application of direct primaries to senators and representatives has been provided for without extended discussion, but the States have been slow in applying the system to the choice of delegates to the national nominating conventions. Wisconsin started the movement and several other States have provided for a direct vote for delegates. The next move is to have the electors of each party in each State at the direct primary instruct their delegates to the national convention as to the party preference for Presidential nominee. A primary law extended to Presidential nominations was adopted by Oregon in 1910 and since that time the Presidential preference primary has been adopted by many States. (See PRIMARY, PRESIDENTIAL PREFERENCE). After all the States have adopted the plan of choosing their delegates to conventions by direct primary, the next logical step (though its adoption is now very problematical) is to provide for the nomination of a Presidential candidate by the direct popular vote of the entire party. This would soon result in a direct vote of the whole country for President and thus eliminate the antiquated electorial college (q.v.). In most cities the direct primary has been discarded in order to eliminate national party politics and in its place non-partisan primaries and nomination by petition only have been substituted. See ELECTIONS.

The earliest system of direct selection of candidates was the Crawford County system used in Pennsylvania in the sixties, but though this was adopted in the Southern, Central and Western States, its use was not general until the nineties. Minnesota adopted the direct primary for Hennepin County in 1899 but Wisconsin by her law of 1903 was the first State to adopt this method for all nominations. The State-wide direct primary is now used in almost all of the States; it was adopted by Oregon in 1904; by Iowa, Missouri. North Dakota, South Dakota, Nebraska and Washington in 1907; by Ohio, Kansas and Oklahoma in 1908; by California, Nevada, Idaho, Tennessee, Michigan and New Hampshire in 1909; by Arizona in 1909 and 1912; by Illinois, Maryland and Colorado in 1910; by Wyoming, New Jersey, Massachusetts and Maine in 1911; by Minnesota, Virginia, Kentucky, Mississippi, Louisiana and Montana in 1912; by New York, Pennsylvania and Florida in 1913; and by Vermont, Indiana and West Virginia in 1915; while in South Carolina, Georgia, Alabama, Arkansas and Texas it is conducted under the rules of the Democratic party but has not been established by statute for all parties. See BALLOT; CONVENTION, POLITICAL; CAUCUS; ELECTIONS.

A., 'Political Parties and Party Problems' (rev. ed., New York 1914).

PRIMARY, Presidential Preference, a method adopted by some States of applying the direct primary to the choice of delegates to national political conventions. A widespread belief that the national conventions, in their entire membership, had not been truly representative of the party voters and did not reflect the preference of the majority resulted in the enactment of laws for the choosing of delegates directly by the party voters in official primaries. The laws passed by the States vary regarding the degree of directness with which the preference is expressed and the measure of certainty of its being carried into effect. Under the California and South Dakota laws, a number of candidates, corresponding to the number of delegates to which the State is entitled, may file a nominating petition as a group, pledged to the interest of a given candidate for President. These names are placed on the ballot together and the voter may by one mark cast his ballot for the entire group at once. Before a group may be placed on the ballot, the law requires that not less than one nor more than three of the persons named reside in the same Congressional district; and the group must also have the endorsement of the Presidential candidate whose cause it has espoused or of a State organization possessing his confidence. In Illinois, New Jersey, New Hampshire and Ohio the Congressional district is the unit for electing delegates. In Illinois the candidate for delegate must file with his nomination petition a statement of his preference for President or a statement that he has no choice; and on the official primary ballot the preference or lack of preference is printed beneath the name of each candidate. In Ohio the delegate files a first and second choice for President, both of which are printed on the ballot, but the candidate as an alternative may state that if elected he will support for President the candidate receiving the majority of the preference votes. The New Hampshire law simply permits candidates for delegate or delegates at large to pledge that if elected they will vote at the national convention for a given candidate for the Presidential nomination as long as his name remains before the convention. The delegates from Oregon and Montana are elected at large, but in order to secure minority representation the voter is allowed to cast his ballot for one person only as a delegate. Those candidates receiving the largest number of votes are declared elected. A direct Presidential preference vote is held at the same time and candidates for delegate pledge themselves under oath to accept the popular choice. Delegates from Pennsylvania and North Dakota are bound by the preference vote but the vote is not binding on delegates from Massachusetts, Minnesota, Nebraska, Texas and Wisconsin. The Iowa ballot contains the names of candidates for President and Vice-President, party national committeemen, delegates at large, district delegates, and alternates of the last two. The voter is also called upon to decide by a vote of yes or no whether district delegates to the national convention shall be instructed by the vote of the State at large or by the vote of the Congressional district. Maryland combines a preference vote with an election of delegates by a State convention. The county delegates to the State convention are instructed by the voters of the county to support a certain candidate and must do so as long as this candidate has the support of nine counties. The Presidential candidate receiving the votes of a majority of the delegates becomes the choice of the State party and must be given the support of the State delegation at the national convention. A majority of the Presidential primary laws are mandatory. Since Presidential primaries are held under the regular primary laws, candidates for delegate, in order to have their names placed upon the ballot, must file nominating papers. Likewise in most of the States having such laws, Presidential candidates, either personally or by duly authorized State organizations, must file petitions signed by a designated percentage of their party supporters in the State. In 1910 Oregon extended her primary law to Presidential nominations and in 1913 applied direct nomination to the office of national committeemen; she was followed in 1911 by New Jersey, North Dakota, Nebraska and Wisconsin; in 1912 by California, Illinois, Maryland, Massachusetts, South Dakota, Montana and Michigan; in 1913 by New Hampshire, New York, Pennsylvania, Ohio, Minnesota and Iowa; in 1914 by Texas, and in 1915 by Vermont, Indiana and North Carolina.

PRIMARY ROCKS, formerly applied by geologists to the earliest rocks, including particularly those owing their present state to igneous agency. Gneiss, various schists and granite were so regarded. At the present time primary is used as equivalent to Palæozoic (q.v.).

PRIMARY VOLTAIC CELL. See ELECTRICAL TERMS.

PRIMATE, since the 4th century of the Christian Church, the title assumed by the bishop of the capital of a province, and hence equivalent to metropolitan or exarch. The Council of Chalcedon decreed that the primacy, or "first place before all," was to be accorded to the "archbishop of Old Rome." In Africa the title belonged to the bishop of Carthage. In other parts of Christendom an attempt was made to distinguish between primates and metropolitans as early as the 9th or 10th century, for one of the capitularies of the early French kings ordains that no metropolitan shall assume the title of primate unless he has a just claim to that honor; and in the 11th century the popes expressly reserved the title only for the leading metropolitans in different countries, and endeavored to subordinate the other metropolitans to them. The resistance to this arrangement was, however, so general and emphatic that the dignity of primate remained little more than a nominal one, entitling the holder of it merely to precedence on public occasions. In France the archbishop of Lyons was appointed primate of the Gauls by Gregory VII in 1079, and the archbishop of Rouen is also primate of Normandy. In the German Empire the archbishop of Salzburg was primate. In Hungary the archbishop of Gran is primate; in Bohemia that of Prague; in Spain that of Toledo. In Poland the primacy belonged to the see of Gnesen. None of these bishoprics any longer retain primatial rights of jurisdiction excepting that of Gran. The office belonged of right to the papal legate, who was president of the Senate and censor of the king. He governed the state during an interregnum, had a court, guards, and a marshal of the palace, and in general enjoyed the highest privileges. In the Church of England both the archbishops still retain the title of primate, the archbishop of Canterbury being distinguished as the primate of all England and the archbishop of York as the primate of England. In the Protestant Episcopal Church of Ireland the archbishop of Armagh is primate as formerly when the church was established.

PRIMATES, the name given by Linnæus to his highest order or group of the *Mammalia*, which included the bats (*Cheiroptera*), the apes, monkeys, and lemurs (*Quadrumana*), and man (*Bimania*). By common consent of zoologists the bats have been removed, leaving the monkeys, lemurs and man as a fairly homogeneous group. Formerly the definition of this order was comparatively easy, but owing to numerous recent palæontological discoveries an almost unbroken series of forms between the lemurs and the *Insectivora* is now known, and the interrelationships between the former and the higher apes, and of the latter with one another and with man, have been shown to be more complex than was anticipated. Leaving out of account the prelemurine fossils, the order may be characterized as follows: There are always complete milk and permanent dentitions, the latter having the various kinds of teeth well differentitated and usually the following formula: Incisors, $\frac{2}{2}$; canines, $\frac{1}{1}$ premolars, $\frac{3}{3}$ or $\frac{2}{2}$, and molars $\frac{3}{3}$ or $\frac{2}{2}$ (rarely). Occasionally there is the loss of an incisor, premolar or canine. The molars are of the simple quadritubercular grinding type, and the premolars are still simpler. In all cases the orbit is surrounded by a bony ring and frequently separated from the temporal fossa by a plate of bone. The clavicles are well developed, the radius and ulna and the tibia and fibula (except in one case) are never coalesced, the scaphoid and lunar bones of the wrist are distinct, and the pollex and hallux (except the latter in man) form opposable thumbs. With a few exceptions among the lemurs and marmosets, the digits are all terminated by flat nails. Except in isolated cases the stomach is always simple, there are two pectoral mammæ and the testes are contained in a scrotum. Concerning the subdivision of the order in suborders and families there are several opinions; but the customary recognition of the sub-order *Prosimiæ* or *Lemuroidea* for the lemurs and their allies, of *Quadrumana* for the monkeys, baboons and marmosets, and of *Anthropomorpha* for the apes and man will serve present purposes. Consult Hartman, 'Anthropoid Apes' (1886); Forbes, 'Handbook of Primates' (1896–97).

PRIMATICCIO, Francesco, frăn-chĕs'kō prē-mä-tēt'chō, Italian painter: b. Bologna, 1504; d. France, 1570. He was a pupil of Innocenzo da Immola and Bagnacavallo, and began in 1525 to study under Giulio Romano. In connection with several of the pupils of the latter he painted the Palazzo del Tè, in Mantua, from Giulio's designs. Through the recommendation of Frederick, Duke of Mantua, Primaticcio was engaged by Francis I of France in 1531 to decorate the palace of Fontainebleau. To his influence were owing not only numerous paintings in fresco and works in stucco which the king caused to be executed, but several branches of painting, as, for instance, enamel painting, and designs for tapestry, were carried to greater perfection through his exertions. Francis sent him to Italy to purchase antique statues, and casts of famous works of art. On the death of Rosso, the royal painter, Primaticcio succeeded to his post, and Francis II appointed him in 1559 superintendent of the royal buildings. He furnished the designs of several architectural works, among them of the tombs of Francis I and Henry II. His works at Fontainebleau, however, gained him more reputation. His was a clever, facile pencil, but he was the slave of mannerism and meretriciousness, and that fluent but artificial elegance which remained so long the characteristic of French art. His frescoes and stucco work have been almost all destroyed; we can only judge of their quality from engravings, and there are no oil-paintings which can with certainty be ascribed to him; even the authenticity of 'The Continence of Scipio' now in the Louvre is sometimes doubted.

PRIME, Edward Dorr Griffin, American Presbyterian clergyman and religious journalist: b. Cambridge, N. Y., 2 Nov. 1814; d. New York, 7 April 1891. He was graduated in 1832 from Union College, and from Princeton Theological Seminary at Princeton in 1838. He filled several pastorates, including that of the Eighty-sixth Street Presbyterian Church, New York, and contributed articles to the *New York Observer* under the signature "Eusebius." With his brother, S. I. Prime (q.v.), he edited the paper 1854–85, and continued to edit it a year longer after his brother's death. He published 'Around the World' (1872); 'Forty Years in the Turkish Empire' (1875); 'Notes, Genealogical, Biographical and Bibliographical of the Prime Family' (1888), etc.

PRIME, Samuel Irenæus, American Presbyterian clergyman and editor: b. Ballston, N. Y., 4 Nov. 1812; d. Manchester, Vt., 18 July 1885. He was graduated from Williams College in 1829, entered the Princeon Theological Seminary and in 1833 was ordained in the ministry. He was in charge of pastorates at Ballston Springs, N. Y., 1833–35; at Matteawan, N. Y., 1835–40. In 1840 he became editor of the *New York Observer* and continued as such until his death, with the exception of a period in 1849 when he was secretary to the American Bible Society, and another in 1850 when he edited the *Presbyterian*. He was one of the founders of the Evangelical Alliance of America in 1866 and its corresponding secretary until 1884, was vice-president of the American Tract Society and was prominently connected with various religious and educational institutions. From 1854 he was a regular contributor to *Harper's Magazine*, where his «Editor's Drawer» became famous, and in 1858 his literary earnings enabled him to purchase the *Observer*, which he made the leading organ of his denomination. His 'Power of Prayer' (1858) reached a sale of 175,000 copies in United States and England and was translated into French, Dutch and Tamil. Among his other books are 'The Old White Meeting-House' (1845); 'Travels in Europe and the East' (1855); 'Letters from Switzerland' (1860); 'Kirwan' (1870); 'Irenæus Letters' (1st series, 1880; 2d series, 1885), etc.

PRIME, William Cowper, American journalist: b. Cambridge, N. Y., 31 Oct. 1825; d. New York, 13 Feb. 1905. He was graduated from Princeton in 1843, studied law, was admitted to the bar in 1846 and engaged in law practice in New York in 1846–61. In 1861–69 he was editor-in-chief of the New York *Journal of Commerce*, was first vice-president of the Metropolitan Museum of Art after 1874 and professor of the history of art at Princeton after 1884. He devoted much time to literature and was an authority on numismatics and Egyptian antiquities. Among his publications are 'The Owl Letters'; 'The Old House by the River' (1853); 'Boat Life in Egypt and Nubia' (1857); 'Coins, Medals and Seals' (1860); 'I Go A-Fishing' (1873); 'Holy Cross' (1877); 'Along New England Roads' (1892); 'Among the Northern Hills' (1895), etc.

PRIME. See CANONICAL HOURS.

PRIME MINISTER, the title of the premier, secretary of state or other officer of state, who in most European countries, at the summons of the sovereign, has succeeded in forming an administration, of which he is the head and which may be named after him. Those who accept office under him are assumed to agree with his policy in the main. Though each member of the ministry administers his own department independently of his colleagues, all important departmental matters are submitted to him, the most important being brought before the whole ministry, and no appointment of moment is made or recommended to the Crown without his knowledge and concurrence. His own patronage is very extensive. In forming an administration, he selects all those who are to fill the various offices, though the appointments are subject to the sovereign's approval. In England it is on his advice that as vacancies occur the archbishops, bishops and deans and the highest judges are appointed and over 100 Crown livings are filled; and on his recommendation that the most envied temporal titles and honorable distinctions — peerages, baronetcies and the Garter, for example — are conferred and such high appointments as the lord-lieutenancy of Ireland, the viceroyalty of India, the principal ambassadorships and colonial governorships and lord-lieutenancies of countries, are made by the Crown. He is the leader of the House of Parliament, of which he is a member. Yet as prime minister he enjoys no legal precedence over his colleagues, his official existence being indeed not recognized by statute. In European governments the prime minister, or premier, is usually charged with the management of diplomatic affairs and in this respect resembles the Secretary of State of the United States.

PRIME NUMBER, an integer indivisible by any number save itself and unity, that is, one which cannot be factored; such number are 1, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, etc. They occur very frequently among the lower numbers and begin to be scarce among the higher thousands. The determination of the prime numbers has remained a mere matter of rejecting factorable numbers; this is done in a quasi-mechanical way by the table called Eratosthenes' sieve, upon which all the numbers to be tested are written at equal intervals and covered in succession by gridiron-like slips of paper, covering first all multiples of 2 (the even numbers may better be omitted at the start), then all multiples of 3 and so on. But even with the modern theory of numbers no rule has been laid down for the periodicity of the occurrence of the prime numbers. Gauss discovered in 1810 that the number of primes less than x was approximately $\int_2^x \frac{dx}{\log x}$; Chebicheff gave a formula for the determination of the number of prime numbers between any two primes; in a monograph dated 1859, Riemann gave an even more exact formula and a very complicated one, also dependent on the integral used by Gauss. The theory of numbers has also shown that «every prime number is (in general in more than one way) a sum of four squares,» but this is equally true of other numbers, inasmuch as (1) every factorable number is the product of two prime numbers and (2) the sum of four squares into the sum of four squares is always a sum of four squares. There is a theorem of Goldbach to the effect that «every even number is the sum of two prime numbers.» Factor tables have been made for all numbers between 1 and 10,000,000 in the attempt to codify the prime numbers; by reference to them it may be instantly discovered whether a given number is prime or not.

PRIMERO, prĭ-mē'rō, or **PRIME,** a card game very popular in England in the 16th century, but now obsolete. The same or a very similar game was played in Italy under the name *primiera* and in France under the names *prime, ambigu*, etc. Primero belonged to the family of games of which the old post and pair and the more modern brag and poker are members.

PRIMITIVE ART. See ABORIGINAL ART.

PRIMITIVE METHODIST CHURCH, a Christian community known previously to 1902 as the Primitive Methodist Connection. It originated with Hugh Bourne (1772–1852), a millwright of Stoke-on-Trent, England, who joined a Methodist society at Burslem, but whose open-air preaching, prayer and singing, the forerunner of the «camp-meeting,» a departure from Wesley's methods, led to his expulsion from the Wesleyan Connection. With William Clowes and some strong supporters, they built a chapel at Tunstall in July 1811, and in February 1812 adopted the name of «Primitive Methodists.» Popularly they were long known both as «Clowesites» and «Ranters» (q.v.). In 1860 when they celebrated their jubilee at Tunstall, the Conference reported in Great Britain 2,267 chapels, 675 ministers, 11,384 local preachers, 132,114 members, 30,988 teachers and 167,533 students, with increasing numbers throughout the British colonies. From 1885 on a movement developed to form the «Connection» into a «Church» which was accomplished in 1902 supporting numerous schools and missions with the *Holborn Review* as its special periodical. The Primitive Methodists are represented in the United States by 94 churches, 74 ministers and 8,600 communicants.

PRIMITIVE SOCIETY AND DEMOCRACY. See DEMOCRACY, HISTORY OF.

PRIMITIVE THOUGHT. See MYTHOLOGY.

PRIMOGENITURE, prĭ-mō-jĕn'ĭ-tūr, seniority of birth and the right by law of the eldest son of a family (and of those who derive through him) to succeed, in cases of intestacy, to the father's real estate, to the absolute exclusion of the younger sons and the daughters. This rule, system or right prevails in Great Britain; but, following the example of revolutionary France, most of the countries of continental Europe have abolished it. Several exceptions to the rule are allowed in the United Kingdom, but, these apart, whenever a man dies intestate leaving real estate, his eldest son is entitled to the whole of it and the rest of the children not otherwise provided for out of the personalty are left without anything. If there is no male heir, the daughters succeed, not singly and in the order of seniority, but jointly. In the United States no distinction is made in the descent of estates to lineal descendants.

PRIMROSE, a popular name for many garden and wild plants, among which the following are probably the best known: Evening primrose (*Œnothera biennis,* etc.); Arabian primrose (*Arnebia cornuta*); Cape primrose (*Streptocarpus* spp.); and various species of the genius *Primula.* This last consists of about 150 species of mostly perennial herbs with rosettes of leaves of various forms (especially under cultivation), and salver-shaped, generally showy, white, yellow, pink, lilac and purple flowers borne in clusters upon scapes. They are natives of the north temperate zone, one species South American, one Javanese, and generally common in mountainous countries. About 40 are Himalayan; a dozen North American. They may be divided into five groups according to their uses as ornamental plants for which purpose they have long been popular. The auricula (q.v.) and the alpine primroses, neither of which are widely popular in America, the former because the climate is believed to be against them, the latter because alpine gardens have not become popular. Third, the yellow or purple-flowered outdoor species such as *P. imperialis* and *P. japonica,* which with winter mulching are grown in the Northern States; the polyanthus group, which contains the oxlip (*P. elatior*) and the cowslip (*P. officinalis*), very popular, fully hardy favorites blooming in early spring; and the greenhouse primroses, such as the Chinese (*P. sinensis*), *P. obconica* and *P. forbesi* (baby primrose), all of which are widely popular houseplants. Propagation is usually by seed, though varieties that do not come true to type may often be propagated by division or cuttings. Seed should be sown soon after its collection, since it quickly deteriorates if allowed to become dry. In general, primroses succeed best in deep, well-drained, loose, rich loam not exposed to the glare of the sun. The polyanthus kinds may be grown in cold frames during the winter, set in beds in early spring, removed after flowering to shady moist situations for the summer, divided in the autumn and planted in cold frames again. The yellow-blossomed kinds are favorites with florists. The greenhouse kinds are sown under glass in early spring and kept growing steadily in flower pots of increasing sizes until the 6-inch size is reached in autumn when they should begin to blossom. The soil for them should be light, loose and rich both in plant food and humus. At the primrose shows there are often 200 to 300 distinct varieties on exhibition, mostly of *P. sinensis,* which has developed many remarkably beautiful forms attractive in foliage as well as flower.

PRIMROSE DAY, in England the anniversary of the death of Benjamin Disraeli, Lord Beaconsfield (q.v.), 19 April 1881. Every member of the Primrose League (q.v.) wears a bunch of primroses on that day in token of alliance with, and support of, the objects of the league.

PRIMROSE LEAGUE, an English political organization founded in 1883 by members of the Fourth party (consisting of Lord Randolph Churchill and others) in memory of Benjamin Disraeli (q.v.), Earl of Beaconsfield. The primrose, as Lord Beaconsfield's favorite flower, was selected as the emblem and name of the league. The members include knights, dames and associates, and are divided into groups called habitations. In the propaganda to perpetuate Lord Beaconsfield's principles of world-wide federation, less reliance is placed on discussion, lectures, etc., than on the appeal to the social elements in human nature. The large membership is due mainly to the efforts of female members.

PRIMULA. See PRIMROSE.

PRIMUM MOBILE, prī'mŭm mŏb'ĭ-lē, *in astronomy,* the ninth or highest sphere of the heavens, whose centre is that of the world and in comparison with which the world is but a point. This the ancients supposed to contain all other spheres within it and to give motion to them, turning itself, and all of them, quite round in 24 hours. See ASTRONOMY.

PRINCE, Morton, American physician: b. Boston, Mass., 21 Dec. 1854. He was graduated at Harvard in 1875, taking his M.D. there in 1879, and since 1880 has been engaged in practice in Boston. Since 1885 he has been physician for nervous diseases at the Boston City Hospital; and in 1902–12 he was professor of nervous diseases at Tufts College, then becoming professor emeritus. Since 1906 he has edited the *Journal of Abnormal Psychology.* Author of 'Nature of Mind and Human Automatism' (1885); 'Disassociation of a Personality' (1906); 'The Unconscious' (1913).

PRINCE, Thomas, American clergyman and historian: b. Sandwich, Mass., 15 May 1687; d. Boston, 22 Oct. 1758. He was graduated from Harvard in 1709, studied in England and was pastor of a church at Combs, Suffolk, England, 1711–16, then returned to Massachusetts accompanied by several of his congregation. On 1 Oct. 1718 he was ordained pastor of the Old South Church, as colleague of the Rev. Joseph Sewall. In 1727 appeared the first volume of his 'Annals of New England,' materials for which he had collected with great care while in England. It was approved by the legislature, but owing to the indifference of the public was never completed. He published also sermons, several works on phases of the early history of New England and 'The New England Psalmbook Revised and Improved' (1758). He made a valuable collection of books by New England authors and manuscripts connected with New England records; this was partially destroyed by the British in 1766, but the remainder was presented to the Boston Public Library in 1860.

PRINCE (from Lat. *princeps*), a title which means literally one who holds the first place. In ancient Rome the title of *princeps senatus* was given to the leading senator, being the one whose name came first in the list and who had the right to record his vote first. In modern times the title of *prince* (or *princess*) is given to all sovereigns generally, as well as to their sons and daughters and their nearest relations. In England, while not generally used, the title is applied in strict heraldic language, as a mode of address to dukes, marquises and earls. In Germany there is a class of sovereigns, ranking next below the dukes, who bear the title of prince as a specific designation. The members of royal families are there called *Prinzen* instead of *Fürsten*, to distinguish them from the class to whom the latter title more particularly belongs. On the Continent there are ancient families not immediately connected with any reigning house who bear the title of prince. Formerly, in France, duke was a title superior to prince. In England the only case in which the title is a territorial one is that of the Prince of Wales (q.v.). See NOBILITY.

PRINCE, The ('Il Principe'), by Niccolò Machiavelli (written 1513, published in a Latin version 1523, and in the original Italian 1532), holds a high place both in history and in literature. Historically the chief document of the centralizing and nationalizing movements of Renaissance Europe, it was produced by the country that most conspicuously failed to centralize and to nationalize. The Wars of the Roses had turned England from feudalism to the strong Tudor monarchy; Louis XI in France had subdued his great nobles and established a national postal system and a royal standing army; Ferdinand and Isabella had united Castile and Aragon, and at the expense of Moors, Jews and heretics had purchased the solidarity of Spain; but Italy, long after these national consolidations, continued to suffer from the ambitions of local despots and condottieri, and from the incessant struggle of secular political bodies with the Pope. Disunited, she was again and again the prey of foreigners; Charles VIII of France in 1494 had taken her without bloodshed, and, as the saying was, «with chalk,» the chalk with which his unrestricted soldiers marked their quarters. It was no wonder that Machiavelli, Florentine historian, diplomatist and patriot, was looking about for the strong man who should liberate and unify Italy. For this imaginary personage 'The Prince' is a textbook in the methods of acquiring and governing a state.

Cesare Borgia had almost carved out an Italian kingdom when his plans were frustrated by the death of his father, Pope Alexander VI, together with his own sickness in that emergency, and his neglect to prevent the election of Julius II. Both his success and his failure made him an ideal example for the ideal Prince to observe. His success was due to ruthless energy and cunning, an imposing personality and boundless self-assertion. His failure was due to adverse chance, which struck just before he had quite consolidated his power, and to his own want of adaptability to his bad luck. The Prince, therefore, first should exercise *virtù*, in which Machiavelli sums up all the forces of the strong individual; and, secondly, should adapt himself to *fortuna*, in which are summed up all the forces of what we now call the environment. When fortune changes, the Prince must change too, lest she ruin him. He must, as Bacon wrote under Machiavelli's influence, «make the wheels of [the] mind concentric and voluble with the wheels of fortune.» The keeping of his promises, for example, after circumstances have changed, may clearly be inexpedient. Nor is his *virtù* to be any more «virtuous» than his attitude toward shifting fortune. He may use any degree of guile and cruelty to attain his end; but these must be judiciously employed — cruelty, for example, sharply and on an egregious scale at the moment of the *coup d'état*, not vacillatingly and in small doses throughout the reign; for the latter policy, both a sign and a cause of weakness, merely makes the Prince despised and hated instead of feared, and may hasten his fall. Like the dishonoring of women, it should be avoided because, by setting large numbers of persons against the Prince, and by making him lose glory, it imperils his success. The sanctions of his conduct are thus wholly human: success and fame among men.

Machiavelli evidently feels that the need for order and unity in the state ought to outweigh whatever ethical scruple the Prince may entertain. Just here is where 'The Prince' becomes the classical document of *Machtpolitik* and *raison d'état*. For in establishing order the Prince must of necessity not only police his own city-state, his Rimini or Perugia, but also acquire other city-states to be consolidated with it into a principality — else the old disorders between states will be kindled anew. Hence Machiavelli's policy of the strong unethical hand must be pursued both within and between states; it is not only intranational but international. The implication is that there is no room for morality either between individuals engaged in the process of forming possible states — i.e., in the process of competing for power, or between states — which are tacitly assumed to be continually struggling with each other to see which shall absorb the others. Just where, if anywhere, this ruthless competition is to cease — just how large the orderly group or principality must be before it can stop expanding for the preservation of its particular type of order (*Kultur*) — 'The Prince' does not tell us; it could not, after all, anticipate the 19th and the 20th centuries.

What makes it permanently interesting, however, is precisely the perpetual recurrence of these questions. In the 18th century, for example, Frederick the Great as Crown Prince writes an *Anti-Machiavel*, which, one is not surprised to find, never seriously affected his policy as king; in the 19th century Machiavelli becomes one of the heroes of *Italia Unita*. In the 19th century, too, political Machiavellianism is strongly supported by a false application of the new competitive theory of evolution — evolution by the survival of those organisms which are stronger than others (*Virtù*), and which fit, or can make themselves fit, their environment (*Fortuna*). This biological false analogy strikes back into actual politics in the Machiavellianism of the 20th century war. We are still confronted with a concept of the state which, assuming that sheer power is its end, aims not only to control all within the national territory, but to take in ruthlessly from without whatever the sovereign deems necessary to his quiet.

From being merely the document of a moment in history 'The Prince' has thus come to be the textbook of continuing political practice, and a perennial source of biological, political and ethical theory. Its method, indeed, which at times seems purely inductive, as based upon the examination of historical facts, without illusions, prepossessions or hypotheses, is based also upon the generalizations of classical writers, and proves in point of fact highly deductive and dogmatic. It assumes, for example, that men are naturally bad until compelled by the legislator or Prince (Carlyle's "hero") to be good; it supposes history to move cyclically; and in the person of the Prince, from whom a moral sense is omitted, it frames a political man who is quite as much an abstraction as is the "economic man" of the *laissez-faire* school. So far from being merely factual, 'The Prince' embodies rather pure and universal types. Unhampered by repression or apology, it sets forth, expressly or impliedly, human tendencies that belong to no one time or place — the adoption of success as the criterion of conduct; the adoption of "the verdict of history" instead of the verdict of ethics, especially in international relations; the implication that what makes ethics is the state itself; and, as has been already indicated, man's striving for fame, his adaptation to his environment or *fortuna* and his natural self-assertiveness or *virtù*.

To this universal content, as well as to its lucid straightforward classic style, are due 'The Prince's' literary eminence and influence. Of the latter it will be possible to mention only a case or two from English literature. Marlowe's 'Tamburlaine' and Shakespeare's 'Richard III' belong to a type of Elizabethan tragedy which takes for its theme the *virtuoso* or individualist on his career of rule and ruin. This theme, though derived, in all probability, from the mediæval tragic theme of the Fall of Princes, is strongly tinged by Machiavelli, with whom Elizabethan dramatists were well acquainted. Bacon's works, too, are under strong Machiavellian influence — his conception of man's dealings with his fellow-man in politics, and with nature in inductive and productive science, being that of "morigeration," or pliancy to the environment.

The best edition of 'The Prince' is that by L. Arthur Burd, Oxford, 1891, with an introduction by Lord Acton, and valuable essays, notes and bibliography. There are convenient modern translations by Ninian Hill Thomson (3d ed., Oxford 1913), Luigi Ricci ('The World's Classics') and W. K. Marriott ('Everyman's Library').

SAMUEL LEE WOLFF.

PRINCE ALBERT, a town in North Saskatchewan, Canada, 542 miles northwest of Winnipeg, situated on the river of that name, on the Grand Trunk Pacific Railway and four branches of the Canadian Northern line. It has a Roman Catholic cathedral, Anglican pro-cathedral and Presbyterian, Methodist, Baptist and Lutheran churches, public and separate schools and colleges and hospitals. The industries include three large lumber companies, cold storage, abattoir and packing plants, planing mills and granite works; and the neighborhood, in addition to its suitability for stock raising, has areas of fine clay suitable for pottery and bricks, and 2,000 square miles of spruce and poplar extend northwards of the city. Pop. about 6,158.

PRINCE ALBERT LAND, Canada, an Arctic island of the Franklin District, separated from the Mackenzie District by Coronation Gulf, Victoria, Dease and the Dolphin and Union straits, along the Northwest Passage. Its southern and southeastern peninsulas are known respectively as Wollaston Land and Victoria Land; Prince Albert Sound is a deep inlet on its eastern coast, and Collinson Inlet another on the north coast. It has not been fully explored.

PRINCE EDWARD ISLAND, Canada, an insular province of the Dominion, and the smallest in area and population, in the southern part of the Gulf of Saint Lawrence, separated east to west from Cape Breton Island, Nova Scotia and New Brunswick by the curving Northumberland Strait, from 10 to 30 miles wide. The greatest length of Prince Edward Island on a curve is about 150 miles, breadth varying from 4 to 34 miles, area, 2,184 square miles; it is the smallest province of the Dominion. The capital is Charlottetown (q.v.), which is connected by rail with all the principal points of the island. Other towns are Summerside, Georgetown and Souris.

Topography, Physical Features and Natural Resources.— The coast-line presents a remarkable succession of large bays and projecting headlands. Of the latter the most prominent are North Cape on the northwest, West Cape on the southwest and East Cape on the northeast; the largest bays are those of Richmond on the northwest, Egmont and Bedeque on the southwest, Hillsborough on the south and Cardigan on the east. The surface undulates gently, nowhere rising so high as to become mountainous, or sinking so low as to form a monotonous flat. The soil consists generally of a light reddish loam, sometimes approaching to a strong clay, but more frequently of a light and sandy texture. The prevailing rock is a Triassic reddish sandstone. The island is well watered by numerous streams and springs. At one time the whole island was densely covered with beech, maple, fir and other trees, and it is still well wooded, only about two-thirds of the area having been cleared. There are no minerals of any importance. The fisheries are valuable; the total value of the catch was $933,682. The most valuable item is the lobster, followed by the mackerel, cod, herring and hake.

Climate.— The climate is much milder than that of the adjoining continent, and the air, generally free from the fogs which spread along the shores of Cape Breton and Nova Scotia, is remarkably salubrious. During the greater part of July, August and September the thermometer during the hotter hours of the day seldom varies more than from 75° to 80° F.

Agriculture.— The island is eminently agricultural and pastoral. Of its total area of 1,397,991 acres, very little is unsuitable for cultivation, but little more than half the area is under cultivation for field crops. The principal products are oats, wheat, potatoes, turnips, apples, etc. In 1916 7,413,000 bushels of oats were raised, of a value of $4,522,000; 578,000 bushels of wheat of a value of $879,000; 6,386,000 bushels of potatoes, of a value of $3,321,000; and 338,000 tons of hay and clover of a value of $3,907,000. Good breeds of horses, cattle, sheep and swine are reared, and dairy farming has become a thriving industry; large quantities of cream, butter and cheese being manufactured, the dairy products in 1916 being valued at $593,659. A recent and flourishing industry is the breeding in captivity of the silver black fox.

Manufactures and Commerce.— The manufactures are chiefly confined to linen and flannels for domestic use; there are also several tanneries, boot and shoe factories, manufactures of tobacco, condensed milk, pork-packing establishments and some shipbuilding. The exports for the year to 31 March 1917 were valued at $589,218, and the exports at $838,647.

Shipping and Communications.— In 1916 the shipping of the province was 130 sailing and 28 steamships, aggregating 11,518 tons, the tonnage of the steamers being 3,495. The Prince Edward Island Railroad, built by the Dominion government, connects the principal points of the island and has a length of 276 miles and a car-ferry service gives connection with the mainland. Telephonic communication extends throughout the island, which is also traversed in all directions by good coachroads.

Government.— The province is administered by a lieutenant-governor nominated by the Crown, who appoints an executive council of eight members, with a legislative assembly of 30 members, half elected on a property qualification, and half on a popular franchise. The province was admitted into the Dominion of Canada in 1873, is represented in the Dominion House of Commons by four members, and has four representatives in the Senate.

Education and Religion.—Adopted in 1851 the free school system is administered by a government superintendent and council. In 1916 18,362 pupils were enrolled in 476 schools conducted by 595 teachers, and $244,572 were expended for education. The membership of the principal religious denominations in 1916 was, Roman Catholics, 41,994; Presbyterians, 27,507; Methodists, 12,209; Anglicans, 4,939; Baptists, 5,905.

History.— Sebastian Cabot is supposed to have sighted Prince Edward Island after discovering Newfoundland in 1497, but with more likelihood the honor is also assigned to Jacques Cartier (1634). It appears on Champlain's map under the name of Saint John and it was later included by the French in their vast and undefined territory of New France, and in 1663 was granted on a feudal tenure to a Sieur Doublet, a French naval officer. Little progress was made in settling the island till after the Peace of Utrecht in 1715, when its fertility attracted numbers of settlers from Cape Breton. It was taken by the British in 1745; restored by the Peace of Aix-la-Chapelle; again fell into British possession after the capture of Louisbourg in 1757, and its inhabitants shared in the Acadian expulsion. It became a dependency of Nova Scotia, was partitioned among a small body of proprietors in 1767 and was erected into a separate province in 1769. In 1862 responsible government was conceded. In 1873 the island was admitted into the Dominion of Canada, and in 1875 a scheme of land purchase expropriated the proprietors. Pop. (1901) 103,259; (1911) 93,727, of which 98.37 per cent were Canadian born. The density per square mile, 42.91, is the highest among the provinces of the Dominions; but the population is declining. Consult Campbell, 'History of Prince Edward Island' (1875); Dawson and Harrington, 'Geological Structure and Mineral Resources of Prince Edward Island' (1882–84).

PRINCE EDWARD ISLAND RAILWAY (Government Railways). It was one of the conditions of the entrance of Prince Edward Island into the Dominion of Canada, which took place 1 July 1873, that the railway under contract and in course of construction for the government of the island should become the property of the Dominion. This railway extended from Charlottetown, the capital, westward to Tignish and eastward to Georgetown, a distance of 195 miles. Other lines have since been constructed, as follows: Charlottetown to Murray Harbor, 48 miles; Montague to Montague Junction, six miles; Emerald Junction to Traverse, 12 miles; Halmira Junction to Elmira, 10 miles: the Vernon Loop, four miles —giving a total of 275 miles. The gauge of the railway is three feet six inches. The cost of the railway and equipment to 30 June 1914 was $8,920,623. The gross earnings for year to 30 June 1915 were $412,520, of which $212,622 were for passengers, and $186,560 for freight. The rolling stock consists of 22 locomotives, 43 passenger train cars and 501 freight cars, besides service cars, etc.

A daily steamer service is maintained between Charlottetown and Pictou, and between Summerside and Point du Chene during the season of navigation, and passengers and freight are carried by ice-breaking steamers during the winter season between Georgetown and Pictou.

PRINCE OF INDIA, a romance by Lew Wallace, published in 1893. The 'Prince of India' is the Wandering Jew.

PRINCE AND THE PAUPER, The, a historical tale by Mark Twain (Samuel Langhorne Clemens) published in 1881. The plot hinges on the remarkable resemblance of a poor street boy to the young English prince, afterward Edward VI.

PRINCE RUPERT, Canada, sea-port and capital of the electoral district Comox-Atlin, British Columbia, on the north end of Kaien Island, about 550 miles northwest of Vancouver and 3,860 nautical miles east of Yokohama, and the Pacific Coast terminus of the Grand Trunk Pacific Railway. It has anchorage for the largest ships, and a marine station and quarantine hospital are located here. It has a hydro-electric plant, modern waterworks and telephone system. Industries include chiefly those allied to the lumber trade, and there are large cold-storage plants. Pop. (1911) 4,184; (1915) estimated 6,500.

PRINCE RUPERT'S DROPS, pieces of glass which have been cooled very suddenly from the melted state by having been dropped into water. They are called *larmes bataviques* (Dutch tears) by the French. The outside of the drop of melted glass is instantaneously solidified by the water, while the inside cools gradually, so that the outside shell is acted upon by very great stresses due to contraction of the internal portions when cooling. In fact the drop is kept in a state of excessive strain by stresses in unstable equilibrium; and if this equilibrium is destroyed by scratching the surface with a diamond, or breaking off the tip of the tail, the strained particles are violently released, and the mass is instantly pulverized. Heat is produced during the pulverization of the drop. This explanation applies to the falling out of the bottom of the very thick flask of unannealed blown glass called the «Bologna flask,» when its surface is scratched. Glass articles — articles of any brittle material—ought to be cooled very slowly from the melted state. The process of slow cooling to which such articles are subjected is called annealing. To anneal glass it is placed in a large furnace which has nearly a red-heat at one end and a lower temperature than 100° C. at the other; after the glass has been passed very slowly from the heated to the cool end it is able to withstand sudden changes of temperature, etc., without fracture.

PRINCE OF WALES, The, in England, a title given to the eldest son of the sovereign and heir apparent to the throne. The title, created and not hereditary, dates from the reign of Edward III. When the principality of Wales came under English domination with the deaths of the native princes Llewellyn in 1282 and David in 1283, Edward I in 1284 is said to have presented his infant son Edward, born at Camarron Castle, to the Welsh people, as a native-born prince. He was not invested with the title, however, until 1301. A statute of the order of the Garter, dated 1805, declares that the Prince of Wales shall, as soon as he receives this title, becomes a knight of the Garter. The arms of the Prince of Wales are the royal arms, with the addition of a label of three points argent, and the distinctive Welsh feature of a plume of three white ostrich feathers, circled by the ancient princely coronet of Wales, bearing the motto badge «Ich Dien» («I serve»).

PRINCE OF WALES ISLAND, the official name of Penang, an island of the Malay Straits Settlement. See PENANG.

PRINCE WILLIAM SOUND, Alaska, an inlet of the Gulf of Alaska, on the south coast, east of the Kenai Peninsula and with Montague Island on the south. It offers an ice-free harbor, the most northerly on the coast, and has spectacularly beautiful scenery. Its glacial phenomena is particularly remarkable, the sound having 11 living glaciers, of which the most striking are the Columbia, Harvard, Yale, Serpentine, Harriman and Surprise. The Columbia is about four miles wide on the sound and reaches in places a height of 300 feet. The rich deposits of copper on the eastern shores and on some of the islands offer splendid possibilities for development. Of the towns, Valdez and Cordova have each about 1,000 population and are coast terminals of railroads running into copper districts in the interior. Smaller towns are Onca, Ellamar and Landloch. Consult Higginson, 'Alaska'; Greely, 'Handbook of Alaska' (1909); 'National Geographic Society Bulletin' (1914).

PRINCEITES, prĭn'sīts. See AGAPEMONE; RELIGIOUS SECTS.

PRINCE'S FEATHER, an annual plant (*polygonum orientale*) of the buckwheat family, with erect spikes of dark-red flowers and leaves inclining to purple. It is a native of India, but has long been cultivated in gardens everywhere.

PRINCE'S ISLAND, or ILHA DO PRINCIPE, ēl'yä dō prēn'sē-pĕ, a Portuguese island off the coast of West Africa; in the Bight of Biafra; nearly midway between Fernando Po and Saint Thomas islands. It is of volcanic character, rising in the south to 3,000 feet; fertile and well-watered, but of little importance since the extinction of the slave-trade ruined its sugar plantations. Its fertility has gained it the name of the Garden of Africa. Cacao is the only important export. The population is concentrated mainly in São Antonio, a town with a fine harbor on the northeast coast. With the neighboring island of Saint Thomé it constitutes a province under a governor.

PRINCE'S ISLANDS (ancient DEMONESI), a group of nine islets near the east end of the Sea of Marmora, about 10 miles southeast of Constantinople. Prinkipo is the largest of the group. They are a favorite summer resort of the Constantinople Greeks, and in old times were frequently a place of exile for those who were in disfavor at the Byzantine court. There are on the islands a Greek church, seminary, monasteries and a naval college. In 1894 an earthquake caused loss of life and destruction of property. Pop. estimated 10,500.

PRINCE'S METAL, *in metallurgy,* a mixture of copper and zinc in imitation of gold.

PRINCE'S PINE, or PIPSESSEWA, a low North American evergreen health-plant (*Chimaphila umbellata*) of the wintergreen family. From its leaves are made a powder and a fluid extract, used in making a herb-medicine for scrofula, rheumatism, etc. Another species is the spotted wintergreen (*C. maculata*).

PRINCESS. See NOBILITY; PRINCE.

PRINCESS, The, by Alfred Tennyson, published in 1847, reprinted in 1848 and in 1850, was acclaimed as «the herald-melody of the higher education of women,» a theme which Tennyson held to be one of the two great problems of the England of his day. The poem is the expression of his belief in a larger training and a fuller life for woman, based on her «distinctive womanhood,» her power of love. The story of the winning of the Princess Ida by the Prince who invades her college but respects her cause is frankly a «medley,» in which armored knights fight tourneys while gowned ladies lecture on the nebular hypothesis. Prologue and conclusion, set amid a Gothic ruin and a Victorian Chautauqua, strike the «mock-heroic» key-note. But Tennyson lacked the true comic spirit that could fuse his theme, satire and sentiment into entire unity of mood and style. Yet the interest and charm of the parts almost conpensate for the lack of integral beauty. The characters, sketches though they are, embody all shades of opinion on women's education, from Lady Blanche, a true militant, to the old king, a father of «antis.» The Princess herself, the one full portrait, whom Tennyson held one of his noblest women, seems a trifle too heroic in her passion for freedom and too abject in her yielding to love. It is not she but the Prince who speaks the poet's famous verdict on the woman question.

No poetry is more Tennysonian than the blank-verse of ‹The Princess,› more filled with his richly-wrought word-harmonies, his memorable nature-pictures painted from the life. Lovelier still are the lyric links, added as an afterthought to ring the changes on the motif of the poem, the love of man and woman for each other and for the child. ‹The Princess› lives, less because it declares that «the woman's cause is man's,» than because it contains ‹Sweet and low,› ‹The splendour falls,› and, most melodious of unrhymed lyrics, ‹Tears, idle tears.› Consult Tennyson, Hallam, ‹Alfred, Lord Tennyson: a Memoir› (2 vols., 1897); Grierson, H. (in ‹Cambridge History of English Literature,› Vol. XIII, ch. 22, and bibliography).

FRANCES W. CUTLER.

PRINCESSE DE CLEVES. ‹The Princess of Cleves› by Madame de la Fayette appeared first under the name of ‹Segrais› in 1678. It is a novel, but it is in form and content in the sharpest contrast to the novels that had up to that time been in vogue. They had been interminable affairs, in 10 and 12 volumes, made up of the most extraordinary adventures, through which paragons of valor were made to pass before their love-laden sighs might with propriety melt the heart of the paragons of beauty who were the objects of their adoration and they might lead them to the altar. This was a short and simple story, scantily furnishing a thin volume, without heroic or gallant adventure, without paragons of beauty and valor and without wedding bells. It is a drama of conscience. A married woman is the heroine. What fixes our attention and interest is the moral experience of a noble character striving to realize a high ideal of duty in a difficult situation. It is such a victory of wise self-control and steadfast will over impulse and passion as Corneille loved to present in his tragedies. It is essentially a novel of character, in which psychological analysis and penetrating observation of human conduct as it displays itself under familiar conditions take the place of breathless action and thrilling situations. The influence of the «Princess of Cleves» was very great, and it is not too much to say that it marks an important turning point in the history of the novel. The great masters of the early 18th century, like Marivaux in France and Richardson in England, who determined the course the modern novel was to take, developed her method and applied it on a much broader canvas, but not always with more perfect results. There is a translation by Thomas Sergeant Perry (Boston 1891).

ARTHUR G. CANFIELD.

PRINCETON, Ill., city and county-seat of Bureau County, on the Chicago, Burlington and Quincy and the Chicago, Ottawa and Peoria railroads, about 100 miles west by south of Chicago. It was settled in 1830, incorporated in 1838 and in 1884 was chartered as a city Since 1915 it has been governed on the commission plan. It is in an agricultural and coal mining region. Its industries are connected chiefly with farm products and the mining and shipping of coal, and the shipping of livestock. It has a number of well-built business blocks, a township high school, the Maton Public Library, a courthouse, city hall, Federal building and the high school library. The city owns and operates the electric-light plant and the waterworks. Pop. 4,300.

PRINCETON, Ind., city and county-seat of Gibson County, on the Southern and the Chicago and Eastern Illinois railroads, about 27 miles north of Evansville. It was settled in 1804, incorporated as a town in 1814 and chartered as a city in 1884. There is a local traction line operated by a public utility company. Princeton is in an agricultural and coal mining region and is also rich in oil and natural gas. The chief industrial establishments are the Southern Railroad shops, the coal mines, oil wells, lumber mills, flour mills, clock works, handle factory, refrigerating and ice plant and several smaller establishments. There are large lumber and brick yards. The city has several churches; and the educational institutions are a high school, public and parish schools and a Carnegie public library, Civic League Club and a Chamber of Commerce. The banks have a combined capital of $250,000. The government is vested in a mayor, who holds office two years, and a council of six members. Pop. 9,000.

PRINCETON, Ky., city and county-seat of Caldwell County, 140 miles, direct, southwest of Louisville, at a junction of the Illinois Central and Ohio, Louisville and Nashville railroads. It is the seat of the Princeton Collegiate Institute. The repair shops of the Illinois Central Railroad are located here and the city has extensive interests in tobacco. There are flour mills, brickyards, an ice plant and a creamery. Pop. 3,015.

PRINCETON, N. J., borough in Mercer County, on an elevation about three miles from the main line of the Pennsylvania Railroad, with which it is connected by a branch line, 10 miles northeast of Trenton, and 50 miles southwest of New York City. It was settled in 1696, but remained a straggling hamlet for some years. The removal of the College of New Jersey from Newark to Princeton, in 1756, gave the place new life, and except when it was occupied by troops, and as a battleground, it has ever since remained a staid college town. On 27 Aug. 1776, the first State legislature of New Jersey met here. The 31st, the members elected William Livingston as governor of the State. Congress assembled here June 1783, and remained in session until November. The removal of Congress from Philadelphia was occasioned by the threatening attitude of discontented soldiers. While in session here, 31 Oct. 1783, the news arrived of the signing of the treaty of peace with England. Princeton has broad, well-shaded streets, and its location on the ridge gives it a fine view over the surrounding country. The colonial architecture has been preserved to quite an extent. The place is noted as being the seat of Princeton University (q.v.). Other educational institutions are Princeton Theological Seminary (Presbyterian), the Rockefeller Institute for Medical Research, Princeton Preparatory School, Saint Joseph's College, the high school and the libraries. Pop. 5,678. Consult Hageman, 'History of Princeton and Its Institutions' (Philadelphia 1870) and Powell, L. P., 'Historic Towns of the Middle States' (New York 1899).

PRINCETON, W. Va., city and county-seat of Mercer County, 75 miles southeast of Charleston, on the Virginia Railway and near the southern border of the State. It was the scene in 1862 of a skirmish between the United States and Confederate forces, the advantage resting with the Confederates. Pop. 3,027.

PRINCETON, N. J., **Battle of,** in the American Revolution. After the battle of Trenton (q.v.), Washington recrossed the Delaware and on 2 Jan. 1777 occupied Trenton with strong outposts at Bordentown and Crosswicks. General Grant, commanding the British troops at New Brunswick, 30 miles distant, was joined by Lord Cornwallis (q.v.), who was preparing to return to England but had been ordered to resume his command in the Jerseys. The British and Hessians, about 8,000 strong, pressed forward to Trenton, whereupon Washington took position on high ground behind Assanpink Creek. On 2 Jan. 1777 the British cannonaded the American position but deferred the attack until morning, when Cornwallis hoped «to bag the old fox.» On the advice of his generals, however, Washington decided to strike the British in the rear, capture their stores at New Brunswick, attack three British regiments under Col. Charles Mawhood at Princeton and divert the war from the neighborhood of Philadelphia to the mountainous regions of New Jersey. On the night of 2–3 of January, leaving his camp fires burning, Washington sent his stores to Burlington, abandoned his camp, and in the morning fell upon the unsuspecting Mawhood, then marching to join Cornwallis. After the first volley the British charged and the Americans fled but were rallied by Washington and soon put the British to flight. Washington then advanced toward Princeton where he routed another British regiment. The British loss was 150 killed and 230 prisoners, while the Americans lost 30 killed, including Gen. Hugh Mercer. Meanwhile, hearing the cannonade, and fearing for his stores at New Brunswick, Cornwallis pursued Washington toward Morristown, but on crossing the Millstone River, the Americans demolished the bridge at Kingston and Cornwallis abandoned the pursuit, taking up position at New Brunswick while Washington encamped at Morristown. Consult Stryker, W. S., 'Battles of Trenton and Princeton'; Johnston, H. P., 'Campaign of 1776' (p. 293 et seq.); Carrington, H. B., 'Battles of the Revolution' (p. 276 et seq.); Lossing, 'Field-Book of the Revolution (Vol. II); Wilkins, 'Memoirs' (Vol. I, pp. 140–150); Wiley and Rines, 'The United States' (Vol. III, pp. 7–10); biographies of Washington, Greene, Knox and others.

PRINCETON, W. Va., **Engagement at.** In the spring of 1862 General Frémont, commanding a military department that included West Virginia, proposed to move from Monterey on Staunton, thence to the New River near Christianburg, his ultimate destination being Knoxville, Tenn. Gen. J. D. Cox, commanding on the Kanawha, was to co-operate by advancing from Gauley Bridge, in two columns, one by Fayette and Raleigh Court House over Flat Top Mountain to Princeton and «the narrows» of New River, the other by the turnpike to Lewisburg. Cox had four brigades; one was left to hold the lower Kanawha Valley; Col. George Crook was sent forward to Lewisburg; and Cox, with the two brigades of Colonels A. Moor and E. P. Scammon, about 2,000 men each, moved on the Fayette and Princeton route. Giles Court House and «the narrows» of New River were reached 7 May, and on the 16th his two brigades, after leaving a detachment at Princeton, were on the East River, and Crook had reached Lewisburg, on the other side of New River, all prepared to joint Frémont's main column at Christianburg. But «Stonewall» Jackson's appearance in the Shenandoah Valley sadly deranged Frémont's plans, and Cox was told to look out for himself. Meanwhile the Confederate brigades of Generals Humphrey Marshall, Harry Heth and J. S. Williams, all under command of Marshall, had been concentrated to protect the Virginia and Tennessee Railroad, and on the 16th Marshall, leaving Heth to hold the passes of New River, marched with about 2,500 men and three guns by the Wytheville road on Princeton, driving out the small detachment Cox had left there, after a stubborn resistance of six hours, continued until 10 P.M., and capturing the camp, with several tents, horses and other things, including the headquarters correspondence. During the night Cox, with Moor's brigade, marched back from East River, ordering Scammon to follow, and at daylight of the 17th found Marshall withdrawing from the town and back to a wooded range of hills south and west of it. Cox advanced and attacked, and Marshall again fell back a mile, to a strong position covering the Wytheville and Wyoming roads, and waited for Heth to come up. Cox made some demonstrations, but seeing that Marshall held a steep wooded ridge, not easily accessible, and had a

large force and some artillery, he waited until Scammon should come up, before making a serious attack. Scammon came up in the evening, closely pursued part way by Heth, and brought information that the Confederates were in great force; and Cox, realizing that his position at Princeton could be turned and his line of communication seized, retreated before daylight next morning to Flat Top Mountain, 25 miles from Princeton, a very strong position, and ordered Crook to halt at Lewisburg. Heth attacked Crook at Lewisburg on the 23d and was badly repulsed. (See LEWISBURG, BATTLE OF). The Union loss at and around Princeton was 23 killed, 69 wounded and 21 missing; the Confederate loss was much less. Consult 'Official Records' (Vol. XII); The Century Company's 'Battles and Leaders of the Civil War' (Vol. II).

E. A. CARMAN.

PRINCETON THEOLOGICAL SEMINARY, a Presbyterian seminary at Princeton, N. J. It was organized in 1812, and for a time the classes were held in the buildings of Princeton College (now Princeton University); in 1815 a tract of land was purchased for the seminary, and a building erected. «The biblical criticism is conservative,» and «the theology taught is that type of Calvinism set forth in the Westminster Confession.» The courses include instruction in Old and New Testament theology, literature and history, homiletics, church history, pastoral theology, systematic theology and Hebrew. The regular course is three years, a fourth year of graduate study is also provided for and arrangement is made for «extra-curriculum» courses at the university. Students who are college graduates are admitted without examination; others must take examination for admission in full standing; students, however, on filing a certificate from the presbytery or ecclesiastical body under whose care they are studying for the ministry may without examination enroll in the classes and receive the certificate for completion of the course, but are not technically considered graduates of the seminary. The degree of bachelor of divinity is conferred on students who have received the degree of bachelor of arts. The buildings include two library buildings, Stuart Hall and three dormitories. In 1917 the institution had 14 instructors, 187 students, 103,000 volumes in its library besides pamphlets, $664,055 invested in grounds and buildings, $3,208,484 in productive funds and $148,692 in total income, and its graduates numbered 6,233. Francis Landey Patton, D.D., LL.D. who was president of Princeton University in 1888–1902, became president and professor of the philosophy of religion at the seminary on retiring from the university and served till 1914, when he resigned and was succeeded by Joseph Ross Stevenson, D.D., LL.D.

PRINCETON UNIVERSITY, located at Princeton, N. J. The first movement toward the establishment of the College of New Jersey was made in 1739 by a committee appointed by the Presbyterian Synod of Philadelphia, but this committee met with little success and the project was laid aside for the time. In 1746 the promoters of the new college, who in the meantime had withdrawn from the Synod of Philadelphia and with others had formed the Synod of New York, again took up the matter and obtained a charter for the new college. In the same year the Log College, which had been conducted by Rev. William Tennent, Sr., near the Forks of Neshaminy, Pa., as a training school for ministerial candidates, was closed by the death of Mr. Tennent, and its leading men joined with the trustees of the new college. A second charter for the College of New Jersey was obtained in 1748. The scope of the college and the powers of the trustees as stated in the two charters were essentially the same, but the second charter was obtained by the original trustees, both because of some doubt as to the validity of the first charter, which had never been recorded verbatim in the records of the secretary of state, and also for the purpose of increasing the number of trustees, making the lay trustees equal in number to the clergymen and giving other religious communions a share in the administration.

The college was opened at Elizabethtown, N. J., in April 1747, with Rev. Jonathan Dickinson as president and was transferred to Newark in the autumn of the same year, where it remained until 1756. In 1752 it had been decided to fix the location permanently at Princeton, and in 1756 the college building (Nassau Hall) was completed and instruction was begun there. The college exercises were interrupted during the Revolution by the presence of both armies, but only one Commencement, that of 1777, was omitted. During the war Nassau Hall was badly damaged, the library scattered and destroyed and the scientific apparatus ruined. In 1783 the Continental Congress sat in Nassau Hall for several months. A law department was established in 1846, but discontinued in 1852 on account of lack of funds. The system of elective studies was introduced in 1870; the John C. Green School of Science was established in 1873; the Graduate School in 1877, and the School of Electrical Engineering in 1889.

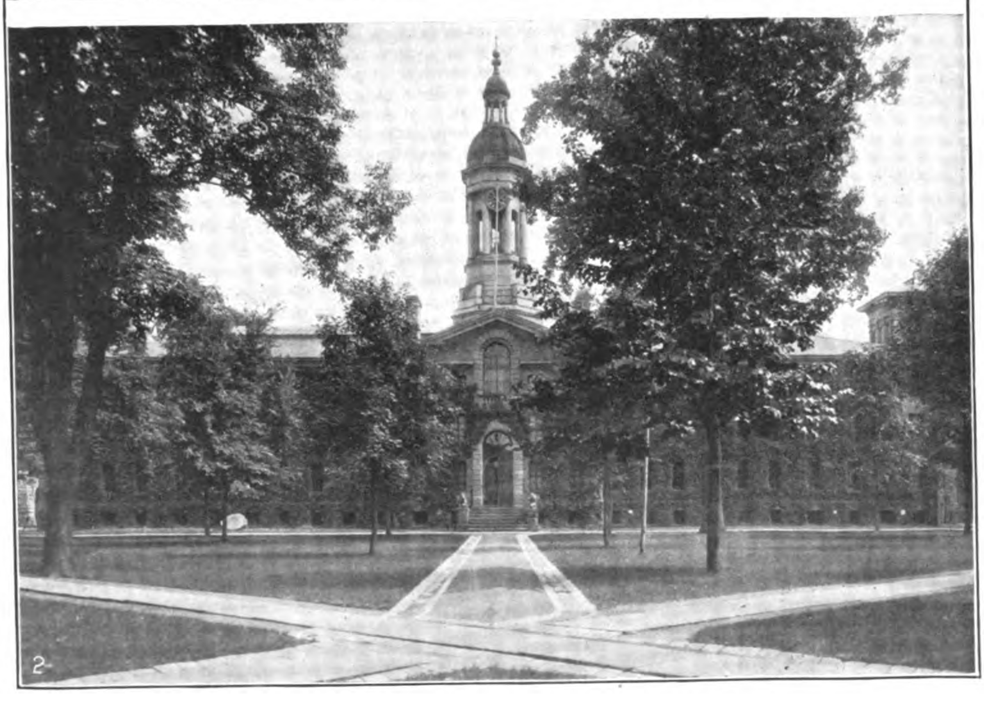
In October 1896, on the occasion of the 150th anniversary of the founding of the college, the title of Princeton University was assumed. In 1900 a plan of alumni representation in the board of trustees was adopted, giving the alumni five elected representatives on the board. The other trustees are elected by the board itself and hold office for life.

The courses now offered by Princeton University may be classified as undergraduate courses in arts and sciences; graduate courses in arts and sciences; and technical courses.

The plan of undergraduate liberal studies provides for two distinct courses: first, the bachelors of arts course (A.B.), in which Latin is required for entrance and forms a prescribed part of the curriculum of the first year; second, the bachelor of science course (B.S.), in which a modern language may be substituted for Latin at entrance.

The Graduate School offers advanced and research work in arts and sciences, leading to the degrees of master of arts and doctor of philosophy.

The technical courses offered are a four-year undergraduate course in civil engineering; and a two-year graduate course in electrical engineering, leading respectively to the degrees of civil engineer and electrical engineer.



1 Stafford Little Hall

2 Nassau Hall

Admission to the undergraduate courses is entirely by examinations, which are conducted by the College Entrance Examination Board. The subjects required for admission vary in the different courses and while certain subjects are definitely required, there is a considerable margin for choice in the subjects offered by candidates. Distinguishing features of the undergraduate courses are: (1) the planning of the requirements for the bachelors degrees so that the student shall receive a broad general training, preserving as far as possible the ideal of the old American college course; (2) the treatment of the student's preparation and college work as a whole and the requirement for graduation of a specific number of units, part of which must be met before entering the university; (3) the requirement that a student shall have completed before the middle of his college course a certain number of units in language including English, in mathematics, science and in philosophy; (4) the divisional elective system, according to which a student must choose in his junior year at least three courses in a division (philosophy, literature, art or history, politics, economics or mathematics, science), in which his work will thereafter be concentrated. His other two courses are unrestricted. Beginning with sophomore year which has only one required course, the student has a full choice of electives within certain limitations; (5) an arrangement whereby students of high standing may by independent study during the summers qualify for graduation in three years. And (6) the preceptorial method of instruction, by which the lectures are complemented by informal conferences between the professors and small groups of students on the reading connected with a course. The preceptorial groups usually consist of from three to six men, thus emphasizing the personal relation between teacher and student. All members of the faculty engage in preceptorial work.

In the undergraduate department there are 40 university scholarships and about 40 endowed scholarships, ranging in stipends from \$100 to \$500. The endowment plans of the university include the founding of over 100 scholarships in memory of Princeton men fallen in the service of the country in the recent European War. The university also offers remission of part of the tuition charge to undergraduates of small means and good scholarship, but no student may hold a scholarship and remission of tuition at the same time. In the Graduate School there are the Jacobus Fellowship and 10 Proctor fellowships with a stipend of \$1,000 each, and in addition about 35 fellowships paying \$600 to \$700, of which 16 are wholly or partly endowed. There are also a number of graduate scholarships paying \$250 and \$100 respectively.

A feature of the Graduate School is the Graduate College of residence, where the graduate students may live amid surroundings which tend to emphasize the proper academic and social life of a community of young scholars. The Graduate College buildings were completed in 1912. In connection with this group of buildings is the Cleveland Memorial Tower, erected in memory of President Grover Cleveland.

The present University Library consists of the Chancellor Green Library, built in 1872–73, and the Pyne Library (1896–97), which are united by a delivery room, 50 by 20 feet. The library collection in 1760, when the first catalogue was printed, consisted of 1,300 volumes. It now numbers about 410,000 volumes besides pamphlets. This includes several special collections and seminary libraries. The Garrett collection of Oriental manuscripts, the Garrett collection of coins, the Hutton collection of death masks and the Meirs collection of Cruikshankiana are also located in the library. There are six departmental libraries: art, astronomy, biology, geology and palæontology, engineering and physics, each selected from the general collection and kept in the Art Museum and the several laboratories. These departmental libraries number over 31,000 volumes. The Princeton Theological Seminary Library of over 100,000 volumes is also open to students of the university.

The university campus contains about 700 acres. Besides Nassau Hall, the library and the Graduate College already mentioned, among the buildings are 16 dormitories, some of them of unusual architectural beauty; Dickinson and McCosh Halls, for classroom work; the Halsted Observatory, the Infirmary, the Marquand Chapel, Alexander Hall; the John C. Green School of Science, used chiefly by the department of civil engineering, the Chemical Laboratory, Palmer Laboratory, for physics and electrical engineering, Guyot Hall, the laboratory of the departments of geology and biology and Madison Hall, containing the university dining halls.

The athletic equipment consists of the Palmer Memorial Stadium, for intercollegiate football, and track; University Field, for baseball; the Gymnasium; Lake Carnegie for rowing; the Brokaw swimming tank; Brokaw, Poe and Goldie fields, providing several baseball diamonds and soccer fields; and 28 tennis courts. Under the direction of the department of hygiene and physical education all freshmen are required to take regular exercise and members of the other classes are encouraged to do so. At least three-fourths of all the undergraduates take part in some form of intercollegiate athletics.

There are no secret societies at Princeton, but there are two literary societies, the Cliosophic and the American Whig, founded prior to the Revolution. Most of the upper classmen are members of eating clubs. All freshmen and sophomores are required to board at the university dining halls.

The productive funds, according to the latest report, amount to \$6,565,000. The annual income from all sources averages \$839,300. The yearly attendance of students is about 1,600, and the faculty numbers about 200.

PRINCIPAL AND AGENT. See Agent.

PRINCIPE, prĕn'thē-pä, Philippines, subprovince of Tayabas, situated on the eastern coast of Central Luzon, bounded on the north by Isabela and on the south by Nueva Ecija; length along the coast, 64 miles; area, 1,216 square miles, with dependent islands, 1,218 square miles. The district is almost entirely mountainous; there are two main ranges, one near the coast, following the coast line, the other parallel with it, with narrow valleys between. Near the towns rice, corn, coffee, cotton, sugar and vegetables are raised, but for home consumption only; there are a few simple mechanical industries, also for domestic use. The chief industry along the coast is fishing and the fish are exported to the provinces to the south. Game is abundant in the mountains and many of the inhabitants are engaged in hunting. The inhabitants of the western slope of the peninsula of Tayabas use the Tagalog dialect; those in the eastern, the Bicoe. In 1902 the former district of Principe was annexed to the province of Tayabas. Pop. about 14,470.

PRINDLE, prĭn'd'l, **Cyrus,** American Methodist clergyman: b. Canaan, Conn., 11 April 1800; d. Cleveland, Ohio, 1 Dec. 1885. He was licensed to preach in 1821 and until his retirement in 1877 occupied various Methodist pulpits in New York, Vermont, Massachusetts and Ohio. Opposed to the attitude of the Methodist Episcopal Church with regard to slavery, he became in 1843 the chief leader in the movement that resulted in the founding of the Wesleyan Methodist Church in America. He was an abolitionist from principle and when he had seen the work to which he and his followers were devoted accomplished in the emancipation of the slaves, he returned to the Methodist Episcopal Church.

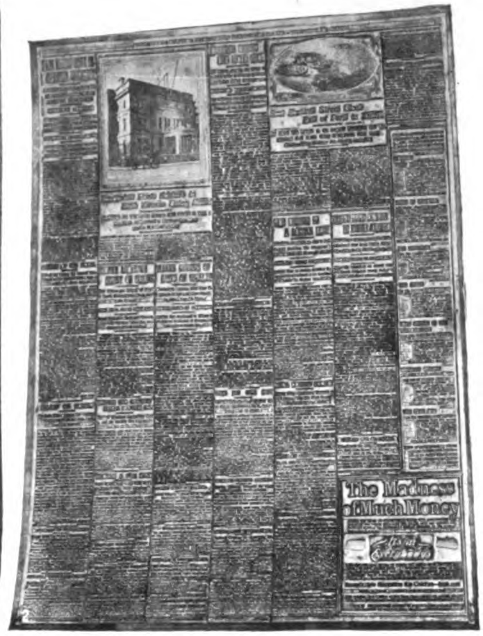
PRINGLE, prĭn'g'l, **Thomas,** Scottish poet: b. Blaiklaw, Roxburghshire, 5 Jan. 1789; d. London, 5 Dec. 1834. He was educated at Edinburgh University and in 1811 became a copyist in the registry office, Edinburgh. He began writing clever satire and attracted the notice of Sir Walter Scott, who in 1817 gave him his notes for an article on the gypsies, which Pringle contributed to the *Edinburgh Magazine*, started by himself and Cleghorn, and known after a rupture with the publisher as *Blackwood's*. In 1820, with 24 others, he emigrated to South Africa, settling finally at Cape Town, where for three years he was librarian of the government library. Pringle worked hard to secure financial support for the colony by pamphleteering and started The South African *Journal* and The South African *Commercial Advertiser*. These were suppressed by Lord Charles Somerset, the governor of the colony, because of their liberal tendencies and Pringle was reduced to poverty. In 1826 he returned to London and in 1827 became secretary of the Anti-Slavery Society. After seeing the triumph of his humanitarian endeavors in the abolition of slavery by England, in 1834, he died on the eve of returning to South Africa. His earlier poems were collected by him as 'Ephemerides' (1828); and the best of these, dealing with South Africa, were reprinted in 'African Sketches,' which included also the 'Narrative' of a residence in South Africa. These productions were characterized by vivid description and tender feeling. He is best known by his poem, 'Afar in the Desert I Love to Ride,' reprinted in the volume of 'African Sketches' (1834). Pringle's 'Poetical Works' with a life were edited by Leitch Ritchie in 1839.

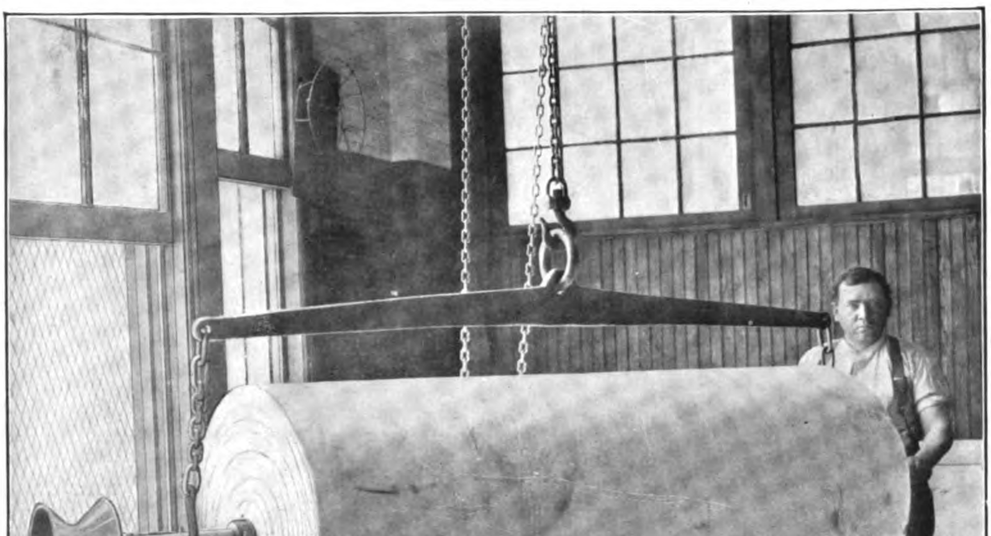
PRINSEP, Valentine Cameron, English artist and author: b. Calcutta, India, 14 Feb. 1838; d. London, 11 Nov. 1904. He was educated for the government civil service, but displayed so much artistic talent that he became a pupil of George Frederick Watts. Oriental, classical, romantic and sporting subjects appealed strongly to him. His first notable exhibition success was gained by his 'The Linen Gatherers' (1876). He was elected R.A. in 1894, and subsequently became professor of painting to the Royal Academy. In 1876 he went to India to paint 'The Declaration of the Queen as Empress,' which was exhibited in 1880. His other paintings include 'Bianca Capella,' his first Academy picture (1862); 'The Fisherman and the Jinn'; 'At the First Touch of Winter'; 'A Minuet'; and 'A Bientot.' Of his two plays, 'Cousin Dick' appeared at the Court Theatre and 'M. LeDuc' at Saint James'. He was also author of 'Imperial India'; 'An Artist's Journal'; 'Virginie'; and 'Abibal, the Tsourian.'

PRINTING, the art of producing impressions from characters or figures on paper or other substance. Printing from movable types is of comparatively modern origin, it being less than 500 years since the first book was issued from the press; yet the principles on which it was ultimately developed existed among the ancient Assyrian nations. Printing from blocks and clay tablets was practised in China as early as 50 B.C. The great discovery was that of forming every letter or character of the alphabet separately, so as to be capable of rearrangement and forming in succession the words, lines and pages of a work, thereby avoiding the labor of cutting new blocks for every page.

The city of Haarlem in Holland claims that Laurens Janszoon Coster there invented the art of printing in 1423, making use of movable types of wood and afterward of lead and tin; but no printed works of his can be identified. The claims of Johannes Gutenberg (q.v.) to this invention are now generally recognized. He without question was occupied in various experimental researches of a secret nature in Strassburg, and possessed in 1438 printing materials, a press, and as it appears movable types. No book, however, was brought out by their use until after Gutenberg had returned (which was about 1450) to his native city of Mainz. Here he associated himself with a wealthy citizen, Johann Faust, who, on learning the secrets of the art, entered into partnership with Gutenberg, and agreed to furnish funds for developing the process. They employed to assist them Peter Schöffer, a scribe whose previous occupation had been the copying of books, and who appears to have been a man of taste and genius, and well fitted to bring a new process of this sort favorably before the public. He has the credit of substituting metallic types cast in plaster molds in the place of those which Gutenberg had previously made by carving pieces of wood and metal, and of still further perfecting the art by the invention of punches in hard metal, by the use of which sharpness of outline could be given to the matrices in which the types were cast, and perfect uniformity be retained in the type by continuing to use the same punches for producing as many matrices as might be required. The inventors succeeded in printing a considerable number of books, the first of which known to have been printed with movable types

PRINTING





1 A page form ready for electrotyping 2 A stereotype plate of a newspaper page
3 A roll of news paper ready for printing

were three editions of Donatus. Printing presses were in operation at Subiaco near Rome in 1465, and the types employed were more like those now called Roman than like the Gothic forms of the Germans, which with the characters imitating handwriting had up to this time alone been used. In 1469 printing was introduced into Milan and Venice; and the productions of the presses of John de Spira and Christopher Valdarfar of the latter city attained great fame for their perfection and beauty. Printing was introduced into Paris in 1470 and into London in 1474. (See CAXTON, WILLIAM). Before the year 1500, it is stated, printing presses had been set up in 220 places in Europe, and a multitude of editions of the classical writers in their appropriate Greek and Latin characters were given to the world. A Greek grammar wholly in Greek types was printed in Milan in 1476. A Hebrew Bible was printed at Soncino in the duchy of Milan in 1488. Italic type was invented about the year 1500 by Aldus Manutius of Venice. From the 17th to the 19th century a great variety of ornamental type came into use, the styles differing from each other in the shapes of the letters, in the heaviness or lightness of the lines and in the shading. Great ingenuity has been exercised in multiplying these varieties in so limited a field. The largest size of type for books was formerly called great primer, and is seen in the largest old Bibles; it is now seldom used. The other old names now going into disuse are English, pica, small pica, etc. See table below. The term pica, however, is retained, being one-sixth of an inch, a convenient standard unit for type measurement.

Great Primer, English, Pica,

Small Pica, Long Primer, Bourgeois,

Brevier, Minion, Nonpareil, Agate, Pearl, Diamond, Brilliant.

Late in the 19th century the «point» system was adopted generally by printers. In this new arrangement one inch equals 72 points and consequently 12-point would make six lines to the inch. The principal types are designated as follows:

Nonpareil	6 point
Minion	7 "
Brevier	8 "
Bourgeois	9 "
Long primer	10 "
Small pica	11 "
Pica	12 "

For handbills or posters special types are employed of extra large sizes and named in multiples of pica, as 20-line pica. From about eight-line up they are commonly made of hard wood. A complete assortment of one size is called a font or fount, and the «sorts» that make up an ordinary font of Roman type are as follows: Three complete alphabets in capitals, small capitals and small or «lower case» letters, making 78 characters; the double letters ff, fi, fl, ffi, ffl (each cast in a single piece on account of the kern or bend of the f not permitting it to stand separately against another f, an i or an l), 5; the diphthongs Æ, Œ, Æ, Œ, æ, œ, 6; figures, 10; marks of punctuation, 6; the apostrophe, hyphen, parenthesis and bracket, 4; four sizes of dashes and braces in five pieces, 9; the characters &, &, $, £, ☞, 5; and the references *, †, ‡, §, ||, ¶, 6; total characters, 129. Besides these, there are required for filling the blanks between words at the end of lines, etc., four sizes of spaces and four of quadrats (the former and the smallest of the latter being subdivisions of the em [m] or square of the size of the type, one equal to it and the other two multiples of it), making altogether 137 sorts.

The early printers cast their own type; made their own ink-balls, or ink-rollers; instructed some local blacksmith to make the iron frames or chases in which the types are confined for printing; and either made or designed the wooden cases and stands that held their type. With the advent of the iron hand press and the cylinder press or machine, press-building became a separate business. (See PRINTING PRESSES). Early in the 19th century the making of type or type founding was separated from the printing office. (See TYPE). Paper-folding machines began to be manufactured about 1860, and as these developed, and other conveniences were discovered, the business of binding became separated. (See BOOKBINDING). About the same time experimental type-composing machines were built, culminating in the linotype or slug-casting machine. (See COMPOSING MACHINES). Stereotyping, electrotyping, photo-engraving, lithography, all have come from the printery and developed into separate arts or industries, and to gain a broad view of modern printing all these subjects should be consulted by the students. At the present time a very large part of the composition work on books and newspapers is performed by machine instead of by hand. One of the great troubles with hand composition is the time necessary for distributing the so-called dead matter after it has served its purpose on the press or in giving the impression for an electrotype. Make-up is the term employed to designate the taking of composed type from the galley and building or making it into a page of the prescribed size, adding titles and folio or page numbers, etc. Proofs are taken from type in galley and also in page form. These are read for errors and corrections are made before going to press. The form or number of pages placed on the press at one time varies from two to 128, according to the size of the type page and the size of the press. Imposition is the placing of the pages on the press in such a manner that when the printed sheet is folded the pages will follow one another in consecutive order. A letter or number called the signature is placed at the foot of the first page of each section and serves as guide to the binder in assembling or gathering the sheets. Stereotyping is the casting of a page in one piece. Its object is to save the wear on new type-faces and also to permit the release of the type for other work. Stereotyping is now performed by electrotyping and by the papier maché process. In the former the type page is impressed on wax, which is then sprinkled with carbon and iron filings, after which it is immersed in a bath of sulphate of copper through which an electric current is passed. Thereupon a copper coating is deposited on the wax filling out the convolutions of the type. After sufficient strength of copper is so deposited the coat is backed up with softer metal, is taken out, trimmed and beveled, and if necessary is made type-high by affixing to a block of hardwood. Papier maché work is the favorite with newspapers. The autoplate machine is now in general use. Its operation is entirely automatic.

Printing rollers consist of a mixture of glue, glycerine, glucose and sugar. The formula of mixture is varied to suit the speed of the machine and the temperature of the pressroom. In summer it is a frequent happening in a pressroom to have one or more rollers melt under high speed.

Previous to 1865, printing was largely a handicraft. It is true that power presses had come into use for daily newspapers, and also that in some of the printing offices the mass of printing was done on presses operated by man-power, either with a hand crank or lever, or by a treadle for the foot. The type was set wholly by hand. The few pictures introduced were either cut laboriously in wood (see Wood Engraving), or they were drawn on transfer paper, and printed lithographically, and these litho-presses were also run mostly by hand. In the period of about 1875 to 1895 the methods of printing underwent an almost complete change, so that modern printing may really be classed as a new art, or a series of developed branches of industry all working to a common end, the attractive and cheap reproduction of reading matter and illustrations. Printing is now mainly the product of machinery, of a great variety of types, intelligently guided by specialists, few of whom are all-round printers, knowing the art in detail. The typecasting and typesetting or linotyping is almost wholly machine work; the presses all run by power, and are mostly fed from a roll of paper or supplied with sheets by automatic feeding-machines. Many presses deliver their product folded; if not folded it usually goes to a folder, and may be also ruled, punched, embossed, numbered or wire-stitched by machinery. The pictures are drawn by professional artists, photo-engraved, and may then be duplicated by electrotyping, and placed with type in forms for printing. Color printing has advanced, both from the lithographic and typographic side, until the most beautiful and artistic reproductions of paintings are sold with cheap periodicals or given away to advertise goods.

When the term printing is used without qualification, typographic printing from relief plates is understood; but there are many other processes properly included in the broad term printing. The most common of these is lithography, which was originally done from a flat porous stone, but is now executed chiefly from aluminum and zinc plates, which are available for rotary presses, and which have vastly increased speeds. Wallpaper printing is also a different art. The typewriter really prints, though we use the word writing for its accomplishment. The neostyle which reproduces typewriting effects, is really a printing machine, and so are a number of other duplicators on the market, as the mimeograph, multigraph, etc.

Charles H. Cochrane,
Author of 'Modern Industrial Progress.'

PRINTING PRESSES. The first printing presses were a development of the cheese or cider press common in all large mediæval households, and needed little change to adapt them to the uses of typography.

Gutenberg's press, upon which he printed his 'Bible' of 36 lines (1450?), his 'Bible' of 42 lines (1455?), and the 'Letters of Indulgence' of 1454, 1455, 1461, consisted of two upright timbers with connecting crosspieces at top and bottom, and with two intermediate cross timbers. The lower one was the support of the form of type. Through the upper passed a large wooden screw, the lower end of which rested on the centre of a wooden platen. After the form of type was fastened to its bed it was inked by hand inking-balls made of wool covered with soft leather. The sheet of paper, previously dampened, was then laid carefully upon the type, and the bed pushed to its place. A wooden lever was thrust into its socket and the platen screwed down, held for a moment and then raised. The bed was drawn out and the printed sheet removed and hung up to dry. For 150 years this simple but effective form of the printing press continued in use, and the books thus printed by Faust and Schöffer at Mainz, Jenson and the Aldi at Venice, Caxton at Westminster, Plantin at Antwerp, the Elzevirs at Leyden and at Amsterdam, and Bade and the Estiennes at Paris have brought their makers the highest fame.

First Improvements.— The first recorded improvements were those of William Janson Blaeuw, of Amsterdam, about 1620. He passed the spindle of the screw through a wooden block, which was guided in the wooden frame, and from it hung the platen. He also invented a device for rolling the bed in and out under the platen, and improved the hand lever for turning the screw. This press was widely used on the Continent, and in England and America, and on such a one Benjamin Franklin worked in London in 1725. One of these, that from the Watt printing house, is now preserved in the Patent Office in Washington. For nearly two centuries this sufficed for books of small editions and for the little-circulated small newspapers and gazettes of the 17th and 18th centuries. The Earl of Stanhope in 1798 made a press with a cast iron frame and greater leverage that had some use in England. George Clymer, of Philadelphia, in 1816 substituted a combination of levers for the screws, and called his invention the Columbian press. He carried it to England and there in 1822 Peter Smith devised a toggle-joint, simple and effective, that replaced the screw and levers.

The final development of the hand press came in 1827, when Samuel Rust, of New York, perfected the Washington press. The iron frame was lightened and strengthened, the

toggle motion was improved and a screw top regulated the pressure. With this improved hand press came the substitution of composition inking rollers for the leather covered ink-balls previously employed. The bed was made to slide in and out on a track by turning a crank connected with two endless bands. A bent lever working in a toggle-joint forced the platen down and coiled springs raised it. To the end of the bed was attached the tympan, a wooden or steel frame over which a cloth was tightly stretched and carrying the blanket to modify the force of the impression. When the bed was run out this was raised to an ob-

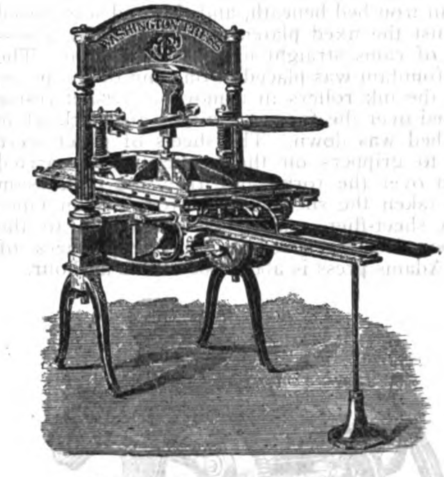

FIG. 2.—Washington Hand Press.

tuse angle. The paper was laid upon this and carefully fitted to adjusting pins; the frisket, a thin frame holding a sheet of paper cut to the size of the form, was folded over the paper to protect it, to steady it and to raise the paper from the type after the impression. This press has been improved in construction, but in principle and form substantially the same press is widely used to-day in the United States as a proof press and for the special work for which it is fitted. Its capacity is about 250 sheets an hour printed on one side. Alike in principle and construction, though differing in detail of depressing and raising the platen, is the Albion hand press as widely used in Great Britain.

The operation of the hand press when type, press, ink and paper had been prepared necessitated these 11 processes: The form was inked by hand; the paper was fitted to its place on the tympan; the frisket was folded over it to hold it; the tympan was folded down over the form; the bed was run under the platen by turning the crank; the platen was forced down by the workman's power applied to the lever; released, it was raised up by the springs; the bed was rolled out by a reverse motion of the crank; the tympan was raised; the frisket opened, and the printed sheet removed. Modern invention has sought to reduce all these to a single automatic process operated by mechanical power. Necessity divided the course of invention into three lines; the small job press and the large book and newspaper press soon widely diverging in type and construction to secure fine printing in one and the greatest speed in the other.

Bed-and-Platen Presses.—The development of the bed-and-platen power press for fine book work and illustrations reached its highest state in the Adams press, invented and patented by Isaac Adams, of Boston, in 1830 and 1836, and improved in many ways by R. Hoe and Company since that firm acquired his business and patents in 1858. Over 1,000 have been manufactured, and a few were reported to be yet in operation in Boston in 1918. Adams, after a few experiments with a timber frame, built his presses of iron and fixed the platen immovably in the frame. The form was placed on an iron bed beneath, and this bed was raised against the fixed platen and lowered by a system of cams straightening a toggle-joint. The ink fountain was placed at one end of the press, and the ink rollers in a movable frisket-frame passed over the face of the type and back while the bed was down. The sheets of paper were fed to grippers on the frisket which carried them over the form, and after the impression was taken the sheets passed forward on tapes to a sheet-flier, which delivered them to the fly-board. The speed of the larger sizes of the Adams press is about 600 sheets an hour.

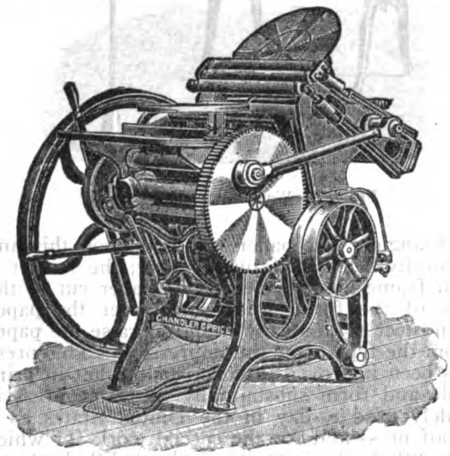

FIG. 3.—Gordon Jobber.

The most successful press designed for small job work substituted for the hand lever and crank a rotary power wheel which could be driven by a treadle by the foot of the operator, or by belt and shafting. The bed was set in a perpendicular frame, and the form was clamped to it. To the bed frame near the bottom was jointed the frame that held the platen. This opened to an angle of about 45 degrees. A crank rod fastened to the wheel brought the platen up to the type form and back at every revolution. On the platen by adjustable pins or quads the position of the paper was exactly fixed. Two thin steel rods automatically folded over the margin of the paper as the platen rose. Above the bed of the press, and at a slight angle, was set a steel inking-disc, about the size of the bed, that slowly revolved, while at every revolution of the driving wheel a pair of ink rollers descended from the inking-disc over the form as the platen fell away, and back to the inking-disc as the platen rose to the dorm again. This automatic inking was even and uniform. This press prints cards, letter-heads, hand-bills and the like. The labor needed is that of a boy or girl to feed and take off the sheets one by one. Many varieties are made, with varying excellence of detail. The Gordon press here illustrated is typical and has been widely used. The capacity is about 1,000 sheets an hour. The Gordon press was followed by a host of imitators. The first real improvement was the use of a cylinder instead of a disc for ink distribution, which came in the Globe machine. This idea was more fully developed in Gally's universal press, and later in Thompson's Colt's armory press, which is also characterized by great strength and rigidity. The Gordon disc type of press was highly developed by Golding of Boston, in a scientifically constructed and rapid machine. The old-style Gordon was reduced in cost of manufacture and has been made in enormous quantities by Chandler and Price, and sold all over the globe.

Cylinder Presses.— The basic principle of the cylinder press — a flat type form passed under an impression cylinder — is as old as Gutenburg's time, when from crude machines of this type copper-plate engravings were struck off; but no practical development of it was made until the beginning of the 19th century. So many patents have been issued since then for various devices to secure excellence or economy of operation that it is possible to note only the most striking and most successful. The first printer to work out a practical cylinder press was Frederick Kőnig, a Saxon by birth, who removed to England in 1806. He associated with him James Bensley, a London printer, and a machinist, a fellow-countryman, Andrew Bauer. The product of their labors was a press which they put in operation in London in 1812. The form of type was placed on a flat bed, which was carried under an impression cylinder that had a three-fold action. On the first third the sheet was fed at the top upon the tympan and gripped, on the second part of the revolution the sheet received the impression and was removed by hand; and on the third the empty tympan came up to receive another sheet. The most efficient device which they invented to roll the bed holding the type form to and fro was this: A long shaft turned by gearing from the outside of the frame carried a pinion on its inner end; the shaft had in its length a universal joint that allowed for an up and down motion of the pinion as it revolved. Underneath and fastened to the bed was a rack, or row of teeth, with a crescent-shaped segment of metal and pins, or studs, at each end. To the outer end of the shaft was attached the wheel connecting with impression cylinder; this wheel, when set in motion, revolved the pinion and moved the bed by means of the teeth in the rack. When the bed reached the end of its appointed course, the pinion turned around over one of the pins or studs against the segment in the rack and immediately re-engaged the teeth on the opposite side and carried the bed back again to the other end, where the reciprocating motion was repeated. König followed this in 1814 by a continuously revolving cylinder, which was slightly reduced in diameter along that part of the periphery not used for the impression so as to allow the bed to return under it freely after the impression. He made also a two-cylinder press of this pattern, and two of these two-cylinder presses were set up in the London *Times* office in that year. Their capacity was 800 impressions an hour. This same year he devised a two-cylinder press — the first perfecting press — by which a sheet was printed on both sides at one continuous operation. The forms were placed one at each end, and the sheet after being printed on one side under one cylinder was by tapes carried over a registering roller to the second cylinder for printing on the reverse side. This machine Applegarth and Cowper, by improvement, made very efficient. Every year showed patents on improvements, but the next of great value was that of Napier in 1828 and 1830. He discarded the tapes for the conveyance of the sheets and substituted "grippers" or "fingers" to clasp the sheets to the cylinder for the impression, and for delivering them after printing. He also made the impression cylinders of small size to make two or more revolutions to each sheet printed, and devised the toggle for raising the cylinder to allow the form to run back without touching.

Köenig and Bauer went to Germany where they later perfected a machine having a bed that rested on and was reciprocated by a four-wheeled truck and crank. They and their successors were the principal makers of printing presses in Germany for 80 years.

The pioneers in introducing cylinder models into the United States were R. Hoe and Company, who had been for some time manufacturing bed-and-platen presses. Robert Hoe sent Sereno Newton (later to be a partner in the house) to England in 1832 to study the new inventions and devise improvements. The Hoe single small cylinder, double small cylinder and large cylinder perfecting press were designed and built, and with added improvements are being manufactured by them to-day. Hoe and Company patented mechanism to drive the bed in 1847. Two racks facing each other on different planes and separated by the diameter of the driving wheel were attached to a hanger fastened on the lower side of the bed. The driving wheel was on a horizontal shaft and moveable sideways, so as to engage first one then the other, of the racks. A roller at either end entering a recess in a disc on the driving shaft in a half revolution brought the bed to a stop and started it in the opposite direction. This was a new principle; a crank action operating directly upon the bed from a shaft having a fixed centre.

As the demand for printing presses grew other makes came into the field. Andrew Campbell designed, perfected and built, about 1865, a single cylinder newspaper and poster press, which became known as the Campbell country press, and which secured the widest sale of any press of that character in its time. By means of a very large gear and reversal mechanism keyed solidly on one end of a drum cylinder, he locked together the bed and cylinder so that register was perfect. The rollers and other mechanism were extremely simple, and he was thus able to sell the presses at a low price. An improved form of this press, styled the complete press, was employed by the early color printers, as McLaughlin Brothers, of New York. Another great success of the Campbell Company was their book and job press, which enjoyed a large sale from 1875 to 1890. This had a small cylinder, called a two-revolution, because it revolved once while the bed was making the return stroke. It employed improved features of ink distribution and sheet delivery. A. B. Taylor and Company were among the early makers of cylinder and double cylinder presses in New York, closely following the lines of the Hoe machines. Cottrell and Babcock began building cylinder presses about 1870, their most notable early production being the stop cylinder, which was popular for a dozen years. Because the cylinder came to a dead stop in taking the sheet, a perfect register was secured, and the other details of the machine being well worked out, it came into use by the best printers. The Hoes also built a stop cylinder to meet the competition. In time Cottrell and Babcock separated, and Babcock brought out the Optimus machine, which was one of the first to deliver its sheet without chance of smutting, printed side up. C. Potter, Jr., also built many cylinder presses, of rather light construction, which sold mostly to country newspaper and job offices. Whitlock followed with a very light and inexpensive cylinder machine, utilizing the Henry bed motion. Walter Scott, who learned printing press building with the Hoes, was one of the most fertile inventors of printing machinery, and established press works in Plainfield, N. J., about 1875. He took out more patents than any other inventor in this field, and developed a long line of useful machinery. About 1880 the half-tone illustration had made such headway, and the demand for superior printing became so imperative, that the dry paper printing on a hard surface came into universal use, and the cylinder presses of the day were all too weak to meet the demands made upon them. All went to building heavier machines, but the Huber and Miehle press builders were among the first to recognize this need, and secured most of the market for fine printing. Automatic paper-feeding machinery has increased the demand for this class of presses. The Miehle, being the faster press of the two, forged ahead, and finally absorbed the Huber Company. It has been widely sold all over the world. The Hoes virtually abandoned the two-revolution fine jobbing press field, but Babcock, Scott, Cottrell and Whitlock built heavier, and remained in the market. Potter quit, and later Campbell, while the Cottrells gradually went into a different class of machinery.

Automatic Presses.— While the above described development of cylinder presses was going on, the small platen press was not forgotten by inventors, who improved upon these machines, and brought out a new class, that are properly styled automatic machines, because they do not require hand feeding of the paper, sheet by sheet. Kidder, of Boston, was one of the first to adapt the reciprocating platen press to use paper fed in from an endless roll, and cut off into sheets after printing. About the same time Meisel of Boston began building special machines, roll-fed, and automatic in operation. These machines were confined to a limited class of work and printed from flat beds. Harris brought out a press in which the type-form was replaced by a curved electrotype plate, mounted on a cylinder, and this not only worked automatically but permitted high speed. This was so successful that a whole line of automatic presses has been brought out by the Harris

Company, which has sold them all over the world. Wood and Nathan improved the old type of Gordon jobber by adding a paper feeding and delivery device, which has become known as the Standard press. Kelly built a small cylinder, self-feeding, automatic press, which is sold by the American Type Founders' Company, and is largely used. The Autopress, Osterlind, New Era and Stokes and Smith presses are others which have successfully entered this field.

Offset Presses.— Late in the 19th century a New Jerseyman named Rubel conceived an offset press, in which the printing was first done on a rubber cylinder, and this rubber cylinder rotated in contact with a printing cylinder, so that a continuous sheet of paper could be run and printed between the cylinders. The idea was developed and the first commercial machines employed by A. H. Kellogg and Company of New York. This machine brought lithographic principles into the field of the typographic printer, and several concerns built them, among the most successful being the Harris Company. They are occupying a wider and wider field, because they permit beautiful artistic illustrations to be executed on a cheap, coarse-finish class of paper. The machines offer special convenience for combining text with illustrations, and are in increasing demand for the printing of illustrated catalogues.

Newspaper Presses.—The demand for faster presses of greater capacity grew enormously with the years of the 19th century, and invention kept pace. The first step forward was the Hoe type-revolving machine, which was put at work in the Philadelphia *Public Ledger* office in 1846. They had put into effect the basic idea of fastening the type to the main cylinder, while smaller cylinders carried the sheets of paper to receive the impression. There was designed an apparatus for fastening the columns of type in a form on a large central cylinder in a horizontal position, each page in its own cast iron bed. «V»-shaped column rules tapering to the base, with a special arrangement for locking up the forms, held the type in place with the surface forming a truc circle. An automatic inking apparatus carried the main ink-well beneath the cylinder, with distributing rollers between the impression cylinders. This first machine was built with four impression cylinders touching the type cylinder so that two were on each side and one as far above the other as possible. The framework of the machine bore four feed tables. At each a boy fed the sheets of paper to the automatic grippers, operated by cams, on the impression cylinders, which carried them around against the revolving forms of the central type cylinder. The printed sheet was conducted out by tapes under the feed board, and the patented sheet-flier, with its long wooden fingers fastened to the shaft and operated likewise by cam and springs, piled them upon the delivery tables. Upon this machine, with 2,000 revolutions an hour, 8,000 sheets were struck off printed on one side. The capacity of the machine was found to be greatly in excess of this, and the number of impression cylinders and accessories was increased to 10, giving the machine a product of 20,000 sheets an hour. Though this machine was cumbersome, and at times threw out type rather liberally, it met a need and the impetus given to the newspaper business was tremendous. Circulations that had been limited to the capacity of the old bed-and-cylinder press were rapidly increased twenty-fold. Many new papers were started. This press maintained its supremacy for 20 years and 175 were built. In 1848 the first sent abroad was set up in the office of *La Patrie* in Paris. Marinoni afterward built similar presses in Paris. The next great step was when there was perfected the process of making curved stereotype plates by the use of flexible paper matrices. A simple adaptation of the bed of the type-revolving machine provided for the clamping of stereotype plates on the cylinders in place of the type forms. The forms could now be duplicated. The large papers such as the New York *Herald*, the London *Daily Telegraph* and the London *Standard* each kept five presses in constant operation as circulation increased.

Web Presses.— There remained yet another step before the increasing requirements of speed could be met. It was taken when William Bullock, an American, of Philadelphia, invented in 1865 the first printing press to print from a continuous web or roll of paper. Thirty years before, Sir Rowland Hill had suggested the possibilities of such a machine based on those that printed cotton cloth from engraved cylinders. But no practical working out of the problem in its details was offered. The Bullock press consisted of two plate cylinders and two impression cylinders, the second of which was made very large to lessen the offset from the first printed side of the paper. The stereotype plates were short of filling the whole circumference of the form cylinders, because the sheets were cut before printing by knives set in the cylinders. This was the radical fault of the press. The sheets were then carried through the press by tapes and fingers and delivered by a series of automatic metal nippers on endless leather belts, placed at such a distance apart as to grasp each sheet successively as it came from the last printing cylinders. The Bullock press was perfected and came into considerable use. The New York *Sun* was the first newspaper to make use of them, and the New York *Herald* soon followed.

In 1868 the London *Times* had gone so far with its own experiments in constructing a rotary perfecting press that it set up the «Walter» press in its office. This had a capacity of 12,000 sheets an hour. It was similar in construction to the Bullock press, except that the cylinders were of uniform size and placed one above the other. The sheets, however, were severed after printing, brought up by tapes and carried to a sheet-flier, which moved back and forth and «flirted» the sheets alternately to boys on either side. This press was equipped with dampening cylinders containing sponges filled with water, and required a very strong and expensive paper. This press was also adopted by the London *Daily News* and the New York *Times*, but has now entirely gone out of use.

To satisfy the demands of small daily papers throughout the country for speed and economy the Duplex press appeared late in the 19th century. It is a flat-bed web-perfecting press and prints directly from the type form with a capacity of from 5,000 to 6,000 per hour of either 4-, 6-, 8-, 10- or 12-page papers. The flat-beds are stationary and the cylinders reciprocate over them. By an ingenious method of handling the web of paper, it is taken from the roll, led to the cylinders, printed on both sides and delivered to the folder. It has been brought to a high degree of perfection.

Rotary Perfecting Presses.— About 1875 the modern rapid rotary perfecting newspaper press was born. Numerous inventors were trying to accomplish the feat of feeding from a continuous roll of paper, printing on both sides at one operation, and delivering the product folded and cut as a complete newspaper. They had to overcome the difficulty of offset, that is, the smutting of the second side from wet ink if printed on at once. They had to secure better and more uniform paper than then ordinarily supplied. They had to cut the roll to separate the sheets while the roll was traveling at a rapid rate. These problems were solved more completely by Andrew Campbell than by any other one man, though the credit of the invention has not been usually accorded to him. He built and operated a press in Jersey City which was the first really satisfactory perfecting newspaper press, but through misunderstandings and disagreement with his financial backers he refused to sign the necessary patent papers, or to protect his invention in any way, and allowed it to become public property. In the meantime the Hoes had worked on the problem, and Stephen D. Tucker had patented a rotary collecting cylinder that was a very useful adjunct. The Hoes were, therefore, able to put together all this knowledge and produce a commercial perfecting press, and by continuing to absorb inventions they have become the leading manufacturers in the world of rapid newspaper presses.

The first machine of this type that R. Hoe and Company built went to London to *Lloyd's Weekly*, and the first to be set up in the United States was used in the office of the New York *Tribune*. The limit of capacity depended on the ability of the web paper to stand the strain of passing through the press. The average speed was 12,000 papers an hour.

The pressure on the newspapers demanded larger than eight-page papers. It became necessary to devise some way to print 10-, 12-, 14- and 16-page papers at one impression. About this time Anthony and Taylor of England patented devices by which the webs of paper could be turned over after printing on one side and the opposite, or reverse side, presented to the printing cylinder. Mr. Hoe bought the patent rights for England and the United States, and with them combined ideas patented by Luther C. Crowell of Boston, who had made a machine for forming paper bags. After costly experiments these ideas were incorporated in a so-called «Double-Supplement» press, which was set up in the New York *Herald* office. Simplicity, speed, accuracy and efficiency had been combined. This press turned out either 4-, 6-, 8-, 10- or 12-page papers at the rate of 24,000 an hour; the odd pages were accurately inserted and pasted in; the papers were cut and delivered folded. This press was really two presses built into one frame. In the secondary part the plate cylinders were half the length of those in the main part and at right angles to them. These were used for the supplements of two or four pages when it was desired to print more than eight pages. Each part was fed by its individual roll of paper. The plates being secured to the cylinders, the two rolls of paper were carried, each through its part of the machine, between two pairs of plate cylinders and impression cylinders and printed on both sides. Then the two webs of paper passed over turning bars, or «angle bars,» with an edge at 45 degrees from its base, by which they were laid evenly and exactly one over the other as a brush from the paste fountain glided along the inner fold, pasting them together. The papers passed on down a triangular «former» that folded them along the centre margin. Thence the printed and folded web of paper passed over a cylinder, from within which a revolving blade projected and thrust the paper between folding rollers, while at the same moment a knife in the cylinder severed the sheet. A rapidly revolving mechanism, resembling in its motion the fingers of a hand, disposed of them accurately on traveling belts that hurried them on to final delivery. Hundreds of this press have been built and operated in this country and abroad. Their efficiency was increased about 1900 by an automatic stereotyping machine called the autoplate (q.v.).

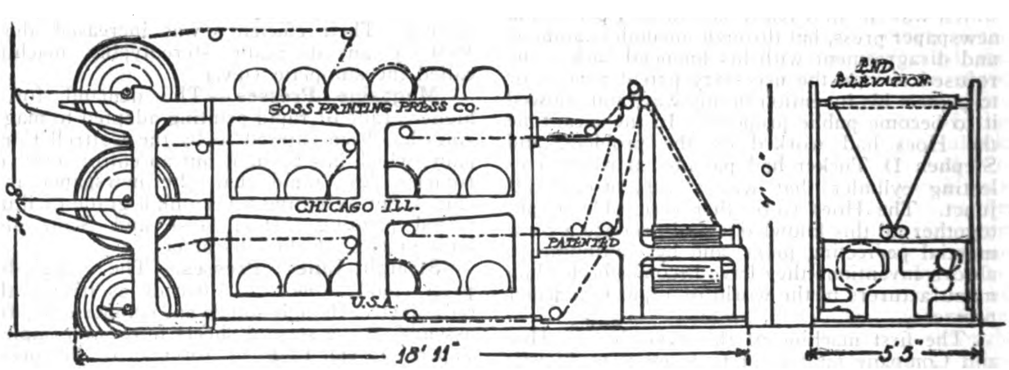
Magazine Presses.— The demand for a higher grade of rapid printing adapted to magazines has been catered to by the Cottrell Company, which has brought out an entire series of rotaries, less rapid than the newspaper machines, but executing a very high grade of illustrated printing. Hoe, Goss and Scott also built presses of this character.

Straight-Line Presses.— The angle-bar press stood alone for a decade as having the only device, though somewhat cumbersome, for assembling the several sheets into one complete paper. Joseph L. Firm, foreman of the pressroom at Frank Leslie's publishing house, however, solved the problem in a new way, and in 1889 patented the straight-line press. His first design was a simple tandem press. Three sets of cylinders were set in a straight line, and the printed product of the first passed over the second, and of the first and second over the third, thus assembling all three sheets over a triangular «former» for folding, cutting and delivering. It was but a step, to secure economy of construction and space, to build the press in tiers instead of tandem. Firm had the usual fortune of poor inventors. His first order, which was for a sextuple press, came from the New York *World*, and its building exhausted his resources. When set up, in 1891, it was so crudely and badly built that, failing to work properly, it was condemned. Poverty followed, but not for long. The Goss Printing Press Company of Chicago became interested in the straight-line press invention, which was being pirated, and bought it, taking Mr. Firm into the company. Litigation followed and established the patent and harmony among the printing press makers. Improvement was rapid. These presses mark the final development of the power printing press. Evolution and the requirements of the publishers of metropolitan newspapers have brought forward presses with various improvements of detail and in increasing sizes, until one press, so-called, is a compound of two, four, six, eight, 12 presses built into one frame, one above the other, side by side or tandem, or all three for economy of space and power and efficiency, but the basic principle is the same,— a web of paper passes between two pairs of plate and impression cylinders and is printed on both sides; it is assembled (if on a double-supplement press or one of greater power), pasted, folded, cut or separated, folded again and delivered ready for the carrier or mail-room, at a speed of 48,000 eight-page papers (the unit of manufacture) an hour; and with an accuracy that denotes exactness and skill of manufacture, excellence of material and utmost care and nicety in adjustment and operation.

The first improvement in the Hoe type of fast press was the quadruple (or four-fold) press built for the New York *World* in 1887. A further advance in 1891 produced the sextuple (a six-fold press), so constructed that the cylinders were all parallel. Its delivery capacity was 72,000 eight-page papers in one hour, or 20 a second.

and delivering its product on the mezzanine floor. In 1903 the New York *Herald* increased the size of its paper from a six-column page to a seven-column page. It was able to make over its presses to accommodate the increased width of the web, though web and cylinders now barely clear the framework. The Duplex Company of Battle Creek, Mich., manufactures what they term a "tubular" perfecting press, in which the plate cylinders are reduced in diameter, becoming literally tubes, that print continuously. These presses are very speedy. H. A. Wise Wood brought out in 1917 an improved perfecting press designed to reduce the strains on the web of paper and permit more rapid printing.

Newspaper Color Presses.— Ever searching for new features, New York newspaper publishers in 1902–03 were planning and designing supplements and main sheets embellished with color printing. Their scientific pressmen and the press-builders were called on to produce the desired effects. Walter Scott of Plainfield, N. J., designed and built a very efficient press that was set up in the office of the New



THE GOSS THREE-DECK STRAIGHT-LINE PRESS.

FIG. 4.— Diagram of the sextuple unit. Dotted line shows the course of the three webs of paper, which are assembled on the triangular "former" or folder. This press is two plates wide, has a capacity of 24,000 four-, six-, eight-, 10- or 12-page papers an hour; or 12,000 16-, 20-, or 24-page papers. It weighs 42,000 pounds and requires 40 horse-power.

In 1896 an octuple (eight-fold) press was built for the New York *World*, with a corresponding increase in output, and four double sextuples, with color-printing attachment, were constructed for the New York *Journal*. Even larger are the six giant double-octuple presses which R. Hoe and Company designed for *Lloyd's Weekly*, and other great newspapers continue to purchase these enormous presses.

The 1902 patterns of the Goss press carry also "color decks," being an arrangement of two extra pairs of cylinders on the top of the machine, enabling the printing of three colors on the first and last pages of the newspaper. Two large Goss presses now in use are in the office of the New York *Herald*,— called duodecuple, or 12-fold. The *Herald* had two octuple presses and needed another. Its available floor space was entirely filled. The makers proposed to build in the air, as the pressroom was lofty, rising above the street level, and did on the same framework build another quadruple press on top of each of the octuples. Each press is now really made up of three quadruples, in tiers. Each can be operated individually; each delivers individually, the top press being fed

York *World* in 1893. This had five two-page wide color cylinders for electroplates set tandem, with a pair of cylinders for printing the reverse side in a single color, usually black. Below was a complementary stereotype cylinder machine for printing four pages in a single color; so that this machine could produce either a four-page paper, one Christmas supplement showing outside pages in five colors and the inside in a single color. By skilfully dividing the ink fountains and combining colors and over-printing, many shades are produced in the same paper, one Christmas supplement showing no less than 36 shades. This press was removed to the office of the *Post-Dispatch*, in Saint Louis, in 1902, where it is still doing very efficient work. To meet increasing demand *The World* had R. Hoe and Company build an angle-bar double color-press in 1894, each side of which printed four (the two outside and the two inside) pages in four colors, and four pages in a single color; and another, a straight-line press, in 1898 with a capacity for four pages in five colors, and four pages in two colors; these two eights can be collected and delivered as a

16-page paper. The press will also produce a 24-page paper with four colors.

Color printing presses have been widely adopted by the American newspapers, and in the new models all the manufacturers offer «color decks.» The popularity of these colored sheets created a demand for illustrated supplements of pictures in one color. This has been supplied by what are called magazine webs and also by machines of the offset type, producing rapid photogravure work.

The skill of the American printing press manufacturers has produced so many designs, adapted to meet every demand of newspaper publishers, large and small, that it is impossible to enumerate the patterns. The presses here illustrated are sufficient to show the types.

In 1918 there were more than 80 factories in the United States producing printing presses, and 56 which made both printing and binding machines. The gross annual production of the former is over $8,000,000, and of the latter over $3,000,000. (See NEWSPAPERS, AMERICAN; PRINTING; PRINTING TRADE, AMERICAN). Consult Hoe, Robert, 'Short History of the Printing Press' (New York 1902), and Hoe, R. M., 'Literature of Printing' (London 1877). Consult also works referred to under article PRINTING.

CHARLES H. COCHRANE,
Author of 'Modern Industrial Progress.'

PRINTING TRADE, American. Although the printing trade had its inception in America considerably prior to the Revolutionary War, it was not until some time after the conclusion of that struggle for liberty that it began to assume the proportions of a national industry. In the year 1775, for example, there were less than 100 printing establishments upon American soil, and these were almost exclusively confined to the coast towns. Even as late as the year 1810 there were but 35 printing shops scattered about throughout the interior of the country, while, in 1775, with the exception of the two or three offices that were located in Massachusetts and Pennsylvania, the art of printing had no inland representation. A few years later a printing establishment was opened at Lexington, Ky.; another soon followed at Pittsburgh, Pa., and the third office was finally located at Cincinnati, Ohio. In almost every instance these printing offices were established for the primary object of printing newspapers, although each of them not only possessed the necessary facilities for the production of job-work, but were also able to print and bind books on the rare occasions upon which such contracts presented themselves.

From the earliest days in the history of the printing trade in America, New York, Philadelphia and Boston have been the three great centres of this industry. Other seaport towns had their local shops, but the bulk of their business was small. In fact, during the first 50 years in the life of the new nation it was Philadelphia that took the lead in every branch of the printing industry, and by the beginning of the 19th century the Quaker City presses, of which there were no less than 110 constantly in operation, were producing more English publications than any city in the world, with the single exception of London. It was here that Matthew Carey, the first great American publisher, established his plant, and with all its daily and weekly newspapers, and its book-printing and binding establishments, Philadelphia was indeed the most important centre of the American printing trade.

Gradually, however, as the demands for printed works increased other cities came into line, Albany, Hartford and Worcester being among those that developed a comparatively large trade. Their chief industry was in the printing of pamphlets. The newspapers of that day contained so little matter that they were easily read, and, as they were passed from man to man, their numerical circulation was extremely small. As the result, therefore, little effort was made to enlarge them, and persons who, like the politicians, wished to reach the general public were compelled to address themselves to the people through the medium of pamphlets. So far as actual literature was concerned the country was practically devoid of authors, and the books which were printed upon American presses were almost exclusively those which had been pirated from English publishers. Later some religious and technical books appeared, but it was many years before general literature displayed any marked development.

In the beginning everything that was used in the art of printing was imported from England. The American printers had English presses. It was from England that they obtained their type. Even the better qualities of printer's ink were imported, for the ink that was produced in the United States was of such an inferior grade that it could be used only in the roughest kinds of jobs. From time to time various American printers made some slight improvements upon the old presses, but no great evidence of progress was shown until the establishment of a permanent type foundry.

Although it was the latter part of the 18th century before there was any permanent estabment for the making of type in the United States, several attempts had previously been made to introduce such an innovation in the printing trade. As early as 1775 Benjamin Franklin had sent the complete equipment for a type foundry from Paris, but the attempt to establish this branch of the industry was not a financial success, and it was accordingly soon discontinued. Some 10 years later a Scotch firm opened a foundry in Philadelphia, but it did not thrive, and the few other scattered efforts that were made to provide American workmen with American-made type met with the same fate. In 1796, however, two Scotchmen opened a type foundry in Philadelphia under the firm name of Binny and Ronaldson, and, as the time now seemed ripe for such an establishment, they were sufficiently successful to be able to continue operations. In 1805 another foundry was opened by the firm of Wing and White, in Hartford, but they found themselves unable to compete with the Philadelphia foundry until, in 1810, the establishment was removed to New York. Two years later the firm of David and George Bruce established a stereotyping plant in New York, and, when the already established foundries refused to supply them with type for their operations, they began to cast it for themselves, and soon became one of the most successful type-making houses in America. Their success, in fact, as much as the increasing demand for type, inspired others to follow their example. In 1816 a foundry was established in Boston; in 1817 another was opened in Baltimore, and, by 1830, there were no less than 12 foundries in full operation in various parts of the country. At the present time there are about 30 of these foundries in the United States, many of which are under the control of the American Type-Founders Company.

In the early days of the printing trade in America stereotyping was, of course, unknown, and the local publishers were accordingly compelled to recompose the type for each new edition that might be required. The introduction of stereotyping by the Bruces in 1813, therefore, suggested such economy that the enterprise could scarcely have failed to meet with favor at the hands of the printers. While the plaster process, the first method of stereotyping in vogue, was invented in England by Lord Stanhope, tidings of this great discovery were soon brought to America, and David Bruce at once set sail for the Old World for the express purpose of securing the information that would enable him to make practical use of the new invention in America. Although the stories that had reached the United States had pictured the new discovery as a perfected invention, Lord Stanhope's experiments had actually by no means been concluded, and, as the result, Bruce found it impossible to acquire anything more than the most superficial knowledge concerning the process. Finding that all material facts were being withheld from him, and that it would be useless to attempt to persuade Lord Stanhope to disclose his secret, Bruce returned to the United States. So far from admitting his defeat, however, he promptly went to work, and, with the little information he had obtained, he managed by his own genius and mechanical skill to make a plate that was in every respect superior to any that had as yet been cast in England. Through his own diligence he had mastered the defects which Lord Stanhope had been unable to overcome, for his plate was not only perfectly level on both sides, but it was of uniform thickness in every part. In fact, so successful was he that an Englishman named Watts, who had succeeded in learning his process, went back to Europe with his knowledge. There he found scores of master-printers who, disgusted with the English invention, were glad to be taught how the American plates were made, and it was through his efforts that both Austria and Germany acquired the art of stereotyping.

From the day on which David and George Bruce opened their foundry in New York they had all the orders that they could fill, for American publishers were quick to appreciate the economical advantage of the new invention. It was the time when the public was just beginning to demand books, and as the plaster casts were not only made without great expense but also guaranteed plates of great durability, printers were eager to stereotype all books that might by any possibility require a second edition. From this simple beginning, therefore, came the great stereotyping industry of America. By 1850, the year in which the making of plaster plates attained its greatest development, there were more than 50 firms engaged in this business in the United States, while more than 1,000 men were employed in the work. Then came the modern improvements — the electrotyping for book-work and the introduction of the papier-mâché process in the making of newspapers — since which time the making of plates has become practically an art by itself.

Prior to 1805 comparatively little printer's ink was made in the United States. Although printers were supposed to know how to mix the compound the preparations that they concocted proved such a poor substitute that all the good inks were imported. In 1805, however, two firms — one in Philadelphia and the other in Cambridgeport — began the manufacture of printing ink, and, since that time, the industry has been steadily extended until there are now about 35 firms engaged in this branch of the printing trade. About 1860 the cheapness of aniline colors inspired a more general use of colored inks, but as many of these tints soon lost their brilliancy they did not become very popular until the chemists had succeeded in correcting this fault.

The period between 1819 and 1833 witnessed many great improvements in the art of printing. One of the most important innovations was the substitution of iron for wood in the making of hand presses. Although wooden presses had been used since the time of Gutenberg they had always proved a handicap to good printing. Even the strongest wood was weak, and as the machine was liable to give way in some part at any pull, the pressman found it impossible to obtain a good impression, even when the type surface was no larger than 12 by 20 inches. As the natural result, all hand-presses were small affairs, and as they required the services of two expert workmen to keep them going the process was as costly as it was slow. In the adoption of the iron press American printers followed the example of their English brethren. The first iron press to be made in America was completed about 1820, but, sometime previous to that date, such presses had been imported from England. Recognizing the advantage of a machine that was capable of printing a sheet three times as large as the old press and with no greater muscular effort, American printers soon demanded them, but, in spite of this demand, it was several years before the wooden presses were relegated to the junk-heap, some of them having been in use, even in New York, as late as 1850. In the beginning presses were made by Turney, Worrall, Wells and Smith, but gradually the business began to centre with Hoe in New York and Ramage and Bronstrup in Philadelphia, until, finally, nearly all the presses were manufactured by these houses.

Another invention that proved an invaluable aid to the progress of the art of printing was the making of elastic rollers for inking the type. The original method of inking was a most laborious system, the application of the ink being made with balls of pelt. Early in the 19th century, however, an English compositor discovered that a composition of glue and molasses, long used in the making of pottery, could be applied in the inking of type, and from this idea was evolved the composition roller which was so necessary to the success of the first machine presses. This roller was first employed in America about 1826. Another invention that played an important part in the production of cheap printing was the improved method of paper manufacture which came with the introduction of Fourdrinier's machine. This, too, was introduced in America soon after 1826, and since that time the growth of the printing industry has been a steady and rapid evolution.

Of course, the great necessity under the new conditions was more rapid printing facilities, and this demand was met by the inventors about 1829. Some 15 years prior to that time a German printer named König went to England to produce a cylinder machine for the use of the London *Times*. While the press that he constructed was rather successful, he returned to Germany before it was perfected, leaving the English inventors to complete the improvement of his work. This they did in many respects, but the credit for the first actual success in the making of cylinder presses is due to the American manufacturers, firms like R. Hoe and Company, who took the somewhat unsatisfactory foreign machines and brought them to a state of comparative perfection. By depending only upon good material and thorough workmanship they produced cylinders that were so much more satisfactory than the foreign goods, that, in spite of the fact that the home product is cheaper, English printers have long found it expedient either to import American printing machines, or to make their own presses from American models.

After 1833, therefore, America needed no further help from England in the development of her printing industry. With the best of paper, ink, type and presses, all made in the United States, and with plenty of money to invest in manufacturing enterprises connected with this trade, it was unnecessary for her to turn to any foreign nation for assistance, and when, in 1830, the system of cloth book-binding was introduced, all the requisites for literary progress were in her own hands.

Of course, with the development of the power press the character of the newspapers of America also began to change. Whereas they had originally been small and dull, having but little news in them, the ability to print many copies enabled them to increase their circulation, as well as their size. In 1833 the New York *Sun*, printing a sheet 11½ by 17 inches on a hand press, could not produce more than 400 copies an hour. As the demand for the paper continued to increase, however, a cylinder press, propelled by a man at a crank, was introduced in 1834, and a year later this was supplanted by a double-cylinder operated by steam power. As other papers in other parts of the country met with similar experiences, the demand for rapid newspaper presses continued, and, by 1845, it was found that even the double-cylinder machine was too slow for the requirements of the constantly growing circulation of the great dailies. See NEWSPAPERS, AMERICAN.

It was to comply with this demand that R. Hoe and Company, in 1847, invented the type-revolving rotary printing press, a machine in which the type was fastened to the cylinder and successively presented to each of the impression cylinders placed around it. For more than 20 years this press was able to meet every demand of periodical publications, but, in 1869, finding that it had at last become too slow, R. Hoe and Company perfected their web-printing machine, a press which prints continuously from stereotyped plates on a cylinder against an endless roll of paper. In spite of the almost incredible speed at which this press can be run, other inventions, which have since been perfected, now enable it, not only to print 4, 8, 12 or even more pages, but at the same time, to fold, count and paste them; to insert sheets or add the necessary covers, or even to print illustrations in many colors. In 1854 William A. Bullock perfected the first cylinder machine that was capable of printing a newspaper from a roll on both sides at the same time, but the other improvements have been the work of R. Hoe and Company, or some of their business rivals like Cottrell, Babcock, Campbell, Potter, Huber, Miehle, Joss and others.

Great as has been the improvement in the making of machine-presses, however, the other branches of the art of printing have succeeded in keeping pace with it. In stereotyping, for example, the invention of the papier-mâché process enabled printers to make a number of impressions of the same page of type, while the demand for a convex plate was met, in 1854, when Charles Craske of New York succeeded in stereotyping a curved surface.

The period between 1833 and the outbreak of the Civil War also witnessed many improvements in the art of printing, the most important being the introduction of fast printing in fine book and job work. The invention of the power press had been a blessing to the newspapers, but, for a long time, book and fine job work was still done on hand presses. It was not until 1836 that Harper and Brothers introduced a power press, although Daniel Fanshaw of New York, the printer of the Bible Society, had 10 power printing machines in operation in his shop prior to that time. These machines were manufactured by Daniel Treadwell of Massachusetts, and, although they were both bulky and inconvenient, they were the best presses on the market until the Adams press came to take their place. During all this period, however, it was believed that cylinder machines were incapable of doing fine work, and it was not until Francis Hart of New York had demonstrated the fallacy of this theory that the incredulous could be persuaded to make the change which the proper development of the trade had so long demanded.

To Joseph A. Adams belongs the credit of devising the American method of making-ready woodcuts, and he it was who first demonstrated the feasibility of the new process of electrotyping by making successful electrotype plates, in 1839. It was in 1838 that the typecasting machine was invented by David Bruce, and about 1850 that the method of printing illustrations on dry paper was discovered.

The art of engraving on wood was practised until comparatively recent times, but the introduction of the art of photo-engraving destroyed its usefulness, for, while wood engravings were extremely costly, the new process made the cheapest of illustrations possible. Lithography, or the art of printing upon stone, has been employed in the United States since 1819. It was not until 1825 that its use became commercially practicable, but since that time this form of printing has developed rapidly.

One of the latest, and, unquestionably, one of the greatest improvements in the art of printing was the invention of the typesetting machine, which is now in such general use in all large establishments that it may be said to have practically supplanted hand composition. It is by such inventions, however, that the printing trade has been revolutionized until it has grown from the small proportions of a business which engaged the attention of less than 500 men to a great national industry.

Printing has increased in volume as much as in quality. In 1900 it was rated as about the 14th United States industry; in 1914 the census returned it as the sixth industry. In 1918 Charles Francis, generally known as the "dean of the printing industry" in America, called attention to the fact that it was entitled to be classed as the third industry of the country, and from some points of view as the second industry. He reminds us that paper is a very necessary part of printing, and that its value has been usually deducted in computing printing production. When gross products are figured the leading United States industries appear as follows, 1914 figures: (1) Slaughtering and meat packing, $1,673,000,000; (2) foundry and machine shop products, $1,373,000,000; (3) printing and publishing, $1,233,000,000; (4) lumber and timber, $1,119,000,000.

When measured by net products, foundry and machine shop products comes first, and if the paper be included printing and publishing is second. The motion-picture industry is now approaching rapidly and bids fair to occupy one of the foremost places. In number of employees drawing wages and salaries, printing, publishing and paper, considered as one industry, ranks third, and in wages paid come second. From the same point of view, in capitalization, foundry and machine shops are first, and lumber and timber, steel works and printing (with publishing and paper), are practically tied for second, third and fourth place. It also appears that one-fourth of the printing in the United States is done in the metropolitan district of New York, while Chicago, Philadelphia and Boston together do another fourth. The total gross United States production of printing and publishing and the paper used in 1914 was $1,233,000,000, which figure does not include paper used for other purposes. The newspaper end of the industry is discussed under American newspapers. The magazines and periodicals, meaning the larger weeklies and nearly all the semi-monthlies, monthly and quarterlies, are produced by what is commonly called the book and job printing branch of the industry, but which is beginning to be known as the periodical, book and job printing branch, because the periodicals constitute the largest portion of its production. The great daily newspaper printing plants and the great printing houses that turn out periodicals, catalogs and books in large numbers, have all developed along factory lines of efficiency, and may correctly be classed with other factories.

CHARLES H. COCHRANE,
Author of 'Modern Industrial Progress.'

PRINTZ, Johan, yō'hän prints, Swedish colonial governor in America: b. Bottneryd, Sweden, about 1600; d. 1663. He fought in Germany in the Thirty Years War with the rank of a lieutenant-colonel of artillery in the Swedish army, but having surrendered Chemmitz in Saxony to the enemy, was deprived of his rank. In 1641, however, he regained the good will of the Crown, was raised to the nobility and made the third governor of the colony established by the Swedes on the Delaware River in 1638. He landed at Fort Christina in 1643 and until his departure from the colony in 1658 maintained the prosperity of the settlement, upheld the Swedish claims, almost unaided, against the English under Sir Edmund Plowden and Lamberton, and against his near neighbors, the Dutch. He built forts on the island of Tinicum near the mouth of the Schuylkill below Philadelphia, at Wilmington, and at New Castle, exerting much influence over the Indians along the Delaware and protecting his trade with them. At Tinicum he built himself a rude mansion, known as "Printz Hall." The influx of settlers during his rule was made up of a good class of farmers who dealt fairly with the Indians and established a precedent of kindliness and justice acted upon so successfully afterward by William Penn. The only record of Printz after he returned to Sweden is that he was made a general, and in 1658 was appointed governor of Jonköping. Consult Acrelius, 'History of New Sweden' (extracts in 'Old South Leaflet,' No. 96); Smith, 'The Thirteen Colonies' (1901); Winsor, 'Narrative and Critical History of America' (1889).

PRINZIP, Gabrilo, Serbian assassin: b. Serajevo, Bosnia, about 1893; d. a prisoner in an Austrian fortress near Prague, 30 April 1918. Though an Orthodox Serb and a member of the Greater Serbian party, he was an Austrian subject, the son of a small innkeeper of Serajevo. It was he who fired the three shots from a Browning pistol which killed the Archduke Francis Ferdinand of Austria and his morganatic wife, the Duchess of Hohenberg, in Serajevo on 28 June 1914. At the time a mere schoolboy and a printer's "devil," Prinzip may be credited with having precipitated the European War by furnishing the Austrian government with a suitable pretext for war against Serbia. He was immediately arrested after firing the shots and subsequently sentenced to imprisonment for life. Prinzip confessed, on 2 July 1914, that he had previously informed the Pan-Serbian Union of his intention to murder the Archduke.

PRIONIDÆ, a family or subfamily of longicorn beetles distinguished from its allies by the margined and usually toothed thorax. They are mostly insects of large size and robust form. Their larvæ are large, soft grubs with small heads but powerful jaws, which bore in wood and are very destructive. They rest in a nearly straight position, not bent or doubled. A number of conspicuous species are found in the United States, several of the most common belonging to the genus *Prionus,* in which the thorax bears three marginal teeth on each side, the joints of the long antennæ fit into one another in an imbricate fashion and number from 12 to 27. These insects are nocturnal, and the males are said to fight fiercely for possession of the females. One of the largest species is *P. brevicornis,* a common black beetle, which flies about in a heedless fashion at dusk. The huge larvæ, as large as a man's finger, live for three years; and are very injurious to the roots of poplar and other trees. A smaller and more slender beetle is *Orthosoma unicolor* which bores passages through the roots of grape vines.

Other species are less destructive, confining their attacks chiefly to the dead wood of stumps and decaying tree trunks. Consult Fabicius, 'System Eleutheratorum'; Olivier, 'Entomologia ou Histoire Naturelle des Insects'; Gyllenhal, 'Insects Suecica'; Dejean, 'Species Général des Coléoptères.'

PRIOR, prī'ŏr, **Matthew**, English poet and diplomatist: b. Wimborne Minster, Dorsetshire (possibly Winburn, Middlesex), 21 July 1664; d. Wimpole, Cambridgeshire, 18 Sept. 1721. He was educated at Cambridge, and in 1688 was chosen fellow of his college, Saint John's. With Charles Montague he wrote in 1687 'The Country Mouse and the City Mouse,' a parody of Dryden's 'Hind and Panther.' Through the Earl of Dorset he was appointed secretary to the English plenipotentiaries at The Hague in 1690; in 1697 he became secretary to the commissioners who concluded the Peace of Ryswick, and on his return from The Hague, secretary to the lord-lieutenant of Ireland, and finally Under-Secretary of State. In 1699 he produced his 'Carmen Secular for the Year 1700.' He succeeded John Locke as commissioner of trade and plantations and sat for a short time in Parliament. At the beginning of the reign of Anne he left the Whigs to join the Tories. Made commissioner of customs in 1711, he was employed in secretly negotiating at Paris the terms of the Treaty of Utrecht, and he remained in France as secret agent and Ambassador till 1714. On the accession of George I, he was impeached on the charge of high treason and kept in custody two years in his own house. During his imprisonment he wrote 'Alma, or the Progress of the Mind,' which, together with his more ambitious work, 'Solomon,' was published in 1718. Having been rendered nearly penniless, he published a folio edition of his poems by subscription. He was buried in Westminster Abbey. Prior made his way chiefly by his wit and social qualities. His poetical powers were at their best in short occasional pieces in the flowing ease and vivacity of narration. Consult Aldine edition of 'Prior's Poetical Works' (1892).

PRIOR, the chief coadjutor of an abbot in the government of an abbey, or the actual ruler of a monastic establishment. Not till the 13th century was prior used as a term significant of authority of rule, but rather of superiority of any kind, as experience, wisdom, advanced age. Till that time the abbot's coadjutor was styled *præpositus* (provost), but now he was called prior and under him in great abbeys was the sub-prior. Then, the head of a small monastery, of Benedictine monks, for example, was called prior. Finally, the chief officer of a convent of Augustinians, or Dominicans, or Premonstratensians, had the same title, while the corresponding officer of a Franciscan house was known as *custos* (guardian); but the heads of houses of the military orders of Saint John of Jerusalem, of Malta and of the Temple were given the title of grand priors. In church history priors are of two kinds: conventual and claustral. A conventual prior is the head of a religious house, either independently, as among the Regular Canons, the Carthusians and the Dominicans, or as superior of a cell or offshoot from some larger monastery. In the former sense he has generally a sub-prior under him. A claustral prior is appointed in houses in which the head is an abbot, to act as superior in the abbot's absence and to maintain the general discipline of the house. Prioresses in religious houses of women, whether abbeys or simply conventual establishments, had much the same authority as priors in religious orders of men.

PRIPET, prĕp'ĕt (Russian, *Pripyat*), a river in the western part of Russia. It has its rise in the government of Volhynia, and is the outlet of several lakes; flows east and southeast and enters the Dnieper. It is about 500 miles long; navigable over 300 miles and is connected with the Vistula and the Niemen by canals. Its upper course is through a vast uninhabited forest region, with large areas of marsh lands. What has become known historically as the Pripet Marshes was the scene of a great offensive movement in the World War by the Russians under General Brussiloff and the Germans and Austrians under Field Marshal von Hindenburg. The Russian operations opened on 3 June 1916 and extended along the entire front from the Pripet Marshes to the Rumanian frontier. The Russians were the first of the Entente Allies to resume the offensive on the Russian front and this was their first signal blow, resulting in the achievement of sweeping successes. Between 4 and 23 June the Russians captured 4,031 officers, 194,041 men, 219 guns, 644 machine guns, 196 bomb mortars, 146 artillery ammunition wagons and 38 searchlights, and cleared all of Bukovina of the enemy.

PRISCIAN, prĭsh'ĭ-an (Latin, Priscianus Cæsariensis, prish-i-ā'nŭs sē-zā-rĭ-ĕn'sĭs), Latin grammarian of the 6th century A.D. From his surname «Cæsariensis» it is supposed that he may have been born at Cæsarea, and it is believed that he lived about 500 A.D, as he is mentionel by Paulus Diaconus as contemporary of Cassiodorus (468–562). Almost all that is known of the facts of his life is that he taught Latin at Constantinople, probably to the imperial court of Justinian, as he is known to have received a salary from the government. His 'Institutiones Grammaticæ,' in 18 books, a most thorough and comprehensive work, has chiefly preserved his fame. A transcript completed at Constantinople by one of his pupils in 527 was reproduced in 1,000 manuscripts in the Middle Ages. Priscian borrowed largely from the first 12 of the 20 chapters of the 3d century 'De compendiosa doctrina' of Nonius Marcellus (q.v.), who was especially indebted to Verrius Flaccus and Aulus Gellius, and a revised and annotated edition of whose work was brought out by Julius Tryphonianus Sabinus in the 5th century. Priscian's 'Institutes' and the grammar composed by Aelius Donates in the 4th century dominated the schools of the Middle Ages and formed the type and source of the Latin and Greek school grammars of modern Europe. The first 16 books treat of the eight parts of speech recognized by the ancient grammarians. The last two are on syntax and are preserved separately in one manuscript, these bearing the title 'De Constructione.' The whole work, successively abridged, formed the basis of instruction in Latin up to the 15th century. The old phrase, «to break the heart of Priscian,» means to violate grossly the rules of grammar. The first edition of his complete works appeared at Venice in 1470, and what has been considered the best, by Krebel, at Leipzig (2 vols., 1819–20). See LANGUAGE, SCIENCE OF.

PRISCILLIAN, prĭ-sĭl'ĭ-an, Spanish religious sectary: b. about 350; d. Treves, 385. He was charged with teaching heresy resembling Gnosticism or the doctrine of the Manichæans and was excommunicated by the Synod of Saragossa (380). However, he was able by his eloquence to cause the judgment to be withdrawn and put to flight his chief opponent, the bishop Ithacius. The bishop later gained the support of Maximus, the usurper at Treves, and secured the condemnation and execution of Priscillian. The followers of Priscillian were known as Priscillianists. Their beliefs included peculiar views of the influence of the heavenly bodies upon men. The sect did not die with its founder, though there was considerable reaction against it at the close of the 4th century, and it disappeared as an organized body before the end of the 6th century, though at all times through the mediæval period its traces appear under various names and forms, especially in northern Spain, in Languedoc and in northern Italy.

PRISM, *in geometry*, a solid consisting of the region intercepted by a number of planes, known as the sides, parallel to a given line and two planes, the so-called bases, parallel to one another. It has similar and parallel bases and its sides form similar parallelograms. The bases may be of any form, and this form (triangular, pentagonal, etc.) gives its name to the prism. *In optics*, any transparent medium, comprised between plane faces, usually inclined to each other. The intersection of two inclined faces is called the edge of the prism, etc., the inclination of one to the other, the refracting angle. Every section perpendicular to the edge is called a principal section. The prism generally used for optical experiments is a right triangular one of glass, the principal section of which is a triangle. It is used to refract and disperse light, resolving it into the prismatic colors. See LIGHT.

PRISON. See PENOLOGY.

PRISON ASSOCIATION OF THE UNITED STATES, National, an organization of reformers and philanthropists, founded in Cincinnati, Ohio, in 1870, under the presidency of Rutherford B. Hayes. There is a board of directors and an executive committee of seven. Meetings are held annually. There are standing committees on criminal law reform, prison discipline, juvenile delinquency, etc. The Association holds annual congresses at which the executive officers of penal institutions throughout the country and others engaged in prison work exchange experiences and discuss the problems that are constantly arising. The national and the various State associations are the outgrowth of a movement in New York City in 1846 which culminated in the organization and chartering of the Prison Association of New York. The purposes of all are substantially to protect the public against criminals; to reform criminals; to defend those accused unjustly; to give first offenders a probationary opportunity; to improve prison management; to provide employment for released prisoners; to aid families of prisoners; to exercise watchfulness over prisoners released on probation and parole, and to secure legislative action to make the purposes effective.

PRISON REFORM. See PENOLOGY.

PRISONER OF CHILLON, The, a narrative poem by Lord Byron based on the story of the imprisonment of François de Bonnivard (1496–1570) in Château de Chillon, situated between Clarens and Villeneuve on Lake Geneva, Switzerland. It was Sir Walter Scott's opinion that as a picture this poem, however gloomy the coloring, might rival any which Lord Byron had drawn. Bonnivard was the prior of Saint Victor, who, having by his efforts to free the Genevese rendered himself obnoxious to the Duke of Saxony, was carried off by emissaries of that potentate and confined for six years in the château, which was really a fortress, believed to have been built in 1238. He was liberated when the Bernese and Genevese forced the surrender of the stronghold.

PRISONERS OF WAR. Ordinarily a prisoner of war is a person belonging to the military and naval forces of a belligerent and who has fallen into the hands of the enemy by capture or otherwise. This definition, however, is both too broad and too narrow, since there are persons attached to an army who if captured cannot be detained as prisoners of war, such for example as chaplains, Red Cross doctors and nurses, while there are others who follow an army without being attached to it, yet who if captured may be held as prisoners of war, such for example as newspaper correspondents, reporters, contractors and the like. But to be entitled to the treatment accorded prisoners of war, The Hague Convention (Art. 13) requires that they must be in possession of a certificate from the military authorities of the army they are accompanying. Until 1907 seamen on a merchant vessel of enemy nationality if captured might be detained as prisoners of war, but The Hague Conference of that year adopted a rule exempting them from liability to be detained in captivity, provided they give a formal promise not to engage in military services during the period of the war. In case they are citizens or subjects of a neutral state they must be liberated unconditionally. The refusal for a time of the German government early in 1917 to release certain American seamen who had been captured while serving as members of the crew of a British armed merchant vessel was in contravention of this rule. On the other hand, the Germans refused to treat as prisoners of war the masters and crews of armed enemy merchantmen who exercised the right to defend themselves against attack by German submarines, and in pursuance of this theory they court-martialed and shot as a sea franc-tireur in 1916 Captain Fryatt, the master of an English Channel steamer, for defending his vessel against destruction by a German submarine. In like manner the Germans refused to treat as prisoners of war Belgian civilians who upon the approach of the German armies took up arms and resisted the enemy, without being under the command of responsible commanders and without being clothed in uniform, this in the face of The Hague provision which allows the civil population in such a case to rise spontaneously and endeavor to beat off the invader, subject only to the condition that they carry their arms openly and conduct their operations according to the laws and customs of war. The reason given by the Germans for refusing to treat such persons as prisoners of war was that they had sufficient time before the arrival of the German armies to perfect an organization and equip themselves with uniforms.

Practice, especially during the World War, makes a distinction between military prisoners and civil prisoners. The former category embraces captives belonging to the armed forces of the enemy; the latter includes enemy aliens arrested and confined in internment camps. The status of both classes of prisoners is essentially the same, however, and the treatment of them has been substantially the same.

In early times it was the custom to torture and even kill prisoners. It was considered a mitigation of their lot to reduce them to slavery, and consequently enslavement, especially among the Romans, came to be a common practice. During the Middle Ages the practice of ransom was introduced under which prisoners might obtain their release by the payment of a sum of money, or they were redeemed from captivity by the state of which they were subjects. But this practice is no longer followed.

The status of prisoners and the treatment which must be accorded them are now regulated in detail by The Hague Conventions of 1907 and especially the convention respecting the laws and customs of war on land. The latter convention at the outset condemns an ancient principle by laying down the rule that prisoners of war are in the power of the hostile government and not of the individuals or corps who capture them. They cannot, therefore, be ransomed or sold into slavery by the individuals who take them. They must be humanely treated. They may not, therefore, be beaten, tortured starved or cruelly punished. Still less may they be put to death, except for crimes punishable by death under the laws of the captor and after due trial and conviction, although the German war manual asserts that they may be killed whenever their presence becomes a danger to the existence of their captor. But the British and American manuals take occasion to express doubt whether such extreme necessities can ever arise that will compel or warrant a military commander in killing his prisoners on the ground of self-preservation. They may of course be punished for acts of insubordination and reasonable measures may be taken to prevent them from escaping. They may indeed be shot while attempting to escape, but if after having escaped they are recaptured they cannot be punished for having escaped. Prisoners are allowed to retain their personal property, except arms, horses and military papers. It is the duty of the government into whose hands they have fallen to feed and clothe them, and as regards board, lodging and clothing they are entitled to the same treatment as the troops of the government which holds them in captivity. The captor may require prisoners, except officers, to work according to their rank and aptitude, but their tasks must not be excessive and must have no connection with the operations of the war. Work done for the state must be paid for at the rates in force for work of a similar kind done by soldiers of the national army, or if there are none in force, at a rate according to the work performed. The wages so paid shall go toward improving their position and the balance shall be paid them after deducting the cost of their maintenance. Officers taken prisoners must receive the same rate of pay as officers of corresponding rank in the country where they are held, the amount to be ultimately returned by their own government.

The Hague Convention declares that prisoners may be set at liberty on parole if the laws of their country allow it, but those so liberated and recaptured while bearing arms against the government which released them are not entitled to the treatment reserved for prisoners of war. The Convention does not deal at all with the subject of exchanges. The Hague Conference of 1899 made it the duty of belligerents at the outbreak of hostilities to establish a bureau of information to answer inquiries about prisoners of war held by them, to collect and keep all objects of personal use, valuables, letters, etc., found on the battlefields and to furnish information to the parties interested regarding prisoners who have been released on parole, or exchanged, or who have escaped or died in hospitals, etc. The provision was renewed in 1907 and the scope of the bureau enlarged. Letters, money orders and postal parcels intended for prisoners of war, or dispatched by them, are exempt from postal charges in the countries of origin and destination as well as in those through which they pass. Finally, The Hague Convention requires that at the conclusion of peace the repatriation of prisoners shall be carried out as quickly as possible.

In all great wars the problem of caring for prisoners has been a difficult one and there have been few in which one or both belligerents were not charged with violating the law regarding the treatment of prisoners. Naturally during the World War when the number of prisoners taken ran into the millions the problem was very great and the charges and counter-charges in respect to ill-treatment have been numerous. Fortunately, in the early months of the war, arrangements were entered into between most of the belligerent governments by which each consented to permit representatives of neutral legations and embassies to visit their prison camps, conduct inspections and make reports to the governments concerned regarding the conditions of the camps in which their nationals were held as prisoners and the kind of treatment they were receiving. Until the United States entered the war, representatives of its legations and embassies in England, Germany, France, Russia and Austria performed this service. They visited the camps without giving previous notice, inspected the barracks, hospitals, kitchens, recreation grounds, etc., conversed with the prisoners, heard their complaints, made recommendations to the camp commandants and in this way were able to bring about many necessary reforms and improvements. Their reports constitute the most trustworthy sources of information regarding the treatment of prisoners that are available.

At the outset the various belligerent governments issued general regulations concerning the treatment which they proposed to accord prisoners held by them and those promulgated by the British and French governments announced that no distinction would be made between the treatment of interned civilians and regular military prisoners. These rules are quite elaborate and cannot even be summarized within the brief limits of this article. They related to housing, food, clothing, medical attendance, pay of officers, wages to be paid prisoners employed, postal facilities, recreation facilities and the like. In the beginning, serious complaints were made in England in regard to the housing facilities provided for British prisoners in Germany and the reports of representatives of the American embassy confirm in many instances the truth of the charges. So far as possible, prisoners captured by Germany were housed in the military barracks but during the early months of the war the number of prisoners captured by the German armies attained such proportions that it became necessary to house them in tents or in hastily constructed buildings which were poorly heated and equipped. As a consequence, the sufferings of the prisoners in the German camps during the first winter of the war were particularly severe. Unfortunately also the camp sites were not well selected, some of them being located on the sandy plains in North Germany where the climate was especially rigorous. According to the reports of the American representatives prisoners in England and France were better housed and their exposure to cold was less serious. During the first year of the war there were many complaints that German prisoners were inadequately clothed and that the supply of blankets was wholly insufficient. The American inspectors found this charge to be true in various camps and called the attention of the German government to the facts.

The most serious complaint, however, related to the quantity and quality of food rations served in the prison camps of Germany. British and French prisoners complained that the food was not only inadequate in amount but was of such a quality that they could not eat it. Food experts attached to the American embassy found this to be true in some of the camps but as to others they reported that there was no substantial ground for complaint. By the beginning of the year 1916 British and French prisoners were depending almost entirely upon the food which they received from home through the parcel post. Russian prisoners, however, appear to have received little or no food through this channel and were compelled, therefore, to subsist on the meagre ration furnished by the German government, which as the years passed became hopelessly insufficient.

Regarding the pay of prisoners who were officers, the British government at the outset allowed German officers half the pay of the corresponding ranks in the British army and without charging them for their subsistence. At the same time the British government offered to allow full pay provided Germany would reciprocate. To this offer, the German government never replied. Subsequently the British government learned that British officers in Germany were receiving only 60 or 100 marks per month according to their rank, from which approximately two-thirds was deducted for food. Thereupon the British government revised its scale of pay for German prisoners held in England and brought it into harmony with the German scale. The French government at the outset adopted the British policy in respect to the pay of officers but altered it later to conform to German practice. Taking advantage of the right recognized by The Hague Convention, Germany organized an elaborate prison labor system, more than 2,000 labor camps being established in various parts of the empire. By the end of the second year of the war it was estimated that between two and three million prisoners were working in the industries of Germany; in fact they largely replaced the millions of Germans who had been called to the colors. Where they were engaged in private work they were leased out to contractors. The rates of pay allowed appear to have varied in different camps and according to the skill of the prisoner, the most common wage being 30 pfennigs per day, although in some cases it was 80 pfennigs, and in a few as much as 1.25 marks. Generally, prisoners were compelled to work and naturally there were many complaints in respect to long hours, excessive tasks, brutality of treatment, starvation and the like. It was also a cause of complaint that the German government refused to permit neutral representatives to visit and inspect the working camps, so that the governments whose nationals were employed in these camps had no means of obtaining information regarding their treatment. There were also frequent complaints among the prisoners that they were compelled to work in industries that were engaged in the manufacture of war materials. In March 1918 the British government committee on the treatment by the enemy of British prisoners made a report which charged the Germans with systematically employing their prisoners in forced labor close behind the firing line on the Western front, thereby exposing them to the fire from the guns of their own and the allied armies. In April 1917 an agreement had been reached between the British and German governments that prisoners on either side should not be employed within 30 kilometers of the firing line. But the British committee charged that the agreement was systematically violated by the German authorities and that the prisoners held by them were sometimes put to work within 10 kilometers of the firing line, in consequence of which many were killed by the fire of their own troops. The excuse given by the German authorities was that they were driven to this cruel measure as an act of retaliation against the British for having themselves violated the agreement. This charge, however, was emphatically denied by the British government. In France as in Germany prisoners were employed not only in camp work but in planting, cultivating the fields, harvesting the crops, repairing roads, work in coal mines, quarries, etc. In Great Britain the same policy was followed although no such extensive system of prison labor was ever organized as was put into effect in Germany. In the United States prisoners were employed in camp work and in the construction of roads in the neighborhoods of the prison camps. Germany's prison population proved an asset rather than a source of expense, not only because of the elaborate system of compulsory labor which the Germans organized but because of the comparatively small outlay necessitated for the feeding of English and

French prisoners, since they depended mainly on the food they received from home through the medium of the parcel post.

Regarding postal facilities, all the belligerents placed restrictions upon the number and length of the letters which the prisoners were allowed to write. The British regulations allowed each prisoner to write two letters a week, each consisting of two pages of ordinary writing paper. In special cases the number and length of letters allowed were unlimited. No limitation was set to the number of letters which a prisoner might receive. The German regulations, however, allowed prisoners to write but two letters a month and one postal card weekly, but exceptions were made in urgent cases. In France at first no restrictions were placed upon the number or length of letters which prisoners were allowed to write but in consequence of the abuse of the privilege and in consequence of the German regulations the French government subsequently felt obliged to introduce certain restrictions. Prisoners in Germany were allowed to receive parcels not exceeding five kilograms in weight, and this privilege was availed of on a large scale by British and French prisoners in Germany for obtaining food from home. There were of course many complaints that letters and parcels never arrived or were detained for long periods of time in the camps before being distributed. There were also the usual complaints in regard to rigorous discipline, especially in the German camps and many charges were made of cruel and harsh treatment and the American representatives found these charges to be well founded in some camps. There was considerable demand in England for the adoption of retaliatory measures against German prisoners in consequence of the alleged mistreatment of British prisoners in Germany, but no such measures appear to have ever been adopted. There was also considerable demand that the commanders and crews of submarines who were guilty of sinking British merchant vessels should when captured be denied the treatment accorded to prisoners of war, but the British government declined to adopt such a policy. It did, however, introduce a policy of differential treatment in regard to such prisoners by segregating them from other prisoners, but otherwise they were treated the same. This policy aroused intense indignation in Germany and in consequence of the threat of the German government to retaliate in kind, the British government abandoned its policy of differential treatment. It is somewhat singular that considering the unprecedented number of prisoners held by most of the belligerent governments no serious efforts appear to have been made looking toward a general system of exchange or releases on parole. At the outset the French government adopted the practice of releasing German officers on parole but it was subsequently abandoned in consequence of the refusal of the German government to accord reciprocity of treatment. Arrangements were concluded between the principal European belligerents for the reciprocal repatriation of interned civilian prisoners of non-military age (see Enemy Alien Problems) and in the year 1916 an agreement was reached between Germany on the one side and Great Britain and France on the other for the transfer to Switzerland of all wounded prisoners held by each government, as well as all prisoners who were suffering from any one of 20 specified diseases or infirmities. In pursuance of these agreements many thousand wounded and incapacitated prisoners were transferred to Switzerland, where although still held as prisoners they enjoyed the privilege of living in a neutral and friendly country. Shortly before the close of the war an arrangement was concluded for the reciprocal repatriation of prisoners who had been in captivity as long as 18 months. The number of such prisoners thus repatriated or transferred to neutral countries was, however, a very small proportion of the total number held by the various belligerent governments.

Professor of Political Science, University of Illinois.

PRISONS. A prison is a place of confinement or of involuntary restraint for the safe custody of criminals and others committed by process of law. There are detention prisons for persons awaiting trial and confinement; prisons for those convicted and sentenced to imprisonment. The former are sometimes called jails and the latter are frequently called penitentiaries or workhouses or houses of correction or reformatories. See Reformatories.

Workhouses and houses of correction are supposed to be used for the older and for petty offenders while reformatories are for those capable of learning a trade or of receiving an education in a school. Confinement prisons and penitentiaries are generally thought of as places for the imprisonment of more hardened or serious offenders, where the discipline is supposed to be firmer and more arbitrary. In actual practice, however, the statutes and sentences to imprisonment do not recognize clearly these distinctions.

Detention prisons came into general use before confinement prisons and penitentiaries, as the former were needed for those whose cases had not been disposed of by the courts, whereas those convicted were, until the latter part of the 18th century, frequently put to death or branded or mutilated and let go, or were deported beyond the seas. Only in certain exceptional cases were the guilty held in custody in surroundings which were always unpleasant and provided with coarse fare and rough lodgings and required to engage in irksome labor. Only one workhouse or house of correction was built in London up to 1550 and a workhouse was established in Amsterdam in 1588. In Lubeck and Bremen there was no institution of this type until 1663. Berne in 1615, Hamburg in 1620, Basle in 1667, Vienna and Breslau in 1670, Luneburg in 1676, Florence in 1677 and Munich in 1687 were among the other European cities to establish and build one such institution, respectively.

The shocking picture of English prisons given us by John Howard during the latter part of the 18th century forced people to think about prisons and awakened the public conscience on both sides of the Atlantic to indescribable evils, particularly the evils of the English detention prisons, and enabled Howard to force a change in England's treatment of offenders. Howard made people see that these prisons were

> "Pestiferous dens, overcrowded, dark, foully dirty; not only ill-ventilated, but deprived altogether of fresh air. The wretched inmates were dependent for food upon the caprice of their gaolers or the charity of the benevolent; water was denied them in the scantiest proportions; their only bedding was putrid straw. Every one in durance, whether tried or untried, was heavily ironed, all alike were subject to the rapacity of their gaolers and the extortions of their fellows. . . . Idleness, drunkenness, vicious intercourse, sickness, starvation, squalor, cruelty, chains, awful oppression and every culpable neglect — in these words may be summed up the state of the gaols of the time of Howard's visitation."

Hundred of these wretches were debtors, guilty only of breaches of financial rules. Hundreds more of them had been committed under legal fictions. The poor father of a family, often shiftless and unfortunate, was locked up only to be joined by his wife and children, who were made penniless by his confinement. Though innocent before the law, yet these unfortunates remained in jail without trial and without redress.

Howard's recommendation that penitentiaries or confinement prisons be established finally bore fruit in the erection of Milbank Prison in England, which was begun in 1813 and partly completed by 1816. However, Newgate in London still remained a public den of iniquity in 1817 when Elizabeth Fry began her remarkable visitations and ministrations to the crazed creatures confined there.

Howard's work in England was paralleled by a similar movement in America, led by the Philadelphia Quakers. To relieve the horrible suffering in the city jail or prison of Philadelphia, these Quakers formed in 1776 The Philadelphia Society for Assisting Distressed Prisoners, but their activities were terminated by the British occupation of the city in the Revolutionary War. Immediately after the close of the war the leading citizens of Philadelphia began a successful agitation for the reform of the barbarous colonial Penal Code. In 1787 the Philadelphia Quakers and others interested in prison reform founded The Philadelphia Society for Alleviating the Miseries of Public Prisons. This society still exists as the leading force in Pennsylvania prison reform, its name having been changed to that of the Pennsylvania Prison Society in 1887. It is, thus, the oldest prison reform society in Europe or America. Its activities were most effective in bettering prison conditions in Pennsylvania. It aided in the reformation of the Criminal Code, introduced preaching into the Walnut Street Prison, devised the Pennsylvania or Separate system of prison administration and brought about a general improvement of discipline in the city prison. The work of the society extended beyond the borders of Pennsylvania. They carried on a correspondence with John Howard in England, exchanging ideas on desirable modes of prison reform and were the centre from which the reform of criminal jurisprudence and prison administration spread into other States of this country. Their success led to the establishment of similar organizations elsewhere. The London Society for the Improvement of Prison Discipline was formed in 1815; the Prison Discipline Society of Boston in 1826; the New Jersey Prison Instruction Society in 1833; and The New York Prison Association in 1845.

America had its own "Newgate," originally the Simsbury Copper Mine. Abandoned as a copper mine it was used by the colony of Connecticut in 1773 as a permanent prison for Tories, and then by the State military authorities. In 1793 it was made the State prison and continued as such until 1827. Richard H. Phelps described this prison in the following language:

> "The appearance of this place forcibly reminds the observer of the walls, castles, and towers erected for the security of some haughty lordling of the feudal ages; while the gloomy dungeons within its walls call to remembrance a bastile or a prison of the Inquisition. Some rude buildings covering access to the caverns were constructed with an enclosure of half an acre or so built of planks with iron spikes upon the top. The passage down the shaft into the cavern was upon a ladder fastened upon one side and resting on the bottom. At the foot of this passage commences a gradual descent for a considerable distance, all around being solid rock or ore. The passages extend many rods in different directions, some of them even leading under the cellars of the dwellings of the neighborhood. . . . On the sides in the niches of the cavern, platforms were built of boards for the prisoners, on which straw was placed for their beds. The horrid gloom of this dungeon can scarcely be realized. . . . From thirty to one hundred were placed together through the night, solitary lodging as practised at Wethersfield afterwards being then regarded as a punishment rather than a blessing to them. The punishments inflicted for prison offenses were flogging, confinement in stocks in the dungeons, being fed on bread and water during the time, double or treble sets of iron, hanging by the heels, etc. A bell summoning the prisoners to work brought them up from the cavern beneath through a trap-door, in irregular numbers, two or three together, and sometimes a single one alone, when under guard of armed soldiers they were conducted across the yard to the smithy. The prisoners were heavily ironed and secured by fetters, and being therefore unable to walk, made their way by jumps and hops. On entering the smithy some went to the side of the forges, where collars dependent by iron chains from the roof were fastened around their necks, and others were chained in pairs to the wheelbarrows. The attendants delivered pickled pork to the prisoners for dinner at their forges, a piece for each thrown on the floor, and left to be washed and boiled in the water used for cooling the iron wrought at the forges. Meat was distributed in a similar manner for breakfast."

As stated, toward the close of the 18th century the Quakers of Philadelphia determined to attempt to reform the offender instead of destroying him or weakening him or mutilating his body. The agitations of John Howard and of the English reformers encouraged them in their activity. In 1796 Rev. Robert J. Turnbull visited the Philadelphia prison and commented upon the orderly condition of the prison as contrasted with public convict labor conditions then abolished. He said of the former conditions:

> "A grand and important defect, though not generally observed, appeared too plain to some of the promoters of the plan, to inspire them with sanguine expectations of its success. It was the inefficacy of the punishments of labor, mutilation, and whipping, inasmuch as they destroyed an important end of punishment, that of the criminal's reformation. . . . The convicts who were sentenced to the wheel-barrow and dispersed along the streets and roads, exhibited, from the difficulty of superintending them, the most shameful scenes of drunkenness, indelicacy, and other excesses in vice. The inconvenience and mischievous effects of the punishment of public labor at length became so intolerable that it was regarded, and with much justice, as a common nuisance."

Caleb Lownes, a leader in the reform movement, thus described the effect of the improved discipline brought about following the changes introduced in 1790:

"When the present plan was at last attempted, the prisoners were informed that the new system was now to be carried into full effect — that their treatment would depend upon their conduct; and that those who evidenced a disposition that would afford encouragement to the inspectors to believe that they might be restored to their liberty, should be recommended to the governor for a pardon, as soon as circumstances would admit; but if they were convicted again, the law, in its fullest rigour, would be carried into effect against them. A change of conduct was early visible. They were encouraged to labour, and a number were employed at carrying stone, and other laborious work, at the building of the solitary cells. Their good conduct was remarked. Many were pardoned, and before one year was expired, their behaviour was, almost without exception, decent, orderly, and respectful. This fact is one of importance, as it disproves an opinion, that has led to much distress and cruelty, and will, I hope, be an encouragement to those who can feel for this unhappy class of mankind, who have so long been victims to the sad effects of a contrary treatment."

The note struck at the Walnut Street Prison in Philadelphia following 1790 began a new era in prison management and treatment which revolutionized prison management all over the world so that the principle of the isolation of the prisoner in a single cell was widely adopted. This Walnut Street plan was later called the Separate or Pennsylvania System as contrasted with the Silent or Auburn System. The Separate System was actually originated contemporaneously in 1790 in the Walnut Street Prison in Philadelphia and in the county gaol at Gloucester, England, but received its full development in the construction of the Eastern Penitentiary of Pennsylvania, authorized by the legislature of that State by a law of 20 March 1821 and erected between 1821 and 1829 according to plans drawn by John Haviland. New Jersey adopted the Pennsylvania system and erected an addition to its prison which was completed in 1820.

Under the Separate or Pennsylvania System, each man was placed in a large cell of solid masonry, closed save for one small opening facing the inside corridor through which the prisoner crawled when he entered his cell, and save for a slit in the upper part of the outer wall far above his head, which provided the only natural light the poor creature had. The cell usually consisted of two rooms, one for the prisoner's bed and the other for his workroom. Each had a very high ceiling. When the heavy, massive wooden door closed over the small hole behind the prisoner who crawled into his cell; when he began his sentence, he was left in solitude to consult his Bible, his work and his own past. He never came out until he died or until his sentence expired. He was occasionally observed by his keeper through a hole in the bottom of the door, and sometimes visited by the prison chaplain. Except for this, he was left to his awful loneliness and solitude.

The Silent or Auburn System provides for the confinement of each prisoner in a single cell by night and for work in silence in a workshop by day. These cells were built of solid masonry in rows, tier upon tier and back to back, with door openings on outside corridors. These cells were in effect caverns of uniform size, high enough for a man to stand in, long enough for him to lie in and about twice as wide as his body when he lay on his back. They were called cell blocks and were enclosed in a building with massive side and end walls in which tiny windows were placed in such a position that the prisoner could never see through them to observe the sky or the earth. These side and end walls were placed far enough away from fronts of the cells and ends of the cell blocks so as to provide a wide corridor on either side of and a wide area at the ends of the cell block and were covered with a solid roof, usually without openings.

The Auburn State Prison was authorized in accordance with this plan in 1816. In 1825 Sing Sing, another New York prison of the same type, was authorized by the legislature. This type of prison architecture, with few changes, has dominated prison construction down to the present day, almost without any exception. The reasons for its continuance have been undoubtedly its flexibility, its simplicity, its low cost of supervision and maintenance and its security. Most of these prisons were furnished with dungeons or sections built like the Pennsylvania system cells except that they were usually dark and were used for the confinement in isolation of those undergoing punishment for infraction of the rules of the prison. With these exceptions, the Silent or Auburn System has predominated in America, but in Europe the Separate System has been more popular. New York allowed separate confinement in 1796, but abandoned it following 1821. Maryland introduced this system in 1809 and terminated its existence in 1838. In Massachusetts separate imprisonment was utilized to some extent from 1811 to 1829. Maine experimented with it for only three years (1824–27). New Jersey introduced it in 1820 and abandoned it in 1828, only to reintroduce it in 1836 and utilize it until 1858. Virginia accepted the Pennsylvania system in 1824 and legislated it out of existence in 1850. Rhode Island found this system a failure after a trial from 1838 to 1844. In Pennsylvania the Separate System was abandoned in the Western Penitentiary in 1869 and legally terminated in the Eastern Penitentiary in 1913, long after it had ceased to exist as a practical fact. With these more or less temporary exceptions the Auburn System was universally adopted in the prison architecture and administration of the United States.

The strongest argument in favor of the Separate or Pennsylvania System is probably that found in the report of the Eastern Pennsylvania Penitentiary inspectors to the legislature in 1830, 40 years after the establishment of the system, which reads in part as follows:

"Intemperance and thoughtless folly are the parents of crime, and the walls of a prison are generally peopled by those who have seldom seriously reflected; hence the first object of the officers of this institution is to turn the thoughts of the convict inwards upon himself, and to teach him to think; in this, solitude is a powerful aid. Hence this mode of punishment, bearing as it does with great severity upon the hardened and impenitent felon, is eminently calculated to break down his obdurate spirit; and when that important object of penitentiary discipline has been gained (and in any prison it frequently is), and when the prisoner has once experienced the [illegible] of th[illegible] principles of this institution on a [illegible] and contrite heart, he learns, and he feels, [illegible] religious reflection, relieved by industrious [illegible]s trade, comf[illegible] support his mental and [illegible] divest his so[illegible] of all its horrors, and [illegible] of much of [illegible]ity. The impression th[illegible]ead of being [illegible]ed, by the sneers of ruf[illegible]hed and fixed [illegible] officers of the prison."

Perhaps the most ardent defense of the Auburn or Silent System is the following description of this system by Louis Dwight, who did more than any other person to secure the almost universal introduction of the Auburn

System throughout the United States. Writing in 1826 he said:

"At Auburn we have a more beautiful example still, of what may be done with proper discipline, in a prison well constructed. It is not possible to describe the pleasure, which we feel in contemplating this noble institution, after wading through the fraud and material and moral filth of many prisons. We regard it as a model worthy of the world's imitation. We do not mean that there is nothing in this institution, which admits of improvement; for there have been a few cases of unjustifiable severity of punishment; but, on the whole, the institution is immensely elevated above the old penitentiaries. The whole establishment from the gate to the sewer, is a specimen of neatness. The unremitted industry, the entire subordination, and subdued feeling of the convicts, has probably no parallel among an equal number of convicts. In their solitary cells they spend the night with no other book but the Bible. From one end of the shops to the other, it is the testimony of many witnesses, that they have passed more than 300 convicts, without seeing one leave his work or turn his head to gaze at them. There is the most perfect attention to business from morning till night, interrupted only by the time necessary to dine. Under these circumstances they are provided with the word of God, by a law of the state which requires that every cell shall be supplied with a Bible or Testament. They also receive the undivided attention of a most wise and faithful religious teacher, who spends all his time in the prison visiting the sick; teaching those who cannot read; preaching in the chapel on the Sabbath the unsearchable riches of Christ; and afterwards in going from cell to cell, to administer the reproof and consolation of religion, to individuals. The influence of the chaplain, according to the testimony of all the officers, is most salutary and powerful; and the various expressions of confidence and affection exhibited towards him by the convicts, is most cheering to himself. It is hardly necessary to add that at Auburn there is an exclusion of all the positive evils of the old system, which arise from crowded night rooms, evil communication, instruction in all the arts of pick pockets, thieves, incendiaries, and counterfeiters; and, above all from the existence of a crime, which is not fit to be named among Christians. These great ends are gained, partly by discipline and partly by construction."

Captain Basil Hall of the English royal navy visted America in 1827 and observed these two systems in operation, which he described in the following language:

"The Auburn plan . . . consists in the strictest solitary confinement at night — in hard labor, but in rigid silence, by day, and always in company, though under constant superintendence; in solitary meals, under lock and key; in regulated marchings to and from their workshops; in subjecting the prisoners to stripes for infractions of the prison rules, and in their never being placed in absolute solitary confinement, except as a punishment of a temporary nature; in having prayers morning and evening said regularly by a resident clergyman, with whom alone the prisoners are allowed to converse, and that only on Sundays.

"The Philadelphia plan is widely different from this. It is intended that the prisoners shall be subjected, during the day as well as night, to separate confinement, either in solitary idleness or in solitary labour; along with which they are to be allowed no more exercise than what they may themselves choose to take in their little courts. The keeper is the only person, besides the clergyman, who is ever to see them, and a Bible is to be placed in each cell. By these means it is expected that, while many of the prisoners will be reformed, a salutary terror will be spread over the evil spirits of the State, and crime will thus be doubly prevented."

The captain in condemning the Philadelphia System said:

"As far as I have been able to learn, all the experiments which have been tried in America on solitary confinement have proved its inefficiency for any purpose of reformation; while there is abundant reason to suppose that in very many cases — I believe a majority — it leads to insanity or to suicide. It is difficult, indeed, to see how any good can spring out of compulsory idleness in prison, when the whole analogy of external life proves it to be the parent of every mischief. It ought always to be borne in mind, also, that it is no part of the object of prison discipline to torture the prisoners, merely as a punishment for his offenses independently of its effect as an example to society. Neither, of course, should a jail be made a place of amusement. It ought certainly to be rendered exceedingly irksome to the culprit; but, as far as he is concerned, its discipline, bodily and mental, should not be more severe than will make him fully sensible to the folly of his past ways. In order to accomplish this at the least expense of permanent human suffering, the criminal should, if possible, be so treated that when he gets out again, and starts afresh in the world, he should be less inclined to do mischief than he was before. The only serious doubt is, whether there is much chance of amendment taking place in a vicious and ill-regulated mind, if left to commune exclusively with its own thoughts, in solitude, with or without labour, but deprived of every ray of cheerfulness to lend efficiency and confidence to virtuous resolutions. The occasional visits of the clergyman may certainly relieve the fearful misery of absolute solitude; but unless the prisoner's mind be more or less habitually enlivened, even these lessons will fall on a soil unprepared to give them efficacy."

Charles Dickens, the novelist, who visited America in 1843, was shocked by the Eastern Pennsylvania Penitentiary, which he described in his 'American Notes' as follows:

"Standing at the central point, and looking down these dreary passages, the dull repose and quiet that prevails is awful. Occasionally there is a drowsy sound from some lone weaver's shuttle, or some shoemaker's last, but it is stifled by the thick walls and heavy dungeon door, and only serves to make the general stillness more profound. Over the head and face of every prisoner who comes into this dark, melancholy house a black hood is drawn; and in this dark shroud, an emblem of the curtain dropped between him and the living world, he is lead to the cell, from which he never comes forth until his whole term of imprisonment has expired. He never hears of wife or children; home or friends; the life or death of any single creature. He sees the prison officers, but with that exception he never looks upon a human countenance or hears a human voice. He is a man buried alive, to be dug out in the slow round of years; and in the meantime dead to everything but torturing anxieties and horrible despair. . . .

"Every cell has double doors; the outer of sturdy oak, the other of grated iron, wherein there is a trap through which his food is handed. He has a Bible, a slate and a pencil, and under certain restrictions, has sometimes other books, provided for the purpose, and pen and ink and paper. His razor, plate and can, and basin hang upon the wall or shine upon the little shelf. Fresh water is let on in every cell, and he can draw it at his pleasure. During the day his bedstead turns up against the wall and leaves more space for him to work in. His loom or bench, or wheel is there and there he labours, sleeps and wakes, and counts the seasons as they change and grow old."

William Crawford (who had investigated American prisons in 1832) and Whitworth Russell, prison inspectors of the Home District of London, were sent to America in 1837 to report upon these two systems. Thev disagreed entirely with the Archives of Hall and Dickens. They felt that the ease of communication between prisoners under the Silent or Auburn System was a grievous source of contamination which was inherent in that system. They recommended the Pennsylvania or Separate System for use in England, because they believed the Separate System of confinement would compensate for the necessary mistakes of the law and the requirements of economy in classifying and in housing prisoners, and also because they erroneously believed it advisable or possible for human beings to be housed under the same roof without communicating with one another. Fortunately, however, their recommendations were never carried out, for the attention of the people of England and of Europe was then directed for a time to the problem of prison administration and away from plans of prison construction.

The men who advocated the separate systems were without a true conception of social living, social control and social growth. They had no proper conception of how dependent man is upon his ability to imitate the good in others if he is to grow and develop. Deprived of the opportunity to imitate others, he shrivels and shrinks up and cannot grow out of delinquency into moral health and stability. The evils which Crawford and Russell saw in the Silent or Auburn System are inherent and in the Separate System also. The remedy for these lies in classification of offenders, and in the erection of special hospitals, schools and prisons for each class or group. Within each such institution the prisoners must be split up into groups and governed in accordance with the needs of each such group. See PENOLOGY.

Both the Separate and Silent Systems presuppose prison government which is autocratic or despotic in form. Transportation of prisoners overseas to Australia and Tasmania greatly changed and differentiated the methods of housing and governing them. Upon their arrival there they were usually placed in close confinement for a time, under some modification of the Separate or Silent System. Then during the next period they were permitted to associate at work under modifications of these systems, and finally were given a "Ticket of Leave," permitting them to go beyond the boundaries of the so-called prison to engage in work under more or less supervision.

The fact that they could be allowed to go beyond the confines of prison to engage in work reacted profoundly upon the management of the prisons and led Capt. Alexander Maconochie, who was the superintendent of the English prisons, to establish in Tasmania, then known as Van Dieman's Land, a new method of prison management, which has modified English prison methods to a considerable degree since that time. He originated the plan, which he outlined to the transportation committee of the House of Commons in London in 1837, of rewarding men for service performed by the grant of marks or credits which should take the place of money as a pecuniary reward for work performed and would secure for them a more speedy release.

Captain Maconochie's system, applied after 1840 in Van Dieman's Land, was modified and extended by Sir Walter Crofton, director of Irish prisons, following 1853. This system, as developed by Crofton and known as the Irish System, may be described as follows:

"The period of cellular incarceration was served at Mountjoy, where there was a prison in two departments, one for men and one for women. The second stage was that of 'progressive classification,' a phrase of which he was the author. His male prisoners were transferred from Mountjoy to Spike Island, where they were divided into five classes: the probation class, third, second, and first classes, and the advanced class. The probation class could be skipped by prisoners who had made a good record at Mountjoy. The majority of those transferred were placed in the third class, where they had to earn nine marks per month for six months, or 54 marks in all, as the condition of promotion. The number of marks to be earned in the second class was the same; and in the first class twice as many, so that they could not pass from the first to the advanced class in less than one year. Under the English system they would then have been entitled to a ticket of leave; but Sir Walter would not grant it until after a test had been applied, in a condition of comparative freedom at a third prison, called an intermediate prison, at Lusk, where they slept in movable iron huts and were occupied almost precisely as freemen would have been, in farming and manufacturing. The prison at Lusk had neither bars, bolts, nor walls. Its aim was to make practical proof of the prisoner's reformation, his power of self-control, his ability to resist temptation, and to train him for a considerable period — never less than six months — under natural conditions, and so to prepare him for full freedom by the enjoyment of partial freedom as a preliminary step."

The Irish Prison System was first introduced into America at Elmira Reformatory in 1876 by Superintendent Zebulon Brockway, aided by Gaylord Hubbell, E. C. Wines, Frank Sanborn and Theodore Dwight. Therefore, in America the Irish System was called the Elmira System, and applied chiefly to young first offenders. The Elmira Reformatory building was constructed on the Auburn plan, but the rigor of silence was relaxed in the schoolrooms and to a certain extent in the shops and in the administration of the military system which Mr. Brockway introduced later on in the management of the institution. A modified marking and grading system was substituted for the definite sentence. The schoolroom and military drill were thus the American developments of the Irish Prison System. Later this enterprising superintendent borrowed therapeutic baths from the insane hospital, which he substituted for the dungeon and the club.

The Irish prison plan was also recommended for State prisons by former Warden Gaylord B. Hubbell of Sing Sing Prison, who visited the Irish and English convict prisons and made a report thereon, to the New York Prison Association, in 1865. In this report Hubbell said:

"Let a farm of two or three hundred acres be purchased (no matter if it is cheap, rough land) situated on the line of the Erie Railroad at some point where building materials and provisions can be procured at the lowest rates. This done, I would procure plans and drawings of the best prisons in this country and in England. Having selected a plan combining the advantages of both, I would erect a new prison, having three distinct divisions, near to one another and on the same farm. The first division should have a capacity of not more than 100 cells and should be arranged for separate confinement only. The second division should have a capacity of 200 cells and should be arranged with suitable workshops, in which to employ 200 convicts, who should work in association during the day and be separated by night. The third division should have dormitories to accommodate 100 to 150 men. In the first division, the prisoners, being kept in solitude, would, of course, take their meals in the cells. In the second division a comfortable dining-hall should be prepared. In the third division all the arrangements should be such as to give as much freedom as possible to the inmates.

"All prisoners sent to the proposed system should, under proper restrictions, be allowed to work their way out; but it should be clearly understood that no prisoner can ever have this advantage more than once. Those who are convicted a second time, after being subjected to this training, should go to some other prison to serve out the whole of their sentence, without any chance or prospect whatever of release or pardon."

The plan thus recommended for a New York State prison was never carried out, but in 1913 and 1914 the State legislature and the government of the city of New York authorized the construction of the New York City Reformatory at New Hampton, N. Y., situated on the main line of the Erie Railroad, 55 miles from New York City. This institution is being constructed much in accordance with the plan outlined by Hubbell, with such modifications of the original system as 53 years of prison and reformatory management have indicated are necessary.

After the development of the Irish prison system and when transportation of prisoners came to an end, certain modifications were made in British prison management. This, as modified, was made to provide three distinct periods or stages of confinement; that of probation endured in separate confinement at a so-called "close" prison; a period of labor in association at a public works prison, and conditional leave for the unexpired portion of the sentence upon parole or "ticket of leave."

During the first period a prisoner was supposed to be confined under autocratic government in accordance with Silent or Auburn System, as modified by certain features of the Separate or Pennsylvania System. In the second or intermediate period the prisoner was allowed a little more freedom and to associate in work with his fellows, while in the third period he was allowed to go beyond the walls of the prison under more or less supervision after the original example of the grant of a «ticket of leave» in Tasmania and in Australia. His permission to be abroad might be forfeited by breaches of the law or by failure to comply with the conditions governing his permit. Out of this has grown the modern parole system.

Reformatories established in most American States prior to 1890, while direct imitations of Elmira, also copied more or less the British «intermediate» prison, which was built for the confinement of the English prisoners during the second stage. The English «Borstal» system is the English adaption of her regular prison system, which provides educational and developmental opportunities for juvenile offenders. It was also derived in part from English investigations of the Elmira System. Some reformatory institutions established in the United States between 1880 and 1900 and nearly all established since that time have been patterned, not only after Elmira, but also after American industrial and vocational schools. The New Jersey and Connecticut reformatories for young men, while modeled after Elmira, have tended toward the British intermediate prison plan.

From the beginning of the 20th century public opinion has been concerned with the shortcomings of prison administration, which investigation has shown to be due in no small part to the antiquated and unserviceable type of building construction which the Silent or Auburn System provided. The form prevents proper classification, and adequate classification must always be regarded as one of the fundamental bases of prison administration. Notwithstanding this fundamental defect in construction, commendable efforts have been made to infuse a new spirit into the administration of these prisons. These attempts to build up a new type of administration in the old type of prisons have but emphasized the fact that adequate classification of prisoners is not entirely possible without the provision of different types or kinds of prisons. Modern penologists now demand that the modern prison system should never place men and women in separate parts of the same prison, and should provide:

1. Sufficient detention prisons for those awaiting trial.
2. Classification or reception prisons where all offenders are committed by the courts immediately after conviction to be observed and classified.
3. Educational, industrial and training school prisons for younger offenders.
4. Industrial prisons, preferably of the farm colony type.
5. Hospital prisons for the criminal insane and for border-line insanity cases.
6. Custodial prisons for the low grade feeble-minded, for other abnormals and for habitual offenders.

A study of prisons constructed recently or at present under construction indicates that prison architecture has broken away from its slavish copying of the Silent or Auburn Systems. Prisons for juveniles, for the insane, for petty offenders, for crippled offenders, for the high grade feeble-minded, for diseased prisoners and for all but the low grade feeble-minded and perverts and habitual offenders, are now frequently designed more like industrial schools, hospitals and labor settlements than like the old bastile of the Auburn type. Small units built in accordance with modern adaptations of the Auburn plan are still serviceable as prisons for the perverted and the hardened offenders.

A very notable development of prison administration has taken place in the Philippines since American occupation. Of particular significance is its development of vocational and industrial training in the Bilibid Prison at Manila, of agricultural colonies and also of the Iwahig Penal Settlement, where prisoners are permitted to live in houses which they are permitted to purchase from their earnings as prisoners. Upon their release they are in turn permitted to sell to the prisoners who have been given the opportunity of serving as part of their sentence at this very remarkable colony. Every division of the prison system in the Philippines aims to do its part in reforming the offender and reclaiming him from a life of evil by fitting him for his return to society. Insofar as it accomplishes this, each unit of that system and the system as a whole is performing the services required of a modern prison.

BURDETTE G. LEWIS,
Commissioner of Department of Institutions and Agencies, State of New Jersey.

PRISONS, Military. See MILITARY PRISONS.

PRISREND, prēs-rĕnd', or **PRIZREN,** prēs-ren', Jugoslavia, a former town of European Turkey and capital of the vilayet of Kossovo, on the right bank of the Rieka, four or five miles from its confluence with the Driu. By the Treaty of Bucharest (25 July 1913), which brought a temporary peace to the Balkan states after three wars, and the agreements for the rectification of the Serbian-Bulgarian and Serbian-Montenegrin frontiers, Serbia obtained, among other territorial gains, 9,973 square miles of the Turkish region formerly known as Kossovo. Here the Serbians created the administrative department of Prisrend, with its capital at the town of the same name. In the early part of the World War this entire region and the adjacent ones in Bosnia, Albania, Montenegro and Bulgaria were the scene of intense fighting. Under the World Peace Treaty of 1919 Prisrend was included in the territory of the new republic of Jugoslavia. The town, under Turkish rule, was the residence of a pasha, and the seat of a Greek metropolitan and a Catholic bishop. Among its buildings were 42 mosques, one Catholic and five Greek churches. It had considerable manufacturing interests, and a large trade with the adjacent country and beyond its borders. Pop. (1915 estimates), department, 227,-425; town, 21,244.

PRITCHARD, prich'ạrd, **Jeter Connelly**, American jurist: b. Jonesboro, Tenn., 12 July 1857. He entered a printing office in early life, removed to Bakersville, N. C., in 1873, and until 1887 was joint editor and owner of the *Roan Mountain Republican*. He served in the State legislature in 1884, 1886 and 1890. In 1887 he was admitted to the bar and engaged in law practice in Marshall, N. C., was president of the State Protective Tariff League in 1891, delegate-at-large to the Republican National Convention in 1892, served as United States senator to fill a vacancy in 1894–97 and in the latter year was re-elected for the term of six years. In 1903 he became an associate justice of the Supreme Court of the District of Columbia; in 1904–11 was United States circuit judge of the 4th circuit; in 1912 became judge of the United States Circuit Court of Appeals.

PRITCHETT, prĭch'ĕt, **Henry Smith**, American astronomer and educator: b. Fayette, Mo., 16 April 1857. He was graduated from Pritchett College, Glasgow, Mo., in 1875 and later studied astronomy under Asaph Hall in the United States Naval Observatory where he became assistant astronomer in 1878. In 1880 he accepted the position of directing astronomer at Morrison Observatory, Glasgow, Mo., and in 1881 was appointed to the chair of astronomy and mathematics at Washington University, Saint Louis, Mo. He was permitted leave of absence in 1882 in order that he might observe the transit of Venus at Auckland, and he also made pendulum observations at Auckland, Sydney, Singapore and Hongkong. He was in Europe on scientific work in 1894–95, was appointed superintendent of the United States Coast and Geodetic Survey in 1897, in 1900 president of the Massachusetts Institute of Technology and in 1906 president of the Carnegie Foundation. Fourteen colleges and universities honored him with the degrees of A.B., Ph.D., LL.D. and Sc.D.

PRIVAT-DOCENT, prē-vät' dō-tsĕnt', in the German university system (and others modeled on it), an instructor whose lectures rank with those of the professor, but who unlike them has no standing in the faculty as a governing body of the university. He receives no fees except directly from his pupils. He must have received the doctoral degree and also be habilitated, that is, successfully defended a thesis, the result of his own research. The post is commonly a means of preparation for university professorship. Many distinguished men, Kant among others, have held the post as a stepping-stone to higher university rank.

PRIVATE BANKERS. See BANKS AND BANKING — PRIVATE BANKS.

PRIVATE CORPORATIONS. See CORPORATIONS, LEGAL.

PRIVATE SAVINGS BANKS. See BANKS AND BANKING — WORLD'S SYSTEMS, PRIVATE BANKS — BANK ORGANIZATION AND MANAGEMENT.

PRIVATE SCHOOLS, institutions under private control as distinct from public, and implying maintenance by private corporations or individuals. But the school may be private, or not public, in its origin and government, and if there are no limitations as to who may be admitted as pupils, it is usually classed as a public school. In the United States private schools embrace a large number of institutions ranging in purpose from elementary to professional education. Thus in the school-year 1915–16 there were reported 1,665,075 pupils in private elementary schools of kindergarten, primary and grammar grades; 155,135 students in private high schools; 6,958 students in private normal schools, and 57,540 students in the various professional schools. More than one-half of the private schools were under the control of religious denominations and had 103,829 students of high school grade. The ordinary professional schools comprised those of theology, law, medicine, dentistry, pharmacy, veterinary medicine and nurse training, the latter in general being connected with large hospitals. In specialized work there were over 1,300 independent commercial and business schools and 762 private high schools giving business courses. These courses included stenography, typewriting, telegraphy, telephony, accountancy and general office service. Soon after the outbreak of the World War in 1914 many large financial institutions, chambers of commerce, boards of trade and colleges and universities established special schools of commerce in preparation for an expected expansion of the foreign trade of the United States after the close of the war, and a larger private specialization of educational effort was developed by the necessities of the government, especially after the United States entered the war. See RUGBY; EDUCATION, AGRICULTURAL, SECONDARY SCHOOLS.

PRIVATEER, the name applied in time of war to a ship owned by a private individual, which under government permission, expressed by a letter of marque, makes war on the shipping of a hostile power. To make war on an enemy without this commission, or on the shipping of a nation not specified in it, is piracy.

Privateering was abolished by mutual agreement among European nations, except Spain, by the Declaration of Paris in 1856; but the United States of America refused to sign the treaty, except on condition that all private property at sea, not contraband, should be exempt from capture. This «Marcy,» or «American,» amendment, as it was called, was not accepted. This doctrine was again affirmed by the United States delegates to the Peace Conference at The Hague in 1898, but was again rejected by the European powers. It is doubtful, however, how far the abolition of privateering would stand in a general war, for it is the natural resource of a nation whose regular navy is too weak to make head against the maritime power of the enemy, especially when the latter offers the temptation of a wealthy commerce. It was usual for the country on whose behalf the privateers carried on war to take security for their duty respecting the rights of neutrals and allies, and their observing generally the law of nations. In the wars of 1793–1814 many English privateers were afloat. But in the same period no less than 10,871 English ships, with over $5,000,000,000, were taken by French «corsairs»; the Breton privateer *Surcouf* took, in two months of 1807, prizes worth $1,456,250. At the American Revolution the new republic fully realized the advantage of its position in preying on the mercantile marine of Great Britain; and in the War of 1812 British commerce suffered severely at the hands of American privateers, of which it was computed that some 250 were afloat. During the American Civil War the Confederate States offered letters of marque to persons of all countries, but no admittedly foreign vessels were so commissioned. During the same period the Congress of the United States empowered the President to grant commissions to privateers, but none such were granted. The Confederate cruisers were at first regarded in the North as mere pirates; and the «Alabama Claims» originated in the charge against Great Britain of allowing the departure of privateers from British ports, where they were fitted out illegally.

The European War produced a new form of privateering, armed with torpedoes, guns and floating mines. The operations of such craft were confined for a while to enemy coast objectives and the waters of adjacent «barred zones»; but the voyage of the German commercial submarine *Deutschland* from Kiel, Germany, to Baltimore, Md., a distance of 4,180 miles, in 1916, and her safe return to Kiel, showed a startling menace to the world's shipping. It demonstrated that the new kind of under-sea craft could cruise in safety a long distance from a home base. The greatest feat of the U-boat type, up to that time, occurred in May and June 1918, when a number of such craft sank many vessels off the Atlantic coast of the United States.

PRIVET, a genus (*Ligustrum*) of shrubs or trees of the order *Oleaceæ*. About 35 species are known, natives of eastern Asia, Australia, with one of the Mediterranean region. They are deciduous or evergreen and bear terminal panicles of small, whitish, generally fragrant flowers, followed by usually black berries which often remain on the plants during winter. They are justly popular plants in shrubberies and some are widely used as hedges since they are erect-growing and stand shearing well. They are readily propagated by means of cuttings, seeds or layers, and will succeed in almost any soil, in full sun, on dry land and under partial shade. The common privet (*L. vulgare*), *L. ibota* and *L. ciliatum* are fully hardy in the Northern States, but the so-called California privet (*L. ovalifolium*), a Japanese species, is doubtfully hardy farther north than New York City. The common privet has half-evergreen, smooth, lanceolate leaves and berries about the size of peas, black, rarely white, yellow or green. The flowers have a strong and sweetish odor; the leaves, mildly astringent, were formerly used in medicine; the berries, which hang on the shrub during winter, have a disagreeable taste, but are food for many kinds of birds, and supply a pink pigment used in map-making and in dyeing. The wood of some of the larger kinds is very hard and is used for making shoe-pegs and for turning. The only insect that is commonly troublesome upon the plants is the privet web-worm (*Diaphania quadristigmalis*).

PRIVILEGE taken in its active sense is a particular law, or a particular disposition of a law, granting certain special prerogatives to some person contrary to the common right. Examples of privilege may be found in all systems of law, as in the case of members of Congress and of the several legislatures when in attendance at their legislative duties; parties as witnesses while attending court, and coming to and returning from the same, electors while going or returning to the election, are all privileged from arrest except for treason, felony or breach of the peace. Privileges from arrest are either general and absolute, or limited as to time or place.

Ambassadors and their servants are absolutely so privileged.

A privilege of arrest for a legislature member is limited to the period of the legislative session and a reasonable time in going and returning.

In the civil law a privilege is a right which the nature of a debt gives to a creditor, entitling him to be preferred before other creditors.

Privileged communications are those statements made by a client to his counsellor or attorney in confidence, relating to some cause or action then pending; such communications cannot be disclosed without the consent of the client. The courts sometimes exclude from evidence, as privileged communications, matters of a judicial, political or professional nature on the grounds of public policy.

In many jurisdictions a writ of privilege or protection is issued by the courts, affording one, under proper circumstances, protection against arrest or from the service of civil process.

A witness is entitled to the privilege of refusing to answer incriminating questions.

A physician cannot be compelled to disclose the secrets of the sick room; a Roman Catholic priest to make confessions public; a clergyman to reveal the confidences of his pastoral relations; or a juror to repeat the considerations of the jury room.

Of ancient and mediæval legislation, the Privilege formed an important branch; in truth, the condition of the so-called «privileged classes» was different socially, civilly and religiously, from that of the non-privileged. In canon law, there were two privileges pertaining to the clergy, the *privilegium canonis* and the *privilegium fori*. By the former, the person of the clergyman, of whatever degree, was protected from violence by the penalty of excommunication against the offender; by the latter, known in England as the "benefit of clergy," the clergyman was exempted from the ordinary civil tribunals, and could be tried only in the ecclesiastical courts. Most of the purely civil privileges have been abolished throughout Europe by modern legislation.

PRIVILEGED COMMUNICATIONS, statements made by a client to his counsellor or attorney in confidence, relating to some cause or action then pending; such communications cannot be disclosed without the consent of the client; the statements of a patient to his physician, of a husband to his wife, of a man or woman to a spiritual adviser, in fact communications or statements between parties placed in a confidential relation one to another are privileged in the sense that one of the parties to such will not be allowed against the objection of the other to testify with reference thereto in a court of justice. Another class of statements which enjoy a measure of privilege are defamatory statements which do not give the injured person a right of action. The statements of legislators, judges, and in some cases of litigants, their counsel, witnesses, etc., come under this class. In the United States, however, it is held generally that such statements render their authors liable to a civil action when made in bad faith and with malicious intent. The privilege, therefore, is conditional rather than absolute. Conditional privilege is also extended to defamatory statements made by a person in the discharge of his duty, whether the latter be public or private. As example of the latter is the information given by an employer to another employer about a person who has been in his employ. If bad faith and malice are proven in such cases the employer giving such information is liable to action. Consult Hageman, 'Privileged Action' (Somerville, N. J., 1899) and McLaughlin and Hart 'Encyclopedia of American Government' (3 vols., New York 1914).

PRIVILEGES AND IMMUNITIES, are those privileges of citizens of each State, in the several States of the North American Union which may not be abridged by State or local laws. The Constitution of the United States, article IV, section 2, paragraph 1, provides that "the citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." By the Fourteenth Amendment (section 1), it is provided that "no state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States, nor shall any state deprive any person of life, liberty, or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the laws." What are the privileges and immunities of the citizens in the several States thus guaranteed? At the outset it may be noticed that personal liberty, the corner-stone of a republican government, is forever placed on a secure foundation by Amendment Thirteen, which declares that "neither slavery nor involuntary servitude, except as a punishment for crime, whereof the party shall have been duly convicted, shall exist within the United States, nor any place subject to their jurisdiction." The imprisonment of duly convicted criminals is not in conflict with this section, nor is the letting of them out for hire to contractors. By Amendment Four, the principle of the English common law that "every man's house is his castle" is adopted in the words "the right of the people to be secure in their persons, houses, papers, and effects against unreasonable searches and seizures shall not be violated." This provision against unreasonable searches and seizures permits in civil and criminal cases searches and seizures in cases expressly authorized by law. Resistance to an illegal seizure is permitted, but no more force is allowed in repelling an intrusion than is under the circumstances absolutely necessary. By Amendment Two, "no soldier shall in time of peace be quartered in any house without the consent of the owner, nor in time of war, but in a manner to be prescribed by law." To secure the citizen against unjust criminal accusations, and to provide him with a proper trial when accused, the Constitution contains a number of safeguards; thus, by section 9, paragraph 2, the privilege of the writ of *habeas corpus* is not to be suspended, unless the public safety in cases of rebellion or invasion, requires. By article III, paragraph 3, jury trial is guaranteed for all crimes except cases of impeachment, and the furthermost important provision is made that such trial is to be had in the State where the crime has been committed, but when not committed within any State, the trial is to be had at such places as Congress may by law have directed. It has been held that the accused is not entitled to a jury trial in the case of petty crimes and misdemeanors, but only in the case of graver crimes, where at common law the accused was entitled to a jury trial. As additional precautions in criminal trials, Amendment Five provides that no person is to be held to answer for a capital or otherwise infamous crime, unless on a presentment or indictment of a grand jury, except in cases occurring in the army or navy; or in the militia during war or in time of public danger. This amendment also provides that a person shall not be put in jeopardy of life or limb twice for the same offense, nor be compelled in any criminal case to be a witness against himself; nor be deprived of life, liberty or property without due process of law. Article VI guarantees a speedy and public trial by an impartial jury and with the assistance of counsel for his defense. Excessive bail, excessive fines, cruel and unusual punishments, all are forbidden by article VIII. Recent legislation, redolent of a period long since passed, shows that the fight of the citizens to safeguard these elementary and hard-won privileges must be never-ending, illustrating again the maxim that "Eternal vigilance is the price of liberty." (See EVIDENCE; LIBEL; INTERNATIONAL LAW; WITNESS). Consult Cooley, T. M., 'Principles of Constitutional Law in the United States' (3d ed., Boston 1898).

PRIVY COUNCIL, in England, the body of advisers of the sovereign which formally sanctions those acts of government not properly the province of Parliament. Privy councillors are nominated, without patent or grant, at the pleasure of the Crown, excepting certain persons appointed ex officio. They hold office for life, or for the life of the sovereign, so that at the accession of a new sovereign the council must be — nominally at least — reconstituted. The number of privy councillors is not limited by law.

Jurisdiction.— The duty of the council, in general, is to advise the king on affairs of state. The Lord President of the Council is required by statute «to manage the debates in Council, to propose matters from the sovereign at the Council Table, and to report to the sovereign the resolution of the Council thereon.» This function, however, is largely theoretical, as there are in fact no debates in council, this body merely giving formal sanction to orders in council, by which the king, on the advice of his ministers, expresses his pleasure with respect to various administrative matters, as for instance the bringing of treaties into effect, grants of charters, the government of colonies and the regulating of departmental business. So, too, the Privy Council performs certain ceremonial functions. For instance, in council a bishop does homage for the temporalities of his see, a minister takes the oath of office and the sheriffs for counties are chosen. The council has, besides, important duties of an administrative or judicial nature which it performs by committee or commission. Several of these committees have only a theoretical connection with the council, acting to all intents and purposes independently. The Cabinet itself, the executive of the United Kingdom, is such a committee, composed of ministers belonging to the Privy Council, but it has completely outgrown the parent body in political importance, having practically superseded it in the functions which this formerly performed. The Board of Trade, now under its own president and regarded as a distinct department of state, was from the first a committee of the Privy Council. The Local Government Board of Agriculture and the Board of Education are similar developments from the council, while the universities committee, the committee «for the consideration of charters of incorporation under the Municipal Corporations Act» of 1882 are still subordinate to the main body. The judicial functions of the Privy Council are carried on by its judicial committee, which includes the Lord Chancellor and the four Lords of Appeal in Ordinary. It is concerned chiefly with appeals from the dominions and colonial and Indian courts, has ecclesiastical jurisdiction and decides concerning petitions for extension of letters patent, copyright, etc. The Privy Council is summoned on a notice of 44 hours. Only on very extraordinary occasions is there a full attendance, the presence of six members being sufficient to constitute a council. Privy councillors have the title of «right honorable» and rank immediately after Knights of the Garter. The premiers of the self-governing colonies are called to the Privy Council.

History.—The Privy Council developed out of the *curia regis* (king's council) of the Norman period, which exercised judicial legislative and administrative functions. Out of the *curia* grew the courts of law and equity and the houses of Parliament besides the Privy Council. After the time of Edward I appeared the *concilium ordinarium,* or ordinary council of the king, which in the 15th century gained the name Privy Council. The Select Council, ultimately the Cabinet, began to emerge from the larger body about the same time. In the time of Edward III the Privy Council was occasionally merged in one assembly with the House of Lords, and in 1640 the Long Parliament reduced the powers of the council. In 1679 Sir William Temple made an unsuccessful attempt to reorganize it, but since then it has dwindled into insignificance when compared with its early authoritative position, and its governmental duties have been assumed by the Cabinet. Ireland has a separate Privy Council. Bodies, somewhat similar and bearing the same name, formerly existed in several of the American colonies and States. Consult Macqueen, 'Appellate Jurisdiction of the Privy Council' (1842); Finlason, 'The Judicial Committee of the Privy Council' (1878); Dicey, 'The Privy Council' (new ed., 1887); Gneist, 'History of the English Constitution' (1891); Anson, 'Law and Custom of the Constitution' (1892).

PRIVY-PURSE, Keeper of the, an officer of the royal household in England, in charge of the payment of the private expenses, including charities, of the sovereign. He has no control over any official or household expenses, and is independent of the great officers of the household.

PRIVY-SEAL (*privatum sigillum*), a British governmental seal formerly appended by the sovereign to such grant or documents as were afterward to pass the great seal; and sometimes used in matters of less consequence, which did not require to pass the great seal, as to discharge a recognizance, debt, etc. No writ, however, which related to the common law could pass the privy-seal. From the time of Henry VIII until the reign of Queen Victoria the privy-seal was the warrant of the legality of grants from the Crown, and the authority for the Lord Chancellor to affix the great seal. Such grants were termed letters patent. The officer who had the custody of the privy-seal was anciently called clerk of the privy-seal, afterward guardian *del* privy-seal; and later Lord Privy-Seal. The Lord Privy-Seal could not put the seal to any grant without good warrant; nor with warrant if it was against the law or inconvenient without first acquainting the sovereign therewith. In 1884 the Great Seal Act stipulated that all documents required to pass the great seal need not be passed under the privy-seal, a warrant under the sign manual countersigned by the Lord Chancellor, Secretary of State or a high treasury official being sufficient. Although without salary and no definite duties, the title of Lord Privy-Seal, with its former rank as fifth great officer of the state and a seat in the Cabinet, is conferred usually upon a peer above the rank of baron, although a commoner may receive the honorary title.

PRIX DE ROME, prē dė rōm (French «prizes of Rome»), awards made by the French government to art students which entitled the winners to advanced courses of studies at l'École or l'Académie de France in Rome.

The institution was founded by Louis XIV, in 1666, at the suggestion of Colbert and was enlarged by Napoleon. Its object is to complete the education of promising students in all branches of art, bv study of the classics in Rome. Those eligible for the prizes are painters, sculptors, architects, musicians and engravers, and the privilege bestowed consists of an annual income of 4,000 francs for four years and exemption from military service. Candidates must be Frenchmen between the ages of 15 and 30, and must have done certain work at the Ecole des Beaux Arts or elsewhere. The competition is so arranged as to comprise only 10 students from each department for the final competition, and these are allowed three months in which to accomplish the work they put in for the prize. While studying at Rome the successful competitor is expected to send to the Salon, or if he be a musician to the Conservatoire, every year, specimens of the work he is engaged in, and thus report progress.

PRIZE, property taken from an enemy in war; that which is seized by fighting, especially a ship, with the goods contained in her; any description of goods or property seized by force as spoil or plunder. The law as to prizes taken at sea is regulated by international law. In order to vest the title of the prize in the captors it must be brought with due care into some convenient port for adjudication by a competent court. In the United States, the court of naval jurisdiction is the Federal District Court, from which cases may be removed under certain conditions to the Circuit Court, or for final adjudgment to the Supreme Court. In Great Britain, the subject of prizes, captures, condemnation, etc., are vested exclusively in the Admiralty Division of the High Court of Justice. (See ADMIRALTY LAW; PRIZE-MONEY). Consult Barclay, T., 'Law and Usage of War' (Boston 1914).

PRIZE COURTS AND PRIZE JURISDICTION. As a general rule when enemy property is captured at sea under circumstances that render it liable to appropriation and confiscation by the captor the rights of the original owner are extinguished. But it may be that there is doubt as to whether the property is really enemy-owned, or whether it was captured in waters where warlike operations may be lawfully carried on, or whether it was not immune from capture by reason of its being in a neutral vessel, and the like. It is now a well-established rule of the law of nations that in all such cases the right of the captor to the property in question ought to be made the subject of adjudication by a court. It is generally admitted that the captor may destroy by sinking or otherwise an enemy prize when there is no doubt as to its character and ownership, and when for lack of a sufficient coal supply or inability to spare a prize crew he cannot take the prize in to a home port for adjudication by a prize court, or when the taking of it in would expose the captor to the danger of destruction or his prize to liability to recapture. The right of destruction in such cases was generally exercised bv Confederate naval commanders during the American Civil War, and it has been exercised on a large scale by German naval commanders during the present war. In both cases the home ports of the captor were blockaded by the enemy and since neutral ports are not open to a belligerent for the sequestration of his prizes the captors had no other alternative than to destroy their prizes. But as to the right to destroy *neutral* prizes without submitting the question of the legality of the capture to a prize court for adjudication, the law and practice of the past is otherwise. Most text-writers on international law maintain that in such cases a captor has no right of destruction. German naval commanders during the recent World War, however, acted on the contrary assumption and made no distinction between enemy prizes and neutral prizes, and whenever possible destroyed both alike without taking them in for adjudication by the courts. Sir Edward Grey recently stated the customary rule when he said "Great Britain has always maintained that the right to destroy is confined to *enemy* vessels only, and this view is favored by other powers." Concerning the right to destroy *neutral* vessels, the view hitherto taken by the greater naval powers has been that, in the event of its being impossible to bring in a vessel for adjudication she must be released. The prize courts of Great Britain for more than two centuries have held this to be a rule of the law of nations and there appears to be no instance during the wars of the 19th century in which a captor deliberately destroyed a neutral prize instead of taking it in for adjudication by a prize court.

The institution of prize courts for the determination of the legality of captures at sea is, however, of modern origin. Prior to the 16th century there does not appear to have been any such institution as a prize tribunal. When, therefore, a capture was made at sea the captor determined for himself by a summary inspection of the ship's papers and an examination of the persons on board whether the vessel or its cargo should be confiscated as lawful prize or allowed to proceed. The only remedy of the owner in such cases was to petition the king for redress. By a British order in council issued in 1585 it was decreed that henceforth all prizes should be brought in for adjudication. Ultimately it became the practice in all countries in time of war to set up tribunals for the purpose of deciding upon the validity of captures made by their cruisers at sea. These tribunals came to be known as prize courts. In England jurisdiction in all matters of prize was conferred upon the High Court of Admiralty by virtue of a special commission issued by the Crown at the outbreak of war, and by the Naval Prize Act of 1864 the Court of Admiralty was constituted a permanent court of prize, independent of any commission issued under the great seal. More recently the High Court of Justice was substituted for the Court of Admiralty as a permanent prize court and its jurisdiction is actually exercised by the Probate, Admiralty and Divorce Division. During the Napoleonic wars the prize court of England was made famous by the decisions of Lord Stowell. During the Crimean War the court was presided over by Dr. Lushington and during the World War it was held by Sir Samuel Evans. Special commissions to decide questions of prize were also issued to various courts in the overseas dominions and the colonies, for example at Alexandria, Malta, Ottawa and other places. Appeals may be taken to the judicial committee of the Privy Council. In the United States the Federal District Courts have original jurisdiction in prize cases but claimants may take appeals to the Supreme Court. In France the prize jurisdiction is exercised by a Council of Prizes consisting of five members. In Germany there were during the World War two prize courts, one located at Hamburg, the other at Kiel, each held by five judges. Cases could be appealed to the Supreme Court of Prize at Berlin, composed of seven judges. Prize courts are municipal tribunals although the law which they apply is international law and the rights which they are called upon to adjudicate are in most cases those asserted by the citizens or subjects of foreign states. They are, in short, practically judges in their own cases and are exposed to the temptation, to the bias and prejudice which may be expected of courts in deciding issues between their own government and foreign claimants. Added to this defect is the absence of an international code of prize law and the consequent divergences of view regarding the rules to be applied. To remove these defects the second Hague Conference in 1907 adopted a convention providing for the establishment of an international prize court, and the International Naval Conference at London in 1909 formulated a code of prize law dealing with such matters as blockade, contraband, the destruction of prizes, transfer of flag, unneutral service and the like. The international prize court was to be composed of 15 judges and upon the court the eight principal maritime powers were to be always represented. From the decisions of national prize courts appeals might be taken to the international tribunal, which it was believed would be more likely to decide the questions submitted to it with less bias and prejudice than could be expected of national courts. Unfortunately, however, owing to differences of opinion among the nations in regard to the constitution of the court it has never been organized, and in consequence of the failure of the powers to ratify the Declaration of London (q.v.) there is as yet no international prize code binding upon the national tribunals. Some states like Germany and France have put into effect prize codes of their own. The United States government issued such a code in 1900 but five years later it was revoked by President Roosevelt (see LAWS OF WAR, THE). Great Britain issued a manual of naval prize law in 1888 but it has since been withdrawn. British prize law is now found mainly in the Naval Prize Act of 1864, the Prize Courts Act of 1894 and various orders in council issued thereunder. The remainder consists of custom and judicial precedent. All authorities are in agreement that although prize courts are municipal tribunals the law which they must apply is international law, but as stated above there are wide divergencies of opinions to what that law is in respect to many questions, and the failure to ratify the Declaration of London leaves the prize courts of each nation free to interpret the customary law according to their own notions and apply such rules as they consider to have become well established. The view that prize courts are bound to apply the law of nations was affirmed by Lord Stowell in the case of the *Maria* as long ago as 1799 and the early commissions issued to the Court of Admiralty required that it should "hear and determine according to the course of admiralty and the law of nations." As late as the year 1916 the judicial committee of the Privy Council in the case of the *Zamora* laid down this principle. "The law which the prize court is to administer," it said, "is not the national law, or, as it is sometimes called, the municipal law, but the law of nations; in other words international law."

But suppose the municipal law of a state is contrary to international law. Must the prize court give effect to the former or the latter? The question was presented to Lord Stowell in 1811 in the case of the *Fox* and he disposed of it rather unsatisfactorily by saying that the court would assume that an order in council of the king which was believed to be contrary to the rules of international law was in accord with international law and that the court could not "without extreme indecency" presume the existence of a conflict. The issue was again raised in England during the World War in the case of the *Zamora* which involved the question as to whether an order of the king in council contrary to the established rule of international law was binding upon the prize court, and upon appeal to the judicial committee of the Privy Council it was held that such an order was not binding. The Privy Council admitted that if an act of Parliament contrary to international law were passed it would be binding upon the prize court, but orders in council stood on a different footing and they were not so binding when in conflict with international law. The idea that the king in council could prescribe or alter the law to be administered by the prize court, it said, was out of harmony with the principles of the British Constitution. The Supreme Court of the United States has long held to the same rule, that is to say, the courts are bound by municipal statutes even when they are contrary to international law, although they are not bound by executive orders which are in conflict with the established principles of international law.

The procedure of a prize court is in the nature of an inquest upon the property which has been placed within its custody, for the purpose of discovering whether it has been lawfully captured and whether it was liable to capture. The proceedings begin by the action of a representative of the captor government in libelling the property, that is, by petitioning the court to hold an inquiry. He submits with the petition the ship's papers, affidavits and other documents which contain evidence of the liability of the ship or cargo to capture and of the lawfulness of the capture. Notice is then given to the claimant in order that he may come forward and assert whatever rights he may have in the property libelled. Ordinarily enemy claimants are not allowed to appear but during the World War the president of the British prize court made an exception in the case of enemy claimants who asserted any right, title or interest under any of The Hague conventions. All such persons were permitted to appear by counsel and assert freely their rights, in spite of their enemy character. Prior to the American Civil War it was considered to be an established rule of prize procedure that the evidence must come in the first instance from the ship's papers and the depositions of the officers and crew of the vessel. Ordinarily extrinsic evidence could not be adduced by the captor. During that war, however, it was found impossible to adhere strictly to the old rule, especially in cases of continuous voyages where it was necessary to prove the actual intention of the shipper. In theory the burden of proof lies upon the captor, but generally in practice it is upon the claimant, and property brought in by the captor rarely escapes condemnation unless the owner can prove that it was not liable to capture. If the character of the evidence referred to above, technically known as evidence «in preparatory,» is deemed sufficient by the court, it renders its decision. If not, what is styled «further proof» is called for and the proceedings take on more of the character of an ordinary judicial trial between litigants.

The British prize court rules of 1914 introduced an important change in the established procedure by allowing cases to be decided in the first instance upon «such further evidence, if any, as might be admitted by the judge.» Under this rule each side was free at the outset, as in an ordinary civil or criminal action, to establish his case by any and all evidence that it could produce. The United States government complained of this new rule and asserted that it was a well-established and long-settled practice to consider at the first hearing only the ship's papers and documents and that the introduction of additional evidence could not be allowed except upon an order of the court for «further proof» and then only after the case had been fully heard upon the facts already in evidence. In short, under the new rule there was no longer a «first hearing» on the evidence derived from the ship and the prize court was no longer precluded from receiving extrinsic evidence from any and every source. To this criticism the British government replied that modern conditions had rendered the old rule obsolete and in any case the practice and procedure of prize courts were not regulated by international law but were determined by each nation for itself. Finally, the procedure referred to in the American note of protest had never been followed by the prize courts of France or any other Continental country; it was not, therefore, international law. The decree of the prize court is usually that the ship or goods or both shall be condemned or released. In the case of enemy ships found in port at the outbreak of war, if not liable to condemnation, decrees detaining them until the end of the war are issued. A large number of such decrees were issued by the British prize court during the World War. Except during the first days of the war there were few captures at sea. Most of the ships which were made the object of prize proceedings were seized in port at the beginning of the war and decrees of detention rather than of condemnation were issued. German merchant vessels encountered on the high seas proceeding to and from British ports, in ignorance of the outbreak of hostilities, however, were condemned by the prize court, in consequence of Germany's failure to ratify the article of The Hague Convention which exempted such vessels from capture.

When a decree of condemnation is issued the vessel in some countries, e.g., France, is condemned to the captors who divide the proceeds of the prize among them. This was the practice in Great Britain until the outbreak of the World War when the rules relating to bounties were altered. The captors no longer receive the prize but the court awards a bounty of £5 to each person actually present or taking part in the capture or destruction of the ships. In 1898 bounties for captures at sea were abolished by an act of Congress. It has always been the British practice to award compensation to neutral merchants by condemning the captor in damages and costs when the latter fails to make out a case against a prize brought in for carrying contraband and there was no good ground for the seizure. But this practice has not been followed on the Continent.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

PRIZE-FIGHTING, fighting with the fists for a reward or prize. The ancient Greeks were the earliest to have prize-fights among their sports, so far as our historic knowledge goes. The *pugilatus* (prize-fighter) fought naked except, at times, for a loin cloth. The sport was so popular that the nation placed gods and heroes among the victors in the *ring*, among them Apollo, Heracles, Tydeus, Polydeuces. It was considered one of the hardest and most dangerous games and death during or soon after the encounter was common. They used the *cæstus*, made of thongs or strips of leather which were tied around the fighters' hands to make the impact of a blow more telling. Later the *cæstus* was loaded with lead and iron, producing frightful weapons. First recorded statements of professional prize pugilism as a popular sport in England date from the end of the 17th century, and the championship started with James Figg of London, who held the title from 1719 to 1730. He built an «amphitheatre» where, as «Master of Ye Noble Science of Defence» (as his printed circular reads), he taught the nobility and gentry «ye use of ye small back sword and quarter-staff at home and abroad.» His encounter with Ned Sutton, in 1727, started with a broadsword bout, after which they took up their unarmed encounter, which was as much a wrestle as a fist-fight. In 1733 a Venetian, «The Gondolier,» fought Bob Whitaker, who appears to have given the Italian a *solar plexus* blow in the last round. His victory was soon followed by his defeat in a true fisticuff encounter with Nathaniel Peartree. Both these British fighters were pupils of Figg, as were also Tom Pipes and George Gretting who fought each other — none challenging the champion Figg. Pipes beat Gretting. In 1734 George Taylor (on Figg's death) claimed the championship, the reason not being quite clear, but none disputed the claim. Jack Broughton became the third champion and introduced the sole bare-knuckled fight with the broadsword and other combats discarded. He also reduced the «rules» of the «ring» to a fine art. The next champion was John Slack, butcher, who beat Broughton in 1750. But the Duke of Cumberland, who had been a great and admiring patron of Broughton, and who had bet $50,000 against $5,000 on him, considered he had been swindled by a palpable fake fight, closed the old amphitheatre and set the police on the trail of the ex-champion. William Stevens, «The Nailer,» pounded the fight out of Slack, after breaking his arm; but only to hold the title some eight and one-half months. Then, from appearances, he «sold» the championship by flagrantly leaving himself open to a blow on the head from his competitor, George Meggs, which felled him, he walking off laughing «none the worse for the fray.» Meggs had to leave London on account of the scandal and was beaten by Millsom, a Bath baker, who held the title for three years. In 1765 Tom Juchau, «The Disher,» defeated Millsom, to be beaten the following year by William Darts, a dyer, at Guilford, with a stake of $5,000, the largest since the Broughton-Slack affair. Darts was knocked out, in 1769, by Lyons, the waterman, the betting 10 to 1 against the latter. Lyons retired and gave back the title to Darts who lost it to Peter Corcoran, a herculean six-foot Irishman, who held the championship till 1776, when he was beaten by Harry Sellers (13th champion) in a match for a stake of $500 and a wager of $3,000. Thomas Jackling (frequently mentioned as Tom Johnson) became 14th champion after beating a number of challengers. «Big Ben» Brain, in 1791, defeated Jackling, but died in 1794, having been a sick man for years before he won the title. Daniel Mendoza, a Jew, held the 16th title, improving the science with his skill and ending the reign of the crude slugger. Mendoza also introduced the profitable occupation of sparring exhibition tours, and built the Lyceum in the Strand, London, for teaching the «noble art.» John Jackson next became champion, in 1795. Nineteenth holder of the title was Jack Bartholomew, who was knocked out by James Belcher, grandson of the 4th champion, Slack, in his 19th year. Next came Hen Pearce («The Game Chicken») as 21st champion, with John Gully, his successor, who retired and became member of Parliament. Thomas Cribb was 23d champion, and beat the American negro (first of his race to enter the ring) Bill Richmond in 1805. Thomas Molyneaux, another American negro, after beating Burrows and Blake claimed a championship match with Cribb, but lost the fight in 1810 and again in 1811. Thomas Winter, under the alias of Spring, took the 24th championship in 1823. Tom Cannon got the title in 1824, and Jem Ward in 1825. James Burke became 27th champion in 1833, but, on his return from an American tour, he was beaten by William Thompson (*Bendigo*) in 1839. Then Ben Caunt, who had beaten Bendigo before he met Burke, was declared champion, losing the title to Nick Ward, but regaining it (as 33d champion). In 1845 Bendigo again won the title. Caunt met «The Michigan Giant,» Charles Freeman, to make an engagement, but the American's seven-foot-three height and 333 pounds of trained fighting flesh and bone caused him to take the giant to England on an exhibition tour. William Perry, «The Tipton Slasher,» became 35th champion in 1850, passing the title over to Harry Broome on a foul in 1851. Tom Paddock was champion (37th) from 1856 to 1858, when he was defeated by Tom Sayers, who became 38th champion heavyweight after having beaten all comers as middleweight till Nat Langham defeated him. Sayers held his own when 1860 brought him a contestant in the American champion, J. C. Heenan («Benecia Boy»). This noted battle in 1860 was stopped by the referee in the 42d round, Heenan blinded in both eyes and Sayers with his right arm out of commission since the seventh round. The draw was never fought out, the world's title being held jointly by both, each presented with a belt. Heenan, in 1863, was beaten by Tom King in England, he becoming the 40th champion. So England had held the championship for two centuries, losing but one battle to the Irishman, Peter Corcoran, and the draw with Heenan. Jem Mace became champion in England in January 1862, only to lose it back to Tom King in November. Heenan, returning to England as the American champion, was knocked out by King, he becoming world champion. Mace next became (1863) champion, beating Joe Goss. America sent Joe Coburn, an Irish-American, to get the belt but in 1864 he returned without a fight and claimed the championship; later in the year Joe Wormald went to England to fight for the championship but on account of an accident lost his engagement stake without a fight. Squabbles and police interference made prize-fighting in England so difficult that the sport had to be carried on in America. Here the police made the carrying out of engagements quite difficult, and in 1868 the meeting of Ned O'Baldwin, the Irishman, and Joe Wormald at Lynnfield, Mass., was broken up by the police. But Mace met Tom Allen near New Orleans in 1870, defeating Allen in 10 terrific rounds. And with Mace's retirement in 1873 we have reached the last English champion. An attempt at reviving prize-fighting in England was made 1889–90, when the engagement was made between the Australians Slavin and M'Auliffe, but the fight at Walworth was stopped and, encountering later, they were both arrested. What the old-time sports called prize-fighting, however, was killed when gloves (even if only four ounces) had to be used by professionals. The brutality of the bare-knuckled prizefights gave place to the more scientific boxing. In 1885 James Smith won the heavyweight championship of England. In 1887 he was defeated by Jake Kilrain of Boston, the latter now becoming the world's champion. John L. Sullivan, of Boston, defeated Kilrain in 1889 in what is thought to have been the last contest in America under London prize-ring rules. Sullivan remained champion until 1892 when he was defeated by James J. Corbett the cleverest boxer the world had hitherto known or perhaps will ever know. In 1897 Robert Fitzsimmons defeated Corbett, but only held the championship three years, losing it to James J. Jeffries at Coney Island, N. Y., in 1900. For eight years Jeffries defeated several aspirants for championship honors, but on

4 July 1910 was defeated at Reno, Nev., by the colored pugilist Jack Johnson. The latter lost his crown to Jess Willard at Havana, Cuba, 5 April 1915. On 4 July 1919, Willard fought Jack Dempsey at Toledo, Ohio, and was defeated in three rounds. (See BOXING). PRIZE-MONEY, in warfare, money paid to the captors of a ship or place where booty has been obtained, the money being realized by the sale of the captured property after the established court, on full evidence, has adjudged it lawful spoil. The amount realized by the sale, placed in the hands of the official accountant of the navy, is distributed ratably, according to rank, among the officers and men who assisted at the capture. See PRIZE.

PRJEVALSKY, przhā-väl'skē, or **PREJEVALSKI,** prā-zhā-väl'skē, **Nicholas,** Russian traveler: b. Otradny, government of Smolensk, 31 March 1839; d. Karakol, West Turkestan, 1 Nov. 1888. Having joined the army in 1855 he assisted in quelling the Polish insurrection of 1861. While stationed in Siberia in 1867 he explored the Usuri region, south of the Amur, and spent 1871–73 in traveling from Peking through southern Mongolia (region of the Ordus) to the Ala-shan, Koko-nor and the upper waters of the Yang-tse-Kiang. In 1876–77 he explored Lob-nor on the borders of East Turkestan and China, and in 1879 reached a point some 160 miles north of Lhassa, when the Tibetan authorities turned him back. He reached Kiachta after a journey of nearly 15,000 miles. In 1883–84 he again crossed the desert of Gobi, but returned without being able to reach Lhassa. When the British began their war against the Tibetans in Sikkim he was placed at the head of a strong expedition, and ordered to reach Lhassa at all hazards. Already weakened by years of hardship, he was unable to endure the fatigues and exposure of another journey, and died on the route to Vernoje, where he intended to equip his expedition. Prjevalsky brought back from these journeys valuable collections of animals and plants, all now preserved at Petrograd. On his return to Petrograd from Siberia, he published a volume of 'Notes on the Ussuri.' Subsequently his accounts of his journeys were published in the 'Proceedings' of the Petrograd Geographical Society in *Petermanns Mitteilungen* and other journals.

PROA. See CATAMARAN.

PROBABILISTS, those philosophers who maintain that certainty is impossible and that we must be satisfied with what is probable. This was the doctrine of the New Academy, particularly of Arcesilaus and Carneades. The last-mentioned philosopher distinguished three principal degrees of probability, according as a representation might be probable when considered by itself alone; probable and unimpeached when compared with others; or thirdly, probable, unimpeached and in all respects confirmed. In morals probabilists are those who teach that in our actions we must follow what seems to us probably right, because in questions of morality demonstrative certainty is not to be attained. There are some Christian teachers (and among them Gury in his 'Compendium Theologiæ Moralis') who taught that a man may follow what is probably right, or what has been decided to be so by teachers of authority, although it may not be the most probably right, or may not seem probable to himself. It is this view that Pascal in his famous 'Provincial Letters' holds up to ridicule. Butler in his 'Analogy' bases his argument on probability, to which he applies the term "moral certainty." There were four schools of probabilism, known as probabilism simple, æqui-probabilism, probabiliorism and tutiorism. The first held it to be lawful to act upon any probable opinion no matter how slight its probability; the second required that the opinion should be "solidly probable," but held that, provided it be really probable, it would be lawful to act upon it, even though the conflicting opinion should be equally probable; the third, in the conflict of probable opinions, would only permit action on the more probable of the two, but it would permit this even when the less probable adverse opinion was the "more safe"; and the fourth required that in all cases the more safe opinion should be followed, even when the less safe opinion was much the more probable.

PROBABILITY, Theory of, is that branch of mathematics which deals with the determination of the degree of belief which, in the absence of full information, should be given to certain classes of statements, or to the past or future occurrences of certain events.

In regard to the great majority of events there is in the mind of every one a state of uncertainty. Under differing circumstances one shows this uncertainty by saying that it is possible or that it is, or is not, probable that some event did or will happen. Ordinarily no attempt is made to establish an exact measure of the probability of an event, such attempt being clearly foredoomed to failure. Not infrequently, however, the first step toward such a measurement is taken by the making of a rough comparison of the probabilities of two events, the conclusion resulting that one of them is *more* probable than the other.

Equally Probable Events.— For certain sorts of events it is possible to proceed farther. Thus, as a next step, it is quite common to find that two events are regarded as *equally* probable. For instance, a coin being tossed, one says that head and tail are equally likely to appear; or, a properly made die being thrown, one estimates that any one of the six faces is as likely to appear as any other. Of course these estimates are made in spite of the belief that, starting from a given initial position, the body moves completely subject to the laws of dynamics, and that from certain influences but one result can follow. The fact is that the observer is so ignorant of the forces applied to the body that his judgment is formed independently of them. He perceives that from the nature of the body only a certain number of events are possible, and he finds no reason for concluding that one event rather than another will occur.

Probability of an Event.— Suppose now that five events are known to be equally probable and that one of them will and only one can happen. Suppose also that if and only if one or another of the first three occurs, a further event E will occur. Then it is commonly said that the odds are 3 to 2 in favor of the event E; and since there are five equally probable events, of which exactly three are concurrent with E, it is said that the mathematical probability of E is $\frac{3}{5}$. In general, *when a specified event E is governed by n equally probable events, of which one will and only one can happen, and when, of m of these, each is decisively favorable to E, all others being decisively unfavorable, the mathematical probability of E is defined to be $\frac{m}{n}$.* In the extreme cases in which none and all of the events, respectively, are favorable to E, the probabilities are said to be 0 and 1, though in each case there is certainty regarding the occurrence of E.

Assume now that, of n equally probable and mutually exclusive governing events, m_1, m_2, ..., m_k are respectively favorable to the further events E_1, E_2, ..., E_k, which are also mutually exclusive. Then the probabilities of E_1, E_2, ..., E_k are respectively $p_1 = \frac{m_1}{n}$, $p_2 = \frac{m_2}{n}$, ..., $p_k = \frac{m_k}{n}$. If now $m_1 + m_2 + \ldots + m_k = n$, one has $\frac{m_1}{n} + \frac{m_2}{n} + \ldots + \frac{m_k}{n}$ 1; or $p_1 + p_2 + \ldots + p_k = 1$. The result may be stated formally as

Theorem 1. The sum of the methematical probabilities of a number of events, of which one must and only one can happen, is unity.

The application of the definition requires the selection of a set of governing events, finite in number, which must be either equally probable or capable of being replaced by a set of equally probable events; it then requires a correct enumeration of the favorable events and of the whole set. Each of these steps may present difficulties, but failure follows most frequently from a wrong selection of the set of governing events. Consider the following example:

Ex. 1. A coin being tossed twice, what is the probability that head appears twice?—One might say that the possibilities, or governing events, are three in number, viz., the appearances of two heads, of a head and a tail, and of two tails, respectively; that of these one is favorable, and that $p = \frac{1}{3}$. But the answer is incorrect because the appearance of two heads, or two tails, is not as probable as that of a head and a tail. The following are really equally probable events: the appearance of head, head; of head, tail; of tail, head; of tail, tail. They are four in number, one being favorable. Hence $p = \frac{1}{4}$.

The solutions of the following problems illustrate the direct application of the definition. Nearly all problems in this subject require the use of the theory of permutations and combinations. See ALGEBRA, *Permutations and Combinations.*

Ex. 2. Two dice being thrown, what is the probability that the throw will be seven?— The equally probable events are the appearances of the several numbers of the first die with those of the second die, and are 36 in number. The favorable cases are the following sets: 1, 6; 2, 5; 3, 4; 4, 3; 5, 2; 6, 1; they are six in number. Hence $p = \frac{6}{36} = \frac{1}{6}$.

Ex. 3. Two dice being thrown twice, what is the probability that at least one double appears? — In either throw any face of one die may be associated with any one of the other. Hence there are 36 equally probable cases for each throw. Each case for the first throw may be associated with each case for the second throw. Hence there are $36^2 = 1{,}296$ cases in all. Of the 36 cases in either throw 30 will fail to yield a double. The association of each of these cases for the first throw with each of these for the second throw will yield all of the *unfavorable* cases. Hence there are $30^2 = 900$ unfavorable cases, and accordingly, $1{,}296 - 900 = 396$ favorable cases. Hence $p = \frac{396}{1296}$.

Ex. 4. (a) From a bag containing five balls some are to be drawn. Find the probability that an even number of balls will be drawn. (b) Find also the probability if the number of balls be n.—(*a*) The total number of cases is the sum of the numbers of ways of drawing 1, 2, 3, 4 and 5 balls, which is $5+10+10+5+1 = 31$. The numbers of ways of selecting 2 and 4 balls are 10 and 5. Hence the number of favorable cases is 15. Hence $p = \frac{15}{31} = \frac{1}{2} - \frac{1}{62}$.

(*b*) The total number of cases is

$$_nC_1 + {}_nC_2 + \ldots + {}_nC_n.$$

The number of favorable cases is $_nC_2 + {}_nC_4 + \ldots$ Now $(1+1)^n = 1 + {}_nC_1 + {}_nC_2 + \ldots + {}_nC_n$,

and $(1-1)^n = 1 - {}_nC_1 + {}_nC_2 \ldots$.

Hence $2^n - 1 =$ total number of cases. Also $2^n - 2 = 2({}_nC_2 + {}_nC_4 + \ldots)$, and so $p = \frac{2^{n-1} - 1}{2^n - 1}$.

Notice that an odd number of balls is more likely to be drawn than an even number.

Another problem remarkable alike for its apparent difficulty, the fine reasoning employed in its solution and the simplicity of its results is the following one:

Ex. 5. At an election two candidates A and B received respectively a and b votes, A being elected. What is the probability that during the counting of the ballots A was always ahead? — The solution is obtained easily after it is shown that of the orders of counting which are unfavorable to the result mentioned exactly one-half begin with a vote for A. The answer is $p = \frac{a-b}{a+b}$, i.e., *the majority divided by the total vote.*

TOTAL PROBABILITY. COMPOUND PROBABILITY.

It may happen that the m governing events favorable to E can be classified into sets of m_1, m_2, ..., m_k events respectively, where $m = m_1 + m_2 + \ldots + m_k$. The probability, p_1, that E will be concurrent with one of the set of m_1 events is $\frac{m_1}{n}$. Then since $\frac{m_1}{n} + \frac{m_2}{n} + \ldots + \frac{m_k}{n} = \frac{m}{n}$, one has $p_1 + p_2 + \ldots + p_k = p$. Stated formally one has

Theorem 2. If an event can happen in several mutually exclusive ways, the probability of its happening at all is equal to the sum of the *probabilities of its happening in the several ways.*— Here p is called the *total probability*, p_1, p_2, etc., the *partial probabilities*. On the other hand the event E whose probability is sought may consist in the concurrence of several independent events. Suppose that these events are $e_1, e_2, \ldots, e_k$, and that for them the total numbers of cases are $n_1, n_2, \ldots, n_k$, respectively, and that the numbers of favorable cases are $m_1, m_2, \ldots, m_k$, respectively. Then for the event E the total number of cases is $n_1 n_2 \ldots n_k$, and of these $m_1 m_2 \ldots m_k$ are favorable. Hence

$$p = \frac{m_1 m_2 \ldots m_k}{n_1 n_2 \ldots n_k} = \frac{m_1}{n_1}\frac{m_2}{n_2} \ldots \frac{m_k}{n_k} = p_1 p_2 \ldots p_k.$$

Hence one has

Theorem 3. The probability of the concurrence of several independent events is the product of the probabilities of their several occurrences.— This theorem can be extended to the cases in which events, not independent, have a specified order, and in such cases the probability of each is to be computed on the hypothesis that the preceding events have happened.

These three theorems form the basis of the whole of the elementary theory. Their application will be illustrated in the solution of the following example:

Ex. 6. A with three coins endeavors to throw more heads in one throw than B can throw with two coins. In case of a tie they throw again. What is the probability of A's winning? —The following ways in which A can win include all cases, and are mutually exclusive. He may (1) throw 3 heads, (2) throw 2 heads and win, (3) throw 1 head and win, (4) he may tie B on the first throw and win on a subsequent throw. Let p be the total probability of A's winning, and p_1, p_2, p_3, p_4 the partial probabilities. The following table gives the chances of various throws by A and B:

Number of heads	3	2	1	0
A's chance	$\frac18$	$\frac38$	$\frac38$	$\frac18$
B's chance	0	$\frac14$	$\frac12$	$\frac14$

Then, by theorem 3, $p_1 = \frac18$, $p_2 = \frac38(1-\frac14)$, $p_3 = \frac38(1-\frac14-\frac12)$. Also p_4 is the product of the probabilities that a tie will occur and that A will subsequently win. The probabilities that a tie will occur with 3, 2, 1, 0 heads are 0, $\frac38 \times \frac14$, $\frac38 \times \frac12$, $\frac18 \times \frac14$. The sum is $\frac{5}{16}$. If a tie occurs, the initial condition is reproduced and A's chance of winning is p. Hence $p_4 = \frac{5}{16}p$. Then, by theorem 2, $p = \frac18 + \frac{9}{32} + \frac{3}{32} + \frac{5}{16}p$, whence $p = \frac{8}{11}$.

PROBABILITIES OF REPEATED EVENTS.

An interesting part of the theory is that relating to repetitions of events. Consider an event whose probability is p, and let $q = 1-p$. Suppose that n trials are made. The probability that the n trials will result in s occurrences and $(n-s)$ failures of the event, in a specified order, is $p^s q^{n-s}$. But the number of different orders is $\frac{|\underline{n}}{|\underline{s}\,|\underline{n-s}}$. Hence the probability that in n trials there will be exactly s occurrences is $\frac{|\underline{n}}{|\underline{s}\,|\underline{n-s}}p^s q^{n-s}$. By considering different values of s one may find the probability that the number of occurrences shall lie between specified limits. Thus if a coin be tossed 10 times, one finds the probabilities of the appearances of exactly four, five and six heads to be $\frac{210}{1024}$, $\frac{252}{1024}$, $\frac{210}{1024}$; and the probability that the number of heads will not differ from five by more than one is $\frac{672}{1024}$ or $\frac{21}{32}$.

An easy problem is the determination of that number of occurrences which is most probable. It is necessary only to compare the results of giving to s consecutive values between zero and n to discover that for the most probable case s must be so chosen that the fraction $\frac{s}{n}$ is as nearly as possible equal to p. Hence in 10 throws, the most probable number of heads is 5 because $\frac{5}{10} = \frac12 = p$. Likewise in 73 throws with one die the most probable number of throws of aces is 12, since $p = \frac16$, and $\frac{12}{73}$ is the fraction having the denominator 73 and being most nearly equal to $\frac16$.

Of particular interest is the case in which the number of trials is very large. In this case the evaluation of the probability may be made approximately by the use of Stirling's formula: $|\underline{n} = n^{n+\frac12}e^{-n}\sqrt{2\pi}$, where e is the Napierian base. By this means many interesting results may be derived. Thus if p_0 denote the probability of that number of occurrences which is most probable, $p_0 = \frac{1}{\sqrt{2\pi npq}}$; and if P_l denote the probability that the number of occurrences shall not deviate from the most probable number by more than l, which does not exceed a small multiple of $\sqrt{n}$, then

$$P_l = \frac{2}{\sqrt{\pi}}\int_0^\gamma e^{-t^2}dt + \frac{e^{-\gamma^2}}{\sqrt{2\pi npq}},$$

where $\gamma = \frac{l}{\sqrt{2npq}}$. The results here obtained are due to James Bernoulli, and are usually combined in a statement of what is called

Bernoulli's Theorem. If an event has a constant probability, p, and if $q = (1-p)$, then, n trials being made, the most probable result is that in which the ratio of the number of occurrences to the number of trials is most nearly equal to p. The number of trials being very great, the probability that the deviation of the number of occurrences from the most probable number shall not exceed l is

$$P_l = \frac{2}{\sqrt{\pi}}\int_0^\gamma e^{-t^2}dt + \frac{e^{-\gamma^2}}{\sqrt{2\pi npq}},$$

where $l = \gamma\sqrt{2npq}$, and l does not exceed a small multiple of $\sqrt{n}$.

For very many purposes in the Theory of Probability the definite integral $\int_0^\gamma e^{-t^2}dt$, is of great importance, and so tables of its values for different values of γ have been prepared. It may be shown, too, that a very good approximation to the value of P_l is given by the equation $P_l = \frac{2}{\sqrt{\pi}}\int_0^{\gamma'} e^{-t^2}dt$, where $\gamma' = \frac{l+\frac12}{\sqrt{2npq}}$.

From the tabulated value of the probability integral, $\frac{2}{\sqrt{\pi}}\int_0^{\gamma'} e^{-t^2}dt$, the following facts regarding P_l become evident. ***First,*** the deviation l being specified, the values of γ' and of P_l decrease rapidly as n increases. In fact if the number of trials be increased sufficiently, the probability that the specified deviation will not be exceeded can be made smaller than any fraction assigned in advance. ***Second,*** if γ' and hence P_l be specified, the corresponding deviation l increases rapidly as n increases, but the relative deviation, or the ratio of the deviation to the number of trials, decreases rapidly.

To illustrate these statements let it be recalled that, a coin being tossed 10 times, the most probable result is five heads and five tails, and the probability that the deviation of the number of heads (from five) should not exceed one was found to be $\frac{21}{32}$. Consider now the cases of 10,000 and 10,000,000 trials. A careless examination might suggest that for the same probability, $\frac{21}{32}$, the corresponding deviations would be 1,000 and 1,000,000 respectively. As a matter of fact, simple computations show that they are not more than 50 and 1,500 respectively.

The very close relation which existed between the theory of probability and the study of games of chance makes it exceedingly interesting to see what conclusions can be drawn regarding the probable results of persistent gambling. Bernoulli's theorem applies directly. Since the conclusions for all cases are similar it will be most satisfactory to consider a simple one.

Suppose, then, that A, with a capital of \$1,000, repeatedly bets \$10 evenly that the toss of a coin will yield head. The game seems fair, and it might appear that in the long run A would neither win nor lose. Notice, however, that A will be ruined whenever he shall have lost 100 times more than he has won. The theory shows that of all possible cases the most probable is that in which the numbers of heads and tails are equal. But the probability of the result is $\sqrt{\frac{2}{\pi n}}$, and it evidently decreases rapidly as n increases. Bernoulli's theorem shows that, if the number of trials be about 25,000, the probability that the deviation shall exceed 100 is about $\frac{2}{10}$. Hence the chance that A will neither win nor lose the amount of his present fortune soon becomes inconsiderable. One may say, then, that in the long run A will either be ruined or will at least double his fortune; and the chances of these events appear to be even. As a matter of fact A is at a serious disadvantage. For many runs of results which might ultimately be favorable to him are excluded because in their beginnings he has so many losses that he must cease play for lack of money. On the other hand all runs which began favorably but ultimately become unfavorable must be counted because A does not stop as long as he wins. Hence the equality of the chances is destroyed.

Mathematical Expectation.

A person who has a possibility of securing without cost a property of any sort places upon that possibility a value which depends upon that of the property and upon the probability of his securing it. In our subject a definite valuation is placed upon such a possibility. This valuation is called its ***mathematical expectation*** and is defined to be ***the product of the value of the property and the probability of getting it.*** More generally, if there are several gains, a_1, $a_2, \ldots, a_n$, with the respective probabilities, $p_1, p_2 \ldots, p_n$, the mathematical expectation arising from these gains is $E = p_1a_1 + p_2a_2 + \ldots + p_na_n$. In this connection losses may be treated as negative gains. It is not denied that such an estimate involves the disregard of many elements, but unquestionably in the applications of this definition which are generally made such disregard is reasonable. To be more specific, it is extremely unlikely that a poor man would regard a possible gain of \$2,000, whose probability is $\frac{1}{2}$, as equivalent to the actual possession of \$1,000. On the other hand such an estimate is made the basis of all insurance business and is justified by the results obtained.

The connection between mathematical expectation and gambling is evident. If a person throws a die and is to receive \$600 in case an ace appears, his expectation is $\$600 \times \frac{1}{6} = \$100$. Unquestionably \$100 would be regarded as a fair entrance-fee to one who could afford to repeat the trial a number of times. In this connection the condition under which a game is said to be *fair* may be mentioned. Suppose that a player has to pay a stake b to enter a game in which his chance of winning a sum a is p. Then for a fair game $b = pa$, or his expectation after his entry must be equal to his stake.

The derivation from the definition of mathematical expectation of certain results which seemed to him to be impossible of acceptance led Daniel Bernoulli to develop a theory of *moral expectation* which has received some considerable attention. Bernoulli laid down the principle that to the possessor of a fortune a the *moral value, v,* of a small gain h is directly proportional to the amount of the increase, and inversely to this present fortune; or that $v = k\frac{h}{a}$ (where k is a constant); and that if the probability of this gain is p, the moral expectation arising from it is $pv = \frac{pkh}{a}$. The results obtained from this estimate differ widely from those obtained under the preceding one. They do, however, become less widely divergent from the latter as a increases, and in fact as a increases indefinitely the two sets of results tend to a perfect agreement.

Probabilities Derived from Experience.

Probabilities of Causes.— Hitherto the determination of the probability of an event has been based directly or indirectly upon certain governing events. A problem of another sort comes up for consideration. In the discussion of this problem and similar ones the word *cause* will be given an unusual meaning. For the present purposes the term will be used to mean a set of circumstances which might have given rise to an event. The problem may be stated as follows:

It is known that an event E has happened, and it is known that one of several causes has given rise to the occurrence of E; it is required to determine the probability that E arose from a specified one of the causes.

A concrete example is furnished by the following problem.

Ex. 7. Two bags contain respectively one white and one black ball, and one white ball and nine black ones. A ball has been drawn from one of the bags, has been observed to be white and has been replaced. What is the probability that it was drawn from the first bag? — Let p be the required probability. There are two ways of computing the probability of drawing a white ball from the first bag. In the first place it is necessary that the first bag should be selected and that, it having been selected, a white ball should be drawn. This gives $\frac{1}{2} \times \frac{1}{2} = \frac{1}{4}$ as a result. In the second place it is necessary that a white ball should be drawn and that, having been drawn, it should have come from the first bag. This yields $(\frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{10})p$. Hence, equating these values one gets $p = \frac{5}{6}$.

Similar reasoning applied to the general case yields the following result:

Theorem 4. If an event E has occurred as a result of one or another of certain causes $C_1, C_2, \ldots, C_n$, whose respective probabilities previous to the occurrence of E were $\pi_1, \pi_2, \ldots, \pi_n$, and if, when any one of the causes, as C_i, is known to be operating, the probability that it will produce E is p_i, then the probability, P_i, that E resulted from C_i is

$$P_i = \frac{p_i \pi_i}{p_1 \pi_1 + p_2 \pi_2 + \ldots + p_n \pi_n}.$$

Apply the result to the following example:

Ex. 8. From a bag containing five balls, each of which is either white or black, four drawings have been made, the ball being replaced after each drawing. The result is three white balls and one black one. What are the probabilities that the bag contains (1) four white, one black ball, (2) three white, two black, (3) two white, three black, (4) one white, four black? — There are four causes: (1) Four white, one black, (2) three white, two black, etc., and before the drawing they were equally probable. Hence $\pi_1 = \pi_2 = \pi_3 = \pi_4 = \frac{1}{4}$. Also $p_1 = (\frac{4}{5})^3 \frac{1}{5}$, $p_2 = (\frac{3}{5})^3 \frac{2}{5}$, $p_3 = (\frac{2}{5})^3 \frac{3}{5}$, $p_4 = (\frac{1}{5})^3 \frac{4}{5}$. Then $P_1 = \frac{64}{146}$, $P_2 = \frac{54}{146}$, $P_3 = \frac{24}{146}$, $P_4 = \frac{4}{146}$.

When the number of causes is very great the formula of theorem 4 becomes unwieldy. It is found that a simpler formula gives an approximate result. The method used in deriving this formula will be illustrated in the following example:

Ex. 9. From among an exceedingly great number, N, of balls, each of which is either black or white, n balls are drawn, each ball being replaced before the next drawing. Of these exactly s are white. What are the probabilities for the various possible numbers of white and black balls in the whole set? — Since before the drawings nothing was known as to the desired result, the a priori probabilities for all numbers of white balls from 0 to N are equal. Now the total number of white balls will be known if the ratio, r, of that number to N be known. Hence equally probable values of this ratio are all proper fractions having N as denominator. Since N is very great, r varies from 0 to 1 by very small increments. *It will now be assumed* that for purposes of approximation r may be treated as varying continuously from 0 to 1. Also, if r is the correct ratio, the probability that in n drawings s white and $(n - s)$ black balls would appear is

$$\frac{\underline{|n}}{\underline{|s}\,\underline{|n-s}}\, r^s(1-r)^{n-s}.$$

If r varies continuously from 0 to 1, the probability of any specified value of r is zero, but the a posteriori probability that the ratio shall lie between r and $r + dr$ is

$$p_r = \frac{r^s(1-r)^{n-s}dr}{\int_0^1 r^s(1-r)^{n-s}dr} = \frac{\underline{|n+1}}{\underline{|s}\,\underline{|n-s}}\, r^s(1-r)^{n-s}dr,$$

since the number of values of $r^s(1-r)^{n-s}$ as r varies from r to $r + dr$ is measured (see *Geometrical Probability*) by dr; and the probability that r shall lie between r_1 and r_2 is

$$P = \frac{\underline{|n+1}}{\underline{|s}\,\underline{|n-s}} \int_{r_1}^{r_2} r^s(1-r)^{n-s}dr.$$

A general theorem might be formulated embodying this result, and such a theorem jointly with theorem 4 would constitute what is called the Theorem of Bayes.

The maximum value (see CALCULUS, INFINITESIMAL, *Maxima and Minima*) of $r^s(1-r)^{n-s}$ is obtained by putting $r = \frac{s}{n}$, and is $\frac{s^s(n-s)^{n-s}}{n^n}$. Then the most probable cause is that in which the actual ratio of the number of white balls to the total number is the same as the corresponding ratio in the observed results.

A discussion of the value of P, which must be omitted, yields the following notable result:

Theorem 5. The probability that, under the conditions of example 9, the ratio of the number of white balls to the total number shall not deviate from its most probable value, $\frac{s}{n}$, by more than $\gamma\sqrt{\frac{2s(n-s)}{n^3}}$ is $\frac{2}{\sqrt{\pi}}\int_0^\gamma e^{-t^2}dt$.

Empirical Probabilities.— The preceding theory finds application in connection with any sets of events which for the purposes of any discussion may justly be compared with the drawing of balls from a bag. In some of the important connections this theory is in fact indispensable. It will be noted that in both of the examples 8 and 9 the inquiry was in regard to the probability of the various possible numbers of white and black balls. But if the ratio of the number of white balls to the total number of balls be known, that ratio furnishes the probability that a further single drawing will produce a white ball; and in general this probability is what is most urgently sought. Probabilities estimated in this way from observed events are called *empirical probabilities.*

Two methods of deriving empirical probabilities are used, one theoretically correct, but leading to troublesome computations, the other avowedly approximate only. The latter method involves the assumption that, of the possible causes of the observed event, that which has the greatest a posteriori probability is the true one. These two methods will be applied to example 8.

Suppose that after the drawing of the balls from the bag the question be asked, "What now is the probability of drawing a white ball?" By the second method the answer would be obtained as follows: The most probable state of the bag is that it contains one black and four white balls. Hence the probability of drawing a white ball is $\frac{4}{5}$.

The following is the other method of treatment: The probability that the bag contains four white balls and one black one and that a white one will be drawn from it is $\frac{64}{100} \times \frac{4}{5}$; that it contains three white and two black and that a white one will be drawn is $\frac{27}{100} \times \frac{3}{5}$; that it contains two white and three black and that a white one will be drawn is $\frac{8}{100} \times \frac{2}{5}$; and that it contains one white and four black, and that a white one will be drawn is $\frac{1}{100} \times \frac{1}{5}$. Hence the probability that a white ball will be drawn is [illegible].

Where the number of causes is greater the difference between the two values is smaller, and theorem 5 shows that when the number is very great the difference can be very small indeed, as it becomes nearly certain that the ratio r differs by very little from $\frac{s}{n}$.

GEOMETRICAL PROBABILITY.

In what precedes it has been assumed except in one case that the number of equally probable events governing the event E is finite. The definition may be extended to include the case in which the number of events is infinite provided appropriate measures for the totalities of cases can be devised. Such measures are available when each case corresponds to a set of values or one or more continuous variables. Problems requiring the adoption of such measures are generally geometrical, and hence this branch of the subject is called *geometrical probability*. Merely an indication of its nature may be given by one or two very elementary examples.

Although the number of points on any line segment cannot be counted, yet their totality may be measured by the length of the segment. Similarly the totality of points in an area may be measured by that area; and so on. The probability that, all values being equally probable, a number less than unity is also less than one-half is ½ because the totality of cases is measured by a unit segment, and that of the favorable cases by half a unit segment. Similarly, if all points within a circle of radius a are equally likely to be selected, the probability that one of them selected, at random, is not distant more than $\frac{a}{2}$ from the centre is $\frac{1}{4}$.

Many very interesting problems have been solved, some of them by exceedingly ingenious methods, but this branch of the subject is quite special and cannot receive further attention here.

In what precedes some important parts of the theory have been indicated. A study of its important applications, notably those to the discussion of errors of observations and to problems of insurance, must be sought elsewhere. The growth of the importance of the subject has been remarkable, for in the beginning it was concerned with problems of gambling, and it has become the basis of all forms of insurance. It has attracted and held the deep attention of nearly all the ablest mathematicians from Cardan to Sylvester and Poincaré. Among its devotees have also been Pascal, Fermat, De Moivre, Leibnitz, the Bernoullis, D'Alembert, Euler, Lagrange, Bayes, Condorcet, Laplace, Poisson, De Morgan, Bertrand and Czuber. The theory has been applied freely, and in many cases rashly, too little attention having been paid to the fact that its applications really lie in the domain of those events whose occurrences may properly be compared to the drawings of balls from a bag. Hence it is necessary to exercise considerable care in connection with the literature of the subject. See LEAST SQUARE, METHOD OF; STATISTICAL METHOD.

GEORGE H. LING,
Dean of the Faculty of Arts and Science, University of Saskatchewan.

PROBATE, *in law,* legal proof of a will. In the United States, probate is granted usually by courts of special jurisdiction in the various States, but sometimes by chancery or common law courts. See WILL.

PROBATE, Court of. See COURT.

PROBATION, *in law,* a method of conditional release of persons convicted of crime, who are kept under constant surveillance and allowed their liberty during good behavior only. Usually the offender is under the supervision of a probation officer. The system originated in Massachusetts in 1878, and since then has grown rapidly in favor among penologists, as being expedient, economical, humane and tending to preserve the self-respect of transgressors. Usually only first offenders guilty of minor crimes are subject to probation. It was adopted in the United Kingdom by statute in 1908.

PROBATION AFTER DEATH, a doctrine favored by some modern theologians as a means of reconciling the idea of everlasting punishment with that of God's supreme mercy and the universal redemption through Jesus Christ: the doctrine differs from the doctrine of Universalism in postulating an intermediate state of the soul after death, of which Universalism knows nothing; and in rejecting the Universalist tenet that *all* will ultimately be saved. Something very like this doctrine of *post mortem* probation, and different from the Catholic doctrine regarding Purgatory, is taught by Clement of Alexandria (*Strom.* vi. 18): «Even if a man passes out of the flesh he must *put off his passions* ere he is able to enter the eternal dwelling.» And he speaks of the angels «who preside over the ascent» of souls as detaining those who have *preserved «any worldly attachment.»*

PROBLEMATISCHE NATUREN ('Problematical Natures'). Like Freytag and Paul Heyse, Friedrich Spielhagen was chiefly concerned, in his novels, with defining the warring elements of German character and the opposing springs of German action in the period before and after the revolution of 1848. Like Freytag and Heyse, Spielhagen saw clearly the dangers that threatened the country, politically, religiously and morally from a reactionary aristocracy; like Heyse and unlike Freytag he saw the hope of the nation in the spread of an enlightened democracy rather than in a spiritual renascence of the ruling classes. Oswald Stein, the hero of his most famous novel, ‹Problematische Naturen,› is the mouthpiece for Spielhagen's revolutionary social theories. He is modelled after those characters of whom Goethe wrote «There are problematical natures that do not fit into any situation and who remain always unsatisfied. For them there arises a terrible conflict that consumes life without enjoyment.» For Spielhagen the conflict itself, even though it ends in defeat, is victory; the mere struggle against the domination of dead ideas is progress. For such a philosophy there could be no better historical background than the Germany of 1848 and after, and ‹Problematische Naturen› with its sequel ‹Durch Nacht zum Licht,› although it squanders material for half a dozen novels, idealizes Teutonic morbidity, and forsakes art for tendency, tells with remarkable vividness, the story of the men and women who lived and thought and fought for freedom in Germany's day of hope. A notable description of the literature of this period is to be found in Julian Schmidt's ‹Geschichte der Deutschen Literatur.›

EDITH J. R. ISAACS.

PROBOSCIS or **NOSE MONKEY**, a rare Bornean monkey (*Nasalis larvatus*), called «Kahau» by the natives, and characterized by a greatly elongated nose, giving a peculiarly ludicrous appearance to the face. The general body-color is a sandy red; the tail is dark above, but light yellow beneath. These monkeys are arboreal in habits, and appear to frequent the neighborhood of streams and rivers, congregating in troops. They are closely allied to the apes of the genus *Semnopithecus*.

PROBUS, Marcus Aurelius, Roman emperor: b. Sirmium, Pannonia, 232; d. there, 282. He early attracted the notice of the Emperor Valerian, who made him tribune and soon placed him at the head of a legion. The brilliancy of his conduct in the African, Persian, Arabian and Germanic campaigns brought him into still more prominent notice. He was made governor of all the Roman provinces in Asia by the Emperor Tacitus and when Florianus, who succeeded his brother Tacitus, was murdered in 276 Probus was immediately proclaimed emperor by universal consent. He drove back the Franks, Alemanni and Vandals, who had invaded Gaul; and in 277 secured the frontier wall between the Danube and the Rhine. He also freed the lands south of the Danube, Egypt and the East from devastating barbarian hordes and concluded an advantageous peace with the Persians. He gave new dignity to the senate, populated desolate tracts in Thrace and Mœsia with barbarians (280) and paid particular attention to agriculture. By 281 peace had been established almost everywhere throughout the Empire. Probus now, for the first time since his accession to the throne, found it possible to go to Rome where he celebrated a triumph either in 281 or 282. He kept his soldiers actively employed in public works. Irritated at being charged with occupations which they deemed degrading, a troop engaged in draining a swamp rose in insurrection and killed him. Probus ranks among the ablest of Roman emperors, combining the qualities of a good commander and wise statesman. Consult Dannhaüser, E., ‹Untersuchungen zur Geschichte des Kaisers Probus› (1909).

PROBUS, Marcus Valerius, Roman grammarian: b. Berytus, Syria, second half of the 1st century A.D. He is chiefly noted for his critical revisions of the most important Latin poets, as for instance Lucretius, Horace and Virgil. He applied to them the methods of the Alexandrian school of critics. A commentary on the Bucolics and Georgics of Virgil under his name has been preserved but is of doubtful authenticity. A biography of Persius, written by him, remains in a commentary on the works of that poet. An extant fragment of his work ‹De Notis› contains the abbreviations used for legal terms. Consult Aistermann, J., ‹De M. Valerio Probo Berytio› (Bonn 1910).

PROCACCINI, prō-kät-chē'nē, the name of a family of artists of the 16th century who under the patronage of the Borromeo family, founded a distinct school of Italian painting at Milan, as the Caracci had done at Bologna. The members of this family were (1) ERCOLE PROCACCINI, called the Elder: b. Bologna, 1520; d. later than 1591. His works, principally at Bologna and Parma, are not remarkable for talent, but exhibit industry and care, although they are not free from the mannerism of his contemporaries. He was in great request as a teacher and after his removal to Milan became the founder of the famous school bearing his name. (2) CAMILLO PROCACCINI, son and pupil of the former: b. Bologna, 1546; d. Milan 1626. He was the most accomplished artist of this school. He profited by studying the school of the Caracci and took Correggio and Parmegiano for his models. His imitation of them is obvious from his work but the result is equally successful. His works are distinguished for spirited composition, exquisite coloring and devotional elevation, but are mannered. Among those at Milan are a ‹Madonna and Child› in the church of Santa Maria del Carmine and an ‹Adoration of the Magi› in the Brera. Many other churches in Milan contain works of his, as do also galleries in Bologna, Dresden, Leipzig, Munich, Stuttgart, Vienna, Madrid. (3) GIULIO CESARE PROCACCINI, brother of Camillo: b. Bologna, 1548; d. Milan, 1626. He likewise strove to equal the school of the Caracci and took for his model Correggio, whom he imitated with so much success that several of his pictures, though far from reaching the grace and harmony of that great master, have often been ascribed to him. This has been the case especially with cabinet pictures of the Fall. His works, all of a religious nature, are to be met with in many churches of Milan especially in the cathedral. In the Annunziata in Genoa is his ‹Last Supper,› by some considered his masterpiece. Others of his works are in galleries in Florence, Genoa, Milan, Parma, Turin, Madrid, Edinburgh, Brussels, Berlin, Dresden, Munich, Petrograd, Stuttgart, Vienna. (4) CARLO ANTONIO PROCACCINI, youngest brother of the two preceding: b. Bologna, about 1555, d. about 1605. He, too, was a pupil of his father, but the least gifted of the three brothers. He painted landscapes, fruits and flowers. Much of his work went to Spain, though some may be found in private collections in Milan. (5) ERCOLE PROCACCINI, called the younger, son of Carlo Antonio: b. Milan, 1596; d. there, 1676. He was a pupil of his uncle Giulio Cesare whom he succeeded as head of the Procaccini School. He painted historical subjects and still life, excelling especially in the latter. Religious subjects by him can be seen in the church of Saint Maria Maggiore at Bergamo in the Brera, Milan, etc. Consult Blanc, C., 'Ecole Bolonaise' (Paris 1874).

PROCEDURE, *in law,* the methods of initiating and maintaining litigation, usually embracing practice, pleading, evidence and the rules governing them. The term is sometimes restricted in its meaning to include only practice. Three widely differing systems of procedure were early developed in England by the courts of common law, courts of admiralty and courts of equity. While changed by statute and otherwise from the early forms, these systems are preserved to-day generally throughout the British Empire and the United States.

As developed in the common law courts, procedure differed radically from that in the courts of admiralty and courts of equity, being distinguished by extreme formality; and as a consequence the substantive rights of the litigants were often entirely disregarded by the rigid manner in which the rules were applied. Dating back to an early period, civil actions in common law courts were commenced by the issuance of the original writ at the instance of the plaintiff, commanding the sheriff to summon the defendant to appear before the court. This writ gave jurisdiction to the court of the subject matter of the action and its service gave jurisdiction over the defendant. The court could compel the attendance of the defendant at any judicial proceeding by issuance of its process known as a judicial writ. The plaintiff's claim was set forth in a prescribed form in the declaration, stating the cause of action in one or more counts and ending with a prayer for relief. (See COMPLAINT; DECLARATION). Then followed the plea or answer by the defendant, replication by the plaintiff and sometimes other pleadings, until an issue was reached. (See ANSWER; PLEA; PLEADING; REPLICATION). The court then directed the attendance of the parties and witnesses at the trial, which was a formal examination of the material facts, usually before a jury. (See JURY; TRIAL). After verdict various remedies were provided for the unsuccessful party. For instance, he could move in arrest of judgment, for a new trial, for a writ summoning a new jury on the ground of misconduct, etc. After judgment the defeated party had a remedy by writ of error, which was acted upon by a higher court. This writ stated the cause of complaint in a general manner and the assignments of error pointed out the particular errors of law alleged to have been committed by the trial court. On denial of these specifications by the opposite party, an issue was raised, which resulted in an affirmance or reversal of the judgment of the lower court. (See ERROR; WRIT). After final judgment the writ of execution followed, by which the judgment was enforced. This was usually effected by seizure of the person or property of the defendant.

Procedure in civil actions in the United States to-day is to a large extent founded on the common law, modified by statutes or by the adoption of codes. Each State has its own distinct system and this is true also of the Federal courts. In both Federal and State courts, civil actions generally are commenced by the service of process called summons upon the defendant. This writ is in some States served by the sheriff or his deputy, but in other States it may be served by the attorney or agent of the plaintiff. In the usual administration of justice to-day, judicial process is indispensable. Until notice is given, the court has acquired no jurisdiction whatever to proceed to judgment. Even in proceedings *in rem,* notice, either actual or constructive, is required in order that the judgment may be valid. (See PROCESS; SUMMONS). Subsequently to the service of the summons a declaration or complaint, stating the cause of action, is served on the defendant by the counsel for the plaintiff, after which may follow the plea, answer, demurrer and various other pleadings. A general demurrer by the defendant denies that a cause of action has been stated and thus a question of law arises to be decided by the court. If the defendant's demurrer is sustained, judgment is rendered for the defendant. In some States, if the defendant's demurrer is overruled, he is allowed to answer and the action proceeds. In some jurisdictions a motion to strike out immaterial matter has supplanted the demurrer as a remedy for formal defects. (See DEMURRER). If the defendant fails to answer, judgment may be taken against him by default. By code in various States, including New York (1848), among other reforms, distinctions between pleading at law and equity have been abolished and liberal provisions made for amendments to pleadings. By statute in other States various similar reforms have been accomplished. In the Federal courts of the United States in actions at law, the procedure of the State in which the court is located is followed, but in equity proceedings the procedure of the State is ignored and made uniform throughout the United States by court rules. A change is foreshadowed, however, in the procedure in the Federal courts in actions at law by the majority report of the Senate Committee on Judiciary (1917), favoring a bill authorizing the Supreme Court to adopt rules regulating the procedure and making it uniform throughout the United States. This bill has also been indorsed by the American Bar Association. Pressure of more important legislation due to the war, however, has caused a postponement of action on the bill. The term «writ of execution» in England at the present day includes the following: elegit, sequestration, capias, fieri facias and attachment. In the United States not all these forms are in use in every jurisdiction, the subject being one that is regulated to a large extent by statute. (See EXECUTION). The writ of error has been abolished in many jurisdictions in the United States and appeal substituted therefor. See APPEAL.

Criminal procedure in England to-day is founded largely on the old system at common law in civil cases, which was superseded by the Judicature Acts, dating from 1873. The arrest of the defendant, usually by warrant, generally follows an indictment by a grand jury in the case of the graver offenses, felony or treason. In the case of the lesser offenses a criminal information is filed by the attorney-general or, in his absence, by the solicitor-general. After an indictment has been found by the grand jury (twelve of whom must concur), the defendant on pleading not guilty is tried by 12 jurors in open court. Until 1907 a verdict in a criminal case of guilt or innocence was final, no appeal existing on the facts. However, a writ of error would lie for mistakes in procedure. By the Criminal Appeal Act of 1907, the right of appeal was given. The law of procedure in criminal cases in Ireland largely follows that of England, while that of Scotland differs to some extent, being regulated by statute passed in 1887. The common law method of trying criminals by a jury of 12 has been adopted in modern times by some European countries. The English system of criminal procedure, almost in its entirety, has been adopted by many of the British colonies. In the United States, criminal procedure is governed largely by statute or by code, but in a general way the procedure in use in England is followed. See CRIMINAL LAW; GRAND JURY; INDICTMENT; INFORMATION.

Procedure in admiralty closely follows that of the civil law, and is exceedingly simple, in marked contrast to the formalities of the common law. An admiralty suit is commenced by the filing of a libel, or complaint, setting forth the nature of the action, after which process is served by a marshal or deputy. Process, in suits *in personam*, may be in the form of a monition in the nature of a summons to appear and answer the suit. In proceedings *in rem* the marshal seizes the vessel or other thing in controversy. The answer in admiralty courts corresponds to the plea of common law, and exceptions are equivalent to pleas in abatement and special pleas in bar. A monition need not necessarily be served personally on the respondent. The court seeks at all times to adjudicate the controversy on its merits, to avoid delays, surprises and unnecessary costs. The rules of practice in courts of admiralty in the United States are substantially the same as those in England, but they are subject to change at any time when found necessary. Unlike the Federal courts in actions at law, courts of admiralty do not conform to the practice of the State courts. Admiralty courts permit the adjudication of several causes in one proceeding if adapted to the ends of justice and if no inconvenience will result therefrom, even extending this to libels *in rem* and *in personam* and cases in contract and tort; but causes entirely unrelated may not be joined. The admiralty courts, in addition to civil jurisdiction, have also limited criminal jurisdiction, but when acting in criminal cases the procedure in some particulars conforms to that of the common law courts, including trial by jury. Appeals from final decrees in the United States are usually taken to the Circuit Court of Appeals, but in certain enumerated cases to the Supreme Court. By certiorari, in cases of great importance, the Supreme Court may review the judgment of the Circuit Court of Appeals. See ADMIRALTY.

Equity procedure, like that of admiralty, lacks much of the formality of the common law. Suit is commenced by the complainant filing a bill, after which, in some jurisdictions in the United States, service of process, called the subpœna, is made on the respondent, who then may answer. On his failure to do so, the complainant is entitled to a decree in his favor. Formerly he could compel the respondent to answer by attachment. Replication by the complainant follows the answer of the respondent. Beyond this equity pleadings do not go, but amendments are allowed in lieu of further pleading. Demurrers and pleas are generally used in equity the same as at common law. Demurrers test the legal sufficiency of a pleading of the opposite party. Liberal provisions are usually made in equity practice for the amendment of demurrers. A plea in effect is a special answer, setting up some fact or facts as a cause for dismissing, delaying, or barring the suit, or why some part of the bill should not be answered. Pleas and demurrers are to-day viewed with some disfavor, as being dilatory and not going to the merits. Recently the Federal courts in the United States abolished pleas and demurrers, and substituted therefor motions and answers. In the absence of statutory modification the equity system does not provide for the trial of issues before a jury duly impaneled in that court, in which it differs radically from the common law. However, when the necessity of a jury arises, the equity court sends the issue to a court of law, where it is tried before a jury according to legal forms. The verdict thus rendered is returned to the court of equity. In the Federal courts usually and sometimes in other courts the judges who preside in the equity cases preside also over the trials at law. Issues are submitted to a jury at common law when material facts which are disputed seem doubtful to the judge of the equity court. Formerly a court of equity could not rehear a cause or reverse a decree after enrolment of the final decree, but to-day a court of equity may review and reverse its own decree on bill of review. This must be brought by a party to the original suit or by some party in privity with him. Appeal also may be taken from a final decree. Appellate jurisdiction must be invoked by appeal, and not by a bill of review. The subpœna in chancery suits to summon a respondent to answer was abolished in England in 1852, and service of a copy of the bill substituted, which practice is also followed by some jurisdictions in the United States. As stated above, by code in some of the States the distinctions between pleading in actions at common law and equity have been abolished. See CODE; EQUITY; SUBPŒNA.

EDWARD F. DONOVAN.

PROCESS, (1) *in anatomy*, an enlargement, such as the zygomatic process of the temporal bone, the vermiform process of the cerebellum, etc.; (2) *in botany*, any extension of the surface; a protrusion whether natural or monstrous; (3) *in law*, a term applied to the whole course of proceedings in a cause, real or personal, civil or criminal, from the original writ to the end of the suit; properly, the summons citing the party affected to appear in court at the return of the original writ. This was sometimes called original process, being founded upon the original writ; and also to distinguish it from mesne or intermediate process, which issues, pending the suit, upon some collateral interlocutory matter; as to summon witnesses, and the like; (4) the term generally applied to the various mechanical and chemical processes by means of which illustrations are reproduced in printing.

PROCESS OF LAW. See DUE PROCESS OF LAW.

PROCESSION, Religious, a solemn march of the clergy and people, attended with religious ceremonies, prayers, singing, etc., in the churches or streets of a town for the purpose of returning thanks for some divine blessing, petitioning for assistance in some great calamity, celebrating the consecration or visitation of church dignitaries, or drawing attention to some great doctrine of the Church. The practice of holding such processions is usually said to have been introduced into the Christian Church in the reign of Constantine. The most celebrated processions which now take place in the Roman Catholic Church are those of the eucharist on Corpus Christi day, and during the week in which it occurs. They owe their origin to John xxii. The processions in honor of Saint Mark and those on Candlemas and Palm Sunday are said to have been instituted by Gregory the Great. Instances of celebrations of this nature are to be found among the Jews in the Old Testament, and as a part of the symbolical worship of nature they were in use among the ancient heathens; thus they formed solemn processions about the fields, which had been sowed, and sprinkled them with holy water to increase their fertility, and to defend them from injuries. The festivals in honor of Bacchus, Ceres, Diana, and other divinities, among the Greeks and Romans, were solemnized with processions, in which the images of the gods were borne about; and similar rites are still found among most heathens. Among the Buddhists these ceremonials are especially imposing. The procession which accompanies the Emperor of China when he goes to offer sacrifices to an idol in some great pagoda is one of the most gorgeous description. In a more restricted sense the term is applied to the solemn entrance of the clergy and their assistants (choir, etc.) into the church proper for the purpose of holding a religious service, or of their departure to the sacristy after the service. Consult Eveillon, J., 'De Processionibus Ecclesiasticis' (Paris 1641); Gretser, J., 'De Catholicæ Ecclesiæ Sacris Processionibus' (Ingolstadt 1600); Vatar, D., 'Des Processions de l'Église' (Paris 1705); Wordsworth, C., 'Ceremonies and Processions of the Cathedral Church of Salisbury' (Cambridge 1901).

PROCESSION OF THE HOLY GHOST, in theology the relation in the Trinity between the Father and the Holy Ghost. The Western Churches believe in what is called the «double procession» as expressed in the Nicene Creed, «Who proceedeth from the Father and the Son.» The Greek Church maintains the «single procession» and omits the words «and the Son.» See FILIOQUE.

PROCESSIONAL CROSSES. See CROSSES AND CRUCIFIXES.

PROCIDA, prō'chē-dā, **John of,** an Italian physician and nobleman: b. Salerno, about 1210; d. Rome, 1298. The tradition which makes him the prime mover in the conspiracy alleged to have brought on the Sicilian Vespers (q.v.) has been discredited by careful investigators, but is the subject of a tragedy by James Sheridan Knowles (q.v.) (1840).

PROCIDA (ancient PROCHYTA), (1) an island in Italy, on the west side of the Gulf of Naples and about 12 miles southwest of Naples, lying nearly midway between the island of Ischia and the coast of the province of Naples. It is about three miles long, northeast to southwest, and little more than one mile broad. The principal town on the island is (2) Procida, or Castello di Procida, which stands on the southeast coast, 12 miles west of Naples. It is fortified, has a good harbor, and a considerable trade. There is a palace on the island which was occasionally used as a residence by the former kings of Naples. On festivals the women assume the Greek costume, consisting of a red upper garment with gold embroidery. It is from this island that John of Procida (q.v.), the reputed originator of the massacre known by the name of the «Sicilian Vespers,» takes his name. Pop. about 15,000.

PROCLAMATION OF EMANCIPATION. See EMANCIPATION PROCLAMATION.

PROCLAMATIONS, Executive, documents issued by an executive in accordance with the powers conferred or in fulfillment of the duties imposed on him by the constitution or expressly by statute, or even in regard to matters toward which it becomes desirable or necessary to draw the attention of the citizens. The issuance of such proclamations is not regulated by any general statute enacted by Congress, and for some, such as the Thanksgiving proclamation, no provision whatever has been made. In accordance with the specific authority conferred on him by the legislative branch of the government the executive may act with special authority in the sale of public lands, establishing forest reserves, applying special provisions of the tariff act, regulating the treatment and status of alien enemies, the jurisdiction of foreign consuls over disputes among seamen, proclaiming a state of war, and extending provisions of the copyright or patent laws to citizens of another country, etc. In time of war the executive's powers are vastly increased, including regulation of railroads and other public carriers, food and fuel supplies, press censorship, establishing blocades, granting pardon to deserters, internment of persons guilty of seditious utterances or of acts tending to impede the prosecution of the war, and not otherwise amenable to punishment or restraint. President Lincoln covered the greatest range in his proclamations, in several cases going to the extent of suspending the writ of habeas corpus in various places. The Supreme Court, however, condemned his suspension of the writ in localities outside the theatre of war. (See EXECUTIVE; PRESIDENT). Consult Fairlie, J. A., 'The National Administration of the United States' (New York 1905).

PROCLUS, philosopher of the Neo-Platonic school: b. Constantinople, 412; d. Athens, 485. He is usually called Diadocleus and sometimes the Lycian, because his parents came from Xanthus in Lycia. He received his first education at Alexandria from the famous Peripatetic Olympiodorus the elder, and completed it at Athens under Syrianus, who ultimately appointed him his successor, and under Asclepigenia, who had learned from her father Plutarchus the doctrines of the Orphic and Chaldaic mysteries and the united theurgic sciences. As a teacher at Athens he was very successful and not only endeavored to unite into a single whole all the philosophical schemes handed down from former ages, but made it his aim to embrace all religions by becoming filled with their spirit. Following out this maxim he composed hymns in honor of the pagan deities, defended and interpreted popular myths, and even conformed to the rites connected with their worship, and considered himself as under their protection. It was probably in consequence of this adherence to the ancient religion of Greece, in opposition to the decrees of the Christian emperors, that Proclus was compelled to withdraw from Athens. He traveled for a year in Asia to study the various religions of its inhabitants. All of them he held in reverence. On his return to Athens, where he remained till his death, he re-opened his school, but now performed his religious services in secret. By his pure morals and religious views he gave his scholars the idea that he had intimate intercourse with gods and demons, and could work miracles. He claims to resemble Plato in supporting his doctrines by an unbroken chain of reasoning, a method that had been altogether neglected by the previous Neo-Platonists. But these pretensions are not borne out by his works. A life of Proclus was written by Marinus, one of his scholars, and his successor in the school at Athens. His extant works include a ‘Sketch of Astronomy,’ in which he gave a short view of the systems of Hipparchus, Aristarchus and Ptolemy; ‘The Theology of Plato’; ‘Principles of Theology’; ‘Principles of Philosophy’; ‘Commentary on the Works and Days of Hesiod’; ‘Life of Homer,’ etc. Many of his works have been collected and edited by V. Cousin in ‘Procli Opera’ (6 vols., Paris 1820–27) and in ‘Procli Opera Inedita’ (Paris 1864). There are also various other editions of some of his writings by J. F. Boissonade (Leipzig 1820); G. F. Creuzer (3 vols., Frankfort o. M. 1820–22); G. Friedlein (Leipzig 1873), and C. E. C. Schneider (1847). Quite a number of his works have been translated into English. The oldest of these translations is called ‘The Descripcion of the Sphere, or Frame of the Worlde’ (Englysshed by W. Salysburye, London 1550?). The other translations, made by Thomas Taylor, are as follows: ‘The Commentaries of Proclus on the Timaeus of Plato’ (London 1820); ‘The Fragments that Remain of the Last Writings of Proclus’ (London 1825); ‘The Philosophical and Mathematical Commentaries of Proclus on the First Book of Euclid's Elements and His Life by Marinus’ (2 vols., London 1788–89); ‘The Six Books of Proclus, the Platonic Successor, on the Theology of Plato, etc.; also a Translation of Proclus' Elements of Theology, etc.’ (2 vols., London 1816); ‘Select Theorems in Proof of the Perpetuity of Time’ (in ‘Ocellus Lucanus on the Nature of the Universe, etc.,’ London 1831); ‘Two Treatises of Proclus, etc.’ (London 1833). There is also a French translation by P. Forcadel de Beziés, ‘Deux Livres de Proclus, du Mouvement’ (Paris 1542). Consult Altenburg, M., ‘Die Methode der Hypothesis bei Platon, Aristoteles und Proklus’ (Rostock 1905); Diehl, Ernst, ‘Der Timaiostext des Proklos’ (in ‘Rheinisches Museum für Philologie,’ n. s., Vol. LVIII, pp. 246–269, Frankfort o. M. 1903); Lindsay, J., ‘Proclus as Constructive Philosopher’ (in ‘Hibbert Journal,’ Vol. CIII, pp. 279–288, Boston 1917); Marinus, N., ‘Vita Procli’ (ed. by J. F. Boissonade, Leipzig 1814).
